Audio-Frequency Response: In accordance with NRSC recommendations.

Carrier Amplitude/Carrier Shift: Less than 5% at any level of modulation percentage.

Out-of-Band Emissions: Per FCC/NRSC requirements, see FCC Rules.

AM Stereo Transmission—Three basic transmission methods were proposed for adding stereo to the standard AM broadcast system. The three methods were:

Mixed Mode: The carrier is amplitude modulated with the (L+R) signal and phase or frequency modulated with the (L−R) signal.

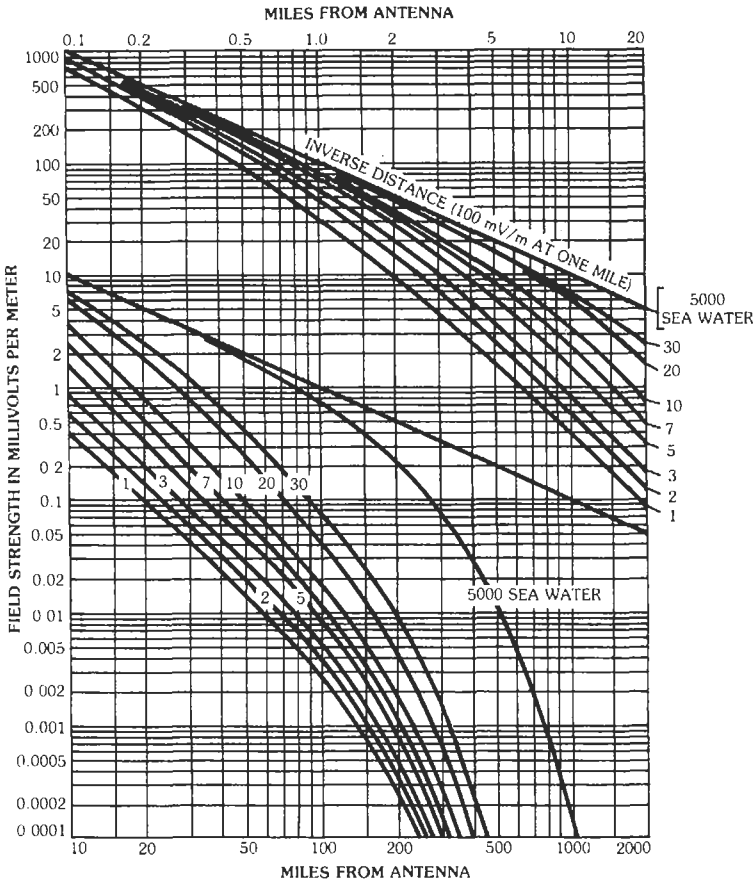

Fig. 3. Ground-wave field strength plotted against distance. Computed for 1600 kilohertz. Dielectric constant = 15. Ground-conductivity values are in millimhos/meter.

Independent Sideband: The upper and lower sidebands of the carrier are modulated with the L and R signals, respectively (Kahn system).

Quadrature: Two phase-locked carriers are amplitude modulated and combined at a fixed phase angle (Motorola system).

A "marketplace approach" has been employed in the US to select the best system, and that manufacturer's technique will become the *de facto* standard. In Canada and Japan, the Motorola system has been standardized, and most US stations also employ this system.

Frequency-Modulation Broadcasting*

Frequency-modulation (FM) broadcast stations are authorized for operation on 101 allocated channels, each 200 kHz wide, extending consecutively from channel 200 on 87.9 MHz to channel 300 on 107.9

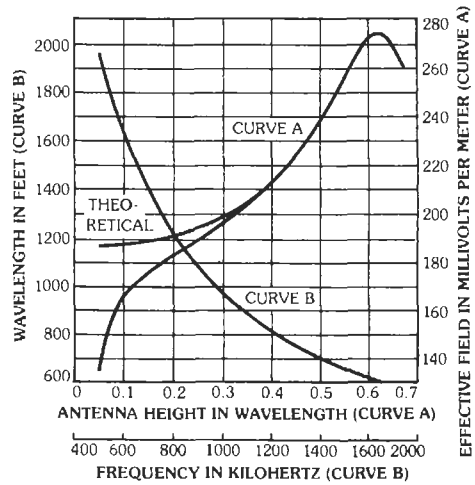

Fig. 4. Effective field at 1 mile for 1 kilowatt (curve *A*). Use for simple omnidirectional vertical antenna with ground system of at least 120 radials $\lambda/4$ long. *From FCC Rules and Regulations.*

* FCC Rules and Regulations, Part 73, Subparts B and C.

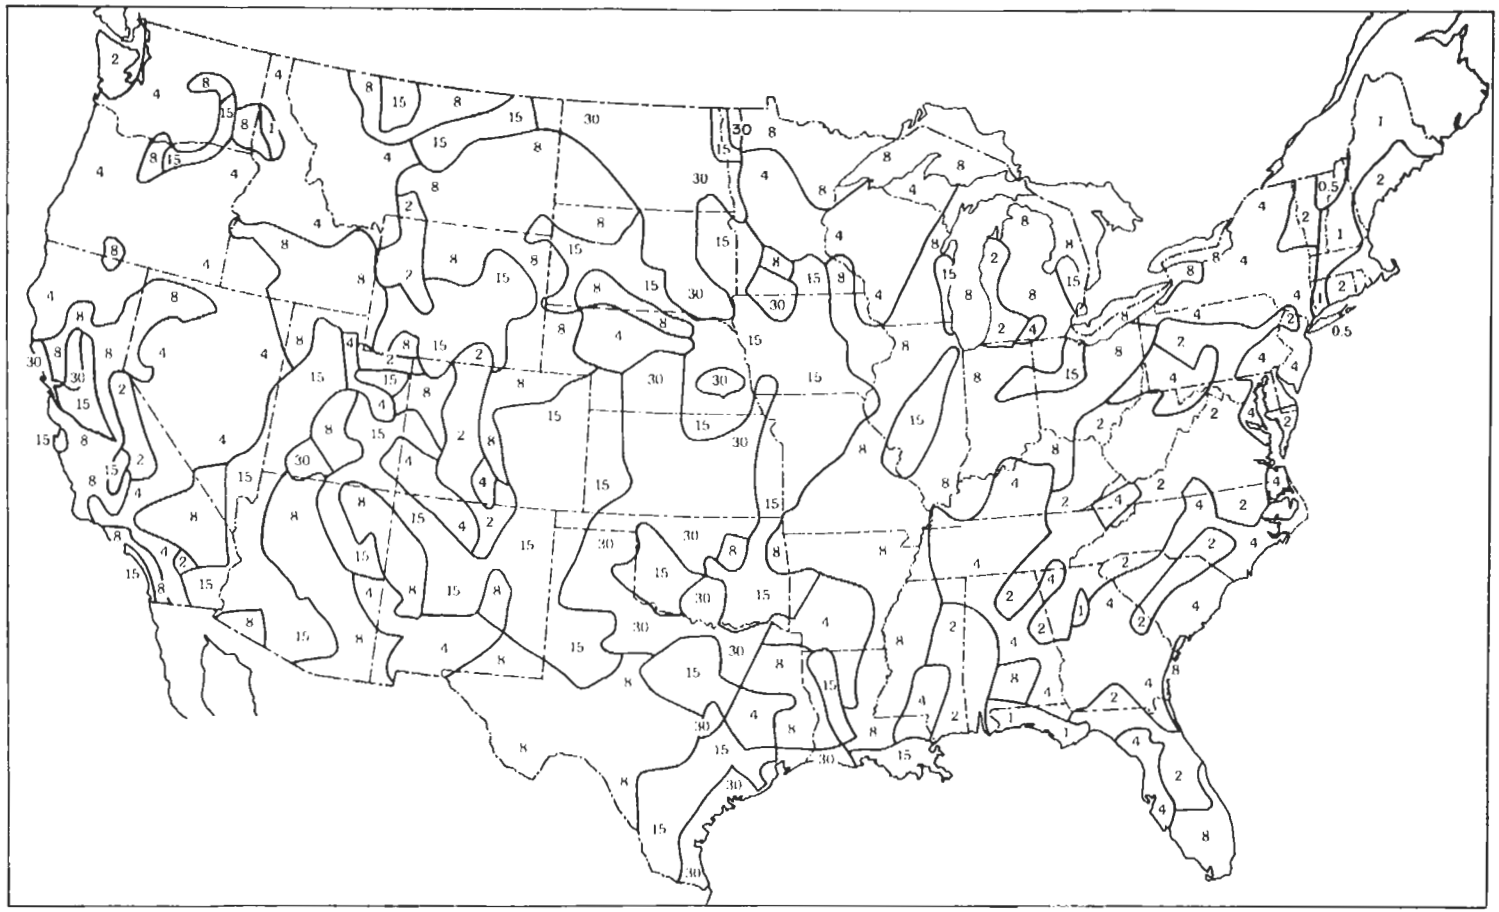

Fig. 5. Estimated effective ground conductivity in the United States. The numbers are in millimhos/meter. The conductivity of sea water (not shown) is assumed to be 5000 millimhos/meter.

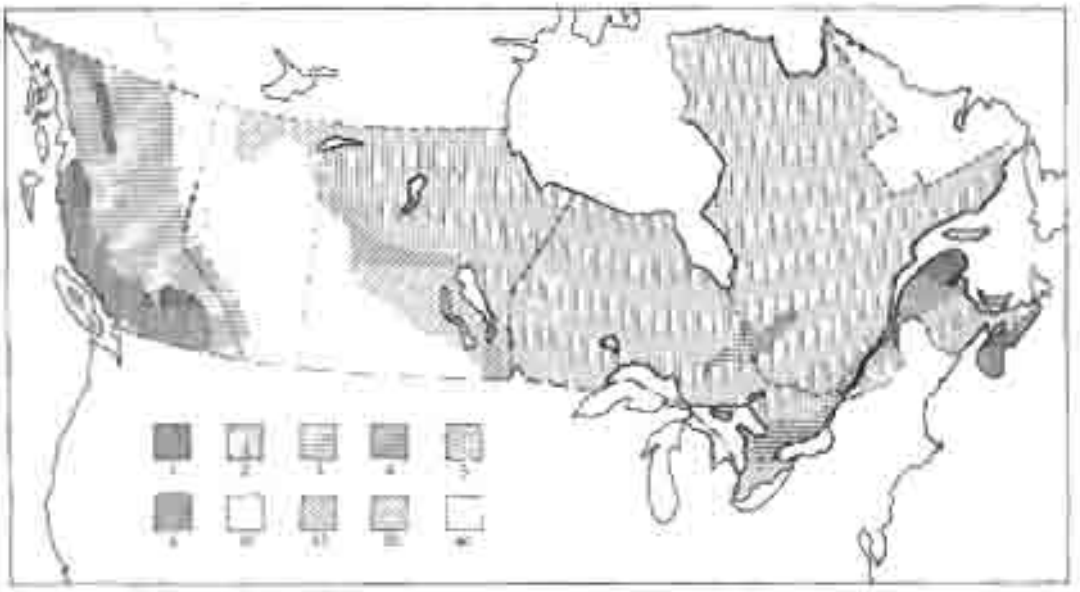

Fig. 6 Estimated effective ground conductivity in Canada.

MHz. Commercial broadcasting is authorized on channels 221 (92.1 MHz) through 300. Noncommercial educational broadcasting is permitted on any channel, but channels 200 through 220 are reserved for such use (see Part 73 of the FCC Rules and Regulations).

Station Classification—An FM station is classified by type in accordance with its authorized maximum operating power and antenna height (Table 2). A "reference distance" has been established for each class to denote the distance to the theoretical limit of its service area (the 1 mV/m contour—see "Coverage" below). A station operating with an antenna height in excess of the maximum for its class must reduce its effective radiated power (ERP) so that its 1 mV/m contour does not exceed the reference distance.

Channel Availability—Channels 221 through 300 are assigned to specific communities in accordance with the Table of Assignments (see Section 73.202 of FCC Rules). The number (and type) of channels assigned to a community is based on population, the limits imposed by cochannel and adjacent-channel interference considerations, and the zone in which the community lies. The Table of Assignments may be amended to add channels upon approval of a petition for rulemaking which includes a showing of need and conformity with the separation standards shown in Table 3. Noncommercial stations operating on channels 217–220 must conform with Table 2 with respect to stations operating on channels 221–223. Stations operating on channels 200 through 216 are authorized based on mutual interference standards in lieu of a Table of Assignments. These standards are expressed in terms of the following interference ratios of desired to undesired signals.

Cochannel:	10:1, or 20 dB
1st Adjacent Channel:	2:1, or 6 dB
2nd Adjacent Channel:	1:10, or −20 dB
3rd Adjacent Channel:	1:100, or −40 dB

The ratios are the magnitude of the field strength from the undesired station determined from the F50,10 curves* at the limit of the protected contour† of the desired station (see "Coverage" below).

Channel 200 is available only for Class D (maximum transmitter output of 10 watts) use in areas not served by a television broadcast station operating on channel 6. Stations on channels 201 through 220 are also subject to

* The protected contour is normally the 1 mV/m or 60 dBu service contour as determined by the F50,50 propagation curves. However, class B stations receive slightly greater protection. Refer to FCC Rules.

† Refer to Fig. 13 in the section on television broadcasting.

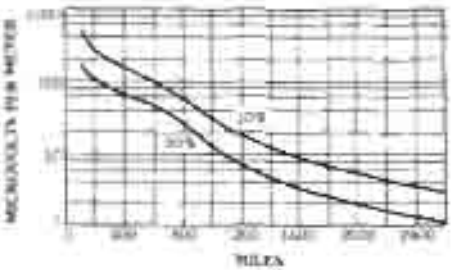

Fig. 7 Sky-wave signals for 10% and 50% of the time. The sky-wave range for frequencies from 540 to 1600 kilohertz is based on a radiated field of 100 millivolts/meter at 1 mile at the pertinent vertical angle.

TABLE 2. CLASSES OF FM STATIONS

Station Class[1]	Maximum ERP	Reference HAAT[2] in Meters (ft.)	Class Contour Distance in Kilometers
A	6 kW (7.8 dBk)	100 (328)	28
B1	25 kW (14.0 dBk)	100 (328)	39
B	50 kW (17.0 dBk)	150 (492)	52
C3	25 kW (14.0 dBk)	100 (328)	39
C2	50 kW (17.0 dBk)	150 (492)	52
C1	100 kW (20.0 dBk)	299 (981)	72
C	100 kW (20.0 dBk)	600 (1968)	92

1. Class B stations are available in Zone I and Class C stations in Zone II. See FCC Rules for zone boundaries.
2. HAAT is height of the antenna radiation center above average terrain elevation. Average terrain is determined by a procedure set forth in the FCC Rules.

maximum power restrictions if located in or near areas served by a television station operating on channel 6.

Coverage—The estimated coverage of an FM station can be determined from the FCC F50,50 curves shown in Fig. 8.* These curves permit the prediction of the field strength that will be exceeded for 50% of the time at 50% of the locations within the contour distance from the transmitter for various combinations of effective radiated power and antenna height above average terrain.

Station Performance—The performance of an FM broadcast station is required to be maintained in accordance with the following general specifications (see FCC

* These curves are approximate only. Official FCC data should be used for engineering designs.

TABLE 3. MINIMUM DISTANCE SEPARATION REQUIREMENTS IN KILOMETERS (MILES)

Relation	Co-channel	200 kHz	400/600 kHz	10.6/10.8 MHz
A to A	115 (71)	72 (45)	31 (19)	10 (6)

C1 to C	270 (168)	209 (130)	105 (65)	41 (25)
C to C	290 (180)	241 (150)	105 (65)	48 (30)

Note: Different criteria apply to stations within 320 km of US-Canadian and US-Mexican borders. Consult FCC Rules and Regulations, section 73.207.

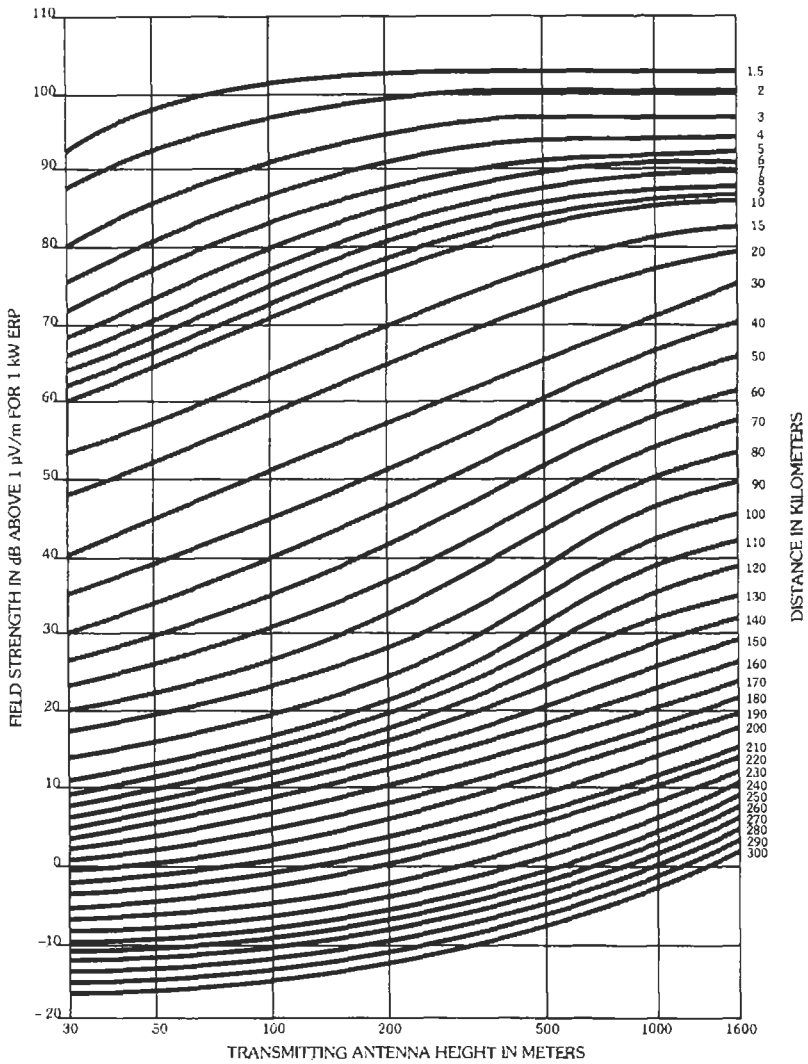

Fig. 8. Estimated field strength exceeded at 50 percent of the potential receiver locations for at least 50 percent of the time (FM channels, receiving antenna height 9 meters). *After FCC Rules and Regulations.*

Rules Section 73.317 for additional details). Key system criteria include:

Modulation Capability: ±75 kHz deviation of carrier for 100% modulation.

Audio-Frequency Response: Within limits shown in FCC Rules for 75 microseconds pre-emphasis.

Polarization: Typically right-hand circular; elliptical or other modes acceptable provided horizontal polarization is dominant.††

Stereophonic Transmission—Most FM stations broadcast in a stereophonic mode that is compatible with monophonic receivers. The stereophonic signal consists of a main channel and a subchannel. The main channel is modulated by the sum of the left (L) and right (R) stereo signals. The subchannel consists of sidebands of a 38-kHz suppressed carrier that is modulated with an L minus R (difference) signal. Since the modulating frequencies can be as high as 15 kHz, the sidebands occupy the baseband spectrum from 23 kHz to 53 kHz (Fig. 9). A pilot carrier of 19 kHz is also transmitted to allow the receiver to generate a phase-locked 38-kHz carrier in order to demodulate the L−R signal. A matrix in the stereo receiver recovers the L and R signals by algebraic operation on the L-plus-R and L-minus-R signals. A monophonic receiver demodulates only the L-plus-R (main channel) signal.

†† An exception to this requirement permits noncommercial stations operating on channels 201–220 to use vertical polarization to reduce interference to television channel 6.

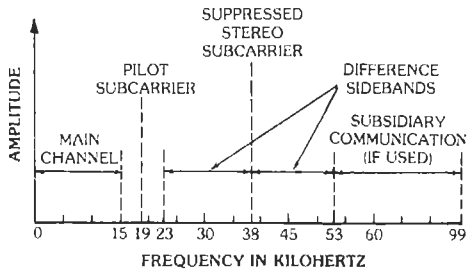

Fig. 9. Resulting stereophonic frequency spectrum.

A recent development in FM stereo modulation called FMX Stereo* employs a compressed L−R signal which modulates a 38-kHz suppressed carrier in a manner similar to the normal stereo difference signal. This signal is transmitted in quadrature to the main L−R signal and is, therefore, transparent to ordinary FM stereo decoders. Receivers equipped with an FMX decoder can demodulate and expand the compressed difference signal for an overall signal-to-noise improvement of 12–15 dB. This improvement helps to mitigate the 17–20 dB signal-to-noise penalty suffered in normal stereo transmission relative to monophonic FM transmission.

Other FM Services—A Subsidiary Communications Authorization (SCA) permits the addition of one or more subcarriers on the main channel; these subcarriers may be used for the transmission of voice or data signals related or unrelated to the broadcast-station operation. The subcarrier is amplitude modulated and is bandwidth limited. (See FCC Rules Section 73.319).

FM Translators—The FCC permits the use of very low power (1 watt east of the Mississippi river and 10 watts west) translators to rebroadcast the signals of FM stations in areas where no reception is possible. The translator station receives the main FM signal "off the air" and rebroadcasts it on a different channel; other methods of program delivery are permissible. Coverage range can be from one to five miles depending on power, antenna height, antenna gain, and terrain. Channels are assigned on a secondary basis (noninterference with operating stations). (See Subpart L, Part 74 of the FCC Rules and Regulations.)

Television Broadcasting (VHF and UHF)

Channel Designations—Television broadcast stations are authorized for commercial and educational operation on the channels shown in Table 4. Assignment of channels to specific communities is made by the FCC, and the channel assignments are designated as commercial (unreserved) or educational (reserved). Actual carrier frequencies are assigned by a plan for carrier offsets to reduce cochannel interference (see "Transmission Standards").

Coverage Data—The channel assignments have been made in such a manner as to facilitate maximum interference-free coverage in the available frequency bands. The radiated power of a particular station is fixed by several considerations. Minimum power is 100 watts visual effective radiated power. No minimum antenna height is specified.

Except as limited for stations using antenna heights in excess of 300 meters (600 meters for channels 14–69) in Zone I and antenna heights in excess of 600 meters in Zones II and III, the maximum visual power in decibels above 1 kilowatt (dBk) is:

Channels	*Maximum Power*
2–6	20 dBk = 100 kilowatts
7–13	25 dBk = 316 kilowatts
14–69	37 dBk = 5000 kilowatts

Zone I is the Northeastern United States. Zone II includes Puerto Rico, Alaska, the Hawaiian Islands, the Virgin Islands, and other parts of the US not in Zones I or III. Zone III is essentially a strip along the southeastern border of the US from Florida to Texas. Zone III cochannel separations reflect the propagation anomalies experienced in the Gulf Coastal Region. Detailed descriptions of the zones are in the FCC Rules and Regulations, Section 73.609. Stations operating with heights in excess of the class/zone maxima must reduce power in accordance with the requirements of 73.614 of the FCC Rules and Regulations.

Grades of service are designated A and B. The signal strengths in decibels above 1 microvolt/meter (dBu) specified for the various channels are:

Channel	*Grade A*	*Grade B*
2–6	68 dBu	47 dBu
7–13	71 dBu	56 dBu
14–69	74 dBu	64 dBu

The transmitter location must be so chosen that, with the effective radiated power and antenna height proposed, the minimum field strength (sometimes referred to as "city grade") predicted over the principal community to be served will be:

Channel	*Signal*
2–6	74 dBu
7–13	77 dBu
14–83	80 dBu

The curves of Figs. 10 through 14* give estimated 50% and 10% time-varying field strengths for VHF and

* FMX Stereo is a registered trademark of Broadcast Technology Partners.

* The curves in Figs. 10 through 14 are approximate only. Official FCC data should be used for engineering designs.

TABLE 4. NUMERICAL DESIGNATION OF TELEVISION CHANNELS

Channel Number	Band (megahertz)	Channel Number	Band (megahertz)	Channel Number	Band (megahertz)
2	54–60	25	536–542	48	674–680
3	60–66	26	542–548	49	680–686
4	66–72	27	548–554	50	686–692
5	76–82	28	554–560	51	692–698
6	82–88	29	560–566	52	698–704
7	174–180	30	566–572	53	704–710
8	180–186	31	572–578	54	710–716

10	192–198	33	584–590	56	722–728
11	198–204	34	590–596	58	734–740
12	204–210	35	596–602	60	746–752
13	210–216	36	602–608	61	752–758
14	470–476	37	608–614	62	758–764
15	476–482	38	614–620	63	764–770
16	482–488	39	620–626	64	770–776
17	488–494	40	626–632	65	776–782
18	494–500	41	632–638	66	782–788
19	500–506	42	638–644	67	788–794
20	506–512	43	644–650	68	794–800
21	512–518	44	650–656	69	800–806
22	518–524	45	656–662		
23	524–530	46	662–668		
24	530–536	47	668–674		

The frequencies between 806 and 890 MHz, formerly allocated to television broadcasting, are now allocated to the land mobile services. Operation, on a secondary basis, of some television translators may continue on these frequencies.

UHF television channels at different heights and powers. The F(50,50) curves are used for the prediction of service, while the F(50,10) curves are used for the prediction of interference. Cochannel TV stations operating with offset carriers are afforded desired-to-undesired interference protection of 28 dB, i.e., F(50,50) − F(50,10) = 28 dB. The antenna height is the height of the radiation center of the antenna above the average terrain. "Average terrain" is determined by averaging the ground elevations between 3 and 16 km from the antenna site, taken along eight radials separated by 45° in azimuth. Effective radiated power is the product of the antenna gain and the antenna input power. Antenna input power is the peak visual output power of the transmitter less transmission-line and diplexer losses. The procedures to be followed in determining the effective radiated power used in the prediction of coverage are detailed in Section 73.684 of the FCC Rules and Regulations.

Directional antennas may be employed to improve service. The ratio of maximum to minimum radiation in the horizontal plane may not exceed 10 dB for channels 2–13, and 15 dB for channels 14–69 if the transmitter power is more than 1 kW. There is no restriction for channels 14–69 if the transmitter power is 1 kW or less.

Transmission Standards—The standards for television transmission in the US, as defined by the FCC, are:

Channel Width: 6 MHz

Picture Carrier Location: 1.25 MHz ± 1000 Hz above lower boundary of the channel.*

Aural Center Frequency: 4.5 MHz ± 1000 Hz above visual carrier.

Polarization of Radiation: Horizontal normal, right-hand circular optional.

Modulation: Amplitude-modulated composite picture and synchronizing signal on visual carrier, together with frequency-modulated audio signal on aural carrier. (See Figs. 15 and 16.)

Scanning Lines: 525 lines/frame interlaced two to one.

Scanning Sequence: Horizontally from left to right, vertically from top to bottom.

Horizontal Scanning Frequency: 2/455 times chrominance subcarrier frequency (15 734 Hz).

Vertical Scanning Frequency: 2/525 times the horizontal scanning frequency (59.94 Hz).

Chrominance Subcarrier Frequency: 3.579 545 MHz ±10 Hz.

Polarity of Transmission: Negative—a decrease in initial light intensity causes an increase in radiated power.

Transmitter Brightness Response: For luminance sig-

* Carrier frequencies may be offset ± 10 kHz (e.g., 1.24 or 1.26 MHz above band edge) for cochannel-interference considerations.

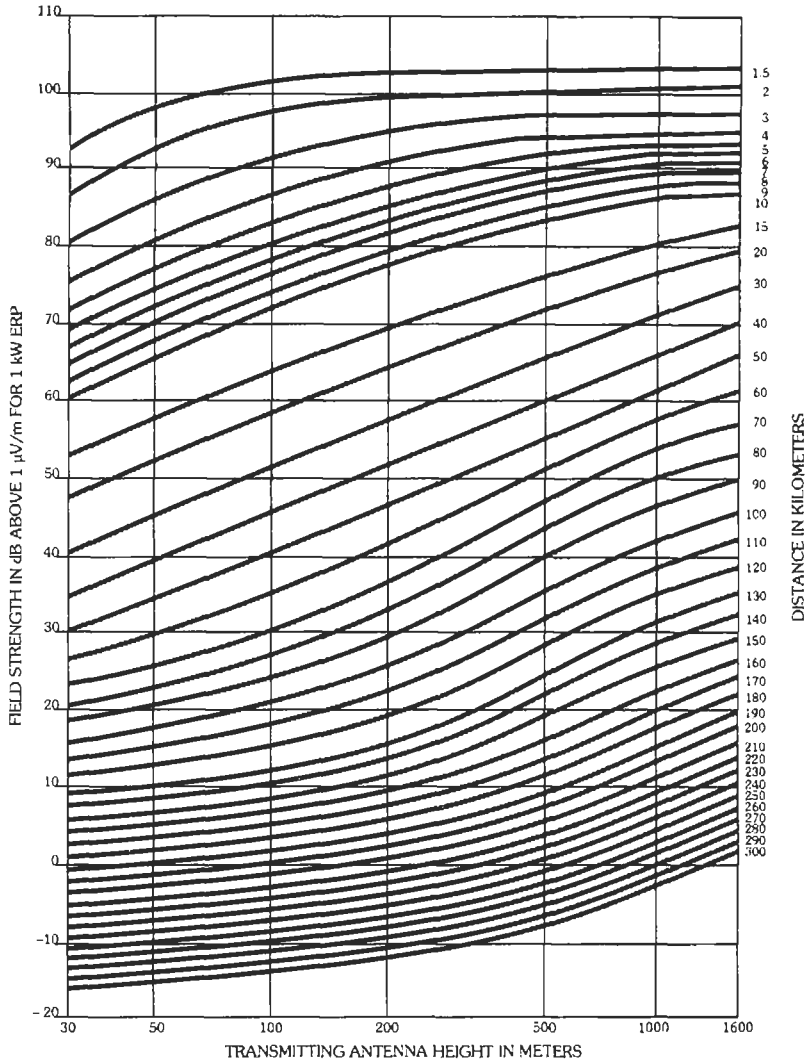

Fig. 10. Estimated field strength exceeded at 50 percent of the potential receiver locations for at least 50 percent of the time for TV channels 2-6. Receiving antenna height, 9 meters. *After FCC Rules and Regulations.*

nal, radio-frequency output varies in an inverse logarithmic relation to the brightness of the scene.

Aural-Transmitter Power: Maximum radiated power is 22% of peak visual effective radiated power.

For color transmission, the luminance component is transmitted as amplitude modulation of the picture carrier and the chrominance components as amplitude-modulation sidebands of a pair of suppressed subcarriers in quadrature (Fig. 17).

The interval beginning with line 17 and continuing through line 20 of the vertical-blanking interval of each field may be used for the transmission of data, test signals, and cue and control signals. Test signals may include signals designed to check the performance of the overall transmission system or its individual components. Test signals or cue and control signals may not be transmitted during that portion of each line devoted to horizontal blanking. Line 19 in each field may be used only for transmission of the standard vertical interval reference (VIR) signal. Line 21 may be used for transmission data such as closed captioning for the deaf. Lines 10–20 may be used for data and text transmission (Teletext) except as noted above.

Aural Transmitter—The TV audio signal is frequency modulated on a carrier 4.5 MHz above the visual carrier. The power level of the carrier may not exceed 22% of the peak visual power. The carrier is

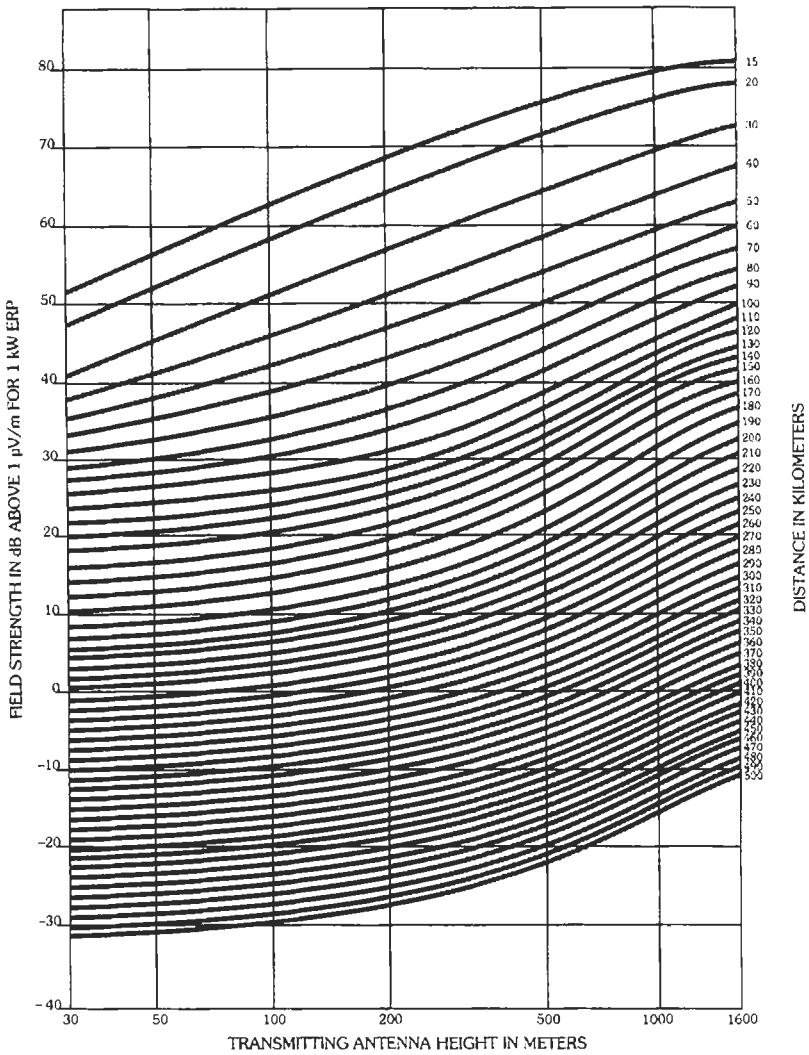

Fig. 11. Estimated field strength exceeded at 50 percent of the potential receiver locations for at least 10 percent of the time for TV channels 2-6 and FM. Receiving antenna height, 9 meters. *After FCC Rules and Regulations.*

deviated 25 kHz for 100% modulation, and the same 75-microsecond pre-emphasis specified for FM broadcasting is used. A multichannel television sound system (MTS) may be employed to provide stereophonic and other audio services. The common system in use is the BTSC (Broadcast Television Sound Committee) format which provides a compatible (L+R) signal, a companded stereo difference signal, a separate audio program (SAP) channel, and a utility audio-data channel (PRO channel). Total aural baseband information must be maintained within a 120-kHz bandwidth.

Cable Television

Cable television (CATV) systems were originally called "community antenna television systems." They had their origin in mountainous regions of Pennsylvania where "off-air" reception of broadcast television stations was difficult, if not impossible. Beginning with crude antennas and amplifiers that delivered a few channels to homes in sparsely populated valleys, CATV systems have evolved into a broadband technology utilizing high-capacity coaxial cables to carry signals in the spectrum from 5 MHz to over 500 MHz and fiber-optic cables with seemingly limitless capacity.

Some modern systems employ multiple cables for separate subscriber and institutional networks, each with two-way capability. Cable TV systems have developed into carriers of more than "off-air" programming from broadcast stations. Modern urban cable systems carry more television signals emanating from satellites and local sources than from broadcast stations.

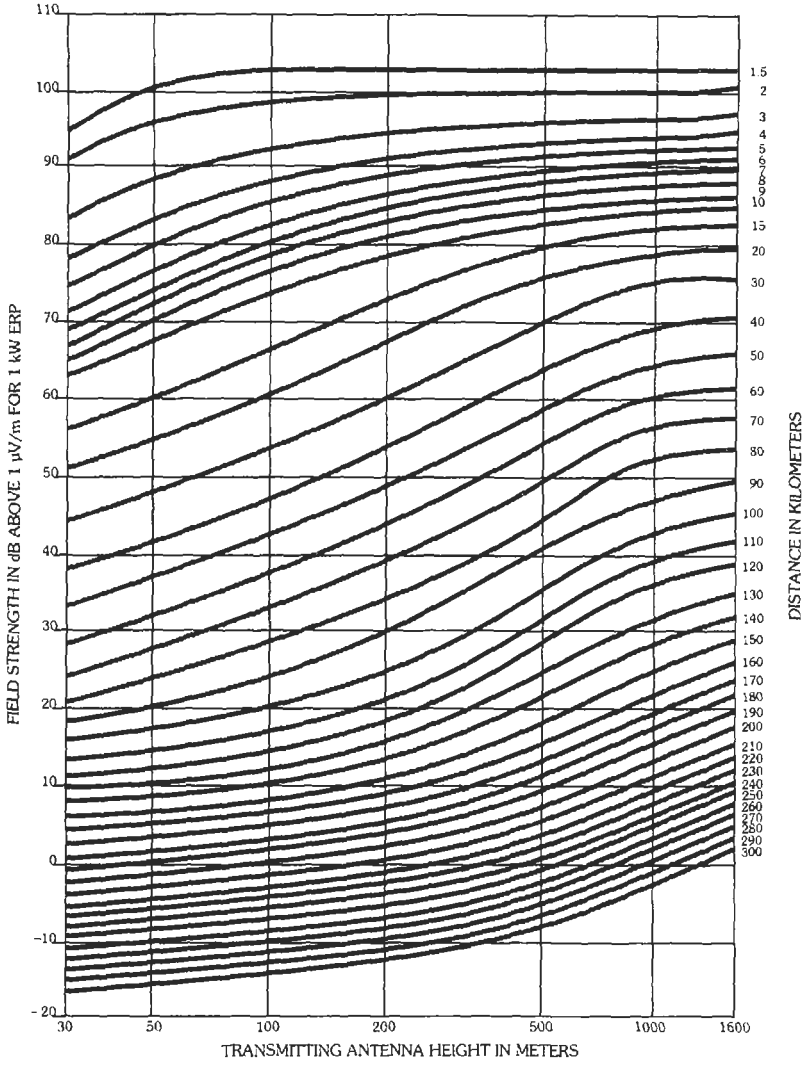

Fig. 12. Estimated field strength exceeded at 50 percent of the potential receiver locations for at least 50 percent of the time for TV channels 7-13. Receiving antenna height, 9 meters. *After FCC Rules and Regulations.*

Converters are used at subscriber locations to change nonstandard channel frequencies to a standard VHF channel (usually between 2 and 6 inclusive) so that ordinary television receivers can demodulate the signals. Most new receivers are being manufactured with "cable ready" tuners capable of tuning more than one hundred channels. The cable channel frequency assignments generally used are given in Table 5.

Bidirectional cable systems normally employ a low-band split (i.e., downstream channels above 50 MHz and upstream channels below 50 MHz) or a midband split with the division occurring near 150 MHz. As the upper limit of usable cable-system frequencies increases, the frequency where the split occurs has been adjusted.

Cable systems are not regulated to any great extent by the FCC,* and the technology has far exceeded the minimum performance requirements set by the Commission. Of particular regulatory concern, however, is the unwanted leakage from poorly constructed and maintained CATV systems of radiations such as spurious signals in radio-frequency bands used for services crucial to the safety of life. The Commission has restricted CATV operation on frequencies which coincide with aviation services (108–137 MHz) and other governmental/public-safety bands.

Some services delivered by CATV systems are tiered to varying levels of subscription fees, and access to the

* FCC Rules and Regulations, Part 76.

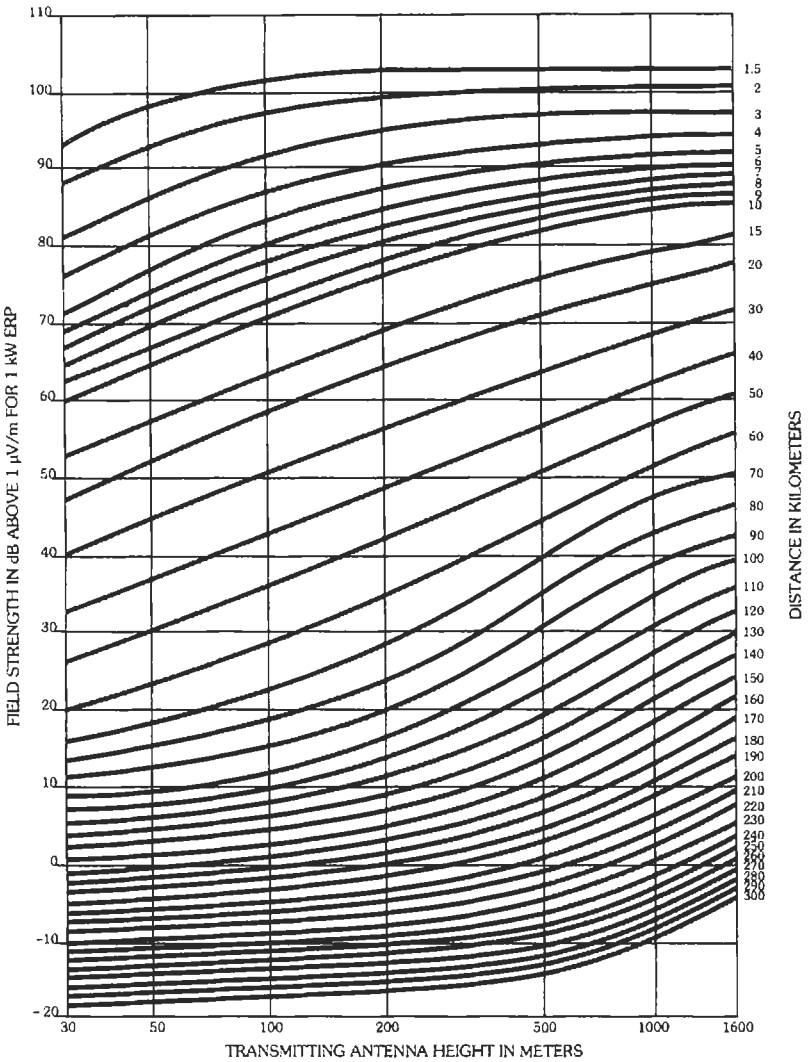

Fig. 13. Estimated field strength exceeded at 50 percent of the potential receiver locations for at least 50 percent of the time for TV channels 14-69. Receiving antenna height, 9 meters. *After FCC Rules and Regulations.*

higher-level tiers is limited by the use of scrambled signals and addressable converters and decoders. Newer technology incorporates provisions for "pay-per-view" access to special-events programming.

One of the limitations on the number of channels a cable system can carry is the distortion due to intermodulation and cross-modulation products resulting from system nonlinearities and the numerous carriers. *Composite triple beat* is a term applied to third-* and higher-order products, which can greatly degrade the performance of a system. One method used to reduce these effects is the employment of coherent oscillators to regenerate (and convert) carrier frequencies such that they are harmonically related (HRC). This intermodulation problem increases with amplifier output levels and builds as amplifiers are cascaded. This then becomes the limiting factor on the length of a system (number of amplifiers in cascade), and, as the number of channels is increased, the amplifier separation must be reduced to compensate for lowered output levels. Extension of systems and system interconnection into large networks are also limited by this constraint.

Fiber-optic, or light-wave cable, systems are being developed which promise to improve many of the transmission characteristics of coaxial-cable (broadband) amplifier systems. While there are few operating CATV systems delivering signals directly to subscribers

* Products of the general type $(2f_1 \pm f_2)$ or $(f_1 + f_2 \pm f_3)$.

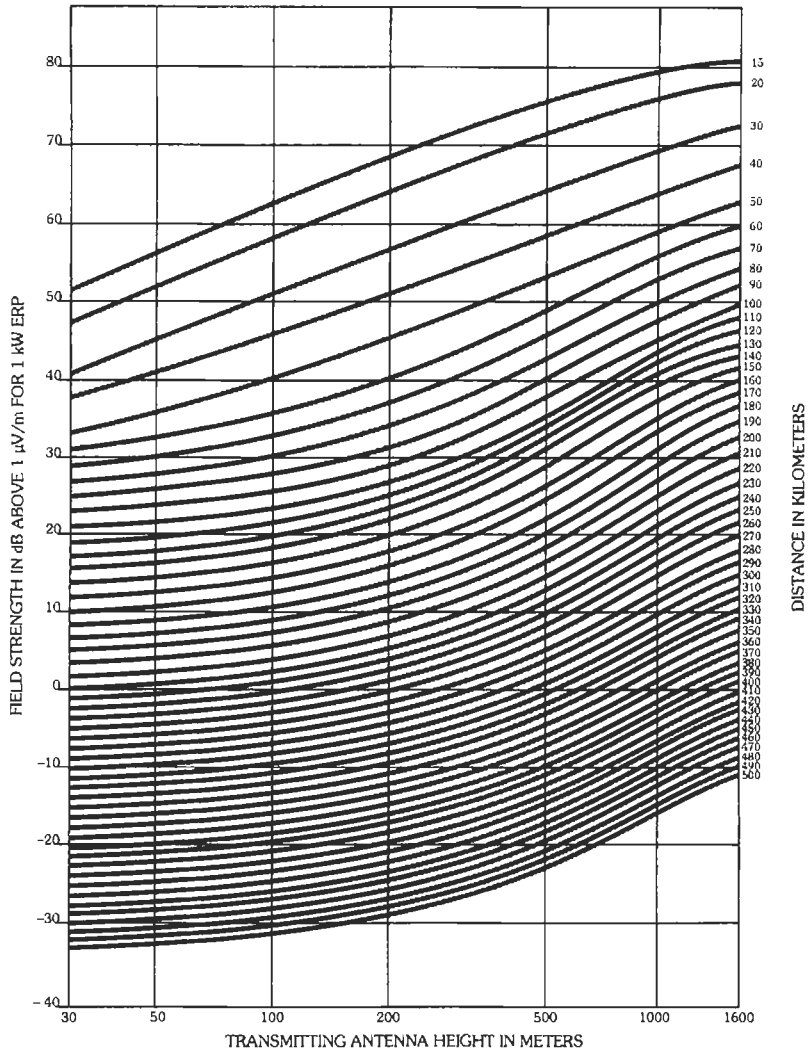

Fig. 14. Estimated field strength exceeded at 50 percent of the potential receiver locations for at least 10 percent of the time for TV channels 14-69. Receiving antenna height, 9 meters. *After FCC Rules and Regulations.*

via fiber optics, this technology is being employed to deliver signals to headends or as "super trunks" to deliver signals to multiple miniheadends in many systems. However, coaxial-cable hardware development has advanced to the point where it has been the most practical method of constructing economical broadband systems; fiber-optic technology has emerged from the developmental stage for this application, and greater use will be seen.

As this section was being written, the FCC had initiated regulatory action which would permit telephone companies to deliver video and wideband information services. If these companies decide to get into this business, they will employ fiber-optic systems, and this could eventually lead to the installation of light-wave capability into most homes and businesses for all communications.

Other Television Services

Translators and LPTV—Television broadcast translators and low-power television (LPTV) stations operate under Subpart G of Part 74 of the FCC Rules and Regulations. A television broadcast translator is a station that rebroadcasts the programming of a broadcast station in an essentially unaltered form. The signals from the originating station may be delivered by direct off-the-air pickup, microwave relay, satellite transmission, or rebroadcast of another translator. An LPTV station is similar to a translator station in terms of

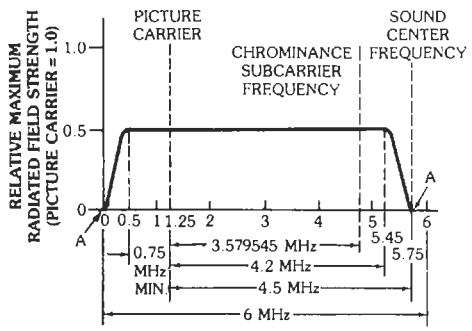

Fig. 15. Radio-frequency amplitude characteristics of television picture transmission. (Drawing not to scale.)

equipment and service area, but it is permitted to originate programming from virtually any source. The technical rules governing translators and LPTV stations are essentially identical.

For VHF stations, the transmitter output power (peak visual) may be up to 10 watts unless the station operates on an unoccupied channel assigned to its community for regular television broadcast use; in this case, 100 watts may be employed. A UHF station may be authorized on any channel with transmitter power up to 1 kW. There is no limitation on effective radiated power for either type of station. If stations employ circular polarization, authorized transmitter power may be doubled for all classes.

The technical standards for operation of these stations are generally the same as those for broadcast stations (A5/F3 modulation) with the principal exceptions relating to carrier-frequency tolerances, spurious emissions, and lower-sideband attenuation characteristics.

Channel assignments are made on the assumption that these facilities are secondary to broadcast stations and must protect existing facilities from objectionable interference. While the service area of a regular broadcast station is defined as the area within the predicted Grade B contour, the service area of an LPTV station is much smaller and generally equivalent to the area within a predicted contour approximating its Grade A service area. Existing LPTV stations are protected from interference from newly proposed LPTV stations.

High Definition Television—High definition television (HDTV) system proposals abound as of the writing of this text. The FCC is considering various systems through the Advanced Television System Committee and the Advanced Television Test Center. The latter is conducting laboratory and field tests on the systems, while the former group is dealing with the development of HDTV transmission standards. A 1993 target date has been established for the completion of the work. Major issues include compatibility of any new system with existing NTSC systems, channel bandwidth requirements, modulation (analog/digital), signal propagation anomaly correction methodologies, and the impact of emerging international standards.

ITFS—Instructional Television Fixed Service (ITFS) stations operate under Subpart I of Part 74 of the FCC Rules in the band 2500–2686 MHz. These stations are licensed to eligible educational entities for the distribution of program material to students enrolled in instructional curricula. Public broadcast stations rendering such services are also eligible. An additional 4 MHz (2686–2690 MHz) is assigned for ITFS response stations. Response channels are intended for use as return links to the originating point for aural infor-

Notes for Fig. 16:

1. H = time from start of one line to start of next line.
2. V = time from start of one field to start of next field.
3. Leading and trailing edges of vertical blanking should be complete in less than $0.1H$.
4. Leading and trailing slopes of horizontal blanking must be steep enough to preserve minimum and maximum values of $(x + y)$ and z under all conditions of picture content.
5. Dimensions marked with an asterisk indicate that tolerances given are permitted only for long-time variations, and not for successive cycles.
6. Equalizing-pulse area shall be between 0.45 and 0.5 of the area of a horizontal-synchronizing pulse.
7. Color burst follows each horizontal pulse, but is omitted following the equalizing pulses and during the broad vertical pulses.
8. Color bursts to be omitted during monochrome transmission.
9. The burst frequency shall be 3.579545 megahertz. The tolerance on the frequency shall be ±10 hertz with a maximum rate of change of frequency not to exceed 1/10 hertz per second.
10. The horizontal scanning frequency shall be 2/455 times the burst frequency.
11. The dimensions specified for the burst determine the times of starting and stopping the burst but not its phase. The color burst consists of amplitude modulation of a continuous sine wave.
12. Dimension P represents the peak excursion of the luminance signal from blanking level but does not include the chrominance signal. Dimension S is the synchronizing amplitude above blanking level. Dimension C is the peak carrier amplitude.
13. Refer to FCC standards for further explanations and tolerances.
14. Horizontal dimensions not to scale in A, B, and C.

mation/data such as student questions and responses. These stations employ very low power and narrowband equipment (250 mW at 125 kHz). The ITFS channels are six megahertz wide and have a standard television broadcast signal format. The channels are presently grouped in bands of four alternately spaced channels (e.g., group A is composed of A-1, 2500–2506 MHz; A-2, 2512–2518 MHz; A-3, 2524–2530, etc.), with adjacent groups interleaved as shown in Table 6. Licensees are permitted to use multiple channels (up to four) based on need and availability. Stations are usually limited to an equivalent isotropically radiated power (EIRP) of 33 dBw unless a directional antenna is employed. The EIRP is further limited by coverage requirements and considerations of interference to other stations in the band (some "grandfathered" facilities of other services remain in the ITFS band). The band is also shared with the broadcast satellite service, and protection to that service is afforded by the Rules.

Reception of ITFS signals usually requires the use of a small parabolic antenna, which is coupled to a down-converter. The down-converter incorporates a low-noise front end (NF < 5 dB) and converts the signal(s) to VHF channels. A block of four channels (group) can be converted in a single device to yield four alternately spaced VHF channels (e.g., 7, 9, 11, 13) or wideband devices can down-convert all 31 channels to VHF "cable" channels in a single block. Four-foot antennas are generally used at distances up to ten miles for received carrier-to-noise ratios of approximately 50 dB.

MDS—The Multipoint Distribution Service (MDS) is a common-carrier service but is included in this chapter on broadcasting because the service is used primarily for the distribution of television program material to subscribers ("pay TV"). It is governed under Subpart K of Part 21 of the FC Rules. This service is assigned 10 MHz of spectrum in the band 2150–2160 MHz, except in the top 50 market areas where the band is extended to 2162 MHz. Channel 1 has "inverted" carrier relationships (i.e., aural carrier below visual carrier) with respect to channel 2 in order to minimize adjacent-channel interference in those locations where two channels are authorized. The band 2156–2160 MHz in smaller markets is too narrow to be used for standard television picture transmission but may be assigned for other purposes.

In all other aspects, MDS stations are very much akin to ITFS stations, including hardware. As in ITFS, reception is accomplished with a down-converter that changes the 2-GHz signal to a standard VHF channel. The higher power generally employed in the MDS service permits the use of smaller receiving antennas and higher-noise-figure down-converters, making home-receiver reception practical.

The FC has allocated groups E, F, and H to the MMDS (Multichannel MDS) service, which has evolved into an "over-the-air" or "wireless" cable service. ITFS licensees are permitted to lease excess capacity to MMDS operators, thus increasing the total channels potentially available to 31–33.

Network Distribution of Broadcast Program Signals

Terrestrial—Most network radio and television programming formerly was distributed by terrestrial microwave systems owned and operated by common carriers (see Chapter 38). Television program transmission is governed by the Network Transmission Committee Standard, NTC-7, which establishes reasonable requirements for a system that is presumed to have over 100 microwave relay stations in tandem. While most programming formerly was carried over facilities belonging to AT&T and other carriers, those facilities are being supplanted by satellite-based systems. The principal advantage of the terrestrial system was its infrastructure which provided many routing alternatives; its primary disadvantage was the poor performance of long repeater cascades (coast-to-coast) as compared to satellite transmission circuits.

Satellite Program Distribution—Space stations in the Domestic Satellite Service are being used extensively for the distribution of television programming. Space stations are located in the geostationary (or geosynchronous) orbit located approximately 23 000 miles in space above the equator. Satellites located between approximately 70° and 145° west longitude can be "seen" from most sites in the continental US except those in the most northerly latitudes. The Public Broadcasting Service (PBS), was the first to distribute its television programming exclusively by the use of satellite channels; its sister organization, National Public Radio (NPR), also distributes its programming almost exclusively by satellite. Now virtually all network TV program distribution is accomplished via satellite.

When a satellite system is viewed as a point-to-point microwave system with only one heterodyne repeater, it is readily apparent that vastly improved performance can be obtained over the terrestrial system if carrier-to-noise limitations can be overcome. With very-low-noise amplifiers (30–50 K), the weak signals from C-band

61	114–120	115.25	118.83	119.75

satellites can be processed to produce signal-to-noise ratios well in excess of 55 dB with antennas 7 to 10 meters in diameter (depending on satellite EIRP at the particular receiving location).

The present domestic satellite system uses C-band transponders (3.7–4.2 GHz down-link and 5.925–6.425 GHz up-link) and K_u-band (11/14 GHz). The C-band is shared with terrestrial common carriers on a coequal basis. Thus, satellite terminals must be coordinated with existing facilities to assure interference-free operation. For this reason, it is frequently difficult to coordinate C-band satellite earth stations in urban areas

* These frequencies shared with other services.

where terrestrial frequency congestion abounds. Techniques such as antenna shielding and IF filtering can sometimes be employed to resolve interference problems.

Satellites with K_u-band (11/14 GHz) transponders eliminate the interference problems while permitting the use of smaller antennas. Interference is not a problem since these bands are not shared with terrestrial users; smaller antennas are usable because of the higher effective gain of both satellite transmitting antennas and earth-terminal receiving antennas. The disadvantages of the band include the much higher potential for signal degradation due to precipitation propagation losses. Distributed, interconnected earth stations can solve this problem. For nonbroadcast applications where less than 99.99% availability is acceptable, K_u-band has become the dominant service.

DBS—Direct Broadcast Satellite transmission has been approved by the FCC. The bands allotted are 12.2–12.7 GHz for down-link and 17.3–17.8 GHz for up-link. Various schemes have been proposed for channelization and modulation formats. Some proponents of high-definition television (HDTV) have proposed the use of DBS as the only available means of broadcasting such programming directly to the public. Direct Broadcast Satellite transmission will further improve on the K_u-band advantage (use of small antennas) by employing high-power transponders that will permit a reduction in antenna size to much less than one meter for practical home reception. It is predicted that as many as 20 DBS satellites could be in operation by the year 2000, offering over 200 HDTV channels for home reception. Digital video compression systems will play an important role in this application, and the development of a practical system could permit a substantial increase in the number of channels while decreasing transponder/bandwidth requirements.

Auxiliary Broadcast Services

In Part 74 of its Rules and Regulations, the FCC has made provision for various auxiliary broadcast services. These are generally channels allocated for delivering programming and associated communications from remote locations to the station. The bands and services include the following.

Remote Pickup Broadcast Stations—Stations in this service are used for the transmission of aural programming material and associated cues and data. Assigned frequencies are in bands at 153 MHz, 161 MHz, 166 MHz, 170 MHz, 450 MHz, and 455 MHz. (See Subpart D of Part 74, FCC Rules and Regulations for limitations on use.)

Aural Intercity and STL Stations—Stations in this service are to be used for relay of aural program material from studio to transmitter and between fixed facilities in other locations. Assigned frequencies are in the band 947–951 MHz. (See Subpart E of Part 74, FCC Rules and Regulations.)

Television Auxiliary Stations—Stations in this service are used for transmission of television programming (aural and visual) between studio and transmitter, for intercity relay, and for remote pickups. Various bands are available at 2 GHz, 7 GHz, 13 GHz, 18 GHz and 23 GHz. (See Subpart F of Part 74, FCC Rules and Regulations for specific channel frequencies and limitations.)

Low Power Auxiliary Stations—Stations in this service are intended for use over very short distances for audio, cues, control, etc., associated with broadcast programs (for example, wireless microphones). Frequency bands are at 26 MHz, 161 MHz, 174–216 MHz, 450 MHz, and 950 MHz. (See Subpart H of Part 74, FCC Rules and Regulations for specific frequency assignments and limitations.)

Frequency Sharing—All users of auxiliary broadcast services must share frequencies. Users must coordinate use of specific frequencies with other local broadcasters to eliminate interference problems.

International Broadcasting Service in the United States

Transmissions from international broadcasting stations located within the United States are intended to be received directly by the general public in foreign countries. International broadcasting is conducted from both government (Voice of America) and privately owned stations. Public Law 80-402, the *United States Information and Educational Exchange Act of 1948,* encourages the participation of the private sector in international broadcasting. Nongovernment international broadcasting stations are licensed by the Federal Communications Commission in accordance with Part 73, Subpart F of the FCC Rules and Regulations. A license for an international broadcasting station will be issued only after a satisfactory showing has been made in regard to the following items, among others:

1. That there is a need for the international broadcasting service proposed to be rendered.
2. That the necessary program sources are available to the applicant to render the international service proposed.
3. That the production of the program service and the technical operation of the proposed station will be conducted by qualified persons.
4. That the applicant is legally, technically, and financially qualified and possesses adequate technical facilities to carry forward the service proposed.
5. That the public interest, convenience, and necessity will be served through the operation of the proposed station.

International broadcasting stations employ frequencies in bands between 5950 and 26 100 kHz. Frequencies authorized by the FCC fall within the following bands, which are allocated exclusively for broadcasting:

Meter Band	*Frequency in Kilohertz*
49	5950–6200
31	9500–9775
25	11 700–11 975
19	15 100–15 450
16	17 700–17 900
13	21 450–21 750
11	25 600–26 100

The band 7100–7300 kHz is also allocated for broadcasting, except in the western hemisphere.

The carrier frequencies assigned begin 5 kHz above the frequency specified for the beginning of each band, and are in successive steps of 5 kHz ending 5 kHz below the frequency specified as the end of each band.

Since international broadcasts cross frontiers, bridge oceans, and span continents, frequency assignments must be regulated internationally. Article 17 of the *Radio Regulations,* International Telecommunication Union, Geneva, 1979, specifies a frequency coordination procedure that member administrations must follow. The FCC has incorporated this procedure into its Rules and Regulations.

Schedules for international broadcasting stations are prepared seasonally and are implemented at 0100 UTC on the first Sunday of March, May, September, and November. The FCC requires licensees to submit their tentative schedules to the Commission six months prior to the start of each season, indicating for the season the frequency or frequencies desired for transmission to each zone or area of reception specified in the license; the specific hours of transmission to such zones or areas on each frequency; and the power, antenna gain, and antenna bearing to be used. The geographical areas to which broadcasts are directed should be designated in accordance with the ITU Geographical Zones for Broadcasting shown in Fig. 18.

Frequencies proposed should be as close as possible to the optimum working frequency, which is defined as that frequency which is returned to the surface of the earth for a specific transmission path and time of day on 90% of the days of the month, and should be chosen so that a given frequency will provide the largest period of reliable transmission to the selected zone or area of reception. The minimum transmitter power permitted for an international broadcasting station licensed by the FCC is 50 kW; the antenna power gain toward the intended reception zone must be at least 10; and the field strength incident in the reception zone, either measured or calculated, should exceed 150 microvolts/meter for 50% for the time. For purposes of calculating interference under practical operating conditions, it is assumed that the field strength in directions other than the main lobe of the antenna is not less than 222 microvolts/meter at 1 kilometer for 1 kilowatt supplied to the antenna.

Frequencies for short-wave broadcasting are very much in demand throughout the world. It has been estimated that between two and three stations often compete for an available channel during prime listening hours in many areas of the world. For this reason, international broadcasting is often subjected to a high level of cochannel and adjacent-channel interference.

International broadcasts may include commercial or sponsored programs, provided that commercial program continuities give no more than the name of the sponsor of the program and the name and general character of the commodity, utility or service, or attraction advertised and the commodity is regularly sold or is being promoted for sale on the open market in

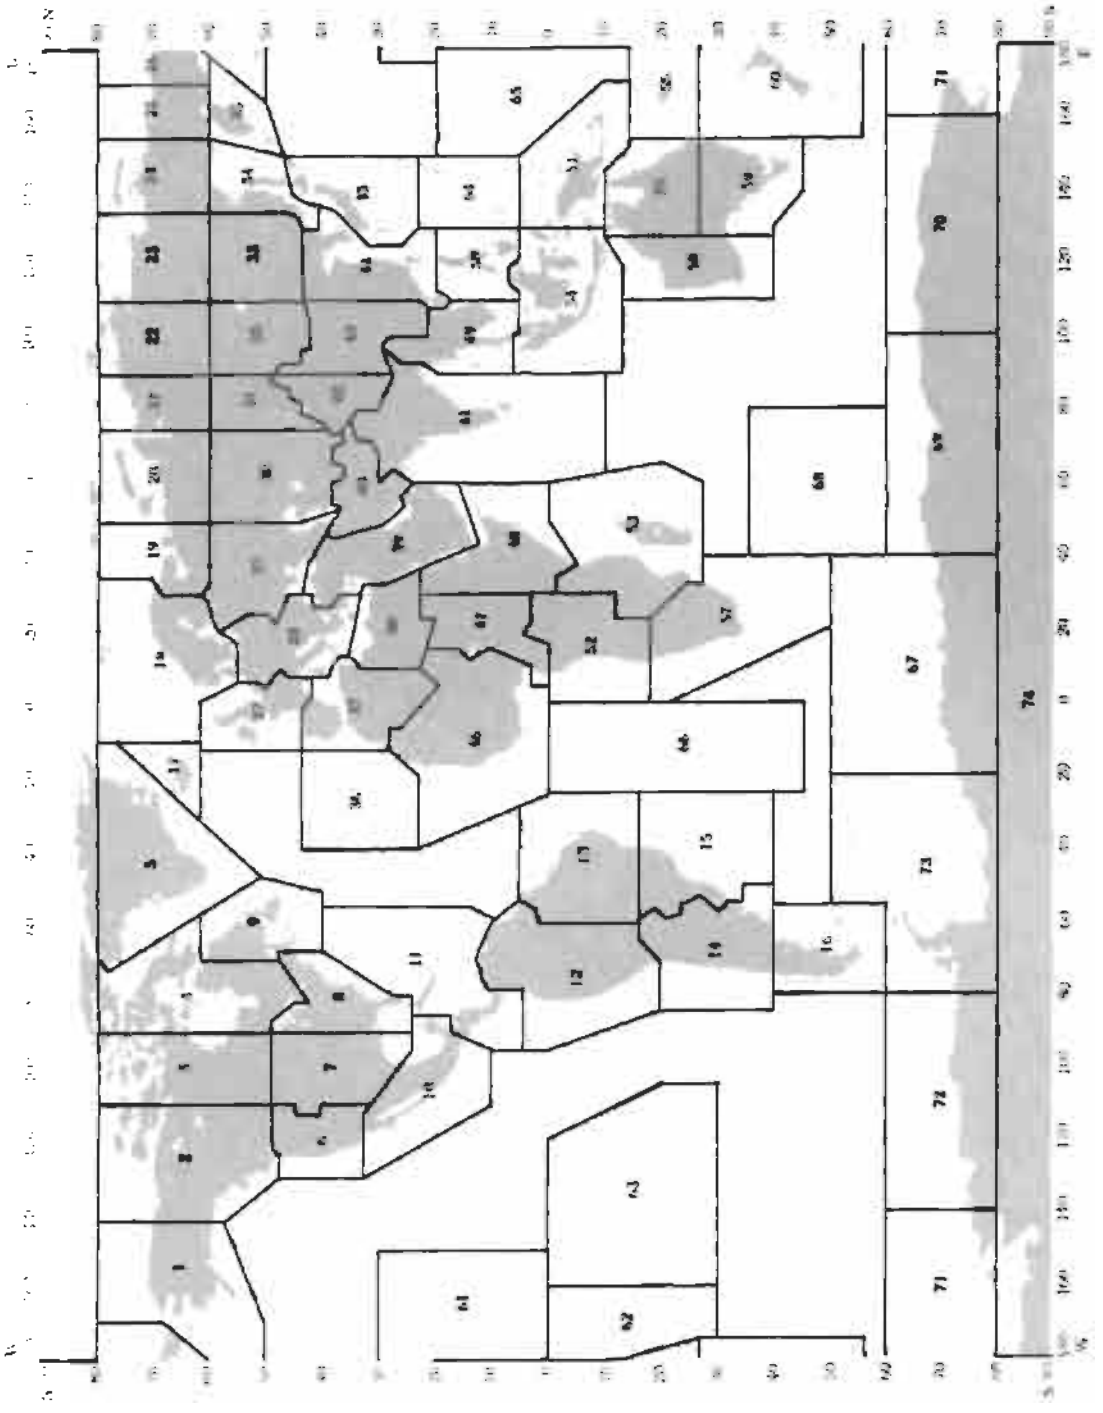

Fig. 18. Geographical Zones for broadcasting

the foreign country or countries to which the program is directed. An international broadcast station may transmit the program of a standard broadcast station or network system provided that the above commercial restrictions are met.

The 1979 World Administrative Radio Conference of the ITU allocated the following additional short-wave spectrum to broadcasting:

kHz
9775– 9900
11 650–11 700
11 975–12 050
13 600–13 800
15 450–15 600
17 550–17 700
21 750–21 850

The band 25 600–26 100 was reduced to 25 670–26 100 when the new allocations became effective.

Although the above WARC-79 extension bands may not be officially implemented until well into the 1990s, they are being used by an increasing number of international broadcast stations on a de facto basis. The FCC assigns frequencies in these bands to US licensed international broadcast stations on the basis of noninterference to other bands. The FCC also assigns frequencies on the same basis between 7305 and 7530 kHz.

At this writing, additional HF spectrum is expected to be allocated to broadcasting at a major international telecommunication conference to be held in Spain during early 1992. This conference, called a *World Administrative Radio Conference of the International Telecommunications Union* (WARC-92) has on its agenda the further expansion of the bands used by international broadcast stations.

The popularity of shortwave broadcasting is on the increase, with at least 600 million radios estimated to be in homes throughout the world. Despite advances expected in the art of broadcasting, short wave is expected to continue to enjoy its unique and important role in the field of human communications well into the 21st Century.

Sources for Federal Communications Commission Documents

The Superintendent of Documents, US Government Printing Office, Washington, D.C. 20402-9371, is the primary source for obtaining the Rules of the FCC. The GPO publishes the *Code of Federal Regulations—Title 47—Telecommunication* that contains, in five volumes, the FCC Rules and Regulations. Individual volumes or the complete set of five volumes may be purchased, and a subscription service for obtaining updates in several forms (microfiche, magnetic tape, paper) is available. In addition, the GPO publishes and sells subscriptions to the biweekly publication *FCC Record* that contains all FCC decisions and actions, specified public notices, etc.

Because of the complexities inherent in maintaining a complete up-to-date set of the often-revised FCC documents, private sources for these publications are also available. Subscriptions are obtainable for FCC and other government rules and regulations. A complete list of such nongovernment sources can be obtained from:

Office of the Secretary
Federal Communications Commission
1919 M Street, N.W., Room 222
Washington, DC 20554
(202) 632-6410

PROGRAM PRODUCTION STANDARDS

If sound or television programs are broadcast in "real time," such broadcasts or telecasts are described as "live." However, live broadcasts are rare occurrences at present. Most broadcasting, except news and special events, is transmitted from recordings, either audio-only (sound recordings) or audio and video (television recordings). The origination equipment, which may include microphones, television cameras, film cameras, synchronizing apparatus, transmitters, and recording systems, is designed to meet industry and government specifications. For recording systems, the primary standards specifications must ensure interchangeability of the recordings between machines. Interchangeability is mandatory if recording and replay in a variety of locations is to be achieved.

There is no inherent reason that standards designed for broadcasting should be especially suited to uses other than broadcasting. Currently, however, professional production facilities for cable television, for most educational and industrial instructional purposes, as well as some systems used for video teleconferencing and computer graphics creation, utilize essentially the same types of equipment as those used for broadcasting and so adhere to similar or identical operating standards. This situation may not prevail in the future because active development of high definition television systems and various kinds of special-purpose digital video systems is underway in many parts of the world and in many disciplines. It is likely that specialized systems, especially digitized video systems for uses such as video teleconferencing and multimedia computer use, will evolve rapidly and will require new and improved standards.

Several scientific and industrial societies and trade associations are involved in preparing documents that define agreed-to specifications for sound and television origination and recording equipment. Listed below are the names, areas of responsibilities, and addresses for many of these groups. For information on the current status of standards, it is important to ask the group concerned, since in these fields the technology is advancing at a rapid pace. Names and addresses of the most important standards organizations are listed later in this chapter.

Sound Recording Systems

The past decade has produced radically new approaches to the recording of sound material for broadcasting and for other uses, including home and automobile listening and portable personal use, perhaps while jogging. For the home market, the long-playing, mechanically reproduced phonograph record has virtually disappeared from stores. In its place has appeared the digitally recorded, laser-read compact audio disk (CD) and the digital audio tape (DAT). Analog magnetic tape recording equipment, mostly using the compact audio cassette first introduced in the mid 1960s, is also to be found in most stores and in most homes. Audio cassettes are dominant in the field of highly portable tape players intended for personal use. The audience for recorded music of all kinds has become very large and very sophisticated.

Broadcasting studios must be equipped to replay the consumer recordings listed above—analog compact audio cassette, CD, and DAT. Thus, given these factors, in recent years there has been a proliferation of standards for the audio recording and broadcasting industries.

Some advanced professional sound recording studios make digital audio recordings on magnetic or optical computer disks, but most professional sound recording facilities continue to depend on magnetic tape as the recording medium. Despite advances in digital technology represented by the CD and DAT, analog sound recording on magnetic tape remains very common. Many professional systems in service today are based on analog technology using gamma ferric iron oxide coated on a plastic tape backing material. They use recording heads of iron or ferritic materials that use high-frequency ac recording bias. Associated playback heads have narrow (short) gaps that drive the input stages of low-noise analog amplifiers. Increasingly, however, professional sound studios and professional recording equipment are being designed to make use of modern digital technology.

Digital Audio Recording—The use of digital techniques to record audio signals has the following advantages when compared to traditional analog techniques:

A. The dynamic range and frequency response of the recording can be greater. Dynamic range is primarily determined by the number of sampling bits per digital word used in the analog-to-digital conversion process. In professional audio applications, 16- to 20-bit words are used, thus providing a theoretical dynamic range of from 96 to 120 dB. The amplitude/frequency response of digital systems is primarily determined by the digital sampling rate and the associated filters used in the digital-to-analog conversion process. For professional use, the sampling rate is usually 48 000 samples per second (48 kHz), and thus the net bit rate of the signal is between 768 000 and 960 000 bits/s. To this bit rate must be added error-detection signals which can account for an increase of 20% or more to arrive at a figure for the gross bit rate finally to be recorded.

   Other sampling rates may be used. For example, for compact disk (CD) recordings, the sampling rate is 44.1 kHz, derived originally from television-system frequency relationships, while some digital audio transmission channels, for example certain long-haul European microwave circuits, use 32-kHz sampling. Digital telephone systems typically sample speech signals at 8 kHz.

B. Deterioration of quality when the original recordings are copied is virtually absent. This situation is quite different in traditional analog recording, where each "generation" of tape copying results in increased noise and distortion compared to the original recording. In typical digital systems, there is no incremental deterioration of the signal after the initial analog-to-digital conversion.

C. The effects of magnetic-tape defects and signal "dropouts" due to dirt can be virtually eliminated by use of powerful digital error detection, correction, and concealment techniques. These techniques almost guarantee that the playback is a duplicate of the original recording. When the error-correction systems are overloaded by exceptionally high bit-error rates, error concealment allows a graceful cover for defective data and is designed to produce a minimal disturbance to the reproduced sound recording.

In addition to more or less conventional tape-transport systems using fixed heads and capstan-based tape-pulling mechanisms, digital audio recorders are available, such as those of the DAT design, that use tape transports based on the rotating-head scanning-assembly concept used in video recording systems. Other designs use magnetic disk mechanisms similar to the hard disks used in computer applications. Rewriteable optical disk recording systems have appeared and are expected to compete strongly with magnetic tape.

Standards and Specifications for Sound-Recording Systems—Several organizations are active in drafting standards and specifications for radio-broadcasting and sound-recording studios. These include the National Association of Broadcasters (NAB), the Electronic Industries Association (EIA), and the Audio Engineering Society (AES). The fundamental specifications for radio broadcasting in the USA are promulgated by the Federal Communications Commission (FCC). There is a description of the FCC Rules and Regulations earlier in this chapter. However, many other aspects of the program production system are dealt with by these other organizations. A survey of the standards available from the various organizations is listed below.

National Association of Broadcasters
Dept. of Science and Technology
1771 N Street, N.W.
Washington, DC 20036-2891

TELEPHONE (202) 429-5346 or 1-800-368-5644
TELEFAX (202) 775-3515

Equipment-related parameters for audio recording and reproducing systems used in broadcasting, including monophonic and stereophonic reel-to-reel magnetic sound recorders, broadcast cassette and cartridge magnetic recording systems, and disk recordings. A complete set of the standards is contained in the publication *NAB's Recommended Engineering Technical Standards*, available from the address listed above. Their titles are:

NAB Standard: Cartridge Tape Recording and Reproduction
NAB Standard: Audio Cassette Recording and Reproduction
NAB Standard: Magnetic Tape (Reel to Reel) Recording and Reproduction
NAB Standard: Disc Recording and Reproduction

Note: NAB also publishes specifications based on reports of the National Radio Systems Committee. These include:

NSRC Interim Voluntary National Standard: Preemphasis/Deemphasis and Broadcast Audio Transmission Bandwidth Specifications. (NRSC-1)
NSRC Interim Voluntary National Standard: Emission Limitation for AM Broadcast Transmission. (NRSC-2)
NSRC Voluntary National Standard: Audio Bandwidth and Distortion Recommendations for AM Broadcast Receivers.

Electronics Industries Assoc.
2001 Pennsylvania Ave. N.W.
Washington, DC 20006
TELEPHONE (202) 457-8716
TELEFAX (202) 457-4901

Equipment-related specifications for a variety of sound broadcasting and sound recording subjects. Consumer Electronics standards are also issued. A selected partial listing of current document titles includes:

CPEB6-A, Preferred Voltage and Impedance Values for the Interconnection of Audio Products
CPEB7, Audio Rectification
SE-101-A, Amplifiers for Sound Equipment
SE-104, Engineering Specifications for Amplifiers for Sound Equipment
EIA-160, Sound Systems
EIA-243, Color Coding for Stereo Pick-Up Leads
EIA/TIA-250-C, Electrical Performance for Television Transmission Systems
EIA-288, Audio Magnetic Playback Characteristic at 7 1/2 IPS
EIA-298, Audio Transmitter Input Impedances for Single Input Transmitters
EIA-517, Car Audio Standard
EIA-157, Method for Determining Air Gap Flux Density and Energy
EIA-549, NSRC AM Preemphasis/Deemphasis and Broadcast Audio Transmission Bandwidth Specifications
EIA-490, Standard Test Methods for Audio Amplifiers
EIA-219, Audio Facilities for Radio Broadcasting Systems
EIA-297-A, Cable Connectors for Audio Facilities for Radio Broadcasting
EIA-560, Standard Method of Measurement for Compact Disc Players

Note: In addition to this selected list of EIA publications, the association publishes an extensive range of standards and other engineering publications concerned with electronics and electronic engineering. Television standards are listed later in this chapter. A catalog may be obtained from the address noted above.

Audio Engineering Society
60 E. 42nd Street
New York, NY 10017
TELEPHONE (212) 661-8528
TELEFAX 212 682-0477

Equipment-related specifications for a variety of sound broadcasting and sound recording subjects. The AES supports the work of the ANSI S4 standards committee. A selected partial listing of current document titles includes:

AES-11D-1991, Plane Wave Tubes: Design and Practice
AES-2-1984 r1991 (ANSI S4.26-1984), Specification of Loudspeaker Components used in Professional Audio and Sound Reinforcement.
AES-3-1992 (ANSI S4.40-1992), Serial Transmission Format of Two-channel Linearly Represented Digital Audio Data (Revision of AES-3-1985, ANSI S4-40-1985)
AES-5-1984 r1991 (ANSI S4.28-1984), Preferred Sampling Frequencies for Professional Digital Audio Applications Employing Pulse-Code Modulation.
AES-6-1982 r1991 (ANSI S4.3-1982), Method for Measurement of Weighted Peak Flutter of Sound Recording and Reproducing Equipment.
AES-7-1982 r1991 (ANSI S4.6-1982), Method of Measuring Recorded Flux of Magnetic Sound Records at Medium Wavelengths.
AES-10-1991 (ANSI S4.43-1991), Serial Multichannel Audio Digital Interface (MADI)

AES-11-1991 (ANSI S4.44-1991), Synchronization of Digital Audio Equipment in Studio Operations.
AES-14-1992 (ANSI 4.48-1992), Application of Connectors, Part 1: XLR Polarity and Gender.
AES-15-1991 (ANSI S4.49-1991), Sound Reinforcement Systems—Communications Interface (PA 422)
AES-17-1991 (ANSI S4.50-1991), Measurement of Digital Audio Equipment.
AES-18-1992 (ANSI S4.52-1992), Format for the User Data Channel of the AES Digital Audio Interface.
AES-19-1992 (ANSI S4.30-1992), Measurement of the Lowest Resonance Frequency of Loudspeaker Cones.

Note: The Audio Engineering Society provides a computer-based data exchange that may be accessed by modem. It provides fully updated information on AES standards. Details for accessing this facility may be obtained from the AES headquarters listed above.

International Sound-Recording Standards—The contents of most of the standards and specifications listed above are duplicated in international standards. For sound recording, international standardization is performed by the International Electrotechnical Commission (IEC), a subdivision of the International Standards Organization (ISO). Responsibility for international sound-recording standards rests with the IEC Technical Committee 60–Recording (TC-60) and its subcommittee SC-60A. Loudspeakers, microphones, and audio-visual systems are standardized by TC-84.

Information on IEC and ISO standards may be obtained from:

American National Standards Institute
1430 Broadway
New York, NY 10018

International exchange of recorded broadcast sound programs is dealt with by the International Radio Consultative Committee (CCIR). Copies of CCIR documents may be ordered from:

National Technical Information Service
US Department of Commerce
5285 Port Royal Road, Box 1553
Springfield, VA 22161

A listing of international standards affecting sound broadcasting is given in the section "International Standards for Broadcasting" at the end of this chapter.

Television Recording Systems

The recording of television signals on magnetic tape, variously described as video tape recording (VTR) or television recording, is a technology that has been used professionally for about 35 years. The invention of the video recorder ranks high among the important technical and cultural developments of the 20th century. Various recording formats are now in professional service. They include the original broadcast format using 2-inch-wide tape (now essentially obsolete) and formats using 1-inch tape, ¾-inch tape, 19-mm tape, and ½-inch tape. The last three tape widths are used for both analog and digital video recording systems, with the tape contained in a box called a cassette. Digital video recording will surely become the dominant professional technology in the immediate future. In addition to these professional formats, there are hundreds of millions of video cassette recorders (VCRs) in homes and institutions around the world. In general, VCR systems use analog recording technology and ½-inch or 8-mm tape. The tape itself is contained in a cassette that is inserted into the front of the recording machine.

Among the formats listed above, all except the obsolete 2-inch format use helical recording technology. In this system, the tape is constrained by mechanical guides to take the shape of a partial helix and is wrapped around a cylinder (the scanner) that rotates rapidly. The scanner also serves as a mounting for the video recording head(s). The tracks that result from the recording process are placed very closely together and at a shallow angle of a degree or two to the reference tape edge. The tracks are quite long, their length amounting to ten or more times the width of the tape. Because the cylinder around which the tape is wrapped rotates rapidly, usually in the 3500–3600 r/min range, the wavelength of the highest recorded modulation frequency (or of a recorded digital data symbol) ranges from 0.7 to 1.1 micron and is well accommodated by the magnetic recording process.

Older recording machine designs, like the 1-inch Type C analog composite helical recorder, use a reel-to-reel tape transport system, where two reels or spools serve to hold the tape in position for passage through the transport mechanism. The tape moves from the supply reel through the recording heads and onto the takeup reel. In all the other listed formats, the tape is contained in a plastic box called a cassette. For recording or playback use, the cassette is inserted into a loading slot in a recording or playing system. The tape is automatically extracted through a slot in the front of the cassette and guided around the helical recording assembly. When this loading process is completed, the machine is ready to receive the commands needed to record or replay a tape.

Professional video recording systems are standardized in North America by the SMPTE (Society of Motion Picture and Television Engineers) and internationally by Technical Committee 60—Recording of the IEC (International Electrotechnical Commission). The 1-inch SMPTE Type C composite recorder has been very heavily used for broadcasting and program production. This format uses full bandwidth FM recording, where the incoming video signal, in composite form, is frequency modulated onto an RF carrier which is then directly recorded on tape. For news gathering and other portable applications, the BetaCam™ and M-II™ analog component systems are frequently used. As

noted earlier, the 2-inch transverse track (quadruplex) recorder is obsolete. The ¾-inch U-format is gradually being replaced by the analog component systems and, soon, by new digital systems still under development.

Digital formats, now in the process of supplanting analog formats, include the 19-mm Type D-1 (component) and Type D-2 (composite) formats and the ½-inch Type D-3 (composite) system. (The "Type" identifiers are assigned by the SMPTE).

For home recording purposes, and for institutional use, the most common video recording formats are two well known VCR systems, the ½-inch VHS format and the 8 mm Video format. Improved, mostly compatible variants of these systems, called S-VHS and Hi-8, are used for some semiprofessional applications. These domestic-use formats incorporate a special process to permit recording of the color part of the video signal in an inexpensive way. The process is called *color under* and is not capable of recording the full bandwidth of color signals produced in the broadcast studio. Color under is an engineering compromise that works very well for a final, distribution tape, but is not well suited for full professional applications. It is anticipated that VHS and Video 8 will encounter competition from low-cost, consumer-market digital recording formats within the next few years. However, now, most video cassettes prepared for rental and sales to the public are VHS or (to a much smaller degree) Video 8.

As highly advanced as the magnetic recording of television signals may be, very many television programs are produced by photographic processes. Motion picture technology is also standardized in North America by the SMPTE. The list of SMPTE standards printed below includes many documents defining the parameters for motion-picture films intended for television and other professional uses.

Standards for Video Magnetic Tape and for Motion-Picture Film Recording Systems for Television use—The standards documents listed below are available from

Society of Motion Picture and Television Engineers
595 West Hartsdale Ave.
White Plains, NY 10607

STANDARDS

SMPTE 1-1990, Video Recording—2-in Magnetic Recording Tape
V98.2-1982, Specifications of Monochrome Video Magnetic Tape Leader
SMPTE 3-1986, Video Recording—Frequency Response and Operating Level of Recorders and Reproducers—Audio 1 Record on 2-in Tape Operating at 15 and 7.5 in/s
SMPTE 4-1989, Television Analog Recording—2-in Magnetic Tape for Quadruplex Recording—Speed
SMPTE 5-1989, Television Analog Recording—2-in Reels
SMPTE 6-1988, Video Recording—Video, Audio and Tracking-Control Records—2-in Quadruplex Tape
SMPTE 7-1988, Motion-Picture Film (16-mm)—Camera Aperture Image and Usage
SMPTE 8-1989, Video Recording—Quadruplex Recorders Operating at 15 in/s—Audio Level and Multifrequency Test Tape
V98.9-1983, Video Recording—Magnetic Tape—Color Leader
SMPTE 11-1989, Video Recording—Quadruplex Recorders Operating at 7.5 in/s—Audio Level and Multifrequency Test Tape
SMPTE 12M-1986, Television—Time and Control Code—Video and Audio Tape for 525-Line/60-Field Systems
SMPTE 13-1988, Video Recording—Cartridge Spools—2-in Quadruplex Tape
V98.18M-1983, Video Recording—1-in Type C Helical-Scan—Basic System and Transport Geometry Parameters
V98.19M-1983, Video Recording—1-in Type C—Records
SMPTE 20M-1985, Video Recording—1-in Type C Recorders and Reproducers—Frequency Response and Reference Level
SMPTE 21M-1986, Video Recording—3/4-in Type E Helical Scan—Records
SMPTE 22M-1986, Video Recording—3/4-in Type E Helical Scan—Cassette
SMPTE 23M-1986, Video Recording—1/2-in Type F Helical-Scan—Records
SMPTE 24M-1985, Video Recording—1-in Reel Dimensions
SMPTE 25M-1989, Video Recording—1-in Magnetic Recording Tape
SMPTE 26M-1989, Video Recording—1-in Helical-Scan Recorders—Raw Stock for Reference Tapes
V98.27M-1983, Video Recording—1-in Type C Reference Recorders—Basic System and Transport Geometry Parameters
V98.28M-1983, Video Recording—1-in Type C Reference Tapes—Records
SMPTE 31M-1989, Television Analog Recording—3/4-in Type E—Small Video Cassette
V98.32M-1983, Video Recording—1/2-in Type H Cassette—Records
V98.33M-1983, Video Recording—1/2-in Type H Cassette—Tape and Cassette
V98.34M-1984, Video Recording—1/2-in Type G Cassette—Records
V98.35M-1984, Video Recording—1/2-in Type G—Cassette and Tape
PH22.40-1984, Motion-Picture Film (35-mm)—Photographic Audio Records—Release Prints
SMPTE 41-1989, Motion-Picture Film (16-mm)—Photographic Audio Records—Prints
SMPTE 48-1989, Motion-Picture Film (16-mm)—Printed Area—Picture and Sound Contact Printing
PH22.55-1983, Motion-Picture Film—Leaders and Cue Marks—35- and 16-mm Audio Release Prints
SMPTE 56-1984, Motion-Picture Film—Nomenclature for Studios and Processing Laboratories

SMPTE 59-1989, Motion-Picture Film (35-mm)—Camera Aperture Images
SMPTE 75M-1988, Motion-Picture Film—Designation of A and B Windings for Raw Stock
SMPTE 83-1990, Motion-Picture Film (16mm)—Edge Numbers—Location and Spacing
PH22.86-1981, Position, Dimensions and Reproducing Speed of Three 200-Mil Magnetic Sound Records on 35-mm and One Record on 17.5-mm Motion-Picture Film
SMPTE 87M-1985, Motion-Picture Film (16-mm)—100-Mil Magnetic Striping
SMPTE 94-1985, Television—Image Areas and Mounts for Slides and Opaques
PH22.95-1984, Motion-Picture Film (35-mm)—Television Image Area
PH22.96-1982, Dimensions for Television Image Area on 16-mm Motion-Picture Film
SMPTE 97-1989, Motion-Picture Film (16-mm)—200-Mil Edge Position Magnetic Audio Record
SMPTE 101-1988, Motion-Picture Film (16-mm)—Perforated 2R-3000 Film—Magnetic Striping
SMPTE 102-1986, Motion-Picture Film (35-mm)—Perforated CS-1870
SMPTE 183M-1985, Motion-Picture Film—Measurement of Photoelectric Output Factor—Photographic Audio Level Test Films
SMPTE 196M-1986, Motion-Picture Film—Screen Luminance and Viewing Conditions—Indoor Theater Projection
PH22.202M-1984, Motion-Pictures—B Chain Electro-Acoustic Response—Control Rooms and Indoor Theaters
SMPTE 203-1987, Motion-Picture Film (35-mm)—Two-Track Photographic Audio Records—Prints
SMPTE 204-1987, Motion-Picture Film (16-mm)—Two-Track Photographic Audio Records—Prints
SMPTE 207M-1984, Television—Digital Control Interface—Electrical and Mechanical Characteristics
PH22.208M-1984, Motion-Picture Film (35-mm)—Recorded Characteristic—Magnetic Audio Records
PH22.209M-1984, Motion-Picture Film (8-mm Type S)—Recorded Characteristic—Magnetic Audio Records
SMPTE 210M-1990, Motion-Picture Film (16-mm)—Magnetic Audio Records—Two Records on 16-mm Magnetic Film
PH22.211M-1984, Motion-Picture Film—16- and 35-mm Variable-Area Photographic Audio Records—Signal-to-Noise Ratio
SMPTE 213M-1984, Motion-Picture Film (16-mm)—Recorded Characteristic—Magnetic Audio Records
SMPTE 214M-1984, Motion-Picture Film (35-mm)—Photographic Audio Reproduction Characteristic
SMPTE 216-1985, Motion-Picture Film (35-mm)—Recorded Characteristic of Magnetic Audio Records—Four-Track Striped Release Prints
SMPTE 217-1985, Motion-Picture Film (70-mm)—Recorded Characteristic of Magnetic Audio Records—Striped Release Prints
SMPTE 218M-1985, Motion-Picture Film (16-mm)—200-Mil Center-Position Magnetic Audio Record
SMPTE 220-1985, Motion-Picture and Television Equipment—Camera Mounting Connections—1/4-inch-20 Thread and 3/8-Inch-16 Thread Tripod Screws
SMPTE 222M-1987, Television—Monitor System Electro-Acoustic Response—Control and Review Rooms
SMPTE 223M-1985, Motion-Picture Film—Safety Film (Includes PH1.25)
SMPTE 224M, Television Digital Component Recording—19-mm Type D-1 Format—Tape Record
SMPTE 225M, Television Digital Component Recording—19-mm Type D-1 Format—Magnetic Tape
SMPTE 226M, Television Digital Component and Composite Recording—19-mm Type D-1 Format—Tape Cassette
SMPTE 227M, Television Digital Component Recording—19-mm Type D-1 Format—Helical Data and Control Records
SMPTE 228M, Television Digital Component Recording—19-mm Type D-1 Format—Time and Control Code and Cue Records
SMPTE 229M-1987, Video Recording—1/2-in. Type L Mode 1—Records
SMPTE 230M-1987, Video Recording—1/2-in Type L Mode 1—Electrical Parameters—Video, Audio, Time and Control Code and Tracking Control
SMPTE 233-1987, Motion-Picture Film (16-mm)—Projectable Image Area
SMPTE 238M, Television Analog Recording—1/2-in Type L—Tapes and Cassettes
SMPTE 240M-1988, Television—Signal Parameters—1125/60 High-Definition Production System
SMPTE 244M, Television Digital Recording—Representation of NTSC Encoded (System M) Video Signal—Active Video Portion
SMPTE 245M, Television Digital Recording—19-mm Type D-2 Composite Format—Tape Record
SMPTE 246M, Television Digital Recording—19-mm Type D-2 Composite Format—Magnetic Tape
SMPTE 247M, Television Digital Recording—19-mm Type D-2 Composite Format—Helical Data and Control Records
SMPTE 248M, Television Digital Recording—19-mm Type D-2 Composite Format—Cue Record and Time and Control Code Record
SMPTE 249M, Television Analog Recording—1/2-in Type M-2—Records
SMPTE 250M, Television Analog Recording—1/2-in Type M-2—Tapes and Cassettes
SMPTE 251M, Television Analog Recording—1/2-in Type M-2—Electrical Parameters of Video, Audio, Time and Control Code and Tracking Control
SMPTE 252M, Television Analog Recording—1/2-in Type M-2—Pulse Code Modulation Audio
SMPTE 253, Television—Three-Channel Parallel Component Analog Video Interface

SMPTE 255M, Television Analog Recording—25.4-mm Type J—High-Definition Signals
SMPTE 256M Television—Specifications for Video Tape Leader

RECOMMENDED PRACTICES

RP 9-1986, Dimensions of Double-Frame 35-mm 2×2 Slides for Precise Applications in Television
RP 14-1988, Plotting Data from Sensitometric Strips Exposed on Type Ib (Intensity Scale) Sensitometers
RP 15-1988, Calibration of Densitometers Used for Black-and-White Photographic Density Measurement
RP 27.1-1989, Specifications for Operational Alignment Test Pattern for Television
RP 27.2-1989, Specifications for Operational Registration Test Pattern for Multiple-Channel Television Cameras
RP 27.3-1989, Specifications for Safe Action and Safe Title Areas Test Pattern for Television Systems
RP 27.4-1985, Specifications for Operational Test Pattern for Checking Jitter, Weave and Travel Ghost in Television Projectors
RP 27.5-1989, Specifications for Mid-Frequency Response Test Pattern for Television
RP 27.7-1987, Specifications for Gray-Scale Operational Alignment Test Pattern for Telecine Cameras
RP 37-1969, Color Temperature for Color Television Studio Monitors (R1982)
RP 38.1-1989, Specifications for Deflection Linearity Test Pattern for Television
RP 41-1983, Evaluation of Color Films Intended for Television
RP 46-1990, Density of Color and Black-and-White Films, Prints and Slides for Television
RP 47-1985, Electronic Method of Dropout Detection and Counting (R1989)
RP 61-1989, Specifications for Azimuth Test Film for 8-mm Type S Audio Reproducers, Magnetic Type
RP 62-1989, Specifications for Flutter Test Film for 8-mm Type S Audio Reproducers, Magnetic Type
RP 63-1989, Specifications for Sound-Focusing Test Film for 16-mm Audio Reproducers, Photographic Type
RP 64-1987, Specifications for Audio-Focusing Test Film for 35-mm Audio Reproducers, Photographic Type
RP 65-1987, Step Optical Reduction Printing of 35-mm Images to 16-mm Prints and Duplicate Negatives
RP 66-1987, Step Optical Enlargement Printing of 35-mm Images from 16-mm Images
RP 67-1989, Specifications for Buzz-Track Test Film for 16-mm Motion-Picture Audio Reproducers, Photographic Type
RP 68-1984, Specifications for Buzz-Track Test Film for 35-mm Motion-Picture Photographic Audio Reproducers
RP 69-1989, Specifications for Scanning-Beam Uniformity Test Film for 35-mm Motion-Picture Audio Reproducers
RP 70-1989, Specifications for Flutter Test Film for 16-mm Audio Reproducers, Photographic Type
RP 71-1977, Setting Chromaticity and Luminance of White for Color Television Monitors Using Shadow-Mask Picture Tubes
RP 72-1977, Specifications for an Illuminator of Test Pattern Transparencies for Television Studio Cameras (R1988)
RP 85-1985, Tracking-Control Record for 1-in Type C Helical-Scan Video Tape Recording
RP 86-1985, Video Record Parameters for 1-in Type C Helical-Scan Video Tape Recording

Video Disk Recordings—The use of optical video disk recordings is increasing. The basic design of the optical video disk system dates to the early 1980s, but various factors, including the availability of low-cost VCR machines, have slowed acceptance of the video disk. The basic process for manufacturing the optical video disk is to etch, in a continuous spiral on a master disk, millions of "pits" that are width modulated by the incoming video signal. This etching is accomplished by a modulated laser beam. Aluminized plastic replicas of the master are then made in large volume and are read (played back) by a low-power laser in the disk player. The recorded and reproduced signal is analog. The fundamental manufacturing process is similar in many ways to that used to produce compact disk (CD) recordings.

Both advantages and disadvantages are evident in the video disk system. For example, a VCR provides the user with the option of recording television programs for later replay; the video disk is, up to now, entirely a playback system. The recording situation may change as the evolution of writeable and erasable optical disks evolves, but it is not clear that costs can be sufficiently reduced to assure success in the consumer market. Even so, the disk offers a series of advantages to the professional user and to demanding consumers. The system allows a high degree of random access; the laser beam may be directed to reproduce any part of the disk, to an accuracy of a single television frame, in less than a second. In addition, the recording system is a wide-bandwidth system and is capable of excellent picture quality. Both of these useful attributes have made the

video disk popular for special applications such as the distribution of recorded instructional and advertising material by industrial users, as well as for educational purposes in schools. It is also true that critical consumers are turning to video disk recordings of motion pictures for television display in their homes. Often the picture quality obtained from the video disk is superior to that obtainable from VCR equipment. The standards for video disk systems are written and published by the IEC, through Technical Committee 60. The address of the IEC is given in the section "International Standards for Broadcasting" at the end of this chapter.

Selected Lists of Television Standards

Listed below are two groups of industrial standards that are useful in television engineering. The EIA list is abbreviated; readers are encouraged to contact EIA headquarters, at the address listed earlier in this chapter in the subsection "Standards and Specifications for Recording Systems." A comprehensive, up-to-date listing is available.

EIA Television Standards (Partial List)

TEP106-B, Worldwide Type Designation System for TV Picture Tubes and Monitor Tubes
TVSB5, Multichannel TV Sound System—BTSC System Recommended Practices
EIA/IS-6, Recommended Able Television Channel Identification Plan
IEB1, Closed Circuit Television Definitions
IETNTS1, Color Television Studio Picture Line Amplifier Output Drawing
EIA-170, Electrical Performance Standards—Monochrome Television Studio Facilities
EIA-312-A, Engineering Specification Outline for Monochrome CCTV Camera Equipment
EIA-330, Electrical Performance Standards for Closed Circuit Television Camera 525/60 Interlaced 2:1
EIA-343-A, Electrical Performance Standards for High Resolution Monochrome Closed Circuit Television Camera
EIA-375-A, Electrical Performance Standards for Direct View Monochrome Closed Circuit Television Monitors 525/60 Interlaced 2:1
EIA-403-A, Precision Coaxial Connectors for CASTV Application (75 Ohm)
EIA-412-A, Electrical Performance Standards for Direct View High Resolution Monochrome Closed Circuit Television Monitors
EIA-420, Electrical Performance Standards for Monochrome Closed Circuit Television Cameras 525/60 Random Interlace
EIA-439, Engineering Specification for Color CCTV Camera Equipment
EIA-508, Electrical Performance Standards for Television Broadcast Transmitters
EIA-563, Standard Baseband (Audio/Video) Interface Between NTSC Television Receiving Devices and Peripheral Devices

Other EIA Standards:
EIA-232-D, Interface Between Data Terminal Equipment and Data Circuit Terminating Equipment Employing Serial Binary Data Interchange
EIA-422-A, Electrical Characteristics of Balanced Voltage Digital Interface Circuits

Note: In addition to this selected list of EIA publications, the association publishes an extensive range of standards and other engineering publications concerned with electronics and electronic engineering. A catalog may be obtained from the address given above in the subsection "Standards and Specifications for Recording Systems."

International Standards for Television Recording—Most of the SMPTE and EIA documents listed above have equivalent specifications in the publications of international standardizing bodies. Video recording standards are produced by the IEC Subcommittee 60B and broadcast program exchange specifications by the CCIR (published in CCIR Volume 11—Television Broadcasting). A listing of relevant IEC and CCIR standards is given later in this chapter. In addition, a set of technical publications concerning video recording of 625-line PAL and SECAM color television signals is available from the Technical Centre of the European Broadcasting Union (EBU), whose address is given later in this chapter.

International Standards for Television Film Systems—Standards defining international specifications for motion picture film are drafted by ISO Technical Committee 36 (TC 36). An abbreviated listing of these documents is contained in the last part of this chapter. In the USA, ISO standards may be obtained from ANSI. In addition, the EBU publishes specifications for motion picture film intended for television use by members of the EBU, and the CCIR publishes specifications, in CCIR Volume 11—Television, for motion picture films to be used for the international exchange of television programs.

DIGITAL TELEVISION SYSTEMS

Introduction—The Basics

Television is a medium for recording and transferring images and sound from one point to another. The image portion of the system is a "light-to-light" system, gathering variations in light at the source via a pickup device (such as a camera) and recreating those variations in light as a visual image via a display device such as a cathode ray tube (CRT). The television system transports the source information by scanning the image and generating a continuous electronic signal that is a representation of the light. Since the variations in light at both the source and the display are continuous, the television signal is inherently an analog signal, a signal whose amplitude as a function of time represents the

visual content of the television image. This analog signal can be transformed into a linear pulse-code-modulation (PCM) digital representation of the image.

Digital forms of television have certain advantages over the analog signal formats. An analog signal can be degraded by the various transport media and processes. These degradations include both linear and nonlinear distortions and the introduction of noise. The degradations are both cumulative and difficult to separate from the analog signal. Digital signals consist of a sequence of two levels of information (logical 1s and logical 0s) that can be sampled and restored as long as the distortion and noise levels do not exceed certain thresholds. Further, digital systems can be encoded with redundant information so that even in the presence of distortion and noise that exceeds the threshold of separation between a 1 and a 0, the original information can be restored. Once a television system has been digitized, the image information is in the form of a series of numbers which can be processed in a uniform and consistent manner.

A digital television system (Fig. 19) consists of an image source, a means such as a camera of converting the image into an analog electronic signal (E_A), a means of transforming the analog signal into a digital signal (analog-to-digital convertor, or A/D), some process (P_D) which is applied to the digital signal, a means of retransforming the resulting digital signal back to the analog domain (digital-to-analog convertor, or D/A), and a means such as a display of reconverting the analog signal back into "light" for the benefit of the observer.

The digital process (P_D) varies according to the application. It can be a variable time delay used for frame synchronization and time-base correction, a video processor that corrects for luminance and chrominance error, an image manipulator that permits digitally generated effects and graphics to be added to the image, a data-compression scheme to reduce the amount of data, or simply a transmission path.

The A/D converter (Fig. 20) consists of four basic components, a band-limiting, antialiasing filter (F_A), a sample-and-hold circuit (S&H) that samples the analog signal, the quantizing unit (Q) that divides the range of each analog signal sample into Q distinct levels, and finally an encoder (ENC) that places a specified code on the output data lines (D_0–D_n) for each of the Q levels. For binary systems, Q is a power of 2 ($Q = 2^B$), where B is the number of bits) and the number of data lines is related to the number of bits ($n = B - 1$).

The D/A converter (Fig. 21) consists of four basic components, a digital input register (REG) in which the bits of the word to be converted are stored for one time period, a decoder (DEC) that converts the data lines into Q distinct analog levels, a resampling (R_c) circuit that corrects for distortions due to the digital sample-and-hold process, and a band-limiting, restoration or reconstruction filter (F_D).

Resolution

The resolution of a television system is a measure of its ability to delineate picture detail. For a number of lines N, normally alternate black and white lines, the width of each line is $1/N$ times the picture height. From this definition, television resolution is expressed as R television lines per picture height (tvl/ph).

Based on early empirically derived data taken from Engstrom* and others and later by Wheeler and Loughren,† it was determined that vertical resolution (R_v) could be expressed as kN_v, where k represented a utilization factor that for 2:1 interlaced CRT devices was in the range 0.64 to 0.71. The factor k is influenced by many variables including the shape of both the gathering beam and the display beam. Work done on progressive scan displays places an upper bound on k of 0.95. Assuming $k = 0.66$, the vertical resolution of the NTSC-M system is given as $R_v = 320$ tvl/ph.

Horizontal resolution (R_h) is a function of the active line period, the aspect ratio (A) of the image, and the bandwidth of the signal (f), and is given as:

$$R_h = 2\,(1/A)P(f)/(F \times L)$$

where,

P = percent active period of the total line period,
F = frame rate,
L = number of scan lines.

For NTSC:

$1/A = 0.75$
$P \approx 52.655/63.555 = 0.828$
$F = 29.97003$
$L = 525$

and $R_h = 78.9 \times 10^{-4}\,(f) = 331.5$ tvl/ph for $f = 4.2$ MHz.

The image resolution and dynamic range of the digital system is limited by seven characteristics:

* Reference 1.
† Reference 2.

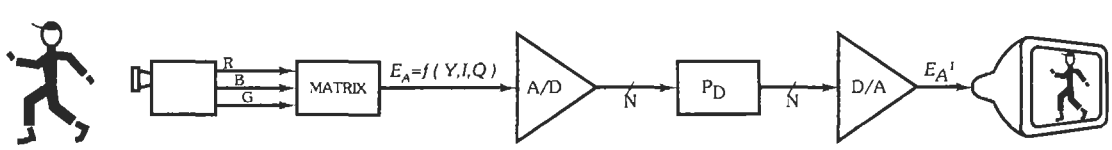

Fig. 19. Digital television system.

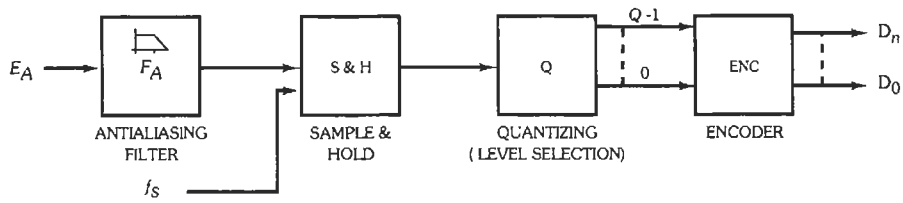

Fig. 20. A/D converter.

1. The resolution limitation (R_h) of the analog signal being converted, as noted above
2. The characteristics of the band-limiting, anti-aliasing filter (F_A) in the A/D converter
3. The frequency (f_S) of the A/D sampling pulse
4. The shape of the sampling pulse at the A/D converter
5. The number of bits (B) in the data word (D_0–D_n) which determines the number of levels (Q) that can be defined
6. The shape of the resampling pulse (f_R) at the D/A converter
7. The characteristics of the band-limiting, restoration filter (F_D) at the D/A converter.*

Sampling and Spectra

An analysis of the television signal spectrum shows that the spectrum is composed of discrete frequency components about harmonics of the line frequency (f_H) and field rate (f_F) (Fig. 22). The analog signal is sampled by the periodic nature of the scanning structure, in that the scanning lines and the creation of image frames have the effect of sampling the analog signal in the temporal (T) and vertical (V) dimensions, respectively. Whenever an analog signal of spectrum f_A is sampled at intervals, such as with a rectangular pulse train with a period of T, (where $1/T = f_S$ and f_S is the sampling frequency) as described in Fig. 23, the sampled signal has a spectrum equal to the original spectrum plus a double sideband of width $2 \times f_A$ repeated every f_S Hz, as shown in Fig. 24. In the NTSC system, most of the energy of the luminance signal is concentrated in a set of sidebands of the line frequency. Most of the energy of the chrominance signal is concentrated in a set of sidebands of the color subcarrier frequency. Since the color subcarrier is an integer multiple (455/2) of the line frequency, these latter sidebands are also related to the line frequency.† In the NTSC system, the temporal sampling frequency (f_F) is 59.94006 Hz, and the vertical sampling frequency is the line rate (f_H), 15.734 + kHz.

As shown in Fig. 20, the first step in the analog-to-digital conversion process is to sample the analog signal with the digital sampling clock of frequency f_S. This produces a third shift in the frequency domain as shown in Fig. 24 by creating a sampling structure in the horizontal (H) dimension.

A close inspection of the process in both the temporal and frequency domains indicates that the sampling process must conform to certain criteria. If the maximum frequency contained within the analog signal is f_A and the frequency of the sampling pulse is f_S, then f_S must be greater than $2 \times f_A$. Fig. 24 shows the result of sampling the spectra with a sampling frequency greater than $2 \times f_A$. When an analog signal is sampled at a rate at least twice its highest frequency component, the sampling is said to meet the *Nyquist criterion*. Fig. 25 shows the result of sampling the spectra with a sampling frequency less than $2 \times f_A$. It is clear that if the frequency of the sampling pulse is less than $2 \times f_A$, the spectra of the original baseband signal and the spectra of the sidebands at the multiples of the sampling frequency of the resultant Fourier transform overlap as shown by the shaded area in Fig. 25. This makes an accurate restoration of the original baseband signal extremely difficult, as the sidebands would appear to have component information that does not really exist.** The erroneous signal content is termed *aliasing*. Fig. 26 shows an example of a sub-Nyquist–sampled, analog baseband signal of a single frequency for illustrative purposes. In this instance, the reconstructed signal

* Reference 3.

† Reference 4.

** Reference 5.

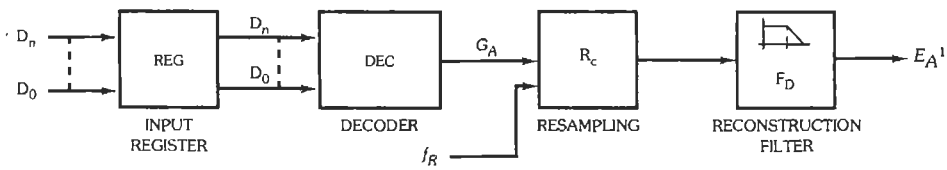

Fig. 21. D/A converter.

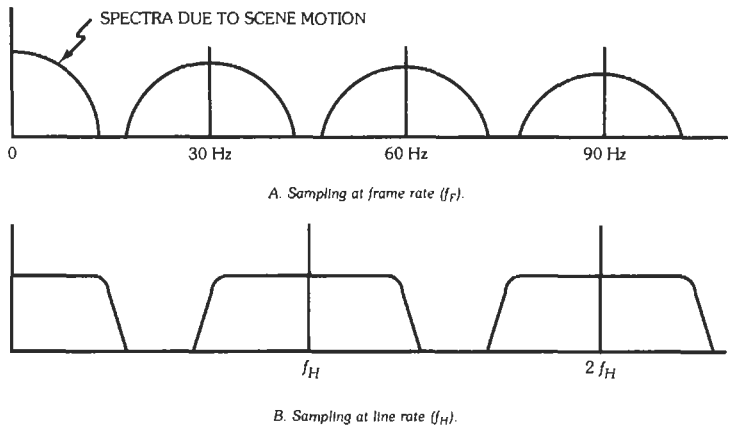

Fig. 22. Sampling spectra.

would have two frequency components where the original signal consisted of a single frequency component.

A low-pass filter is inserted at the first stage of the A/D converter to limit the frequency content of the analog signal to within the Nyquist criteria. This filter is often referred to as an *antialiasing* filter.

In television systems, the sampling clocks selected not only meet the Nyquist criteria but also are generally multiples of the horizontal line rate (f_H) of the system. A sampling clock which is a multiple of f_H produces a sampling structure which is orthogonal as shown in Fig. 27.

Orthogonal structures are line, field, and frame repetitive, meaning that the samples "line up." Such structures simplify the process of digital filtering. Further, it is also desirable for the sampling-pulse frequency of encoded systems such as NTSC to be multiples of the color subcarrier. In the NTSC system, a sampling clock that is $4f_{sc}$, or four times the color subcarrier, is also a harmonic of the line rate and, therefore, orthogonal. This simplifies the separation of luminance and color from an encoded signal. A picture sample (X), or pel, on one line has a luminance (Y) and chroma ($+C$) component ($X = Y + C$). If the picture element in the next line is the same, it will have the same luminance (Y) value, but the chroma value will be 180° out of phase ($X = Y - C$). One-half the sum of the two equals Y, and one-half the difference of the two equals C:

$$\tfrac{1}{2}\,[(Y + C) + (Y - C)] = Y$$

$$\tfrac{1}{2}\,[(Y + C) - (Y - C)] = C$$

The television systems of the broadcast 525-line and 625-line standards are all derived from a relationship to

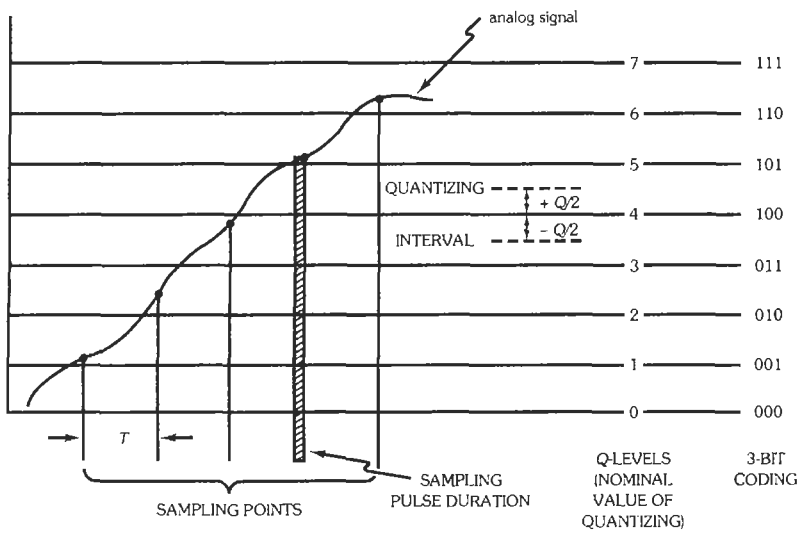

Fig. 23. Sampling an analog signal.

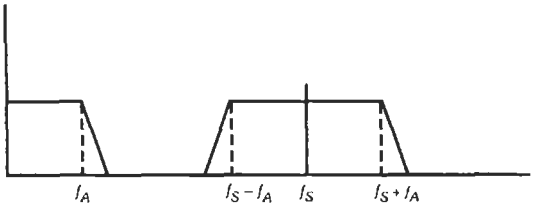

Fig. 24. Sampling—Nyquist criterion ($f_S \geq 2f_A$).

4.5 MHz as shown in Fig. 28, and therefore, the line, field, frame, and sampling frequencies have integer submultiple relationships. This also helps when samples based on one sampling structure must be translated (standards converted) into an alternative sampling structure. The sampling structures for the proposed advanced television (ATV) systems are also orthogonal.

Quantizing and Dynamic Range

The analog signal having been separated into discrete samples, the second step is to quantize the samples. Quantizing a set of values (or samples) is simply the act of describing each member of the set of values as a multiple of a basic unit, dividing the range of values into Q quantizing levels. The range of values which can be represented is 0 to $Q-1$. In binary systems, $Q = 2^B$, where B equals the number of bits. A segment of an analog signal waveform is shown in Fig. 23 with the periodic sampling signal and an eight-level quantizer ($Q = 2^3$) superimposed. If we assume that each level represents 0.125 V, then the range of the input signal that can be accurately represented is 0 to 0.875 V (0 to 7 times 0.125 V). The levels need not be uniformally quantized (equally spaced) to provide a linear sampling of the analog signal, but in most systems, the levels are uniformally quantized.

The sampled analog signal is discrete in time but remains continuous in amplitude. However, the quantizing process assigns all analog values within a specific quantizing interval the same quantizing value, the nominal value for that interval. This produces a quantizing error in the restored, reconverted analog signal; this error is known as *quantizing noise*. As shown in Fig. 23, the quantizing error can not exceed $\pm Q/2$.

The theoretical maximum peak-to-peak signal–to–quantization-noise ratio (SNR), or dynamic range, of the quantized signal is determined by the number of

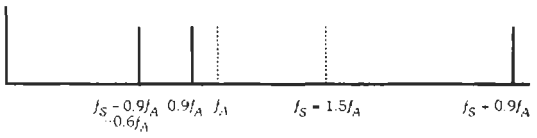

Fig. 26. Sub-Nyquist sampling—single frequency.

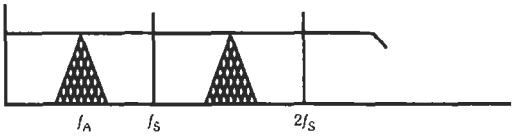

Fig. 25. Sub-Nyquist sampling ($f_S < 2f_A$).

levels (Q) selected, but is also influenced by the shape of the sampling pulse and the relationship between the maximum bandwidth of the signal, f_A, and the sampling frequency, f_S. The analog signal contains noise, and, as a very over-simplified explanation, the sampling process tends to "average" the noise in a sample. The equation for SNR of a quantized signal is:

$$\text{SNR} = K + 20 \log Q$$

and since Q can be replaced in binary systems by 2^B,

$$\text{SNR} = K + 20 \log 2^B = K + B \times 20 \log 2 = K + B \times 6.02$$

In uniformally quantized, pulse-coded modulation (PCM) systems, K has been derived as:

$$K = K_P + 10 \log [f_S/(2 \times f_A)]$$

where K_P is the component due to the application of uniformally quantized sampling and is given as 10 log 12. Therefore,††

$$K = 10.79 + 10 \log [f_S/(2 \times f_A]$$

For the example of a 4.2-MHz NTSC signal, sampled at four times the color subcarrier in a ten-bit system (Q = 1024),

$$\text{SNR} = 10.79 + 10 \log (14.318/8.4) + 10 \times 6.02 = 73.30$$

Composite and Component Signal Coding

The transmitted television signal format in the United States is the NTSC-M format, a composite signal consisting of the luminance (Y) information, the chrominance information as two signals (I and Q) quadrature modulated onto a color subcarrier, and the synchro-

nization pulses. This signal is also the format used in many instances in television production facilities for distribution and recording of the television signal. The analog television signal originates in the camera as a tricolor signal representing the red (R), green (G), and blue (B) components of the signal. The R, G, and B components are matrixed to form the Y, I, and Q signals as described in Fig. 19 and Table 7. The analog television signal also appears in its component form in some portions of the production facility, such as in the production of graphics or special effects in order to avoid the limitations in both luminance and chrominance signal bandwidth and cross-color and cross-luminance distortions inherent in the NTSC system and the signal degradation caused by multiple decoding of the composite signal back into its components and the re-encoding to the composite form.

The digital television signal may be implemented in either the composite or component representation of the television signal. The composite representation is based on the sampling of the NTSC encoded signal and is described in the section "Composite Encoded Signals: SMPTE 244 (NTSC and PAL)." The component representation accepts separate baseband tricolor stimulus signals and individually samples and quantizes them. The component representation of the video signal can be in one of many tristimulus formats. The most common formats are (1) a luminance signal, Y, and two color-difference signals, $k_B(B - Y) = C_B$ and $k_R(R - Y) = C_R$; and (2) the baseband R, G, and B signals. The component representations are discussed in the section "Component Coding of Signals: SMPTE 125 and CCIR 601."

Bit-Parallel and Bit-Serial Interfaces

The composite and component signal format interfaces are both electrically and mechanically similar in both the parallel data format and serial data format. The parallel interface consists of a unidirectional, eleven-pair interconnection between a transmitting equipment and a receiving equipment. Video data, timing reference information, and ancillary signals are time multiplexed and transferred on ten data pairs in NRZ form. An eleventh pair provides a synchronous clock. The serial interface consists of a unidirectional, bit-serial single interconnection between a transmitting equipment and a receiving equipment.

The data signals are in the form of binary information coded in 8- or 10-bit words. These signals are:

Video data
Timing reference codes
Ancillary data, including audio services
Identification codes such as video index information

The signaling sense of the voltage appearing across the interconnection cable is positive binary and defined as follows (refer to Fig. 29):

1. The A terminal of the transmitter shall be negative with respect to the B terminal for a binary 0 (LOW or L or OFF) state.
2. The A terminal of the transmitter shall be positive with respect to the B terminal for a binary 1 (HIGH or H or ON) state.
3. In these interfaces, all digital-signal time intervals are specified at the half-amplitude points. All transitions are specified between the 20% and 80% amplitude points.
4. In the parallel signal interface, the data lines are designated DATA 0 through DATA 9. The group of ten signals is identified by placing parentheses around the range of subscripts included, as DATA (0–9). When 8-bit signals are conveyed by the interface, DATA (2–9) are used and DATA (0–1) are set to zero. DATA 9 is always the most significant bit.*

Composite Encoded Signals: SMPTE 244 (NTSC and PAL)

The Society of Motion Picture and Television Engineers (SMPTE) developed a common composite interface that serves the needs of both 525-line/59.94-Hz NTSC systems and 625-line/50-Hz PAL systems. The characteristics of the interface are summarized for the 525-line case in Table 8.†

Component Coding of Signals: SMPTE 125 and CCIR 601

The Society of Motion Picture and Television Engineers (SMPTE) and the European Broadcasting Union (EBU), working jointly, developed a common component interface that serves the needs of both 525-line/59.94-Hz systems and 625-line/50-Hz systems. The interface is documented in CCIR (International Radio Consultative Committee) Recommendation 601 and in SMPTE 125M. The characteristics of the interface are summarized in Tables 9 and 10.

The Y, C_B, and C_R signals are transmitted at the 4:2:2 level equivalent of the CCIR document 601 digital hierarchy for television signals, with a nominal sampling frequency of 13.5 MHz for the luminance signal and 6.75 MHz for each of the color-difference signals.

Because of the existence of both 8-bit and 10-bit equipment, all synchronizing signals (EAV, SAV, ANC) must be detected by reference to the 8 most significant bits only.

In the parallel data format, data is transmitted across the interface on ten data pairs: DATA 0 through DATA 9. DATA 9 is the most significant bit (MSB). For the 10-bit system, 1016 of the 1024 levels [digital levels 4 (004_H) through 1019 ($3FB_H$)] of the ten-bit word are used to express quantized values. For the 8-bit system, data values 1 through 254 (01_H–FE_H) may be used to express quantized signal values.

The digital code words that describe the video signal are conveyed as a 27-megaword/second multiplex in the following order:

$$C_B, Y, C_R [Y], C_B \ldots$$

where the three words C_B, Y, and C_R refer to the co-sited samples; the following [Y] is an isolated luminance-only sample. The C_R, C_B samples are co-sited with the odd (1st, 3rd, 5th, . . .) Y samples on each line, as shown in Fig. 30. The first video data word in the active line period is C_B.

Synchronization and Blanking Interval Considerations

The digital interfaces provide for the transmission of synchronization and ancillary data that may be multiplexed into the data stream during video blanking intervals. In each of the component systems, four specific sample words or interface clock intervals are reserved for the end-of-active-video (EAV) timing reference, and four specific sample words are reserved for

TABLE 9. ENCODING PARAMETERS FOR COMPONENT TELEVISION AT 4:2:2 LEVEL

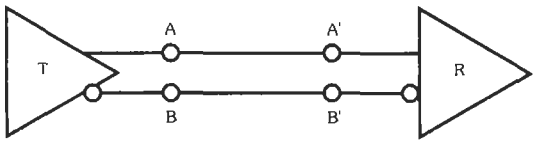
Parameter	525-Line, 59.94-Fields/s	625-Line, 50-Fields/s
Coded signals	Y, C_B, C_R	
No. of samples, total line		
Luminance signal (Y)	858	864
Each color-difference signal (C_B, C_R)	429	432
Sampling structure	Orthogonal (line, field, and picture repetitive). C_B and C_R samples cosited with odd Y samples in line.	
Sampling frequency		
Luminance signal	13.5 MHz	
Each color-difference signal	6.75 MHz	
Multiplexed parallel data interface clock rate	27.0 MHz	
Serial interface clock rate	270 MHz	
Form of coding	Uniformly quantized PCM, 8 or 10 bits per sample, for the Y, C_B, and C_R signals.	
Number of samples per digital active line		
Luminance signal	720	
Each color-difference signal	360	

the start-of-active-video (SAV) timing reference. The timing reference signals are contiguous with the video data, when present, and continue through the vertical-blanking interval. The EAV and SAV timing references are the digital horizontal-synchronization signals and occur on every line. The interval starting at EAV and ending with SAV is the digital horizontal-blanking period.

Any interface clock intervals not required to carry video information may be used to carry ancillary

TABLE 10. QUANTIZATION LEVELS FOR COMPONENT TELEVISION AT THE 4:2:2 LEVEL

Parameter	Quantization
Correspondence between video signal levels and quantization levels	
Luminance signal	8 bit systems: 220 quantization levels with the black level corresponding to level 16 (10_H) and the peak white level corresponding to level 235 (CB_H) 10 bit systems: 877 quantization levels with the black level corresponding to level 64 (040_H) and the peak white level corresponding to level 940 ($3AC_H$)
Each color difference signal	8 bit systems: 225 quantization levels symmetrically distributed about level 128 (80_H) corresponding to the zero level 10 bit systems: 897 quantization levels symmetrically distributed about level 512 (200_H) corresponding to the zero level
Quantization level assignments	8 bit systems: 254 of 256 levels (digital levels 1 through 254) of the eight-bit word are used to express quantized values. Data levels 0 (00_H) and 255 (FF_H) are reserved to indicate timing references. 10 bit systems: 1016 of 1024 levels (digital levels 4 through 1019) of the ten-bit word are used to express quantized values. Data levels 0 (00_H) through 3 (03_H) and 1020 ($3FC_H$) through 1023 ($3FF_H$) are reserved to indicate timing references.



T = Transmitter
R = Receiver
A,A' = Data line
B,B' = Return line

information. In each system, a specific interface clock interval is designated line-word 0 for the purpose of reference only. All the other sample words per total line are therefore numbered 1 to *N*, where *N* is one less than the ratio of the interface clock frequency to the line frequency. For example, in SMPTE 125M, the ratio of the 27-MHz interface clock frequency to the 15.734-kHz line frequency is 858. The sample words are, therefore, numbered 0 to 857.

The EAV and SAV references consist of a four-word sequence in the following format:

3FF 000 000 XYZ

The first three words are a fixed preamble. The fourth word contains information providing even field (field 2) identification, the state of vertical blanking, and the state of horizontal blanking.

Because of the existence of both 8-bit and 10-bit equipment, for detection purposes all values in ranges 000–003 and 3FC–3FF must be considered equivalent to 000 and 3FF, respectively.

In each system, the half-amplitude point of the leading or falling edge of the analog horizontal-sync signal (OH) is described as coincident with a specified sampling point.

Ancillary Data Signal Format

Ancillary data may be inserted in any portion of the data stream not occupied by timing-reference signals or video data. Two categories of the ancillary data, horizontal ancillary data (HANC) and vertical ancillary data (VANC), are defined for different portions of the data stream. The same three-word header is used to identify both HANC and VANC ancillary data, although 8-bit representation of the header is permitted for VANC only.

Horizontal ancillary data is permitted in all horizontal intervals. It is not permitted in the active portion of the lines. HANC data is of 10-bit format, and each block of HANC data is preceded by the three-word ancillary-data header, 000 3FF 3FF. The ancillary header may occur multiple times during each horizontal-blanking period if different blocks of data are transmitted.

All permitted data identification words and data formats will protect the values 000 to 003 and 3FC to 3FF.

Vertical ancillary data is permitted only in the active portion of specified lines of the vertical interval. In some systems, certain lines are reserved for digital vertical-interval time code (DVITC) and video index. VANC data is of the 8-bit format, and each block of VANC data is preceded by the three-word ancillary-data header, 000 3FF 3FF. The ancillary header may occur multiple times during each line period if different blocks of data are transmitted.

Advanced Television Systems

ATV Systems—The abbreviation ATV refers to television systems that provide improved audio and video quality or enhance the current television systems. The term ATV embraces both enhanced definition television (EDTV) and high definition television (HDTV). The term HDTV is generally accepted as referring to systems which provide approximately twice the resolution of the current NTSC services in both the horizontal and vertical dimensions. The term EDTV is generally accepted as referring to systems which provide improved resolution when compared to the current NTSC services but which do not qualify as HDTV systems. The audio performance of an ATV system should approximate that of current CD technology.

An interface signal format has been defined for a 525-line, 59.94-fields/s, wide-screen (wide screen aspect ratio = 16:9 = 1.7777:1) digital color television system. The system is an upscaled version of SMPTE 125M, modified to accommodate the requirements for the wide aspect-ratio images. The standard NTSC aspect-ratio image is 4:3 = 1.3333:1. The ratio of 1.7777 to 1.3333 is 1.3333 = 4/3. Therefore, the values in Table 9 and those in Table 11 have the relationship of 4/3.

HDTV—At least three different HDTV production systems have been developed for possible use in NTSC countries. The three systems are the 1125/60/2:1, 1050/59.94/2:1, and 787.5/59.94/1:1 systems, where the first value is the number of lines per frame, the second value is the number of fields per second, and the third quantity (X:Y) is the interlace factor. All three systems feature a wide-screen aspect ratio (16:9 = 1.7777:1).

An interface signal format has been defined for the 1125-line, 60-fields/s, 2:1-interlaced digital color

TABLE 11. ENCODING PARAMETERS FOR WIDE-SCREEN COMPONENT TELEVISION AT 4:2:2 PRODUCTION LEVEL*

Parameter	525-Line, 59.94-Fields/s	625-Line, 50-Fields/s
Coded signals	Y, C_B, C_R	
No. of samples, total line		
Luminance signal (Y)	1144	1152
Each color-difference signal (C_B, C_R)	572	576
Sampling structure	Orthogonal (line, field, and picture repetitive). C_B and C_R samples cosited with odd Y samples in line.	
Sampling frequency		
Luminance signal	18.0 MHz	
Each color-difference signal	9.00 MHz	
Multiplexed parallel data interface clock rate	36.0 MHz	
Serial interface clock rate	360 MHz	
Form of coding	Uniformly quantized PCM, 8 or 10 bits per sample, for the Y, C_B, and C_R signals.	
Number of samples per digital active line		
Luminance signal	960	
Each color-difference signal	480	

* Reference 15.

TABLE 12. ENCODING PARAMETERS FOR WIDE-SCREEN HDTV 1125/60 COMPONENT TELEVISION AT 4:2:2 PRODUCTION LEVEL*

Parameter	1125/60/2:1 System
Coded signals	Y, C_B, C_R $Y = 0.701\ G + 0.087\ B + 0.212\ R$ $C_B = (B - Y)/(1.826)$ $C_R = (R - Y)/(1.576)$
No. of samples, total line	
Luminance signal (Y)	2200
Each color-difference signal (C_B, C_R)	1100
Sampling structure	Orthogonal (line, field, and picture repetitive). C_B and C_R samples cosisted with odd Y samples in line.
Sampling frequency	
Luminance signal	74.250 MHz
Each color-difference signal	37.125 MHz
Multiplexed parallel data interface clock rate	148.50 MHz
Form of coding	Uniformly quantized PCM, 8 or 10 bits per sample, for the Y, C_B, and C_R signals
Number of samples per digital active line	
Luminance signal	1920
Each color-difference signal	960

* Reference 16.

TABLE 13. ENCODING PARAMETERS FOR COMPONENT 1050- AND 1250-LINE TELEVISION AT 4:2:2 LEVEL*

Parameter	1050-Line, 59.94-Fields/s	1250-Line, 50-Fields/s
Coded signals	Y, C_B, C_R	
No. of samples, total line		
Luminance signal (Y)	2288	2304
Each color-difference signal (C_B, C_R)	1144	1152
Sampling structure	Orthogonal (line, field, and picture repetitive). C_B and C_R samples cosited with odd Y samples in line.	
Sampling frequency		
Luminance signal	72.0 MHz	
Each color-difference signal	36.0 MHz	
Multiplexed parallel data interface clock rate	144 MHz	
Serial interface clock rate	1440 MHz	
Form of coding	Uniformly quantized PCM, 8 or 10 bits per sample, for the Y, C_B, and C_R signals.	
Number of samples per digital active line		
Luminance signal	1920	
Each color-difference signal	960

HDTV electronic production system. The suggested parameter values are given in Table 12.

An interface signal format has been defined for the 1050-line, 59.94-fields/s, 2:1-interlaced digital color HDTV television system. Since the 1050-line system is a doubled, upscaled version of the 525-line system described in SMPTE 125M, the digital-system parameter values that apply to the 1050-line system could also apply to a 1250-line, 50-fields/s, 2:1-interlaced system. The suggested parameter values are given in Table 13.

TABLE 14. ENCODING PARAMETERS FOR COMPONENT 787.5-LINE TELEVISION AT 4:2:2 LEVEL*

Parameter	787.5-line, 59.94-fields/s
Coded Signals	Y, C_B, C_R
No. of samples, total line	
Luminance signal (Y)	1596
Each color-difference signal (C_B, C_R)	798
Sampling structure	Orthogonal (line, field, and picture repetitive). C_B and C_R samples cosited with odd Y samples in line.
Sampling frequency	
Luminance signal	75.336 MHz
Each color-difference signal	37.668 MHz
Multiplexed parallel data interface clock rate	150.672 MHz
Serial interface clock rate	1506.72 MHz
Form of coding	Uniformly quantized PCM, 8 or 10 bits per sample, for the Y, C_B, and C_R signals.
Number of samples per digital active line (square pixels system)	
Luminance signal	1280
Each color-difference signal	640

* Reference 18.

An interface signal format has also been defined for a 787.5-line, 59.94-fields/s, 1:1 progressive scanned digital color HDTV television system. The suggested parameter values are given in Table 14.

INTERNATIONAL STANDARDS FOR BROADCASTING

CCIR Documents

The CCIR (International Radio Consultative Committee) is a branch of the International Telecommunications Union (ITU), a specialized agency of the United Nations. Thus the CCIR is a treaty organization related directly to the United Nations. The CCIR is concerned with generating documents dealing with the preparation, transmission, and reception of all kinds of information using radio signals, with the term "radio" being taken in the broadest sense. The CCIR has established several Study Groups, each dealing with specific aspects of radio communications. Each Study Group is further subdivided into smaller groups, each of which is assigned responsibility for the documents in a specialized area of interest. The scopes of the various groups are described below.

The Study Groups of interest in radio and television broadcasting are Study Group 10—Sound Broadcasting Service, and Study Group 11—Television Broadcasting Service. Also related and of interest to broadcasters is the work of the CMTT (Joint Committee on Television Transmission), a group set up jointly by the CCIR and the CCITT (International Telephone and Telegraph Consultative Committee). The latter organization is a branch of the ITU that deals with telegraph and telephone transmission systems. The CMTT is concerned with the transmission of signals over long distances through facilities that include a mixture of the responsibilities of the CCIR and CCITT.

The CCIR and CMTT produce documents of various kinds. Categories include Recommendations and Reports (the two most important), as well as Questions, Study Programs, Decisions, Resolutions, and Opinions. The documents are reviewed every four years. During this interval, there are two or three preliminary meetings of the Study Groups and their subgroups, to review proposals submitted by members. These proposals may take the form of modifications to existing documents, or the submission of entirely new documents. The agreements of the Study Groups after the last preliminary meeting are reviewed and approved at the final, or Plenary, Assembly of the CCIR, convened each four years.

The CCIR Plenary Assembly documents are published within a year of the Plenary in thirteen volumes, one for each Study Group. The volumes are bound in paper, with a green cover traditionally used for the English text. Hence, they are colloquially known as the "Green Books." They are available from the International Telecommunication Union in Geneva, Switzer-

land and, in the United States, from the National Technical Information Service (see the earlier subsection "International Sound-Recording Standards" for the address).

The work of the CCIR is organized into the following groups and committees:

Study Group 10—Broadcasting Service (Sound)
- Study Group 10A-1, Amplitude-modulation sound broadcasting
- Study Group 10A-2, Sound broadcasting in the tropical zone
- Study Group 10B, Frequency-modulation sound broadcasting
- Study Group 10C, Audio-frequency characteristics of sound broadcasting signals

Study Group 11—Broadcasting Service (Television)
- Study Group 11A, Characteristics of systems for monochrome and colour television
- Study Group 11B, Ancillary television services
- Study Group 11C, Control, measurement and international exchange of television programmes
- Study Group 11D, Picture quality and parameters affecting it
- Study Group 11E, Planning of television networks, protection ratios, television receivers and antennas
- Study Group 11F, Digital methods of transmitting television information.

Joint Working Group 10/11F, Exchange of recorded sound programmes

Joint Working Group 10/11G, Exchange of recorded television programmes

Joint Working Group 10/11H, Use of film in television

Joint Working Group 10/11I, Utilization and synchronization of different programme supports

Selected CCIR Recommendations

Listed below are some of the more important Recommendations ("Rec") issued by the CCIR in the broadcasting, recording, and transmission fields.

- Rec 265-6, Standards for the international exchange of programmes on film for television use
- Rec 407-4, International exchange of sound programmes recorded in analogue form
- Rec 408-5, Standards of sound recording on magnetic tape for the international exchange of programmes
- Rec 450-1, Transmission standards for FM sound broadcasting at VHF
- Rec 469-5, *Analogue television tape recording.* Standards for the international exchange of television programmes on magnetic tape
- Rec 470-2, Television systems
- Rec 500-4, Method for the subjective assessment of the quality of television pictures
- Rec 501-2, Appraisal of programmes on colour film intended for television use
- Rec 562-3, Subjective assessment of sound quality
- Rec 601-2, Encoding parameters of digital television for studios
- Rec 602-1, Exchange of television recordings for programme evaluation
- Rec 642-1, Limiters for high-quality sound-programme signals
- Rec 646, Source encoding for digital sound signals in broadcasting studios
- Rec 647-1, A digital audio interface for broadcasting studios
- Rec 648, Digital recording of audio signals
- Rec 649, Measuring methods for analog audio disk and tape recordings
- Rec 653-3, Teletext systems
- Rec 656, Interfaces for digital component video signals in 525-line and 625-line television systems
- Rec 657-1, *Digital television tape recording.* Standards for the international exchange of television programmes on magnetic tape
- Rec 709, Basic parameter values for the HDTV standard for the studio and for international programme exchange
- Rec 710, Subjective assessment methods for image quality in high definition television
- Rec 711, Synchronizing reference signals for the component digital studio
- Rec 713, Recording of HDTV images on film.
- Rec 714, International exchange of programmes electronically produced by means of high definition television
- Rec 715, International exchange of ENG recordings

IEC Publications

The International Electrotechnical Commission (IEC) publishes standards on a wide range of electrical and electronic subjects. IEC publications may be purchased through ANSI in New York. The headquarters address of the IEC is:

International Electrotechnical Commission
3, rue de Varembé
PO Box 131 - 1211 Geneva 20
Switzerland
TELEFAX (+41 22) 7333843

Important to this chapter are the IEC publications produced by Technical Committee 60, Recording. Some of these are listed below:

- Pub. 94, Magnetic tape sound recording and reproducing systems
- Pub. 347, Transverse track video recorders
- Pub. 386, Method of measurement of speed fluctuations in sound recording and reproducing equipment
- Pub. 461, Time and Control code for video tape recorders

Pub. 503, Spools for 1 in (25.4 mm) video magnetic tape
Pub. 558, Type C helical video tape recorders
Pub. 574-10, Audio cassette systems
Pub. 602, Type B helical recorders
Pub. 698, Measuring methods for television tape machines
Pub. 712, Helical-scan video-tape cassette system using 19 mm (3/4 in) magnetic tape, known as U-format
Pub. 735, Measuring methods for video tape properties
Pub. 756, Time base stability of non-broadcast video recorders
Pub. 767, Helical-scan video tape cassette system using 12.65 mm (0.5 in) magnetic tape on type beta format
Pub. 774, Helical-scan video tape cassette system using 12.65 mm (0.5 in) magnetic tape on type VHS
Pub. 841, Audio recording—PCM encoder/decoder system
Pub. 843, Helical-scan video tape cassette system using 8 mm magnetic tape—Video 8
Pub. 883, Measuring method for chrominance signal-to-random noise ratio for video tape recorders
Pub. 1016, helical-scan digital component video cassette recording system using 19 mm magnetic tape (format D-1)

In addition to the recording specifications shown above, IEC also publishes the work of related technical groups, including TC 12, *Radiocommunications (including SC-12A, Receivers)*, TC-84, *Equipment and systems in the field of audio, video and audiovisual engineering*, and of JTC-1, *ISO/IEC Joint technical committee for information technology*.

ISO Recommendations

The International Organization for Standardization (ISO) has primary responsibility for the standardization of mechanical systems. ISO publications are available through ANSI in New York. The headquarters address for ISO is:

International Organization for Standardization
1, rue de Varembé
Case postale 56
CH-1211 Geneva 20
Switzerland

The standardization of electrical and electronic systems is primarily the province of the IEC. Standards for motion picture films are drafted by ISO Technical Committee 36—Cinematography. A partial list of ISO TC 36 documents for television broadcasting appears below:

ISO 23:1976, Camera usage of 35 mm motion-picture film
ISO 25:1976, Camera usage of 16 mm motion-picture film
ISO 26:1985, Projector usage of 16 mm motion-picture films for direct front projection
ISO 490:1978, Magnetic stripes and magnetic recording head gaps for sound records on 16 mm motion-picture film perforated along one edge
ISO 1188:1984, Recorded characteristic for magnetic sound records on full-coat 16 mm motion-picture film
ISO 1189:1986, Recorded characteristic for magnetic sound records on 35 mm motion-picture film excluding striped release prints
ISO 1223:1985, Picture areas for motion-picture films and slides for television—position and dimensions
ISO 3640:1982, Motion-picture prints and sound records for international exchange of television programmes
ISO 4242:1980, Recording head gaps for two sound records on 16 mm magnetic film—positions and width dimensions
ISO 6035:1983, Viewing conditions for the evaluation of films and slides for television—colours, luminances and dimensions

Selected EBU Publications

The European Broadcasting Union publishes a well regarded technical journal (*The EBU Review—Technical*) and a wide variety of technical documents. The EBU supplies a comprehensive catalog of these publications that can be obtained from their Geneva headquarters:

European Broadcasting Union
Ancienne Route, 17A
Case postale 67
CH-1218 Grand Saconnex/Geneva
Switzerland
TELEFAX (+41 22) 798 58 97

Included in the scope of EBU publications are documents in the following categories:

Lists of broadcasting stations in the European area, updated frequently
"Tech 3000" documents that reproduce committee reports and study results
EBU Technical Monographs, documents of a thorough tutorial nature
EBU Official Technical Texts, including *Technical Standards*, *Technical Recommendations*, *Technical Statements*, and *Technical Information Sheets*

More than 200 of these technical documents are available by mail order from EBU. Examples of a few of the EBU documents include:

Tech 3094, Specifications for the basic signals recommended by the EBU for the synchronization of television sources
Tech 3097, EBU time-and-control codes for television tape-recordings (625-line television systems)
Tech 3238, Methods for measuring the main characteristics of television cameras
Tech 3252, Standard for recording digital television signals on magnetic tape in cassettes
N6-1989, Helical-scan television recording on 25.4 mm tape
N12-1990, Time-and-control codes for television tape recording
N13 and supplements, Digital television tape recording
R20-1987, Exchange of television programmes recorded on transverse-track, format B or format C tapes
R48-1991, Allocation of audio channels in the D-1 and D-2 digital television tape recording formats

36 Radar

Merrill I. Skolnik

INTRODUCTION TO RADAR

Radar is an electromagnetic sensor that greatly extends one's ability to detect reflecting objects (or targets) at long or short range and to accurately locate targets in fair, as well as poor weather. Since its introduction during the second world war, radar has been a vital part of air defense in its many forms and for other military missions such as battlefield surveillance, fighter/attack aircraft, ballistic missile defense, and antisubmarine warfare. It has also been important for many nonmilitary applications including weather observation (precipitation, severe storms, winds, and wind shear), observing beneath the ever-present clouds of a planet like Venus, probing below the surface of the Earth, high-resolution imaging of the Earth's surface in three dimensions, and for mapping of sea ice for the more efficient routing of shipping in northern regions. Targets of interest to radar have been aircraft, ships, missiles, spacecraft, vehicles, people, birds, insects, as well as the natural environment.

Radar operates by radiating from an antenna, a known waveform, usually a series of short-duration pulses. After a portion of the radiated energy is reflected by a target and returned to the radar, it is received by the antenna and processed in the receiver to detect the presence of a target and to determine something about its nature. Two of the basic measurements made by a radar are *range* (distance) and *angular location* of a target. By observing the location of a target over time, the radar can establish its trajectory, or *track*, and predict the target's future location. Many modern radars use to advantage the shift in frequency (relative to the frequency that was transmitted) of the echo signal from a moving target. The shift of the echo signal frequency from a moving target is caused by the doppler effect, something familiar from high school or college physics. The doppler frequency shift is proportional to the *radial velocity* of the target, so it can be used to separate the frequency-shifted signals from moving targets (such as aircraft) from large undesired stationary *clutter* echo signals from the land, sea, and weather. It is an important part of MTI (moving target indication), pulse doppler, and CW (continuous wave) radars that have to detect small moving targets in the midst of very large clutter echoes. The doppler shift is also the basis for meteorological radars that detect and recognize hazardous weather effects to provide information about the environment not readily available by other means. In addition to the usual measurements of range, angular location, relative velocity, and target track, radar sometimes can obtain information about the size, shape, symmetry, and surface properties of a target.

A simple block diagram illustrating the major subsystems of a radar that might be used for air surveillance is shown in Fig. 1. The transmitter is usually a *power amplifier* such as a klystron, traveling wave tube,

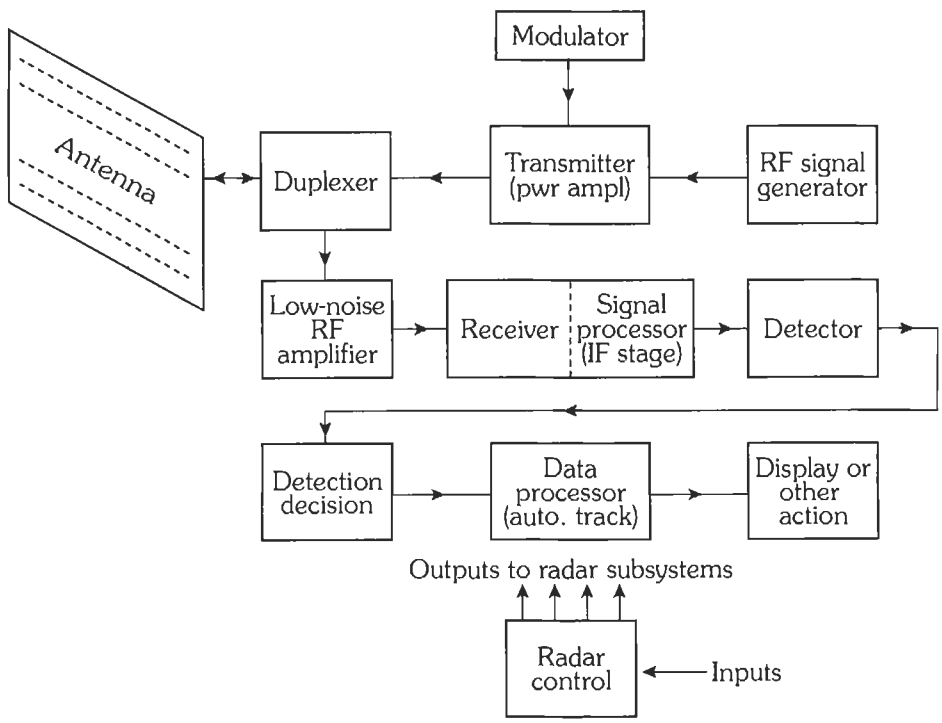

Fig. 1. Simple block diagram of a generic radar system.

or transistor. Although the magnetron oscillator was widely used in the early days of radar, its limited average-power, poor stability, and inability to generate sophisticated modulated waveforms restrict its application to radars with only modest capability. The first stage of the receiver is often a *low-noise transistor amplifier*. In a superheterodyne receiver, the echo is converted by a *mixer* and *local oscillator* (not shown) to an intermediate frequency (IF), where the signal is amplified and subject to signal processing to extract the desired signal and reject or attenuate undesired signals and noise. An important example of a *signal processor* is the *matched filter* that maximizes the ratio of the peak-signal-to-mean-noise output of the receiver, which in turn maximizes the detectability of the desired signal. In a receiver with a matched filter, the peak-output-signal-to-mean-noise-power ratio is $2E/N_0$, where E = signal energy and N_0 = noise power per unit bandwidth. Thus detectability of a radar signal when a matched filter is used does not depend on the shape of the signal or its bandwidth, but only on its total energy. The *detector* stage following the IF stage extracts the signal modulation from the carrier frequency. In a radar where there are no undesired clutter echoes to compete with the detection of the desired target echoes, the detector stage is an *envelope detector* (also called the second detector). In a radar that employs the doppler frequency shift to separate (by the use of filters) desired moving targets from undesired fixed clutter echoes, the detector stage is a *phase detector*. It requires a reference signal (not shown) that is a faithful representation of the transmitted signal so as to recognize that the echo signal has experienced a doppler shift. A *video amplifier* (not shown) following the detector amplifies the signal and a decision is made whether the receiver output is due to a target (signal plus noise) or is due to noise alone. The *detection decision* is based on observing when the receiver output exceeds a predetermined threshold whose level depends on achieving an acceptable probability of false alarm. In early radars the detection decision was made by an operator viewing a radar display, but in modern radars the decision whether or not a target has been detected is made automatically without direct operator intervention.

The received signal is digitized for processing, either after the detector stage (in the video) or before the detector (in the IF), especially in radars that depend on the doppler frequency shift for detection of moving targets. Digital processing makes it possible to automatically detect and accurately track many hundreds or thousands of targets so as to present fully processed tracks rather than individual detections or "raw" (unprocessed) radar data. The automatic tracker is an example of a *data processor*. The processed output of the radar or the established tracks of targets might be displayed to an operator or used to perform some automated operation. The *antenna* can be one of several different forms of mechanically steered parabolic reflectors, a mechanically steered planar array, or one of several types of electronically steered phased arrays. The *duplexer* is the device that allows a single antenna to be time-shared between the transmitter and the receiver.

A typical long-range air-surveillance radar might have a resolution in the range dimension of about one or two hundred meters. When required, a radar can have a range resolution of a small fraction of a meter. The beamwidth of a radar antenna might typically be one or two degrees, but some operational radars have had beamwidths as small as 0.3 degree. Thus the resolution in the cross-range dimension (determined by the beamwidth and the target range) is usually much worse than the range resolution. It is possible, however, to achieve high resolution in the cross-range dimension comparable to the resolution achieved in the range dimension by employing synthetic aperture radar (SAR). Here the resolution of a large antenna is obtained by utilizing a small antenna on a moving platform, such as an aircraft, to store the received echoes over a relatively long time so as to synthesize (virtually) in a digital processor the equivalent of a large antenna. The output of a SAR is usually a high resolution map or image of a target scene.

Radar is generally found within what is known as the microwave region of the electromagnetic spectrum from about 400 MHz to 40 GHz; but there have been many operational radars in the VHF region (30 to 300 MHz) as well as in the HF region (3 to 30 MHz). An HF over-the-horizon radar can reach out to ranges of about 2000 nmi by utilizing refraction from the ionosphere. Radar has also been considered for use at frequencies higher than the microwave region, at millimeter wavelengths. Laser radars are found in the IR and optical regions of the spectrum, where they can provide precision range and radial-velocity measurement.

PREDICTION OF RADAR RANGE*

The radar range equation is important not only for predicting the range performance of a radar, but to act as a focus for radar design and for better understanding the factors that affect radar performance. The simple form of the radar range equation is

$$P_r = P_t G A_e \sigma / [(4\pi)^2 R^4] \qquad \text{(Eq. 1a)}$$

where

P_r = received echo signal power in watts,
P_t = transmitted signal power in watts,
G = antenna gain,
A_e = antenna effective area in square meters,
σ = radar cross section of the target in square meters,
R = range to the target in meters.

* Reference 1.

If a single antenna is used for both transmitting and receiving, as is usually the case, $G = 4\pi A_e/\lambda^2$, where λ is the radar wavelength in meters. Then

$$P_r = P_t G^2 \lambda^2 \sigma / [(4\pi)^3 R^4] \qquad \text{(Eq. 1b)}$$
$$= P_t A_e^2 \sigma / [4\pi \lambda^2 R^4]$$

The maximum range R_{max} of a radar occurs when the received signal $P_r = S_{min}$, the minimum detectable signal. The minimum detectable signal is a statistical quantity limited by receiver noise. It can be written as

$$S_{min} = kT_0 B F_n (S/N)_1 \qquad \text{(Eq. 2)}$$

where

k = Boltzmann's constant,
T_0 = standard temperature (290 K),
kT_0 = 4×10^{-21} W/Hz
B = receiver bandwidth in hertz,
F_n = receiver noise figure,
$(S/N)_1$ = minimum signal-to-noise ratio required for reliable detection.

The received echo signal power can be increased by integrating (adding) a number of echo signal pulses n. This can be incorporated into the radar equation by dividing S_{min} by $nE_i(n)$, where $E_i(n)$ is the efficiency with which the n pulses can be integrated. Since the average power P_{av} is more indicative of radar capability than is the peak power, it is introduced via the relation

$$P_{av} = P_t \tau f_p \qquad \text{(Eq. 3)}$$

where

τ = pulse width in seconds,
f_p = pulse repetition frequency in hertz.

With the above, the form of the radar equation suitable for calculating the range is

$$R_{max} = \left[\frac{P_{av} G^2 \lambda^2 \sigma n E_i(n)}{(4\pi)^3 k T_0 F_n (B\tau) f_p (S/N)_1 L_s} \right]^{1/4} \qquad \text{(Eq. 4)}$$

The radar system losses L_s (number greater than one) have been included. For most radars designed with a matched filter receiver (a filter that maximizes the output signal-to-noise ratio), the product $B\tau \approx 1$. [In Eq. 4, $(S/N)_1/nE_i(n)$ is the required signal-to-noise ratio per pulse $(S/N)_n$.]

Fig. 2 shows the relationship of the required signal-to-noise ratio $(S/N)_1$ to the probability of detection and the probability of false alarm. The probability of detection is usually taken as 0.90, but sometimes it is quoted as 0.5 or 0.8. Its choice is usually the prerogative of the customer. The probability of a false alarm is given here as

$$P_{fa} = 1/BT_{fa}$$

where

B = receiver bandwidth in hertz,
T_{fa} = average time between false alarms.

The reciprocal of P_{fa} is n_f, the false-alarm number. The false-alarm time T_{fa} is usually specified for radar performance rather than the probability of false alarm or the false-alarm number.

Fig. 3 is a plot of the integration-improvement factor $nE_i(n)$ as a function of n. The number of pulses returned from a target when an antenna of beamwidth θ_B degrees rotates at a rate of ω_m revolutions per minute, with a pulse repetition rate of f_p Hz is

$$n = \theta_B f_p / 6\omega_m \qquad \text{(Eq. 5)}$$

Failure to include the many factors that contribute to the system losses L_s can result in considerable difference between the calculated range and the actual range. Losses include:

- Loss in the transmission line connecting the antenna to the transmitter and receiver.
- Loss in the duplexer, rotary joint, and other microwave components.
- Beam-shape loss, to account for the fact that the radar equation employs the maximum gain rather than a gain that changes pulse to pulse as the antenna is scanned past the target.
- Signal processing losses, which can sometimes be surprisingly large.
- Loss due to degradation of transmitter power and receiver noise figure.

The system losses from all factors might be from 10 to 20 dB, or even greater. (A loss of 16 dB reduces the radar range by a factor of two.)

FLUCTUATING TARGET MODELS

The complex nature of most radar targets causes the radar cross section to vary with changing aspect. Fluctuations in the radar cross section are difficult to specify precisely; however, four simple statistical models first described by P. Swerling (Reference 2) are often used for computing the radar range. The statistical nature of the radar cross section σ for cases 1 and 2 is described by the probability density function

$$p(\sigma) = (1/\sigma_{av}) \exp[-\sigma/\sigma_{av}] \qquad \text{(Eq. 6a)}$$

where σ_{av} is the average cross section. Cases 3 and 4 are described by

$$p(\sigma) = (4\sigma/\sigma_{av}) \exp[-2\sigma/\sigma_{av}] \qquad \text{(Eq. 6b)}$$

In cases 1 and 3, it is assumed that the echo pulses received from a target on any one scan are of constant amplitude throughout the entire scan but are independent (uncorrelated) from scan to scan. In cases 2 and 4, the cross-section is assumed to be independent from

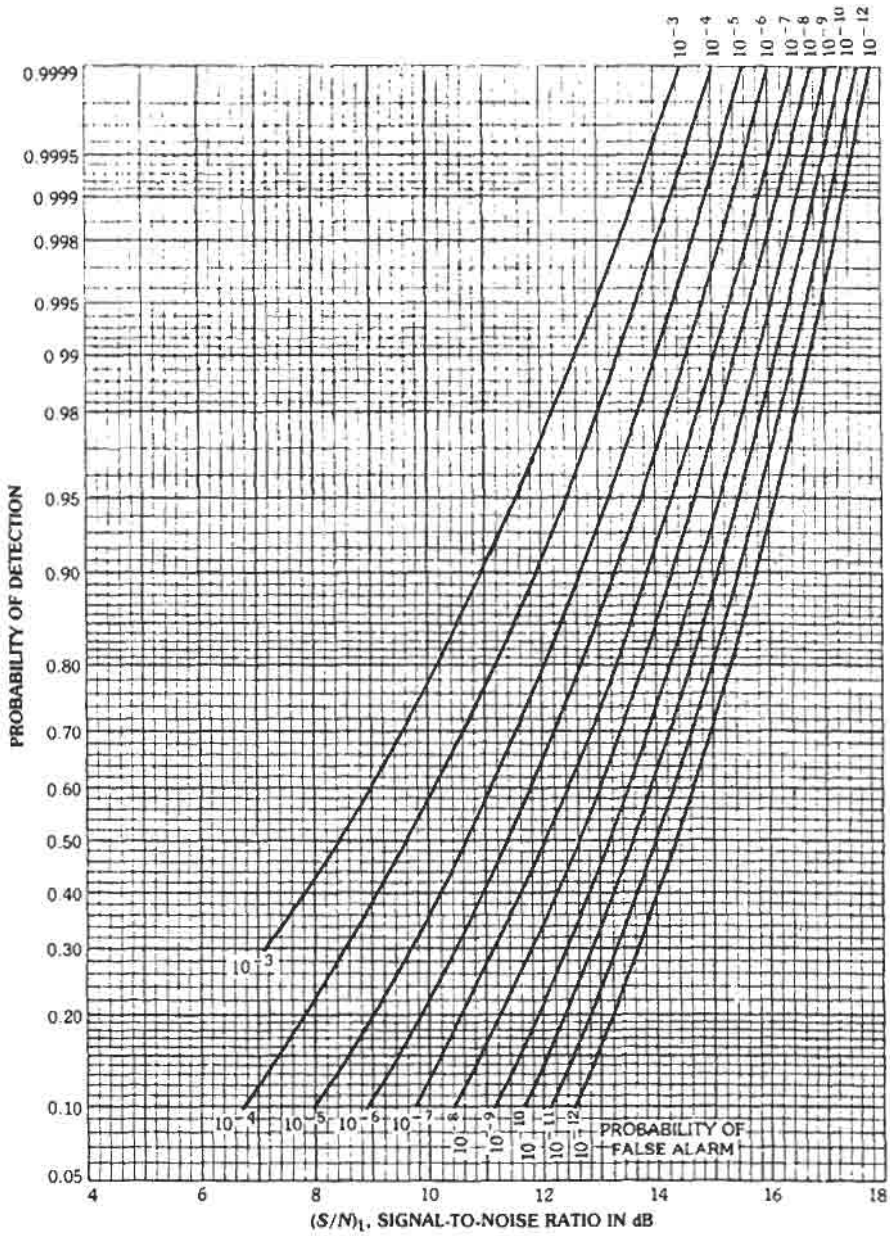

Fig. 2. Probability of detection for a sine wave in noise as a function of the signal-to-noise (power) ratio and the probability of false alarm. (*Courtesy McGraw-Hill Book Co.*)

pulse to pulse. When these models are used, the signal-to-noise ratios and the integration improvement factors inserted in the radar equation are different from those used for a constant cross section. The required values can be found in several references (References 3–7); however, a simple approximate method (Reference 1) for most purposes can be obtained using Figs. 2, 4, and 5 with the following procedures:

A. Find the signal-to-noise ratio from Fig. 2 corresponding to the desired values of detection probability P_d and false-alarm probability $P_{fa} = 1/BT_{fa}$.

B. From Fig. 4, determine for the desired Swerling case the correction factor to be applied to the signal-to-noise ratio found from Fig. 2.

C. Find the integration improvement factor $nE_i(n)$ from Fig. 5.

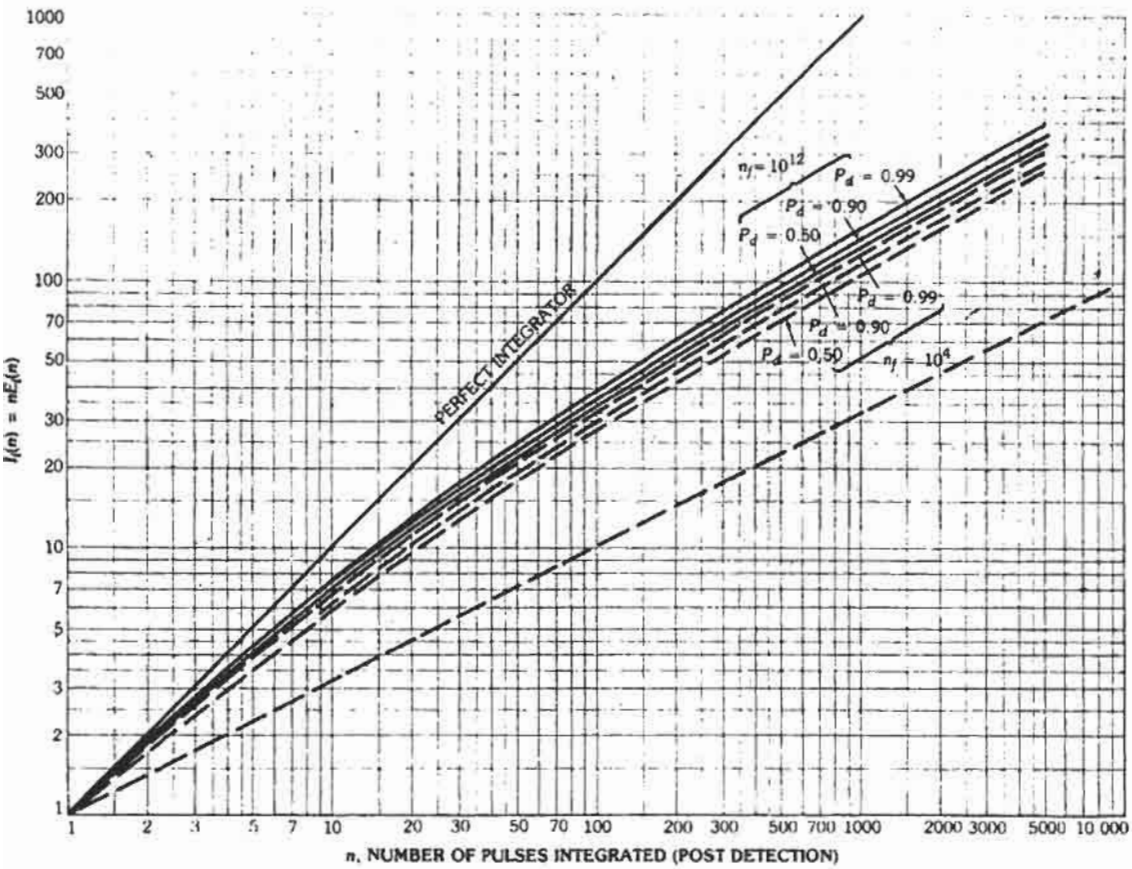

Fig. 3. Integration-improvement factor, assuming square-law detector. P_d = probability of detection, $n_f = T_{fa}B$ = false alarm number. T_{fa} = average time between false alarms, B = bandwidth. (*Courtesy McGraw-Hill Book Co.*)

Note that in cases 2 and 4 when $P_d \leq 0.9$ and the number of pulses are large ($n > 20$ for case 2 and $n > 10$ for case 4), cases 2 and 4 can be replaced by the nonfluctuating target model (indicated in Fig. 5 as case 5).

A more general expression for describing the statistical properties of the radar target cross section is the chi-square distribution of degree $2m$, whose probability density function is

$$p(\sigma) = [m/(m-1)!\sigma_{av}](m\sigma/\sigma_{av})^{m-1} \exp(-m\sigma/\sigma_{av}) \quad \text{(Eq. 7)}$$

The Swerling cases 1 and 2 are given by the chi-square distribution with $m = 1$; the other two cases are given with $m = 2$.

RADAR CROSS SECTION OF TARGETS*

The radar cross section of a complex target, such as an aircraft or ship, varies considerably with change in aspect or change in frequency so that a single number cannot adequately describe the radar cross section of a target. Nevertheless, Table 1 lists "example" values for various targets at microwave frequencies. These are for illustrative purposes to show the relative "sizes" of common targets as "seen" by radar.

OTHER FORMS OF THE RADAR EQUATION

The radar equation is used for the calculation of range; but it is also used as a basis for assessing the tradeoffs in radar design. The simple forms of the radar equation given above (Eqs. 1 and 2) are seldom sufficiently complete, however, and they must be extended. Each specific radar application has some particular requirements or constraints that can result in a slightly different form of the radar equation. Examples are presented below. All symbols used in the equations are defined at the end of this section.

* References 1 and 8.

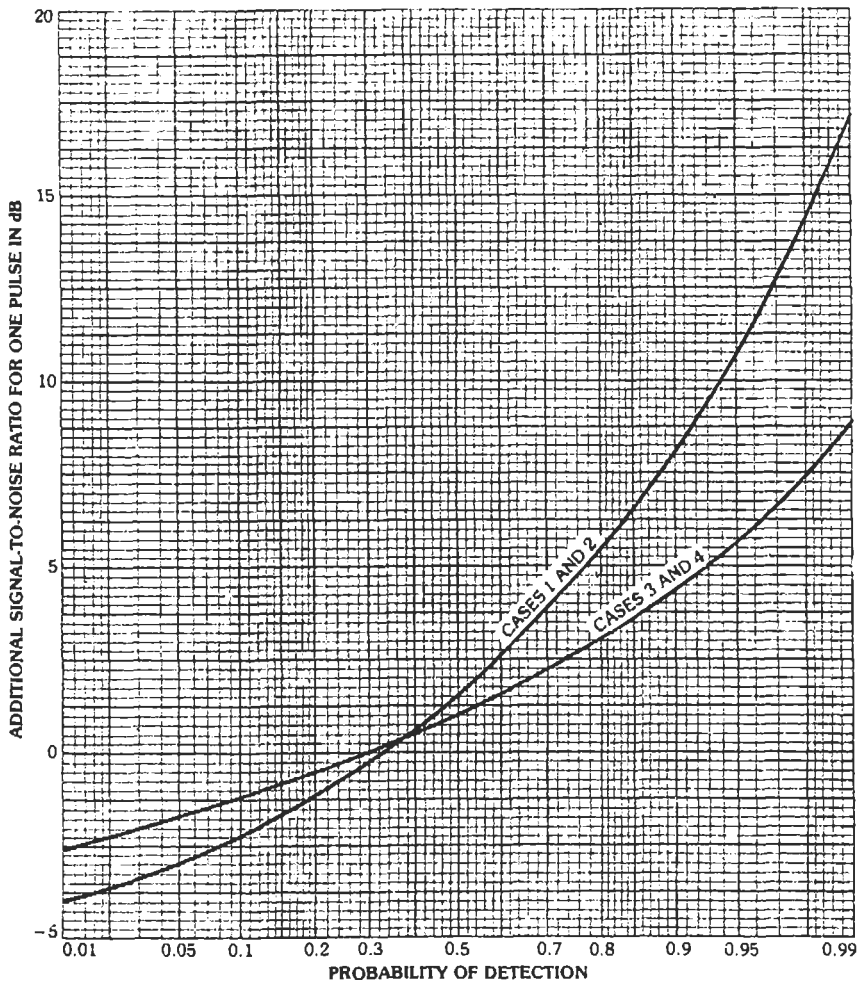

Fig. 4. Additional signal-to-noise ratio required to achieve a particular probability of detection, when the target cross section fluctuates according to the Swerling models, as compared with a nonfluctuating target; single hit, $n = 1$. To be used with Fig. 2 to find $(S/N)_1$. (*Courtesy McGraw-Hill Book Co.*)

Surveillance Radar Equation

$$R_{\max}^4 = \frac{P_{av} A_e \sigma E i(n)}{4\pi k T_0 F (S/N)_1 L_s} \cdot \frac{t_s}{\Omega} \qquad \text{(Eq. 8)}$$

This equation applies to a radar that must observe all targets within an angular region of solid angle Ω steradians once every t_s seconds. When the surveillance radar utilizes a conventional rotating fan beam whose elevation beamwidth is θ_e, the solid angle Ω equals $2\pi \sin \theta_e$, and t_s is the azimuth rotation period (or revisit time).

Tracking Radar Equation

Equation 4 is basically the tracking radar equation, where $n/f_p = t_0$ is the signal integration time. (It has also been called the searchlight equation.)

Surface Clutter Range Equation

$$R_{\max} = \sigma n_c / [(S/C)_0 \sigma^\circ \theta_a (c\tau/2) \sec \psi] \qquad \text{(Eq. 9)}$$

This equation describes the detection of a target when viewed at a low grazing angle ψ in the presence of surface clutter of radar cross section per unit area σ°. It assumes that the received clutter echo power is much greater than receiver noise. The effective number of pulses integrated, n_c, will depend on the decorrelation time of the clutter. (With completely stationary clutter, there is no integration improvement so that $n_c = 1$.)

Volume Clutter Radar Equation

$$R_{\max}^2 = \sigma G n_c / [(S/C)_0 \eta (\pi^3/4) (c\tau/2)] \qquad \text{(Eq. 10)}$$

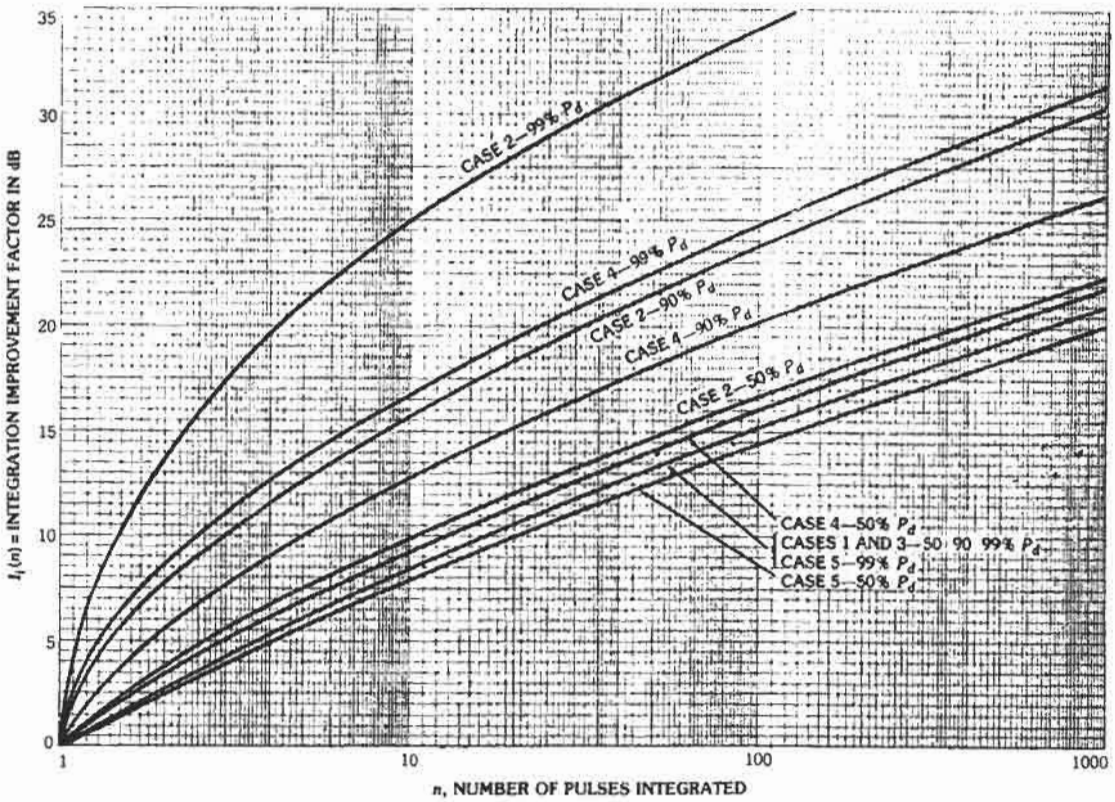

Fig. 5. Integration-improvement factor as a function of the number of pulses integrated for the four Swerling cases (cases 1 to 4) and the constant cross section (case 5). (*Courtesy McGraw-Hill Book Co.*)

The reflectivity η is the radar cross section of the clutter per unit volume.

Noise Jamming Radar Equation (Surveillance)

$$R_{\max}^2 = \frac{P_{av} G E_j(n)}{G_{SL} L_s} \cdot \frac{\sigma}{(S/N)_1} \cdot \frac{t_s}{\Omega} \cdot \frac{B_j}{P_j G_j} \qquad \text{(Eq. 11)}$$

This equation assumes that the jamming noise enters the antenna sidelobes whose gain is G_{SL}. When the jamming enters the main beam, $G_{SL} = G$. The jammer power P_j is spread over a bandwidth B_j and is radiated by an antenna whose gain is G_j.

Noise Jamming Radar Equation (Tracking)

$$R_{\max}^2 = \frac{P_{av} G^2 E_j(n) t_0}{4\pi G_{SL} L_s} \cdot \frac{\sigma}{(S/N)_1} \cdot \frac{B_j}{P_j G_j} \qquad \text{(Eq. 12)}$$

When the jamming noise enters the radar via the main beam, $G_{SL} = G$.

Self-Screening Range Equation

This is the range at which the radar echo signal S received from a target exceeds the received jamming noise power J by the amount S/J. It is also called the cross-over range. The self-screening range is found from either Eq. 11 or 12 (depending on the application) by setting $G_{SL} = G$, setting $(S/N)_1 = S/J$, and calling $R_{\max}$ the self-screening range R_{ss}. The value of required S/J is often taken to be the same as $(S/N)_1$ found for receiver noise.

Weather Radar Equation

$$\overline{P}_r = 2.4\, P_t G \pi r^{1.6} / [R^2 \lambda^2 L_s] \qquad \text{(Eq. 13)}$$

This equation is employed by radar meteorologists to relate the average echo signal power $\overline{P}_r$, to the rainfall rate r (mm/hr). It assumes that rain uniformly fills the radar resolution cell.

TABLE 1. "EXAMPLE" VALUES OF RADAR CROSS SECTION

Target	σ (square meters)
Conventional unmanned winged missile	0.1
Small single-engine aircraft	1
Small fighter or 4-passenger jet	2
Large fighter	6
Medium bomber or medium jet airliner	20
Large bomber or large jet airliner	40
Jumbo jet	100
Helicopter	3
Small open boat	0.02
Small pleasure boat	2
Cabin cruiser	10
Ship, grazing angle greater than zero	Displacement tonnage expressed in m^2
Pickup truck	200
Automobile	100
Bicycle	2
Man	1
Large bird	10^{-2}
Medium bird	10^{-3}
Large insect (locust)	10^{-4}
Small insect (fly)	10^{-5}

Synthetic Aperture Radar Equation

$$\frac{S}{N} = \frac{2P_{av}\rho_a^2\sigma^\circ\delta_{cr}\delta_r}{\pi f k T_0 F_n R S_w L_s \sin^2\psi} \qquad \text{(Eq. 14)}$$

This equation relates the signal-to-noise ratio of a resolution cell (sometimes called a pixel) with range resolution δ_r and cross-range resolution δ_{cr} located within a swath S centered at a range R. The above takes account of the combined restriction on cross-range resolution and swath necessary to avoid ambiguities in either range or cross range.

HF Over-the-Horizon Radar Equation

$$R_{max}^2 = \frac{P_{av}G_tG_r\lambda^2\sigma F_p^2 T_c}{(4\pi)^3 N_0 (S/N)_1 L_s} \qquad \text{(Eq. 15)}$$

The transmitting antenna gain G_t and the receiving antenna gain G_r are shown separate since two different antennas are often used for transmit and receive. The propagation loss is accounted for by F_p (number less than unity), and T_c is the coherent processing time. The noise power per unit bandwidth N_0 (W/Hz) at the receiver is determined by external noise.

Symbol Definitions

The symbols used in the above radar equations are defined as follows.

A_e = antenna effective aperture in square meters
B = receiver bandwidth in hertz
B_j = jammer bandwidth in hertz
c = velocity of propagation in meters/second
δ_{cr} = cross-range resolution in meters
δ_r = range resolution in meters
$E_i(n)$ = efficiency in integrating n pulses
η = volume clutter of reflectivity, or radar cross section of clutter per unit volume, in meters^{-1}
f = radar frequency in hertz
f_p = pulse repetition frequency in hertz
F_n = receiver noise figure
F_p = propagation factor
G = antenna gain
G_j = jammer antenna gain
G_r = radar receiving antenna gain
G_{SL} = antenna sidelobe gain
G_t = transmitting antenna gain
k = Boltzmann's constant = 1.38 x 10^{-23} joules/kelvin
L_s = system losses
λ = wavelength in meters
n = number of echo pulses received per target
n_e = effective number of pulses integrated
N_0 = noise power per unit bandwidth
Ω = solid angular region (steradians) of radar coverage
P_{av} = average power in watts
P_j = jammer power in watts
P_r = average received signal power in watts
P_r = received signal power in watts
P_t = peak power in watts
ψ = grazing angle
r = rainfall rate in millimeters/hour
R = range in meters
R_{max} = maximum radar range in meters
ρ_a = antenna efficiency
$(S/C)_0$ = minimum signal-to-clutter ratio necessary to detect a target with a specified probability of detection and probability of false alarm, for a single pulse
S/N = signal-to-noise ratio in a SAR resolution cell
$(S/N)_1$ = minimum signal-to-noise ratio necessary to detect a target with a specified probability of detection and probability of false alarm, for a single pulse
S_w = swath width in meters
σ = radar cross section of target in square meters
σ° = radar cross section of surface clutter per unit area
t_s = scan time, or revisit time, in seconds

t_0 = n/f_p = signal integration time in seconds
T_c = coherent processing time in seconds
T_0 = standard temperature = 290 K
τ = pulse width in seconds
θ_a = azimuth beamwidth in radians
θ_e = elevation beamwidth in radians
v = velocity in meters/second

RADAR LETTER BANDS

The frequency bands in which radar operates have traditionally been designated by letters of the alphabet. This nomenclature is given in Table 2 along with the International Telecommunication Union frequency allocations for "radiolocation." There are other letter-band nomenclatures that have been employed in the past for various purposes, but those of Table 2 have been accepted as a Standard by the Institute of Electrical and Electronic Engineers (IEEE) and are the only ones that should be employed for *radar*.

RADAR ANTENNAS

The half-power beamwidth of a radar antenna of dimension D is

$$\theta_B = \beta\lambda/D \qquad \text{(Eq. 16)}$$

where beamwidth θ_B is in degrees, and wavelength λ and dimension D are in the same units. The constant β depends on the shape of the illumination (current distribution) across the aperture. It is sometimes called the normalized beamwidth. The choice of aperture illumination determines the normalized beamwidth and the peak side-lobe level. Equation 16 is plotted in Fig. 6 for $\beta = 65$ which is a typical value for horn-fed parabolic reflector antennas. The Taylor illumination is often used in radar-antenna design. It is characterized as having its first $\bar{n} - 1$ sidelobes equal, beyond which the sidelobe amplitude decreases with increasing angle. The variation of the beamwidth as a function of the sidelobe level of a planar antenna designed with a Taylor circular aperture illumination is shown in Fig. 7 for various $\bar{n}$ (References 9 and 10). For a Taylor line source, the beamwidths of Fig. 7 are reduced by the (approximate) factor $\bar{n}/(\bar{n} + 0.25)$.

Table 3 illustrates how the antenna beamwidth, null width, peak sidelobe level, and the relative antenna gain vary as the aperture illumination becomes more tapered at the ends of the aperture compared to the illumination at the center of the antenna. The example in this table is that of an aperture illumination defined as $\cos^N(\pi x/2)$, where N is an integer, x is the normalized distance from the center of the aperture, and $|x| \leq 1|$. The $\cos^N(\pi x/2)$ aperture illumination is not commonly

TABLE 2. RADAR LETTER-BAND NOMENCLATURE

Band Designation	Nominal Frequency Range	Specific Radiolocation (Radar) Bands Based on ITU Assignments for Region 2
HF	3 – 30 MHz	
VHF	30 – 300 MHz	138 – 144 MHz
		216 – 225
UHF	300 – 1000 MHz	420 – 450 MHz
		850 – 942
L	1 – 2 GHz	1215 – 1400 MHz
S	2 – 4 GHz	2300 – 2500 MHz
		2700 – 3700
C	4 – 8 GHz	5250 – 5925 MHz
X	8 – 12 GHz	8500 – 10 680 MHz
K_u	12 – 18 GHz	13.4 – 14.0 GHz
		15.7 – 17.7
K	18 – 27 GHz	24.05 – 24.25 GHz
K_a	27 – 40 GHz	33.4 – 36.0 GHz
V	40 – 75 GHz	59 – 64 GHz
W	75 – 110 GHz	76 – 81 GHz
		92 – 100
mm	110 – 300 GHz	126 – 142 GHz
		144 – 149
		231 – 235
		238 – 248

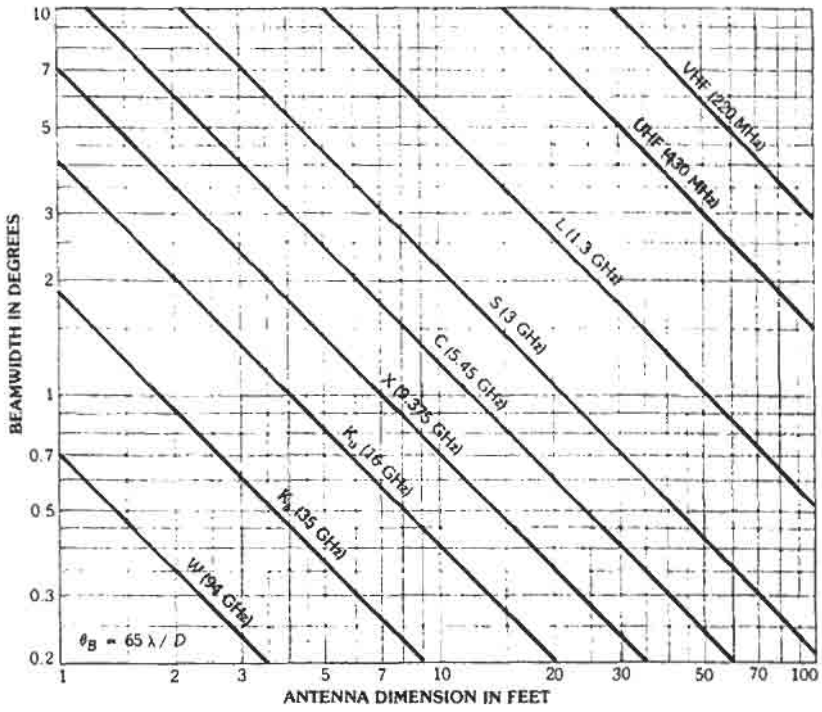

Fig. 6. Antenna beamwidth as a function of the antenna dimension for the various radar letter bands.

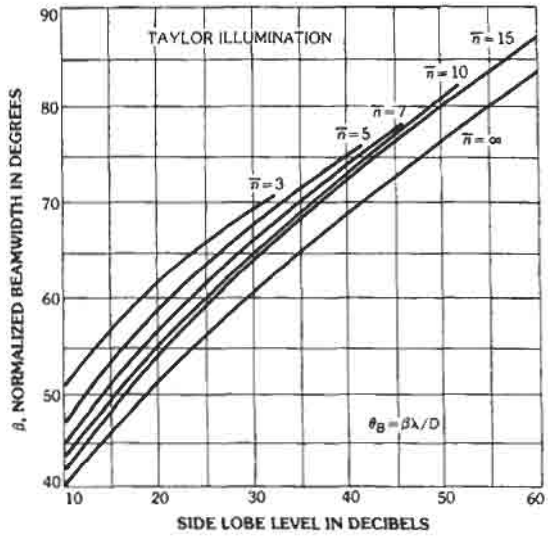

Fig. 7. Normalized beamwidth, β, as a function of the peak sidelobe level for the Taylor circular aperture illumination in which the first $\bar{n} - 1$ sidelobes are all equal. (After Reference 10.)

used for radar antennas, but it is a convenient analytical representation that illustrates the effect that the shape of the aperture illumination has on the characteristics of the antenna pattern. When $N = 0$, the aperture illumination is constant (uniform) across the aperture. It has the greatest gain and the narrowest beamwidth for a given size aperture, but its peak sidelobe is high (–13.2 dB below the peak of the main beam). As N increases, the peak sidelobe decreases, but the antenna gain decreases and the beamwidth increases. Thus low antenna sidelobes are obtained by tolerating a reduction in gain and a wider beamwidth (or by using a bigger antenna).

Antenna Gain

A useful expression for the gain of "typical" reflector antennas, when no better information is available about the antenna other than its beamwidths, is (Reference 11)

$$G_D \approx 26{,}000/\theta_B \phi_B \qquad \text{(Eq. 17)}$$

where θ_B and ϕ_B (in degrees) are the half-power beamwidths measured in the two principal (orthogonal) planes.

Cosecant-Squared Antenna Loss

The cosecant-squared antenna has a conventional beam shape in elevation from $\phi = 0$ to $\phi = \phi_0$ (ϕ = elevation angle), but its gain is proportional to $\csc^2\phi/\csc^2\phi_0$ from $\phi = \phi_0$ to $\phi = \phi_m$. It is used mainly to shape the

TABLE 3. ANTENNA CHARACTERISTICS FOR COSINE APERTURE ILLUMINATION

Aperture illumination	3-dB beamwidth (radians)	Null width (radians)	Peak sidelobe (dB)	Relative gain (relative loss)
N = 0	0.88 λ/D	2 λ/D	13.2	1.00 (0 dB)
N = 1	1.20 λ/D	3 λ/D	23	0.81 (0.92 dB)
N = 2	1.45 λ/D	4 λ/D	32	0.667 (1.18 dB)
N = 3	1.66 λ/D	5 λ/D	40	0.575 (2.40 dB)
N = 4	1.93 λ/D	6 λ/D	48	0.515 (2.88 dB)

elevation pattern of an air-surveillance radar antenna so as to more efficiently cover the region where aircraft are expected to fly. For small ϕ_0 and large ϕ_m the loss in gain of a cosecant-squared antenna relative to the gain of a conventional antenna of beamwidth ϕ_0 (in radians) is approximately

$$L_c \approx 2 - \phi_0 \cot \phi_m \qquad \text{(Eq. 18)}$$

Antenna Errors

The gain of an antenna when the rms phase error (radians) of the aperture illumination is $(\overline{\delta^2})^{1/2}$ is approximately (Reference 12)

$$G = G_0 \exp(-\overline{\delta^2}) \qquad \text{(Eq. 19)}$$

where G_0 = no-error antenna gain. In a reflector antenna, the phase error might be due to deformation of the reflecting surface from its true value. For a circular paraboloidal reflector antenna of diameter D with antenna efficiency ρ_a, and with an rms mechanical tolerance ε measured in the same units as the wavelength λ, the maximum gain that can be achieved due to the resulting phase errors is

$$G_{max} = (\rho_a/43)(D/\varepsilon)^2, \qquad \text{(Eq. 20)}$$

which occurs at a wavelength

$$\lambda_{max} = 4\pi\varepsilon \qquad \text{(Eq. 21)}$$

The gain of a phased array antenna with $\overline{\delta^2}$ = mean-square phase error, $\overline{\Delta^2}$ = mean-square (relative) amplitude error, and P_e = fraction of the elements operative, is approximately (Reference 12)

$$G \approx G_0 P_e/(1 + \overline{\delta^2} + \overline{\Delta^2}) \qquad \text{(Eq. 22)}$$

where G_0 = no-error gain.

When discrete phase shift is employed, as in digital phase shifters, the sidelobe level due to the quantization is approximately (Reference 13)

$$\text{rms sidelobe level} \approx 5/(2^{2B}N) \qquad \text{(Eq. 23)}$$

where

B = number of bits in the phase shifter,
N = total number of elements in the array.

The above assumes a random distribution of the quantization phase error across the aperture. If the quantized phase error is periodic, the peak lobe relative to the main beam is

$$\text{Peak quantization lobe} = 1/2^{2B} \qquad \text{(Eq. 24)}$$

Its position is

$$\sin\theta_q \approx (1 - 2^B)\,\theta_0 \qquad \text{(Eq. 25)}$$

where θ_0 = angle to which the beam is steered. The maximum pointing error due to quantization is

$$\Delta\theta_0 = (\pi/4)(1/2^B)\,\theta_B \qquad \text{(Eq. 26)}$$

where θ_B = beamwidth.

COVERAGE

The curvature of the earth limits the coverage of an earth-based radar. From simple geometrical considerations, the distance d (in nautical miles) to the horizon from a radar at height h (in feet) is

$$d = 1.23\sqrt{h} \qquad \text{(Eq. 27)}$$

This assumes that the refraction of the radar energy by the atmosphere can be represented by an effective earth radius 4/3 times the actual radius. If the target is at a height h_t the distance between the radar and target when the line of sight just grazes the surface of the earth is given by

$$d_0 = 1.23\,(\sqrt{h} + \sqrt{h_t}) \qquad \text{(Eq. 28)}$$

where d_0 is in nautical miles and h and h_t are in feet.

The presence of the earth causes part of the energy to be reflected from the surface. This reflected wave can interfere either constructively or destructively with the direct wave to produce a series of maxima (lobes) and minima (nulls). The angle of the first (lowest) lobe in radians is given by

$$\theta_1 = \lambda/4h \qquad \text{(Eq. 29)}$$

where

λ = wavelength
h = radar antenna height.

Both λ and h are measured in the same units. This equation assumes a flat earth.

An example of the elevation lobing pattern resulting from constructive and destructive interference for a 900 MHz radar is shown in Fig. 8.

DOPPLER FREQUENCY SHIFT

The *doppler frequency shift* of an echo signal reflected from a moving target is

$$f_d = (2v \cos\theta)/\lambda \qquad \text{(Eq. 30)}$$

where

f_d is the frequency shift in hertz,
v is the velocity of the target in meters/second,
λ is the wavelength in meters,
θ is the angle defined by the direction of target travel and the radar line of sight to the target.

The relative velocity is $v_r = v \cos\theta$. The doppler frequency shift per knot of relative velocity (f_d/v_r) is plotted in Fig. 9. When v_r is in knots and λ in meters, an approximate expression (to an accuracy of about 3 percent) for the doppler frequency shift is the following:

$$f_d\,(\text{Hz}) \approx v_r\,(\text{kt})/\lambda\,(\text{m}) \qquad \text{(Eq. 31)}$$

In a pulse radar, the measurement of the doppler frequency shift is ambiguous if the doppler frequency is greater than the Nyquist rate, which in this case is twice the pulse repetition frequency (prf). When the prf is equal to the doppler frequency f_d or some multiple, the target velocity cannot be distinguished from stationary clutter; *i.e.*, it will appear to have no doppler shift. The relative velocity that produces a doppler frequency equal to the prf or some multiple is called a *blind speed*. The blind speeds are given by

$$v_b = n\lambda f_p/2 \qquad \text{(Eq. 32)}$$

where

v_b is the blind speed in meters/second,
λ is the wavelength in meters,
f_p is the pulse repetition frequency in hertz,
n is an integer.

The first blind speed (Fig. 10) is approximately (to an accuracy of about 3 percent)

$$v_1\,(\text{kt}) \approx \lambda\,(\text{m}) f_p(\text{Hz}) \qquad \text{(Eq. 33)}$$

PULSE RADARS THAT EMPLOY DOPPLER

There are three types of pulse radars that extract the doppler frequency shift, or relative velocity, in addition to the range information. These are:

1. A *moving target indicator* (MTI) radar in which the pulse repetition frequency (prf), denoted by f_p,

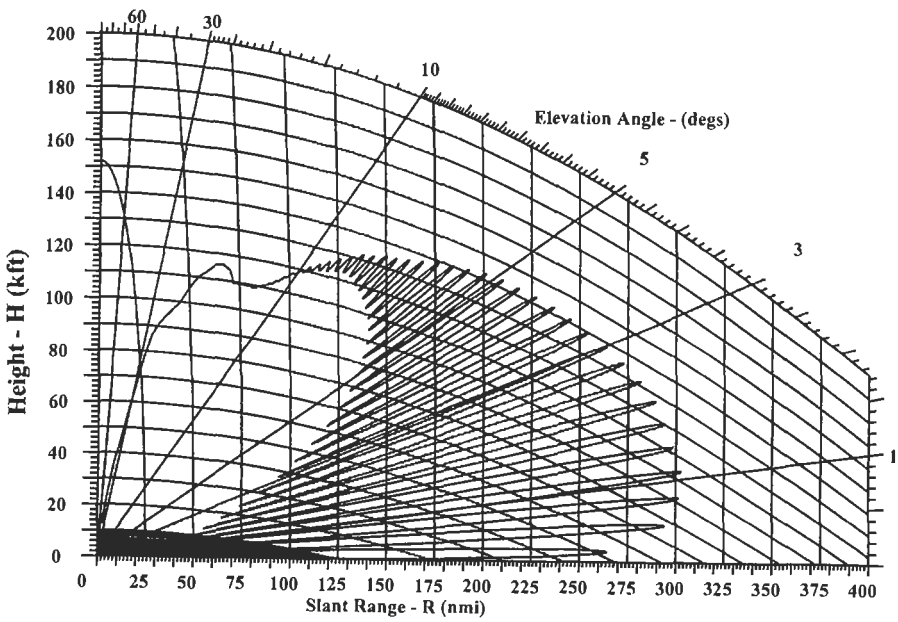

Fig. 8. Calculated elevation coverage of an air-surveillance radar at a frequency of 900 MHz, showing the uneven coverage due to the lobing that results from constructive and destructive interference between the direct and the surface-reflected waves. (*Courtesy of Vilhelm Gregers-Hansen, Naval Research Laboratory.*)

is low enough to have no range ambiguities; *i.e.*, its maximum unambiguous range $R_{unam} = c/2f_p$. On the other hand, the MTI radar has ambiguities in doppler and many blind speeds (due to doppler frequency ambiguities) where moving targets are not detected.

2. A *high pulse repetition frequency pulse doppler radar* in which the prf is large enough to have no blind speeds [as given by Eq. (32)] within the expected values of target doppler frequencies. There will be, however, many range ambiguities because of the high prf. Range ambiguities are

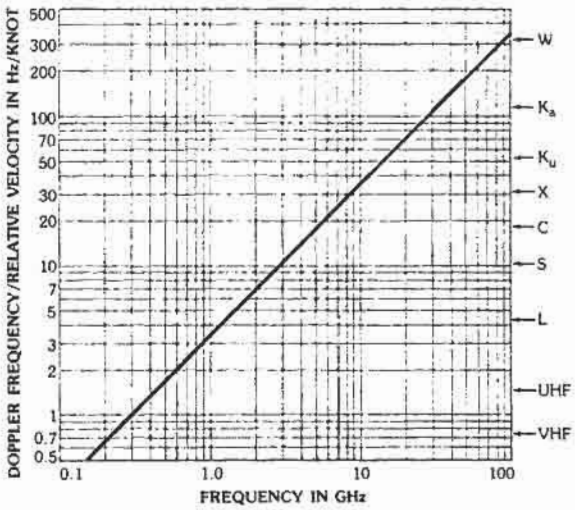

Fig. 9. Doppler frequency shift per unit relative velocity (hertz per knot) as a function of radar frequency.

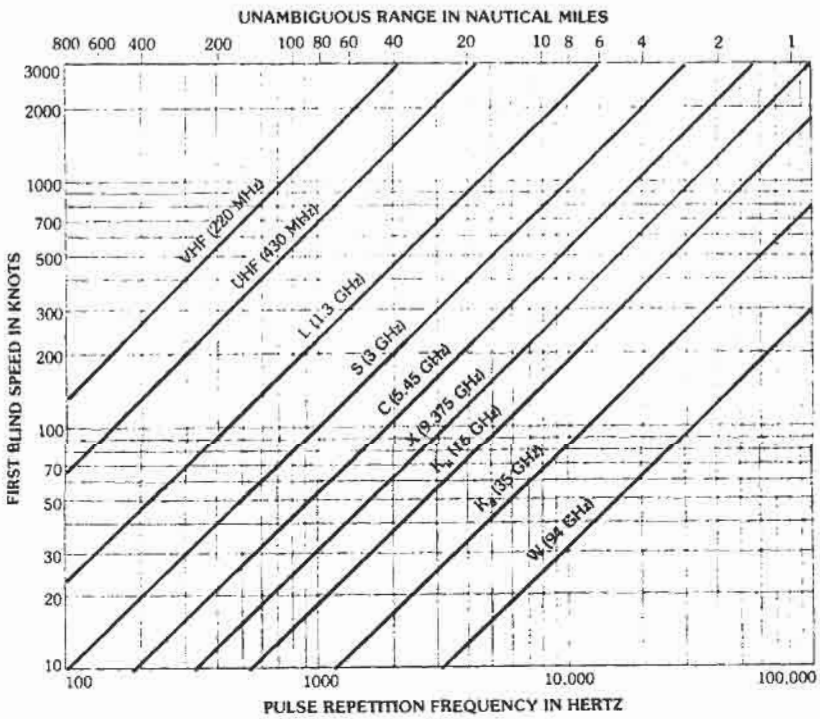

Fig. 10. First blind speed in an MTI or pulse doppler radar as a function of the pulse repetition frequency and the radar frequency.

resolved and the true range is found by transmitting three separate waveforms, each at a different prf. (In theory, only two different prfs are required to resolve range ambiguities, but in practice at least three are needed.) An advantage of a high-prf pulse doppler radar is that it can readily detect targets with a high relative-velocity since such echoes do not compete with the echoes from clutter that are at lower doppler frequencies. It has much poorer performance, however, against low relative-velocity targets which compete with the large clutter echoes seen by this type of radar in its antenna sidelobes because of the high prf.

3. A *medium prf pulse doppler radar* has both range and doppler ambiguities. It will not detect high relative-velocity targets as well as can a high-prf pulse doppler radar, but it will detect low relative-velocity targets better because its low prf sees less clutter than does the high prf.

Most ground-based air-surveillance radars that must see aircraft in the midst of clutter are generally MTI radars. When flown in an aircraft for purposes of air-surveillance, these are called AMTI, or *airborne moving target indicator radar*. AMTI radars are very good for airborne air-surveillance radars at UHF, but result in too many blind speeds when employed at the higher microwave frequencies. The high-prf and the medium-prf pulse doppler radars can both be used for airborne air-surveillance purposes at the higher frequencies. (The S-band AWACS, or AN/APY-1, airborne air-surveillance radar utilizes a high-prf pulse doppler waveform.) An X-band fighter/attack radar in a modern military aircraft might employ on a time-shared basis three widely differing prfs, depending on the operational situation. When no clutter is present (as when the antenna beam is looking up above the surface of the earth), a low prf waveform without any doppler processing might be employed. (The low prf waveform will provide the greatest range, if no clutter is present.) When searching for a target in clutter, the high prf and the medium-prf pulse doppler waveforms might be interleaved. The high prf would be looking for high-speed approaching targets at long range and the medium prf would be looking for slower-speed targets at shorter ranges.

The doppler frequency shift is important for many purposes in radar. In addition to the MTI, AMTI, and pulse doppler radars, the doppler frequency is the key to such radars as

- *Doppler weather radars*
  Nexrad, whose output is regularly shown on TV weather broadcasts.
  Terminal Doppler Weather Radar (TDWR). These are located in the vicinity of major airports to warn aircraft, that are landing or taking-off, of the presence of dangerous wind shear.
  Wind profiler, that measures as a function of altitude the wind speed and direction for both weather prediction and the efficient routing of aircraft.
  Airborne weather-avoidance doppler radar, that detects dangerous wind shear to warn the pilot of danger during take-off or landing.
- *Synthetic aperture radar (SAR)*, (for mapping a scene on the surface of the earth, and the *inverse synthetic aperture radar (ISAR)*, for imaging a target well enough to recognize it from other similar targets. (SAR is more usually thought of as an antenna synthesized in a digital processor, but it was originally invented as a doppler radar and can be described as depending on the doppler effect.)
- *Doppler navigator*, a multi-beam radar which can provide the vector velocity of an aircraft which carries it.
- *HF over-the-horizon radar*, which depends on the doppler frequency to detect aircraft and ships in the presence of large clutter echoes. The doppler spectrum of the sea echo obtained by an HF radar can also be used to extract the strength and direction of the winds over the ocean.

The continuous wave (CW) radar also depends on the doppler frequency shift to detect targets in clutter and/or to measure relative velocity.

MTI RADAR

The MTI radar uses a digital implementation of a time-domain filter composed of "delay lines" to pass desired moving targets, but to reject stationary clutter. The simplest type of MTI time-domain filter uses a single delay line to subtract the received radar echoes from the echoes received one pulse repetition period previously. A single delay-line canceler has a frequency response given by

$$H_1(f) = 2 \sin \pi f_d T_p \qquad \text{(Eq. 34)}$$

where

f_d = doppler frequency,
T_p = pulse repetition period.

When n single delay-line cancelers are used in cascade the frequency response is

$$H_n(f) = 2^n \sin^n \pi f_d T_p \qquad \text{(Eq. 35)}$$

An arrangement of n delay lines in cascade with $N = n + 1$ taps (one at the input of each delay line and one at the output of the last delay line), whose outputs are weighted by the coefficients of the binomial series with alternating sign before summing, produces a response equivalent to that of Eq. 35 for the n cascaded delay-line cancelers. This is sometimes called an *N-pulse canceler* and is an example of a *transversal* filter (also called a *nonrecursive* filter). The transversal filter may be used with weightings other than the binomial coefficients with alternating sign to give a tailored frequency response. Feedback can also be employed in a cascade of delay-line cancelers to shape the frequency response further. This is called a *recursive* filter. Its "infinite" duration transient response, however, can

limit its usefulness, especially for military radars subject to hostile electronic countermeasures.

Many air-surveillance radars used for air-traffic control employ a staggered prf rather than a constant prf. A staggered or multiple prf MTI radar is one that uses more than one pulse repetition period. Four or five stagger periods might be used. For example, the periods of an *L*-band air surveillance radar might be in the ratio of 28:30:27:31 (Reference 15). A staggered prf is used to increase the first blind speed beyond that given by Eq. 32. If the individual periods of the multiple PRF waveform are designated by $T_1, T_2, \ldots, T_N$, and if they are related by the ratios $n_1/T_1 = n_2/T_2 = \ldots = n_N/T_N$, where $n_1, n_2, \ldots, n_N$ are integers, then the first blind speed when N different periods are used is

$$v_1 = [(n_1 + n_2 + \ldots + n_N)/N]v_B \qquad \text{(Eq. 36)}$$

where v_B is the first blind speed as given by Eq. 32 for a nonstaggered waveform with a constant period equal to the average of the N periods, or $(T_1 + T_2 + \ldots + T_N)/N$. In the above example with four staggered periods, $n_1 = 25$, $n_2 = 30$, $n_3 = 27$, and $n_4 = 31$, the first blind speed of the staggered waveform is 28.25 times that of a waveform with constant pulse repetition period. The staggered prf can also be used with a transversal filter of unequal spacings and with amplitude weights to shape the frequency response of the doppler filter.

Still another method for providing doppler filtering in an MTI or pulse doppler radar is to generate a bank of narrow-band doppler filters. These can be obtained using a transversal filter with phase weights rather than amplitude weights. N pulses processed as a filter bank will produce N contiguous narrow-band filters. The filter bank has the advantage over other methods in (1) separating desired moving targets from undesired moving clutter (such as rain), (2) providing a measure of the target's radial velocity, and (3) improving the signal-to-noise ratio compared to other filters. Of all these advantages, the first (separating aircraft echoes from rain) has been the most important.

In the above, several methods for providing doppler filtering have been briefly mentioned. Each has its advantages and limitations, and no one method is superior in all cases to the rest. Thus "engineering judgement" is needed when selecting the type of filtering to be used in any doppler radar application.

MTI Performance Limitations

The performance measure used to describe the ability of an MTI to see targets in clutter is the *MTI Improvement Factor*, defined as the signal-to-clutter ratio at the output of the MTI processor divided by the signal-to-clutter ratio at the input, averaged uniformly over all target relative velocities of interest. *Clutter Attenuation* is the ratio of the clutter power at the canceler input to the clutter residue at the output, normalized to the attenuation of a single pulse passing through the unprocessed channel of the canceler. *Subclutter Visibility* is the ratio by which the target echo power may be weaker than the clutter echo power and still be detected with specified detection and false alarm probabilities. All target relative velocities are assumed equally likely.

The performance of an MTI radar is limited by clutter fluctuations, antenna scanning, and equipment instabilities.

Clutter Fluctuations—The improvement factor of an N-pulse canceler with $n = N - 1$ delay lines, or n cascaded delay-line cancelers, is

$$I_N = (2^n/n!)\,(f_p/2\pi\sigma_c)^{2n} \qquad \text{(Eq. 37)}$$

where

f_p = pulse repetition frequency,
σ_c = standard deviation of the clutter spectrum which is assumed to be of Gaussian shape.

This is plotted in Fig. 11. The standard deviation of the clutter spectrum in hertz is related to the standard deviation of the velocity spread in meters/second by the expression $\sigma_c = 2\sigma_v/\lambda$. "Typical" values of σ_v are (Reference 14):

Heavily wooded hills, 20 mph wind: 0.2 m/s
Sparsely wooded hills, calm day: 0.02 m/s
Sea echo, windy day: 0.9 m/s
Rain clouds: 2 m/s
Chaff: 1 m/s

The Gaussian model (and Eq. 37) does not apply for heavy clutter. The exponential clutter model needs to be used when improvement factors are greater than 20 or 30 dB, as has been described by Billingsley (Reference 16).

Antenna Scanning—The limitation to the improvement factor for n delay-line cancelers in cascade is

$$I_n = (2^n/n!) \times (0.6n_B)^{2n} \qquad \text{(Eq. 38)}$$

where n_B = number of pulses received within the half-power beamwidth as the antenna scans by the target.

Equipment Instabilities—The improvement factor in a doppler radar can be limited by the instabilities in such things as the transmitter frequency, stalo and coho oscillator phase or frequency, phase shift in the transmitter, and changes in the pulse width and pulse amplitude. Simple expressions can be found in the literature for the limitation on the improvement factor due to these equipment instability effects when a single or a double delay-line canceler is used; but most modern radars employ more sophisticated doppler filters and thus require more sophisticated analysis of the effect of equipment instabilities.

Digital Quantization—The limit on the improvement factor in a digital MTI due to the finite size of the quantization interval of the A/D converter is approximately

$$I_q \approx 6 \times \text{number of bits} \qquad \text{(Eq. 39)}$$

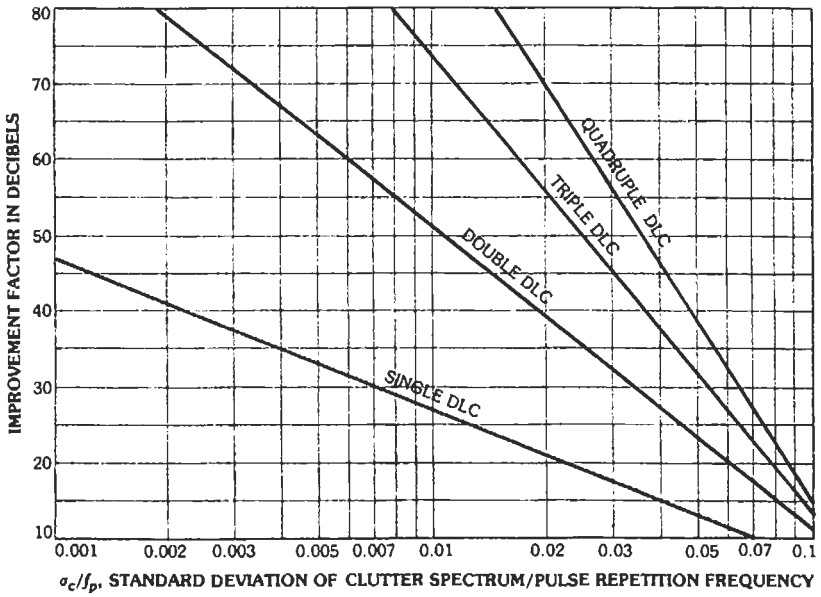

Fig. 11. The improvement factor as a function of σ_c/f_p (ratio of the standard deviation of the clutter and the pulse repetition frequency) for single and cascaded delay-line cancelers (DLC) as given by Eq. 37.

where I_0 is in decibels. For example, an eight-bit A/D converter limits the improvement factor to 48 dB. In practice one or two additional bits must be added to account for receiver noise in the lower quantization levels and the limitations introduced by a limited dynamic range. In the previous example, a 10 bit A/D converter would likely be used if the limitation on the improvement factor had to be 48 dB.

PULSE COMPRESSION

Pulse compression allows a radar to utilize a long pulse to achieve a large radiated energy, but with the range resolution of a short pulse of wide bandwidth. It achieves this by modulating the long pulse of width T to obtain a bandwidth $B >> 1/T$. The received signal is passed through a matched filter to produce a compressed pulse of width $1/B$. The pulse compression ratio, which is the duration of the long pulse divided by the duration of the short (compressed) pulse, is equal to BT. Frequency and phase modulations have both been used for pulse compression. Amplitude modulation could also be employed, in principle, but it is seldom found in practical pulse compression systems.

Table 4 gives the major types of pulse compression waveforms that have been employed in radar.

Doppler tolerant waveforms, such as the linear-FM modulation and the polyphase code, can be processed using a single matched filter even though the received signal experiences a wide range of doppler frequency shifts. *Complementary codes* consist of pairs of equal-length codes which have the property that the time sidelobes of one code are the negative of the other so that they can be canceled to result in no sidelobes, theoretically. (This is generally difficult to obtain in practice.) The *pulse burst* is a series of pulses transmitted as a group before any echo signals are received (as when a long minimum range can be tolerated). Further information about pulse compression may be found in Chapter 6 of Reference 1.

CLUTTER

Clutter echoes are those received from undesired scatterers such as land, sea, rain, snow, chaff, clouds, birds, insects, aurora, and meteors. Good radar practice requires that these clutter echoes be eliminated or minimized so as to prevent degraded detection of desired target echoes. It is especially important to limit the amount of clutter echoes presented to automatic detection and tracking (ADT) systems so that overloading of the tracking computer does not occur by trying to establish tracks based on the echoes from clutter rather than from targets.

Surface clutter is described by the dimensionless parameter σ°, defined as the clutter cross section per unit area illuminated. Fig. 12 is a plot of the mean value of σ° for sea clutter as a function of the grazing angle. It applies for a medium sea (10–20 knot winds). At the lower grazing angles, sea clutter increases slowly with increasing winds above 15 to 20 knots (a few tenths of a decibel per knot). Below about 5 knots

TABLE 4. PULSE COMPRESSION WAVEFORMS

Type	Description	Pulse Compression Ratio	Peak (Time) Sidelobe	Comments
Linear FM (chirp)	Linear modulation of the frequency over the range Δf in a time T.	$\Delta f \times T$	–13.2 dB; but with weighting in the frequency domain on receive, sidelobes can be –30 dB with loss in SNR of about 1 dB.	Widely used. Especially applicable to very high resolution. Doppler tolerant.
Binary phase code; also known as linear recursive sequences, pseudorandom sequences, P-N sequences, and maximal length sequences.	A pulse of width T is divided into N subpulses of width τ, where $N = T/\tau$. The phase of each subpulse is either 0 or π radians, chosen at random or pseudorandom.	N, the number of subpulses.	Approximately $0.5/N$ (in the best of cases)	Sidelobes are not low, especially with a doppler shift.
Barker code	A form of binary phase code that has all its time sidelobes equal to $1/N^2$ that of the compressed pulse peak power.	N	$1/N^2$	Limited to $N \leq 13$. Longer pulse compression ratios can be had with compound Barker codes in which each segment of a Barker code is modulated by a Barker code, but no decrease in sidelobes is obtained.
Frank polyphase code with variants due to Lewis and Kretschmer known as P codes. Phase quantization less than π radians.	A pulse of width T is divided into M^2 equal subpulses. The phase of each subpulse is chosen so that a linear FM waveform is approximated with a phase quantization equal to $2\pi/M$ radians.	M^2	$1/\pi^2 M^2$	Doppler tolerant for aircraft velocities. Lower sidelobes than other pulse compression methods.
Costas codes; also known as discrete frequency shift codes and time-frequency codes	A pulse of width T is divided into M subpulses, and the carrier frequency is changed subpulse to subpulse, with frequency steps separated by the reciprocal of the subpulse width. Frequencies are selected in a definite order from the M frequency steps over a band $\Delta f = M/\tau$, where $\tau = T/M$.	$\Delta f \times T = M^2$	$1/M^2$ in regions away from the central peak response; $(2/M)^2$ near the central peak response.	Produces a thumbtack ambiguity diagram. For a given value of M, there can be a large number of different Costas codes.
Nonlinear FM	Frequency is varied nonlinearly over a band Δf in a time T.	$\Delta f \times T$	Depends on the nonlinear waveform used.	Low sidelobes can be obtained with matched filter processing without a loss in SNR. Can obtain a thumbtack ambiguity diagram.
Stretch	Transmits a linear FM waveform of bandwidth Δf over a time T, but processes the received signal with circuitry of bandwidth $\Delta f/a$ (where $a > 1$). The region where pulse compression occurs is over a restricted range interval $1/a$ that of conventional FM pulse compression.	$\Delta f \times T$	As with linear FM pulse compression.	The time waveform is "stretched" by a factor of a so as to achieve a reduction of processing bandwidth by $1/a$. Used for target recognition applications.

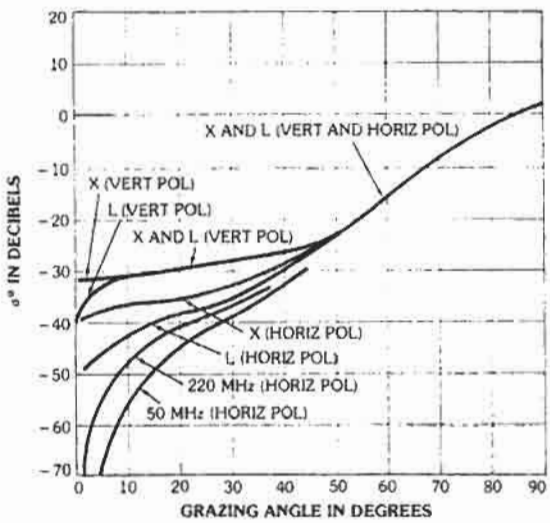

Fig. 12. Composite of σ^0 data for a "medium" sea, as a function of the grazing angle.

wind velocity, sea clutter decreases rapidly with decreasing wind.

Land clutter is difficult to describe because of the many factors that affect it. Fig. 13 is a plot of the mean value and variance of rural clutter measured at low grazing angles (Reference 16). It is seen that the mean is relatively independent of frequency, but the variance decreases with increasing frequency. The following are a few of the many findings from the extensive measurements reported by Billingsley in Reference 16 for land clutter when viewed at low grazing angle:

- Most of the significant clutter echoes come from spatially localized or discrete vertical features;

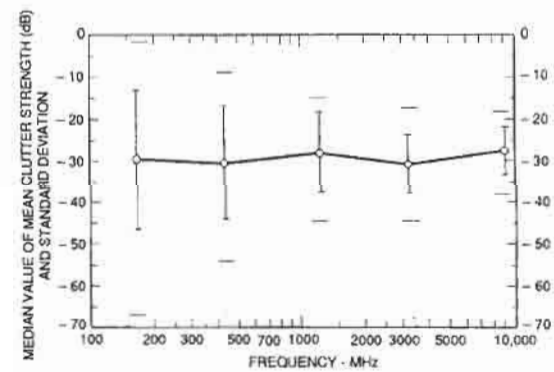

Fig. 13. Ground clutter of rural terrain at low gazing angles as a function of frequency, showing mean values of clutter strength (open circles), standard deviation (vertical bars), and the extreme measured values (horizontal bars). (After J. Billingsley, Reference 16.)

such as trees, fences, buildings, and high regions of terrain.
- The effect of vertical discrete objects on the overall clutter strength is large even when these objects are relatively sparse.
- The variation of the average clutter echo with weather, season, and from day-to-day is small.
- There is little difference in the clutter echo between vertical and horizontal polarization.
- Measured amplitude distributions "almost never pass rigorous statistical hypothesis tests for belonging to Weibull, lognormal, or other theoretical distributions that have been tried."
- The chief characteristic of clutter is its variability.

The radar echo from volume clutter, such as rain, is described by the volume reflectivity, η, defined as the radar cross section per unit volume. The volume reflectivity of rain in the microwave region is

$$\eta = 7f^4 r^{1.6} \times 10^{-12} \qquad \text{(Eq. 40)}$$

where

η is the volume reflectivity in meters^2/meter^3,
f is the radar frequency in gigahertz,
r is the rainfall rate in millimeters/hour.

This expression assumes that the backscatter from rain is described by Rayleigh scattering, which is applicable when the radar wavelength is large compared to the circumference of the raindrop.

The approximate number of hours per year that various rainfall rates are exceeded in Washington, DC are as follows:

Rainfall Rate, mm/hr	Number of hrs/yr
0.25 (drizzle)	500
1 (light rain)	230
4 (moderate rain)	65
16 (heavy rain)	10
40 (excessive rain)	2

An alternate description of rainfall rate, instead of millimeters/hour, is the reflectivity factor $Z = 200r^{1.6}$, where r is the rainfall rate in mm/hr and Z is in mm^6/m^3. This measure is often used by radar meteorologists. It is usually expressed in decibels and abbreviated dBZ. For example, a rainfall rate of 4 mm/hr is equivalent to 32.6 dBZ.

The following brief statements review the general nature of radar clutter:

- Clutter can be more harmful than receiver noise in limiting the ability of a radar to detect targets.
- It is far more difficult to characterize clutter than to characterize receiver noise.
- Land clutter is a more serious limitation than sea clutter.
- The available information on land clutter at low grazing angles is quite good. With the possible exception of vertical incidence, the description of land clutter at higher grazing angles is not as

good. Theoretical models of clutter echo are poor and remote sensing results over land might be misleading.

- The theory of radar sea clutter at HF and VHF is readily described by Bragg scatter. On the other hand, Bragg scatter does not apply at the higher microwave frequencies. "Sea spikes" are the dominant clutter mechanism at these frequencies.
- Rain clutter can seriously affect the performance of radars at L band and higher. Unless doppler processing is used, S band and higher frequency radars are seriously degraded (clobbered) in rain.
- Snow generally is not as serious as rain in reducing radar performance.

RADAR MEASUREMENT ACCURACY

The rms error, δM, in making a measurement of a radar parameter M in the presence of Gaussian noise and in the absence of any bias can be written conceptually in the form

$$\delta M = kM/(2E/N_0)^{1/2} \qquad \text{(Eq. 41)}$$

where

E is the received signal energy,

N_0 is the noise power per unit bandwidth,

k is a constant of the order of unity.

(Note that $2E/N_0$ is also the peak-signal-to-mean-noise ratio at the output of a matched filter.) For a range measurement (time delay), k depends on the shape of the signal spectrum and M can be taken as the rise time of the pulse. For a doppler frequency measurement, k depends on the shape of the time waveform and M is the spectral resolution (or the reciprocal of the observation time). For an angle measurement, k depends on the shape of the antenna aperture illumination and M is the beamwidth.

RMS Range Measurement Error

Rectangular pulses are seldom truly rectangular in that they have a finite rise and a finite fall time. A quasi-rectangular pulse (Reference 1) is more realistic than a perfectly rectangular pulse since it is a pulse which has passed through a filter so that it has a rounded shape rather than have unrealistic rise and fall times with infinite slopes. The theoretical rms range error for such a pulse when the noise is Gaussian is

$$\delta R = (c\tau/2)/[1.3(2E/N_0)^{1/2}] \qquad \text{(Eq. 42)}$$

where

c = velocity of propagation

τ = half-power time duration.

RMS Doppler Frequency Measurement Error

Rectangular pulse of width τ.

$$\delta f = \sqrt{3}/[\pi\tau(2E/N_0)^{1/2}] \qquad \text{(Eq. 43)}$$

Quasi-rectangular pulse of half-power width τ.

$$\delta f = 1/[2.6\tau(2E/N_0)^{1/2}] \qquad \text{(Eq. 44)}$$

RMS Angle Measurement Error

Uniform aperture illumination:

$$\delta\theta = 0.628\theta_B/(2E/N_0)^{1/2} \qquad \text{(Eq. 45)}$$

where θ_B = half-power beamwidth.

Cosine aperture illumination:

$$\delta\theta = 0.73\theta_B/(2E/N_0)^{1/2} \qquad \text{(Eq. 46)}$$

TRACKING WITH RADAR

There are at least four different radar methods for obtaining the track of a target, as described below.

Single-Target Tracker (STT): The single-target tracker continually engages one target with a high data rate. Ten target observations per second is a typical data rate for military tracking radars. Tracking in range and angle is performed with a closed-loop servo system so as to keep the radar positioned on a moving target. *Monopulse* trackers are the most accurate tracker and have a high degree of resistance to deliberate countermeasures, which is why it has been the preferred tracking method for military air defense systems based on the STT. In a monopulse radar, the angle measurement in one coordinate is determined by using two beams slightly displaced (squinted) in angle. Transmission occurs on the sum of the two squinted beams and reception on both the sum and the difference of the two beams. The angle measurement is obtained with the difference pattern. The sum pattern provides detection and the measurement of range. The sum pattern signal also acts as a reference signal to determine in which direction is the angle error. To provide angle measurements in two angle coordinates, four squinted antenna beams are required. A monopulse tracker has three receiving channels: a range channel and two angle channels.

The *conical scan* STT is much simpler than a monopulse tracker in that it needs only one receiving channel to extract the angle measurement in two angle coordinates. A single offset (squinted) antenna beam is rotated typically at a rate of about 30 Hz. The conical scan tracker time-shares a single beam to sequentially obtain the angle measurements in two coordinates; whereas, a monopulse radar obtains its angle measurements simultaneously. Conical scan radars are used where accuracy and vulnerability to electronic counter-

measures are less important than a simpler, lower cost system.

Automatic Detection and Track (ADT): A conventional rotating air-surveillance radar such as employed for air-traffic control obtains an azimuth angle measurement on each rotation, or scan, of the antenna. Tracks can be established based on this lower scan rate (revisit times from 4 to 12 s). Automatic tracking is combined with automatic detection and is called automatic detection and track. The data rate is considerably slower than that of a single-target tracker, but a single ADT system might be able to hold in track many hundreds or thousands of aircraft targets. Tracking is done open loop in that the position of the antenna is not controlled by the processed tracking data as it is in a closed-loop STT.

Phased Array Radar Tracking: Multiple targets can be tracked on a time-shared basis with an agile electronically steered phased array radar. Tracking is not closed loop, but it combines the high data rate of a STT with the ability of an ADT to hold a large number of targets in track.

Track While Scan (TWS): This term has been applied to both the ADT and to a radar which rapidly scans a limited angular sector to maintain tracks with a moderate data rate on a modest number of targets. TWS is now almost always applied to the latter meaning rather than to an ADT system. Angle information can be obtained in a TWS radar by using two scanning fan beams perpendicular to each other, one for the azimuth angle measurement and the other for the elevation angle measurement. A TWS radar can also be obtained with a single cluster of four monopulse beams scanning in a raster fashion to provide the required volume coverage.

37 Radio Navigation Systems

Revised by
D. G. Jablonski

INTRODUCTION

Electromagnetic waves at radio and microwave frequencies can be used for the precise measurement of time, distance, and direction. Several factors make this possible. First, one can generate extremely accurate timing signals using a variety of techniques, including atomic clocks. In addition, radio and microwave signals can be generated coherently, so that their frequency and phase are well controlled and easily measured. Because of the low ambient thermal noise at these frequencies, radio signals can be detected at extraordinarily low power levels (~ −160 dBW using time integration techniques). In addition, the diverse propagation characteristics of radio waves, as a function of frequency, permit engineers to exploit over-the-horizon transmission at low frequencies, and sight-limited propagation at high frequencies. The high resolution afforded by the short signal wavelengths at higher microwave frequencies, the effects of constructive interference at all frequencies, and the always useful Doppler effect are also utilized to good advantage in modern radio navigation systems.

However, in recent years, there has been considerable change in the radio navigation systems deployed throughout the world. In particular, several time-honored systems, including Omega and the Transit satellite system, are no longer operational. Efforts to develop the Microwave Landing System (MLS), which was intended to replace the existing Instrument Landing System (ILS) used by aircraft, have been reduced greatly, at least in the United States. In their stead, the Global Positioning System (GPS) has been deployed and declared operational, and is now the system of choice for worldwide radio navigation. The Russian counterpart to GPS, the GLONASS system, is also operational, and an additional worldwide satellite-based radio navigation system, called Galileo, is under development in Europe. In addition, various military communications systems, such as the Joint Tactical Information Distribution System, or JTIDS, have an incipient radio navigation capability for their users.

In addition to the new systems, the venerable VOR, TACAN, DME, and Air Traffic Control Radar Beacon System (ATCRBS) remain stalwarts of the commercial and military aircraft navigation infrastructure.

Major Navigation Agencies

Airlines Electronic Engineering Committee (AEEC), Annapolis Science Center, Annapolis, Maryland: A division of Aeronautical Radio, Inc. (ARINC) and owned by the scheduled US airlines. Publishes technical standards for avionics purchased by the scheduled airlines.

Airline Owners and Pilots Association (AOPA), Washington, DC: Defends the needs of the airline industry and pilots with regard to safety-of-life issues, frequency allocation that affects radio navigation systems, etc.

Department of Transportation, United States Coast Guard (USCG), Washington, DC: Operates the Loran-C navigation system for marine and aeronautical navigation; operates and maintains a beacon system for differential GPS in the coastal regions of the United States and along the Mississippi River.

Federal Aviation Administration (FAA), Washington, DC: Operates navigation aids and air traffic control systems for both civil and military aircraft in the US and its possessions.

Federal Communications Commission (FCC), Washington, DC: The agency that licenses transmitters and operators in the United States and aboard US registered ships and aircraft.

International Air Transport Association (IATA), Montreal, Canada: The international association representing scheduled airlines.

International Civil Aviation Organization (ICASO), Montreal, Canada: A United Nations agency that formulates standards and recommended practices, including navigation aids, for all civil aviation.

International Telecommunication Union (ITU), Geneva, Switzerland: An agency of the United Nations that allocates frequencies for best use of the radio spectrum.

RTCA, formerly Radio Technical Commission for Aeronautics, Washington, DC: Supported by contributions from industry and government agencies. Participation by manufacturers, users, and others in the recommended standards for aviation electronics. The ICAO and the FAA adopt many of these standards, at least in part.

Radio Technical Commission for Maritime Services (RTCM), Washington, DC: Functions similar to those of RTCA; however, addresses primarily marine issues.

PROPAGATION

Issues

A detailed understanding of the propagation characteristics of radio waves is essential to the implementation of radio navigation systems. In low-frequency navigation systems, complex propagation models may be used to correct for nonhomogeneous propagation paths. In addition, in most radio navigation systems, errors may result from the contamination of the signals with multipath signals that have traveled by a nondirect path that is often variable. This is of increasing importance as the operational bandwidth of systems increases. This is due to a phenomenon known as frequency-selective fade, in which a portion of the signal spectrum suffers from frequency-specific multipath effects. To reduce multipath effects, the following techniques are commonly used in navigation systems.

Pulse Transmission

Through the use of an appropriate pulse length and repetition rate combined with a means in the receiver to recognize the leading edges of the pulses, the desired direct signal may be separated from a signal that has traveled a longer path (sky wave for low-frequency systems and multipath for higher-frequency systems). Pulse transmission techniques are effectively used in Loran-C, DME, with ATCRBS transponders, and radar systems.

Space Diversity

The larger the aperture of the antenna system, the greater is the statistical probability that the desired signals will add linearly, while the multipath signals add randomly. This approach is effectively used in Doppler VOR systems. Antenna directivity and polarization are frequently used to reduce interference from undesired multipath signals. Horizontal polarization is used in the ILS system, and vertical polarization is used in VOR and DME systems.

Frequency Diversity

While the line-of-sight path remains the same at all radio frequencies, indirect paths may vary with frequency. In such cases, spectrum-spreading techniques, such as Code Division Multiple Access (CDMA), may achieve the same result as space diversity.

RADIO NAVIGATION SYSTEMS

The following subsections provide information on radio navigation aids ranging from the now obsolete low-frequency Omega system through the current satellite system, the Navstar Global Positioning System (GPS).

Omega

The Omega system was a worldwide VLF navigation system used for marine and enroute air navigation. In Omega, the system CW transmitting stations sequentially transmit long, but precisely timed, pulses at four frequencies: 10.2 kHz, 11.3 kHz, 13.6 kHz, and 11.05 kHz. Position information is obtained by measuring the relative phase differences of the received signals. Since lines of constant phase for the signal from a particular transmitter are hyperbolic in shape, OMEGA is known as a hyperbolic system. The inherent accuracy of the Omega system is limited by propagation corrections that must be applied to the receiver. These corrections vary depending on location and the time of day. In many cases, accuracies of 2 nautical miles (rms) day and 4 nautical miles night could be achieved in most of the coverage areas. Note that worldwide coverage is achieved by the choice of VLF for the operating band. Only three transmitter stations are needed to achieve worldwide coverage. The choice of VLF results in the complex propagation issues reflected in the dependence of system accuracy on time-of-day.

Loran-C

Loran-C is a long-range (as opposed to worldwide) hyperbolic radio navigation system that possesses an inherent high degree of accuracy at ranges of 800 to 1000 nautical miles. The Loran-C system transmits synchronized, phase-coded pulses from a master station and two or more secondary stations at 100 kHz. Note the difference in operating frequency compared to the VLF OMEGA system. The Loran-C transmitting stations form a chain characterized by the group repetition interval (GRI) in which the pulses are repeated. A GRI starts with the master station transmitting eight pulses, each spaced one millisecond apart, followed by a ninth pulse two milliseconds later. The master station transmission is followed after a prescribed coding delay by transmissions from each of the secondary stations in the chain, each transmitting eight pulses at one-millisecond intervals. Phase coding is used to differentiate the master pulses from those of the secondaries. The pulse spacing and phase code allow the ground wave (direct propagation path) to be differentiated from the varying sky wave.

A typical Loran-C receiver makes use of a microprocessor for signal processing, navigation computation, and control. Through the use of microprocessors and other signal-processing and timing integrated circuits, the cost of high-quality navigation has continued to decrease. Although there have been plans to deactivate Loran-C, it is still in use in the United States and elsewhere. The accuracy of the system is one quarter of a mile absolute and less than 100 feet for measurement of relative position.

Radio Beacons

Radio beacons are nondirectional transmitters that operate in the low-frequency and medium-frequency bands. A radio direction finder is used to measure the relative bearing to the transmitter with respect to the heading of an aircraft or marine vessel. The aeronautical nondirectional beacons (NDBs) operate in the 190–415 kHz and 510–535 kHz bands. These beacons transmit either a coded or modulated CW signal for station identification. The coded signal is generated by modulating the carrier, and the upper carrier is keyed for the Morse-code identification. The aeronautical-beacon accuracy is in the range ± 3 degrees to ± 10 degrees, and the marine-systems accuracy is maintained to within ± 3 degrees. Aeronautical NDBs are used to

supplement the combined VOR/DME system for transition from enroute to precision approach facilities and as nonprecision approach aids. These aeronautical systems are considered one of the ICAO standard radio navigation aids.

VOR (VHF Omnidirectional Range)

The VOR transmits continuous-wave signals on one of the 20 assigned channels in the 108 to 118 MHz bands with 100-kHz channel separation. A nondirectional 30-Hz reference signal with a ± 480-Hz frequency modulation on a 9960-Hz subcarrier is transmitted along with a carrier radiating from a rotating antenna with a horizontal cardioid pattern. The cardioid antenna pattern rotates at a 30-Hz rate, allowing the airborne receiver to determine its bearing from the station as a function of phase between the reference and the rotating signal. The VOR system has line-of-sight limitations in that at altitudes above 5000 feet the range is approximately 100 nautical miles and above 20 000 feet the range is approximately 200 nautical miles. The enroute VOR stations are rated at 50 watts. The accuracy of the VOR ground station is better than ± 1.4. (However, the station magnetic declination is usually allowed to increase to 2 before being reset.) The total system error (rss of the ground and airborne system plus flight technical error) is less than ± 4.5 degrees.

Distance measuring equipment (DME) installations are often colocated with the VOR stations to provide ranging information. In the United States and other countries, TACAN (Tactical Air Navigation) installations are colocated with the VORs to provide a navigation system utilized primarily by the military. A combined VOR/DME/TACAN installation is known as a "VORTAC" station. They are typically located in cleared fields with good line-of-sight in all directions and are readily visible to passersby.

ILS (Instrument Landing System)

At present, the instrument landing system operating in the 108–112 MHz band is the primary worldwide, ICAO approved precision landing system. An alternate system, the microwave landing system (MLS) was scheduled to replace the ILS by the year 2000. However, in the United States, development of the Microwave Landing System was deferred in most cases in favor of the long-term adoption of GPS as a precision landing system. However, approval of GPS as the sole means of navigation for precision landing has not yet occurred, and ILS remains in widespread use as the system of choice.

An ILS normally consists of two or three marker beacons, a localizer, and a glide slope to provide vertical and horizontal guidance information. The localizer, operating in the 108–112 MHz band, is normally located 1000 feet beyond the stop end of the runway. The glide slope is normally positioned 1000 feet after the approach end of the runway and operates in the 328.6–335.4 MHz band. Marker beacons operating along the extension of the runway centerline at 75 MHz are used to indicate decision height points for the approach or distance to the threshold of the runway.

Azimuth guidance provided by the localizer is accomplished by use of a 90-Hz-modulated left-hand antenna pattern and a 150-Hz-modulated right-hand pattern as viewed from the aircraft on an approach. A 90-Hz signal detected by the aircraft receiver will cause the course deviation indicator (CDI) to deviate to the right. A 150-Hz signal will drive the CDI vertical needle to the left when the aircraft is right of the centerline course. When the aircraft is on the centerline, the CDI vertical needle will be centered. A total of 40 channels are provided by the ILS localizer system, each being paired with a possible glide-slope channel.

Vertical guidance is provided by the glide-slope facility that is normally located to the side of the approach end of the runway. A total of 40 channels are provided in the 328.6–335.4 MHz band; each is paired with one of 40 ILS localizer channels. The carrier radiated in the antenna pattern below the glide slope is amplitude modulated with a 150-Hz signal. The pattern above the glide slope produces a signal with 90-Hz amplitude modulation. When the approaching aircraft is on the glide slope, the CDI horizontal (glide slope) needle will be centered.

The marker-beacon facilities along the course provide vertical fan markers to mark the key productions along the approach. The inner marker is normally at the runway threshold; the middle marker is about 3500 feet from the threshold; and the outer marker is usually 5 miles from the runway. A DME on one of the 20 paired channels with the localizer channels may also be used for indicating position during the approach.

The quality of the ILS installations varies depending on the equipment, terrain, and calibration. The ICAO has established the categories in Table 1 for minimum approach ceiling and forward visibility.

TABLE 1. CATEGORIES FOR MINIMUM APPROACH CEILING AND FORWARD VISIBILITY

Category	Minimum Ceiling (feet)	Forward Visibility (feet)
I	200	2600
II	100	1200
III-A	50	700
III-B	35	150
III-C	0	0

DME (Distance Measuring Equipment)

The airborne equipment (interrogator) generates a pulsed signal that is recognized by the ground equipment (transponder); the transponder then transmits a reply that is identified by the tracking circuit in the interrogator. The distance is computed by measuring the total round-trip time of interrogation, reply, and fixed delay introduced by the ground transponder. The airborne interrogator transmits about 30 pulse pairs per second on one of the 126 allocated channels between 1025 and 1150 MHz. The ground transponder replies on one of the paired channels in the 962–1024 MHz band or 1151–1213 MHz band. A DME and a colocated VOR constitute the ICAO standard ρ-θ system.

TACAN (Tactical Air Navigation)

The TACAN system provides both omnibearing and distance-measuring capability. The rotating directional horizontal-plane radiation pattern produces the azimuth signal, which contains a coarse (15 Hz) and a fine (135 Hz) azimuth element. The rotation of the pattern at 15 Hz results in a modulation of the carrier with a composite 15-Hz sine wave. Reference signals are transmitted by coded pulse trains to provide the phase reference. The airborne receiver obtains bearing by comparing the 15-Hz and 135-Hz sine waves with the reference pulse groups. The TACAN system operates in the 960–1215 MHz band with 1-MHz channel separations.

MLS (Microwave Landing System)

The microwave landing system is an ICAO-approved replacement for the current ILS system. However, the advent of GPS has placed many of the plans for deployment of MLS on hold. In the United States, there are no plans for widespread deployment of MLS. The MLS system is based on time-referenced scanning beams (TRSB), referenced to the runway, which enable the airborne unit to determine precise azimuth angle and elevation angle. The angular position of the aircraft is determined by measuring the time intervals between the TO and FROM azimuth antenna beam scan and the UP and DOWN scan of the elevation antenna pattern. The time interval represents a unique position within the range of the scanning beams. The azimuth scan is typically 60 degrees either side of the runway centerline, and the elevation scan is from 0 to 30 degrees. The signal format provides for 360-degree azimuth coverage for future implementation. 200 channels in the 5000–5250 MHz band provide the azimuth and elevation angle functions. Range information is provided by DMEs operating in the 960–1215 MHz band. An option is included in the signal format to permit a special-purpose system operating in the 15 400–15 700 MHz band.

ATCRBS (Air Traffic Control Radar Beacon System)

The ATCRBS ground interrogator transmits at 1030 MHz with a rotating (5 Hz enroute and 2.5 Hz terminal areas) directional antenna pattern. The interrogator transmits approximately 400 pulse pairs per second and receives replies from aircraft transponders that are within the beam of the antenna pattern. The airborne transponder replies at 1090 MHz with one of the 4096 pulse codes available. The decoded replies are displayed on the surveillance radar ppi along with primary radar returns. An omnidirectional pulsed pattern is also radiated from the ground to suppress unwanted sidelobe replies. This system is often referred to as secondary surveillance radar.

Transit

The Transit satellite navigation system consisted of a constellation of satellites in approximately 600-nautical-mile polar orbits. The system, now deactivated, was operated by the US Navy. The satellites broadcast ephemeris information continuously at 150 MHz and 400 MHz. A receiver measures successive Doppler shifts of the signal as the satellite approaches or passes the user. The geographic position of the receiver is then calculated from the satellite position information (transmitted from the satellite every two minutes) and the measurement of the Doppler shift. Normally only one frequency (400 MHz) is used for navigation, and the other is used when ionosphere correction (for improved accuracy) is performed. Coverage was worldwide but not continuous due to the relatively low altitude and the low number of satellites. The update of navigation (time between satellite fixes) was as short as 1 hour and up to 8 hours, depending on latitude. The Transit system has been replaced by the Global Positioning System (GPS).

TCAS (Traffic Alert and Collision Avoidance Systems)

The TCAS collision avoidance system permits aircraft to interrogate each other's transponder beacons. The response to an interrogation is processed to provide relative range information. Relative altitude information is derived from a comparison of the altimeter information coded into the transponder's reply and the interrogating aircraft's knowledge of its own altitude. When automatic computer computations indicate that a collision is probable, either a traffic advisory (TA) or a resolution advisory (RA) is provided to the pilot of the interrogating aircraft. The more sophisticated RA

is available only in the TCAS-II implementation. The RA directs the pilot to perform a specific maneuver to avoid a collision. TCAS-I is installed on small commercial aircraft (10–30 passengers) and TCAS-II on large transport aircraft.

NAVSTAR/Global Positioning System

The Global Positioning System (GPS) is a worldwide satellite navigation system developed by the US Department of Defense. Shown in notional form in Fig. 1, it is currently operational with 27 satellites. Operation of the system is based on accurate knowledge of the position of each satellite with respect to the time and distance from a satellite to the user. Each satellite transmits a unique ephemeris data table, which is periodically updated by the master control station. The user's position is determined relative to the satellites by processing signals received from at least four satellites. The time-of-arrival difference measurements are used to obtain the distance to each of the satellites. A time correction then relates the satellite system to earth coordinates.

The satellite signals are transmitted at two L-band frequencies (L_1 at 1575.42 MHz and L_2 at 1227.6 MHz) to permit corrections for ionospheric delays in propagation. The L_1 signal is modulated with a P and a C/A pseudorandom noise code in phase quadrature, in a manner similar to quadrature phase shift keying (QPSK). The L_2 signal broadcasts the P code, but will be upgraded to include the C/A code.

The P code is a long-period (T = 38 weeks) code operating at 10.23 Mb/s. The C/A code is a short code (T = 1 mS) readily acquired but operating at 1.023 Mb/s, which provides a less accurate measurement. The C/A codes are different for each of the deployed satellites. Gold codes are used to minimize the cross-correlation between the signals from different satellites. This prevents a GPS receiver from inadvertently interpreting the signal from one satellite as being from another.

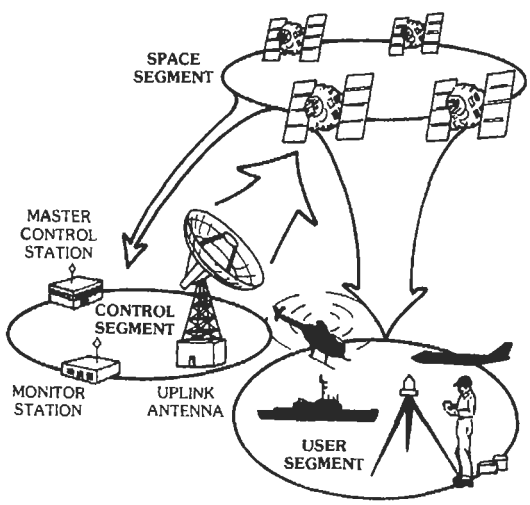

Fig. 1. Global Positioning System.

The same P-code sequence is used for each satellite. However, the 38 week-long code is broken into separate week-long offsets to enable the receiver to differentiate the signals from the various satellites. The P/Y code is reset weekly at midnight, Greenwich meantime (GMT).

The P code designation stands for "precise," whereas C/A is an abbreviation for "Coarse/Acquisition." The latter designation is because of the common practice in P-code receivers of first acquiring the C/A code, then transitioning to P code operation. Some military receivers, however, have a "direct-P" acquisition capability.

Simultaneous tracking of the pseudo-random noise (PRN) codes from several satellites allows both identification of the satellites and calculation of the signal transit time from each satellite. The latter is accomplished by measurement of the phase shift required to match the codes from each satellite with versions of the same codes generated within the GPS receiver. This is accomplished using digital delay-lock loop technology. Note that this is a classic example of a direct-sequence spread spectrum system. Since each satellite transmits its pseudorandom noise sequence at the same carrier frequency, GPS is also an archetypal Code Division Multiple Access (CDMA) system.

In addition to permitting re-use of the same frequency by each satellite, the use of PRNs yields significant "processing gain." This permits GPS receivers to operate effectively with extremely small (~ –160 dBW) satellite signals. The despreading process used in the receiver also yields significant immunity to jamming and interference.

Navigation is accomplished by using the measured time-delays of the received satellite signals to infer the range from the GPS receiver to each satellite. With precise knowledge of the orbital location of the satellites, the receiver is able to compute its position.

In order to obtain the most accurate possible information about the location of each satellite, the L_1 and L_2 signals are also continuously modulated with a 50 b/s data stream. Known as the navigation message, this signal contains the "almanac" and "ephemeris" which together comprise a tabulation of the orbital parameters of the various satellites, as well as timing corrections for the atomic clocks onboard each satellite.

The operation of a typical GPS receiver is illustrated in Fig. 2. The received signal is detected using a series of nested tracking loops (which are located in the IFU portion of the system shown in the figure). Separate loops are used for each satellite. The pseudorandom noise sequences are first tracked in the code loop. Once this occurs, a second loop locks on to the carrier signal at the L_1 or L_2 frequency. In addition to providing improved range calculation, the carrier loop mea-

sures the Doppler shift of the satellite signals. Thus, carrier loop tracking provides direct information concerning the relative velocity between the satellites and the GPS receiver.

Once code and carrier loop tracking is accomplished for each of at least four satellites, range information is fed into a Kalman filter. The Kalman filter algorithm is implemented in software on a microprocessor contained in the GPS receiver. In sophisticated navigation systems, the Kalman filter may accept additional inputs from an inertial navigation system.

The P code is typically encrypted before being broadcast by the satellites. This prevents its utilization by the non-military community. Encryption also prevents an unauthorized party from "spoofing" the system by generating an incorrect signal that is perceived by a GPS receiver to be legitimate. When encrypted, the P code signal is known as the Y code, and the encryption process is known as "anti-spoof," or AS.

In addition to anti-spoof, the operators of the GPS constellation can introduce deliberate timing errors into the C/A code signal to reduce its accuracy. Known as selective availability, or "SA," this deliberate reduction in system accuracy was deactivated by Presidential order on May 1, 2000. Consequently, the accuracy of C/A code receivers is now much better than it used to be. The accuracy is now limited by the uncertainty associated with the frequency dependent propagation delays introduced as the satellite signals pass through the ionosphere and troposphere.

The P/Y code compares measurements made at both the L_1 and L_2 frequencies to estimate these additional delays. Since the C/A code is not currently transmitted as part of the L_2 signal, there is not currently a convenient means for correcting for the ionosphere delays as part of C/A code operation. However, planned future improvements to the GPS signal include transmitting the C/A code on the L_2 frequency. In deference to military needs, a third signal, the "M" code, added to the L_1 and L_2 channels, is planned for exclusive military use. A new civilian signal, L_5, will be added at a frequency of 1176.45 MHz.

The navigation message is formatted in five subframes, each of six seconds duration, which makes up a data frame that is 30 seconds long and contains 1500 bits. The data are nonreturn to zero (NRZ) at 50 b/s and are common to the P and C/A signals on both the L_1 and L_2 frequencies. Each data subframe starts with a telemetry word and the C/A to P code handover word. The initial eight bits of the telemetry word contain a preamble that facilitates the acquisition of the data message.

The accuracy of a position fix varies with the capability of the user's equipment and with the satellite geometry with respect to the user. Now that the Selective Availability feature has been disabled, low cost C/A code receivers have accuracies that are limited to the uncertainties associated with ionospheric delays, which can be as large as 30 feet. The P-code, when used with signals at both the L_1 and L_2 frequencies, eliminates this source of error, and is fundamentally more accurate than the C/A receivers due to its higher chipping rate (10.23 MBPS as opposed to 1.023 MBPS). This yields real-time accuracies that can be better than 10 meters. However, the actual accuracy achieved at any point in time depends on the relative

geometry between the user and the observed satellites. For example, an ideal situation would be to have one or more satellites be directly overhead, and for a minimum of three additional satellites to be slightly above the horizon at 120-degree intervals.

Accuracy can be further improved by utilizing additional satellites. Many GPS receivers now have the capability to track up to 12 satellites simultaneously. Because the GPS constellation, as currently deployed, has 27 satellites, it is conceivable that more than 12 might be visible simultaneously. However, the accuracy improvement due to tracking more than 12 satellites is likely negligible.

Differential GPS

Another approach to improving accuracy is to use differential GPS, in which one measures the difference in position between two receivers. It is quite common for benchmark locations to be surveyed with considerable accuracy. A GPS receiver located at the benchmark then provides real-time calibration of the GPS-derived position versus its "ground-truth" fix. Correction signals, which are useful for receivers as far as a few hundred miles away, are then broadcast using a variety of beacon systems. For example, the Coast Guard operates a beacon system at frequencies of approximately 300 kHz in the coastal areas of the United States and along the Mississippi River. Many low-cost receivers are already pre-equipped to process this differential correction signal. Accuracies to better than 6 feet are routine with differential GPS. With additional time-integration and/or post-processing, accuracies to the sub-centimeter level have been achieved.

Future Trends

In order for GPS to serve as the single-navigation source for commercial air transportation, its accuracy, availability, and reliability must be improved. The plan for accomplishing this is known as the Wide Area Augmentation Service, or WAAS. This will be a network of ground-based reference systems whose correction signals are broadcast via a network of geostationary satellites. WAAS-capable receivers will also utilize integrity checking algorithms to verify that the instantaneous operation of the system meets the strict requirements of a safety-of-life navigation system.

To further improve the accuracy of C/A code receivers, it is planned to include the C/A signal on the L_2 broadcast, thus allowing for elimination of ionospheric delays. To further separate the needs of military users from those of civil users, a third signal, the M-code, is planned for inclusion at the L_1 and L_2 frequencies. A new signal, L_5, will be broadcast for civilian use at 1176.45 MHz.

In a similar fashion, a Local Area Augmentation Service (LAAS) will enable GPS to be used for Category-I and higher instrument landings without the need for conventional ILS equipment.

An additional alternative to the ILS, for the military, is the Joint Precision Approach and Landing System (JPALS). Communication networks, such as the Joint Tactical Information Distribution System (JTIDS) will also provide an incipient radio navigation capability to its users.

A system known as automatic dependent surveillance (ADS) is being developed in which aircraft broadcast their own navigation data to other, nearby aircraft.

Finally, the existing Russian GLONASS System and the Proposed European Gallileo System provide similar capabilities to GPS. The GLONASS system, which is a frequency division multiple access (FDMA) system, as opposed to a CDMA system like GPS, has a questionable long-term future for economic reasons. Likewise, development and deployment of Gallileo is likely to be affected by economic considerations.

38 Common Carrier Transmission

Revised by
Ludwell Sibley

THE SWITCHED TELECOMMUNICATIONS SYSTEM

The telecommunications system combines many elements that work together to provide a variety of services. It is a network of networks, owned and operated by multiple parties. In this section we consider two applications of the switched network: voice service and ISDN, and a special case, the Digital Subscriber Line.

Conventional Voiceband Service

Switched voiceband connections for speech or data use (including facsimile and data approaching 56 kb/s) are set up by giving appropriate instructions from the subscriber's telephone set or other terminal. Every subscriber is connected to a local end-office switching system via a loop; consequently, there is a loop at each end of a switched connection. To connect between loops served by different end offices, it is necessary to use a trunk route.

The route may be a single trunk connected directly between end-office switching systems. Other local trunks provide access to and from "wireless" carriers for cellular-mobile, paging, and similar services; to a Public Safety Answering Point for "911" emergency service; or to an Internet Service Provider (ISP).

Alternatively, the trunk route may consist of several trunks routed through one or more tandem switching systems. Such a call may involve trunks between the switching facilities of exchange and interexchange carriers (domestically) or of different operating administrations (internationally). Direct trunks and trunks to tandem switching systems are generally limited to the exchange area, covering tens of miles or occasionally a few hundred miles. When a connection must be made over greater distances, the trunk route passes through toll-connecting and intertoll trunks and is switched by toll switching systems in accordance with a routing plan which is usually dynamically controlled according to traffic load.

As a matter of terminology, the local end office is commonly referred to as a "Class 5" office. This identification is a remainder of a one-time switching plan that used a hierarchy of toll switching offices, up through "Class 1." The hierarchy has been replaced by a plan in which all toll switching offices have essentially equal rank, but the "Class 5" office remains.

Integrated Services Digital Network Service

ISDN is a multi-use network in which wholly digital transmission is provided between customer locations, with digital telephones and data terminals being used. Access from the subscriber to the serving central office is defined in terms of "B" channels (64 kb/s each) and "D" channels (16 or 64 kb/s). The "B" channels carry voice, data, and video traffic in digital form, while the subscriber controls service (signaling and supervision) via a two-way message link on the "D" channel. There may be two "B" channels and one "D" (in basic-rate access) or 23 "B" channels and one "D" (in primary-rate access).

Digital connections are established in a way comparable to that for conventional voice service. Pairs or multiples of "B" channels may be used ("bonded") together for 128 kb/s or higher speeds.

The following material gives information about the various transmission elements (e. g., loops and trunks) and about the signaling systems used to set up, hold, and disconnect the channels.

THE EXCHANGE PLANT

Subscriber Sets

The 500-type subscriber set is the historical basis for standards for analog subscriber instruments (ANSI/TIA/EIA-470-B-97), even though later telephones are usually designed quite differently. Fig. 1 illustrates transmission performance of a 500-type set on two hypothetical connections involving relatively short and relatively long loops. Fig. 2 shows the test configuration for this measurement. Fig. 3 gives the relative transmitting and receiving volume levels for this set as a function of loop length.

In current standards, the performance of telephone sets is defined in terms of loudness rating. Two parameters are of particular interest: the transmitting and receiving objective loudness ratings.

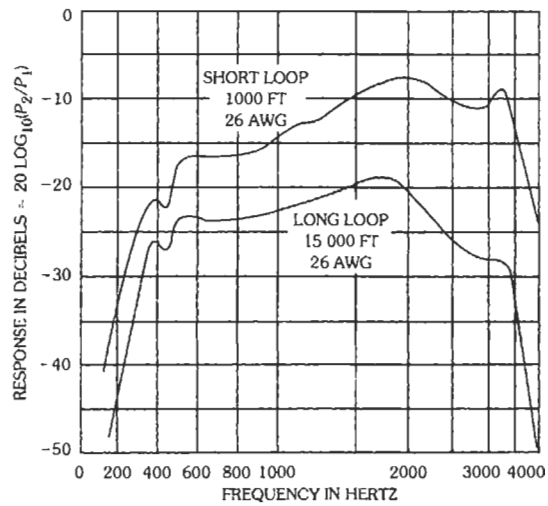

Fig. 1. Comparison of overall response. (From W. F. Tuffnell, "500-Type Telephone Set," *Bell Laboratories Record*, Vol. 29, September 1951, pp. 414–418. © 1951 Bell Telephone Laboratories, Inc.)

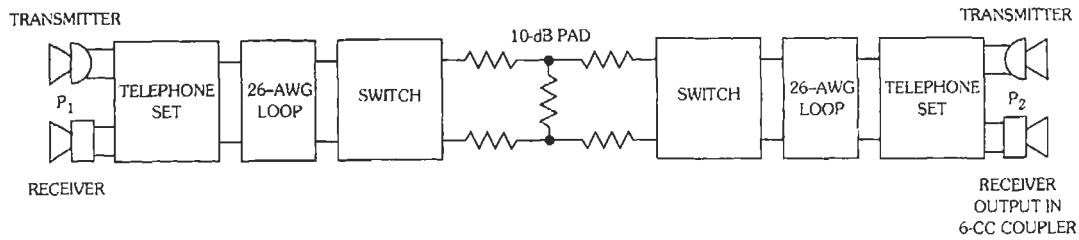

Fig. 2. Test arrangement for Fig. 1. (From W. F. Tuffnell, "500-Type Telephone Set," *Bell Laboratories Record*, Vol. 29, September 1951, pp. 414–418. © 1951 Bell Telephone Laboratories, Inc.)

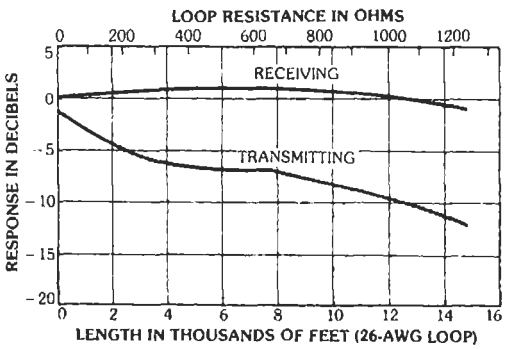

Fig. 3. Relative volume levels. (From W. F. Tuffnell, "500-Type Telephone Set," *Bell Laboratories Record*, Vol. 29, September 1951, pp. 414–418. © 1951 Bell Telephone Laboratories, Inc.)

Transmitting objective loudness rating (TOLR) is a measure, in decibels, of the efficiency with which a telephone set converts acoustic pressure at the set transmitter to an electrical output voltage. This loss-like acoustic-to-electric quantity is given by:

$$\text{TOLR} = -20 \log_{10} V_t / S_m$$

where

V_t = Loudness output voltage of the transmitting component (in millivolts across 900 ohms resistive),

S_m = Loudness sound pressure at the mouth reference point (in pascals).

Receiving objective loudness rating (ROLR) is a measure, in decibels, of the efficiency with which a telephone set converts an electric source voltage to an acoustic pressure output at the receiver. This electric-to-acoustic loss-like quantity is given by:

$$\text{ROLR} = -20 \log_{10} S_e / \left(\tfrac{1}{2} V_w\right)$$

where

V_w = Loudness open-circuit voltage of the electric source (in millivolts),

S_e = Loudness sound pressure at the ear (in pascals).

Fig. 4 shows the average TOLR versus loop length, measured for nine recent-vintage subscriber sets with electronic transmitters. The figure includes performance standards from standard ANSI/TIA/EIA-470-B-97 (upper and lower desirable limits, and mean performance), and includes the 500-type carbon-transmitter set as a reference model. The figure pertains to operation with a 400-ohm 48-volt battery-feed circuit as found in many central offices, and a 900-ohm ac termination. Results are similar with a regulated (constant-current) battery-feed circuit also commonly used in central offices. Fig. 5 gives the corresponding ROLR figures.

Typical subscriber-set dc internal resistance is 200 to 300 ohms, up to a maximum of 430 ohms for all equipment and wiring at the customer's premises.

Transmission standards for digital telephone sets are intended to give comparable performance. They are given in standard ANSI/TIA/EIA-579-A-98.

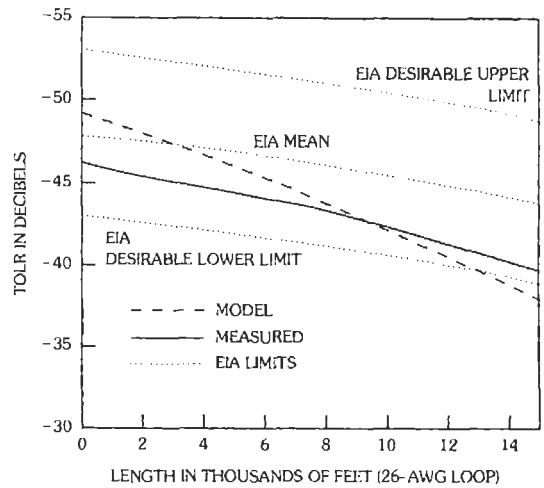

Fig. 4. Transmitting objective loss rating.

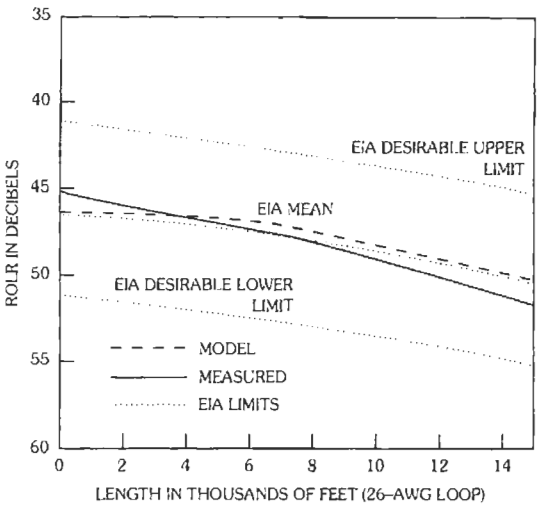

Fig. 5. Receiving objective loss rating.

Subscriber Loops

Design Objectives—The performance objectives for loops are generally as follows:

Loss—The loss of an analog subscriber loop, including any carrier link, should be less than 9.0 dB at 1000 Hz.

Noise—The noise objective for subscriber loops is typically 20 dBrnC at the customer interface.

Current—For satisfactory transmission and signaling performance, subscriber-loop dc current is generally held between 20 and 65 milliamperes. The customer-premises equipment is assumed to have a dc resistance up to 430 ohms.

Resistance Design—The design practice for most subscriber loops using wire facilities, before the wide use of digital loop carrier (DLC) facilities, was the "Resistance Design" plan. It used a maximum loop length of 24 kilofeet and a maximum loop resistance of 1500 ohms, with the objective to achieve a distribution of loss values clustered broadly in the vicinity of 3 to 4 dB. Limits on bridged-tap (temporarily unused extensions of the loop for flexibility in future use) and rules for loading were included to provide satisfactory transmission. On loops extending beyond 18 kft (including bridged tap), inductive loading was applied with 88-mH coils at 3, 9, 12, etc. kft from the central office. The added inductance was intended to reduce the transmission loss due to shunt capacitance up to about 3500 Hz within the voice band, at the expense of transmission at higher frequencies. Central-office switches, either digital or electronic analog, typically have signaling and supervision limits of 1600 ohms or more, leaving loop resistance limited only by the need to provide 20 mA or more of loop current. For longer loops, resistance above 1500 ohms was permitted, with the use of signaling-range extension and transmission gain. However, such long wire loops are now unusual because loops of nine kilofeet or even less are usually candidates for carrier facilities.

Digital Loop Carrier—Although it was first introduced to serve customers at great distances from an end office, the declining relative cost of electronics, and the demand for digital services like ISDN or DSL, have made DLC attractive economically. As a result, roughly half of North American loops use it. Where carrier is applied to loops, transmission and signaling are generally better than with loops on wire facilities. (A typical carrier channel has a 1004-Hz loss of 2 dB, but some later designs insert extra loss when the distribution cable is short, in order to prevent excessive loudness.) With carrier facilities, or with wire loops close to the central office, a Carrier Serving Area (CSA) plan is commonly used for new or rehabilitated facilities. Fig. 6 shows a typical carrier system used with CSA loops. With the CSA plan, the carrier remote terminal is placed no farther from the subscriber than 12 kft (9 kft if purely 26-gauge cable), and bridged

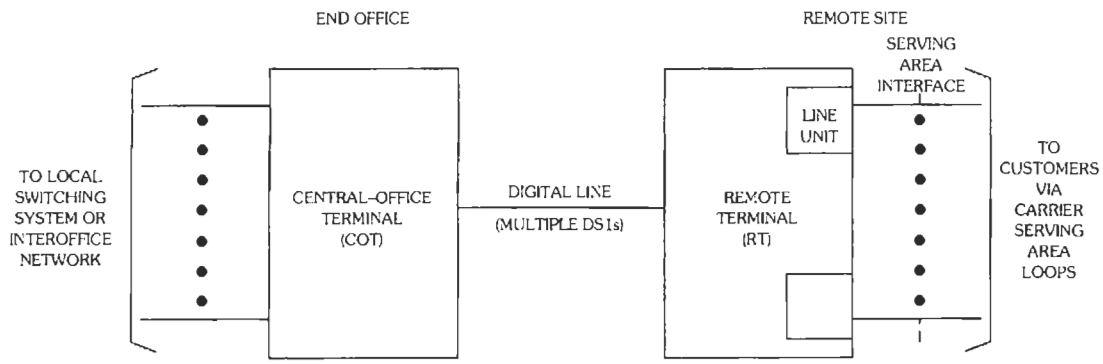

Fig. 6. Universal digital loop carrier system.

taps are restricted. Loading coils are not needed over these lengths and, in the interests of high-speed digital services, are not used. The figure shows a "universal" system in which each channel emerges individually from the CO terminal (COT) for physical cross-connection to the switch or (for a special service) an interoffice facility. With integrated carrier, the COT function is integrated into the switch, and there is no terminal as such.

The remote terminal may be placed on the premises of a customer needing many lines. The system normally uses conventional 64-kb/s PCM coding, although 32-kb/s coding is available as an option in some systems.

High-Speed Digital Services—The CSA Plan is fully compatible with the digital subscriber line for ISDN basic-rate access, while the Resistance Design plan is compatible up to 18 kft. The standard ISDN two-wire loop carries the two "B" channels, the "D" channel, and a maintenance channel at 12 kb/s, for a total of 160 kb/s. The line signal is quaternary, resulting from 2B1Q coding (two binary pulses recoded into one quaternary). A midspan repeater, and removal of loading coils, is sometimes used for range extension beyond 18 kft. Most versions of the DSL family (see below) are intended for use up to the 12–18 kft maximum zone.

Fiber in the Loop (FITL)—Where conventional telephone service is provided by means of optical fibers, a terminal device comparable to a DLC terminal is used at or near the subscriber's location. It is designed to accommodate the very low dc resistance and transmission loss of the metallic drop cable and station wiring.

Wireless Access—In deep-rural areas, there is currently an application of digital radio, operating at an 8- or 16-kb/s coding rate, for subscriber loops in the Basic Exchange Telecommunications Radio Service. This involves access from a digital radio terminal on the subscriber's premises to a "radio port" connecting with the central office. The overall design intent is to provide voice performance equivalent to that of wire facilities although the low bit rate precludes use for high-speed data or facsimile service.

Local Interoffice Trunks

Local interoffice trunks interconnect end-office switching systems and tandem switching systems. Telecommunications administrations use objectives for transmission loss that may depend on the type of trunk. Digital trunks between digital switches are inherently lossless, so the loss of a built-up connection is fixed by the decoding level at the end office (for an analog connection) or at the customer equipment (for a digital connection). Local trunks are short enough that talker echo is not a problem. Fixed-loss design objectives are usually used. In an analog network, a direct trunk between end-office switching systems is the only trunk in a connection and may have a loss objective between 3 and 6 dB. Objectives for trunks between analog end-office switches and tandem switching systems are typically 3 dB, with 0 dB as the objective for trunks between tandems.

THE TOLL TRANSMISSION PLANT

Exchange-Access Trunks

Toll connecting trunks (in the United States, exchange-access trunks) interconnect an end-office switching system and a toll switching system. Present transmission design objectives require a loss of between 2 and 4 dB in such trunks, or use of echo cancellers, to compensate for the imperfect impedance match to an analog subscriber loop at the end office. The match is relatively poor because one or two compromise impedances cannot closely simulate the variety of impedances of loops of different constructions and lengths.

Intertoll Trunks

Overall Connection Loss—Intertoll trunks connect toll switching systems. The connection loss of a digital trunk or combination of digital trunks, as stated before, is set by the decode level. On long connections it is common practice to include digital echo cancellers to improve singing margin and block echoes. Echo-canceller technique involves formulating an estimate of the echo that will result from a signal reflected back onto the four-wire side of a hybrid that converts from four-wire trunking to a two-wire loop. That estimate is subtracted from the signal on the return path. The echo-canceller device produces the echo estimate by means of a signal processor (filter) for which parameters are set by correlation techniques. Previous practice, on analog intertoll trunks, was to use a "Via Net Loss" transmission plan with loss increasing with trunk length so as to mask echoes. On very long trunks, above 1850 miles, the VNL plan converted to zero loss and relied on an echo suppressor, a switching device which momentarily inserted loss into the idle direction of transmission in order to block the echo path.

Delay—Delay, by itself, is seldom annoying in speech communication unless it reaches a value of approximately 600 milliseconds. Delays encountered in terrestrial transmission plant are well below this value, but a round-trip delay of this magnitude occurs on circuits operating via synchronous-orbit satellites. Further delays occur in low-bitrate speech coders, echo cancellers, digital cross-connection systems, voice packetizers, cryptographic devices, etc.

Echo Objectives—In the absence of echo cancellation, echo return loss (ERL) must be held to high levels to assure satisfactory echo performance of toll

facilities. The ERL objective for analog loops at the end office is typically 11 dB. With the general use of four-wire switching, this is the only relevant echo source in a built-up connection. (Historically, in the important special case of a two-wire interface to a toll connecting trunk at an analog toll office, the ERL was held to a minimum 16 dB, with an objective of 22 dB.)

DIGITAL SUBSCRIBER LINE

An emerging application of network elements having great near-term importance is the Digital Subscriber Line. This facility does not necessarily provide switched service in the usual sense—its most visible application is for "always-on" access to an ISP. In that sense, it is a private-line channel from one user to a DSL access multiplexer (DSLAM). The DSLAM aggregates the data traffic from a group of users, usually by packet switching via Asynchronous Transfer Mode (ATM) techniques in the interoffice environment. (See Chapter 26.)

This is an emerging technology whose standards are still evolving, with a variety of pre-standard and proprietary versions being made available. Some implementations of them use equipment built into the line card of a digital switch or DLC terminal to minimize the effort of installation. The core idea is to send bidirectional digital data, usually on a two-wire loop, at previously unattainable speeds by use of combinations of signal processing, automatic equalization, error correction, and echo cancellation. The base facility is the nonloaded copper subscriber loop. The terminals compensate for signal attenuation at high frequencies, irregularities in transmission and echoes caused by bridged taps and changes in gauge at splices, crosstalk from the other direction of transmission and other DSL systems in the same cable, errors caused by impulse noise, and even radio-frequency interference from broadcast stations.

On a given loop, the speed attainable may be controlled by either the technical conditions of the loop or by marketing considerations of the service provider.

"DSL," also called xDSL, is actually a family of approaches having somewhat different uses. Table 1 is a snapshot of the major present contenders. The distance and speed capabilities are subject to change as the technology matures.

IDSL

The ISDN DSL uses the technology discussed above under ISDN basic-rate access (160 kb/s bidirectional, no analog telephone on the same pair, 2B1Q coding). It is usable for non-ISDN applications, at the same speed, to distances beyond the capabilities of other DSLs.

ADSL

For many important uses, the flow of data to/from the subscriber is asymmetric: a small traffic of files and controls toward the network (upstream), and a large volume of data downstream. Such applications include Internet downloads, major file transfers, and streaming compressed video. This implies the value of an Asymmetric DSL.

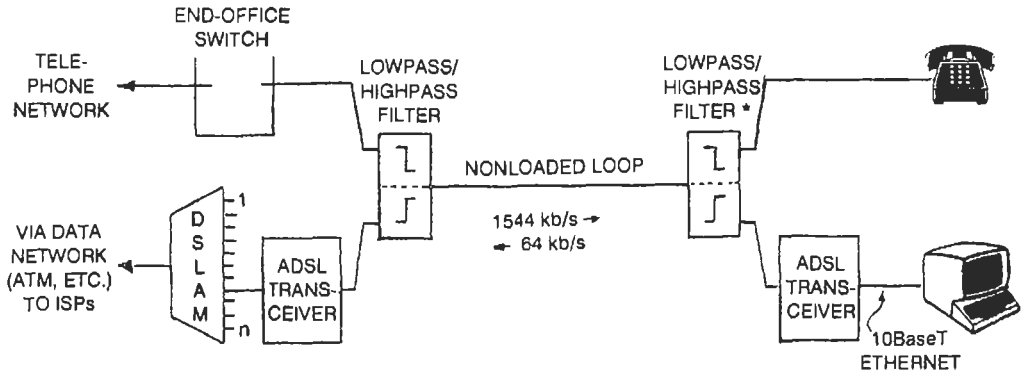
Fig. 7 illustrates such a line. At the central office or carrier remote terminal, a low-pass filter connects the voicegrade end-office switch to the loop, while a high-pass filter attaches an ADSL transceiver. Data to/from the transceiver may be aggregated from multiple users and sent to an ISP or other site.

At the subscriber end, a second low-pass/high-pass filter (splitter) separates voiceband and ADSL signals.

TABLE 1. DIGITAL SUBSCRIBER LINES

Name	Cable Pairs Used	Max. Loop Length kft	Speed Downstream Mb/s	Speed Upstream Mb/s	Operates Above Voice ?
IDSL	1	18*	0.16	0.16	No
ADSL	1	18	1.54	0.064–1.0	Yes
ADSL "Lite"	1	18	1.0	0.16	Yes
HDSL	2	18	1.544	1.544	No
SDSL	1	10	0.16–2.048	0.16–2.048	No
RADSL	1	21.3	0.64	0.128	Yes
	1	18	1.544	0.176	Yes
	1	12	12	1.0	Yes
VDSL	1	1	52	1.52–2.3	Yes

* Without repeater.
Speeds shown are examples / ranges only.



DSLAM: DSL ACCESS MULTIPLEXER
* OMITTED FOR ADSL LITE
NOTE: AT THE CO OR DLC RT, THE FILTER, ADSL TRANSCEIVER, AND DSLAM MAY BE COMBINED INTO SWITCH OR DLC EQUIPMENT.

Fig. 7. Asymmetric digital subscriber line.

ADSL "Lite"

The ADSL concept assumes a common filter at the subscriber end to separate the telephones from the data signal. In mass-market applications this requires installation effort and possibly added wiring. By giving up the use of the filter, it is possible to obtain service with some modest sacrifice in speed. (The ADSL transceiver must contend with varying line impedance, depending on the usage of the telephones. Some telephones may rectify the data signal and generate interfering noise, requiring addition of a plug-in low-pass-only filter.)

RADSL

The Rate Adaptive DSL is an ADSL variant intended to supply downstream service at speeds up to 12 Mb/s (to 12 kft), 1.544 Mb/s (to 18 kft), or 640 kb/s (to 21 kft). Upstream speeds vary proportionately: 1 Mb/s, 176 kb/s, and 128 kb/s, respectively. The terminals automatically "fall back" or raise speed upon occurrence of changes in the loop.

VDSL

The Very-High-Speed DSL is intended to deliver asymmetric data at speeds up to 52 Mb/s over relatively short distances, typically in a campus situation or as the distribution link from a multiplexed fiber terminal.

HDSL

The High-Speed DSL variant is intended to provide a symmetric DS1-level facility (1.544 Mb/s) over two cable pairs, thus avoiding the time and expense of adding a string of intermediate regenerators. Symmetric DSLs may be attractive as a means of multiplexing several voice lines, plus data, over a common facility.

SDSL

The Symmetric DSL is intended to supply bi-directional data over one wire pair at, depending on loop condition, up to the E1 (2.048 Mb/s) rate.

INTERNATIONAL RECOMMENDATIONS

Overall System Design

A summary of the ITU-T (formerly CCITT) recommendations for system objectives and design criteria for circuits used in international telecommunications service is given in Chapter 2.

Loss

The ITU-T recommends that international analog toll circuits be given an insertion loss of 0.5 dB for each 500 kilometers of length or fraction thereof, assuming that the international circuit is derived from carrier systems in cable or radio relay. The result approximates VNL within 0.33 dB for lengths up to 2500 km.

Echo Control

The ITU-T recommends that the overall loss of a connection be adjusted so that echo signals are sufficiently attenuated or, alternatively, that an echo canceller or suppressor be fitted if the loss adjustment results in an excessive insertion loss.

QUALITY OBJECTIVES AND DEFINITIONS

Noise

Noise—Noise, in its broadest definition, is any undesired signal in a communication channel. Noise may be classified as quantizing, or signal-dependent, noise; thermal, or white, noise; impulse noise; crosstalk; tone interference; and miscellaneous.

When noise is measured on a voiceband communication channel, a weighting network is often inserted ahead of the detector to account for the varying subjective annoyance from noise of different frequencies into telephone sets, or differing interference into a data modem (MOdulator–DEModulator). For noise measurement on channels of bandwidth greater than voice, weighting networks with correspondingly greater bandwidths are used.

Quantizing Noise—Noise occurring in the presence of signal, resulting from a mismatch between the exact value of an analog signal and the closest available quantizing step in a digital coder.

Thermal Noise—Noise arising from random electron motion, occurring on all transmission media and in all communications apparatus. It is characterized by uniform energy distribution over the frequency spectrum and by a normal or Gaussian distribution of voltage or current.

Impulse Noise—Noise consisting of irregular pulses of short duration and relatively high amplitude. Some sources of impulse noise induced in communication channels are an erroneous digital coding bit caused by an error on a transmission facility, crosstalk from dc signaling systems, lightning, or transients due to switching in adjacent power circuits.

Tone Interference—Interference due to single tones or complex periodic waveforms.

Miscellaneous Noise—Interferences that cannot readily be placed in any of the preceding categories.

Reference Noise—One picowatt (10^{-12} watt) of power. Also commonly stated as –90 dBm (90 dB below one milliwatt).

dBrn—Decibels above reference noise. The dBrn is the unit of measurement of noise power used in the IEEE Standard 743-1995 noise-measuring set. For measuring noise on voice communication channels, the noise-measuring set is normally equipped with a "C-message" weighting network. When this filter is used, the unique network response causes the reading to deviate from what would be obtained with some other network. Readings in dBrn taken with the C-message network are designated "dBrnC." The calibration tone is 0 dBm (1 mW) at 1000 Hz, which reads 90 dbrn with or without the C-message weighting network. One milliwatt of white noise, limited to the band of 0-3 kHz, reads 88 dBrn.

The noise objective in present use is that, on any digital connection, the noise should not exceed 17 dBrnC, as controlled mainly by the decoder at the receiving end.

pWp—Picowatts, psophometrically weighted. The unit of noise power measured with the ITU-T-recommended psophometer ("noise meter"). The meter is frequency-weighted by a curve comparable to the C-message weighting curve. The reference tone is –90 dBm (1 picowatt) at 800 Hz. The psophometer is defined as measuring the internal (open-circuit) voltage of an equivalent noise generator having impedance of 600 ohms and delivering noise power to a 600-ohm load. For convenience in comparison, the psophometric voltage may be converted to dBm. In such a case, a tone of 0 dBm at 1000 Hz will read +1 dBm on the psophometer; one mW of white noise, limited to the 0–3 kHz band, reads –2 dBm.

Levels and Loss

Reference Level Point—An analog point in a communication circuit arbitrarily chosen as a reference location for signal-level measurements. Common equivalent terms are "0 dB transmission level point," "zero level," "zero level point," "0 dB TL," "0 dB TLP," and "0 TLP."

Relative Level—The relative level at any point in a circuit is the power gain or loss in decibels between the 0 TLP and the point under consideration. Reference of signal and interference powers to the 0 TLP is convenient in system design and maintenance. Relative level is expressed in such terms as "–3 dB TLP." Common practice is to define the input of a digital coder in a switch or transmission system as the 0 TLP. At the distant end, the corresponding decoder is conventionally at a TLP of –3 dB, –6 dB, etc. Signal and/or interference powers may be referred to the 0 TLP with a phrase such as "a signal power of –16 dBm0," which indicates the power of the signal if it were measured at the 0 TLP. The 0 TLP may not be accessible for measurement and, in fact, need not even exist in a given system.

Net Loss—The net loss of a transmission channel is the ratio of the signal powers at the input and the output of the channel, usually expressed in decibels (dB). By custom, the net loss of a channel is understood to be measured at 1004 hertz in the American and Canadian plant and at 1020 (formerly 800) hertz in international practice (ITU-T). (The measurement frequency is displaced slightly from 1000 Hz to keep it from being a subharmonic of 8000 Hz, the sampling rate in a digital coder, to avoid generation of distortion products.)

Insertion Loss—The ratio of the power delivered from a source to a load, to the power delivered from

the same source to the same load through a transducer (network, channel). The definition may be applied to the loss or gain effect caused by the insertion of a gain element (repeater) or equalizer into a transmission channel. The concept is equally applicable to the channel as a whole.

Transducer Loss—The ratio of the maximum power available from a source to the power delivered by that source to a load through a transducer (network, channel). The transducer loss of a channel differs from the insertion loss only because the maximum power from the source is substituted for the power from that source to that load.

Echo and Stability

Return Loss—A measure of the match between the two impedances on either side of a junction point. Return loss is defined by:

$$RL\ (dB) = 20 \log_{10} [(Z_1 + Z_2)/(Z_1 - Z_2)],$$

where Z_1 and Z_2 are the complex impedances of the two halves of the circuit. When the impedances are not matched, the junction becomes a reflection point. The return loss expresses the ratio of incident to reflected signal power. It is often made effectively infinite by introducing echo cancellation into a four-wire portion of the circuit.

Echo Return Loss (ERL)—The weighted power-averaged return loss at the reflection point. The ERL expresses in decibels the ratio of the power of a broadband incident signal to that of the correspondingly broadband reflected signal. Both powers are measured through a weighting network covering the band of approximately 500–2500 Hz.

Singing Return Loss—The same as echo return loss, but over a narrower band near the lower or upper edge of the voice band, e.g., 200–500 Hz or 2500–3200 Hz. The extremes of the band are used because singing usually takes place there.

Talker Echo—A signal returned to the talker after making one or more round trips between the talker and a distant reflection point. Fig. 8 depicts the echo paths associated with a connection between two end offices connected via two toll or tandem offices. The first talker echo is generally the most important. Echoes that are sufficiently loud and sufficiently delayed are annoying and interfere with the speech process.

Listener Echo—A signal first returned toward the talker at a distant reflection point and then reflected again toward the listener (Fig. 8). The listener echo mixes with the original signal, adding to its strength at some frequencies and diminishing it at others. It can result in amplitude distortion and/or reduced singing margin.

Singing Margin—The singing margin of a two-wire circuit is defined as the amount by which the combined losses of the two directions of transmission may be reduced before oscillation (singing) occurs. Inadequate singing margin results in distortion that is often described as sounding hollow or "like a rain barrel."

Crosstalk

Crosstalk—Interference from other communication channels is called crosstalk. It is classified as near-end and far-end crosstalk.

Near-end crosstalk is measured on a channel at a receiving point near the sending point of the interfering channel. Far-end crosstalk is measured on a channel at a receiving point near the receiving point of the interfering channel. In far-end crosstalk, the two channels transmit in the same direction.

Crosstalk may occur via capacitive or inductive coupling, in a cable or item of terminal equipment; via imprecise timing of sampling gates, in a multichannel digital terminal using a shared coder; via intermodulation of channels assigned to different frequency bands, in an analog transmission system; by insufficient antenna discrimination between two cochannel signals

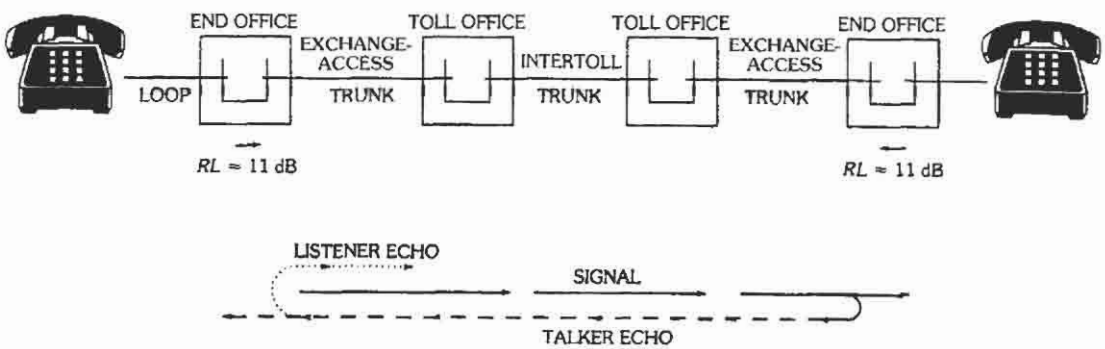


Fig. 8. Return losses and echo paths in a toll connection.

using different polarizations, in a radio system; etc. Crosstalk between digital transmission lines manifests itself by degrading the error margin of one line or both.

Crosstalk is also classed as intelligible and unintelligible. Intelligible crosstalk can be understood by the listener; because it diverts attention, it has more interfering effect than unintelligible cross talk. Crosstalk into a voice-frequency circuit from adjacent voice-frequency circuits may be intelligible. Crosstalk due to incomplete suppression of sidebands, or to intermodulation of two or more frequency-multiplexed channels, is generally unintelligible. Such crosstalk is often classed as miscellaneous noise. Where a coupling path between transmission facilities gives rise to intelligible or nearly intelligible cross talk, normal practice is to design the system so that the probability that a customer will hear a "foreign" conversation does not exceed one percent.

Digital Performance

On digital facilities and services, transmission quality is commonly defined in terms of three parameters:

Bit Error Ratio (BER)—The number of errors in a given number of transmitted bits (e. g., one error in 10^8 or a BER of 10^{-8}).

Errored Second (ES)—A one-second transmission interval that contains one or more bit errors.

Error-Free Second (EFS)—The converse of ES.

Severely Errored Second (SES)—Conventionally, a one-second transmission interval having a BER of 10^{-3} or more.

As examples, the following performance objectives and limits have been used:

Parameter		ES	EFS	SES
	BER	%	%	Per day
DSL Design Objective	10^{-7}			
Local DS1 Svc.	10^{-7}	216	99.75	15
Local DS3 Svc.	2×10^{-10}	432	99.5	15

FACILITIES

Wire

Multiconductor copper cable is widely used in pair counts up to 2700 or even higher. Cable insulated with paper pulp or polyethylene, in sizes of 22, 24, and 26 American Wire Gauge, are most common for voiceband, DSL, and carrier frequencies up to several megahertz. The transmission characteristics of typical paired cables are given in Table 2. The data cover the voiceband and higher frequencies: 40 kHz (DSL), 225 kHz (HDSL), and 772 kHz (T1 carrier spans). While most longer loops and interoffice trunks utilize carrier transmission, it is possible to use loaded cable, by itself or with voice-frequency repeaters. Open-wire facilities have generally disappeared, even in rural areas. For carrier transmission frequencies up to 60 MHz, multiple coaxial cable facilities have been used. Such cables have occasionally been converted to digital transmission.

Repeaters

General—If cable loss exceeds limits, it is necessary to add gain to the circuit. Amplifiers for this purpose are termed "voice-frequency repeaters." They are used mainly for transmission-range extension on some local loops, special-service circuits, etc. Two types of repeater are typically used: four-wire and hybrid. Both provide independent gain and equalization for each direction of transmission.

Four-Wire Repeaters

Four-wire repeaters are associated with four-wire cable facilities, generally as voice-frequency extensions of carrier transmission systems in full-duplex data circuits and the like. The associated repeaters can be used in applications requiring more gain and/or equalization than can be obtained with two-wire repeatered facilities.

Hybrid Repeaters

Two-wire hybrid repeaters are found in special subscriber-loop applications. For two-wire facilities, the gain and equalization elements are coupled to the facility with four-wire hybrids (of transformer or electronic types), as shown in Fig. 9. To assure stability of the internal gain loop, hybrid balance is controlled by design and adjustment of the balance networks which should exactly match the impedance seen at the cable-facility interface. Any mismatch limits the gain capability

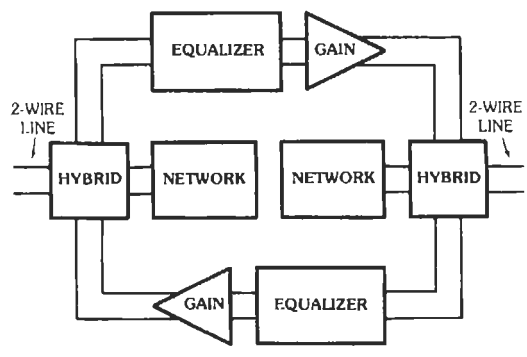

Fig. 9. A typical hybrid repeater.

TABLE 2. CHARACTERISTICS OF TYPICAL TELEPHONE CABLES*

	Frequency	Primary Constants				Nonloaded Secondary Constants				H88 Loaded** Secondary Constants

** H88 loading involves use of 88-mH loading coils at 6000-ft intervals. Data apply to cables with 3000-ft end sections on both ends.

of the repeater. Where precise automatic balancing of the hybrid is desired, a design may be used in which the four-wire path includes a digital coder and decoder in each direction, along with a digital echo canceller. The canceller provides the equivalent of a very high degree of hybrid balance.

Fiber-Optic Facilities

Glass-fiber optic transmission facilities (see Chapter 22) have generally displaced wire facilities as a more economical and higher-performance alternative for carrier transmission. Fiber-optic facilities are used for both digital trunk carrier and digital subscriber carrier systems and, in sizes up to 864 fibers, are finding direct application in subscriber loops as well. Transmission speeds up to OC-192 (10 Gb/s) on a single wave length are commonplace in the long-haul environment, and extensions of capacity are available by use of wavelength-division multiplexing (WDM), in which 40 wavelengths or more may be carried simultaneously. Optical amplifiers may be used on particularly long fiber lines, especially in submarine cables. Fiber facilities, in "self-healing" ring configurations, are often used to improve service reliability.

Carrier Systems

General—As suggested before, when many telecommunications channels are needed between two points, it is usual to use a carrier system to multiplex many channels over one medium. Media used for such systems include glass fibers, cable pairs, and microwave radio (terrestrial or satellite).

Multiplexing Techniques—Two basic techniques are used for the transmission of multiple channels over a single transmission medium:

Time-division systems, usually digital, in which each communication channel is allotted a discrete time slot within a sampling frame, occupying essentially the entire wideband frequency spectrum for the allotted time. The original practice was to multiplex directly, with a fixed destination; another technique of growing importance is to convert the bitstream into packets for transmission and routing, usually to multiple destinations.

Frequency-division systems, in which a unique band of frequencies within the wide frequency spectrum of the medium is allotted to each communication channel on a continuous-time basis. This technique is found mainly in radio systems, and in wavelength-division multiplexing in fiber-optic systems.

Modulation Techniques—Several modulation methods may be employed with either of the multiplexing techniques. Pulse-code modulation is the most common time-division modulation technique, although adaptive differential PCM, delta modulation, and other techniques are also found occasionally. Several frequency-division modulation techniques are in use, including frequency modulation and amplitude modulation, both double- and single-sideband. See Chapters 23 and 24 for a more detailed discussion of modulation techniques.

Trunk Carrier—Trunk carrier systems operate between switching offices, using either trunk terminations built into digital switches (now usual) or discrete carrier terminals (channel banks) that deliver analog voice channels.

Circuit Multiplication—For voice connections through digital submarine cables, digital circuit-multiplication systems may transcode the 64-kb/s speech signal to 32 kb/s and perform speech interpolation (connecting a talker to the channel only when speech is present). This yields a typical circuit multiplication of 5:1.

Common-Carrier Hierarchies—There are several agreed-upon bundle sizes or multiplex levels for carrying channels in common-carrier systems. Most of the standards are covered in ITU-T documents. In digital transmission, the basic entity is a 64 kb/s channel in which the nominal 4-kHz voice signal has been filtered (to minimize aliasing) and sampled at 8 kHz, with each sample encoded into eight bits. Digital data at up to 64 kb/s can be substituted for the digitized voiceband signal. Fig. 10 gives the digital hierarchy levels corresponding to bit rates, and the numbers of usable 64-kb/s time slots, recommended by ITU-T. The figure is couched in terms of the basic DS1 transmission rate of 1544 kb/s as used in North America. Not defined by ITU-T, but also occasionally used in the United States and Canada, is a DS1C level intermediate between the first and second levels. Fig. 11 gives the corresponding hierarchy for the basic E1 rate of 2048 kb/s as used in Europe. The figures diagram the levels, multiplexes, digital line systems, and references to ITU-T documents that give more detailed specifications for the two generic hierarchies. These various hierarchy levels are not timed from a common clock; they are termed the Plesiochronous Digital Hierarchy.

In North America most local interoffice trunks, and virtually all toll connecting trunks, are digital due to the synergy between digital transmission and switching. At digital-signal levels 1 and 2, the bit stream may be carried on wire pairs with regenerators, or via channels on a higher-level multiplex system using fiber or radio as its base facility. Radio may be used for higher bit rates between 45 and 155 Mb/s, and optical-fiber media up to 40 Gb/s. Rapid advances in technology, such as low-loss/low-dispersion single-mode fiber, have led to the introduction of additional bit rates into the digital hierarchy. The Synchronous Optical Network (SONET) [or, in ITU-T terms, Synchronous Digital Hierarchy] involves ten unique transmission speeds for use on fiber or suitable digital microwave systems. These are synchronous multiples of 51.840 Mb/s, as listed in Table 3. SONET multiplexers accept and deliver DS1- and DS3-level signals, on either a

terminal or a drop-and-add basis, and produce optical signals at the OC-1 through OC-768 levels. Pairs of channels may be "concatenated" to be passed together through multiplexers, making a pair of OC-3s, for example, into an OC-3c.

NETWORK-CONTROL SIGNALING

Subscriber-Loop Signaling

Supervision and Ringing—In conventional (non-ISDN) use, subscriber-loop signaling uses direct current in the loop to provide supervisory signals. These (on-hook: loop open; off-hook: loop closed) are used to detect when the calling subscriber is requesting service and when the called subscriber answers. A ringing signal for summoning the called subscriber to the telephone or activating other terminal equipment is commonly transmitted as a high-voltage, low-frequency signal (at least 40 V rms, 20 Hz, at the subscriber terminal) to actuate a bell or electronic ringer.

Address Signaling—Dual-Tone Multifrequency Signaling (DTMF)—A tone signaling technique is in wide use for subscriber lines. Its advantages are speed of service, reduced holding time of registers in the switching system, and ease of end-to-end signaling for such applications as voicemail or radio paging. At the subscriber set, the keypad, when pressed by the caller, sends pairs of audio-frequency tones to the central office, each pair representing a numeric digit. Eight frequencies are provided, with the six combinations beyond the 10 required for numerics being used for special signals. The DTMF signaling code is given in Table 4.

Address Signaling—Dial Pulsing—In this system, numerics are transmitted as dial pulses obtained by opening and closing the loop at a rate of 8 to 12 pulses per second. The number of pulses in a train represents the dialed digit (10 pulses for the digit 0). This system originated with the rotary subscriber dial, but commonly uses pulses generated electronically.

ISDN—Subscriber-loop signaling in ISDN applications employs the D-channel to handle data packets for call-control functions.

Interoffice Signaling

Common-Channel Signaling—Trunks between switching systems (whether exchange or toll) may use either signaling on a per-trunk basis or common-channel signaling (CCS). The principle of CCS, introduced in an early form in the mid-1970s, is to transmit all signaling and address information pertaining to a group of trunks over a dedicated data network. This is particularly attractive with electronic switching systems because the signaling information is a stream of data from the stored-program controller in the first place. Advantages include speed, flexibility to provide processing-intensive services, and low cost. By removing the need to signal by time-sharing any transmission bits on digital trunks (see below), CCS makes it possible to offer "clear-channel capability." This capability suits applications such as ISDN, where the user may send any digital bit pattern without constraint, including long strings of zeroes. Fig. 12 shows the signaling network used for CCS, in which individual switches have redundant pairs of data links to Signal Transfer Points (STPs). The pairs of STPs are duplicated in a quad configuration. For access to routing information for advanced (intelligent-network) services like number portability between carriers, other data links connect to Service Control Points (SCPs) giving access to data bases.

DC Signaling—Short voice-frequency trunks, consisting primarily of wire facilities, may use dc signaling for both supervisory and numeric signals.

Loop Reverse-Battery Signaling—Two-wire one-way trunks do not require full-duplex signaling. Loop reverse-battery signaling has frequently been used on them. At the terminating end of the trunk, the switching-system trunk circuit (a signaling interface) provides central-office battery, nominally 48 volts, over the facility to the originating end. The originating end applies a loop closure to seize the circuit and sends address information toward the terminating end in the form of dial pulses. The terminating trunk circuit provides supervision toward the originating end by reversing the polarity of battery applied to the trunk in an off-hook condition.

E and M Lead Signaling—E and M signaling is symmetric, and is thus suited to two-way trunks. With it, the signaling paths are separated from the trunk circuit and reside between the trunk circuit and the line. Signaling between a trunk circuit and the signal chan-

nel of a transmission facility occurs over two independent pairs of leads: the M lead and its return wire, which send signals outgoing from the trunk circuit; and the E lead and its return wire, which receive signals incoming to the trunk circuit. "E and M" historically stems from designations of the interconnecting leads on signaling-circuit drawings.

Signaling on Carrier-Derived Channels—Where CCS is not used, circuits without dc continuity use techniques whereby signaling information is transmitted either by designated bits in the pulse stream of a digital carrier system or by audio frequencies within the voice channel (in-band signaling).

A- and B-Bit Signaling—In digital carrier systems, including DLC, supervisory and address information may be assigned to specific bits in the pulse stream. These bit positions are derived by time-sharing the least significant speech bit during one frame out of six, obtaining a 1.333-kb/s signaling bit stream. This stream is subdivided into A and B bits for multistate signaling, or may be further subdivided into A, B, C, and D bits.

Single-Frequency (SF) Signaling—Single-frequency in-band signaling is now rare; its use is effectively limited to frequency-division multiplex carrier systems and special private-line applications. It uses a tone frequency of 2600 hertz. The tone is transmitted at a level of –8 dBm0 during pulsing, and –20 dBm0 for continuous tone in the on-hook state.

Multifrequency (MF) Signaling—For speed in setting up interoffice connections in a non-CCS environment, multifrequency signaling may be applied on trunk circuits. Digit information is sent by combinations of two of five audio tones: 700, 900, 1100, 1300, and 1500 hertz. A sixth tone, 1700 Hz, is used in combination with 1100 Hz as a "start [of] pulsing" (KP) signal, and in combination with 1500 Hz as an "end of pulsing" (ST) signal. Receipt of the ST signal at the end of the digit signals starts call processing. Table 4 gives the MF signaling code. The three tone pairs not listed are used for specialized purposes in operator-services systems

and special networks for "Enhanced 911" service. Each tone is customarily transmitted at a level of –6 dBm0. Tone pairs are sent at 7 to 10 pulses per second and the KP signal is nominally 90–120 ms in duration.

Signaling Systems—ITU-T—For ITU-T Recommendations, refer to Chapter 2.

39 Switching Networks and Traffic Concepts

Revised by Amos E. Joel, Jr.

PART 1; COORDINATE SWITCHING NETWORKS

DEFINITIONS OF TERMS

Concentration: The function associated with a switching network having fewer outlet than inlet terminals.

Coordinate switch: A rectangular array of crosspoints in which one side of the crosspoint is multiplied in rows and the other side in columns.

Crosspoint: A two-state switching device containing one or more elements that have a low transmission impedance in one state and a very high one in the other.

Expansion: The function associated with a switch or switching network having more outlet than inlet terminals.

Folded network: A network in which each terminal can serve as either inlet or outlet and which is capable of completing a path between any pair of inlet-outlets.

Full availability: Property of a switch or switching network capable of providing a path from every inlet terminal to every outlet terminal.

Internal blocking: The inability to interconnect an idle inlet to an idle outlet because all possible paths between them are already in use.

Nonblocking network: A network in which there is at all times at least one available path between any idle inlet and any idle outlet, regardless of the number of paths already occupied.

Nonfolded network: A network in which inlets and outlets are separate and which is capable of completing a path between any inlet and outlet.

Single-linkage array: The mesh or spread of interconnections between the stages of a switching network whereby every switch of one stage has one connection to every switch of the adjacent stage.

Space-division switching network: A switching network in which the transmission paths are physically distinct.

Switching network: That part of a switching system that establishes transmission paths between pairs of terminals.

Switching stage: Those switches in a switching network that have identical parallel functions.

Time-division switching network: A switching network in which the transmission paths are separated in time.

SPACE- AND TIME-DIVISION SWITCHING

Most of the switching systems of the world have utilized space-division analog switching. Recently, combinations of space and time division have become almost universal in new switching systems, employing primarily pulse-code modulation on multiplexed lines. Because there is duality between time-division and space-division switching and the principles are more easily understood in terms of space division, space division will be used in describing switching-network principles. This will be followed by a description of how to map time-division into space-division networks.

PROPERTIES OF COORDINATE SWITCHING NETWORKS

The simplest coordinate switch has a number of "crosspoints" that can give an inlet to the switch a connection to an outlet. (In most applications, only one connection will be desired at a time, but this is not always a requirement.) It is convenient to give a number of inlets identical access to a number of outlets so that the network can be arranged in a single piece of apparatus (switch) as shown in Fig. 1A. Such a switch is known as a rectangular coordinate switch.

In electromechanical coordinate switches, the connecting devices may be individual contact-making relays, in which case the number of complete relays (coil and a set of contacts) required is the product of the numbers of inlets and outlets. Alternatively, the whole crosspoint array may be provided by a crossbar switch in which a single relay coil is associated with each row and column of the switch, and the concurrent energizing of a row coil and column coil closes an individual set of contacts. In electronic switches, the crosspoints may be solid-state elements, usually transistors.

The rectangular switch discussed so far is nonblocking—any idle inlet can reach an idle outlet. For small numbers of inlets and outlets, this is an efficient arrangement, but when the inlets and outlets are more than twenty to thirty, the number of crosspoints can be reduced significantly by replacing the single switch by a number of interconnected smaller coordinate switches, arranged in a multistage coordinate switching network in one of many possible ways, as will be described. If blocking is acceptable, the number of crosspoints can be reduced even more.

SINGLE-STAGE COORDINATE SWITCHES

Fig. 1A shows a rectangular-coordinate switch interconnecting inlets from N lines and outlets to M other lines. When interconnection is possible at every crosspoint, the switch provides full availability and is said to be nonblocking. The particular switch shown in Fig. 1A acts as a concentrating switch so that, although the switch is nonblocking, an idle inlet may be blocked because there is no idle outlet. Such concentration switches are often used to bring higher traffic loads per circuit to the subsequent stages of a multistage system in order to use switches more efficiently. A rectangular switch with full availability requires NM crosspoints.

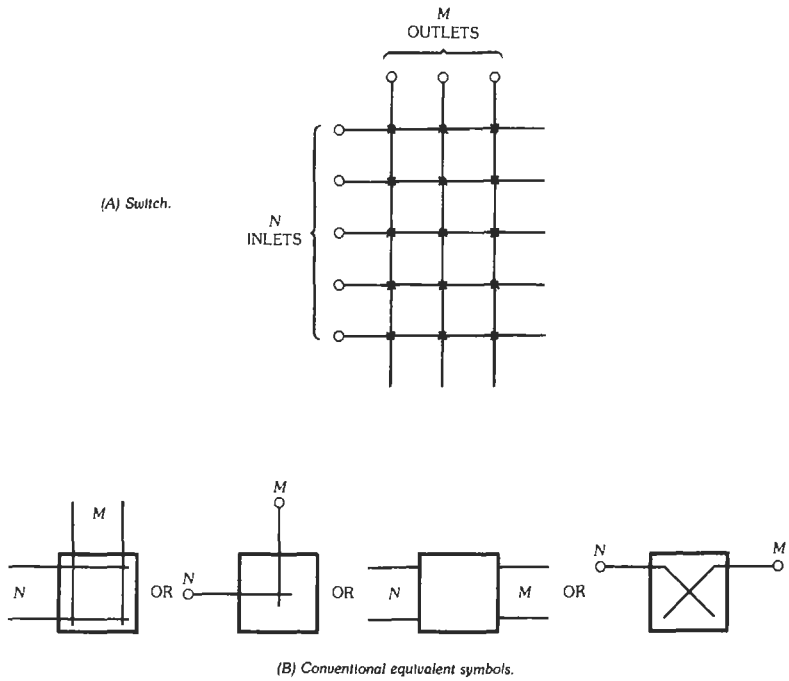

Fig. 1. Single-stage rectangular coordinate switch (full availability).

If full availability is not a requirement, an economy of crosspoints can be achieved by use of a limited-availability (restricted-access) coordinate switch. Fig. 2 shows a square switch with five inlets and five outlets in which every inlet has access to only three of the outlets. The grading is said to be homogeneous when, as shown, each set of three outlets is unique.

When the outlets from a switch are connected to the same lines or trunks as are the inlets to the switch, a triangular "folded" arrangement may be used. Fig. 3 shows a triangular switch for N inlets-outlets. The switch provides full availability and is nonblocking.

$$\text{Number of crosspoints required} = N(N-1)/2$$

Fig. 4 shows a symmetrical two-stage network with square switches. This formed the basic frame arrangement of many electromechanical switching systems in which the limited size of the crossbar switch was compensated for by introducing two stages of switching—in the decimal planned system, expanding the access of a ten-by-ten crossbar switch to 100. This increase is achieved at the cost of introducing blocking; that is, an idle inlet can no longer reach every idle outlet regardless of the number of calls in progress. In fact, it is easy to see that every call from an inlet on primary switch 1 to an outlet on secondary switch 1 blocks all possible calls from other inlets on primary switch 1 to other outlets on secondary switch 1. Such an arrangement would usually give intolerable service, so three or more stages are generally used to provide parallel paths between inlet and outlet.

Fig. 5 shows a three-stage network where now there are several possible paths between any inlet and any outlet. The ability to search for one of several paths reduces blocking materially below the single path of the primary-secondary arrangement previously discussed.

It should be noted that while the number of crosspoints of a particular network is a first-order approach to its cost, there are other factors such as control cost, path setup time, and physical design that may make the most favorable design for a particular application quite different from the one that minimizes crosspoints.

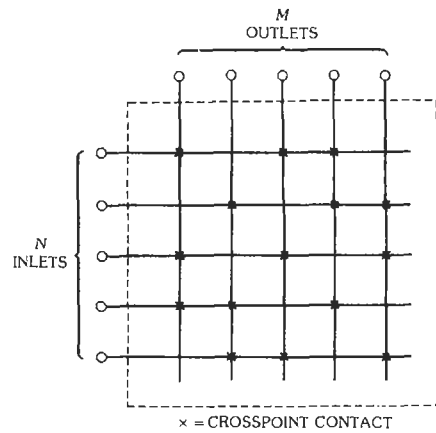

Fig. 2. Single-stage square coordinate switch (limited availability).

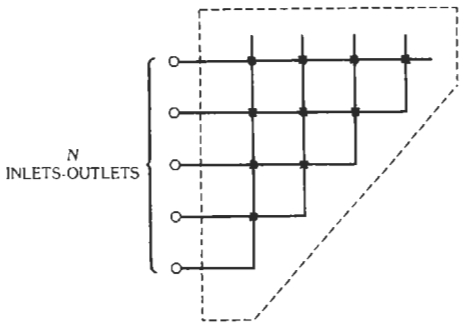

Fig. 3. Single-stage folded (triangular) switch.

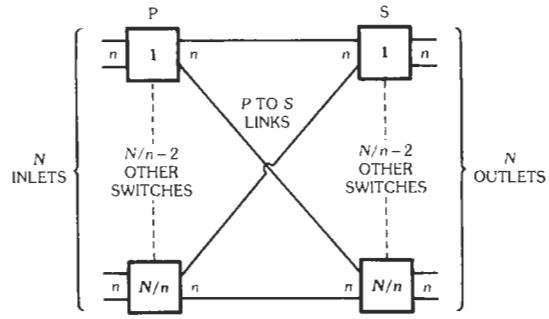

Fig. 4. Symmetrical two-stage switch.

BLOCKING AND NON-BLOCKING NETWORKS

In the following paragraphs, configurations for blocking and nonblocking networks will be described. The choice of network depends to a large extent on the service objectives, cost objectives, control capability, and, where a network covers a wide range of quantities of inlets and outlets, how additional switches and terminals can be added to the network without expensive rearrangement and changes in control methods.

Nonblocking 3-Stage Networks

A. General Case—Fig. 6 shows part of a network that presents no internal blocking (see definition). Let N = number of inlets, M = number of outlets, S = number of center-stage switches, n = number of inlets per first stage switch, and m = outlets per final-stage switch. When $N \neq M$, the condition for nonblocking is given by $S = n + m - 1$.

The number of crosspoints required is given by

$$X = (n + m - 1)[N + M + (NM/nm)]$$

A minimum number of crosspoints is obtained when $m = n$ and when n satisfies the equation

$$NM/(N + M) = n^3/(n - 1) \qquad \text{(Eq. 1)}$$

Columns 1 and 2 of Table 1 show corresponding values of n and $NM/(N + M)$ that satisfy equation 1, from which the optimum value of n for given values of N and M may be selected. Fig. 7 shows part of the network.

The number of crosspoints required is then given by

$$X_{\min} = (2n - 1)[N + M + (NM/n^2)]$$

B. Symmetrical Case—Fig. 8 shows part of a symmetrical nonblocking network, where $M = N$ and $m = n$. The condition for nonblocking is given by

$$S = 2n - 1$$

The number of crosspoints required is given by

$$X = N(2n - 1)[2 + (N/n^2)]$$

A minimum number of crosspoints is obtained when n satisfies the equation

$$N = 2n^3/(n - 1) \qquad \text{(Eq. 2)}$$

Columns 1 and 3 of Table 1 show corresponding values of n and N satisfying equation 2, from which the optimum value of n may be selected.

For large values of n, beyond the range of practical three-stage networks (see **C** below)

$$2n^2 \rightarrow N$$

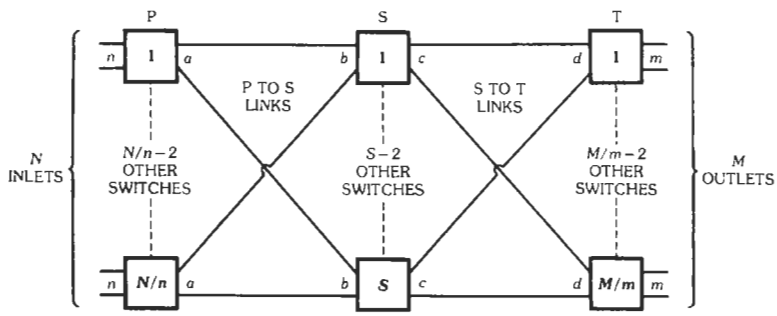

Fig. 5. Three-stage network—general case.

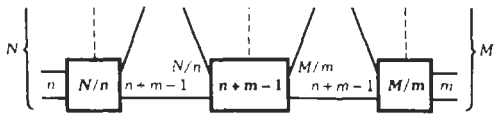

Fig. 6. Nonblocking three-stage network.

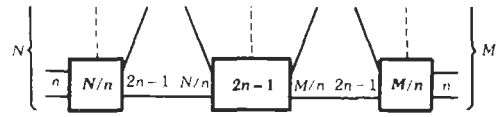

Fig. 7. Nonblocking three-stage network with minimum crosspoints.

Columns 1 and 4 of Table 1 show corresponding values of n and N satisfying the equation

$$N = 2n^2 \qquad \text{(Eq. 3)}$$

The optimum value of n selected by using column 3 is either equal to or one less than the value indicated by column 4.

C. Comparison of 3-Stage Network and Single-Stage Switch—A single-stage, full-access switch is inherently nonblocking. The most favorable nonblocking three-stage network requires fewer than NM crosspoints if

$$NM/(N + M) > n^2(2n - 1)/(n - 1)^2$$

Table 2 shows, for some practical values of n, the limiting value of $NM/(N + M)$ below which a single-stage switch requires fewer crosspoints.

Table 3 compares single-stage switches and three-stage symmetrical nonblocking networks for typical values of N and n, where N/n is integral (see **D** below), to illustrate the trends of design choices.

D. Practical Nonblocking 3-Stage Network with Minimum Crosspoints—When a nonblocking network with a minimum number of crosspoints is sought, the indicated optimum value of inlets, n, per primary-stage switch may be such that N/n is not integral. The desired result may be achieved by providing some of the primary-stage and tertiary-stage switches with $(n - 1)$ inlets and outlets, respectively, by adjusting the sizes of the secondary-stage switches, and by superimposing two sets of interstage linkages.

The method is illustrated in Fig. 9, a nonblocking network for 100 inlets and 100 outlets requiring a minimum number of crosspoints. The value $n = 6$ is selected from column 3 of Table 1. The nearest multiple of 6 that exceeds 100 is 102. Thus, 17 primary-stage switches are required, 15 with 6 inlets each and 2 with 5 inlets. The larger switches require $2n - 1 = 11$ outlets each, cross-linked to 11 secondary-stage switches (links shown by continuous lines). The smaller switches require $2n - 2 = 10$ outlets each, cross-linked to 10 only of the secondary-stage switches (links shown by dashed lines). Thus, the secondary-stage switches also are of two sizes. The total number of crosspoints is 5291 (as compared with 5423 for a nonblocking network for 102 inlets and outlets, with $n = 6$). The crosspoint saving may not be worth the added control complexity.

E. Extension to 5-Stage and 7-Stage Networks—If the number of inlets and outlets on each secondary-stage switch of a three-stage network is large, it is advantageous to use a five-stage network. One possible arrangement is shown in Fig. 10, in which each secondary switch of a symmetrical three-stage network conforming to Fig. 8 is expanded into a nonblocking three-stage subnetwork.

If $N > 160$, a five-stage nonblocking network can be designed—by judicious selection of parameters n and a—which requires fewer crosspoints than the most favorable nonblocking three-stage network. The advantage increases slowly with N; at $N = 240$, the advantage is less than 5%.

The number of crosspoints is given by

$$X = N(2n - 1)\{2 + (2a - 1)[(2/n) + (N/n^2a^2)]\}$$

TABLE 1. RELATIONSHIP OF n, N, AND M IN NONBLOCKING 3-STAGE NETWORKS

n	$NM/(N+M)$ (Eq. 1)	N (Eq. 2)	N (Eq. 3)

9	91.1	182.2	162
10	111.1	222.2	200
11	133.1	266.2	242
12	157.1	314.2	288

*The only two integral solutions of equation 2.

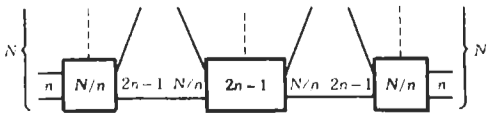

Fig. 8. Symmetrical nonblocking network with minimum crosspoints.

A minimum number of crosspoints is obtained when n and a satisfy the equations

$$N = 2na^3/(a - 1)$$
$$= [na^2(2n^2 + 2a - 1)]/[(2a - 1)(n - 1)]$$

When the number of inlets and outlets, N, is such that the switches of the center stage of a five-stage network become large, each center-stage switch can with advantage be expanded in like manner into a nonblocking three-stage assembly. The result is a seven-stage network that is nonblocking overall.

F. "Folded" Nonblocking 3-Stage Networks—Fig. 11 shows the case in which the outlets from the tertiary-stage switches of a symmetrical three-stage network are connected to the same lines or trunks as are the inlets to the primary-stage switches. The number of crosspoints required to ensure no internal blocking is significantly less than in the case described in **B** above, provided the inlet-outlets are able to handle both incoming and outgoing traffic and the network control can set up paths in either direction. Such a network is said to function as a "folded" network.

The condition for nonblocking is given by

$$S = n$$

The number of crosspoints required is given by

$$X = N[2n + (N/n)]$$

A minimum number of crosspoints is obtained when n satisfies $2n^2 = N$. Corresponding values of n and N may be selected from columns 1 and 4 of Table 1.

As in the previous networks, when the network becomes large, further crosspoint savings can be achieved by substituting three-stage nonblocking networks for large rectangular switches.

G. Source Reference—Further information for the design of nonblocking multistage coordinate switching networks may be obtained from C. Clos, "A Study of Non-Blocking Switching Networks," *Bell System Tech. J.*, March 1953.

Networks With Internal Blocking

General Case—When internal blocking is allowed, it is possible to design a multistage network that requires many fewer crosspoints while providing full availability between the inlets and the outlets—but introducing a measure of blocking. The number of secondary-stage switches, S, required in a three-stage network to interconnect N inlets and M outlets, with a selected value of n, may be represented in a practical case as shown in Fig. 12 by $S = kn$, where k(constant) $< (2n - 1)/n$ determines the blocking.

The number of crosspoints required is given by

$$X = kn[N + M + NM/n^2)]$$

A minimum number of crosspoints is obtained if n satisfies

$$n^2 = NM/(N + M)$$

The number of crosspoints is then given by

$$X_{\min} = 2k[NM(N + M)]^{1/2}$$

When the inlets and outlets of a symmetrical network are connected to the same lines or trunks, it is advantageous to arrange the network to function as a "folded" network (see **F** above).

Traffic-Carrying Capability of Blocking Networks—Exact calculation of the probability of blocking in a multistage network is difficult. Order-of-magnitude estimates can be made by using the method described by C. Y. Lee, in which the number of parallel paths, r, possible for a connection is used. If a_1, a_2, and a_{s-1} designate the occupancy of links leaving stages 1, 2, and $s - 1$ of an s-stage network, the probability, P, of blocking is approximated by:

$$P = [1 - (1 - a_1)(1 - a_2) \ldots (1 - a_{s-1})]^r$$

More detailed methods of calculating blocking in switching networks may be found in the publications of the Institute of Switching and Data Technics, University of Stuttgart, Stuttgart, Germany.

TIME-DIVISION SWITCHING

Time division with pulse-code modulation has for many years been used as a method of multiplexing a number of telephone conversations on a digital carrier. With the same methods, a great reduction in active

elements in a switching network can be achieved; in fact, it is advantageous to switch channels from digital carriers without demodulating them. The prevalence of digital transmission systems and the rapid advance of digital technology have made the present trend completely toward digital switching.

Conceptually, each time slot in a digital carrier can be thought of as a separate traffic path separated by the dimension of time rather than that of space as in the networks discussed so far. There are three usual time-division network configurations. In the first, the time slots in one digital stream are inserted into similarly positioned time slots in an output stream. This forms the basis of the "space division" part of many time-division networks, as will be discussed.

In the second configuration, the information in one time-slot position of the input digital stream is inserted in a different position in the output digital stream (which may have a different bit rate).

Hybrid between the first two configurations is the taking of a sample of an analog inlet signal, encoding it and placing it in a selected time slot in an output digital

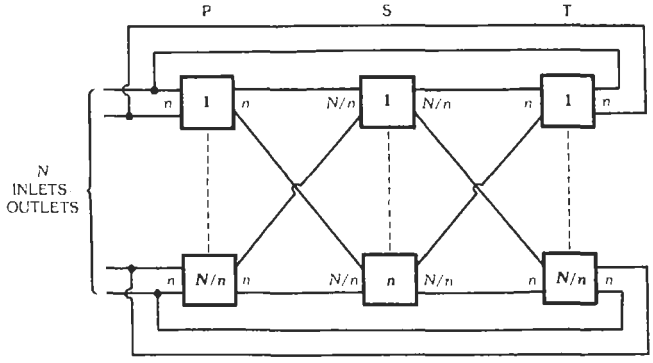

Fig. 11. Folded nonblocking three-stage network.

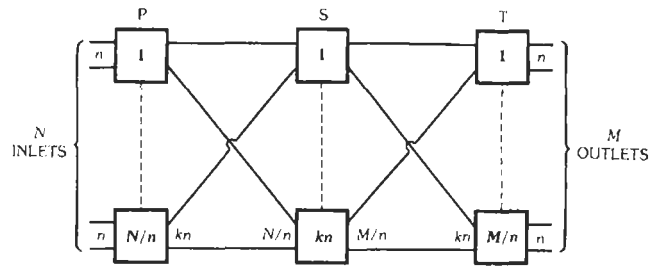

Fig. 12. Three-stage network with internal blocking.

stream, and the converse. This configuration is usual in the first stage of a time-division line-switching system.

The last two configurations require storage of signals—one store or register for each input or output time slot, whichever is larger. This type of time-division switching stage is known as *time slot interchange* (*TSI*).

The first configuration is analogous to a set of crosspoints arranged to connect n inlets to n outlets but with each inlet having access to only one outlet. It is achieved, of course, with only one physical crosspoint. This crosspoint can be combined with others in a rectangular array to provide the equivalent of n rectangular switches in which all the same-positioned time slots of a number of inlet digital streams have access to like-positioned slots in a number of outlet streams.

The second and third configurations correspond to a rectangular switch in which any inlet, path, or time slot has access to any outlet.

Because digital transmission is generally unidirectional, two paths must be established, one for each direction of transmission. This may be done by pairing the transmitter and receiver for each inlet and outlet. A connection is set up through parallel networks from the transmitter of the inlet to the receiver of the outlet and from the receiver of the inlet to the transmitter of the outlet. Crosspoints in the parallel networks are controlled in common.

The above arrangement cannot be used on folded networks where the ability is needed to connect any inlet-outlet to any other, because connections would be made from transmitter to transmitter. It can, however, be implemented by placing all the transmitters on one side of a nonfolded network and all the receivers on the other. Independent paths are then set up for each direction of transmission.

All coordinate switching networks considered above are used in what has become known as *circuit switching*, where each path is assigned for the duration of a voice message or conversation. For data messages, a technique known as *packet switching* is used widely. Here data messages are usually divided into uniform-length segments. The address of the called station is prefixed onto each segment or packet as it is transmitted into an idle time slot.

For small networks, such as local area networks (LANs), the address is detected by the station to which it is being sent, and the switching consists of removing the packet from the transmission medium. This is a distributed $1 \times N$ switching network.

As networks become larger or are interconnected, congestion may be encountered in finding idle time slots. In a packet switching network, the packets may be sent over any of several independent paths that might reach the called station. In such networks, each packet is assigned a number, and the called station checks that each is received and places them in order.

In emerging large data networks, packets of a given message are sent through the same network nodes over a virtual circuit. Buffer storage is used to hold the packets temporarily. If there is insufficient storage, packets may be lost.

Multistage coordinate switching networks are the basis for switching packets buffered for virtual circuit switching. Two-by-two matrices have the advantage that out of a possible 16 states only two are useful. Paths are sought through networks consisting of only 2×2 matrices, sometimes called *beta* elements, based upon the first binary digit (bit) address read from the beginning of each transmitted packet. When only 2×2 matrices are used, nonblocking cannot be achieved by the technique shown in Figs. 6 and 7. It can be shown that with $(2 \log_2 n) - 1$ stages of beta elements almost nonblocking can be achieved. The network divides into a mirror image as shown in Fig. 13. Half of the stages are known as a *baseline* network and the other half as the *inverse baseline*.

Appended to each packet as it leaves an input buffer are address bits used to control the state of a beta element at each successive stage of a switching network. A routing network, called a *Banyan* network (Fig. 14), allows the same address to be used to reach a particular output regardless of the input source.

It is possible that packets launched simultaneously from different inputs will collide or cause congestion at the output of any beta element. For this reason, steps must be taken to add intermediate buffers between network stages or to avoid the same routing for packets destined to the same output address.

Adding sorting stages to the network can prevent collisions within the network as packets move toward their destinations. Stages with this pattern, or *shuffle*, of link interconnection (Fig. 15) are known as *batcher* networks.

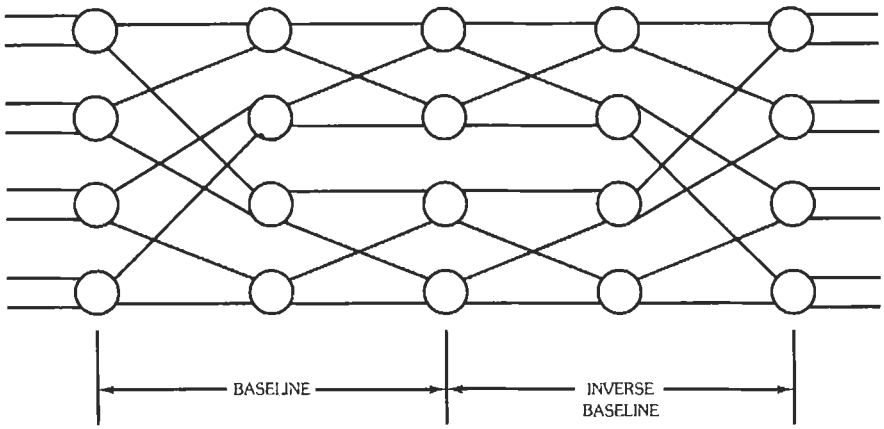

Fig. 13. Basic network of beta element.

Eventually, collisions will occur at the last stage. Various strategies to deal with such conflicts have been proposed. Most involve delaying all but one packet by additional buffers or feedback through delay stages.

The techniques described in this section are used in designing switching networks for serving a plurality of high-speed (fast) digital input lines carrying packets that arrive at random. (For this reason this technique has become known as *fast packet switching*.) Currently, there is a trend toward converting most digital messages, be they voice, images, video, or data, into fixed-sized packets, called *cells*. By the use of uniform-sized cells, each service may use its required portion of the capacity of the same switching network, and all services are switched ubiquitously.

Like packets, these cells arrive at the switch asynchronously or at random. When switching networks are used for this application, they are known as *asynchronous transfer mode* or *ATM* networks.

PART 2: TRAFFIC CONCEPTS

DEFINITIONS OF TERMS

Busy hour: The continuous one-hour period that, on consecutive days in the busy part of the year, contains the maximum average traffic intensity.

Call: A discrete engagement or occupation of a traffic path.

Calling rate: The average number of calls placed during the busy hour.

Call-second, call-minute, call-hour: Units of traffic quantity representing the occupation of a circuit for a second, minute, or hour.

Equated busy-hour call (EBHC): A European unit of traffic intensity equal to 1/30 of an erlang.

Erlang: The international dimensionless unit of traffic intensity. One erlang is the traffic intensity represent-

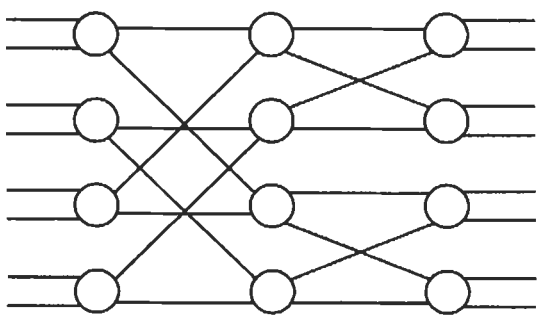

Fig. 14. Banyan routing network.

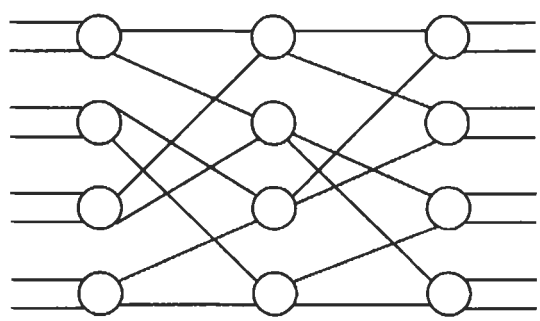

Fig. 15. Shuffle sorting network.

ed by an average of one circuit busy out of a group of circuits over some period of time.

Full-availability group: A group of traffic-carrying trunks or circuits in which every circuit is accessible to all the traffic sources.

Grade of service: A measure of the probability that, during a specified period of peak traffic, a call offered to a group of trunks or circuits will fail to find an idle circuit at the first attempt. Usually applied to the busy hour of traffic.

Holding time: The duration of occupancy of a traffic path by a call. Sometimes used to mean the average duration of occupancy of one or more paths by calls.

Hundred call-second per hour (CCS): A unit of traffic intensity equal to $\frac{1}{36}$ of an erlang.

Infinite sources: The assumption that the number of sources offering traffic to a group of trunks or circuits is large in comparison with the traffic load. A ratio of ten or higher is often considered "infinite."

Limited-access group: A group of traffic-carrying trunks or circuits in which only a fraction of the circuits is accessible to any one group of the traffic sources.

Limited sources: The assumption that the number of sources offering traffic to a group of trunks or circuits must be included in loss-probability calculations. Used in the binomial and Engset loss-probability equations.

Lost calls cleared: The assumption that calls not immediately satisfied at the first attempt are cleared from the system and do not reappear during the period under consideration. Used in the Erlang B loss-probability equation.

Lost calls delayed: The assumption that calls not immediately satisfied at the first attempt are held in the system until satisfied. Used in the Erlang C delay-probability equation.

Lost calls held: The assumption that calls not immediately satisfied at the first attempt are held in the system until served or abandoned. The sum of waiting and service time is assumed equal to what the service time would have been without delay. Used in the Poisson loss-probability equation. (When the service time is a negative exponential, this assumption has the same effect if holding and service times are independent and the distribution of the caller's holding time to abandon is a negative exponential with the mean equal to that of the service time.)

Occupancy: The traffic intensity per traffic path. One hundred percent occupancy implies all paths busy.

Traffic concentration: The average ratio of the traffic quantity during the busy hour to the traffic quantity during the day.

Traffic density: See Traffic intensity.

Traffic flow: See Traffic intensity.

Traffic intensity: The average number of calls present on a group of traffic paths over a period of time.

Traffic load: See Traffic intensity.

Traffic path: A channel, time slot, frequency band, line, trunk, switch, or circuit over which individual communications pass in sequence.

Traffic quantity: The aggregate engagement time or occupancy time of one or more traffic paths.

TRAFFIC MEASURES

In the terminology of traffic, there are three concepts that often cause confusion and need to be differentiated.

Traffic Quantity

Traffic quantity represents the total number of channel uses in units of time. It is of particular use for billing or other volume calculations but is not useful by itself. Where only this gross daily quantity is available, an estimate can be made of the busy-hour traffic by making an assumption about the proportion of daily traffic appearing in the busy hour. Direct busy-hour measurements are preferable, however, for calculating the traffic performance of a traffic-carrying facility. The latter is a function of traffic intensity, which is the quantity of traffic carried during a period of time.

Traffic Intensity

Traffic intensity, often called traffic load, is the average number of calls present during a period of time. It can be measured by averaging periodic counts of the number of calls present during the period or, alternatively, by summing the duration of calls within the period and dividing by the period length.

Call Intensity

For many traffic-carrying elements, the number of calls making up the total traffic load is immaterial; the load represented by two calls of ten minutes duration has the same impact as one call of twenty minutes duration. This is the case for switching-system processors and controllers, where the duration of calls on the traffic-carrying paths is irrelevant. Call intensity, or call rate, in calls per time unit, is frequently used, therefore, in estimating traffic loads on control equipment. Often the time unit is an hour and is implied, as in "a line calling rate of 3."

TRAFFIC EQUATIONS AND TABLES

Grade of Service

The overall "grade of service" of a switching system or trunk system refers to the ratio of calls that are not completed at the first attempt to the total number of

attempts to establish a connection through the system during a specific period of time, usually the busy hour. The traffic capacity of a switch, switching network, or trunk group is the traffic load that will, on the average, provide the grade of service that is chosen as the service objective.

For measurement purposes, it is sometimes easier to observe the proportion of time that all circuits are busy than to count the total of offered and carried calls (or carried and lost calls). For the usual assumptions of random calling, infinite sources, and a level value of offered traffic, the proportion of calls blocked and the proportion of time all circuits are busy are equal. This relation does not persist for assumptions of peaked traffic, smooth traffic, or limited sources.

Choice of Formula

The most important factors determining the choice of formula for estimating grade of service are as follows:

A. The statistical nature of the call originations
   - Random from infinite sources
   - Random from finite sources
   - Peaked from infinite sources
   - Smooth from infinite sources
   - Periodic

B. The probability distribution of the call holding time

C. The availability of the circuits serving the traffic
   - Full access
   - Limited access in a graded multiple
   - Limited access through a switching network

D. The behavior of calls when blocked
   - Lost calls cleared
   - Lost calls delayed
   - Lost calls held
   - Lost calls retried at a later time

Traffic Equations

The two most commonly used equations in trunk service estimation are the Erlang B and the Poisson. In general, the Erlang B is a good estimator of single-hour service, while the Poisson is a good estimator of the service given on the average over a busy season during which the offered load varies over a wider range than would be expected from the assumptions of random offered traffic. In general, the use of the Poisson equation is not recommended for grades of service that exceed 0.10 (10% blocking).

In small networks, it may be necessary to take limited sources into account. This results in the Engset and binomial equations as indicated below.

The Erlang B equation is given by

$$B(c,a) = (a^c/c!)/\sum_{x=0}^{x=c} a^x/x!$$

The corresponding Engset equation for limited sources is solved only by iterative techniques. Tables are available for this purpose.*

The Poisson equation is given by

$$P(c,a) = e^{-a}\sum_{x=c}^{\infty}(a^x/x!)$$

The corresponding binomial equation is given by

$$P(c,n+1,r) = \sum_{x=c}^{n}\binom{n}{x} r^x(1-r)^{n-x}$$

Finally, the Erlang C equation is given by

$$C(c,a) = (a^c/c!)[c/(c-a)]/\{\sum_{x=0}^{c-1} a^x/x! + (a^c/c!)[c/(c-a)]\}$$

where,

a = offered load in erlangs,
c = number of circuits,
n = number of limited sources less one,
r = load offered by an idle source.

Although the above equations are derived on the assumption of a negative exponential distribution of holding times, they are reasonable approximations for most distributions encountered in practice.

The Erlang B equation is particularly useful in estimating the load that will be carried on and overflowing from a direct group of trunks to which random traffic is offered. Calls that find all direct circuits busy are directed to an alternate route. The traffic carried on the direct route will be $a[1 - B(c,a)]$, and the traffic overflowing will be $aB(c,a)$, where a = the random offered traffic. The overflow traffic is no longer random, and other approximations are necessary to estimate the grade of service given by an alternate trunk group to overflow traffic. For this purpose, it is necessary to estimate the variance of the overflow traffic, or more conveniently, the ratio of the variance to the mean. This latter quantity is known as the *peakedness* of the traffic. (Random traffic from an infinite source has a peakedness of one.) Peakedness, z, of traffic overflowing from c trunks offered a erlangs under the LCC assumptions is given by:

$$z = 1 - aB(c,a) + a/[c + 1 + aB(c,a) - a]$$

When a number of overflow loads from a number of direct groups are combined, the peakedness of the total is given closely by

$$z = \sum_{x=1}^{n} z_x a'_x / \sum_{x=1}^{n} a'_x$$

where a'_x is the overflow load from the xth source.

---

*Telephone Traffic Theory, Tables and Charts. Berlin-Munich: Siemens Aktiengesellschaft, 1970.

An approximation to the grade of service given by a group of trunks to peaked traffic may be made with the equation

$$P = B(c/z, y/z)$$

(See D. W. Hill and S. R. Neal, "Traffic Capacity of a Probability Engineered Trunk Group," *Bell Syst. T. J.*, Vol. 55, No. 7, September, 1976, for closer approximations.)

Delays

Many control systems operate on a delay basis, and it is convenient to have an equation for estimating delays. Under the Erlang C assumptions, the delay has a mean of

$$d(c,a,h) = [c/(c - a)]C(c,a)h$$

If calls are served in order of arrival, the length of delay for delayed calls will be negative exponential.

Approximations to other service time distributions are given by

$$d(c,a,h) = [c/(c - a)]C(c,a)h(1 + V/h^2)/2$$

where,

V is the variance,
h is the average of the holding time distribution.

Legend:

All loads in erlangs
B = Lost calls cleared, Erlang B
P = Lost calls held, Poisson

For calls served in order of arrival, the negative exponential is an approximation to the delay distribution of delayed calls.

Table 4 gives values of loads for objective losses over a range of loads and trunks for the Poisson and Erlang B formulas. For computer use, advantage can be taken of the following recurrence relation for computing the infinite source loss formulas:

$$\text{Let } E(c+1,a) = (c/a)[E(c,a) + 1]$$

$$\text{and } E(0,a) = 1$$

Then for lost calls cleared

$$B(c,a) = 1/E(c,a)$$

and for lost calls delayed

$$C(c,a) = 1/\{[(c-a)/c][E(c,a) - 1] + 1\}$$

For lost calls held:

$$\text{Let } D(c,a) = [(a/c) + 1]D(c-1,a) - (a/c)D(c-2,a)$$

$$\text{and } D(-1,a) = 0$$

$$D(0,a) = 1$$

Then

$$P(c,a) = 1 - e^{-a} D(c-1,a)$$

THEORY OF SOUND WAVES*

Sound (or a sound wave) is an alteration in pressure, stress, particle displacement, or particle velocity that is propagated in an elastic material, or the superposition of such propagated alterations. Sound (or sound sensation) is also the sensation produced through the ear by the above alterations.

Wave Equation

The behavior of small-amplitude sound waves is given by the wave equation

$$\nabla^2 p = (1/c^2)(\partial^2 p/\partial t^2) \qquad \text{(Eq. 1)}$$

where,

p is the instantaneous pressure increment above and below a steady pressure (pascals),
t is the time in seconds,
c is the velocity of propagation in meters/second,
∇^2 is the Laplacian.

The quantity p is a function of time and of the three coordinates of space. For the particular case of rectangular coordinates x, y, and z (in meters), the Laplacian is given by

$$\nabla^2 \equiv (\partial^2/\partial x^2) + (\partial^2/\partial y^2) + (\partial^2/\partial z^2) \qquad \text{(Eq. 2)}$$

Plane Waves—For a plane wave of sound, where variations with respect to y and z are zero, $\nabla^2 p = \partial^2 p/\partial x^2 = d^2 p/dx^2$; the latter is approximately equal to the curvature of the plot of p versus x at some instant. Equation 1 states simply that, for variations in x only, the acceleration in pressure p (which is the second time derivative of p) is proportional to the curvature in p (which is the second space derivative of p).

Sinusoidal variations in time are usually of interest. For this case, the standard procedure is to put p = (real part of $\bar{p}e^{j\omega t}$), where the phasor $\bar{p}$ now satisfies the equation

$$\nabla^2 \bar{p} + (\omega/c)^2 \bar{p} = 0 \qquad \text{(Eq. 3)}$$

The velocity phasor $\bar{v}$ of the sound wave in the medium is related to the complex pressure phasor $\bar{p}$ by

$$\bar{v} = -(1/j\omega\rho_0) \text{ grad } \bar{p} \qquad \text{(Eq. 4)}$$

The specific acoustic impedance $\bar{Z}$ at any point in the medium is the ratio of the pressure phasor to the velocity phasor, or

$$\bar{Z} = \bar{p}/\bar{v} \qquad \text{(Eq. 5)}$$

Spherical Waves—The solutions of equations 1 and 3 take particularly simple and instructive forms for the case of one-dimensional plane and spherical waves in one direction. Table 1 summarizes the pertinent information.

For example, the acoustic impedance for spherical waves has an equivalent electrical circuit comprising a resistance shunted by an inductance. In this form, it is obvious that a small spherical source (r is small) cannot radiate efficiently since the radiation resistance $\rho_0 c$ is shunted by a small inductance $\rho_0 r$. Efficient radiation begins approximately at the frequency where the resistance $\rho_0 c$ equals the inductive (mass) reactance $\rho_0 r$. This is the frequency at which the period ($1/f$) equals the time required for the sound wave to travel the distance $2\pi r$.

Sound in Gases

The acoustic behavior of a medium is determined by its physical characteristics and, in the case of gases, by the density, pressure, temperature, specific heat, coefficients of viscosity, and the amount of heat exchange at the boundary surfaces.

The velocity of propagation in a gas is a function of the equation of state ($PV = RT$ plus higher-order terms), the molecular weight, and the specific heat.*

For small displacements relative to the wavelength of sound, the velocity is given by

$$c = (\gamma p_0/\rho_0)^{1/2} \qquad \text{(Eq. 6)}$$

where,

γ = ratio of the specific heat at constant pressure to that at constant volume,
p_0 = the steady pressure of the gas in newtons/meter^2,
ρ_0 = the steady or average density of the gas in kilograms/meter^3.

The values of the velocity in a few gases are given in Table 2 for 0 degrees Celsius and 760 millimeters of mercury barometric pressure.

The velocity of sound, c, in dry air is given by the experimentally verified equation

$$c = 331.45 \pm 0.05 \text{ meters/second}$$

$$= 1087.42 \pm 0.16 \text{ feet/second}$$

for the audible-frequency range, at 0 degrees Celsius and 760 millimeters of mercury with 0.03-mole-percent content of CO_2.

TABLE 1. SOLUTIONS FOR VARIOUS PARAMETERS

Factor	Type of Sound Wave: Plane Wave	Type of Sound Wave: Spherical Wave
Equation for p	$\partial^2 p/\partial x^2 = (1/c^2)(\partial^2 p/\partial t^2)$	$(\partial^2 p/\partial x^2) + (2/r)(\partial p/\partial r) = (1/c^2)(\partial^2 p/\partial t^2)$
Equation for $\bar{p}$	$(d^2\bar{p}/dx^2) + (\omega/c)^2\bar{p} = 0$	$(d^2\bar{p}/dx^2) + (2/r)(d\bar{p}/dt) + (\omega/c)^2 p = 0$
Solution for p	$p = F[t - (x/c)]$	$p = (1/r)\,F[t - (x/c)]$
Solution for $\bar{p}$	$\bar{p} = \bar{P} \exp(-j\omega x/c + j\theta)$	$\bar{p} = (1/r)\,\bar{P} \exp(-j\omega r/c + j\theta)$
Solution for $\bar{v}$	$\bar{v} = (p/\rho_0 c) \exp(-j\omega x/c + j\theta)$	$\bar{v} = (p/\rho_0 cr)\,[1 + (c/j\omega r)] \exp(-j\omega\, r/c + j\theta)$
$\bar{Z}$	$\bar{Z} = \rho_0 c$	$\bar{Z} = \rho_0 c/[1 + (c/j\omega r)]$
Equivalent Electrical Circuit for $\bar{Z}$		
p = excess pressure in pascals (newtons/meter^2)
$\bar{p}$ = complex excess pressure in pascals (newtons/meter^2)
t = time in seconds
x = space coordinate for plane wave in meters
r = space coordinate for spherical wave in meters

$\bar{v}$ = complex velocity in meters/second

$\bar{Z}$ = specific acoustic impedance in rayls (newton-seconds/meter^3)
c = velocity of propagation in meters/second
$\omega = 2\pi f$; f = frequency in hertz
F = an arbitrary function
θ = phase constant
ρ_0 = density of medium in kilograms/meter^3
$\bar{P}$ = peak amplitude of the phasor (units dependent on wave type)

The velocity in air for a range of about 20 degrees Celsius change in temperature is given approximately by

$$c = 331.45 + 0.607T_c \text{ meters/second}$$

$$= 1052.03 + 1.106T_f \text{ feet/second}$$

where T_c is the temperature in degrees Celsius and T_f is the temperature in degrees Fahrenheit. For values of T_c greater than 20 degrees, the following equation may be used:

$$c = 331.45 \times (T_k/273)^{1/2} \text{ meters/second}$$

where T_k is the temperature in kelvins.

For other corrections, if extreme accuracy is desired, reference should be made to the literature.*

From Equation 5 and Table 1, characteristic impedance is equal to the ratio of the sound pressure to the particle velocity.

$$\bar{Z} = \bar{p}/\bar{v} = \rho_0 c \cos\phi$$

For plane waves, $\phi = 0$ and $\cos\phi = 1$. For spherical waves, $\tan\phi = \lambda/2\pi r$, where λ = wavelength of the acoustic wave, and r = distance from the sound source. For r greater than a few wavelengths, $\cos\phi \approx 1$.

Characteristic impedance $\rho_0 c$ in newton-seconds/meter^3 for several gases at 0 degrees Celsius and 760 millimeters of mercury is given in Table 2.

Sound in Liquids

In liquids, the velocity of sound is given approximately by

$$c = (1/K\rho_0)^{1/2}$$

* Hardy, H. C., Telfair, D., and Pielemeier, W. H. "The Velocity of Sound in Air." *Journal of the Acoustical Society of America*, Vol. 13, January 1942, pp. 226–233.

TABLE 2. GASES

Gas	Symbol	Density (g/L)	Velocity (m/s)	$\Delta v/\Delta t$ (m/s °C)	$\rho_0 c$ (N · s/m^3)
Air, dry		1.293	331.45	0.59	428.6
Argon	A	1.783	319	0.56	596
Carbon dioxide	CO_2	1.977	259	0.4	511
Carbon monoxide	CO	1.25	338	0.6	421
Helium	Hc	0.178	965	0.8	173.2
Hydrogen	H_2	0.0899	1284	2.2	114
Neon	Ne	0.900	435	0.8	383
Nitrogen	N_2	1.251	334	0.6	418

where,

c is the velocity in meters/second,
K is the compressibility in meter-seconds^2/kilogram and may be regarded as constant.

For most liquids,

$$K = (47 \times 10^{-8})/981$$

Figures for the velocity of sound in meters/second through some liquids are given in Table 3.

Sound in Solids

See Chapter 4, Tables 17, 18, and 19.

Sound Intensity

The sound intensity is the average rate of sound energy transmitted in a specified direction through a unit area normal to this direction at the point considered. Intensity is a vector quantity. In the case of a plane or spherical wave (several wavelengths from the source) in a fluid, the intensity in the direction of propagation is given by

$$I = p^2/\rho c \qquad \text{(Eq. 7)}$$

The units of I are watts/meter^2.

Sound-Pressure Level (SPL)

It is sometimes convenient to use the decibel scale to express the ratio between any two sound intensities. Since sound pressure is usually proportional to the square root of the corresponding sound intensity, sound-pressure level (SPL) is defined as

$$\text{SPL} = 10 \log_{10} (p^2/p_0^2) \qquad \text{(Eq. 8)}$$

where p_0 is 20 micropascals in air.*

At times, sound pressure is measured in units other than pascals. Table 4 lists the SPL for a quantity of one in these other units (e.g., 1 atmosphere).

ELECTRICAL ANALOGIES FOR ACOUSTICAL AND/OR MECHANICAL SYSTEMS**

Analysis of electromechanical-acoustical transducers, mechanical systems, or acoustical systems can be facilitated by the use of electrical analogies. Two forms of electrical analogies are possible: (1) force or pres-

* The reference of 1 micropascal is usually used for liquids and all other media.

127.6	1 pound/foot^2	(psf)
170.8	1 pound/in^2	(psi)
194.1	1 atmosphere	(atm)
74	1 microbar	(μbar)

sure-voltage analogue and (2) force or pressure-current analogue. Tables 5 and 6 tabulate the pertinent quantities in these two analogies.

In a specific problem in which it is desired to represent an acoustical or mechanical system by an electrical circuit, a choice must be made between the force-voltage and force-current analogies. If the system includes electrical as well as mechanical or acoustical elements, as in a motor or a loudspeaker, for example, the choice is dictated by the type of coupling between the electrical and mechanical parts. However, if the system is entirely mechanical or acoustical, the choice is arbitrary and depends upon personal preference. In any event, given the equivalent circuit derived on the basis of one analogy, the equivalent circuit corresponding to the other analogy can be derived by taking the dual of the given circuit.

In a system that combines acoustical and mechanical quantities, it is necessary to establish a common frame of reference. Usually, it is easiest to convert acoustical quantities to mechanical quantities, as for example, integrating the pressure over a piston (loudspeaker or microphone) to calculate the force, etc.

HEARING*

The auditory system consists of the periphery sensors, acoustic neurological transducers, the ears, the eighth cranial nerve leading to a programming and priority switching center at various levels of the brain stem, and finally to the auditory area of the cortex located near the Sylvian fissure of the frontal-lobe convolution.

The auditory system does much more than detect minute sounds. Among other functions, it preferentially places more weight on certain preprogrammed characteristic sounds, localizes the direction of most sounds by a variety of ingenious techniques, and initiates involuntary actions for visual acquisition of the source.

The hearing mechanism was probably evolved to help man survive in a hostile environment, and not for linguistic communication or for musical entertainment.

The apparent loudness attributed to a sound varies not only with the sound pressure, but also with the frequency (or pitch) of the sound. In addition, the way it varies with frequency depends on the pressure. Fig. 1 illustrates experimentally determined equal loudness contours (SPL) as a function of frequency.

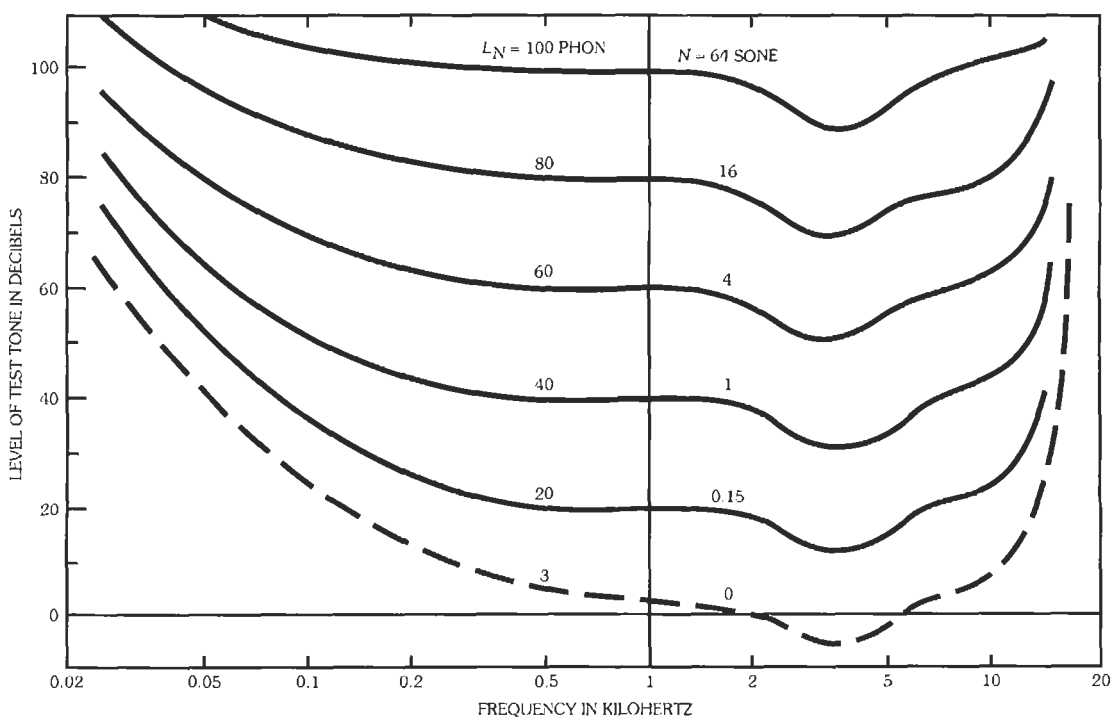

Fig. 1. Equal loudness contours. (*After Zwicker and Fastl*, Psychoacoustics—Facts and Models. *Springer Verlag, 1990.*)

MEASUREMENT OF SOUND

Sound Level Meters

A Sound Level Meter (SLM) is an instrument designed to measure directly sound-pressure levels while incorporating frequency weighting networks which approximate the inverse of equal loudness contours at various levels. The current American National Standard Specification for Sound Level Meters (ANSI S1.4A-1985) designates three alternate frequency weighting networks (Fig. 2) which correspond to the inverse of an experimentally determined moderate level "equal noisiness contour" and a "flat," or unweighted, measure. (In the latter case, the measurement bandwidth is determined by the microphone and electrical network characteristics.) Standard SLM also complies with International Electro-technical Commission (IEC) 651.*

An SLM measures the "quasi-root-mean-square" (rms) value of a time-varying sound pressure. Table 7 lists the rms detector time constant and corresponding label as given in ANSI S1.4A-1985. In addition, some SLMs incorporate a peak-hold (p) which captures the instantaneous largest sound pressure level.

An integrating-averaging SLM provides a "true-integrating" detector circuit in lieu of the quasi-rms detector. These meters are built in accordance with IEC-804. Typically, they measure time-average sound level (also called equivalent sound level) and sound exposure level.*

In text, complete description must be given for any measurement made (e.g., 55 dB B-weighted slow). In equations, SPLs are abbreviated as L_{AF} for A-weighted fast, L_{BI} for B-weighted impulse, L_{pC} for C-weighted peak, etc. Maximum should not be confused with peak. Peak refers to an instantaneous measure, while maximum refers to a detected level [e.g., max A-weighted slow ($L_{AF\max}$)].

* Definitions for these terms are given in the next section.

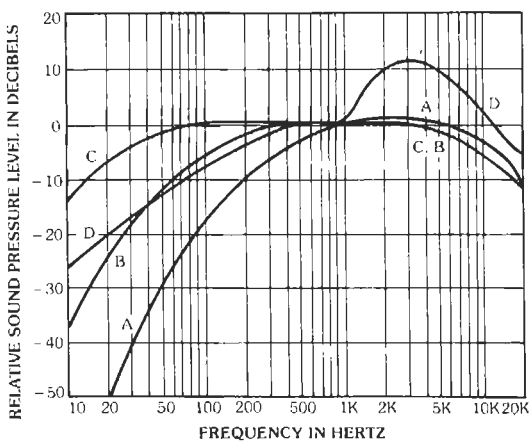

Fig. 2. IEC Standard A, B, and C weighting curves for Sound Level Meters. (*EPA*. Public Health and Welfare Criteria for Noise. *550/9-73-002. p. 2-2.*)

TABLE 7. SOUND LEVEL METER TIME CONSTANTS

Label	RMS Detector Time Constant
Slow (S)	1 s
Fast (F)	0.1 s
Impulse (I)	35 ms

Measurement and/or Laboratory Microphones and Their Calibration

Current measurement and/or laboratory microphones are generally capacitor, electret, or ceramic (piezoelectric) types. These are chosen because of their flat frequency response, low noise, and stability. One-inch and 1/2-inch microphones are the most common with smaller sizes also available. Capacitor microphones require a polarization voltage but are not potentially as susceptible to aging or temperature effects. All three are very high impedance devices requiring a FET follower close coupled for impedance transformation. For a given size, the ceramic microphone is on the order of 20 dB less sensitive than the capacitor or electret microphone.

Calibration is normally performed with a close-coupled single-frequency acoustical source. The acoustical signal may be generated mechanically (pistons driven by a cam and motor) or electromechanically. Typical frequencies are 1000 Hz and 250 Hz. Other frequencies, high pressure, and reciprocity calibrators are also available as needs dictate, but are generally not required.

Sound Level

In recent years it has become customary to measure most environmental or industrial work-place (occupational) noise with the A-weighting. In the United States, A-weighted SPL is the commonly designated sound level. (Special high-amplitude impulse sounds, such as sonic booms or explosions, which can noticeably vibrate structures are measured with C-weighting.)

Sound Power Level

One is usually concerned with the acoustic power radiated by some source of noise or radiated purposefully by a transducer such as a loudspeaker. Typically, these sources have a directivity pattern Q which is a function of angle. Radiated power is the normal component of the intensity integrated over an imaginary surface encompassing the source. (Sufficiently far from

TABLE 8. ACOUSTIC POWER AND SOUND POWER LEVELS OF TYPICAL NOISE SOURCES* (A-WEIGHTED)

the source, the intensity is proportional to the pressure squared.) Table 8 lists the PWL for some common noise sources.

DEFINITIONS

The following definitions are in accordance with ANSI S12.9-1988 and ANSI S12.7-1986.

Instantaneous sound pressure—Total instantaneous pressure at a point in the presence of a sound wave minus the static pressure at that point. Unit: pascal (Pa).

Sound power (level)—(A.) Sound power: The radiated acoustic power in a stated frequency band. Unit: watt (W). (B.) Sound power level: Ten times the common logarithm of the ratio of the sound power to the reference sound power, W_0, of 10^{-12} watts. Unit: decibel (dB).

$$L_w = 10 \log W/W_0$$

where W is the radiated acoustic power in watts and W_0 is the reference power of 10^{-12} watts.

Sound pressure (level)—(A.) Sound pressure: Root mean square of the instantaneous sound pressures in a stated frequency band and during a specified time interval, unless another time-averaging process is indicated. Unit: pascal (Pa). (B.) Sound pressure level: Ten times the common logarithm of the square of the ratio of the sound pressure to the reference sound pressure, p_0, of 20 micropascals. Unit: decibel (dB).

Sound (Level)—(A.) (Frequency-weighted) sound pressure: Root mean square of the instantaneous sound pressure which is filtered (frequency-weighted) with a standard frequency characteristic (e.g., A or C, etc.) and exponential time weighted in accordance with the

standardized characteristics slow (S), fast (F), impulse (I), or peak, both weightings as specified in ANSI S1.4A-1985. The time weighting should be specified. The frequency weighting should be specified; otherwise, A-weighting will be understood. Unit: pascal (Pa). (B.) Sound level: Ten times the common logarithm of the square of the ratio of the frequency-weighted (and time-averaged) sound pressure to the reference sound pressure, p_0, of 20 micropascals. Unit: decibel (dB). NOTE: A, C, or octave band sound levels are all sound levels having different frequency weightings which must be specified.

Time-average sound (level)—(A.) Time-average (frequency-weighted) sound pressure: (1) square root of the quotient of the time integral of frequency-weighted squared instantaneous sound pressures divided by the time period of integration in seconds; or (2) square root of the quotient of the sound exposure, in pascal-squared seconds, in a specified time period, divided by the time period of integration in seconds. Unit: pascal (Pa). (B.) Time-average sound level: Ten times the common logarithm of the square of the ratio of time-average (frequency-weighted) sound pressure to the reference pressure, p_0, of 20 micropascals. Unit: decibel (dB). NOTES: (1.) Time-average sound level is also termed equivalent-continuous sound level or equivalent-continuous frequency-weighted sound pressure level. (2.) A, C, or octave band time-average sound levels are all time-average sound levels having different frequency weightings which must be specified.

Peak sound pressure (level)—(A.) Peak sound pressure: For any specified time interval, the maximum absolute value of the instantaneous sound pressure in that interval. Unit: pascal (Pa). (B.) Peak sound pressure level: Ten times the common logarithm of the square of the ratio of the peak sound pressure to the reference sound pressure of 20 micropascals. Unit: decibel (dB).

Sound pressure (level)—(A.) Maximum sound pressure: For any specified time interval, the maximum value of the sound pressure in that interval. Unit: pascal (Pa). (B.) Maximum sound pressure level: Ten times the common logarithm of the square of the ratio of the maximum sound pressure to the reference sound pressure of 20 micropascals. Unit: decibel (dB).

Sound exposure (level)—(A.) Sound exposure: Time integral of squared, frequency-weighted instantaneous sound pressure. The time period of integration should be specified when the sound exposure of the background noise is a significant contributor to the total sound exposure, when the data may be useful for identifying a source, or when the time period of integration is otherwise useful. The frequency weighting should be specified; otherwise, A-weighting will be understood. Unit: pascal-squared second (Pa^2s). NOTES: (1.) One pascal-squared second is called a sound exposure unit. (2.) In principle, sound exposure is independent of the time period of integration. However, in practice, a measurement of sound exposure may be limited by the square of the equivalent sound pressure of the background noise multiplied by the time period of integration. In such a case, the time period of integration should be specified. (3.) Some instruments for measurement of sound exposure include a threshold sound level below which the instrument does not accumulate contributions to the integral. If the threshold sound level is above the level of the background noise, then the time period of integration need not be stated, but the threshold should be stated. (4.) For most transient sounds such as an aircraft flyby or a vehicle pass-by, etc., the A-frequency weighting is preferred. For short-duration, high-energy impulsive sounds, the C-frequency weighting is preferred, and measurements are to be made in accordance with ANSI S12.4-1986. (B.) Sound exposure level: Ten times the common logarithm of the ratio of sound exposure to the reference sound exposure (E_0) of 400 micropascal-squared seconds [400 $(\mu Pa)^2 s$]. Unit: decibel (dB). NOTES: (1.) In a given measurement time period of T seconds, the sound exposure level (L_{ET}) is related to the time-average sound (pressure) level (L_{pT}) as follows:

$$L_{ET} = L_{pT} + 10 \log_{10}(T/t_0)$$

where t_0 is the reference duration of 1 second. (2.) A, C, or octave-band sound exposure levels are all sound exposure levels having different frequency weightings which must be specified.

ENVIRONMENTAL NOISE

Current methods to assess environmental noise embody several relatively simple concepts. A fundamental concept is loudness. The human ear is more sensitive to the middle frequencies than it is to very low or very high frequencies.* So for purposes of noise assessment, the sound measured by a microphone, like the sound "measured" by the human ear, is filtered to remove much of the low and high frequencies. The International Organization for Standardization (ISO) and the American National Standards Institute (ANSI) recommend the A frequency-weighting curve to accomplish this filtering, and in the USA (as in most countries), the Federal Environmental Protection Agency (USEPA), the Federal Aviation Administration (FAA), etc., have adopted the use of this A frequency-weighting curve, a curve which removes much of the low and high frequencies (references 2 and 3).†

* Middle frequencies are about middle C to four octaves above middle C on the piano.

† The Illinois property-line-noise-source regulations go further and divide the sound spectrum into octave bands so as to create an environment which is more acceptable to communities than would be an environment regulated only by the A-weighting curve. These regulations go a second step further and divide the sound spectrum into 1/3 octave bands in order to regulate "pure tones" which may be particularly bothersome.

The first rule of current environmental noise assessment makes use of the concept of loudness. In effect, it states: All else being equal, a louder noise is more annoying to a community than is a quieter noise. In other words, all else being equal, community annoyance grows as loudness increases.

Environmental noise regulations typically take one of two forms. Either they are specified as simple SPL limits at some measurement locations or they are specified by time-integrated quantities. The former are similar in concept to "speed limits" or "discharge limits" and are relatively easy to enforce. They may take the form of property line limits such as so many decibels (A-weighted, slow) or may even be expressed as octave band or 1/3-octave band limits. (Some SLMs include an octave band filter set; others have octave and 1/3-octave filter sets available as attachments. The filters are specified by ANSI S1.11-1966 and IEC 225.) For vehicular sources, the limits are usually specified in terms of a maximum A-weighted fast (or slow) level at a reference distance (typically 15 m).

Airports, highways, railways, and other large, distributed time-varying sources are usually regulated and assessed by the use of time-integrated measures. Extensive research over the past three decades has shown that these time-integrated measures better correlate with human and community response than do the single event limits described above, but they are more difficult to use for purposes of enforcement. Time-integrated measures incorporate the second and third rules of current noise assessment procedures.

The second rule of environmental noise assessment deals with the duration or repetition of a sound. Basically, it states: For the same loudness, a longer-duration sound is more annoying than a shorter-duration sound, and sounds repeated many times are more annoying than are sounds repeated only a few times.

The third rule of noise assessment deals with the time of day. It basically states: All else being equal, sounds during some period(s) of the day result in greater overall net community annoyance than do these same sounds during other periods of the day.

In terms of noise assessment these three rules imply:

(1) We use a filter (or filters) proportional to hearing to measure the "loudness,"*
(2) We add up all the sound an event or operation creates to account for the duration as well as the loudness,
(3) We add in each event or operation separately to account for repetition, and,
(4) We count each event or operation at night as equal to ten daytime events.

To do all of this, we predict or measure the sound exposure of each event or operation. Sound exposure can be thought of as a measure of the loudness multiplied by the time it takes for the event or operation to occur, i.e., loudness times duration.

Next, we add up the sound exposure of each individual event or operation in order to develop the total sound exposure. In this fashion, we account for *all* of the noise. This point is very important and frequently misunderstood. Each event or operation in and of itself can be annoying, can interfere with communications, etc. But the noise impact to a community experiencing 10 or 100 of these events each day is far greater than is the impact to a community experiencing just one of these events.

Finally, we multiply the sound exposure of each event or operation which occurs at night by ten, or we divide its criterion sound exposure by ten before assessing the noise. In this way, we apply a nighttime adjustment. This, too, is a very important factor in assessing noise.

Two measures, defined below, are typically used to quantify noise impact. One is sound exposure (SE), and the other is time-average sound. These two are related by the time period of measurement. Sound exposure is proportional to the *total* sound energy during the time period, and time-average sound is the average sound during this same time period. Sound exposure and time-average sound level are usually expressed in decibels with reference to the standard reference pressure, p_0, of 20 μPa or the standard reference sound exposure, SE_0, of 400 $(\mu Pa)^2$-s.

In the United States, with the help of the National Academy of Sciences (NAS), the US Environmental Protection Agency (USEPA) created the day-night sound level (DNL) as the descriptor of choice for composite environmental noise assessment (references 2 and 3).* This descriptor, DNL, is really a measure of total day-night sound exposure as described in ANSI S12.9-1988 (reference 4).† In reality, measures such as DNL model the relation: Average community response is proportional to total sound exposure received by that community during a typical day. The underlying measure in DNL is total day-night sound exposure (DNSE) which is given by:

$$\text{DNSE} = \text{Total } SE_{\text{Day}} + (10)(\text{Total } SE_{\text{Night}})$$

and

* The Illinois property-line-noise-source octave-band level spectra are very similar to the inverse of equal loudness spectra and thus yield results monotonically related to loudness.

* The best summary of references 2 and 3 is: *Protective Noise Levels—Condensed Version of EPA Levels Document*. U.S. Environmental Protection Agency, EPA 550/9-79-100, November 1978.

† Sound exposure is exactly analogous to the concept of light exposure as used in photography. It is the product of the sound intensity times the duration of the sound. Sound exposure is discussed in Chapter 3 of reference 4, and a formal definition based on ANSI S12.9-1988 is given in Chapter 4 of reference 4.

$$DNL = 10 \log [DNSE/(T_0 SE_0)]$$

where

T_0 = 86 400, the number of seconds in a day

This is the actual way we calculate or measure DNL.

ASSESSMENT OF WORKPLACE-INDUSTRIAL NOISE

A Sound Level Meter (SLM) set on the A-scale can be used to assess industrial noise for hearing hazard. For enforcement purposes, the US Department of Labor (DOL) has set 90 dB (*A*) as the limit for eight hours of exposure per day. Most industrial noise is not uniform and continuous, and so the regulations of DOL include procedures for determining the equivalent exposure. These procedures incorporate a 5-dB trading rule in that halving the exposure time allows the noise limit to rise by 5 dB.* The present limits are given in Table 9.

As an alternative to using an SLM to measure industrial noise exposure, several personnel dosimeters are available that directly measure a worker's dose (usually as a percent of the eight-hour limit). These devices directly incorporate the 5-dB trading rule in their electronics.

Exposure to impulsive or impact noise should not exceed 140 dB peak sound pressure level.

* Most European countries use a 3-dB or equal energy rule, and the USAF uses a 4-dB rule.

TABLE 9. PERMISSIBLE NOISE EXPOSURES*

Duration per Day, Hours	Sound Level, dBA Slow Response
8	90
6	92
4	95
3	97
2	100
1½	102
1	105
½	110
¼ or less	115

* When the daily noise exposure is composed of two or more periods of noise exposure of different levels, their combined effect should be considered, rather than the individual effect of each. If the sum of the following fractions: $C_1/T_1 + C_2/T_2 + \ldots C_n/T_n$ exceeds unity, where C_n indicates the total time of exposure at the nth noise level and T_n indicates the total time of exposure permitted at that level, then the mixed exposure should be considered to exceed the limit value.

SOUND IN ENCLOSED ROOMS*

Indoors, acoustics is of concern for a variety of reasons. Auditoria, broadcast studios, etc., require low background noise levels and "good" acoustical design; offices require varying background levels and communications capabilities depending on use; and in the industrial workplace, conservation of hearing and ability to communicate are usually the primary concerns.

In any room, the reverberant SPL increases as the acoustic power entering the room increases and decreases as sound absorption in the room increases and/or as sound power flows from the room. Sources of sound may be internal to rooms, such as machinery or loudspeakers, or may be external. In the latter case, the sound flows through walls, windows, ventilation ducts, etc., from other building spaces or components, or from outdoors. In either case, the sound field in a room is composed of two parts, the direct field and the reverberant field. The direct field of a source is

$$p = \rho c k D Q^{1/2} / 2\pi^{1/2} r \qquad \text{(Eq. 9)}$$

where,

$k = (2\pi f/c)$ (rad/m),
p = pressure (N/m^2),
c = speed of sound (m/s),
ρ = density of air (kg/m^3)
D = source strength (m^3/s·rad),
Q = directivity (rad)†,
r = distance from the source (m).

Near a source, the sound field may be very complicated; the pressure and velocity may not be in phase, and hence the power radiated is not proportional to the pressure squared. This is particularly a problem when determining the noise power radiated by machinery in the industrial environment.‡

By substitution in equation 9, the direct field intensity (I_d) of a source can be written as

$$I_d = WQ/4\pi r^2 \qquad \text{(Eq. 10)}$$

where,

W = radiated source power (watts),

* See, for example, reference 2.5, 2.6, or 2.8.

† The directivity factor of a source is the ratio of the sound pressure squared, at some fixed distance and specified direction (such as the axis of a loudspeaker), to the mean-square sound pressure at the same distance averaged over all directions from the source. The distance must be great enough so that the sound appears to diverge spherically from the effective acoustic center of the source.

‡ Sound-intensity meters are a valuable aid in these situations, as they indicate the direction of the intensity.

Q = directivity (rad),
r = distance from the source (meters).

The total intensity (I) in an enclosed room (direct plus reverberant field) is

$$I = WQ/4\pi r^2 + 4W/R \qquad \text{(Eq. 11)}$$

The quantity R is the room constant defined by

$$R = S\bar{\alpha}/(1 - \bar{\alpha}) \qquad \text{(Eq. 12)}$$

where,

S = total surface area of the room,
$\bar{\alpha}$ = average room absorption coefficient.

Fig. 3 illustrates the sound fields in a room. In terms of the sound pressure level,

$$\text{SPL} = \text{PWL} + 10 \log (Q/4\pi r^2 + 4/R) + K \qquad \text{(Eq. 13)}$$

where,

K = 0.2 dB if metric units are used,
K = 10.5 dB if English units are used.

Standing Sound Waves

Resonant conditions in sound studios cause standing waves by reflections from opposing parallel surfaces, such as ceiling-floor and parallel walls, resulting in serious peaks in the reverberation-time/frequency curve. Standing sound waves in a room can be considered comparable to standing electrical waves in an improperly terminated transmission line where the transmitted power is not fully absorbed by the load.

In properly proportioned rooms, resonances can be effectively reduced and standing waves practically eliminated by introducing numerous absorbing surfaces disposed obliquely. Thus, large-order reflections can be avoided by breaking them up into numerous smaller reflections. The object is to prevent sound reflection back to the point of origin until after several absorbing reflections.

The most desirable ratios of dimensions for broadcast studios are given in Fig. 4.

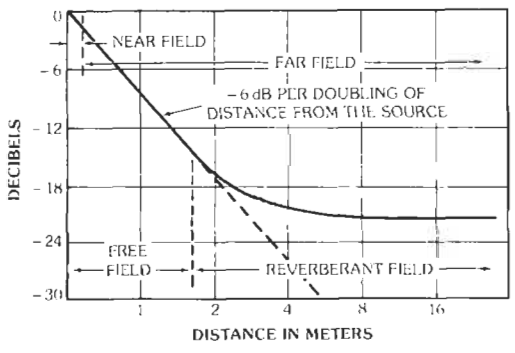

Fig. 3. Description of the sound field around a sound source in a reverberant room. (*From Ginn, K. B.* Architectural Acoustics. *Brüel and Kjaer, 1978.*)

Reverberation Time

Reverberation time varies with frequency and is measured by the time required for a sound, when suddenly interrupted, to die away or decay to a level 60 decibels below the original sound. Measurement of reverberation time is the easiest way to find the average absorption coefficient ($\bar{\alpha}$) and its associated value of reflectivity ($1 - \bar{\alpha}$) in an acoustic environment. Conversely, absorption coefficients and room sizes are used to predict the reverberation time for new construction or remodeling.

Measurement of Reverberation Time

The reverberation time of an enclosed space that already exists is an important quantity that is relatively easy to measure. The degree of accuracy required is determined by the use to which the data will be put. The majority of day-to-day reverberation measurements are taken with quite satisfactory results by using the interrupted-noise method (Fig. 5).

The Schroeder-Kuttruff method (Fig. 6) employs a 2.7-ms rectangular pulse that is used to excite a standard ⅓-octave bandpass filter. The resulting "ringing" of the filter provides a statistically reliable signal that allows highly repeatable decay recordings and excellent resolution of the EDT.

Calculation of Reverberation Time

The Sabine equation (equation 14 for room dimensions in feet, equation 14a for room dimensions in meters) is commonly used to calculate reverberation time.

$$RT_{60} = 0.049V/S\,\bar{\alpha} \qquad \text{(Eq. 14)}$$
$$RT_{60} = 0.161V/S\,\bar{\alpha} \qquad \text{(Eq. 14a)}$$

where,

RT_{60} is the time in seconds required for a sound to decay 60 dB,
V is the volume of the room,
S is the boundary surface area,
$\bar{\alpha}$ is the average absorption coefficient.

The value of $\bar{\alpha}$ is:

$$\bar{\alpha} = (s_1\alpha_1 + s_2\alpha_2 + \ldots s_n\alpha_n)/S \qquad \text{(Eq. 15)}$$

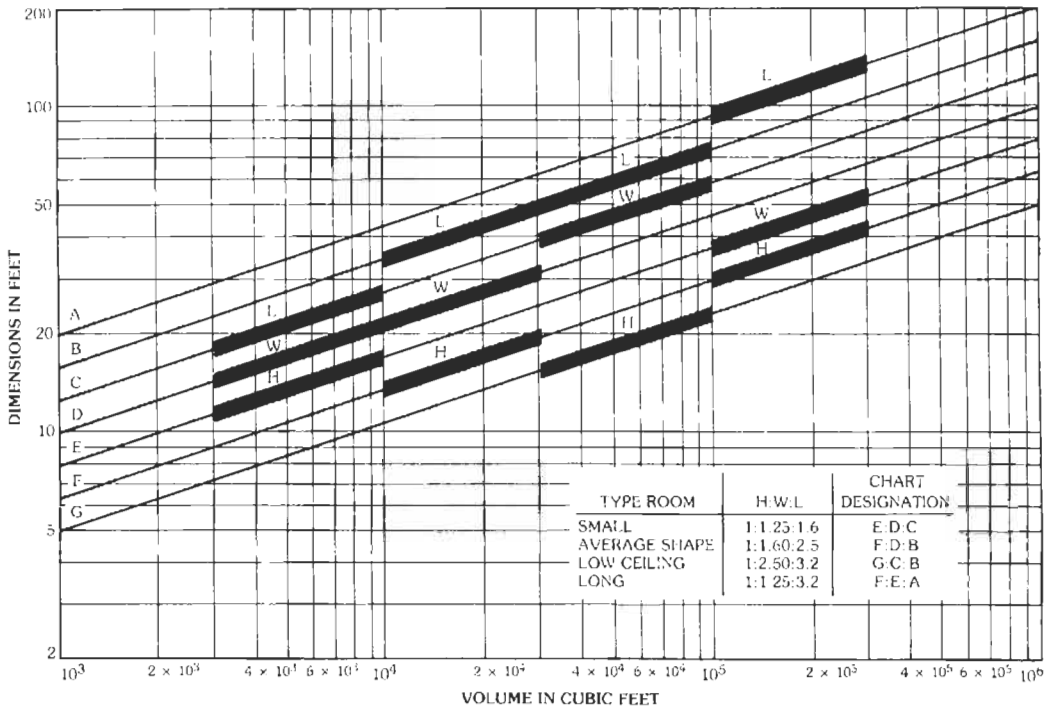

Fig. 4. Preferred room dimensions based on $2^{1/3}$ ratio. Permissible deviation is 5 percent. (*Courtesy Acoustical Society of America and RCA.*)

where,

s_1, s_2, etc., are boundary surface areas,
α_1, α_2, etc., are the absorption values for the boundary areas with which they are associated,
$s_n\alpha_n$ is the total absorption of the people, furniture, etc., present in the room.

Note that $S\bar{\alpha}$ can be replaced by A, the total absorption in the room. This concept is useful when considering the effects of surfaces plus objects or people in the room.

In the limiting case, the Sabine equation predicts a finite reverberation time in a room with 100% absorption present, and for true absorption values in excess of 0.63, this equation can give α values in excess of 1.0 (100% absorption). The Norris-Eyring equation (equation 16 or 16a) gives $\bar{\alpha}$ values from 1.0 to 0 for true absorption values when calculated from actual RT_{60} measurements.

$$RT_{60} = 0.049V/[-S \ln(1 - \bar{\alpha})] \quad \text{(Eq. 16)}$$

with room dimensions in feet or

$$RT_{60} = 0.161V/[-S \ln(1 - \bar{\alpha})] \quad \text{(Eq. 16a)}$$

with room dimensions in meters.

If the value of RT_{60} is measured and the corresponding value of $\bar{\alpha}$ is calculated, insertion of this value of $\bar{\alpha}$ into the expression $-\ln(1 - \alpha)$ converts the $\bar{\alpha}$ value into a Sabine $\bar{\alpha}$. For example, $-\ln(1 - 0.63) = 0.99$.

Absorption Coefficients

When tables of absorption values are examined, it is important to know which formula was used in determining the numerical values. If the values were obtained from the Sabine equation, be sure to use the Sabine

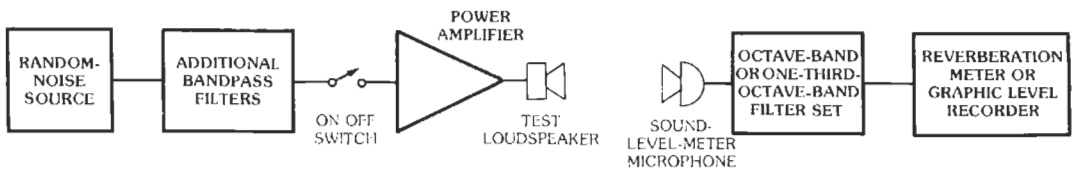

Fig. 5. The interrupted-noise method.

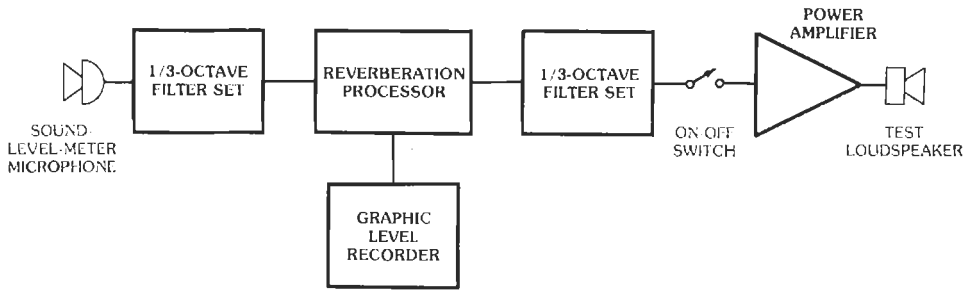

Fig. 6. The Schroeder-Kuttruff method.

equation variations consistently for any further manipulations of the data. If the Norris-Eyring equation was used, remain consistent in its use for any further manipulations of the data. The Sabine formula is used in measuring and specifying most building materials. Hence, the Sabine equation must be used unless the absorption values are converted (see above). Table 10 gives absorption coefficients of some typical building materials.

Optimum Reverberation Time

Optimum, or most desirable, midfrequency (500–1000 Hz) reverberation time varies with room size and use, such as music, speech, etc. (see Fig. 7).

INDOOR DESIGN NOISE LEVELS AND SPEECH COMMUNICATION

Preferred Speech Interference Levels/ Speech Interference Levels

Noise interference with speech is usually a masking process. For many noises, the measurement and calculation of articulation index can be simplified further by the use of a three-band analysis.* The bands chosen are the octave bands centered on 500, 1000, and 2000 Hz. The arithmetic average of these three SPLs in these three bands gives the quantity called the three-band preferred octave speech-interference level (PSIL). One can use this level for determining when telephone use or speech communication is easy or difficult and what changes in levels are required to improve the situation (Figs. 8 and 9).

For satisfactory intelligibility of difficult speech material, maximum permissible values of speech-interference levels for men with average voice strengths are given in Fig. 9, which is an extension by Webster of Beranek's work.* It is assumed in this chart that there are no reflecting surfaces nearby, that the speaker is facing the listener, and that the spoken material is not already familiar to the listener. For example, the speech-interference level in a factory might be 80 dB, which is high. The chart indicates that the two people must ordinarily be no more than two feet apart in order to be understood satisfactorily. If the words spoken are carefully selected and limited in number, intelligible speech will be possible at greater distances.

If a number of conversations are to be held in the same reverberant room, the procedure is more complicated. This chart cannot be used on the basis of the background-noise level before the conversations are in progress, because a given conversation will be subject to interference from the noise produced by all the other conversations. The general procedure for calculating a speech-interference level under those conditions has not been completely worked out.

Not only background, equipment, and other occupant noise affects speech intelligibility. In a live room (too much reverberation), speech syllables are smeared by reflected noise at the other end, even though the noise is not very great. That is, if the distance from speaker (or loudspeaker) to listener is too great or the room too reverberant, then the speaker's own sound energy may make the speech unintelligible. As a rule of thumb, the direct field from the speaker (or loudspeaker) must exceed his (its) own reverberant field by 6 dB in order to maintain good speech intelligibility and prevent feedback.

Interior Design Noise Levels

Table 11 contains a list of planning levels for activities conducted in interior spaces.* The (interior) planning levels for *exterior noise and for interior equipment that is not continuously operated* are given in terms of L_{eq} values. *Continuous noise sources*, for example ventilating systems or other mechanical equipment, emit steady-state noise that is measured in terms of L_s.* The sources must be considered separately. As indicated in the right-hand column of Table 11, permissible L_s values are 5 and 10 dB less than L_{eq} values for the same activity.

Interior steady-state noise levels more than 5–10 dB below the levels specified in Table 11 are not desirable. Annoyance will actually increase with the lowered background noise levels because individuals will hear intruding sounds that normally would be masked by the steady-state noise. Occasionally, where adequate noise insulation cannot be provided, increasing the continuous background noise levels over the values shown in Table 11 will provide better masking of intruding intermittent sounds. For such occasions, the characteristics of both the intruding noises and the background noise should be considered during the design of the facility.

SOUND ISOLATION†

Sound entering a room from external areas can be controlled by quieting the source, by adding absorption to the source room (if the source is indoors) to lower the

* In offices or office-type environments, Preferred Noise Criteria Curves (PNC) are frequently used to select and specify the ambient.

* L_s is the A-weighted noise level produced by the ventilation or mechanical systems (or other interior noise sources) which operate more or less continuously. The L_s value for design should be the noise level produced in the space during the time of occupancy while the equipment is at the typical mode of operation.

† See, for example, references 2.1 through 2.11.

TABLE 11. INTERIOR NOISE ENVIRONMENT PLANNING LEVELS

Activity	All Noise Sources L_{eq} (dB)	Continuous Interior Sources* L_2 (dB)**
Sleeping	45	40
Other residential activities (conversations, radio or TV listening, etc.)	50	40
Classrooms, libraries, churches, hospitals	45	40
Offices—private, conference	45	40
Offices/work spaces, telephone use satisfactory	55	45
Work spaces—occasional speech communication or telephone use	60	55
Work spaces—infrequent speech communication, telephone use infrequent	70	65
Concert halls, large auditoriums, theaters, or churches	30	25
Broadcast, TV, and recording studios	35	30
Small auditoriums, theaters, or churches	45	40

* Typically, ventilation systems and mechanical equipment in near-continuous operations.

** The L_2 value is given in terms of A-weighted noise level. The approximate noise criteria (NC) curve values are 8 dB less than the A-level values.

ambient level in the source room and hence the energy striking the party* surface, and by increasing the transmission loss of the party surface. Sound travels from sources into receiving rooms directly through building elements such as walls, windows, or doors or indirectly through "sound leaks" such as cracks, HVAC, plumbing, electrical facilities, plenums above suspended ceilings, corridors, etc.

Sound isolation should be contrasted with absorption. Efficient sound absorbers such as glass fiber or open-cell polyurethane foam do not contain or isolate sound. Efficient sound isolators or containers such as heavy walls do not absorb sound.

In the United States, the sound isolating value of walls and other elements is frequently specified in terms of STC (see ASTM E413-87). More recently, it is also specified in terms of ΔL_A, the A-weighted sound reduction between typically furnished small rooms (see ASTM E597-87). Where usable, ΔL_A has the advantage of easier field measurement than STC.

Walls

Figs. 10, 11, and 12 illustrate many building details and their corresponding STC and ΔL_A values. The total noise reduction between a source room and a receiving room is a function of the area of the party surface and the absorption in the receiving room. Small amounts of energy entering a very reverberant room will build up to high levels. Large wall areas with adequate STC being used to isolate a recording studio from a machine room will likely fail. Thus, party boundaries between noise-critical and noisy spaces should be minimized or eliminated.

Doors

Solid-core wood doors and hollow metal doors filled with insulation are generally better sound isolators than hollow-core doors; however, the amount of air space around the edges of the door is usually the controlling sound path. (See also the section on sound leaks.) For maximum sound isolation there must be a soft gasketing or weather stripping around the door to provide an airtight seal. The gasket must not be so stiff that it is difficult to close the door.

Resilient Channels

Frequent mention is made of the use of *resilient channels* to improve the noise-isolation performance of typical constructions. Typically, these channels are made of light-gauge metal in a Z-section, with one flange of the channel firmly attached to a stud or joist, and the other flange of the channel providing support for one or two layers of gypsum wall board. Because of the spring-like action of the metal between the two flanges, the gypsum board is able to vibrate independently of the wall supports.

In normal rigid constructions, sound energy from the source room passes directly from one surface (wall or floor), through the structural support (studs or joists), to the surface on the opposite side, causing this second surface to vibrate and thus reradiate sound energy from the source room. However, resilient channels reduce this structural continuity. Now, most of the sound energy from one side of the wall or floor will pass through the airspace between the studs or joists. This structural discontinuity greatly improves the sound isolation of the construction. Because the sound path in this case is through the wall or floor cavity, it is especially useful to have a sound-absorbing blanket of glass fiber or mineral wool insulation in the cavity air space. When resilient channels are not used, this insulation offers very little benefit, but when the resilient channels are used, this insulation should always be added.

It is very easy to short-circuit the isolation provided by the resilient channel. For example, wall-hung cabinets require rigid contact with the wall; they must be fastened directly to the studs, thus eliminating the isolation of the resilient channel. In general, use of the channels for wall constructions is not recommended; however, in special instances and for ceilings, which are out of direct contact and abuse, resilient channels can be very helpful.

For ceilings and walls, resilient channels might typically be attached 24 inches on center at right angles to the floor joists or studs. Gypsum board is then attached to the channels with screws (Fig. 13).

For wall installations, manufacturers often recommend that a 3-inch-wide continuous filler strip be applied at the base. This will provide good mechanical support for the baseboard and gypsum board against damage without sacrificing much resilience.

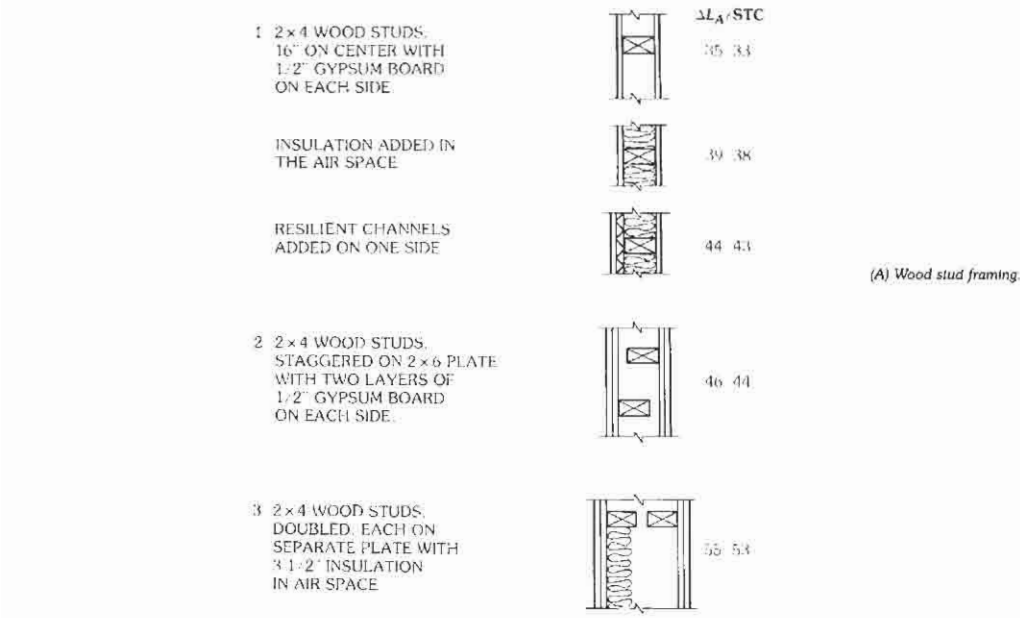
Weighting of Components

Each structural component (window, door, ceiling plenum, etc.) in a composite wall or sound path will contribute sound energy to the receiving room in proportion to the percentage of the total area occupied by that element. Therefore the ΔL_A value for the element must be weighted to correct for the area it occupies.

To weight the contribution of each element, use Table 12. For example, a wood solid-core door has a ΔL_A rating of 27 when fully gasketed; it occupies 20% of the wall area with a neighboring office. Therefore, its weighted contribution to the noise reduction between rooms is $27 + 7 = 34\ \Delta L_A$.

By looking at the weighted ΔL_A value for each structural component or flanking path or leak (described later), it is readily apparent what the controlling noise path is in any isolation analysis. Consider the

* The party surface is the surface (e.g., wall or ceiling) common to two spaces.



(A) Wood stud framing.

Insulation and resilient channels should always be used together.

Fig. 12. Floor/ceiling-system sound isolation.

example in Table 13. The door in this example is the "weak link." Improvements to other components will be of no benefit unless the ΔL_A value of the door is upgraded or its area is reduced.

The acoustical contributions for all sound-transmitting structural components (wall, door, window, etc.) must be combined to determine the performance of the composite wall. Since ΔL_A values for each element represent a *reduction* in sound from one side of the sound path to the other, the overall, combined ΔL_A value will decrease when the elements are combined (Table 14). For example: To determine the composite ΔL_A for the wall example, first combine ΔL_A 36 and ΔL_A 34. These two values differ by 2 dB; therefore, subtract 2 dB from the lower ΔL_A value: ΔL_A 34 less 2 dB = ΔL_A 32. Next, combine ΔL_A 32 and ΔL_A 42. These two values differ by more than 9 dB; therefore, subtract nothing from the lower ΔL_A value: ΔL_A stays at 32.

Flanking

Flanking is the transfer of sound through secondary sound paths that go around the common wall barrier between two spaces. These indirect passages can seriously degrade the sound isolation performance of an otherwise acceptable construction.

Typical flanking paths, A, B, C, D, and E, are shown in Fig. 14. In addition, flanking paths F and G are structural connections, which are less suitable for analysis with specific ΔL_A sound-isolation performance ratings. In these cases, a sound from a source room will be transmitted to a receiver room by way of a common wall or floor surface.

It is most important to break the structural paths that connect two spaces. Floors, rafters, and joists should not span between separate dwelling units. Interior

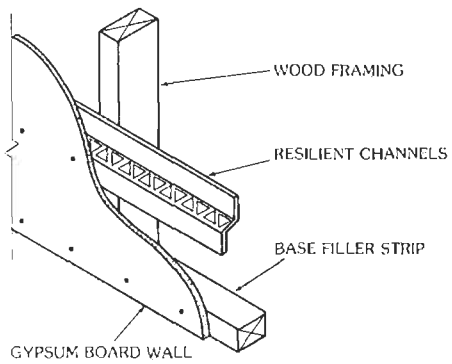

Fig. 13. Installation of resilient channels.

wallboard skins should not span between noise-sensitive spaces.

Leaks

Leaks are sound paths through open air passages caused by poor detailing, inadequate field supervision, and sloppy workmanship. They represent a major cause for poor performance of partitions and can be easily resolved by proper caulking and sealing of all openings and penetrations between spaces. Typical locations of leaks are shown in Fig. 15.

The noise isolation value of an untreated hole in a wall is, of course, $\Delta L_A = 0$. Depending on the size of the leak, the noise isolation performance of an entire wall or other structural component can be severely degraded. Fig. 16 plots this effect.

For example, consider a perfectly good composite construction with $\Delta L_A = 50$ and a typical area of 100 square feet (9 square meters). A crack only 0.01 inch (2.5 mm) high along the base of a wall 12 feet (4 meters) long would be a total opening of about 1.4

square inches. The ΔL_A performance would be degraded from 50 to 39. Also consider that a typical properly installed door with a 1-inch undercut for rugs or ventilation has an opening of about 40 square inches.

SOUND-REINFORCEMENT SYSTEMS*

Listeners should be almost unaware of the operation of a sound-reinforcement system. There should be adequate level, high intelligibility, and natural sound.

The purpose of a sound system is to boost the message or program sufficiently above the ambient level. Ideally, the amplification at the receiver should be unity. That is, the sound level at a receiver's ear should be about 65–70 dB, or the level generated by a speaker at a listening distance of 1 meter. In most auditoria or lecture rooms, the background level is not a problem, but in sports arenas, spectator noise can raise the ambient such that the direct sound amplification at the receiver must be much greater than unity. It has been found that about 9 dB of amplification at the receiver is the most that can go undetected—the sports-arena situation frequently requires more.

In general, a sound-reinforcement system may contain a single loudspeaker cluster or a distribution of loudspeakers. If the sound originates from a stage or performance arena, then a single cluster should be used if the sound is to be natural. An arrangement of two loudspeakers flanking the stage is inappropriate; the two speakers create interference patterns and an unnatural sound. If one speaker cluster cannot maintain sufficient level all the way to the rear of an audience, then

* Yerges, Lyle F. *Sound, Noise, and Vibration Control.* New York: Van Nostrand-Reinhold Co., 1969.

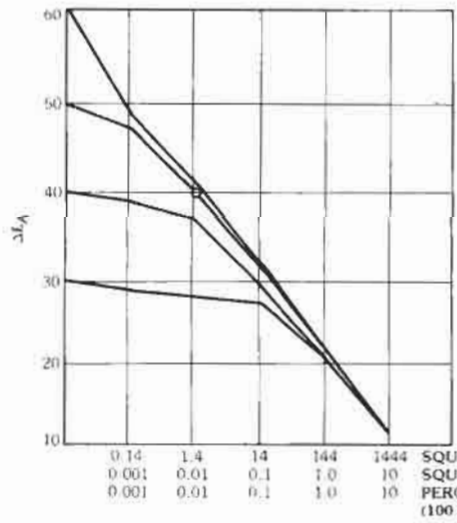

Fig. 16. The effect of leaks on ΔL_A value of partition system.

additional speakers can be added closer to the rear with appropriate time-delay hardware so that the sound remains realistic and in correct time phase with the source. Distributed loudspeaker systems are used when there is no identifiable source. Situations requiring distributed systems include paging, such as in offices, and background music, such as in food stores.

A rule of thumb for placing loudspeakers in a distributed system is:

$$D = 2(H - 4)$$

where,

D = distance between speaker centers in feet,
H = ceiling height in feet.

or

$$D = 2(H - 1)$$

where D and H are in meters.

The center of a single speaker should be aimed at the most distant centrally located receiver. The directivity pattern (vertically and horizontally) should be chosen to provide a uniform sound field to the audience given the elevation and plan of the room.*

41 Lasers

Joseph T. Verdeyen and Thomas A. DeTemple

The term "laser" is an acronym for *L*ight *A*mplification by *S*timulated *E*mission of *R*adiation. The first demonstration of an electronic amplifier using stimulated emission was in the microwave frequency domain where the acronym "maser" is used. Stimulated emission has been observed in amorphous and single crystal solids, semiconductors, and dyes and in atomic, molecular, and ionized gases. Fig. 1 shows the spectral region of operation of the various types of lasers, a smoothed version of atmospheric transmission, common detector classes, and transmissive materials for various optical functions. Since the operation of lasers is dependent on quantum interactions, they are known as quantum electronic devices.

ELEMENTARY RELATIONSHIPS

In order for a quantum electronic device to amplify (or attenuate) at a frequency ν_{21}, there must be a set of allowed energy levels (or bands) E_2 or E_1 in the material separated by the Planck spacing.

$$E_2 - E_1 = h\nu_{21} \qquad \text{(Planck's law)} \quad \text{(Eq. 1)}$$

An atom can make discontinuous jumps between these energy levels, accompanied by either the emission or absorption of a photon by one of three processes (Fig. 2).

A. *Stimulated emission* occurs when an external applied wave causes an atom to yield its potential energy given by Eq. 1 to the inducing wave. This added energy (photon) propagates in the same direction, at the same frequency and phase, and in the same sense of polarization as the stimulating field. This results in amplification of the wave.

B. *Absorption* occurs when the atom increases its potential energy by Eq. 1, thereby decreasing the wave energy by the same amount, and results in attenuation.

C. *Spontaneous emission* is the name for a $2 \rightarrow 1$ radiative transition for which there is no apparent external influence and which yields a photon at the frequency given by Eq. 1 in any of 4π directions. It is the cause of noise in quantum electronic amplifiers; however, discharge lamps produce most of their radiation by this process.

The rate of production of electromagnetic energy by the above processes is given by

Spontaneous:	$h\nu_{21}A_{21}N_2$	(Eq. 2)
Stimulated:	$h\nu_{21}B_{21}N_2g(\nu)I_\nu/c'$	(Eq. 3)
Absorption:	$h\nu_{21}B_{12}N_1g(\nu)I_\nu/c'$	(Eq. 4)

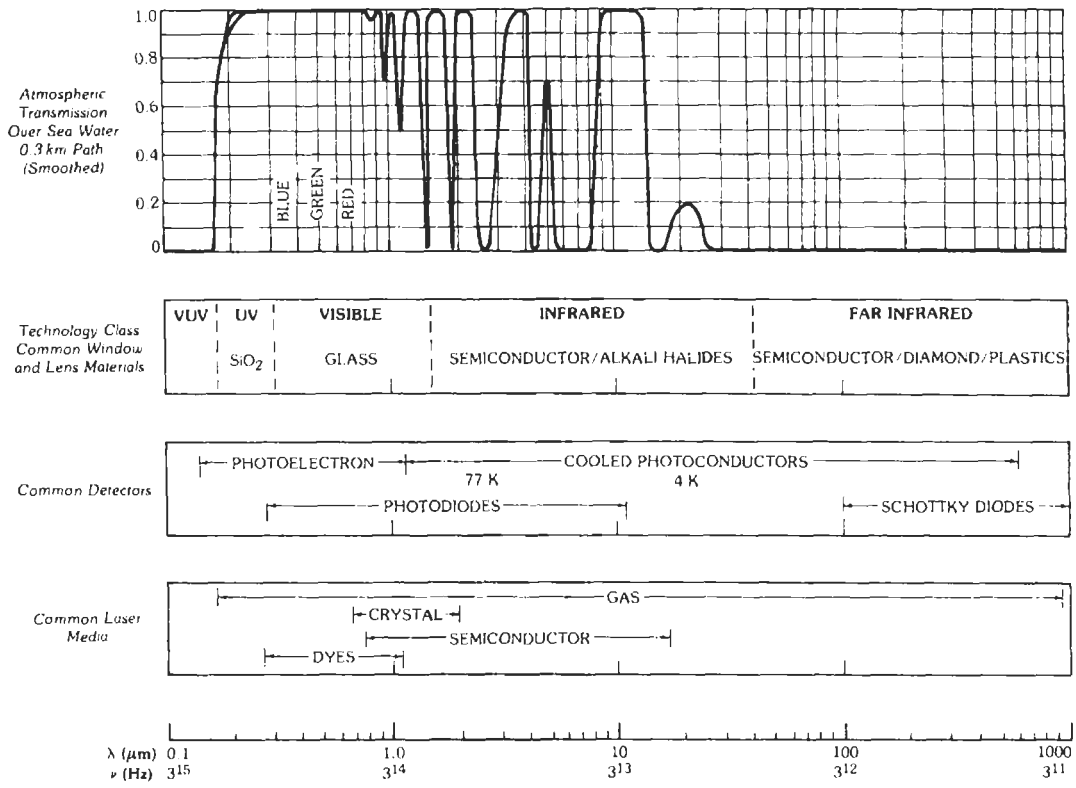

Fig. 1. Regions of operation of various types of laser and examples of the technology required in the various domains.

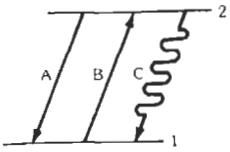

Fig. 2. Radiative processes between two levels in an atom. (The letters A, B, and C refer to stimulated emission, absorption, and spontaneous emission of radiation.)

where,

$N_{2,(1)}$ is the density of atoms in energy state 2 (1),
A_{21}, B_{21}, and B_{12} are the Einstein coefficients,
$g(\nu)$ is the line shape function,
I_ν is the intensity (watts/area) of the externally applied wave,
$c' = c/n$ is the velocity of propagation of the wave,
n is the index of refraction of the material.

The Einstein coefficients are interrelated.

$$A_{21}/B_{21} = 8\pi n^3 \nu^3/c^3 \qquad B_{21}/B_{12} = g_1/g_2 \qquad \text{(Eq. 5)}$$

where $g_{2(1)}$ is the degeneracy of the state, i.e., number of quantum levels with the same energy.

At thermal equilibrium, the ratio of the population of the two energy states, E_2 and E_1, which are separated by Eq. 1 is given by the Boltzmann distribution:

$$N_2/N_1 = (g_2/g_1) \exp[-h\nu_2/kT] \qquad \text{(Eq. 6)}$$

THE LINE SHAPE FUNCTION

The function $g(\nu)d\nu$ has the following physical interpretations:

A. It is the fraction of the spontaneous emission from state 2 to state 1 that appears in the frequency interval ν to $\nu + d\nu$.
B. It is the relative strength of interaction between the medium and the wave for stimulated emission or absorption.
C. It is the line profile of an optically thin transition.

Since it is a probability function, it obeys a normalization condition

$$\int_0^\infty g(\nu)\, d\nu = 1 \qquad \text{(Eq. 7)}$$

Transitions in the near IR through the UV in low-pressure gases (a few Torr) are broadened by the thermal motion of the atoms, which leads to a Doppler broadened (Gaussian) line shape:

$$g_D(\nu) = [(4 \ln 2)/\pi]^{1/2}(1/\Delta\nu_D) \exp \{(-4 \ln 2)[(\nu - \nu_{21})/\Delta\nu_D]^2\} \qquad \text{(Eq. 8)}$$

with

$$\Delta\nu_D = (8kT/Mc^2)^{1/2}\nu_{21} \qquad \text{(Eq. 9)}$$

where,

M is the mass of the atom (or molecule),
T is the temperature,
$\Delta\nu_D$ is the *f*ull-*w*idth-at-*h*alf *m*aximum (FWHM) of the transition centered at ν_{21}.

At higher pressures and/or longer wavelengths (lower frequency), elastic gas collisions broaden the transition, and the homogeneous (Lorentzian) line shape function becomes:

$$g(\nu) = \Delta\nu_h/2\pi[(\nu - \nu_{21})^2 + (\Delta\nu_h/2)^2] \qquad \text{(Eq. 10)}$$

with

$$\Delta\nu_h = (1/2\pi)[A_2 + k_2 + A_1 + k_1 + 2\nu_{col.}] \qquad \text{(Eq. 11)}$$

In Eq. 11, the A's are the total radiative decay rates of levels 2 and 1, the k's are total quenching rates of the two states, and $\nu_{col.}$ is the elastic collision rate of the active atoms or molecules with the other gas constituents. Usually, the elastic-collision term dominates, and one refers to the resulting line profile as "pressure broadened."

Seldom does one attempt to describe the line shape of a transition in a solid or band-to-band transition in semiconductors by elementary functions such as those used in Eqs. 8 and 10. Rather, one depends on the experimental determination of the line profile (e.g., C above) and often approximates $g(\nu)$ by

$$g(\nu) \simeq 1/\Delta\nu \qquad \text{(Eq. 12)}$$

where $\Delta\nu$ is the FWHM of the spontaneous emission of an optically thin line.

AMPLIFICATION IN A QUANTUM SYSTEM

The net rate of increase of an externally applied electromagnetic wave $I\nu$ (watts/area) per unit of length of active material is the difference between the stimulated rate of Eq. 3 and the absorptive rate given by Eq. 4:

$$dI_\nu/dz = h\nu_{21} B_{21}[N_2 - (g_2/g_1) N_1] g(\nu) I_\nu/c' \qquad \text{(Eq. 13)}$$

If $N_2 < (g_2/g_1) N_1$, one has a "normal" population with a positive "temperature" specified by Eq. 6; such a medium will attenuate an electromagnetic wave. If $N_2 > (g_2/g_1) N_1$, one has an "inverted" population with a "negative" temperature, and this medium will amplify an electromagnetic wave. By combining Eqs. 5 and 13, one obtains the *small-signal gain coefficient* given by

$$\gamma_o(\nu) \triangleq (1/I_\nu)(dI_\nu/dz) = A_{21}(\lambda^2/8\pi)\, g(\nu)[N_2 - (g_2/g_1) N_1] \qquad \text{(Eq. 14)}$$

where $\lambda = \lambda_o/n$. The collection of terms multiplying N_2 is often referred to as the *stimulated emission cross section* (i.e., "area")

$$\sigma_{se}(\nu) = A_{21}\ (\lambda^2/8\pi)\ g(\nu_{21}) \qquad \text{(Eq. 15)}$$

The absorption cross-section refers to the factors multiplying N_1 in Eq. 14.

$$\sigma_{abs}(\nu) = (g_2/g_1)\ \sigma_{se}(\nu) \qquad \text{(Eq. 16)}$$

The small-signal gain of the medium of length l is given by the expression

$$G_o = \exp \gamma_o(\nu) l \qquad \text{(Eq. 17)}$$

The subscript "o" in Eqs. 14 and 17 implies that the intensity of the stimulating wave is sufficiently small so as to create negligible perturbation on the density of atoms in the two states.

If the intensity is large enough, the populations, $N_{2,1}$, in Eq. 14 are functions of the intensity, I_ν, of the stimulating wave. For homogeneously broadened CW systems, the *saturated gain coefficient* is given by

$$\gamma(\nu) = \gamma_o(\nu)/[1 + (I_\nu/I_s)\ \bar{g}\ (\nu)] \triangleq (1/I_\nu)\ dI_\nu/dz \qquad \text{(Eq. 18)}$$

where,

$\gamma_o(\nu)$ is the small-signal value,
$\bar{g}(\nu)$ is the line shape function normalized to unity at line center,
I_s is the saturation intensity given by

$$I_s = h\nu_{21}/\tau_2\ \sigma_{se}(\nu_{21}) \qquad \text{(Eq. 19)}$$

In Eq. 19, τ_2^{-1} is the decay rate of state 2 due to all causes—radiation plus quenching, and $\sigma_{se}(\nu_{21})$ is the stimulated-emission cross section given by Eq. 15 evaluated at line center.

The overall gain, G, of the amplifier is thus a function of the input intensity and is found by integrating Eq. 18 from 0 to l.

$$\ln G + (I_{in}/I_s)\ \bar{g}(\nu)\ (G - 1) = \gamma_o(\nu) l \qquad \text{(Eq. 20)}$$

where $G = I_{out}/I_{in}$.

The maximum intensity that can be extracted from an amplifier by stimulated emission is given by

$$(I_{out} - I_{in})\Big|_{max} = \gamma_o(\nu_{21}) I_s l \qquad \text{(Eq. 21)}$$

For inhomogeneously broadened transitions the saturated law is modified:

$$\gamma(\nu) = \gamma_o(\nu)/(1 + I_\nu/I_s)^{1/2} \qquad \text{(Eq. 22)}$$

where all factors are as defined previously, and Eqs. 20 and 21 must be suitably modified.

LASER THRESHOLD

Oscillation with an inverted population is possible provided sufficient feedback is provided, usually in the form of an open cavity. In general, the necessary condition for oscillation is that net round-trip gain must exceed 1 so that an initially small wave can grow in amplitude as it passes around the feedback path. For a simple system such as that shown in Fig. 3, the threshold condition is

$$R_1 R_2 T_a^2 T_b^2 \exp [2\ \gamma_o(\nu) l] \geq 1$$

or

$$\gamma_o \geq (1/l) \ln (1/\sqrt{R_1\ R_2}) + (1/l) \ln (1/T_a\ T_b) \triangleq \alpha \qquad \text{(Eq. 23)}$$

In Fig. 3, the power transmission coefficients for the windows at the ends of the laser cell are T_a and T_b, and those of the mirrors are $T_1 = 1 - R_1$ and $T_2 = 1 - R_2$. Implicit in Eq. 23 is the assumption that the population inversion exists long enough to allow many transits back and forth between mirrors.

If the transition is homogeneously broadened, then oscillation will occur on a cavity mode that has the highest gain-to-loss coefficient ratio γ_o/α. For the simple laser shown in Figs. 3 and 4, this would correspond to the cavity mode nearest line center. If the transition is inhomogeneously broadened, multimode oscillation is possible on those cavity modes at frequencies ν_q such that $\gamma_o(\nu_q)/\alpha > 1$.

CW Oscillation

For the simple laser shown in Fig. 3, there are three types of losses: internal discrete losses represented by the imperfect transmission by the windows, a residual loss due to imperfections in the medium, and external or coupling losses by virtue of the transmission through the mirrors. The photon flux inside the cavity builds up to a large intensity so that the gain coefficient (Eq. 18 or 21) saturates at the threshold value given by Eq. 23. If the mirrors are highly reflecting, little power escapes the cavity; if the mirrors have too large a transmission coefficient, the laser fails to oscillate. The transmission coefficient of M_2 that provides maximum output power from the laser illustrated in Fig. 3 is

$$T_2 = -L + (g_o L)^{1/2}; \qquad (T_1 = 0) \text{ (Eq. 24)}$$

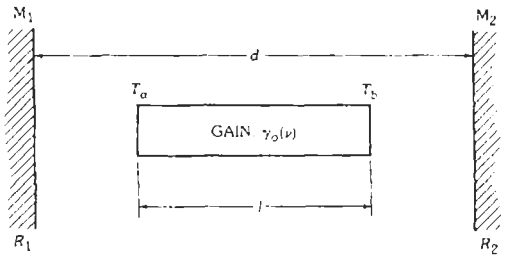

Fig. 3. A simple laser.

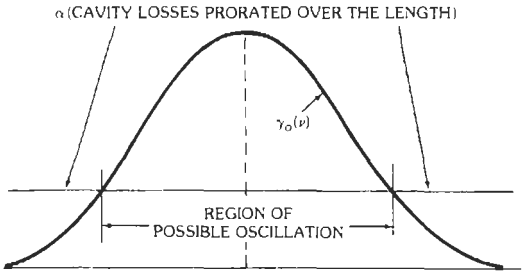

Fig. 4. Spectral bandwidth available for oscillation.

where,

$g_o = \gamma_o \cdot 2l$ is the gain coefficient integrated over the double pass through the active medium,
$L = \alpha_{int} \cdot 2l$ is the integrated internal losses given by

$$\alpha_{int} = (1/2l)\,[\ln(1/R_1) + \ln(1/T_a^2T_b^2)] + \alpha_{residual} \quad \text{(Eq. 25)}$$

The output intensity (through M_2) is given by

$$I_{out} = (I_s/2) \cdot [g_o/(L + T_2) - 1]\,T_2 \quad \text{(Eq. 26)}$$

For T_2 given by Eq. 24, the output intensity is given by the expression

$$I_{out} = (I_s/2) \cdot [\sqrt{g_o} - \sqrt{L}]^2 \quad \text{(Eq. 27)}$$

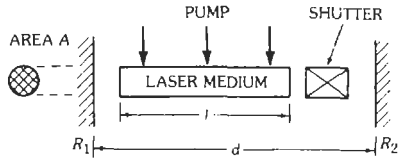
If $\sqrt{g_o} >> \sqrt{L}$, then $I_{out} \simeq (I_s\, g_o)/2 \simeq \gamma_o l I_s$.

Transient Operation

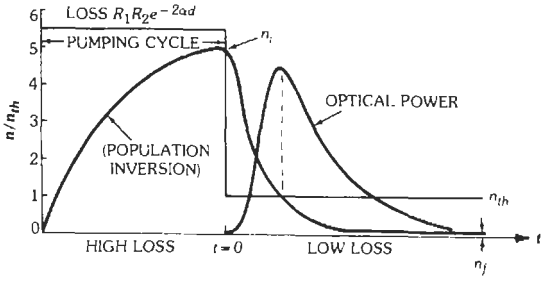
The previous discussion presumes steady-state or CW laser oscillation. However, some lasers are operated in a pulsed mode with rather spectacular results, as discussed below.

If the upper laser level has a lifetime that is long compared to the pumping duration, then it is a candidate for Q-switching. The scheme is similar to that used for radar modulators in which energy is slowly stored in a capacitor, transmission line, or PFN and then is rapidly discharged into the magnetron load. In the laser scheme, the energy is stored in the upper quantum state and is then extracted by stimulated emission.

The scheme is illustrated in Fig. 5. The Q of the laser cavity is spoiled (intentionally) during the time the upper state is being populated by the external pump, thus preventing lasing. When the upper state has reached an equilibrium with the pump, the cavity Q is restored to its high value. The population inversion is larger than threshold for CW oscillation, and thus stimulated emission rapidly amplifies the photons initially present in the cavity. This buildup occurs so rapidly that one can neglect any pumping on the time scale of the output pulse; in fact, it is so rapid and intense that the population inversion is driven below threshold for CW oscillation.



(A) The optical cavity



(B) Time evolution of the population difference and the optical pulse.

Fig. 5. Q-switching of a simple laser. (*From J. T. Verdeyen, Laser Electronics. Englewood Cliffs, N. J.: Prentice-Hall, Inc., 1981; Fig. 9-5.*)

The parameters that characterize the Q-switched pulse are:

n_i = initial number of inverted atoms or molecules in the cavity
n_{th} = the inversion required for CW oscillation in the high-Q cavity
n_f = the final inversion in population (see Fig. 5)
$T = t/\tau_c$, time divided by the passive cavity lifetime

The peak power produced by such a laser is given by:

$$P_p = k(h\nu/\tau_c)\,[(n_i - n_{th}/2) - (n_{th}/2)\ln(n_i/n_{th})] \quad \text{(Eq. 28)}$$

where k is the coupling factor on the order of 1/2.

The output energy of the Q-switch pulse is given by

$$W_{out} = k \cdot [(n_i - n_f)/2]h\nu \quad \text{(Eq. 29)}$$

and the final inversion is found from a solution to

$$n_f/n_i = \exp[-(n_i - n_f)/n_{th}] \quad \text{(Eq. 30)}$$

Inasmuch as the maximum energy that could be extracted is $n_i \cdot h\nu/2$, Eq. 29 can be written as:

$$W_{out} = k \cdot [(n_i - n_f)/n_i] \cdot (n_i h\nu/2) \quad \text{(Eq. 31)}$$

The quantity $(n_i - n_f)/n_i$ is called the energy extraction efficiency and is plotted in Fig. 6A. The time evolution of this Q-switch pulse requires a numerical solution of the coupled differential equations. A typical solution is shown in Fig. 6B for various values of the ratio n_i/n_{th}. A

(B) The time evolution of the Q-switched pulse, time normalized to the passive cavity lifetime.

Fig. 6. Characteristic parameters of Q-switching. (*From J. T. Verdeyen,* Laser Electronics. *Englewood Cliffs, N.J.: Prentice-Hall, Inc., 1981: Figs. 9-7 and 9-8.*)

rough estimate for the FWHM of the pulse can be found by combining Eqs. 28 and 31:

$$\Delta t_{1/2} \simeq W_{out}/P_p \qquad \text{(Eq. 32)}$$

Modelocking

If the system is inhomogeneously broadened, the laser may oscillate on many cavity modes within the spectral bandwidth available for oscillation (Fig. 4). If these modes can be locked together in a definite phase sequence, then the time-domain representation of the output consists of a series of pulses at a repetition rate equal to the round-trip transit time of a photon in the cavity.

Each individual pulse is very short; typically, 0.1 to 2 ns is common, with 30 fs (30×10^{-15} s) being the shortest presently recorded. The time evolution of these pulses is related to the spectral distribution of modes by the Fourier transform pair (see Chapter 7). Rough rules of thumb for the pulse characteristics are:

$$\text{Peak power} = N \times \text{average power} \qquad \text{(Eq. 33a)}$$

$$\text{Pulse repetition rate} = c'/2d \qquad \text{(Eq. 33b)}$$

$$\text{Pulse width} = (2d/c')/N \approx 1/\Delta v \qquad \text{(Eq. 33c)}$$

where,

N is the number of modes locked,
$2d/c'$ is the round-trip transit time,
Δv is the FWHM of the transition.

OPTICAL CAVITIES

Optical cavities perform the essential function of providing positive feedback for the quantum electronic amplifier so as to obtain oscillation. The spontaneous emission from the upper state of the quantum system is reflected by the mirrors and amplified by the inverted population. The cavity also selects the oscillation frequency within the spectral bandwidth defined in Fig. 4. The laser depends upon stimulated emission for amplification, and that rate is a maximum at the resonant frequencies of the cavity since the electromagnetic energy is a maximum under these conditions.

The resonant buildup of electromagnetic energy in any cavity is due to the near-perfect phase addition of the various partial waves bouncing back and forth between the mirrors. In general then, the resonant frequency of any cavity is determined by

Round-trip phase shift

= Integral multiple of 2π radians (Eq. 34)

If one assumes a uniform plane wave for the normal mode of the simple Fabry-Perot cavity shown in Fig. 7A, then Eq. 34 reduces to

$$v_q = q\, c'/2d \qquad \text{(Eq. 35)}$$

where,

c' is the velocity of light in the medium between the mirrors,
q is an integer.

Typically $d \simeq 0.1$ to 1.0 m for solid-state and gas lasers, and thus $c'/2d \simeq 150$ MHz to 1.5 GHz,

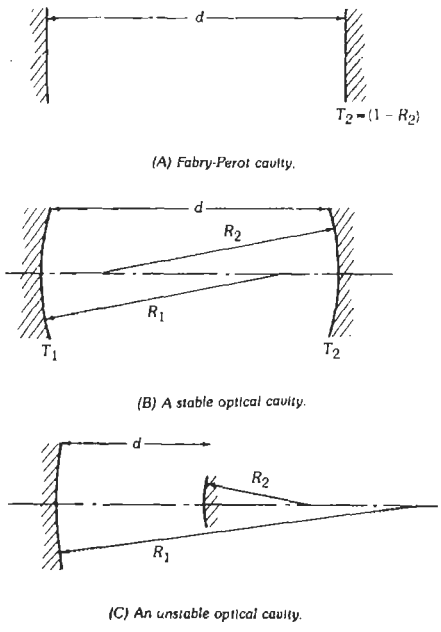

Fig. 7. Typical cavities used with lasers.

considerably smaller than the line width of many transitions (approximately 5 to 100 GHz).

Most optical cavities use one or more focusing elements in the manner indicated in Figs. 7B and 7C. The cavity shown in Fig. 7B is *stable* in the sense that the maximum excursion of a paraxial ray from the axis of the cavity is bounded. However, a ray will "walk off" the surfaces of the feedback mirrors of Fig. 7C; hence, this cavity is classified as *unstable*. Simple cavities such as those shown in Fig. 7 are stable if

$$0 \leq g_1 g_2 \leq 1 \qquad \text{(Eq. 36)}$$

where,

$$g_{1,2} = 1 - d/R_{1,2} \qquad \text{(Eq. 37)}$$

If the equality is not satisfied, the cavity is unstable. The stability criterion given by Eq. 36 is quite often embodied in a graphical format such as shown in Fig. 8. The dashed curves illustrate the equiloss contours for the unstable cavity. The quantity Γ is related to the mean fractional power lost per pass by $\Gamma = 1 - L$. For stable cavities, the diffraction loss (i.e., loss around edges of the mirrors) is very small; most of the loss of electromagnetic energy is transmission through the mirrors.

Unstable cavities have a very large mode volume and thus can utilize the stimulated emission from a large number of atoms. The losses from around the edges of the mirrors are usually large compared to the loss from direct coupling—usually by design. One can relate Γ, the mean fraction of the power that survives a single pass through the cavity, to the cavity g parameters by

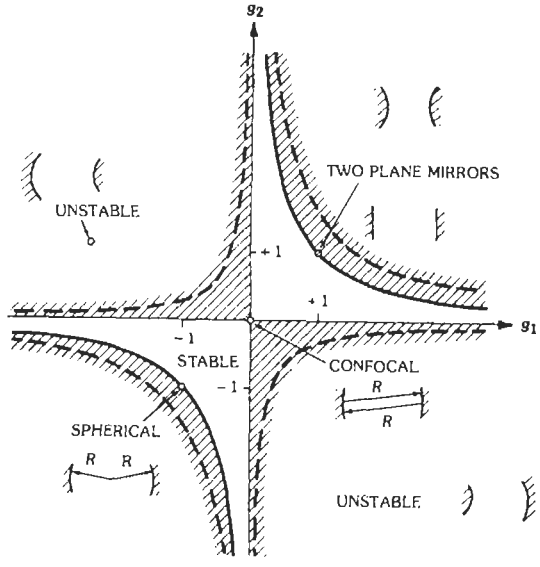

Fig. 8. Graphical display of the stability of optical cavities.

$$\Gamma = \pm \frac{1 - [1 - (g_1 g_2)^{-1}]^{1/2}}{1 + [1 - (g_1 g_2)^{-1}]^{1/2}} \qquad \text{(Eq. 38)}$$

where the choice of the sign is determined by the requirement that $0 < \Gamma < 1$. This leads to the equiloss contours shown in Fig. 8.

If all external sources of electromagnetic energy for the resonant mode of a cavity are suddenly removed, the energy will decay with time constant τ_p, called the photon lifetime:

$$dW/dt = -W/\tau_p \qquad \text{(Eq. 39a)}$$

$$\tau_p = \frac{\text{Time for a round trip}}{\text{Fraction of energy lost per round trip}} \qquad \text{(Eq. 39b)}$$

where W is the energy stored in the cavity.

For the simple cavity shown in Fig. 7B, this leads to the expression

$$\tau_p = (2d/c)/(1 - R_1 R_2) \qquad \text{(Eq. 40)}$$

where all losses except those due to imperfect mirror reflectivities have been neglected.

The photon lifetime is directly related to the cavity Q by the equation

$$Q = 2\pi \times \frac{\text{Energy stored}}{\text{Energy lost in a cycle}} \qquad \text{(Eq. 41a)}$$

or

$$Q = \omega_o W/(-dW/dt) \qquad \text{(Eq. 41b)}$$

where ω_o is the (angular) resonant frequency of the

cavity. The differential equation of Eq. 41b is the same as Eq. 39a and relates Q and τ_p by

$$\tau_p = Q/\omega_o \qquad \text{(Eq. 42a)}$$

The full-width at half maximum (FWHM) of the cavity resonance is given by the familiar formula

$$\Delta\omega = \omega_o/Q \quad \text{or} \quad \Delta\nu = \nu_o/Q \qquad \text{(Eq. 42b)}$$

Hence

$$\Delta\omega\tau_p = 1 \qquad \text{(Eq. 42c)}$$

HERMITE-GAUSSIAN BEAM MODES

Stable cavities such as that shown in Fig. 7B produce a beam whose electric field is described by

$$E_{m,n}(x,y,z) = E_o(w_o/w(2))\, H_m(\sqrt{2}x/w)\, H_n(\sqrt{2}y/w) \cdot \exp[-(x^2+y^2)/w^2] \cdot \exp[-jk(x^2+y^2)/2R(z)] \cdot \exp\{-j[kz - (1+m+n)\tan^{-1} z/z_o]\} \qquad \text{(Eq. 43)}$$

where H_m is a Hermite polynomial and $k = \omega/c$. The mode indices, m and n, refer to the variation of the TEM field in the x and y directions similar to the convention used for waveguides. The interrelationships between the parameters in Eq. 43 are listed below.

$$w^2(z) = w_o^2\,[1 + (z/z_o)^2] \qquad \text{(Eq. 44a)}$$

$$R(z) = z\,[1 + (z_o/z)^2] \qquad \text{(Eq. 44b)}$$

$$z_o = \pi w_o^2/\lambda \qquad \text{(Eq. 44c)}$$

$$H_n(u) = (-1)^n (\exp u^2)\,(d^n/du^n) \exp(-u^2) \qquad \text{(Eq. 44d)}$$

The plane $z = 0$ is defined to be the location where the spot size, w, is a minimum and the wave-front curvature becomes planar ($R = \infty$). The spot size of the beam will expand by $\sqrt{2}$ when it has propagated a distance z_o from $z = 0$. The interrelationships are plotted in Fig. 9 for the $TEM_{o,o}$ mode.

Notice that in the far field the beam expands as if it were a spherical wave of limited angular extent and originating at $z = 0$. Angle θ is the angular divergence of the beam given by

$$\theta = 2\lambda/\pi w_o \qquad \text{(Eq. 45)}$$

and is an important laser characteristic.

The characteristic parameter, z_o, and the location of the plane $z = 0$ are related to the radius of curvature of the mirrors and the spacing for the cavity shown in Fig. 7B by:

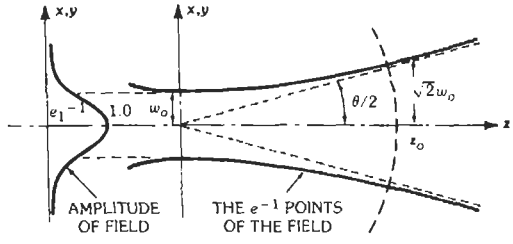

Fig. 9. The expansion of a $TEM_{o,o}$ mode.

$$z_o^2 = (\pi w_o^2/\lambda)^2 = \frac{d(R_1 - d)(R_2 - d)(R_1 + R_2 - d)}{(R_1 + R_2 - 2d)^2} \qquad \text{(Eq. 46a)}$$

$$z_1 = d(R_2 - d)/(R_1 + R_2 - 2d) \qquad \text{(Eq. 46b)}$$

$$z_2 = d(R_1 - d)/(R_1 + R_2 - 2d) \qquad \text{(Eq. 46c)}$$

The resonant frequencies of the $TEM_{m,n}$ modes differ slightly from those predicted by Eq. 35:

$$\nu_{m,n,q} = (c'/2d)\,\{q + [(1+m+n)/\pi] \cos^{-1}(g_1 g_2)^{1/2}\} \qquad \text{(Eq. 47)}$$

COMMON LASERS

Gases, impurity doping in crystalline and amorphous solids, direct bandgap semiconductors, and dyes dissolved in various solvents are the common materials used for lasers. All have a common theoretical framework, but the details of the excitation route differ from one type to another as illustrated in Table 1.

The excitation can be either pulsed or CW, resulting in the corresponding temporal characteristic of the laser radiation. With the exception of the semiconductors, the wall-plug efficiency of most lasers is typically less than 1%; the CW CO_2 gas laser system is an exception with efficiencies of 10–20% being common. Therefore, many very high power lasers are operated in a pulsed mode so as to dissipate the waste heat associated with the excitation. Many lasers, such as N_2 at 0.337 μm, require pulsed operation since only a transient inversion can be created.

Table 2 lists some common high-power pulsed lasers; typical pulse widths and the optical energy produced are shown. Table 3 lists common CW lasers. It should be noted here that even a milliwatt (10^{-3} W) coherent laser is potentially hazardous to the eye. Consequently, wavelength-selective eyeglasses are recommended, since even the backscatter of high-power lasers from rough surfaces can exceed this level.

TABLE 1. COMMON EXCITATION MECHANISMS FOR VARIOUS LASERS

Material	Excitation Route
Gases	Electric discharge. Optical pumping, chemical reactions.
Impurity doping in solids	Optical pumping usually with incoherent flash lamps, halogen lamps, or semiconductor LEDs.
Semiconductor	Carrier injection.
Dyes	Coaxial flash lamps, N_2 laser, excimer, or harmonics of YAG (0.532 μm, 0.355 μm) for pulsed operation; argon or krypton ion lasers for CW operation.

The output of various dyes depends on the solvent, the concentration of the dye, and the source of excitation. This is illustrated in Fig. 10, where the relative energy versus wavelength is plotted for the common sources of excitation. Flash-lamp-pumped dyes produce the highest energy per pulse, approximately 0.2 J, and the longest pulse width, approximately 0.2 μs, but typically at a rather slow repetition rate of a few pulses per second. The N_2 laser at 0.337 μm or the second and third harmonics of Nd:YAG are used to produce high power (tens of kilowatts) and short pulse widths (5 ns) at moderate repetition rates of 10–100 pps. Continuous-wave dye lasers are usually excited with the lines from an argon or krypton ion laser. While the conversion efficiency of the dye is quite reasonable (10–25%), the electrical efficiency of the pump laser is usually less than 0.1%.

Titanium-doped sapphire lasers, pumped by argon ion lasers, have tuning characteristics which are similar to those of near-infrared dye lasers, but with a higher output power. Typical tuning curves for this laser are shown in Fig. 11.

Many of the far-infrared lasers, using various gases such as CH_3OH, are pumped by the CO_2 laser. Fig. 12 illustrates the range of powers and frequencies available when such a pumping scheme is used.

SEMICONDUCTOR LASERS

Population inversion, and thus optical gain in the sense of Eq. 14, may be obtained in a direct bandgap semiconductor exhibiting radiative recombination of electrons and holes provided there is, simultaneously in space and time, a large density of electrons in the conduction band and holes in the valence band such as that provided by the junction region of a diode under heavy forward bias where large numbers of electrons and holes exist.

Such a diode is shown in Fig. 13 for a homojunction laser consisting of, for example, heavily doped regions of GaAs to form a pn junction. Under forward bias, electrons are injected into the p region, leading to an "inverted" population of width 1 μm or so perpendicular to the junction. The light (L) output is directly proportional to the recombining carriers and thus is directly related to the injected current (I). At low currents, the device acts as a LED. Beyond a threshold current, stimulated emission of recombination takes place, and the slope of light output versus current shows a dramatic increase. Due to the short recombination lifetime (typically 10^{-9} second), one is able to amplitude modulate the light output by simple current modulation.

Semiconductor lasers that involve only one material (e.g., GaAs) are classified as *homo*junctions; those that utilize a different material on one side of the active region are called single heterostructures (SH); if both sides use different materials, the device is called a double heterostructure (DH). Usually, the different materials used to obtain a heterostructure have a different bandgap and index of refraction than that of the active region. A typical configuration for a double heterostructure is shown in Fig. 14. The higher bandgap confines the carriers, and change in index of refraction guides the electromagnetic mode. Due to the small size of the active region, the divergence angle of the mode may be on the order of 10–20° and is different in the planes parallel or perpendicular to the junction.

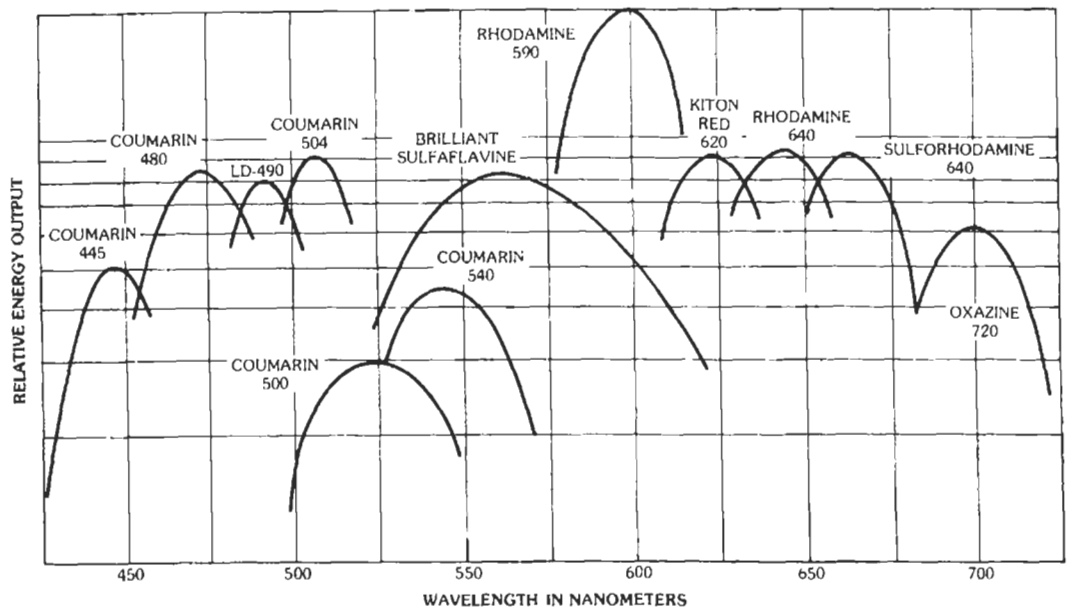
Fig. 15 shows the emission ranges of semiconductor lasers obtained with various combinations of III-V and IV-VI materials. For a given material system, the emission range corresponds to different crystal compositions and not the wavelength tuning of a single laser. Typical threshold currents for heterostructure lasers are in the range from 1 to 50 mA; output powers range from 1 to 50 mW. The very-long-wavelength diodes require cryogenic cooling.

NONLINEAR OPTICS

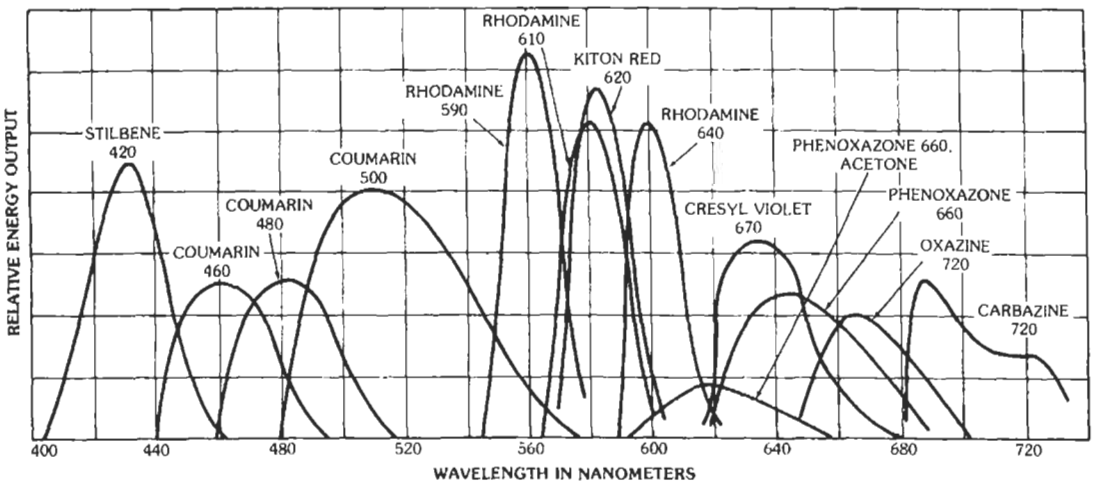
As in the case of other electronic devices, under suitable conditions the ordinary linear behavior of transparent materials becomes nonlinear. These nonlinearities, which are caused by strong optical or low-frequency electric fields, are used in the frequency and amplitude control of light.

The various effects are described by a simple Taylor series expansion of the microscopic polarization

$$P = \epsilon_0\chi^{(1)}E + \epsilon_0\chi^{(2)}EE + \epsilon_0\chi^{(3)}EEE + \cdots \quad \text{(Eq. 48)}$$



(A) Coaxial flash lamp pumped dyes (Candela Corp.).



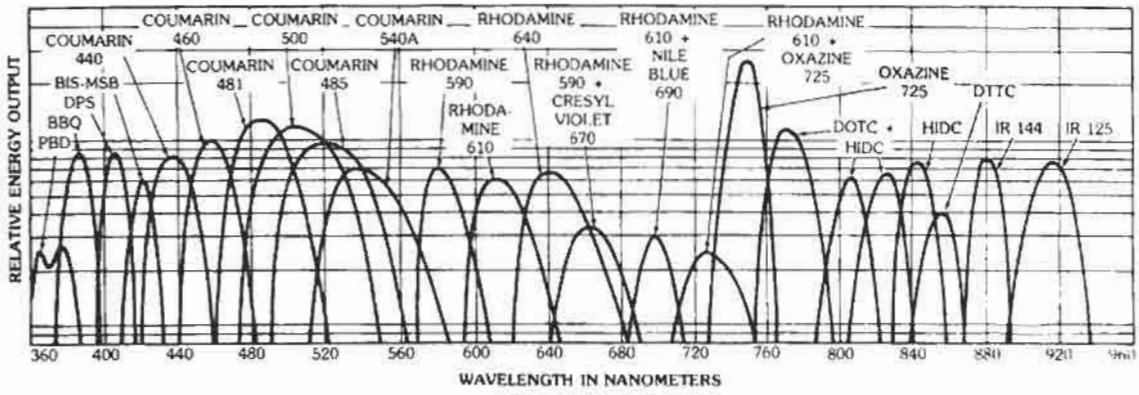
(B) Nd: YAG pumped dyes (Quanta-Ray).

Fig. 10. Typical tuning curves for various dyes when

so that the normal index of refraction is given by $n^2 = 1 + \chi^{(1)}$.

If the symmetry property of the material is such that a reversal of the sign of all coordinates causes no change in the spatial arrangement of the atoms, the material is said to be centrosymmetric. Applying the reversal to P and E, one sees that the $\chi^{(2)}$ coefficient must be zero in centrosymmetric systems but that $\chi^{(1)}$ and $\chi^{(3)}$ are not. Accordingly, the lowest order or quadratic nonlinearity is seen in noncentrosymmetric systems which comprise 21 of the 32 known crystal classes.

In general, $\chi^{(1)}$ has nine components. If one chooses a natural coordinate system that reflects the symmetry axis of the material, $\chi^{(1)}$ becomes diagonal with three components only. This is referred to as the principal axis frame. In the principal axis frame $\chi^{(2)}$ has at most 27 components while $\chi^{(3)}$ has 3^4 components. Not all components are separately distinguishable, so it is possible to reduce the independent number down to 18 for $\chi^{(2)}$. This is done by noting that the ith component of the quadratic part of the polarization is $P_i = \sum_k \sum_l$



(C) N_2 pumped dyes (Molectron)

excited by the indicated sources. (*Courtesy Exciton Corp.*)

$\epsilon_0 \chi^{(2)}_{ikl} E_k E_l$, so a new parameter is accordingly defined as $d_{iq} = \epsilon_0 \chi^{(2)}_{i(jk)}$ where q is a contracted index for the jk combination in parentheses (the Voight notation). Principal axes along x, y, and z are labeled 1, 2, and 3 so that q ranges from 1 to 6 according to the jk combinations 11, 22, 33, 23, or 32; 13 or 31; and 12 or 21, respectively. So, for example, $\chi^{(2)}_{x(yz)} = \chi^{(2)}_{1(23)}$ contributes to d_{14}. With this, d is a 3×6 matrix with at most 18 elements.

The symmetry of the individual system is then used to deduce which elements are nonzero. Since $\chi^{(2)}$ is the same order tensor as that used to describe the piezoelectric effect, the nonzero elements are well known and are compiled in Chapter 4. Similarly, the individual values for d_{iq} for various materials and optical frequencies are tabulated elsewhere. The same kind of symmetry-based reductions can be applied to $\chi^{(3)}$ for crystals, but none are used for amorphous materials.

A specific example is for the crystal class $\bar{4}2m$, which is appropriate to the common nonlinear material potassium dihydrogen phosphate (KDP). For this class, $\chi_1^{(1)} = \chi_2^{(1)} \neq \chi_3^{(1)}$, and

the optical frequency, which may act as a driving term for a new field component at 2ω. Since the growth tends to occur on spatial scales long compared with the wavelengths, the full set of Maxwell's equations can be reduced to a first-order equation for the evolution of the field amplitude. The growth of the harmonic is governed by

$$d(E_{2\omega})/dz = A\,E_{\omega}^2 \exp(i\Delta kz) \qquad \text{(Eq. 50)}$$

where,

$\Delta k = k(2\omega) - 2k(\omega) = 2k_o[n(2\omega) - n(\omega)]$,
$k_o(\omega) = \omega/c$,
A = a constant proportional to the d_{iq} elements, the exact form of which depends on the field orientations and the d matrix.

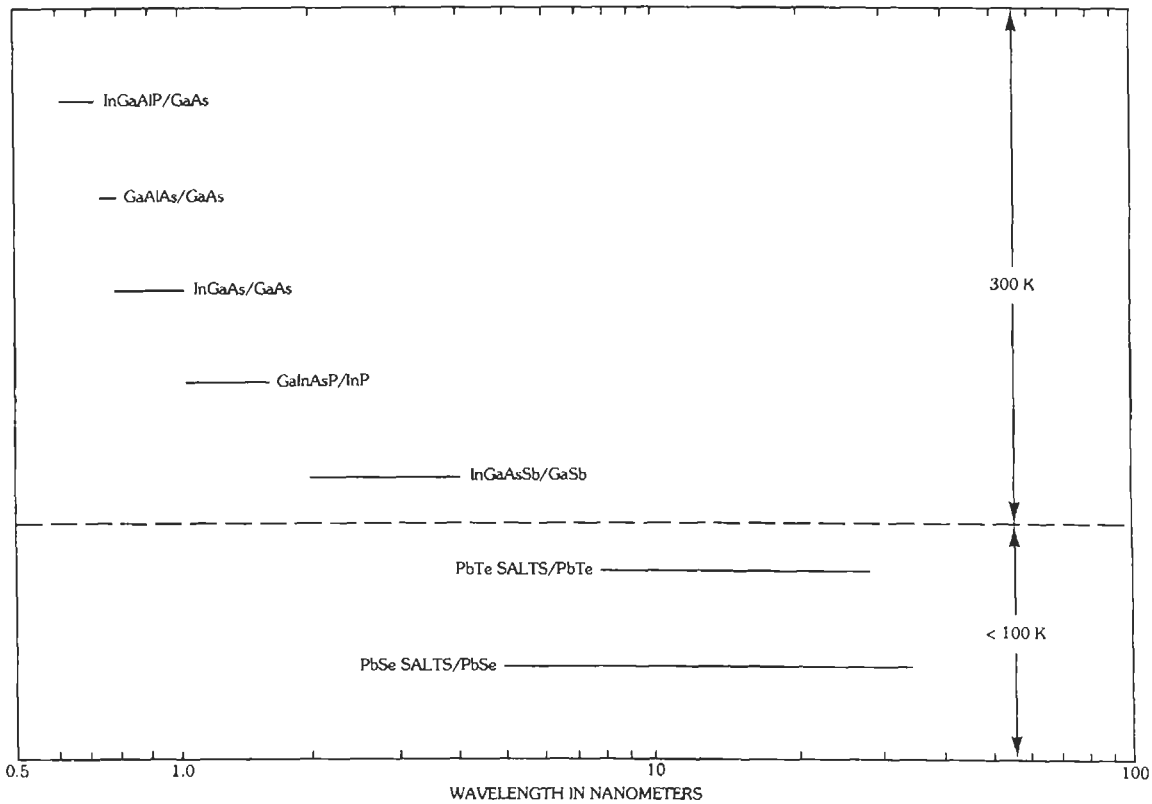

Fig. 15. Common CW compound semiconductor lasers grouped according to the active-layer material and substrate material. The wavelength range refers to different chemical compositions.

If E_ω is approximately constant, $E_{2\omega}$ is seen to be harmonic in z if $\Delta k \neq 0$. If $\Delta k = 0$, then $E_{2\omega} \simeq z$, and the growth increases with distance. This latter case is clearly favorable and requires $\Delta k = 0$; it is referred to as a phase-matched condition.

Since most materials are normally dispersive, $n(2\omega) > n(\omega)$, the phase-matched condition is not automatic. It can be achieved by using the anisotropic properties of the index of refraction. An important linear optical class of materials used as harmonic generators is uniaxial, for which $n_1 = n_2 \neq n_3$. Other classes are isotropic, $n_1 = n_2 = n_3$, and biaxial, $n_1 < n_2 < n_3$. For the uniaxial class, $n_1 = n_2 = n_o$, the *ordinary* index of refraction, and $n_3 = n_e$, the *extraordinary* index of refraction. If $n_e > (<) n_o$, the material is said to be positive (negative) uniaxial.

A wave polarized in the x-y or 1-2 plane (ordinary ray) has an index of refraction equal to n_o. A wave polarized with a field component along the z or 3 axis (optic axis) is an extraordinary ray and has an effective index of refraction, n_{eff}, given by

$$1/n_{\text{eff}}^2 = cos^2\ \theta/n_o^2 + \sin^2\ \theta/n_2^2 \quad \text{(Eq. 51)}$$

where θ is the angle between the optic axis and the direction of propagation. A common representation of these is a polar plot of $n(\theta)$, which is referred to as an index surface. Fig. 16A shows the index surface for a negative uniaxial crystal.

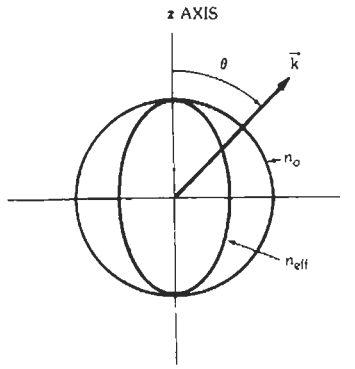
Phase matching may be achieved if the index-surface curves at ω and 2ω cross as shown in Fig. 16B. For $n_e(2\omega) < n_o(\omega)$, there is an angle θ_m for which $n_{\text{eff}}(2\omega) = n_o(\omega)$. Since the angular width of the phase matching ($\Delta kL = \pi$) is comparable to the divergence angle of a laser, the phase matching of this type is referred to as critical phase matching. In some cases, the temperature dependence of n_o and n_e is sufficiently different that phase matching can be achieved at elevated temperatures.

Under fully phase-matched conditions, the harmonic intensity is given by

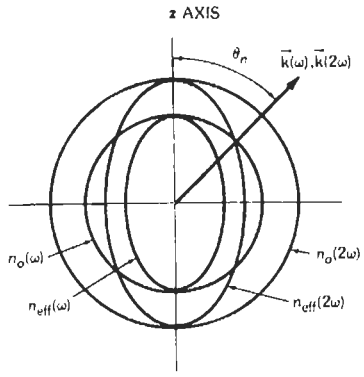
$$I_{2\omega}(z) = I_\omega(0) \tanh^2 [AE_\omega(0)z] \underset{z\to\infty}{\rightarrow} I_\omega(0) \quad \text{(Eq. 52)}$$

which shows the full conversion capability of the process, which has an initial growth of

$$I_{2\omega}(z) = A^2 E_\omega^2(0) I_\omega(0) z^2 \cong I^2(0) z^2 \quad \text{(Eq. 53)}$$



(A) Negative uniaxial crystal.



(B) Phase matching.

Fig. 16. Wave vectors in a uniaxial crystal.

The term $AE_\omega(0)$ represents an inverse conversion distance, l_{conv}, such that at $z = l_{conv}$, 58% of the fundamental has been converted to a harmonic. For practically all materials with large d values, l_{conv} on the order of centimeters requires initial pumping intensities of 10–100 MW/cm^2. Although the d_{iq} values tend to be larger at lower frequencies, the equivalent A terms tend to be numerically about the same. Hence, harmonic generation by this method tends to be efficient, 50–80%, but requires large powers. Representative nonlinear materials and coefficients are listed in Table 4.

Pockels Effect

A second effect associated with $\chi^{(2)}$ is the Pockels, or linear electro-optic, effect used to amplitude modulate light. Here, the nonlinear polarization is at the optical frequency and is proportional to $E_\omega E^0$, where E^0 is a nonoptical field. The effect, which has the same basic d matrix as for the case of second-harmonic generation, leads only to a shift in the index of refraction caused by E^0. The effect is described by a three-dimensional version of the index surface called the index ellipsoid, which relates n_{eff} to the displacement vector rather than to the direction of propagation. With no applied field, the index ellipsoid is of the general form

$$1 = D_1^2/n_1^2 + D_2^2/n_2^2 + D_3^2/n_3^2 \quad \text{(Eq. 54)}$$

where D_i are the normalized displacement vectors along the principal axis. The effective index of refraction is simply the length of this vector.

The effect of E^0 is to distort the index ellipsoid. The distortion is expressed in terms of a new matrix, r, which structurally is the transpose of the d matrix. The generalized index ellipsoid is then

$$1 = \sum_{i=1}^{3}\left[D_i^2/n_i^2 + D_i^2\sum_{j=1}^{3}\Delta B_{(ii)j}\right] + \sum_{i=1}^{3}\sum_{j\neq i}^{3} D_iD_j\sum_k \Delta B_{(ij)k} \quad \text{(Eq. 55)}$$

where $\Delta B_{(ij)k} = r_{(ij)k}E_k^0$, and the indices in parentheses are contracted according to the Voight notation. Continuing with the example of $\bar{4}2m$ crystals,

$$r = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ r_{41} & 0 & 0 \\ 0 & r_{52} & 0 \\ 0 & 0 & r_{63} \end{bmatrix}$$

and $r_{41} = r_{52}$. The resulting index elipsoid is

TABLE 4. NONLINEAR OPTICAL COEFFICIENTS

Material	Class	λ (μm)	r_{qk} (10^{-12}m/V)	d_{iq}/ϵ_o (10^{-12}m/V)	Class
KDP	$\bar{4}2m$	1	$r_{63} = -9$	$d_{14} = 0.49$	Uniaxial
			$r_{41} = 8.6$	$d_{36} = 0.47$	
GaAs	$\bar{4}3m$	10	$r_{41} = 1.6$	$d_{14} = 134$	Isotropic
CdTe	$\bar{4}3m$	10	$r_{41} = 6.8$	$d_{14} = 16.7$	Isotropic

$$1 = D_1^2/n_o^2 + D_2^2/n_o^2 + D_3^2/n_e^2 + 2D_2D_3r_{41}E_1^0 + 2D_1D_3r_{52}E_2^0 + 2D_1D_2r_{63}E_3^0 \quad \text{(Eq. 56)}$$

The problem then reduces to finding a new principal axis frame for which the index elipsoid is diagonal.

Two special cases exist. For longitudinal modulators, the optical field is perpendicular to E^0, whereas for transverse modulators, it is parallel to E^0. Fig. 17A illustrates the former, for which the index ellipsoid is diagonal in the indicated primed axis for $\bar{4}2m$. The index ellipsoid is then

$$1 = D_1'^2[1/n_o^2 - r_{63}E_3^0] + D_2'^2[1/n_o^2 + r_{63}E_3^0] + D_3^2/n_e^2 = D_1'^2/n_1'^2 + D_2'^2/n_2'^2 + D_3^2/n_e^2 \quad \text{(Eq. 57)}$$

For all materials, the product $r_{qk}E_k^0$ is small compared with the indices of refraction, so in the primed axis the new indices of refraction are approximately $n_1' \cong n_o + (1/2)\, n_o^3 r_{63}E_3^0$ and $n_2' \cong n_o - (1/2)\, n_o^3 r_{63}E_3^0$. A wave originally polarized along the 1 axis will have equal field components along the 1′ and 2′ axes, each of which propagates with a different phase velocity. After exiting from the crystal, the net optical polarization will be rotated from the incident polarization by an amount proportional to $n_1' - n_2' = n_o^3 r_{63}E_3^0$. Amplitude modulation is accomplished by placing a polarizer after the crystal. For this orientation, the transmission, T, through the crystal-polarizer combination is given by

$$T = \sin^2(\Gamma/2) \quad \text{(Eq. 58)}$$

where,

Γ is the retardation given by $\omega(n_1' - n_2')L/c = \omega n_o^3 r_{63}E_3^0 L/c = \pi V/V_{1/2}$,
$V = E_3^0 L$,
$V_{1/2} = \pi c/\omega n_o^3 r_{63}$, the half-wave voltage.

The half-wave voltage is the most important parameter in specifying electro-optic modulators.

For the transverse case shown in Fig. 17B, the retardation becomes

$$\Gamma = (\omega/c)\,(n_o - n_e - \tfrac{1}{2}\, n_o^3 r_{63}E_3^0)L \quad \text{(Eq. 59a)}$$

$$= \Gamma_m - \pi V/V_{1/2} \quad \text{(Eq. 59b)}$$

where,

$V = E_3^0 t$,
$V_{1/2} = 2\pi ct/\omega n_o^3 r_{63}L$,
Γ_m = a fixed retardation due to the natural birefringence.

In practice, $t/L \ll 1$, so the half-wave voltage in the transverse case is considerably smaller than in the longitudinal case.

Half-wave voltages of 1–10 kV are not uncommon so that for high-frequency modulation, operational voltages are typically less than $V_{1/2}$. Because of the $\sin^2$ dependence, small modulating voltages lead to a distortion, since $\sin^2\theta \simeq \theta^2$ for small θ. This can be eliminated by optically biasing the system to the 50% transmission point by using a quarter-wave plate between the polarizer and crystal as shown in Fig. 17C. With this arrangement, the transmission becomes

$$T = (1 + \sin\Gamma)/2 \quad \text{(Eq. 60)}$$

and results in a change in transmission linear in $V(\Gamma)$ for small modulation. Hence, the standard amplitude modulator is a three-element device. For certain types of crystals, a reduction of the half-wave voltage can be achieved by using multiple crystals connected optically in series but electrically in parallel.

The intrinsic material response is almost instantaneous, so the system response time tends to be determined simply by circuit effects. If these are made small, a second frequency limitation occurs because of the finite optical transit time through the crystal. Operation above 1 GHz generally requires a traveling-wave modulation wherein a certain type of phase matching is used.

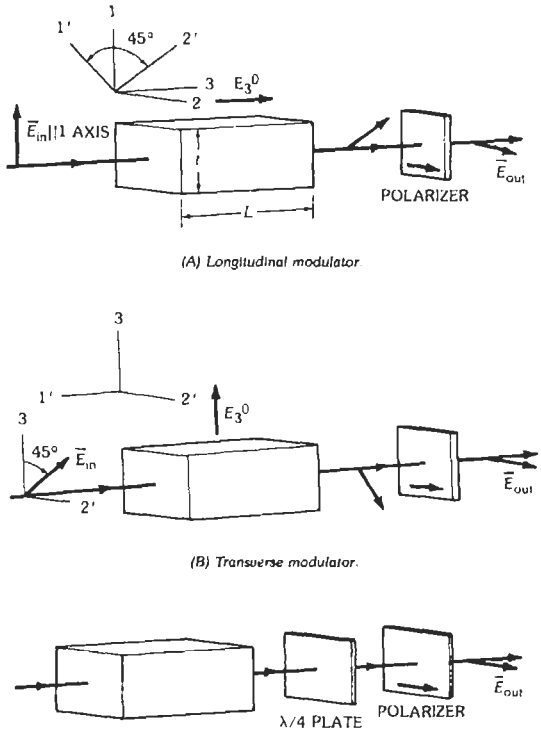


Fig. 17. Configurations for amplitude modulation of light.

If the incident optical field is oriented along the primed principal axis, no rotation of the polarization occurs, but modulation of the phase velocity exists. By this method, phase modulation may be achieved.

Stimulated Raman Emission

There are many other different effects associated with $\chi^{(2)}$ and $\chi^{(3)}$ nonlinearities depending on the number of different fields present. Frequency tripling into the deep ultraviolet is commonly done with gases for which $\chi^{(3)}$ is significant. Similarly, another third-order effect leads to a self-induced index of refraction change and causes focusing and defocusing of a beam by virtue of its radial intensity variation.

One important $\chi^{(3)}$ effect used to frequency shift light is the stimulated Raman effect. Here, a polarization and hence a gain is created at frequency ω' due to a strong field at ω where $\hbar\omega - \hbar\omega' = \Delta E$, a characteristic atomic or molecular energy, typically a vibrational energy in a molecule. The interaction can also be viewed as an inelastic scattering process wherein the shift is determined by the characteristic energy. It is possible to have stimulated rotational, vibrational, and electronic Raman scattering with shifts ranging from a few to a few thousand wave numbers. Representative Raman materials and shifts are listed in Table 5.

In the usual Raman situation, the gain is large, so the conversion can be very efficient in terms of photons. In terms of power, the conversion efficiency is limited by the Manley-Rowe limit of $\hbar\omega'/\hbar\omega$. Typically, the requirements for pump intensities lie in the range 10–100 kW/cm^3.

The normal Raman effect occurs when $\omega' < \omega$ and is called a Stokes wave. The growing first Stokes can reach a sufficient intensity to act as a pump for a second Stokes, and so on. With the presence of a strong pump and first Stokes, an anti-Stokes wave may be generated at $\omega'' = \omega + \Delta E/\hbar$. Hence, under normal conditions a number of Stokes and anti-Stokes waves may be created. A Raman cell is usually constructed locally because of its simplicity.

42 Computer Organization and Programming

John Wakerly

INTRODUCTION*

Computers come in all shapes and sizes, from large corporate data-processing machines that fill a room to tiny microcontrollers buried deep in automobiles, stereo systems, and toasters. Even though computers span a wide range of sizes, capabilities, and cost, they share a great many characteristics and operating principles. The goal of this chapter is to describe general principles of computer organization and programming that apply to computers of any category.

Taken as a whole, a computer is an incredibly complex system, with many more levels of detail than, say, the noncomputer part of a radio. Fortunately, a computer system *is* structured into many levels, so that it is easy to understand if taken one level at a time; see Fig. 1.

Hardware

Central to the organization, or indeed existence, of a computer is its *architecture*. The architecture of a computer is really an abstract concept—it is just a definition of the functionality of the computer as seen by a machine-language programmer. A user of a particular computer architecture does not care how its functions are achieved, only that they match their definitions. An example of a particular computer architecture, the Motorola 68000, is given later in the chapter.

At the next level down is *implementation*, the logic structures used to accomplish the functions defined by the architecture. An implementation consists of a block diagram of the system hardware modules, their interconnections, and further refinements of the internal logic structure of each module. Note that implementation is still a somewhat abstract concept in that an implementation can exist on paper without the machine actually having been built. Chapter 43 discusses logic design—the tools and techniques for designing hardware modules.

The lowest level of detail in a computer is its *hardware realization*—the electronic circuits and other components from which the computer is built. Realization encompasses integrated-circuit technologies, such as those discussed in Chapter 20, as well as packaging, interconnections, and all other physical details of the machine.

The bottom three levels of a computer just described are often grouped together and simply called "the hardware." The higher levels in Fig. 1 are usually grouped together as "software."

Software

Computer *software* consists of the instructions and data that the computer hardware manipulates to perform useful work. A sequence of instructions for a computer is called a *program*. The data manipulated by a program is called a *data base*, a *file*, *input*, or simply *data*, depending on its nature and extent.

The most primitive instructions that can be given to a computer are those interpreted directly by hardware, in the *machine language* of the computer. Machine-language instructions are encoded as strings of bits in the computer memory, often one instruction per memory location. The processor fetches machine instructions from memory and executes them one by one.

Since it is difficult for humans to read and recognize strings of bits, machine-language programs are written in *assembly language* and translated into bit strings by an *assembler*. Assembly language represents machine instructions by mnemonic names and allows memory addresses and other constants to be represented by symbols rather than bit strings.

Most programs are written in *high-level languages* that allow common operations such as expression evaluation, repetition, assignment, and conditional action to be invoked in a single high-level *statement*. Popular high-level languages include BASIC, FORTRAN, and Pascal.

Few computers execute a high-level language directly. Therefore, a *compiler* is needed to translate a high-level-language program into a sequence of machine instructions that performs the desired task.

Assemblers and compilers are not the only *software tools* that a programmer may encounter. Other useful tools related to program development are interpreters, simulators, and on-line debuggers. Like a compiler, an *interpreter* processes a high-level-language program. Unlike a compiler, an interpreter actually executes the high-level-language program one statement at a time, rather than translating each statement into a sequence of machine instructions to be run later. Most BASIC environments use an interpreter.

A *simulator* is a program that simulates individual machine instructions, usually on a machine other than the one being simulated. A typical use of a simulator is to test programs to be run on a processor before the processor hardware is available. An *on-line debugger* executes a program on a machine one or a few instructions at a time, allowing the programmer to see the effects of small pieces of the program and thereby isolate programming errors (*bugs*).

Text editors are used to enter and edit text in a general-purpose computer, whether the text is a letter, a report, or a computer program. *Text formatters* read text with imbedded formatting commands and produce formatted documents such as this book. Text editors and formatters belong to the area of computing known as *word processing*.

In a medium to large computer system, cooperating

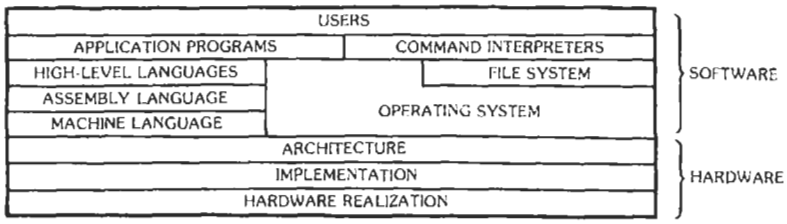

Fig. 1. Levels of detail of a computer.

programs run under the control of an *operating system*. An operating system schedules programs for execution, controls the use of I/O devices, and provides utility functions for all of the programs that run on the computer. Programs and text stored on disks and other mass-storage devices are managed by a *file system*, a collection of programs for reading, writing, and structuring such information in "files." The operating systems in most computers include file systems. Even a very small computer with no mass-storage or file system has a simple operating system, at least to monitor inputs and accept commands from the outside world.

Computer Data Types

The basic unit of information storage in a digital computer is the *bit*, which has a value of either 0 or 1. Obviously a single-bit data type is not very useful for numeric computation, since it only allows us to count from 0 to 1.

By assembling two or more bits into a string, we can represent more than two values or conditions. The bits in a string of n bits can take on 2^n different combinations of values.

Strings of eight bits are usually referred to as *bytes*. The name "byte" was invented at IBM in the early days of electronic computers. The name for a string of four bits is fancifully derived from the byte—the *nibble*.

A bit string manipulated by a computer in one operation is usually called a *word*. Some computers have a *word length* as short as four bits, others as long as 64 bits or more. For many minicomputers and microcomputers, the nomenclature has been standardized to use "word" to describe 16-bit strings and "double word" or "long word" to describe 32-bit strings.

Bits, nibbles, bytes, and words are easy data types to classify because they require differing amounts of storage in the computer memory. There are other data types that are classified not by how much storage they take, but by how they are interpreted and used by the computer hardware and software. For example, the following three data types, all using an eight-bit byte, might be defined for a microcomputer:

Unsigned integer: The byte represents an unsigned integer between 0 and 255.

Signed integer: The byte represents a signed integer between −128 and +127.

Character: The byte represents an ASCII character.

Even though all three data types are stored exactly the same way in the computer memory, they may be manipulated differently by the hardware and software.

NUMBER SYSTEMS AND ARITHMETIC

Decimal and Binary Positional Number Systems

Positional number systems are used in all computers and almost all day-to-day business of people. In a *positional number system*, a number is represented by a string of digits in which each digit position has an associated weight. For example, the value D of a 4-digit decimal number, $d_3d_2d_1d_0$, is

$$D = d_3 \cdot 10^3 + d_2 \cdot 10^2 + d_1 \cdot 10^1 + d_0 \cdot 10^0$$

Each digit d_i has a weight of 10^i. Thus, the value of 6851 is computed as follows:

$$6851 = 6 \cdot 1000 + 8 \cdot 100 + 5 \cdot 10 + 1 \cdot 1$$

A decimal point is used to allow negative as well as positive powers of 10 in a decimal number representation. Thus, $d_1d_0 \cdot d_{-1}d_{-2}$ has the valuc

$$D = d_1 \cdot 10^1 + d_0 \cdot 10^0 + d_{-1} \cdot 10^{-1} + d_{-2} \cdot 10^{-2}$$

In a general positional number system, each digit position has an associated weight of b_i, where b is called the *base*, or *radix*, of the number system. The general form of a number in such a system is

$$d_{p-1}d_{p-2} \cdots d_1d_0 \,.\, d_{-1}d_{-2} \cdots d_{-n}$$

where there are p digits to the left of the point and n digits to the right of the point, called the *radix point*.

The value of the number is

$$D = \sum_{p-1 \geq i \geq -n} d_i \cdot b^i$$

the summation of each digit times the corresponding power of the radix. If the radix point is missing, it is assumed to be to the right of the rightmost digit. Except for possible leading and trailing zeros, the representation of a number in a positional number system is unique. (Obviously, 34.85 equals 034.85000, and so on.)

The *binary radix* is used in almost all computers. The allowable digits, 0 and 1, are called *bits*, and each bit d_i has weight 2^i. In the examples below, subscripts distinguish between radix-2 and radix-10 numbers.

$$10001_2 = 1 \cdot 16 + 0 \cdot 8 + 0 \cdot 4 + 0 \cdot 2 + 1 \cdot 1 = 17_{10}$$

$$110.011_2 = 1 \cdot 4 + 1 \cdot 2 + 0 \cdot 1 + 0 \cdot 0.5 + 1 \cdot 0.25 + 1 \cdot 0.125 = 6.375_{10}$$

The leftmost bit of a binary number is called the *high-order* or *most significant bit (MSB)*; the rightmost is the *low-order* or *least significant bit (LSB)*.

Octal and Hexadecimal Numbers

Most computer software uses either the *octal number system* (radix 8) or the *hexadecimal number system* (radix 16) to represent binary numbers. Table 1 shows the binary numbers from 0 through 1111 and their octal, decimal, and hexadecimal equivalents. The octal system uses eight digits, 0–7. The hexadecimal system requires 16 digits, so the letters A–F are used in addition to the digits 0–9 of the decimal system.

The octal and hexadecimal number systems are useful for representing binary numbers because their radices are powers of two. Since a string of three bits can take on eight different combinations, it follows that each 3-bit string is uniquely represented by one octal digit, according to the third and fourth columns of Table 1. Likewise, a 4-bit string is represented by one hexadecimal digit according to the fifth and sixth columns of the table.

Thus, it is very easy to convert a binary integer to octal (or hexadecimal). Starting at the binary point and working left, we simply separate the bits into groups of three (or four) and replace each group with the corresponding octal (or hexadecimal) digit:

$$1010110001110_2 = 101\ 011\ 000\ 110_2 = 5306_8 = 1010\ 1100\ 0110_2 = AC6_{16}$$

$$1101100111010100 1_2 = 011\ 011\ 001\ 110\ 101\ 001_2 = 331651_8 = 0001\ 1011\ 0011\ 1010\ 1001_2 = 1B3A9_{16}$$

Conversion from octal or hexadecimal to binary is easy, too. We simply replace each octal or hexadecimal digit with the corresponding 3- or 4-bit string. And to convert from octal to hexadecimal or vice versa, we first convert to binary:

$$1573_8 = 001\ 101\ 111\ 011_2 = 0011\ 0111\ 1011_2 = 37B_{16}$$

TABLE 1. BINARY, DECIMAL, OCTAL, AND HEXADECIMAL NUMBERS

Binary	Decimal	Octal	3-Bit String	Hexadecimal	4-Bit String
0	0	0	000	0	0000
1	1	1	001	1	0001
10	2	2	010	2	0010
11	3	3	011	3	0011
100	4	4	100	4	0100
101	5	5	101	5	0101
110	6	6	110	6	0110
111	7	7	111	7	0111
1000	8	10	—	8	1000
1001	9	11	—	9	1001
1010	10	12	—	A	1010
1011	11	13	—	B	1011
1100	12	14	—	C	1100
1101	13	15	—	D	1101
1110	14	16	—	E	1110
1111	15	17	—	F	1111

General Positional Number System Conversions

In the more general case, conversion between two bases cannot be done by simple substitutions; base-10 arithmetic operations are generally required.

The base-10 value of a number in any base can be found from the expansion formula given earlier:

$$D = \sum_{p-1 \geq i \geq -n} d_i \cdot b^i$$

We convert each digit d_i of the number to its base-10 equivalent and expand the formula using base-10 arithmetic. For example:

$$1BE8_{16} = 1 \cdot 16^3 + 11 \cdot 16^2 + 14 \cdot 16^1 + 8 \cdot 16^0$$

$$= 7144_{10}$$

$$3176_8 = 3 \cdot 8^3 + 1 \cdot 8^2 + 7 \cdot 8^1 + 6 \cdot 8^0$$

$$= 1662_{10}$$

In the opposite direction, to convert a decimal number D to base b, we perform a series of divisions by b. In the first step, we divide D by b; the remainder is used as the least significant digit (LSD) of the desired result, and the quotient is used as the input to the next step. At each succeeding step, we divide the input number by b, use the remainder as the next-higher-order digit of the result, and use the quotient as the input to the next step. Since a remainder is always less than b, it is always representable as a single base-b digit. The process eventually terminates when a zero quotient is produced. Examples are given below.

89 ÷ 2 = 44 remainder 1 (LSB)

÷ 2 = 22 remainder 0

÷ 2 = 11 remainder 0

÷ 2 = 5 remainder 1

÷ 2 = 2 remainder 1

÷ 2 = 1 remainder 0

÷ 2 = 0 remainder 1 (MSB)

$89_{10} = 1011001_2$

3417 ÷ 16 = 213 remainder 9 (LSD)

÷ 16 = 13 remainder 5

÷ 16 = 0 remainder 13 (MSD)

$3417_{10} = D59_{16}$

Addition and Subtraction of Nondecimal Numbers

Addition and subtraction of nondecimal numbers by hand uses the same technique that we learned in grammar school for decimal numbers; the only catch is that the addition and subtraction tables are different. Table 2 gives the addition and subtraction tables for binary numbers. To add two binary numbers X and Y, we add together the least significant bits with an initial carry (c_{in}) of 0, producing sum ($x + y + c_{in}$) and carry (c_{out}) bits according to the table. We continue processing bits from right to left, including the carry out of each column in the sum for the next column. Two examples of decimal additions and the corresponding binary additions are shown below, with the carries shown as a bit string, C.

C		101111000
X	190	10111110
Y	+141	+10001101
$X + Y$	331	101001011

C		001011000
X	173	10101101
Y	+ 44	+00101100
$X + Y$	217	11011001

TABLE 2. BINARY ADDITION AND SUBTRACTION TABLE

c_{in}	0	0	0	0	1	1	1	1
x	0	0	1	1	0	0	1	1
y	0	1	0	1	0	1	0	1
$x+y+c_{in}$	0	1	1	0	1	0	0	1
c_{out}	0	0	0	1	0	1	1	1
b_{in}	0	0	0	0	1	1	1	1
x	0	0	1	1	0	0	1	1
y	0	1	0	1	0	1	0	1
$x-y-b_{in}$	0	1	1	0	1	0	0	1
b_{out}	0	1	0	0	1	1	0	1

Subtraction is performed similarly, except with borrows (b_{in} and b_{out}) instead of carries:

B		001111100
X	229	11100101
Y	− 46	−00101110
$X - Y$	183	10110111

Addition and subtraction tables can be developed for octal and hexadecimal numbers, or any other desired base. However, rather than memorize tables, many computer engineers use hand-held "hex calculators" to perform arithmetic on binary, octal, and hexadecimal numbers.

Representation of Negative Numbers

So far, we have dealt only with positive numbers. There are many ways to represent negative numbers.

The representation of decimal numbers used in everyday business is called the *signed-magnitude system*. In this system, a number consists of a magnitude and a symbol indicating whether the magnitude is positive or negative. The signed-magnitude system can be applied to binary numbers quite easily by using an extra bit position to represent the sign. Traditionally, the most significant bit (MSB) is used to represent the sign (0 = plus, 1 = minus), and the lower-order bits contain the magnitude. In this system, there are two representations of zero, "plus zero" and "minus zero."

To add two signed-magnitude numbers, we follow the rules that we learned in grammar school. If the signs are the same, we add the magnitudes and give the result the same sign. If the signs are different, we subtract the smaller magnitude from the larger and give the result the sign of the larger. To subtract signed-magnitude numbers, we change the sign of the subtrahend and proceed as in addition.

Despite the conceptual simplicity of the signed-magnitude system, for performance and efficiency reasons negative numbers in a computer are usually represented in *complement number systems*. In such a system, a number is negated not by inverting a sign bit, but rather by "taking the complement."

Complement number systems can be defined for any base or radix, but we shall concentrate on the base-2 radix complement, commonly called the *twos-complement* system. In this system, we assume that a binary number, B, has n bits,

$$B = b_{n-1}b_{n-2}\cdots b_1b_0,$$

so that the radix point is on the right and the number is an integer. If any operation produces a result that requires more than n bits, we throw away the extra high-order bit(s).

By definition, the twos complement of an n-bit number, B, is obtained by subtracting B from 2^n. If B is between 1 and $2^n - 1$, this subtraction will result in another number between 1 and $2^n - 1$. If B is 0, the result of the subtraction is b^n; this has the form $100\cdots00$, where there are a total of $n + 1$ bits. We throw away the extra high-order bit and get the result $00\cdots00 = 0$. Thus there is only one representation of zero in the twos-complement system.

From the foregoing, it might seem that a subtraction operation is needed to form the twos complement of a number B. However, this subtraction is avoided by rewriting 2^n as $(2^n - 1) + 1$ and $b^n - B$ as $((2^n - 1) - B) + 1$. Since $2^n - 1$ has the form $11\cdots11$, any n-bit number B may be subtracted from it by simply complementing each bit of B. Thus, the twos complement of B is obtained by complementing the individual bits of B and adding 1. Some examples of 8-bit numbers and their twos complements are shown below.

$17_{10} =$ 00010001_2
11101110 (complement bits)
$+1$
$11101111_2 = -17_{10}$

$119_{10} =$ 01110111_2
10001000 (complement bits)
$+1$
$10001001_2 = -119_{10}$

$0_{10} =$ 00000000_2
11111111 (complement bits)
$+1$
$1|\,00000000_2 = 0_{10}$

$-99_{10} =$ 10011101_2
01100010 (complement bits)
$+1$
$01100011_2 = 99_{10}$

The decimal value of a twos-complement number can be obtained from the same expansion formula that we showed for unsigned numbers, except that the weight of the MSB is -2^{n-1} instead of $+2^{n-1}$ (for example, $-119 = -128 + 8 + 1$ above).

Some computers use the *ones-complement* system, in which the complement of an n-bit number, B, is defined to be $2^n - 1 - B$. Thus, the ones complement of a number is obtained by simply inverting its bits. Although taking the complement is faster, addition may be slower than in the twos-complement system, requiring an "end-around carry" operation. Also, there are two representations of zero, $00\cdots00$ and $11\cdots11$.

Twos-Complement Addition and Subtraction

Twos-complement numbers, regardless of sign, are added by ordinary binary addition, ignoring any carries beyond the MSB. The result is always the correct sum as long as the range of the number system is not exceeded. Some examples of decimal addition and the corresponding 4-bit twos-complement additions illustrate this:

+3	0011	−2	1110
+ +4	+0100	+ −6	+ 1010
+7	0111	−8	1|1000
+6	0110	+4	0100
+ −3	+1101	+ −7	+1001
+3	1|0011	−3	1101

If an addition operation produces a result that exceeds the range of the number system, *overflow* is said to occur. Addition of two numbers with different signs can never produce overflow, but addition of two numbers of like sign can, as shown by the following examples:

−3	1101	+5	0101
+ −6	+1010	+ +6	0110
−9	1|0111 = +7	+11	1011 = −5
−8	1000	+7	0111
+ −8	+1000	+ +7	+0111
−16	1|0000 = +0	+14	1110 = −2

Fortunately, there is a simple rule for detecting overflow in addition: an addition overflows if the signs of the addends are the same and the sign of the sum is different. Most computers have built-in hardware for detecting overflow.

Two numbers may be subtracted by negating the subtrahend and adding the result to the minuend. A twos-complement number is negated by taking its twos complement. Thus, negating the subtrahend and adding the minuend can be accomplished with only one addition operation as follows: Perform a bit-by-bit complement of the subtrahend, and add the complemented subtrahend to the minuend with an initial carry of 1 instead of 0. Examples are the following:

		1—initial carry
+4	0100	0100
− +3	−0011	+1100
+1		1|0001

		1—initial carry
+3	0011	0011
− +4	−0100	+1011
−1		1111

		1—initial carry
+3	0011	0011
− −4	−1100	+0011
+7		0111

Overflow in subtraction can be detected by examining the signs of the minuend and the *complemented* subtrahend, using the same rule as in addition.

Since twos-complement numbers are added and subtracted by the same basic binary addition and subtraction algorithms as unsigned numbers, most computers have only one type of addition or subtraction instruction that handles both signed and unsigned numbers. However, a program must interpret the results of such an instruction differently, depending on whether it thinks it is dealing with signed numbers (e.g., −8 through +7) or unsigned numbers (e.g., 0 through 15).

Thus, most computers have an *overflow* flag to indicate that the range of signed numbers has been exceeded, and a *carry* or *borrow* flag to indicate that the range of unsigned numbers has been exceeded. Addition and subtraction instructions affect both flags, but a program looks only at the flag for the number system it is using. Also, a program interprets the MSB of a number as a sign bit only when dealing with signed numbers.

Binary Multiplication

In grammar school, we learned to multiply by adding a list of shifted multiplicands computed according to the digits of the multiplier. The same technique can be used to obtain the product of two unsigned binary numbers as shown below:

11	
× 13	
33	
11	
143	
1011	multiplicand
× 1101	multiplier
1011	
0000	shifted multiplicands
1011	
1011	
10001111	product

Forming the shifted multiplicands is trivial in binary multiplication, since the only possible values of the multiplier digits are 0 and 1.

Instead of listing all the shifted multiplicands and then adding, in a computer it is more convenient to add each shifted multiplicand as it is created to a *partial product*. The previous example is repeated in Chart 1, calculated with this technique.

When we multiply an n-bit word and an m-bit word in a computer, the resulting product will take at most $n + m$ bits to express. Therefore, a typical multiplication instruction multiplies two n-bit words and produces a $2n$-bit double-word product.

Multiplication of signed numbers can be accomplished by using unsigned multiplication and the usual grammar-school rules: Perform an unsigned multiplication of the magnitudes, and make the product positive if the operands had the same sign, negative if they had different signs.

Binary Division

The simplest binary division algorithm is also based on the technique we learned in grammar school, as shown in Chart 2. In both the decimal and binary cases, we mentally compare the reduced dividend with multiples of the divisor to determine which multiple of the shifted divisor to subtract. In the decimal case, we first pick 11 as the smallest multiple of 11 less than 21, and then pick 99 as the smallest multiple less than 107. In the binary case, the choice is somewhat simpler, since the only two choices are zero and the divisor itself. Still, a comparison operation *is* needed to pick the proper shifted divisor.

Unsigned division in a computer processor is complementary to multiplication. A typical division instruction accepts a double-word dividend and a single-word divisor, and produces single-word quotient and remainder. Such a division *overflows* if the divisor is zero or the quotient would take more than one word to express. The second situation occurs only if the divisor is less than or equal to the high-order word of the dividend.

Fixed-Point and Floating-Point Representations

All of the number systems discussed so far fix the binary point to the right of the rightmost bit. Thus, a 16-bit unsigned number lies in the range 0 through +65 535. This type of number system is most appropriate for programs that count objects or otherwise deal with integer quantities. However, many programs must deal with fractional quantities. For example, in a scientific program that computes a table of positive sines, it might be convenient to fix the binary point to the right of the *leftmost* bit of a 16-bit number, so that numbers range between 0 and 1.999 969 482 421 875 in increments of 0.000 030 517 578 125 (2^{-15}).

In either case, the binary point is fixed in a particular location for all numbers in the system. Thus, the system is called a *fixed-point representation*. Addition and subtraction may be performed directly on fixed-point numbers without regard to the location of the binary point; however, scaling may be required after multiplication and division operations.

To avoid error-prone bookkeeping and to represent a large range of numbers with relatively few bits, a *floating-point representation* can be used to encode explicitly a scale factor in each number. Similar to numbers in scientific notation, a floating-point number has two variable components, the mantissa (M) and the exponent (E). The value of the number is $M \cdot R^E$, where R is a fixed *radix*. In decimal scientific notation, the radix is 10, while in the floating-point representations of most computers, the radix is 2.

Within a computer, a floating-point number is represented by a bit string containing explicit fields for the mantissa and the exponent; the radix is implicit. The number of mantissa bits determines the precision of the number system, while the number of exponent bits determines the dynamic range of the system (the ratio between the largest and smallest nonzero numbers). Both the mantissa and the exponent are signed numbers, allowing representation of a large range of positive and negative numbers with absolute values both greater than and less than 1. Floating-point formats in typical

computers use a total of 32 bits or more for the mantissa, exponent, and sign fields.

Many computers use a "single precision" floating-point format developed by the IEEE Standards Committee. This format uses a 24-bit mantissa and an 8-bit exponent to represent signed numbers with absolute values in the range of about 2^{-127} to 2^{+127} (10^{-38} to 10^{-38}). The IEEE standard also specifies a 64-bit ("double precision") format and gives guidelines for extended formats (e.g., 128-bit "quad precision" format).

Computer systems may use either of two methods to provide floating-point operations. Some computers have built-in hardware and instructions to process floating-point numbers in a prescribed format. Others have software programs that operate on floating-point numbers using sequences of primitive arithmetic instructions. The hardware approach typically performs operations 100 times faster than the software approach.

A computer that "supports" floating-point numbers is one that provides a minimum set of floating-point instructions including addition, subtraction, multiplication, division, and comparison of floating-point numbers, and conversion to and from integer fixed-point format. Special algorithms are needed to perform these instructions, including scaling or "normalization" of operands and results, as well as arithmetic manipulations of mantissas and exponents.

BCD Representation

The *binary-coded decimal (BCD)* number system encodes the digits 0 through 9 by their 4-bit unsigned binary representations, 0000 through 1001. The codes 1010 through 1111 are not used. Conversions between BCD and decimal representations are trivial, a direct substitution of four bits for each decimal digit. Two BCD digits may be packed into one byte; thus one byte may represent the values from 0 to 99 as opposed to 0 to 255 for a normal unsigned 8-bit binary number. Binary-coded decimal numbers with any desired number of digits may be obtained by using a string of bytes, one byte for each two digits.

Computers "support" BCD representation by providing instructions that perform arithmetic on packed-BCD numbers. Some computers have a "decimal adjust" instruction that corrects the result of an ordinary 8-bit add instruction, assuming that the operands were packed-BCD bytes. Others have decimal add, subtract, multiply, and divide instructions that operate directly on packed-BCD bytes, words, or arbitrary-length strings of bytes.

Character Codes

A string of bits in a computer need not represent a number; in fact most input and output of contemporary computers is nonnumeric. The most common type of nonnumeric data is *text*, strings of characters from some character set. Each character is represented in the computer by a bit string according to an established convention.

The most commonly used character code is ASCII, the American Standard Code for Information Interchange. This code represents each of 128 different characters by a 7-bit string, as shown in Table 3. Thus, the text string "Yeccch!" is represented by a rather innocent looking list of seven 7-bit numbers:

1011001 1100101 1100011 1100011 1100011
1101000 0100001

Some of the 7-bit strings in ASCII denote device control functions instead of "printing" characters. For example, CR (0001101) returns the print head or cursor on a printer or display to the first column, and LF (0001010) advances to the next line. Most of the other control characters are intended for use by data communication links, but different computer systems may use these characters for different functions.

Most computers manipulate an 8-bit quantity as a single unit, a byte, and store one character in each byte. The disposition of the extra bit when 7-bit ASCII is used depends on the system or program. Sometimes this bit is set to a particular value, sometimes it is ignored, and sometimes it is used to encode an additional 128 non-ASCII characters.

An important feature of ASCII is that the bit strings for letters and digits form a reasonable numerical sequence, so that text strings can be sorted by computer instructions that compare numerical values.

BASIC COMPUTER ORGANIZATION

A computer system consists of three major subsystems: processor, memory, and input/output (I/O), as shown in Fig. 2.

Processors

The *processor* (or *central processing unit, CPU*) is the heart of the computer. Shown in Fig. 3, a simple processor contains control circuits for fetching and executing instructions, an arithmetic logic unit (ALU) for manipulating data, and registers for storing processor status and a small amount of data. It also has interface circuits for controlling and communicating with the memory and I/O subsystems.

Different processors have different organizations, both in their internal implementations and in their architectures as seen by programmers. Typical organizations can be roughly classified as accumulator-based processors, general-register processors, and stack machines. Recently, a number of new general-register processor architectures have employed principles of *reduced instruction-set computing (RISC)* to obtain performance advantages over older processor architec-

tures. Processors are also classified by the size of the data units that they can manipulate in a single instruction, typically 8, 16, 32, or 64 bits.

The simplest processor architecture organization is *accumulator based*. Such a processor has only one or two registers, called *accumulators*, in which arithmetic and logical operations and data transfers take place. Popular 8-bit microprocessors for embedded-control applications are accumulator based. For example, the Intel 8051 and the Zilog Z80 are single-accumulator processors; the Motorola 68HC11 is a two-accumulator processor. Accumulator-based processors usually have other special-purpose registers, in addition to the accumulator(s), for address manipulation and other operations.

Processors with more than two registers for arithmetic and logical operations are classified as *general-register processors*. In such processors, any operation can be performed using any (or almost any) register. The IBM 370, the DEC VAX, and most other mainframes and minicomputers have general-register processors. The Motorola 68000, 68020, 68030, and 68040 microprocessors, used in Apple's Macintosh computers, are the most widely used 32-bit general-register microprocessors. Later in this chapter, we use a subset

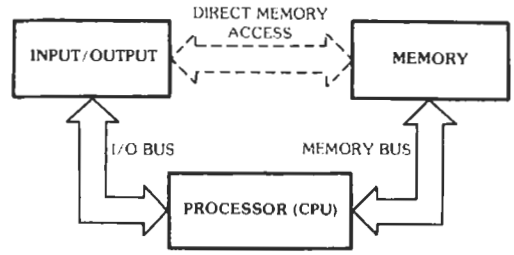

Fig. 2. Block diagram of a typical computer.

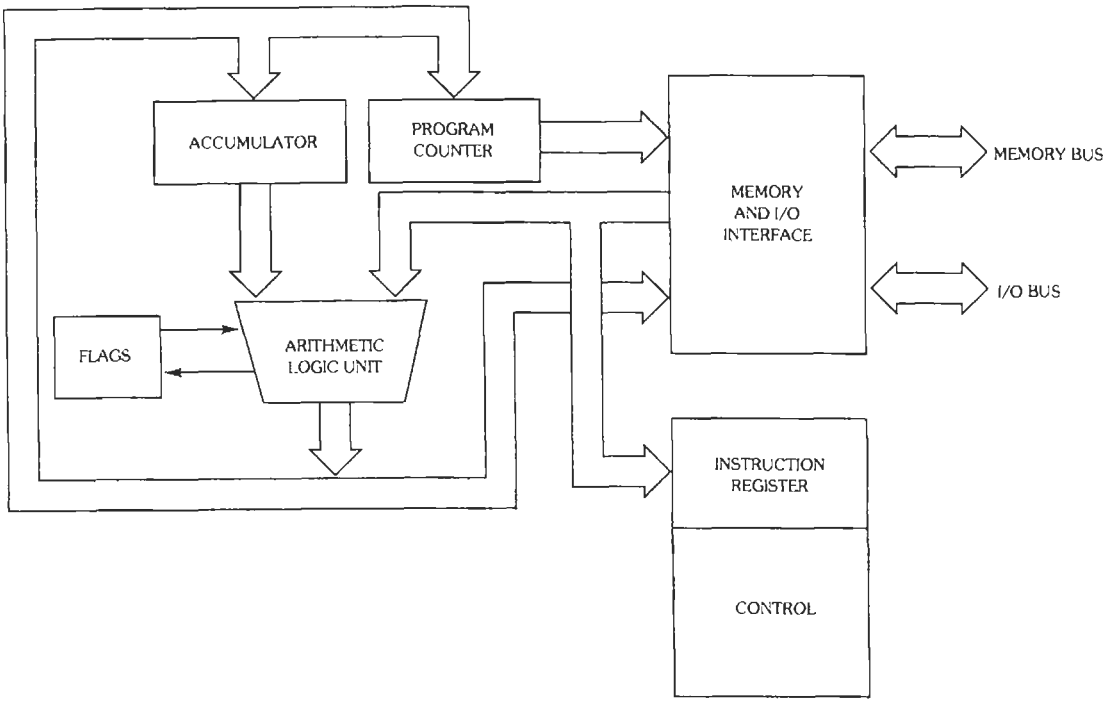

Fig. 3. Block diagram of a simple processor.

of the 68000 architecture to illustrate microprocessor organization and programming.

RISC processors are general-register processors whose instructions have been reduced to a simple, uniform set in order to streamline the implementation of the processor, thereby increasing the speed at which individual instructions are executed. RISC implementations are also characterized by the use of *pipeline* hardware, which allows three or more instructions to be in various stages of execution at any moment, and *caches*, which give the processor instant access to frequently-used instructions and data without having to wait for relatively slow main memory. As a result of these and other features, a typical RISC processor can execute an average of close to one instruction per clock cycle. Advanced RISC processors use *superscalar* and *superpipelining* techniques to execute an average of one to two or more instructions per clock cycle. Popular 32-bit RISC architectures include the Sun SPARC, the Silicon Graphics MIPS, and the Intel 960. The DEC Alpha and the IBM, Motorola, and Apple POWER have 64-bit architectures; the SPARC and MIPS architectures have recently been extended to 64 bits.

Intel's original 16-bit microprocessor, the 8086, is best classified as a single-accumulator processor with many special-purpose registers. Intel's 32-bit extensions to the 8086 architecture, including the 386 and the 486 families, superimposed a general-register structure on the original special-purpose registers, giving it more of the flavor of a general-register architecture. Recent high-performance implementations of the 386/486 architecture, including the so-called 586 family, have incorporated many of the same implementation methods first applied to RISC and to older mainframe architectures, in order to approach the same high levels of performance that are possible with "pure" RISC architectures.

A *stack machine* has neither general registers nor accumulators, only a stack pointer, SP, that contains the address of a pushdown stack in memory; all operations are performed on the stack. Many of Hewlett-Packard's desktop and hand-held calculators, for example, are stack machines. Also, most accumulator and general-register processors have at least a few stack-oriented instructions.

Typical RISC processors do not typically have stack-oriented instructions, but their programs can implement stacks using appropriate combinations of simple instructions. Likewise, several high-level programming languages, including FORTH and PostScript, have a stack-based view of the world that can be achieved by appropriate combinations of instructions in any processor, stack machine or not.

Memory

The *memory* (or *main memory*) of a computer contains storage for instructions and data, and is tied to the processor via the memory bus in Fig. 2. A *bus* is

simply a bundle of wires or any other physical medium for transferring information. A computer memory has some number of *locations*, each of which stores a b-bit quantity. In most contemporary computers, each location stores an 8-bit *byte*. Associated with each location in the memory is a unique binary number called the *address*. If there are n locations, then the addresses range from 0 to $n - 1$.

The key feature that distinguishes main memory from other forms of storage in a computer is *random access*—the processor has equally fast access to every location in memory. Random access memory is analogous to a wall of post office boxes; a postal clerk can deposit mail in any box with equal ease. Compare this with the *serial access* method of a letter carrier who visits locations sequentially, in the order of the route. Magnetic tapes provide serial-access memory in computer systems.

Fig. 4 shows how the processor accesses main memory in a typical small computer system. The memory is an array of n locations of b bits each. To read the data stored at location X, the processor places the number X on the address bus, and activates a read control signal; the memory responds by placing the contents of location X on the data bus. To write a value V at location X, the processor places X on the address bus and V on the data bus and activates Write; the memory immediately writes the value V in the specified location. Subsequent reading of address X will now return the value V.

Fig. 5A provides a conceptual view of a memory with 2^{16} bytes; a 16-bit address uniquely specifies any byte in this memory. Larger memories use more address bits.

Fig. 5B shows the physical memory organization used in 32-bit Motorola 68000-family microprocessors. Notice that although the memory is 32 bits (4 bytes) wide, each byte has its own address. Also, more bytes (2^{32}) can be addressed, since addresses are 32 bits wide. In the 68000 memory, a 16-bit *word* is defined as two consecutively numbered bytes, and a 32-bit *long word* is four consecutive bytes. For example, "word 2" consists of bytes 2 and 3, and "long word 4" consists of bytes 4 through 7. A word whose address is a multiple of two, or a long word whose address is a multiple of 4, is said to be *aligned*.

Fig. 5C shows the physical memory organization used in 32-bit Intel 80x86 microprocessors (the 80386 and its successors). The memory organization is similar to that of the 68000 family, except that the byte numbering within a word is reversed. (Somehow, it is befitting that the 68x and x86 families should have their byte order reversed!)

A 4-byte quantity in the 80x86 is called a *double word*. The 80x86 allow words and double words to be *nonaligned*. For example, "word 7" in Fig. 5C consists of bytes 7 and 8, with byte 7 occupying the most significant position in the word. However, aligned words can usually be accessed in physical memory faster than nonaligned ones.

Note that "word" doesn't mean the same thing in all processor architectures. For example, in most RISC architectures, "word" refers to a 32-bit quantity, and a 16-bit quantity is called a *halfword*.

Several types of memories are commonly used in computer main memory systems. With a *read/write memory (RWM)*, a processor can store data at any address and read back the stored information at any time. Most semiconductor RWMs are *volatile*, in that the stored information disappears when power is removed.

With a *read-only memory (ROM)*, a processor can read the contents of any address at any time, but data values can be stored only once, when the ROM is manufactured. The key advantage of a ROM is that it is a *nonvolatile;* that is, its contents are preserved even if no power is applied.

A *programmable read-only memory (PROM)* is similar to a ROM, except that the customer may store data values (i.e., "program the PROM") using a *PROM programmer*. A PROM chip is manufactured with all its bits at a particular value, typically 1. The PROM programmer can be used to set desired bits to the opposite value. In PROMs that use bipolar technology,

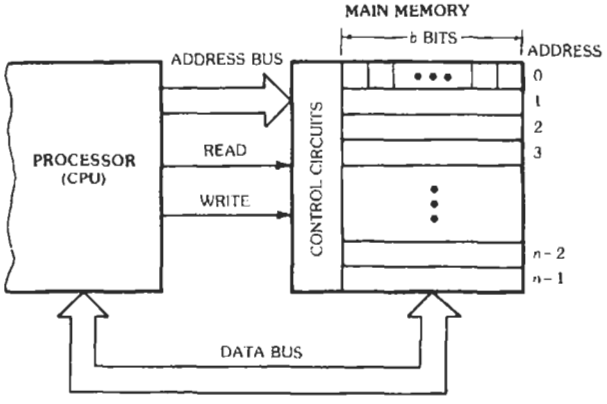

Fig. 4. Main memory in a typical computer.

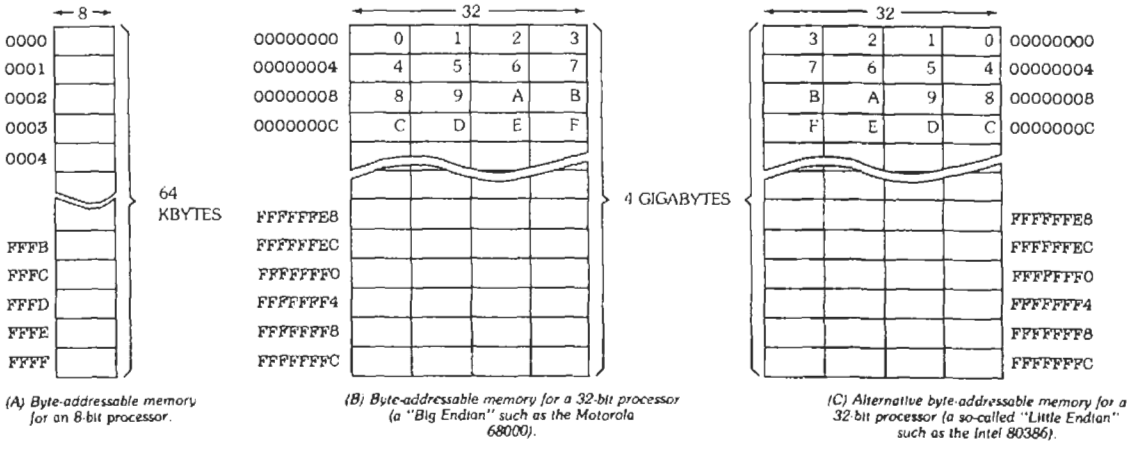

(A) Byte-addressable memory for an 8-bit processor.

(B) Byte-addressable memory for a 32-bit processor (a "Big Endian" such as the Motorola 68000).

(C) Alternative byte-addressable memory for a 32-bit processor (a so-called "Little Endian" such as the Intel 80386).

Fig. 5. Memory organizations.

this is typically done by vaporizing tiny fuses inside the PROM corresponding to each bit. In MOS PROMS, this is typically done by forcing electrons into tiny insulated wells corresponding to each 0 bit, where they can remain trapped for 10 years or more.

An *erasable programmable read-only memory (EPROM)* is similar to a PROM, except that the EPROM can be "erased" to the all-1's state by exposing it to ultraviolet light. An *electrically erasable programmable read-only memory (EEPROM or E^2PROM)* is similar to an EPROM, except that it may be erased electrically.

Every computer has RWM for storing variable data. Depending on the computer and the application, the programs may also be stored in RWM, or they may be stored in ROM, PROM, EPROM, or EEPROM. Storing programs in EEPROM is especially advantageous in embedded-control applications, since software can be updated (for example, via modem) without requiring the chip to be physically replaced.

All of the memories described above are *random-access memories*, because the processor has equally fast access to every memory location. However, computer jargon has developed so that the acronym "RAM" most commonly refers to read/write memory only.

Input/Output

The *input/output (I/O)* subsystem of a computer contains *peripheral devices* for communicating with, observing, and controlling the world outside the computer. Peripheral devices include terminals, printers, communication devices, and mechanical sensors and actuators. Also included in the I/O subsystem are *mass storage devices* such as magnetic tapes and disks. These devices are used to store information not needed in the main memory at all times, such as applications programs and text files. Not all computers have mass storage devices, but all useful computers have at least one peripheral device, since by definition a peripheral is the only means for the computer to communicate with the outside world.

The processor writes and reads information to and from peripherals by means of I/O instructions that place commands and data on the I/O bus. In many computers, both main memory and peripherals share the same physical bus. Going one step further, some processors communicate with their peripherals using registers that masquerade as memory locations. In such computer systems, the processor makes no distinction between accessing main memory and accessing peripherals.

In simple computer systems, there is no direct path from peripherals to main memory; the only way to transfer data between a peripheral and memory is for the processor to read it from the peripheral and store it in memory, or vice versa. However, systems requiring a higher data transfer rate incorporate *direct memory access (DMA)*, a link between a special peripheral controller and memory that allows a peripheral to read and write memory without processor intervention.

PROCESSORS AND PROGRAMMING

The Motorola 68000 microprocessor family, used in Apple's Macintosh computers, contains several different microprocessor chips that share a common base architecture. The 68000 architecture is an excellent example of a general-register processor, and we'll use it to introduce general concepts of processor architecture and assembly-language programming in this section.

Organization of a General-Register Processor

Fig. 6 shows the conceptual organization of a typical 68000-family processor. This processor accesses a

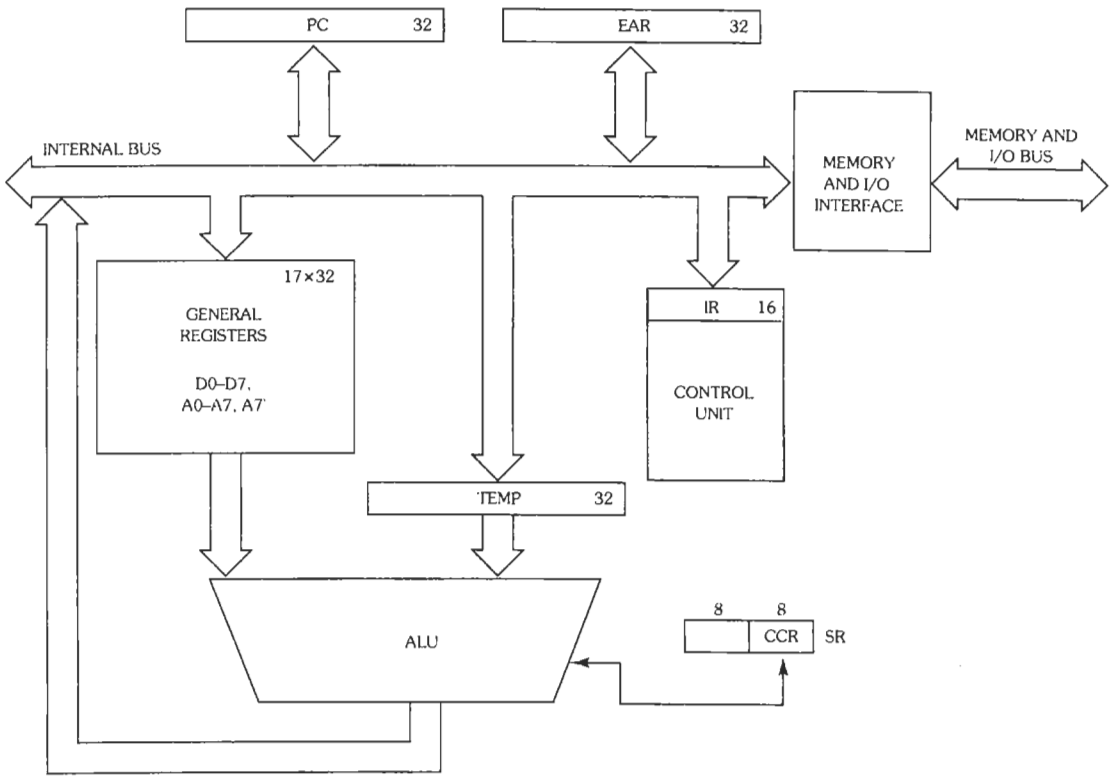

Fig. 6. Organization of a 68000 processor.

memory of up to 2^{32} bytes (16 megabytes) arranged as in Fig. 5B. Thus, an address is specified by a 32-bit number (4 bytes, or a longword).

The operation of the 68000 (or almost any other computer processor) consists of endless repetition of two steps: read the next instruction from memory (the *fetch cycle*) and perform the actions it requires (the *execution cycle*). Several registers and functional units are involved in instruction fetching and execution:

- *Program counter (PC):* A 32-bit register that holds the memory address of the next instruction to be executed.
- *Instruction register (IR):* A 16-bit register that holds the first word of the currently executing instruction.
- *Effective address register (EAR):* A 32-bit register that, when required, holds a memory address at which the processor reads or writes data during the execution of an instruction.
- *General registers (D0–D7, A0–A7, A7'):* A set of seventeen 32-bit registers containing data and addresses. Registers D0–D7 are called *data registers*, and A0–A7 and A7' are called *address registers*. Register A7 is the *user stack pointer (SP or USP)*, and A7' is the *supervisor stack pointer (SSP)*.
- *Temporary register (TEMP):* A 32-bit register that holds operands or intermediate results during the execution of an instruction.
- *Condition code register (CCR):* A set of 1-bit flags that the processor sets or clears during the execution of each data manipulation instruction.
- *Status register (SR):* A 16-bit register whose high-order byte contains "processor control" bits and whose low-order byte is the CCR.
- *Arithmetic and logic unit (ALU):* Operates on one or two 8-, 16-, or 32-bit quantities, producing a like-sized result.
- *Control unit:* Decodes instructions and controls the other blocks to fetch and execute instructions.
- *Memory and I/O interface:* Reads and writes memory and communicates with I/O (Input/Output) devices as commanded by the control unit.

Although all of the blocks above are essential to the internal operation of the 68000, only the registers PC, D0–D7, A0–A7, A7', and SR are explicitly manipulated by instructions and have values that are meaningful after the execution of each instruction. Such registers comprise the *processor state*, and may be shown in a

programming model for the processor, as in Fig. 7. Only these registers are of concern to a programmer.

Instruction Formats

For the purposes of illustration, we introduce a subset of the complete 68000 instruction set. Instructions in the subset are one to four words long.

The first word of each instruction is called the *opcode word*. It contains an operation code (*opcode*) and zero, one, or two *effective-address (EA) fields*. The opcode uniquely specifies the operation to be performed, while each EA field specifies the register or memory location that contains an *operand* to be manipulated by the instruction.

If an operand is a variable stored in memory, then an additional instruction word may be used in computing the address of the memory location. If the operand is an "immediate" constant, then one or two additional instruction words may contain the constant value.

As shown in Fig. 8, the instructions in the subset use six different formats for the opcode word, as required by different operations and operand types. There are many other formats used by the full 68000 instruction set.

To understand why a particular set of formats is used in a given processor architecture, one must understand the goals, optimizations, and compromises of the architects, which is beyond the scope of this chapter. When you look at the formats in Fig. 8, you will often ask, "Why did they do *that*?" This question is easier to answer in view of the full 68000 instruction set, because there are many more instructions to be encoded, but even the full set of 68000 instructions is encoded somewhat irregularly.

In RISC architectures, instruction formats are quite a contrast from those of the 68000. A hallmark of RISC architecture is that all instructions have the same, fixed width (one word), and there are very few distinct instruction formats. This greatly simplifies and speeds up instruction fetching and decoding.

Returning to the 68000, most of its data-manipulation instructions can operate on bytes, words, or longwords. The operand size is encoded as part of the opcode in MOVE instructions (Fig. 8A) and in the size or op-mode field in other instructions (Figs. 8B and 8C).

Instructions that reference memory contain a 6-bit EA field that specifies the location of the operand; MOVE contains two such fields. In all of these instructions, the EA field can specify one of several "addressing modes" as discussed shortly. Some addressing modes require an additional word of addressing information to be appended to the instruction, thus giving rise to two- to four-word instructions.

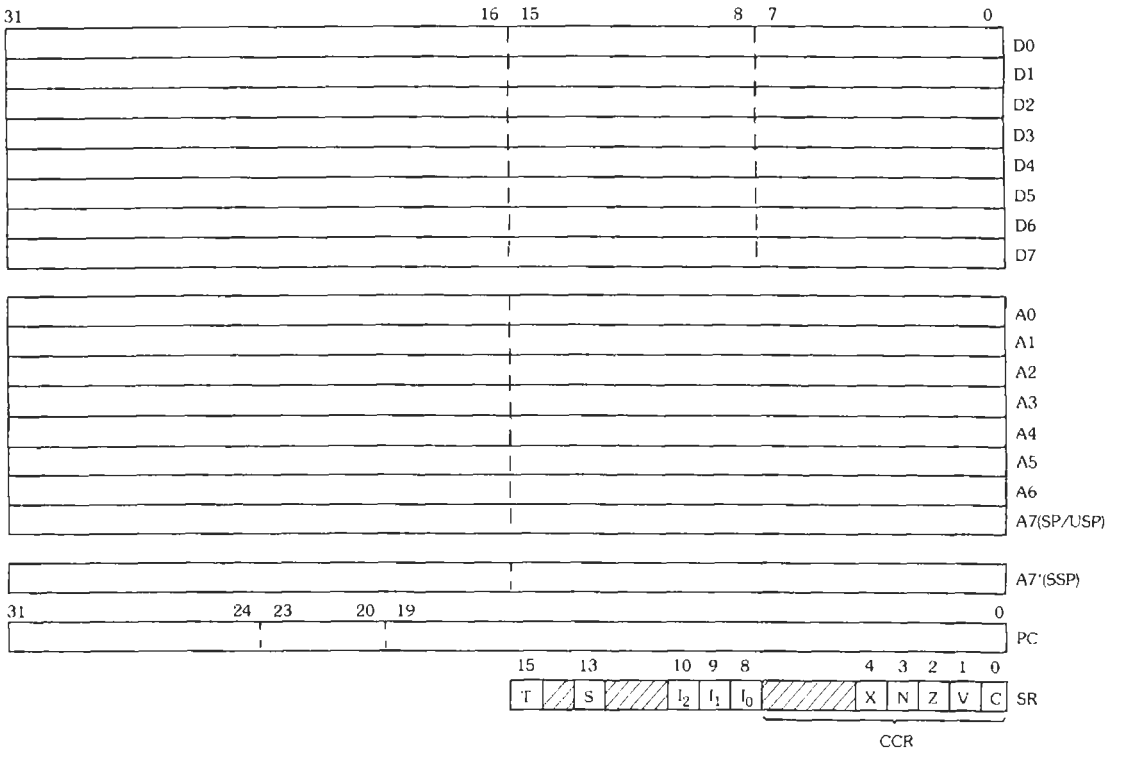

Fig. 7. Programming model for the 68000.

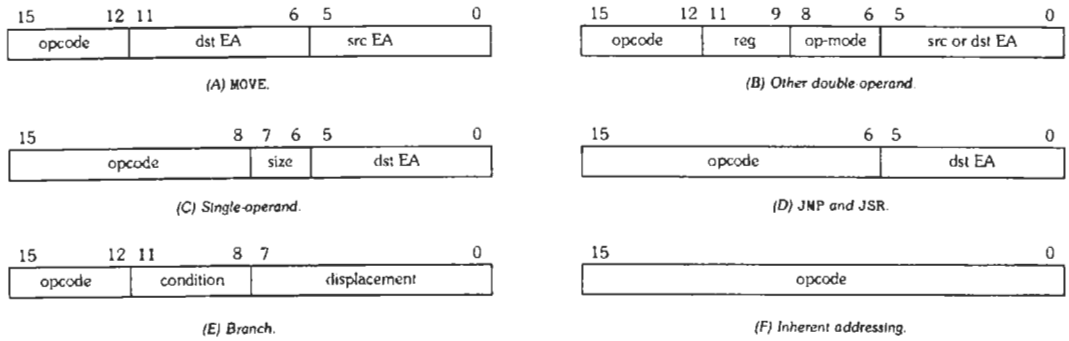

Fig. 8. Format of the opcode word of typical 68000 instructions.

Instruction Set

Table 4 lists a subset of the 68000 instruction set; the full 68000 has many more instructions. There are several different formats for the opcode word, as was shown in Fig. 8. Associated with each opcode word is an alphabetic *mnemonic* that we can use to name and recognize the operation performed by that instruction.

Note that our subset of the 68000 uses only four of the eight possible binary values in the 3-bit op-mode field; the complete 68000 uses them all, as listed in Table 5. In both the subset and the complete 68000, there are still more variations in each instruction according to the addressing modes specified for the source (src) and destination (dst) fields, as discussed in the next subsection. After that, we will describe the actual operations that are performed by each instruction.

Addressing Modes

In the 68000, an operand is specified by a 6-bit source or destination EA field in the instruction, consisting of a 3-bit addressing mode designator and a 3-bit register number, as shown in Fig. 9. In conjunction with the reg field, the eight mode combinations are used as follows:

- 0 reg specifies a data register (D0–D7) that contains the operand.
- 1 reg specifies an address register (A0–A7) that contains the operand.
- 2–6 reg specifies an address register that is used, possibly in combination with other values, to determine the effective address of an operand in memory.
- 7 reg does not specify a register at all; instead, the three reg bits specify one of five addressing modes that do not use a general register; three combinations are left over for future expansion.

A full treatment of 68000 addressing modes is beyond the scope of this chapter, but we shall discuss here the seven most important ones, which are summarized in Table 6.

In *register-direct addressing*, the operand is contained in one of the data registers D0–D7 or in one of the address registers A0–A7. As suggested by the dash lines in Fig. 7, word operations on the data registers use the low-order 16 bits, while byte operations use only the 8 low-order bits; the high-order bits in both cases are unaffected.

Word operations on the address registers also use the low-order 16 bits, but a write operation into an address register extends the most significant bit of the low-order word into the high-order word. This is consistent with the *short-addressing model* of the 68000 memory shown in Fig. 10, in which a 16-bit number can specify a memory address in the highest or lowest 32-kbyte portion of a 4-gigabyte (32-bit) address space.

Byte operations are not allowed on address registers, since an "address" should normally be at least a 16-bit quantity. The complete 68000 instruction set provides long-word operations on address registers, in order to handle addresses up to 32 bits long.

Register-direct addressing is not allowed with the 68000 JMP and JSR instructions, since it does not make sense to jump to a register.

In *immediate addressing*, a 1-, 2-, or 4-byte operand is contained in the second and possibly third word of the instruction, as appropriate for the size of the operation; with 1-byte operands, the high-order byte of the immediate word is unused. Thus, to place the value 1234_{16} in register D5, we could use the instruction, `MOVE.W #$1234,D5`. By convention, the notation "#" denotes an immediate operand, while the dollar sign ($) denotes a hexadecimal value. The machine language instruction occupies two words as shown in Fig. 11A.

With immediate addressing, the operand is *constant* value. Immediate mode cannot be used for a "destination" operand, since it would require the instruction to modify itself. Thus, `MOVE.W D5,#$1234` is not allowed.

In *absolute short addressing*, the instruction contains a 16-bit absolute memory address for the operand. The

TABLE 4. A SUBSET OF THE INSTRUCTION SET OF THE 68000

Mnemonic	Operands	Format	Opcode Word	XNZVC	Description
MOVE.B	asrc,ddst	a	0001ddddddssssss	-**00	Copy asrc to ddst (byte)
MOVE.W	asrc,ddst	a	0011ddddddssssss	-**00	Copy asrc to ddst (word)
MOVE.L	asrc,ddst	a	0010ddddddssssss	-**00	Copy asrc to ddst (long)

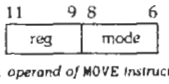
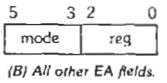
CMPA.L	asrc,An	b	1011rrr111ssssss	-	Set CCR using An—asrc (long)
CLR.B	ddst	c	0100001000dddddd	-0100	Set ddst to 0 (byte)
CLR.W	ddst	c	0100001001dddddd	-0100	Set ddst to 0 (word)
CLR.L	ddst	c	0100001010dddddd	-0100	Set ddst to 0 (long)
NOT.B	ddst	c	0100011000dddddd	-**00	Complement bits of ddst (byte)
NOT.W	ddst	c	0100011001dddddd	-**00	Complement bits of ddst (word)
NOT.L	ddst	c	0100011010dddddd	-**00	Complement bits of ddst (long)
BNE	offset	e	01100110oooooooo	-----	Branch if result nonzero (Z = 0)
BEQ	offset	e	01100111oooooooo	-----	Branch if result zero (Z = 1)
JMP	cdst	d	0100111011dddddd	-----	Jump to cdst address
JSR	cdst	d	0100111010dddddd	-----	Jump to subroutine at cdst address
RTS		f	0100111001110101	-----	Return from subroutine

Notes: asrc = any source operand, cannot be an address register in byte instructions.
csrc, cdst = control source or destination operand, cannot use register, autoincrement, autodecrement, or immediate addressing modes.
dsrc = data source operand, cannot be an address register.
ddst = data destination operand, cannot use address register direct, immediate, or relative addressing.
Dn = one of the data registers, D0–D7. An = one of the address registers, A0–A7.
offset = 8-bit signed integer added to PC if branch is taken.
s = bit in src field; d = bit in dst field; r = bit in reg (An or Dn) field; o = bit in offset field.
Condition Code Bits:
N—most significant bit of result was 1.
Z—result was zero.
V—operation caused twos-complement overflow.
C—addition or subtraction caused a carry or borrow from most significant bit, or shift caused a 1 bit to "fall off" the end.
X—when affected, same as C (but not always affected).
Effects of instructions on condition code bits:
-: not affected;
1: always set to 1;
0: always cleared to 0;
*: set according to operation result as detailed above.



(A) dst operand of MOVE instructions



(B) All other EA fields.

Fig. 9. Operand effective-address (EA) fields in the 68000.

TABLE 5. TYPICAL USE OF THE OP-MODE FIELD IN THE MOTOROLA 68000

Value (binary)	Operand Size	Register Type	Operation
000	byte	data	reg op src → reg
001	word	data	reg op src → reg
010	long	data	reg op src → reg
011	word	addr	reg op src → reg
100	byte	data	dst op reg → dst
101	word	data	dst op reg → dst
110	long	data	dst op reg → dst
111	long	addr	reg op src → reg

most significant bit of this 16-bit address is extended to produce a 32-bit address in the top or bottom 32 K-bytes of the address space, consistent with Fig. 10. Thus, the instruction `MOVE.W $4322,D5` Fig. 11B reads the 16-bit value currently stored at memory location `$4322` and copies (*loads*) it into register D5; the contents of memory are not disturbed. By convention, the absence of the modifier "#" denotes an absolute operand.

In the other direction, `MOVE.W D6,$5432` Fig. 11C *stores* the value of D6 into memory location `$5432`, without disturbing D6. Thus, an operand with absolute addressing is typically a *variable*, since the program may store different values into the specified memory location at different times.

Since MOVE instructions have two EA fields, they can perform memory-to-memory moves. For example, `MOVE.W $2222,$4444` is a three-word long instruction that copies the contents of memory word `$2222` to memory word `$4444`. Immediate-to-memory moves are also possible; for example, `MOVE.W #$1234,$4444` loads memory word `$4444` with the value `$1234`.

In *address-register indirect addressing*, the specified address register (`An`) contains the address of the operand. In this mode, not only is the operand a variable, but so is its address. Each time that the instruction is executed, the address register may "point to" a different memory location. This mode is useful for dealing with arrays, lists, and other data structures; we will give an example in a later section on Indirect Addressing.

In *based addressing*, the specified address register (`An`) contains a *base address* that is "near" the desired operand. The instruction contains a 16-bit, signed displacement value, `displ6`, which is added to the base address to obtain the effective address of the operand. Note that this sum is *not* written back into the address register, which remains unchanged.

Quite often, the base address is the starting address of a block of memory that has been reserved to store data. The displacement value `displ6` specifies the relative position of a particular datum in that block.

While absolute addressing requires a particular datum to be stored at the same absolute address every time the program is executed, based addressing allows addresses to be changed. For example, before giving control to a user's program, an operating system could reserve a block of memory for the user program to store variables, and pass its base address to the user program in an address register, say A5. The user program would refer to all variables using based addressing with fixed displacements (`displ6` values) from the base address

TABLE 6. SOME ADDRESSING MODES OF THE 68000

Name	mode	reg	Notation	Operand	Extra Words
Data-register direct	0	0–7	`Dn`	`Dn`	0
Address-register direct	1	0–7	`An`	`An`	0
Immediate	7	4	`#data`	`data`	1 or 2
Absolute short	7	0	`addr`	`MEM[addr]`	1
Address-register indirect	2	0–7	`(An)`	`MEM[An]`	0
Based	5	0–7	`displ6(An)`	`MEM[An+displ6]`	1
Relative	7	2	`raddr16(PC)`	`MEM[(raddr16-PLC)+PC]`	1

Notes: Dn denotes a data register: D0–D7.
An denotes an address register: A0–A7 or SP (same as A7).
`data` is an 8-, 16-, or 32-bit value as appropriate for the size of the operation.
`addr` is the 16-bit absolute memory address of the operand.
`displ6` is a 16-bit value that is sign extended to 32 bits before being combined with the address register.
`raddr16` is a relative address within 32 768 bytes of the instruction. The extension word contains a 16-bit displacement (`raddr16`–PLC, where PLC is the address of the extension word) that is sign extended to 32 bits and added to the PC to obtain the effective address of the operand when the instruction is executed.
`MEM[x]` is the 8-, 16-, or 32-bit value beginning at memory address `x`, as appropriate for the size of the operation.

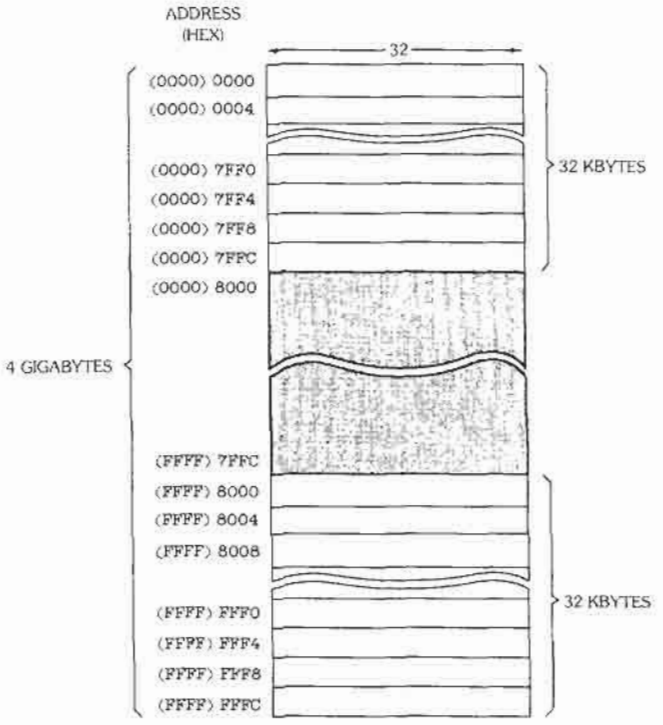


Fig. 10. Short-addressing model for memory in the 68000 family.

contained in A5. This technique is used extensively in programs written for the Macintosh computer.

Relative addressing is used to access constant data that is stored in the same block of memory as the program instructions themselves. Instead of specifying the absolute address of the operand, relative addressing specifies a *relative displacement*—the difference between the instruction address and the operand address. When the program runs, the instruction address (contained in the PC) and the relative displacement (contained in the extension word) are added to form the effective address of the operand. Instructions and operands that use relative addressing are *position independent*—the difference between instruction and the operand addresses remains constant even if the program and its constant data are picked up and moved to a different block of memory. Like based addressing, relative addressing is used extensively in position-independent programs written for the Macintosh and other computers.

The full 68000 processor and other "complex instruction-set computer" (CISC) processors provide many more addressing modes than shown here, in an attempt to provide efficient access to the data structures that are most commonly used in programs. For example, the full 68000 has "autoincrement" and "autodecrement" modes that are often used to access pushdown stacks, and based-indexed and memory indirect modes that are used to access arrays of records and records of arrays.

In contrast, RISC processors are normally characterized by the dearth of addressing modes that they support. In fact, typical RISC processors support only two of the addressing modes described in detail above —immediate and register indirect. Using just these two modes, a RISC processor can emulate any of the more complex addressing modes using a sequence of simple instructions that combine and adjust address values in whatever way is desired.

Operands and Operations

The first part of Table 4 contains double-operand instructions. Most instructions have three variations, indicated by ".B," ".W," and ".L" suffixes, for operating on byte, word, and longword data.

Each double-operand instruction has a "source" operand and a "destination" operand. The 68000 restricts the addressing modes that can be used to specify operands depending on the type of the operand (source or destination), the size of the operand (byte, word, or longword), and the instruction (e.g., MOVE vs MOVEA). In Table 4, `asrc` denotes the most general source operand, which may use any addressing mode (unless the operand is a byte, in which case address register direct addressing is not allowed). A `dsrc` operand may use any mode except address register direct. Similar restrictions apply to the destination operand types `adst` and `ddst`, with the additional

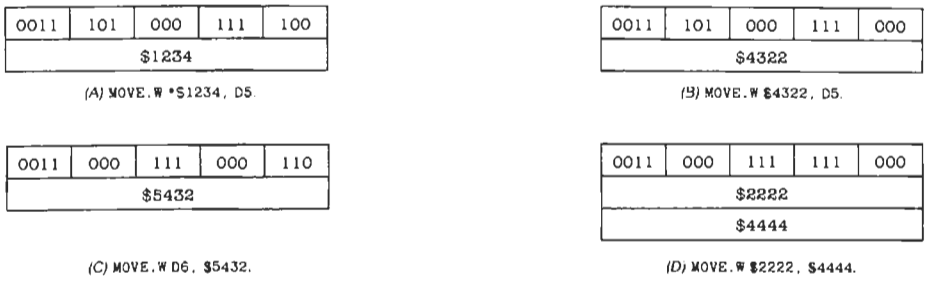

Fig. 11. Encodings of various machine instructions.

restriction that immediate and relative addressing are not allowed. In some cases, operands may be only an address register or a data register; these are explicitly indicated in the table as An or Dn, respectively.

Special cases like the ones described above are the sort of thing that drives compiler writers crazy, and historically motivated the architecture of RISC microprocessors. In a typical RISC microprocessor, any register may be used as the source or destination of any operation, and any operation can use any register. However, memory can be accessed only with two basic, essential instructions—LOAD (from memory) and STORE (into memory). As a result, a compiler has a much better chance of using all of the resources of the processor in an efficient manner.

Now we return to the operations of the 68000. The MOVE instructions simply copy data from one place to another—the operand specified by the `src` field is copied to the place specified by the `dst` field, without disturbing the `src` data. Since `src` and `dst` may use different addressing modes, a MOVE instruction can copy from register to register, register to memory, memory to register, or memory to memory. The MOVEs are the only instructions that provide all these addressing options; other instructions do not provide memory-to-memory operation or register-to-memory operation (except arithmetic on data registers).

The MOVE instructions affect four of the condition code bits as a side effect. The condition code bits store information about the results of most operations. For example, when affected the *zero bit* (Z) is set to 1 if the instruction produces a zero result (all bits 0), and to 0 if the instruction produces a nonzero result. An instruction that affects the Z bit can be followed by a *conditional branch instruction* to perform one of two possible actions depending on the value of Z, as we will describe at the end of this section.

MOVEA is a special version of the MOVE instruction used only when the `dst` operand is an address register. Its encoding is consistent with that of MOVE, and it differs only in that it does not affect the condition codes; this reflects the 68000 designers' philosophy that the "arithmetic" value of an address should have no significance, and that address registers should contain only addresses. In keeping with this philosophy, note also that instructions with single-byte operands cannot have an address register as an `src` or `dst` operand, since in the 68000 addresses are never as short as one byte.

The LEA instruction is sort of a half-hearted MOVE. Rather than actually read its operand, LEA merely computes the effective address of the operand and deposits it in an address register for later use. This instruction is a result of the 68000 designers' philosophy that, while 32-bit addresses are "expensive" (it would waste a lot of program memory to carry one or two addresses in every instruction), address *registers* are "cheap" (there are eight of them available). Therefore, if a memory operand is going to be referenced more than once, it makes sense to compute its address only once and keep the address lying around in an address register where it can be quickly and inexpensively used later as needed. We will address this subject in more detail in a later section on Indirect Addressing. But before leaving LEA, also notice that in keeping with the 68000 designers' philosophy about the nature of addresses, the LEA instruction does not affect the condition bits.

The ADD instructions perform a twos-complement addition of a source operand and a data register, and store the result in the data register. The condition codes are affected, so that an ADD may be followed by a conditional branch to test the value of the result. The AND instructions are similar to the ADDs, except that they perform a bit-by-bit logical AND of their operands.

The ADDA instructions add to an address register; there is no byte version of this instruction since addresses are never only 8 bits wide. An ADDA instruction is typically used to compute the address of a particular item in a complex data structure. Like other instructions with address-register destinations, ADDA does not affect the condition bits.

The CMP and CMPA instructions subtract an `src` operand from a register, and set the condition codes according to the result, without affecting either operand. Thus, CMP and CMPA may be used to compare two operands for equality or other relationships, without disturbing the current values of the operands.

The second part of Table 4 contains instructions that have just one destination operand. The CLR instructions set their operand to 0, obviously useful for initializing variables. The NOT instructions complement each bit of

their operand, useful in conjunction with AND instructions for isolating bits in a single byte or word where different bits or fields contain unrelated data. Note that these instructions do not work on address registers, once again because of the philosophy that addresses have no arithmetic or bitwise significance.

The third part of Table 4 contains "program control" instructions that can affect the normally sequential fetching and execution of instructions. The BNE and BEQ instructions add an offset value to the PC if the Z bit is 0 or 1, respectively. Otherwise, execution continues with the next instruction.

The 68000 processor interprets the `offset` field of a branch instruction as a signed, twos-complement integer in the range −128 to +127. Since instructions must start on even addresses (word boundaries), the range is actually restricted to −128 to +126. At the time that the processor tests the branch condition, the PC is already pointing to the next instruction, and so the branch offset is limited to −128 to +126 bytes from the next instruction.

According to this convention, if the branch offset is 0, the next instruction should be executed whether the condition is true or false. However, since such an instruction performs no useful work and would therefore never be used, the designers of the 68000 used the `offset=0` case to specify another instruction type in the full instruction set. Also, since instructions are aligned on word boundaries, odd offsets such as −127 are not used; the 68020 uses this to encode yet another instruction type.

The JMP instruction in the 68000 is equivalent to the GOTO instruction in C, Pascal, and most other high-level languages. It unconditionally transfers control to an instruction starting at the destination address. It does this by simply replacing the current value of the PC with the destination address.

The JSR and RTS instructions are used to call and return from subroutines, as we will discuss in detail in a later section on Subroutines.

A MACHINE LANGUAGE PROGRAM

Table 7 shows the values stored in memory for a sequence of instructions and data that form a program for multiplying 123 by 456. A list of machine instructions stored in memory, as defined by the two left-hand columns of the table, is called a *machine language program*. Even though they don't mean much to a human reader, these two columns completely specify the operations to be performed by the computer. The remaining columns of Table 7 are an *assembly-language*

TABLE 7. MEMORY CONTENTS FOR A SEQUENCE OF INSTRUCTIONS AND DATA

Machine Language		Assembly Language			
Address (hex)	Contents (hex)	Label (sym)	Opcode (mnem)	Operand (sym)	Comments

Notes: hex = hexadecimal; sym = symbolic; mnem = mnemonic.

program that gives the same information in a much more understandable symbolic form. In the next two subsections, we will discuss assembly language and then describe the actual behavior of the machine-language program.

Assembly Language

Machine language and assembly language are not the same thing. The *machine language* of a computer is the set of bit strings recognized as instructions; the actions performed by each machine instruction are defined by the computer hardware. *Assembly language* is a software tool, a symbolic language that can be directly translated into machine language by a system program called an *assembler*. The output of an assembler is an *object module* containing the bit strings that make up the machine language program, and information that tells a *loader* program where to place these bit strings in the computer memory.

The process of developing programs in assembly language is illustrated in Fig. 12. A typical programmer uses a *text editor* to create a text file containing an assembly language program. The names *source file* and *source program* are often used for assembly language and high-level language text files. The assembler accepts a source program as input, checks for format errors, and produces an object module containing the machine language program. A loader then loads the object module into the memory of the target machine. There the machine language program is run, possibly with the aid of a *debugger*.

The loader, debugger, and machine language program described above *must* run on the target machine; the text editor and assembler may run there or on a different machine. An assembler that runs on one machine and produces object modules for another is called a *cross assembler*. For example, it is possible to create an assembly language program by using a text editor on a laptop computer, transfer the source file by using a serial data link to a workstation that runs a cross assembler, and transfer (or *download*) the object module to a loader in an embedded microcomputer by way of another serial data link.

Although every computer manufacturer defines a standard assembly language for a new machine when it is introduced, other vendors may define different assembly languages for the same machine. While the effect of each machine language instruction is fixed in hardware, the person who defines an assembly language is free to specify:

- A mnemonic for each machine language instruction
- A standard format for the lines of an assembly language program
- Formats for specifying addressing modes and other instruction variations
- Formats for specifying character and integer constants in different bases
- Mechanisms for associating symbolic names with addresses and other numeric values
- Mechanisms for defining constant data to be stored in memory along with the instructions when the program is loaded
- Directives that specify how the program is to be assembled

In a typical assembly language for the 68000 or any other processor, each line has four fields arranged as shown below:

```
LABEL  OPCODE  OPERANDS  COMMENTS
```

The LABEL field is optional. A *label* is simply an identifier (or *symbol* in assembler parlance), that is, a sequence of letters and digits beginning with a letter. Every symbol in an assembly language program is assigned a value at the time that it is defined; the assembler program keeps track of labels and their values

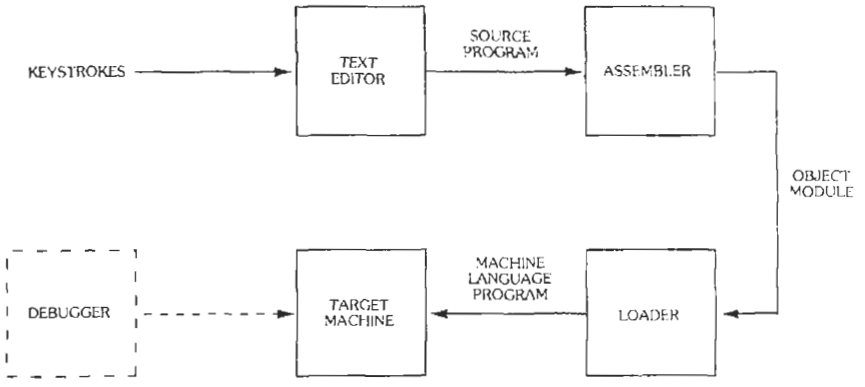

Fig. 12. Assembly language program development.

by an internal *symbol table*. For example, in the statement below,

```
START  MOVE.W   XX,D0      D0 := con-
tents of memory location XX.
```

the value of the symbol START equals the memory address at which the MOVE.W instruction is stored. In general, the value of a symbol is the memory address at which the corresponding instruction or data value is stored (except with the EQU pseudo-operation, described later). Each symbol may be defined only once, but may be referenced as often as needed.

Symbols only have values at the time a program is being assembled, that is, at *assembly time*. Symbols exist in the source text of the program, and in the environment of the assembler, but do not appear in the machine-language program. For instance, when our example program is loaded into memory (at *load time*) or is actually run (at *run time*), there is no way to discover, simply by looking at the object module or at memory, that the programmer had associated the symbol MULT with address $00001000, or even that there had been a symbol MULT at all. (However, *symbolic debuggers* may access this information in the run-time environment by referring to a copy of the source code and the symbol table that were used by the assembler.)

The OPCODE field contains the mnemonic of either a machine instruction or a pseudo-operation or assembler directive. In 68000 assembly language, many opcode mnemonics have a *size suffix* of .B, .W, or .L to indicate the size of the operands and operation. The size suffix is optional for operations that have only one size (such as LEA).

Depending on the contents of the OPCODE field, the OPERAND field specifies zero or more operands separated by commas. An operand is an expression consisting of symbols, constants, and operators such as + and −. The simplest expression consists of a single symbol or constant.

In 68000 assembly language, a sequence of decimal digits denotes a *decimal constant*, and a sequence of hexadecimal digits preceded by $ denotes a *hexadecimal constant*. *Character constants* are surrounded by single quotes (e.g., 'A') and have the corresponding ASCII value.

The COMMENTS field is ignored by the assembler, but it is used by the programmer to convey a high-level explanation of the program to human readers. It is also possible to use an entire line as a comment by placing and asterisk (*) at the beginning of the line.

Four different *assembler directives* appear in Table 7; their functions are described below:

- ORG (origin). The operand is the address at which the next instruction or datum is to be deposited when the program is loaded into memory. Subsequent instructions and data are deposited in successive memory addresses.
- DS.W (define storage—word). The operand is a number of memory words to be skipped without storing any instructions or data, thereby reserving space to be used by variables in a program.
- DC.W (define constant—word). The specified word value is stored into memory when the program is first loaded into memory, thereby establishing a constant value that may be accessed when the program is run.
- EQU (equate). The identifier in the label field is assigned the value in the operand field, instead of the value in the address field. This makes the identifier a synonym for a constant value for the duration of the assembly process.
- END (end assembly). This pseudo-operation denotes the end of the text to be assembled. Its operand, if present, is the address of the first executable instruction of the program.

Of course, there are many other directives in a full assembly language, and different assembly languages may use different names and conventions for the same thing.

The input of an assembler is the text file containing the source code, while the output consists of an object module (or "object file" or "binary file") and a listing similar to Table 7.

To understand a little more about how an assembler works, it is useful to examine the Address column in the listing. The Address column indicates the address at which the assembler "thinks" that it should assemble the instruction on the current line. By default, this address is initialized to zero.

The ORG directive tells the assembler to start assembling subsequent instructions starting from a new address, and hence changes the Address column on the *next* line. Some directives, such as EQU, do not assemble any instructions or data and therefore do not affect the Address column at all. Others, such as DS.W, advance the Address value but do not cause anything to be loaded into the corresponding memory location at load time.

For its own and the programmer's use, the assembler creates a *symbol table* that lists the numeric value associated with each symbol. As evident in Table 7, in most cases the symbol receives the value of the Address column in the line in which it is defined, except in the case of EQU statements, which assign the symbol the value in the Operand column. In all cases, the symbols and their values exist only at assembly time.

Many instructions in the 68000 are more than one word long. It is therefore convenient to compress the program listing, showing all words associated with the same instruction on one line as in Table 8.

OPERATION OF A SIMPLE PROGRAM

We are now ready to explain the program in Table 8. It multiplies MCND by MPY by initializing the product to 0 and then adding MCND to it MPY times.

Notice that the values of the multiplier and multiplicand are "passed" to the program in fixed memory locations, $101A and $101C, that are initialized to 123 and 456 when the program is loaded. If, after loading the program, we start the program at location $1000, it will indeed compute the product of 123 and 456. Alternatively, if after loading the program we place different numbers in locations $101A and $101C, then the program will compute the product of the new numbers. In any case, the program "returns" its result by placing the result in memory location $1018, which may be examined by whoever ran the program in the first place.

The program uses registers to accumulate the product (in D0) and to keep track of the multiplier count (in D1), because registers can be accessed faster than main memory in most computers, and hence the program will run faster. In fact, we could optimize the program to run even faster by placing MCND into a register (say D2) before entering the multiplication loop.

The program execution is traced by Table 9, which shows the values of relevant registers and memory *after* each instruction is executed. Only the low-order words of PC, D0, and D1 are shown; the high-order words are not affected by this program. During its execution, the program executes 374 instructions, including three instructions in a loop that is executed 123 times.

So, the program begins by setting D0 to zero and copying MPY into D1. The MOVE instructions set the condition bits in CCR according to the value stored. In particular, the Z bit is set to 1 if a zero value (0000_{16}) was stored, or else Z is cleared to 0. Therefore, if MPY is zero, the Z bit is 1 when the BEQ DONE instruction is first reached, and the branch will be taken, leaving zero in D0. The purpose of this instruction is to exit the program with a product of 0 if the multiplier happens to be zero. Notice that the branch instruction gives a *relative offset* of $0A, so that either the next instruction (at address $1008) or the instruction at the branch offset (address $1008+$0A = $1012) is executed.

If the BEQ branch is not taken, then the two ADD instructions add MCND to the product in D0 and subtract 1 from the loop count in D1. Like a MOVE instruction, an ADD instruction sets Z to 1 if its result is zero. Thus, if D1 has *not* been reduced to zero, the BNE instruction will branch back to address $1008. (The 8-bit signed offset $F6, interpreted in twos-complement, equals −$0A; hence the branch is to address $1012−$0A = $1008.)

Eventually, after executing the loop 123 times, the program reaches the MOVE instruction at address $1012, which saves the accumulated product in memory. Finally, the program unconditionally jumps to address $7008, where we assume there exists a debug monitor that prints out or gives the user some way to examine the computational result stored at location $1018.

Indirect Addressing

The program in Table 8 manipulated only simple variables and constants. More complicated data structures such as arrays, stacks, queues, records, and lists are used in almost all programs. Consider the problem

of initializing the components of an array of five bytes to zero. An assembly language solution is shown in Table 10. Note that the operand expressions Q+1, Q+2, and so on are evaluated at assembly time. The choice of a five-component array above was very judicious—the corresponding program for a 100-component array would have 101 instructions! *Indirect addressing* avoids this problem by taking the address from an address register at run time. Thus we can write a loop to initialize an array, in which an address register points to a different array element on each iteration of the loop.

The program in Table 11 solves the array initialization problem by using indirect addressing. As shown in Fig. 13, it initializes A0 to point to the first component of Q, and A1 to point just past the last component of Q. Then it executes a loop that clears successive components of Q, incrementing A0 once per iteration of the loop. The CMPA instruction compares the contents of A0 with A1, which was initialized to contain the address just past the last array component. CMPA sets Z to 1 if A0 and A1 are equal, which causes the BNE instruction to terminate the loop.

Notice the use of the LEA instruction in Table 11, in particular the second one, which initializes A1. Performing this initialization outside the main loop reduces the length and execution time of the instructions inside the loop. An obviously less desirable alternative would have been to put the LEA instruction inside the loop, right before CMPA.

Not only does the program in Table 11 occupy fewer bytes than the one in Table 10, but it also stays the same length for an array of any size. The program is easily modified to work on a different length array by changing the occurrences of the length "5" to the desired length.

Many other variations on indirect addressing are found in the full 68000 and most other CISC processors. RISC processors, on the other hand, typically have register indirect addressing as their one and only memory addressing mode.

Subroutines

A *subroutine* is the machine language equivalent of a procedure or function in C, Pascal, and other high-level languages: a sequence of instructions, defined and stored only once, that may be invoked (or *called*) from many places. In order to use subroutines, we need instructions to save the current value of the PC (the *return address*) each time the subroutine is called, and restore it when the subroutine is finished. In the 68000, these instructions save and restore PC by use of a stack.

A *pushdown stack* (or simply a *stack*) is a one-dimensional data structure in which values are entered and removed one item at a time at one end, called the *top of stack*. A register called the *stack pointer* (SP) points to the top of stack. An item is entered by a *push* operation that advances the stack pointer to the next available memory location and then stores the item at the top of stack. An item is removed by a *pop* operation that removes the item at the top of stack and then backs up the stack pointer.

In the 68000, the JSR and RTS instructions perform subroutine calls and returns using address register A7 (also called SP) as a stack pointer. Any 68000 program

00003105			END	INIT	

that uses subroutines is required to reserve a small area of memory for a pushdown stack for return addresses. At the beginning of such a program, the stack pointer SP must be initialized to point at this area by a `MOVE.W #addr,SP` instruction.

As shown in Fig. 14, SP points to the top item in the stack, or just past the stack area if the stack is empty. SP is decremented by 2 before each word is stored on the stack, and incremented by 2 after each word is popped from the stack.

Since a return address may be up to 32 bits wide, two words on the stack are used for each return address. As usual, the high-order word of the 32-bit return address is stored in the lower-numbered address.

The JSR `addr` instruction saves the address of the next instruction by pushing it onto the stack and then jumps to the instruction at location `addr`, the first instruction of the subroutine. At the end of the subroutine, RTS pops an address from the stack into PC, effecting a return to the original program sequence.

A stack is the most appropriate data structure for saving return addresses, because it can store more than one return address when subroutines are *nested*, that is, when one subroutine calls another. The number of levels of nesting is limited only by the size of the memory area reserved by the programmer for the stack.

A detailed example program using subroutines is presented in Table 12. Before describing it, we should

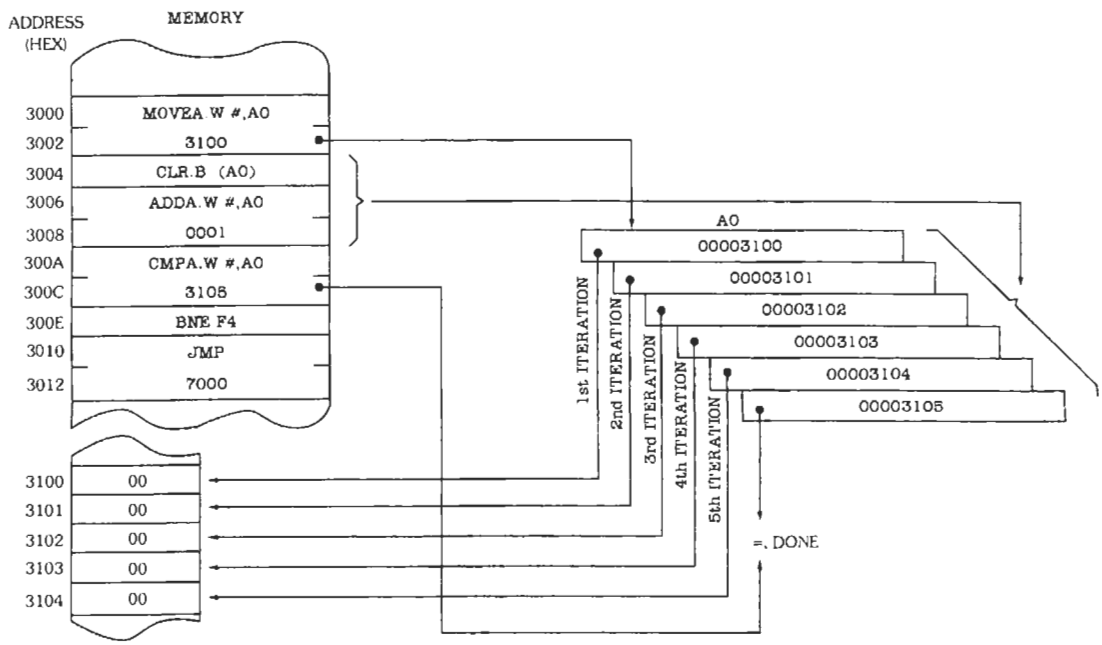

Fig. 13. Effects of indirect addressing.

point out a few additional assembly language pseudo-operations and features that it uses:

- DS.B (define storage—byte). The operand specifies a number of memory bytes to be skipped without storing any instructions or data, thereby reserving space to be used by variables in a program.
- DC.B (define constant—byte). The specified byte values are stored into memory when the program is first loaded into memory, thereby establishing a constant value that may be accessed when the program is run.
- * (program location counter). When used in an expression, the symbol "*" denotes the current address at which assembly is taking place.

The program in Table 12 contains a main program and two subroutines. The main program initializes SP to point to an 8-word stack. A stack of four words would have been sufficient for the two nested subroutines in this program, but it is a good practice to provide "headroom" in case programming errors, modifications, or interrupts increase the space required.

The main program loads a 16-bit word into the low-order word of D0 and calls a subroutine WCNT1S that counts the number of 1 bits. WCNT1S splits the low-order word of D0 into two bytes and calls a subroutine BCNT1S to count 1's in each byte. The usefulness of subroutines is evidenced by the fact that BCNT1S can be called more than once and with a different byte to be processed each time.

Fig. 15 shows the state of the stack after each instruction that affects it. When WCNT1S returns to the

main program, the stack is again empty and D1 contains the 1st count. The main program terminates by jumping to the operating system.

The individual subroutines in Table 12 are worth discussing. On entry, WCNT1S expects the input word to be in D0, which it writes into a memory word that is read back as two individual bytes passed to BCNT1S. The memory write and reads are used because there are no instructions to directly break out the high-order byte of a register.

When BCNT1S is entered, it expects the input byte to be in D0. The subroutine checks each bit position for a 1 and maintains a count in D1 accordingly. It uses a table of eight "mask bytes," each having a 1 in a different bit position. At each iteration of the loop, A0 contains the address of a mask byte, and a correspond-

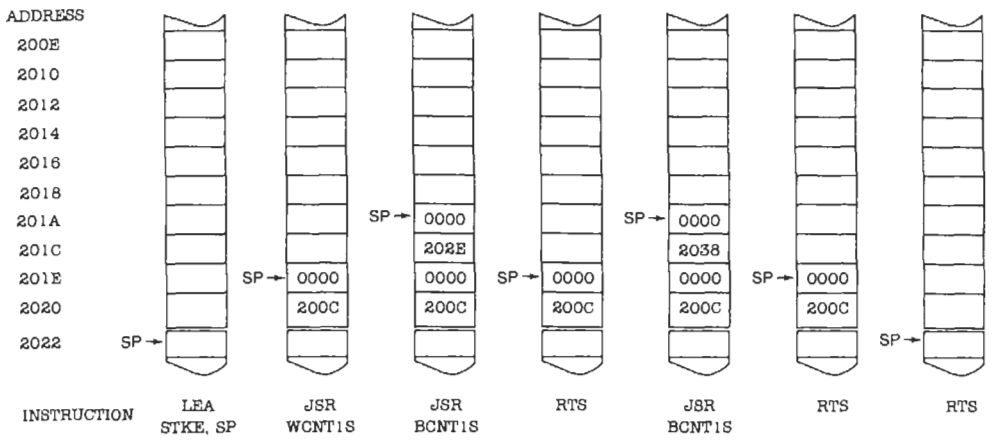

Fig. 15. Stack contents after the execution of instructions in Table 12.

ing bit of D0 is tested by the AND.B D0,D2 instruction. AND.B produces a nonzero result if and only if the tested bit of D0 is 1.

Like procedures and functions in high-level languages, subroutines are the key to structuring assembly language programs. A typical program is divided into many "modules," each of which is a subroutine with inputs, outputs, and local data.

INPUT/OUTPUT

Of the three major subsystems of a computer, input/output has experienced the biggest evolution, because of the explosion of computer applications and the hundreds of different devices that are now part of computer systems. In the 1950s, few computer architects would have predicted that some day more computers would be used in automobiles than in any other application, and that one of the most common output devices would be a fuel-injected carburetor.

Despite the proliferation of devices, fairly standard techniques are still used to connect typical devices to a computer system, as described in this section.

Buses

Fig. 2 showed the basic organization of a computer as consisting of processor, memory, and input/output (I/O). The processor communicated with the I/O subsystem by means of an I/O bus. In Fig. 16, we expand our view. Like a memory bus, the I/O bus in Fig. 16 contains data, address, and control lines. The address lines allow a program to select among different I/O devices connected to the system, while the data lines carry the actual data being transferred.

Devices and Interfaces

The I/O subsystem in Fig. 16 contains both devices and interfaces. A *peripheral device* (or *I/O device*) performs some function for the computer. An *I/O interface* (or *device interface*) controls the operation of a peripheral device according to commands from the computer processor; it also converts computer data into whatever format is required by the device and vice versa. Also as shown in the figure, a peripheral device is often housed separately from the processor, while the interface is almost always packaged together with the processor and memory in one "CPU box."

There are many different peripheral devices that convert computer data into forms that are useful in the world outside the computer; such devices include displays, printers, plotters, digital-to-analog converters, mechanical relays, and fuel-injected carburetors. Many other devices convert data from the outside world into forms usable by the computer; examples include keyboards, text scanners, joysticks, analog-to-digital converters, mechanical switches, and crash detectors. The sole purpose of some devices is simply to store data for later retrieval; these are called *mass storage devices* and include magnetic disks and tapes.

Sometimes the dividing line between an interface and the device it controls is fuzzy. For example, Fig. 17 shows the circuitry associated with a simple mechanical keyboard. The encoder circuit converts a mechanical switch depression into a 7-bit number in the ASCII code. The bus interface can place this number on the I/O bus on demand by the processor. So it seems that the device interface consists of the Encoder and Bus Interface blocks. However, in a typical system the encoder is packaged with the keyboard; then only a small number of wires are needed between the encoder (in the keyboard package) and the bus interface (in the CPU box). Most computer designers would say that the Encoder block is part of the keyboard and the device interface consists of the Bus Interface block alone. Fortunately, the dividing line is unimportant to I/O programs that deal with the keyboard. More important is the "I/O programming model" that an I/O program sees, as discussed next.

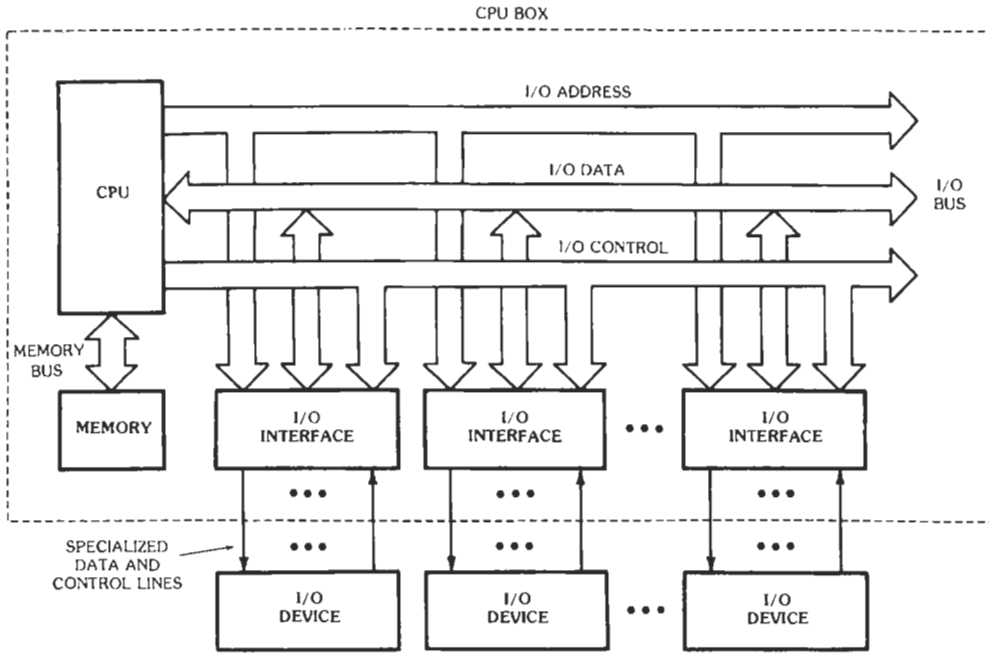

Fig. 16. Input/output (I/O) subsystem.

Ports

An *I/O port* (or *I/O register*) is a part of a device interface, a group of bits accessed by the processor during I/O operations. The "I/O programming model" of the keyboard in Fig. 17 contains one 8-bit I/O port named KBDATA, as shown in Fig. 18. The high-order bit of KBDATA is always 0. The low-order bits of KBDATA contain the output of the Encoder block in Fig. 17, that is, the 7-bit ASCII code for the key that is currently being depressed, or 0000000 if no key is depressed.

In order to read data from the keyboard in Fig. 17, a program must execute an instruction that transfers the contents of KBDATA into one of the processor registers. Once the data is in the processor, it can be manipulated like any other data. Although the interface "writes" keyboard data into KBDATA, the port is read-only from the point of view of the processor; any attempt by the processor to write data into KBDATA has no effect. Therefore, we can call KBDATA an "input port."

Fig. 19A shows a very simple output device that interprets an 8-bit byte as two 4-bit BCD digits and displays the digits on two seven-segment displays. The I/O programming model consists of one 8-bit port, DIGOUT, shown in Fig. 19B. In order to display two

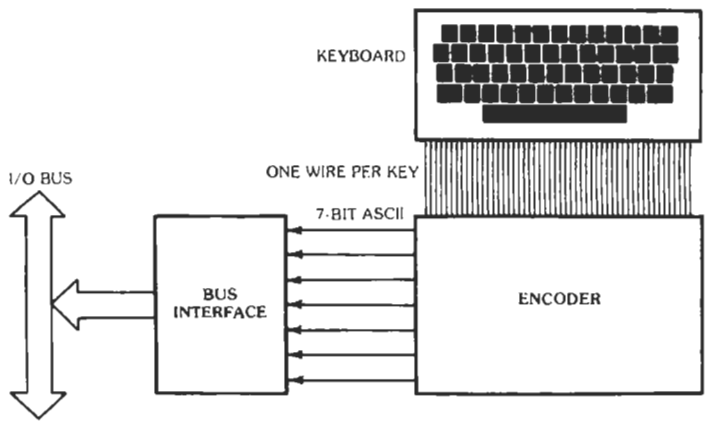

Fig. 17. Keyboard and interface.

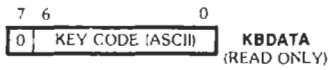

Fig. 18. Programming model for a keyboard.

digits, the processor must transfer an 8-bit value into DIGOUT. In this case, DIGOUT is an "output port" and is write-only from the point of view of the processor; an attempt to read it produces an undefined value.

I/O Programming

So far, nothing has been said about how I/O-port data is transferred to and from processor registers. This subsection discusses two techniques that are used in different processors to perform I/O transfers.

In *isolated I/O*, the ports are accessed by special I/O instructions. For example, 80x86 processors have two instructions for transferring the contents of an I/O port to and from registers:

```
IN   rn,pn    REGISTER[rn] ←
                        INPUTPORT[pn];

OUT  pn,rn    OUTPUTPORT[pn] ←
                        REGISTER[rn];
```

The IN and OUT instructions perform simple data transfers, as do load and store instructions, except that they access an array of I/O ports instead of an array of memory bytes. Since the main memory and the I/O ports are on different buses, the "address spaces" accessed by memory reference and I/O instructions are different, even though they both may happen to use 16- or 32-bit addresses.

It has been observed that I/O buses are very similar to memory buses, and that I/O instructions are similar to load and store instructions on memory. *Memory-mapped I/O* takes advantage of the similarity by eliminating the I/O bus and I/O instructions.

Fig. 20 shows the hardware organization of a computer with memory-mapped I/O. Both the main memory and all I/O ports communicate with the processor by way of a shared Memory and I/O Bus. Each I/O port has an address in the main memory address space of the processor. An input port responds to any instruction that reads at its address; an output port responds to any instruction that writes at its address. Typically, the system designer reserves a portion of the total address space for I/O ports, for example, the top 4 kilobytes. However, theoretically a hardware designer can locate an I/O port at any address, as long as there is no memory at that address also.

Memory-mapped I/O is a necessity in processors that have no special I/O instructions. The PDP-11 was the first minicomputer to require memory-mapped I/O; the 68000 and all RISC processors also require it. Memory-mapped I/O has a number of advantages:

- No opcodes or processor circuits are used up for I/O instructions.
- All memory reference instructions, not just loads and stores, may be used to manipulate I/O ports.
- The number of available I/O port addresses is virtually unlimited.
- The hardware bus structure is simplified.

There are also disadvantages:

- Part of the memory address space is used up.
- Interfaces may need more circuitry to recognize longer addresses.
- Memory reference instructions may be longer or slower than optimized I/O instructions.

A simple Motorola 68000 program using memory-mapped I/O is shown in Chart 3.

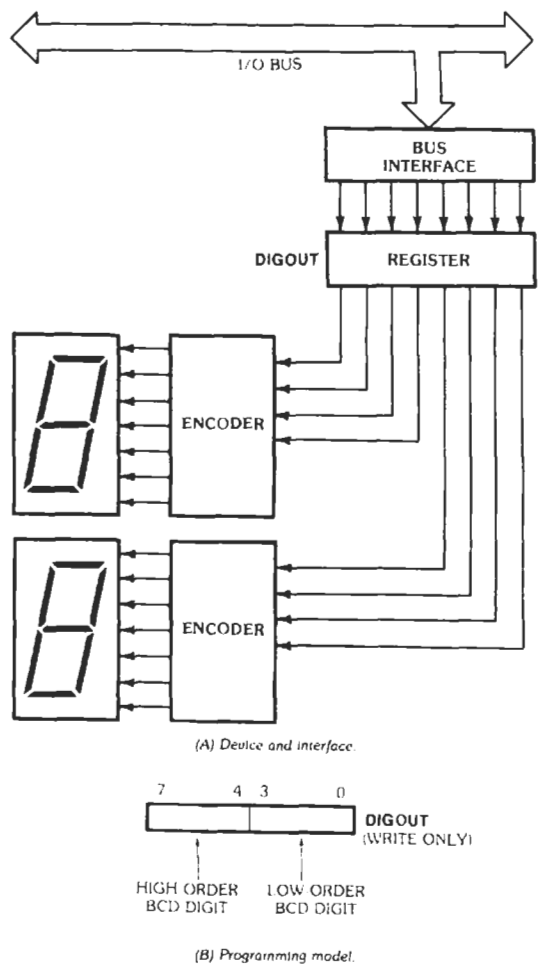

Fig. 19. Seven-segment display.

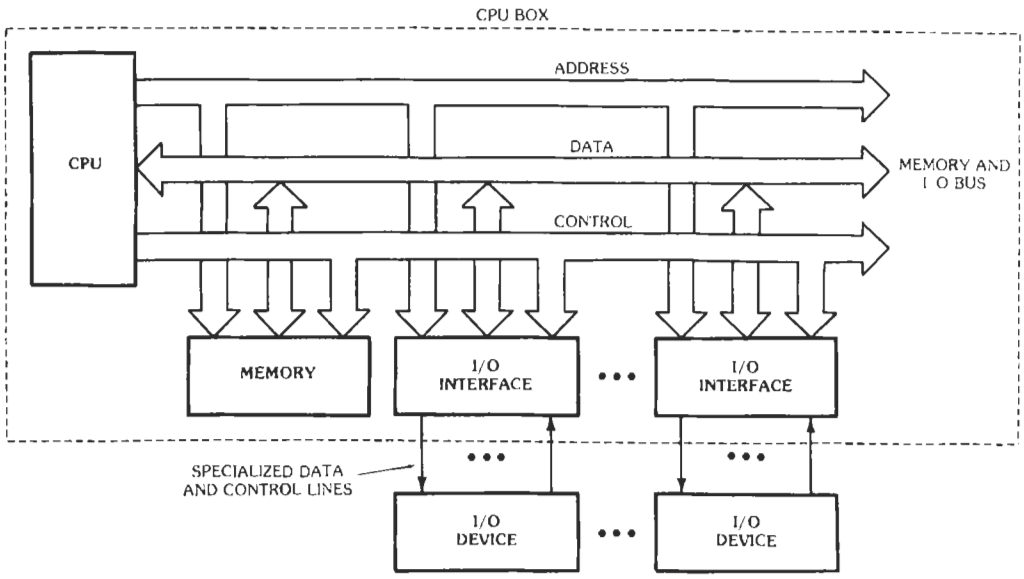

Fig. 20. Memory-mapped I/O structure.

CHART 3. KEYBOARD INPUT AND DISPLAY OUTPUT FOR THE 68000

```
*
*           Read two decimal digits from the keyboard and display them on the
*           seven-segment display. Ignore illegal characters.
*
KBDATA      EQU         $F004           Keyboard input port address.
DIGOUT      EQU         $F008           Seven-segment display port address.
*
*           First, a subroutine to read one decimal digit, convert it to 4-bit bcd,
*           and return the result in register D0.
RDDIG       MOVE.B      KBDATA,D0       Read current character.
            BEQ         RDDIG           Wait for a key to be pressed.
WAITUP      MOVE.B      KBDATA,D1       Now the character is in D0,
            BNE         WAITUP           wait for the key to be released.
            CMP.B       #$30,D0         Was it a valid decimal digit?
            BLT         RDDIG           Not if it is less than ASCII '0' ...
            CMP.B       #$39,D0
            BGT         RDDIG           ... or greater than ASCII '9'.
            ADD.B       D0,#-$30        Convert ASCII '0'-'9' to 0-9.
            RTS                         Done, return.
*
*           Now, the main program.
DIGDSP      JSR         RDDIG           Read high-order decimal digit into D0.
            ASL.B       #4,D0           Shift left 4 bits
            MOVE.B      D0,D2            and save in D2.
            JSR         RDDIG           Read low-order decimal digit.
            OR.B        D2,D0           Merge (logical OR) with high-order digit.
            MOVE.B      D0,DIGOUT       Send to seven-segment display.
            JMP         DIGDSP          Do another pair of digits.
            END         DIGDSP
```

43 Logic Design

Edward J. McCluskey

INTRODUCTION

The distinguishing feature of the circuits to be discussed in this chapter is the use of two-valued, or binary, signals. There will be some deviation of the signals from their nominal values, but within certain limits this variation will not affect the performance of the circuit. If the variations exceed these limits, the circuit will not behave properly, and steps must be taken to confine the signals to the proper ranges. When the statement is made that the signals are two-valued, what is really meant is that the value of each signal is within one of two (nonoverlapping) continuous ranges. Since the operation of the circuit does not depend on exactly which value within a given range the signal takes on, a particular value is chosen to represent the range, and the signal is said to be equal to this value. The exact numerical value of the signal is not important. It is possible to have two circuits perform the same function and have completely different values for their signals. In order to avoid any possible confusion that might arise because of this situation and to simplify the design procedures, it is customary to carry out the logic design without specifying the actual values of the signals. Once the logic design has been completed, the actual values must be assigned to the signals in the course of designing the detailed electrical circuit. For the purposes of the logic design, arbitrary symbols are chosen to represent the two values to which the signals are to be restricted. An algebra* using these symbols is then developed as the basis for formal design techniques. The development of such an algebra will be described next.

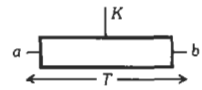
POSTULATES

The two symbols most commonly chosen to represent the two logic values taken on by binary signals are 0 and 1. It should be emphasized that these logic symbols have no numerical significance. For an electronic circuit that has its signals equal to either 0 or 5 volts, logical 1 usually represents 5 volts and logical 0 represents 0 volts. This choice—in which 1 corresponds to the more positive physical value—is called *positive logic*. *Negative logic* uses logic 1 for the more negative physical value; it is much less common than positive logic, but is natural when the active signal value corresponds to the lower physical value (as in PMOS, for example). We will use positive logic here.

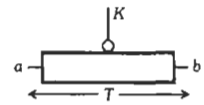
Other symbols such as T and F, H and L, or + and − are also used. Logicians like T and F. IC data books favor H and L.

Switching variables are used in logic networks to represent the signals present at gate inputs and outputs.

*This algebra will be called *switching algebra*. It is identical with a Boolean algebra and was originally applied to switching circuits (reference 1) by reinterpreting Boolean algebra in terms of switching circuits rather than by developing a switching algebra directly, as will be done here.



K	T	State
0	0	Open
1	1	Closed



K	T	State
0	1	Closed
1	0	Open

Fig. 1. The transmission, T, of a switch.

Switching variables can also represent the state of a switch. Fig. 1 shows this. The switch operation is defined as the two switch terminals (a and b) being connected together if and only if the *control variable*, K, equals 1. When $K = 0$, there is an open circuit between the two switch terminals. There is a variable, T, associated with the switch that equals 1 when the terminals are connected together and that equals 0 when there is an open circuit between the terminals. The variable, T, is called the *transmission* of the switch. (It is also possible to associate with the switch a variable that equals 1 only when the switch is open. Such a variable is called the *switch hindrance*. This was used in the very early papers on switching theory in connection with contact networks. The transmission concept is the standard usage at present.)

The first postulate of the switching algebra can now be presented. This is merely a formal statement of the fact that switching variables are always equal to either 0 or 1. (In the statements of postulates and theorems that follow, the symbols X, Y, Z, X_1, X_2 . . . , X_n will be used to represent switching variables.)

$$(P1)\ X = 0 \text{ if } X \neq 1 \qquad (P1')\ X = 1 \text{ if } X \neq 0$$

To implement general switching networks, it is necessary to be able to obtain, for any signal representing a switching variable, a signal that has the opposite value. A circuit for realizing this function is called an *inverter*. Fig. 2 shows two of the most common inverter symbols.

If X represents a switching variable, the symbol X' is used to represent the signal having the opposite value. This notation is specified formally in the second switching-algebra postulate:

$$(P2)\quad \text{If } X = 0, \text{ then } X' = 1$$

$$(P2')\quad \text{if } X = 1, \text{ then } X' = 0$$

Fig. 2. Inverter symbols.

The two symbols, X and X', are not two different variables, since they involve only X. In order to distinguish them, the term *literal* is used, where a literal is defined as a variable with or without an associated prime, and X and X' are different literals. The literal X' is called the *complement** of X. Similarly, 0 is called the complement of 1, and 1 is called the complement of 0. The logical operation of the inverter can now be described in terms of switching algebra. If X_1 represents the input signal and X_0 the output signal, then $X_0 = X_1'$, since X_0 is high when X_1 is low, and vice versa.

Multiple-input gates require additional algebraic operations. A two-input AND gate will be considered first. If X_1 and X_2 represent its two inputs and X_0 its output, Fig. 3A shows its logical performance. This table is also correct for the transmission, X_0, of two switches, X_1 and X_2, in series. The operation represented is identical with ordinary multiplication and will be defined as multiplication in the switching algebra developed here. Thus, the equation for an AND gate, or two switches in series, is $X_0 = X_1X_2$.

The table for an OR gate, or two switches in parallel, is shown in Fig. 4A. This table will be taken as the definition of switching-algebra addition.† It is identical with ordinary addition except for the case $1 + 1 = 1$. The remaining postulates are merely restatements of the definitions of multiplication and addition:

(P3)	$0 \cdot 0 = 0$	(P3′)	$1 + 1 = 1$
(P4)	$1 \cdot 1 = 1$	(P4′)	$0 + 0 = 0$
(P5)	$1 \cdot 0 = 0 \cdot 1 = 0$	(P5′)	$0 + 1 = 1 + 0 = 1$

*Some authors use the symbols $\bar{X}$ or $\sim X$ to indicate the complement of X.

†This operation is also called logical addition, and some writers use the notation $x_1 \vee x_2$ rather than $x_1 + x_2$.

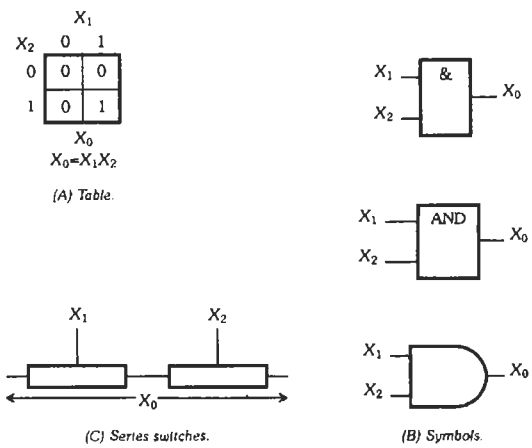


Fig. 3. The AND function.

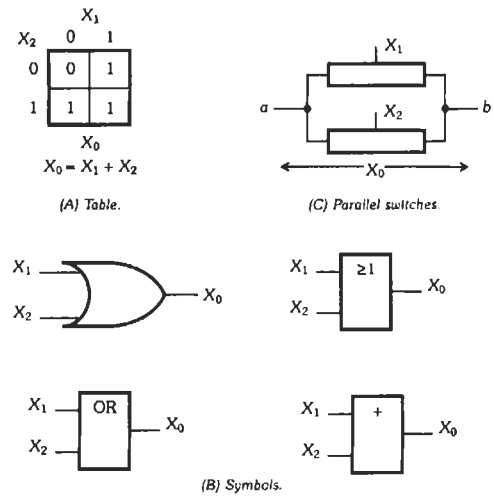

Fig. 4. The OR function.

All the postulates have been stated in pairs. These pairs have the property that when (0 and 1) and (+ and ·) are interchanged, one member of the pair is changed into the other. This is an example of the general *principle of duality*, which is true for all switching-algebra theorems since it is true for all the postulates. This algebraic duality arises from the fact that either 1 or 0 can be assigned to the high voltage or to an open circuit. If 0 is chosen to represent a high voltage, the expression for an AND gate becomes $x_0 = x_1 + x_2$. Similarly, the transmission of two switches in series is equal to $x_1 + x_2$ if 0 is chosen to represent a closed circuit.

ANALYSIS

Analysis of a circuit consists in examining the circuit and somehow determining what the behavior of the circuit will be for all possible inputs. The switching algebra developed in the previous section is sufficient for the analysis of those switching circuits that are known as *combinational switching circuits*. A combinational switching circuit is defined as one for which the outputs depend only on the present inputs to the circuit. The other type of circuit, called a *sequential switching circuit*, is one for which the outputs depend not only on the present inputs but also on the past history of the inputs. Acyclic networks (networks with no feedback loops) of gates are always combinational. Sequential circuits typically contain latches, flip-flops, or feedback loops.

Combinational circuits are analyzed by writing an algebraic function for each output. These are functions of the input variables from which the condition of each output can be determined for each combination of input conditions. For a switch network, these output functions are the transmissions between each pair of external

terminals. Only two-terminal networks will be considered for the present. In a gate network, an output function specifies those input conditions for which the voltage of an output node will be at the high level.

Fig. 5 shows a very simple analysis example. In an acyclic network, there will be at least one gate, such as the OR gate in Fig. 5, that has only network inputs connected to it. The output of such gates can be written down directly. There will then be other gates that have either input variables or expressions on all their inputs; the AND gate in Fig. 5 is such a gate. It is then possible to write expressions for the output of all these gates. By repeating this procedure, an expression will eventually be obtained for the network output.

A procedure for using these output functions to determine the circuit performance is to substitute a set of values for the input variables and then use the postulates to simplify the resulting expressions. A value for the output function will be obtained that specifies the output for the particular input combination chosen. For example, if the input combination $X_1 = 1, X_2 = 1, X_3 = 0, X_4 = 1$, is chosen, the output function of Fig. 5 becomes

$$f = X_1X_2(X_3 + X_4)$$

$$= 1 \cdot 1(0 + 1) = 1(1) = 1$$

By carrying out this procedure for all possible input combinations, it is possible to form a table that lists the output for each input combination. Such a table describes completely the circuit performance and is called a *table of combinations.** Table 1 is the table of combinations for the circuit of Fig. 5.

SYNTHESIS

To design a combinational circuit, the procedure just described must be reversed. The designer writes a table of combinations that specifies the desired circuit performance. From this table, an algebraic function is written from which a circuit can be derived. A concise means of specifying the table of combinations, called a *decimal specification*, is to list the numbers of the rows for which the output is to equal 1. For Table 1, this specification is:

$$f(X_1, X_2, X_3, X_4) = \Sigma(13, 14, 15)$$

*In logic, the table is called a *truth table*, and some writers use this term when discussing switching circuits.

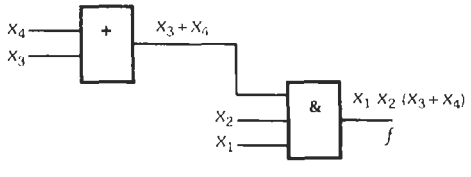

Fig. 5. Simple example of analysis of a gate network.

TABLE 1. TABLE OF COMBINATIONS FOR $f = X_1X_2(X_3 + X_4)$

	X_1	X_2	X_3	X_4	f
0	0	0	0	0	0
1	0	0	0	1	0
2	0	0	1	0	0
3	0	0	1	1	0
4	0	1	0	0	0
5	0	1	0	1	0
6	0	1	1	0	0
7	0	1	1	1	0
8	1	0	0	0	0
9	1	0	0	1	0
10	1	0	1	0	0
11	1	0	1	1	0
12	1	1	0	0	0
13	1	1	0	1	1
14	1	1	1	0	1
15	1	1	1	1	1

where the Σ signifies that the rows for which the function equals 1 are being listed. It is also possible to list the rows for which the function equals 0, such a list being preceded by the symbol Π to indicate that it is the zero rows which are listed. This specification for the preceding table is

$$f(x_1, x_2, x_3, x_4) =$$
$$\Pi(0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12).$$

In order to avoid any ambiguity in these specifications, it is necessary to adopt some rule for numbering the rows of the table of combinations. The usual procedure is to regard each row of the table as a binary number and then use the decimal equivalent of this binary number as the row number. The output-column entries are not included in forming the binary row numbers. There is nothing special about decimal numbers other than the fact that they are the most familiar; any other number base, such as octal, could be used. The reason for using a number system other than binary is simply that binary numbers take too much space to write down.

It has been pointed out that the table of combinations is a complete specification for a combinational circuit. The first step in designing a circuit is to formulate such a table. There are no general formal techniques for doing this. When a sequential circuit is being designed, it is customary to reduce the sequential-design problem to (several) combinational problems, and formal techniques exist for doing this. However, when a combinational circuit is being designed, no formal techniques are available, and it is necessary to rely on common sense. This is not too surprising, since any formal technique must start with a formal statement of the problem, and this is precisely what the table of combinations is. As an example of how this is done, the table of combinations for a circuit to check binary-coded decimal digits for the 8, 4, 2, 1 code is shown in Table

TABLE 2. TABLE OF COMBINATIONS FOR CIRCUIT TO CHECK BINARY-CODED-DECIMAL DIGITS

	b_8	b_4	b_2	b_1	f	
0	0	0	0	0	0	
1	0	0	0	1	0	
2	0	0	1	0	0	
3	0	0	1	1	0	
4	0	1	0	0	0	
5	0	1	0	1	0	
6	0	1	1	0	0	
7	0	1	1	1	0	
8	1	0	0	0	0	
9	1	0	0	1	0	
10	1	0	1	0	1	
11	1	0	1	1	1	
12	1	1	0	0	1	Invalid code words
13	1	1	0	1	1	
14	1	1	1	0	1	
15	1	1	1	1	1	

2. This circuit is to deliver an output whenever a digit having an invalid combination of bits is received.

In forming a table of combinations, there very often are rows for which it is unimportant whether the function equals 0 or 1. The usual reason for this situation is that the combination of inputs corresponding to these rows can never occur (when the circuit is functioning properly). As an example of this, consider a circuit to translate from the 8, 4, 2, 1 BCD code to a Gray (cyclic binary) code. When the circuit is working correctly, the input combinations represented by rows 10 through 15 of the table of combinations cannot occur. Therefore, the output need not be specified for these rows. The symbol d will be used to indicate the output condition for such a situation.* The output conditions so denoted are called *don't-care conditions* (see Table 3). It is possible to include the d rows in the decimal specification of a function by listing them after the symbol d. Thus, the decimal specification for g_1 of Table 3 would be

$$g_1(b_8,b_4,b_2,b_1) = \Sigma(1, 2, 5, 6, 9) + d(10, 11, 12, 13, 14, 15)$$

$$= \Pi(0, 3, 4, 7, 8) + d(10, 11, 12, 13, 14, 15)$$

Canonical Expressions

After the table of combinations has been formed, the next step in designing a circuit is to write an algebraic expression for the output function. The simplest output functions to write are those that equal 1 for only one row of the table of combinations or those that equal 0 for only one row. Two functions correspond to each row: one that equals 1 only for the row and one that equals 0 only for the row (see Table 4). These functions are called *fundamental products* or *minterms* and *fundamental sums* or *maxterms*, respectively. Each fundamental product or sum contains all the input variables. The rule for forming the fundamental product for a given row is to prime any variables that equal 0 for the row and leave unprimed variables that equal 1 for the row. The fundamental product equals the product of the literals so formed. The fundamental sum is formed by a completely reverse, or dual, procedure. Each variable that equals 0 for the row is left unprimed, and each variable that equals 1 for the row is primed. The fundamental sum is the sum of the literals obtained by this process. The algebraic expression for any table for which the output is equal to 1 (or 0) for only one row can be written down directly by choosing the proper fundamental product (or sum). For example, the output function specified by $f(x_1, x_2, x_3) = \Sigma(6)$ is written algebraically as $f = x_1x_2x_3'$, and the output function $f(x_1, x_2, x_3) = \Pi(6)$ is written as $f = x_1' + x_2' + x_3$. The fundamental product corresponding to row i of the table of combinations will be denoted by p_i, and the fundamental sum corresponding to row i will be denoted by s_i.

The algebraic expression that equals 1 (or 0) for more than one row of the table of combinations can be written directly as a sum of fundamental products or as a product of fundamental sums. A function f that equals 1 for two rows, i and j, of the table of combinations can be expressed as a sum of the two fundamental products p_i and p_j: $f = p_i + p_j$. When the inputs correspond to row i, $p_i = 1$ and $p_j = 0$, so that $f = 1 + 0 = 1$. When the inputs correspond to row j, $p_i = 0$, $p_j = 1$, and $f = 0 + 1 = 1$. When the inputs correspond to any other row, $p_i = 0$, $p_j = 0$, $f = 0 + 0 = 0$. This shows that the function $f = p_i + p_j$ does equal 1 only for row i and j. This argument can be extended to functions which equal 1 for any number of input combinations—they can be represented algebraically as a sum of the corresponding fundamental products (see Table 5). An algebraic expression that is a sum of fundamental products is called a *canonical sum*. An arbitrary function can also be expressed as a product of fundamental sums. This form is called *canonical product*. The canonical product for a function that is equal to 0 only for rows i and j of the table of combinations is given by $f = s_i \cdot s_j$. For row i, $s_i = 0$ so that $f = 0$. For row j, $s_j = 0$ so that $f = 0$, and for any other row $s_i = s_j = 1$ so that $f = 1$. In general, the canonical product is equal to the product of all fundamental sums that correspond to input conditions for which the function is to equal 0.

It is possible to write a general expression for the canonical sum by making use of the following theorems*:

(T1) $x + 0 = x$ (T1′) $x \cdot 1 = x$

(T2′) $x \cdot 0 = 0$

*In the literature, the symbol ϕ is also used.

*The theorems are presented formally in the next section.

TABLE 3. TABLE OF COMBINATIONS FOR CIRCUIT TO TRANSLATE FROM BCD 8, 4, 2, 1 CODE TO GRAY CODE.

	BCD-Code Inputs				Gray-Code Outputs			
	b_8	b_4	b_2	b_1	g_4	g_3	g_2	g_1
0	0	0	0	0	0	0	0	0
1	0	0	0	1	0	0	0	1
2	0	0	1	0	0	0	1	1
3	0	0	1	1	0	0	1	0
4	0	1	0	0	0	1	1	0
5	0	1	0	1	0	1	1	1
6	0	1	1	0	0	1	0	1
7	0	1	1	1	0	1	0	0
8	1	0	0	0	1	1	0	0
9	1	0	0	1	1	1	0	1
10	1	0	1	0	*d*	*d*	*d*	*d*
11	1	0	1	1	*d*	*d*	*d*	*d*
12	1	1	0	0	*d*	*d*	*d*	*d*
13	1	1	0	1	*d*	*d*	*d*	*d*
14	1	1	1	0	*d*	*d*	*d*	*d*
15	1	1	1	1	*d*	*d*	*d*	*d*

If the value of the function $f(x_1, x_2, \ldots, x_n)$ for the i-th row of the table of combinations is f_i ($f_i = 0$ or 1), then the canonical sum is given by

$$f(x_1, x_2, \ldots, x_n) = f_0p_0 + f_1p_1 + \cdots + f_{(2^n-1)}p_{(2^n-1)} = \sum_{i=0}^{2^n-1} f_ip_i$$

For the function $f(x_1, x_2) = \Sigma(0, 2)$ the values of the f_i are $f_0 = f_2 = 1, f_1 = f_3 = 0$ so that

$$\begin{aligned} f(x_1, x_2) &= 1 \cdot p_0 + 0 \cdot p_1 + 1 \cdot p_2 + 0 \cdot p_3 \\ &= p_0 + 0 + p_2 + 0 \\ &= p_0 + p_2 \\ &= x_1'x_2' + x_1x_2' \end{aligned}$$

In a similar fashion, a general expression for the canonical product can be obtained by using the theorems

(T2) $x + 1 = 1$

(T1) $x + 0 = x$ (T1′) $x \cdot 1 = x$

The resulting expression is

$$\begin{aligned} f(x_1, x_2, \ldots, x_n) &= (f_0 + s_0)(f_1 + s_1) \cdots (f_{(2^n-1)} + s_{(2^n-1)}) \\ &= \prod_{i=0}^{2^n-1} (f_i + s_i) \end{aligned}$$

For $f(x_1, x_2) = \Sigma(0, 2) = \Pi(1, 3)$ this becomes

$$\begin{aligned} f(x_1, x_2) &= (1 + s_0)(0 + s_1)(1 + s_2)(0 + p_3) \\ &= 1 \cdot s_1 \cdot 1 \cdot s_3 \\ &= s_1 \cdot s_3 \\ &= (x_1x_2')(x_1' + x_2') \end{aligned}$$

Networks

A technique for obtaining an algebraic expression from a table of combinations has just been described. A circuit can be drawn directly from this expression by reversing the analysis procedures. The circuit for a single fundamental product is just an AND gate with appropriate inputs or a series connection of switches. For a canonical sum involving more than one fundamental product, the circuit consists of a number of

TABLE 4. TABLE OF COMBINATIONS SHOWING FUNDAMENTAL PRODUCTS AND FUNDAMENTAL SUMS

	x_1	x_2	x_3	Fundamental Product	Fundamental Sum
0	0	0	0	$x_1'x_2'x_3'$	$x_1 + x_2 + x_3$
1	0	0	1	$x_1'x_2'x_3$	$x_1 + x_2 + x_3'$
2	0	1	0	$x_1'x_2x_3'$	$x_1 + x_2' + x_3$
3	0	1	1	$x_1'x_2x_3$	$x_1 + x_2' + x_3'$
4	1	0	0	$x_1x_2'x_3'$	$x_1' + x_2 + x_3$
5	1	0	1	$x_1x_2'x_3$	$x_1' + x_2 + x_3'$
6	1	1	0	$x_1x_2x_3'$	$x_1' + x_2' + x_3$
7	1	1	1	$x_1x_2x_3$	$x_1' + x_2' + x_3'$

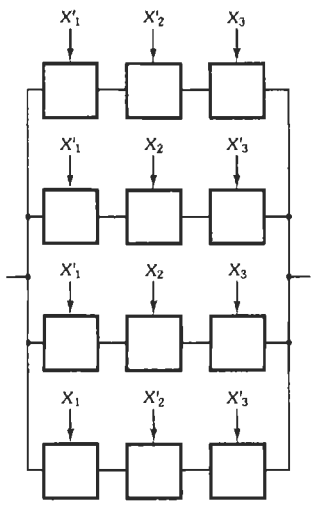
$(x_1' + x_2' + x_3)(x_1' + x_2' + x_3')$

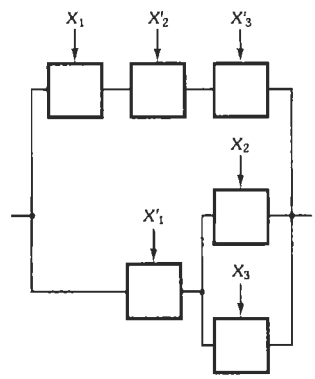
parallel subnetworks, each subnetwork corresponding to one fundamental product, or a number of AND gates with their outputs connected as inputs to an OR gate. This is shown in Figs. 6A and 7A. Similarly, the switch network corresponding to a canonical product consists of a number of subnetworks in series, each subnetwork corresponding to one fundamental sum and consisting of switches in parallel (Fig. 6B). The gate network corresponding to a canonical product consists of a number of OR gates with their outputs connected as the inputs of an AND gate (Fig. 7B).

It follows that, for any arbitrary table of combinations, a network whose performance corresponds to the table of combinations can be constructed of*:

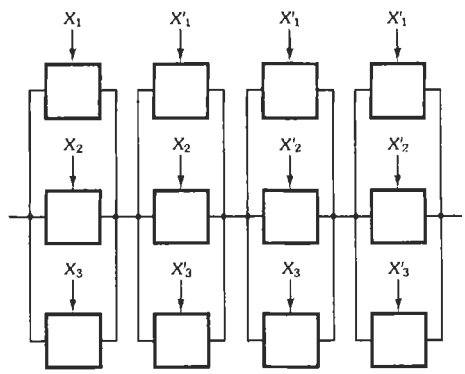
*This assumes there is no limit on the number of elements used.



(A) Network derived from canonical sums.



(C) Economical network.



(B) Network derived from canonical product.

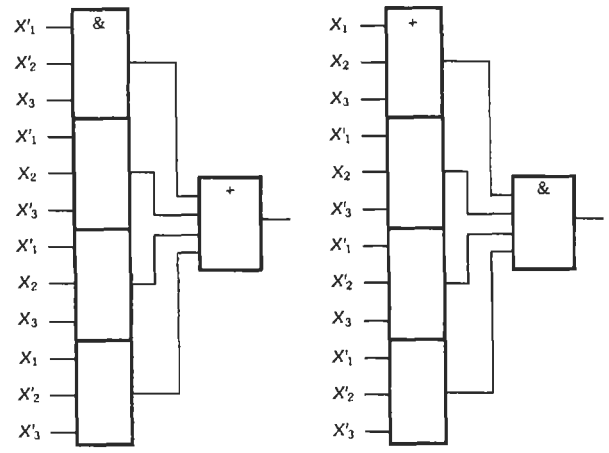

Fig. 7. Gate networks for Σ (1, 2, 3, 4).

1. AND gates, OR gates, and inverters, or
2. Switches

In a certain sense, this completes the design procedure. A method has been presented for going from an arbitrary table of combinations to a circuit diagram. However, the canonical circuits so designed are usually very uneconomical and therefore unsatisfactory. An example of this can be seen by comparing the circuits of Figs. 6A, 6B, 7A, and 7B with those of Figs. 6C and 7C. In order to design satisfactory circuits, it is necessary to have procedures for simplifying them so that they correspond to simpler circuits.

THEOREMS

To design an efficient switching circuit, one formulates the desired circuit performance as an algebraic expression and then manipulates the expression into a form from which a desirable circuit can be arrived at directly. The manipulations are carried out by means of the theorems that will be presented in this section.

Single-Variable Theorems

The switching-algebra theorems that involve only a single variable are shown in Chart 1. Note the three theorems, T2, T3, and T3′, that are false for ordinary algebra. Theorems T3 and T3′ can be extended to $X + X + X + \cdots + X = nX = X$ and $X \cdot X \cdot \cdots X = X^n = X$.

Two- and Three-Variable Theorems

Chart 2 lists the switching-algebra theorems that involve two or three variables. Theorems T7 and T7′ are used to eliminate terms from algebraic expressions so that the corresponding elements can be removed from the corresponding networks. Theorem T10′ is not true for ordinary algebra even though its dual, T10, is.

In reducing algebraic expressions, Theorems T11 and T11′ are very important and are used frequently, as is illustrated in the example that follows. This example shows how the theorems are used to manipulate a given algebraic expression into some other form. Very frequently, the form desired is one that has as few literals

CHART 1. SWITCHING-ALGEBRA THEOREMS INVOLVING ONE VARIABLE

(T1) $X + 0 = X$	(T1′) $X \cdot 1 = X$	(Identities)
(T2) $X + 1 = 1$	(T2′) $X \cdot 0 = 0$	(Null elements)
(T3) $X + X = X$	(T3′) $X \cdot X = X$	(Idempotency)
(T4) $(X')' = X$		(Involution)
(T5) $X + X' = 1$	(T5′) $X \cdot X' = 0$	(Complements)

CHART 2. SWITCHING-ALGEBRA THEOREMS INVOLVING TWO OR THREE VARIABLES

(T6)	$X + Y = Y + X$	(T6′)	$XY = YX$	(Commutative)
(T7)	$X + XY = X$	(T7′)	$X(X + Y) = X$	(Absorption)
(T8)	$(X + Y')Y = XY$	(T8′)	$XY' + Y = X + Y$	
(T9)	$(X + Y) + Z = X + (Y + Z) = X + Y + Z$			
(T9′)	$(XY)Z = X(YZ) = XYZ$			(Associative)
(T10)	$XY + XZ = X(Y + Z)$			
(T10′)	$(X + Y)(X + Z) = X + YZ$			(Distributive)
(T11)	$(X + Y)(X' + Z)(Y + Z) = (X + Y)(X' + Z)$			
(T11′)	$XY + X'Z + YZ = XY + X'Z$			(Consensus)
(T12)	$(X + Y)(X' + Z) = XZ + X'Y$			

occurring as possible. The number of literal occurrences corresponds roughly to the number of gate inputs in a gate network.

Theorem T12 has no dual (T12′), for the dual would be identical with the original theorem.

Example

By use of the theorems, the expression

$$(c' + abd + b'd + a'b)(c + ab + bd)$$

is to be shown equal to

$$b(a + c)(a' + c') + d(b + c)$$

	$(c' + abd + b'd + a'b)(c + ab + bd)$
(T12)	$c'(ab + bd) + c(abd + b'd + a'b)$
(T10)	$abc' + bc'd + abcd + b'cd + a'bc$
(T6)	$abc' + abcd + bc'd + a'bc + b'cd$
(T10)	$ab(c' + cd) + bc'd + a'bc + b'cd$
(T8′)	$ab(c' + d) + bc'd + a'bc + b'cd$
(T11′)	$ab(c' + d) + bc'd + a'bc + a'bd + b'cd$
(T10)	$abc' + abd + bc'd + a'bc + a'bd + b'cd$
(T6)	$(abd + a'bd) + abc' + bc'd + a'bc + b'cd$
(T10)	$bd(a + a') + abc' + bc'd + a'bc + b'cd$
(T5)	$bd(1) + abc' + bc'd + a'bc + b'cd$
(T1′)	$bd + abc' + bc'd + a'bc + b'cd$
(T6)	$bd + bc'd + abc' + a'bc + b'cd$
(T7)	$bd + abc' + a'bc + b'cd$
(T6),(T10)	$d(b + b'c) + abc' + a'bc$
(T8′)	$d(b + c) + abc' + a'bc$
(T10)	$d(b + c) + b(ac' + a'c)$
(T12)	$d(b + c) + b(a + c)(a' + c')$

n-Variable Theorems

The switching-variable theorems that involve an arbitrary number of variables are shown in Chart 3. Three of these theorems (T13, T13′, and T14) cannot be proved by perfect induction. For these theorems, the proofs require the used of finite induction.* Theorems T13 and T13′ are proved by first letting $n = 2$ and using perfect induction to prove their validity for this special case. It is then assumed that the theorems are true for $n = k$, and this is shown to imply that they must then be true for $n = k + 1$. This completes the proof, the details of which are given in the reference. Theorem T14 is proved by using Theorems T13 and T13′ along with the fact that every function can be split into the sum of several functions or the product of several functions. By successively splitting the function into subfunctions and using T13 and T13′, it is possible to prove T14.

Theorem T14, which is a generalization of T13, forms the basis of a method for constructing complementary networks. Two networks having outputs T_1 and T_2 are said to be *complementary* if $T_1 = T_2'$. The complementary network for any given network can be designed by writing the output, T_1, for the first network, then forming T_1' by means of T14, and then designing a network having output T_1'. For example, if $T_1 = (x + y)[w(y' + z) + xy]$, then $T_1' = x'y' + (w' + yz')(x' + y')$.

It was pointed out in connection with Figs. 6 and 7 that the canonical networks are generally uneconomical. By manipulating the canonical sum or product with the aid of the theorems just presented, it is usually possible to obtain algebraic expressions that correspond to more economical networks than the canonical networks. The following example shows how this is done

*See reference 2.

CHART 3. SWITCHING-VARIABLE THEOREMS INVOLVING n VARIABLES

	(DeMorgan's theorems)
(T13)	$(X_1 + X_2 + \cdots + X_n)' = X_1'X_2' \cdots X_n'$
(T13′)	$(X_1X_2 \cdots X_n)' = X_1' + X_2' + \cdots + X_n'$
	(Generalized DeMorgan's theorem)
(T14)	$f(X_1, X_2, \ldots, X_n, +, \cdot)' = f(X_1', X_2', \ldots, X_n', \cdot, +)$
	(Expansion theorem)
(T15)	$f(X_1, X_2, \ldots, X_n) = X_1 f(1, X_2, \ldots, X_n) + X_1' f(0, X_2, \ldots, X_n)$
(T15′)	$f(X_1, X_2, \ldots, X_n) = [X_1 + f(0, X_2, \ldots, X_n)][X_1' + f(1, X_2, \ldots, X_n)]$

for the networks of Figs. 6 and 7. The final expressions correspond to the networks of Figs. 6C and 7C.

$$f = X_1'X_2'X_3 + X_1'X_2X_3' + X_1X_2X_3 + X_1X_2'X_3'$$

$$f = X_1'X_2'X_3 + X_1'X_2X_3 + X_1X_2X_3' + X_1X_2'X_3'$$

$$f = X_1'X_2'X_3 + X_1'X_2X_3 + X_1'X_2X_3 + X_1'X_2X_3' + X_1X_2'X_3'$$

$$f = X_1'X_3(X_2' + X_2) + X_1'X_2(X_3 + X_3') + X_1X_2'X_3'$$

$$f = X_1'X_3(1) + X_1'X_2(1) + X_1X_2'X_3'$$

$$f = X_1'X_3 + X_1'X_2 + X_1X_2'X_3'$$

$$f = X_1'(X_3 + X_2) + X_1X_2'X_3'$$

Many of the theorems of ordinary algebra are also valid for switching algebra. One that is not is the cancellation law. In ordinary algebra, it follows that X = Z if X + Y = Y + Z. In switching algebra, this is not true. For example, it is generally true that $X + XY = X + 0$, but it is not necessarily true that $XY = 0$. This can be easily verified by writing out the tables of combinations for $f_1(X,Y) = X + XY$, $f_2(X,Y) = X + 0$, and $f_3(X,Y) = XY$. Similar remarks apply to the situation in which $XY = XZ$ does not imply that $Y = Z$.

GENERAL GATE NETWORKS

The previous discussion of gate networks in this chapter has been concerned solely with networks constructed of AND gates and OR gates. This can be considered only an introduction to the topic of gate networks, for other types of gates are equally important. In this section, networks with other types of gates will be considered.

Any arbitrary switching function can be realized by a network of AND gates, OR gates, and inverters. A natural question to ask in this connection is whether all three types of elements are necessary. Inverters are required if the inputs to the network consist of signals representing the input variables but not of signals representing the complements of the input variables. The situation when signals representing the complements are available is called *double-rail logic*, and when the complements are not available, the term *single-rail* is used. Both techniques are employed, but for the purposes of the present discussion it will be assumed that complements are not directly available (single-rail logic). The function $f(x) = x'$ cannot be realized by a network of AND gates and OR gates only.

Arbitrary functions can require inverters, but maybe AND gates and inverters can realize any function. That OR gates are not necessary is easily demonstrated, for it is possible to construct a network having the function of an OR gate and using only AND gates and inverters. This is done by making use of DeMorgan's theorem—$X + Y = (X'Y')'$—as illustrated in Fig. 8. Thus, any network consisting of AND gates, OR gates, and inverters can be changed into a network containing only AND gates and inverters by using the replacement shown in Fig. 8 to remove the OR gates. By duality, a similar technique can be used to remove the AND gates instead.

Since it is not possible to use only inverters to realize arbitrary functions, a minimum set of elements has now been determined. Because it is possible to construct a network containing only AND gates and inverters for any arbitrary function, the AND gate and inverter are said to form a *complete gate set*. Similarly, the OR gate and inverter form a complete gate set.

The two operations of the AND function and the complement can be combined in a single gate, the NAND gate, shown in Fig. 9. This is a very common integrated-circuit gate. It comprises a complete gate set in one gate since: (1) an inverter is obtained if all inputs are connected to the same source, as in Fig. 9C; (2) an AND gate is formed by combining two NAND gates, as in Fig. 9D.

Two symbols for the NAND gate are shown in Fig. 9A. This is because the basic NAND-gate function $(XY)'$ can also be written as $X' + Y'$ by using DeMorgan's Theorem (T13). Use of the two symbols facilitates analysis and synthesis using these gates. The small circles ("bubbles") in Fig. 9 indicate inversion, and from a logical standpoint each bubble can be replaced by an inverter.

(D) AND connection.

Fig. 9. NAND gate.

Another very common integrated-circuit gate is the NOR gate shown in Fig. 10. It is the dual of the NAND gate and is also a single gate that is sufficient to implement a network for any arbitrary switching function.

The other important IC gate type is the *sum modulo two*, or *EXCLUSIVE*-OR (XOR) gate,* which has a high output only when an odd number of its inputs are high. The table of combinations for a two-input XOR gate is given in Table 6. This table shows that the output of an

*The term XOR is used since a two-input gate has a 1 output if one *but not both* of the inputs is equal to 1. The OR gate (sometimes called INCLUSIVE OR) has a 1 output if one or both inputs are equal to 1.

1	1	0

(B) Table of combinations.

Fig. 10. NOR gate.

XOR gate with input x_1 and x_2 is given by $x_1 \oplus x_2 = x_1'x_2 + x_1x_2'$. It is easily demonstrated that the XOR operation is commutative and associative; that is,

$$x \oplus y = y \oplus x \quad \text{and} \quad (x \oplus y) \oplus z = x \oplus (y \oplus z)$$

If both inputs of an XOR gate are connected together to x, the output is given by $x \oplus x = xx' + x'x = 0$. The fact that this operation is associative means that any network composed only of XOR gates is equivalent to a single XOR gate with all inputs connected directly to it. This is illustrated in Fig. 11. Because of the facts that $x \oplus x = 0$ and $x \oplus 0 = x$, it is possible to remove any duplicated inputs so that the resulting network contains only one gate for which no input appears more than once. Since this gate, called the *reduced gate*, cannot function as an inverter, it follows that no network containing only XOR gates can be equivalent to an inverter. Thus the XOR gate is not a complete set by itself.

The XOR gate can perform as an inverter if a signal representing a constant 1 is available, since $x \oplus 1 = x1' + x'1 = x'$ (see Fig. 12). It is still not possible to construct an OR gate by using XOR gates and a 1 signal, for the output of the reduced gate will still be of the form $X \oplus Y \oplus 1$, which does not equal 1 when either or both of X and Y are equal to 1. A complete set can be formed by using both AND gates and XOR gates. As demonstrated above, any arbitrary function can be realized by a network containing only AND gates and inverters. By using XOR gates as in Fig. 12 to replace the inverters, it is possible to obtain a network containing only AND gates and XOR gates.

Canonical expressions involving AND, OR, and inverter operations have been derived. It is possible to obtain similar canonical expressions for any complete set. The canonical expression using AND and XOR for two-variable functions is

$$f(x, y) = g_0 \oplus g_1 \cdot x \oplus g_2 \cdot y \oplus g_3 \cdot x \cdot y$$

where,

$$g_0 = f_0$$

$$g_1 = f_0 \oplus f_2$$

$$g_2 = f_0 \oplus f_1$$

$$g_3 = f_0 \oplus f_1 \oplus f_2 \oplus f_3$$

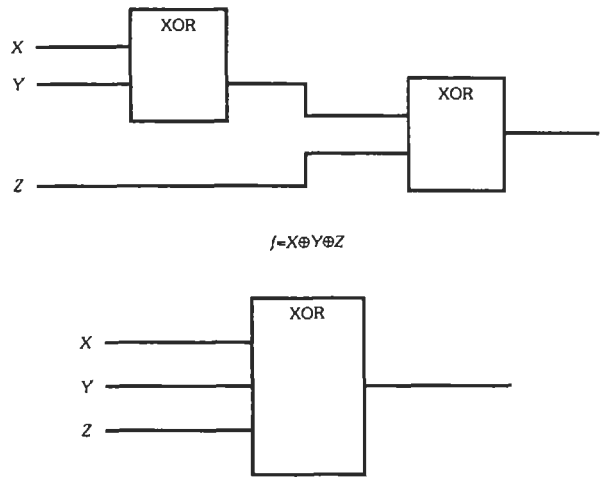

Fig. 11. Equivalent networks of XOR gates.

Thus for $f(x,y) = \Sigma(0,3) = x'y' + xy$

$g_0 = 1$

$g_1 = 1$

$g_2 = 1$

$g_3 = 0$

so that

$$f(x,y) = 1 \oplus x \oplus y$$

THE MAP METHOD

One important aspect of logic design is concerned with obtaining very efficient circuits. It is often desirable to minimize the total number of gates used for a specified maximum propagation delay through the circuit. No general algorithms are known for obtaining this objective. The best that can be done in an algorithmic fashion is to solve this minimization problem for networks that are limited to having at most two gates between any input and any output. This problem is important because: (1) the solution corresponds directly to a minimum PLA (programmable logic array) realization, (2) it is a minimum-delay solution, and (3) the resulting expressions are good starting places from which to derive efficient multistage networks. This section presents an introduction to the topic of two-stage minimization.

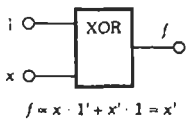

Fig. 12. Use of a constant 1 signal to form an inverter from an XOR gate.

The simplest sum-of-product-terms form of a function will be called a *minimal sum.** The sum-of-products form that has the fewest terms will be taken as the minimal sum. If there is more than one sum-of-products form having the minimum number of terms, and if these forms do not all contain the same total number of literals, then only the form(s) with the fewest literals will be called the minimal sum(s). For example, the function $f = x'yz + xyz + xyz'$ can be written as $f = yz + xyz'$, $f = x'yz + xy$, and $f = yz + xy$. Each of these forms contains two terms, but only the third form is a minimal sum, since it contains four literals, while the other two forms contain five literals each. The minimal sum corresponds to a gate circuit in which two-rail circuit inputs are connected to AND gates and the outputs of the AND gates form the inputs to an OR gate whose output is the circuit output. Such a circuit is called a *two-stage circuit,* since there are two gates connected in series between the circuit inputs and output. It is also possible to have two-stage circuits in which the circuit inputs are connected to OR gates and the circuit output is obtained from an AND gate. The minimal sum just defined corresponds to the two-stage circuit in which the output is derived from an OR gate and which contains the minimum number of gates.

The basic method for obtaining the minimal sum is to apply the theorem $XY + X'Y = Y$ to as many terms as possible and then to use the theorem $XY + X'Z + YZ = XY + X'Z$ to eliminate as many terms as possible.

Example:

$$f = x'y'z' + x'y'z + xy'z + xyz$$
$$x'y'z' + x'y'z = x'y'$$
$$xy'z + xyz = xz$$

$f = x'y' + xz$ Minimal sum.

*This is called "minimal" rather than "minimum," since there may be more than one such form.

Example:

$$f = w'x'y'z + w'x'yz + w'xy'z + w'xyz + wxy'z' + wxy'z + wx'y'z' + wx'y'z$$

$$w'x'y'z + w'x'yz = w'x'z$$
$$w'xy'z + w'xyz = w'xz$$
$$wxy'z' + wxy'z = wxy'$$
$$wx'y'z' + wx'y'z = wx'y'$$
$$w'x'z + w'xz = w'z$$
$$wxy' + wx'y' = wy'$$

$f = w'z + wy'$ Minimal sum.

Example:

$$f = xyz + x'yz + xy'z$$
$$xyz = xyz + xyz$$

$$f = (xyz + x'yz) + (xyz + xy'z)$$

$f = yz + xz$ Minimal sum.

The last example illustrates the fact that it may be necessary to apply the theorem $XY + X'Y = Y$ several times, the number of literals in the terms being reduced each time. A single term may be paired with more than one other term, as shown in this example. The process of comparing pairs of terms to determine whether or not the theorem $XY + X'Y = Y$ applies can become very tedious for large functions. This comparison process can be simplified by using an "n-cube map," which is called a *Karnaugh map* when used for minimization.

Maps for Two, Three, and Four Variables

A map for a function of two variables, as shown in Fig. 13, is a square of four cells, or a 2-cube map. The value 0 or 1 that the function is to equal when $x = 1$, $y = 0$ (the entry in the 10 location or 2 row of the table of combinations) is placed in the cell having coordinates $x = 1$, $y = 0$. In general, the scheme for filling in the map is to place a 1 in all cells whose coordinates form a binary number that corresponds to one of the fundamental products included in the function and to place a 0 in all cells whose binary numbers correspond to fundamental products not included in the function. This is done very simply by writing a 1 in each cell whose decimal designation (decimal equivalent of the binary number formed by the coordinates) occurs in the decimal specification of the function and writing 0s in the remaining cells.

The maps for functions of three and four variables are direct extensions of the two-variable map and are shown in Figs. 14 and 15. Maps for more than four variables are possible, but they are much more difficult to use and will not be discussed here.

Prime Implicants

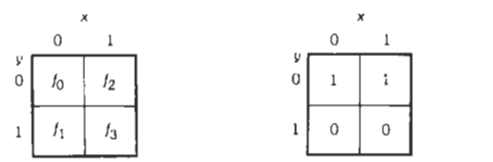
Two fundamental products can be "combined" by means of the theorem $XY + XY' = X$ if their corresponding binary numbers differ in only 1 bit. For the fundamental products $wxyz$ and $wxyz'$,

$$wxyz + wxyz' = wxy$$

The corresponding binary numbers are 1111 and 1110, which differ only in the lowest-order bit position. The fundamental products $wxyz$ and $w'xyz'$ cannot combine, and their corresponding numbers, 1111 and 0110, differ in the first and last bit positions.

Fundamental products that can be combined correspond to adjacent cells on the n-cube map. Thus cells that represent fundamental products that can be combined can be determined very quickly by inspection. In carrying out this inspection process, it must be remembered that cells such as f_4 and f_6 or f_1 and f_9 in Fig. 15 must be considered to be adjacent.

In a four-variable map, each cell is adjacent to four other cells, corresponding to the four bit positions in which two binary numbers can differ. In inspecting a map to determine which fundamental products can be combined, only cells with 1 entries (*1 cells*) need be considered, since these correspond to the fundamental products included in the function. Fig. 16 shows a four-variable map with adjacent 1 cells encircled. Notice that the 0111 cell is adjacent to two 1 cells. The rule for writing down the algebraic expression corresponding to a map is that there will be one product term for each pair of adjacent 1 cells and a fundamental product for each 1 cell that is not adjacent to any other 1 cell. The fundamental products are written down according to the rule: Any variable corresponding to a 0 in the binary number formed by the coordinates of the corresponding 1 cell is primed; the variables corresponding to 1s are left unprimed. The product terms corresponding to pairs of adjacent 1 cells are obtained by the same rule, with the exception that one variable is



(A) General form. (B) Map for $f = x'y' + xy' = \Sigma(0,2) = \Pi(1,3)$.

(B) Map for
$f = w'x'y'z' + w'x'y'z + w'xyz' + w'xyz + wxyz' + wxyz$;
$f = \Sigma\,(0,1,6,7,14,15) = \Pi\,(2,3,4,5,8,9,10,11,12,13)$.

Fig. 15. Four-variable map.

not included in the product. The variable excluded is that corresponding to the bit position in which the coordinates of the two 1 cells differ (see Fig. 16).

The situation in which it is possible to combine two of the terms obtained from pairs of the fundamental products must be considered next. In such a situation, four of the fundamental products can be combined into a single product term by successive applications of the $XY + XY' = X$ theorem. A function that is the sum of four such fundamental products is $f = wxyz + wxyz' + wxy'z + wxy'z'$. Application of the theorem to this function yields

$$f = (wxyz + wxyz') + (wxy'z + wxy'z')$$

$$= wxy + wxy' = wx$$

The characteristic property of four fundamental products that can be combined in this fashion is that all but two of the variables are the same (either primed or unprimed) in all four terms. The corresponding four binary numbers are identical in all but two bit positions. The corresponding cells on a map form "squares" (Fig. 17A) or "lines" (Fig. 17B) of four adjacent cells. For such a group of four cells on the map of a function, the corresponding products term is written just as for two adjacent cells, except that two variables corresponding to the two bit positions for which the cell coordinates change must be omitted.

It is also possible that eight of the fundamental products can be combined. In this case, all but three of the variables are identical (either primed or unprimed) in all eight terms.

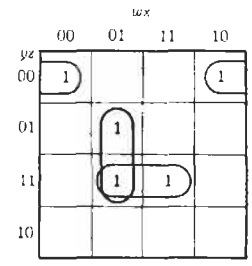

Fig. 16. Four-variable map with adjacent 1 cells encircled. $f = \Sigma\,(0,5,6,8,15) = x'y'z' + w'xz + xy$.

The general rule is that, if in 2^i fundamental products all but i of the variables are identical (primed or unprimed), then the 2^i products can be combined and the i variables that change can be dropped.

In searching for a minimal sum for a function by means of a map, the first step is to encircle all sets of cells corresponding to fundamental products that can be combined (see Fig. 18). If one such set is contained in a larger set, only the larger set is encircled.* In Fig. 18 the set (0101, 0111) is not encircled. The encircled sets and the corresponding product terms will be called *prime implicants*.† These are exactly the terms that would result from repeated applications of the theorem $XY + XY' = X$. The terms appearing in the minimal sum will be some or all of the prime implicants.

Formation of Minimal Sums

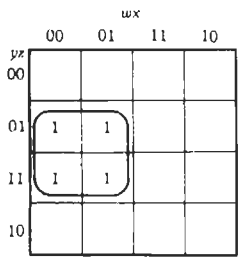
Once the prime implicants have been formed, the minimal sum can be determined directly from the map. The rule that must be followed in choosing the prime implicants that are to correspond to terms of the minimal sum is: *each 1 cell must be included in at least one of the chosen prime implicants*. The problem of obtaining a minimal sum is equivalent to that of selecting the fewest prime implicants. This rule is based on the fact that, for each combination of values of the input variables for which the function is to equal 1, the minimal sum must equal 1, and therefore at least one of its terms must equal 1. More simply, the map corresponding to the minimal sum must have the same 1 cells as the map of the original function.

A procedure for determining the minimal sum is first to determine whether any 1 cells are included in only one prime implicant. In Fig. 19, an asterisk has been placed in each 1 cell that is included in only one prime implicant. A 1 cell that is included in only one prime implicant is called a *distinguished 1 cell*.

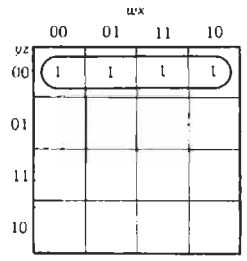
A prime implicant that includes a 1 cell that is not included in any other prime implicant is called an

*This corresponds to using the theorem $X + XY = X$.

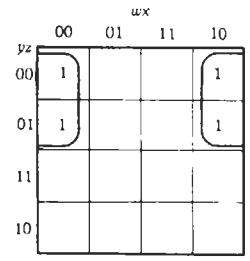
†This term was introduced by W. V. Quine. It is derived from the terminology of mathematical logic, but it has received widespread use in connection with logic design.



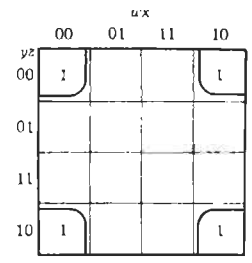
(A) $f = w'z$



(B) $f = y'z'$



(C) $f = x'y'$

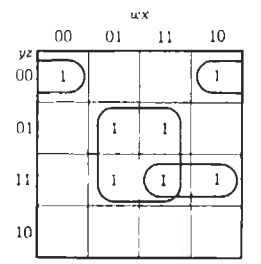


(D) $f = x'x'$

Fig. 17. Four-variable maps showing sets of cells corresponding to four fundamental products that can be combined.

essential prime implicant and *must be included in the corresponding minimal sum.*

In Fig. 19A, both prime implicants are essential and must be included in the minimal sum. A minimal sum does not always consist only of essential prime implicants. In Fig. 19B, only the essential prime implicants are shown. Cell 7 is not included in any of these, so another prime implicant that includes cell 7 must be present in the minimal sum. Fig. 19C shows the function of Fig. 19B after removal of the essential prime implicants. One of the two prime implicants shown must be included in the minimal sum, and the larger is chosen because the corresponding term contains fewer literals. The final minimal sum is $f = y'z + wz + w'yz' + xz$. There are some functions, such as that shown in Fig. 19D, that do not contain any essential prime implicants. For such functions, the minimum number of prime implicants required in the minimal sum can be determined by trial and error. The function of Fig. 19D has two minimal sums,



$f = \Sigma(0,5,7,8,11,13,15) = xz + x'y'z' + wyz$

Fig. 18. Map showing prime implicants.

$$f = wxy' + w'xy + xyz'$$

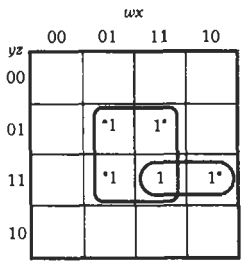
and

$$f = wxz' + xy'z + w'xy$$

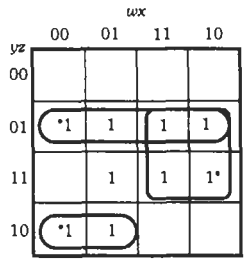
The addition of d terms does not introduce any extra complexity into the procedure for determining minimal sums. Any d terms that are present are treated as 1 terms in forming the prime implicants, with the exception that no prime implicants containing only d terms are formed. The d terms are disregarded in choosing terms of the minimal sum. No prime implicants are included in order to ensure that each d term is contained in at least one prime implicant of the minimal sum.

The explanation of this procedure is that d terms are used to make the prime implicants as large as possible so as to include the maximum number of 1 cells and to contain as few literals as possible. No prime implicants need be included in the minimal sum because of the d terms, for it is not required that the function equal 1 for the d terms. An example of a function with d terms is given in Fig. 20.

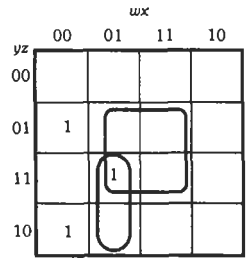
It is often convenient to avoid determining all the prime implicants. This can sometimes be done by searching for 1 cells that are contained in only one prime implicant and thus determining the essential prime implicants. A 1 cell is selected, and the prime implicant or prime implicants that include the 1 cell are determined. If there is only one prime implicant, it is essential and must be included in the minimal sum. This procedure is continued until all the 1 cells are included in prime implicants of the minimal sum.



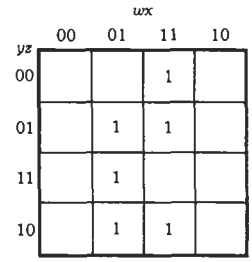
(A) $f = \Sigma(5,7,11,13,15)$, minimal sum: $f = xz + wyz$.



(B) $f = \Sigma(1,2,5,6,7,9,11,13,15)$, essential prime implicants.

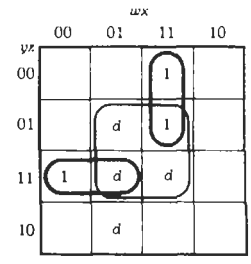


(C) (B) after removal of the essential prime implicants.



(D) $f = \Sigma(5,6,7,12,13,14)$, no essential prime implicants present.

Fig. 19. Determination of minimal sums.



$f = \Sigma(3,12,13) + d(5,6,7,15)$ Minimal sum: $f = wxy' + w'yz$

Fig. 20. Determination of minimal sum for a function with *d* terms. Prime implicants used in minimal sums are shown darkened.

SEQUENTIAL CIRCUITS

The methods developed above are applicable to combinational circuits—circuits whose outputs are determined completely by their present inputs. Many digital circuits satisfy this restriction; however, there are also many circuits that do not. Circuits whose outputs depend not only on the present inputs but also on previous inputs are called *sequential circuits*.

The difference between a combinational circuit and a sequential circuit is analogous to the difference between the two types of combination lock shown in Fig. 21. Lock A is open or closed depending only on the present setting of its dials; past settings are unimportant, just as, in a combinational circuit, past inputs are unimportant in determining the present circuit outputs. Whether lock B is open or not depends not only on which number the pointer is selecting but also on which numbers the pointer stopped at previously. Similarly, the output of a sequential circuit depends on previous as well as present inputs.

In order for the output of a sequential circuit to depend on past inputs, the circuit must have some mechanism to retain information about previous inputs. This mechanism is some type of memory element. The first memory element used in electronic logic circuits is now called a *latch*. A latch constructed of NOR gates is shown in Fig. 22. This circuit is called a *set-reset latch* or *SR latch* (S represents the set input and R represents the reset input).

The operation of the circuit is illustrated in the figure. When S = 1 and R = 0 as in Fig. 22A, the circuit is "set," and the output values are Q = 1, $\overline{Q}$ = 0. The shading of the top NOR gate of this figure indicates that the output of that gate is "forced" by an external signal (S in this case). If S is then changed to 0, the circuit remains in the set condition, as shown in Fig. 22B. Changing S back to 1 returns the circuit to the situation of Fig. 22A. If, instead, R becomes 1, the circuit becomes "reset," and the conditions of Fig. 22C are present. The circuit remains in the reset state if R is returned to 0 as in Fig. 22D. Thus, when S and R are

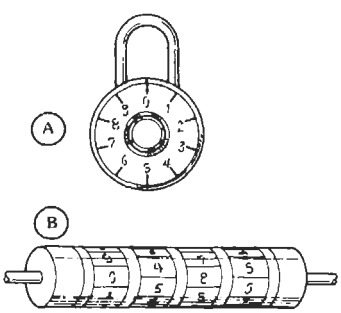


Fig. 21. Two types of combination lock.

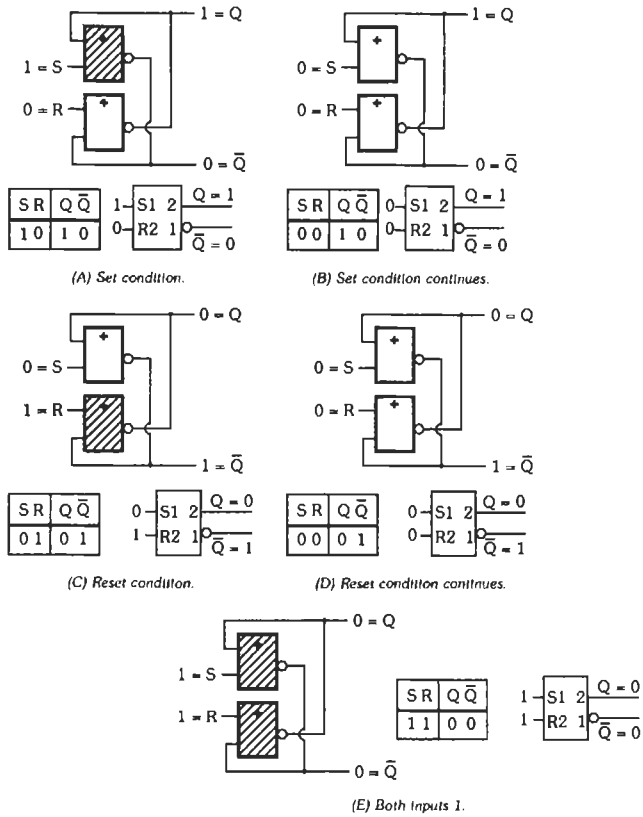

Fig. 22. Set-reset latch constructed of NOR gates.

both 0, the output indicates which of S or R was last equal to 1—the circuit "remembers" the last nonzero input condition. Waveforms illustrating the latch operation are shown in Fig. 23. Fig. 22 includes tables showing the circuit conditions, and the logic symbol for a set-reset latch with the appropriate signal values. A table typical of those used by manufacturers to summarize the circuit operation is shown in Table 7.

Definitions of the SR latch do not specify the circuit operation with both inputs at 1. This is because the circuit action with S = R = 1 is very dependent on the specific implementation. Usually, networks containing SR latches are designated so that the S = R = 1 input condition never occurs.

For a specific circuit design, the action of an SR latch with both inputs equal to 1 is, of course, fixed. The result of placing 1s on both inputs to the NOR-gate SR latch is shown in Fig. 22E: both gates have their outputs forced to 0. A disturbing feature of this is that the outputs are no longer complementary. Despite the drawbacks, there are situations in which use of the S = R = 1 input state can be very useful.

An important characteristic of this circuit is that when an input value is changed, any effect on the output appears immediately after the new input appears. The new output is delayed only by the propagation times of the devices in the circuit. All latches have this property, but it is sometimes emphasized by calling them *transparent latches.**

TABLE 7. SR LATCH OPERATION

S	R	Q_n
0	0	Q_{n-1}
1	0	1
0	1	0
1	1	F

A word of warning is appropriate here. The terminology used in connection with bistable circuits such as the set-reset latch can be confusing since there is a lack of consistency and care in naming such circuits. It does appear that this situation is improving and will continue to get better as the new IEEE Standard—*Graphic Symbols for Logic Functions* (reference 3)—gains wider acceptance. The symbols used here follow the spirit of the new Standard, which is discussed in more detail in references 4 and 5.

The discussion in this chapter is an introduction to some of the basic issues involved in logic design. It is far from complete. For a more thorough coverage on this topic, the interested reader is referred to reference 5, from which much of the material of this chapter has been drawn.

44 Probability and Statistics

Surendra M. Gupta

INTRODUCTION

Probability and statistics concepts have very useful applications in science and engineering. This chapter briefly introduces some of the important concepts of probability and statistics.

In probabilistic modeling one often refers to a *random experiment*, which represents an experiment that can be repeated time and again under similar circumstances, but which yields unpredictable results at each trial. For example, tossing a die is a random experiment where the result is a number from the sample space {1, 2, 3, 4, 5, 6}. A random experiment may consist of observing or measuring elements taken from a set that is known as a *population*. A real number associated with the result of a random experiment is called a *random variable* or *variate*. A variate may be *discrete* or *continuous*.

Discrete Probability Distribution

A discrete variate takes its value from a finite or denumerable set $\{x_1, x_2, \ldots, x_n\}$ described by its *probability function*, p_k, defined as the probability of obtaining x_k as a result of one trial. p_k has the following properties:

$$0 \le p_k \le 1$$

and

$$\sum_{\text{all } k} p_k = 1$$

A discrete variate can be described by its *cumulative probability function* as

$$P(x) = \sum_{x_k \le x} p_k$$

A discrete variate of multiple dimensions is described by its *joint distribution*. For example, if (x_j, y_k) are the coordinates of a point in the (x, y) plane, then $p(x_j, y_k)$ is the joint probability distribution such that $x = x_j$ and $y = y_k$. In addition,

$$p_1(x_j) = \sum_{\text{all } k} p(x_j, y_k)$$

and

$$p_2(y_k) = \sum_{\text{all } j} p(x_j, y_k)$$

are, respectively, the *marginal probabilities* that $x = x_j$ independent of y and that $y = y_k$, independent of x. Also,

$$p(x_j \mid y_k) = p(x_j, y_k) / p_2(y_k), \quad p_2(y_k) > 0$$

and

$$p(y_k \mid x_j) = p(x_j, y_k) / p_1(x_j), \quad p_1(x_j) > 0$$

are, respectively, the *conditional probabilities* that $x = x_j$ given that $y = y_k$ has already occurred, and that $y = y_k$ given that $x = x_j$ has already occurred.

Finally, x_j and y_k are said to be *independent* if $p(x_j, y_k) = p_1(x_j)p_2(y_k)$ for all x_j and y_k.

Continuous Probability Distribution

A continuous variate takes its value from a nondenumerable set described by its *probability density function*, $p(x)$. The probability that one trial of the experiment gives a result between x and $x + dx$ is $p(x)dx$. The *cumulative distribution function*, $P(x)$, is defined as the probability that the continuous variate is less than or equal to x. It can be represented mathematically as

$$P(x) = \int_{-\infty}^{x} p(s)ds$$

Note that the following properties hold:

$$P(x_1) \ge P(x_2) \text{ if } x_1 \ge x_2$$

$$P(-\infty) = 0$$

$$P(+\infty) = \int_{-\infty}^{+\infty} p(s)ds = 1$$

$$P(x) \ge 0$$

$$p(x) = dP / dx$$

A continuous variate of multiple dimensions, or *multivariate*, is described by its *joint distribution*. For example, if (x, y) are the coordinates of a point in a plane, then $p(x,y)dxdy$ is the probability that the multivariate has its x-coordinate between x and $x + dx$ and its y-coordinate between y and $y + dy$. In addition,

$$p_1(x) = \int_{-\infty}^{\infty} p(x,y)dy$$

and

$$p_2(y) = \int_{-\infty}^{\infty} p(x,y)dx$$

are the *marginal probability density functions*, which means that $p_1(x)dx$ is the probability that the variate x lies between x and $x + dx$ independent of y, and $p_2(y)dy$ is the probability that the variate y lies between y and $y + dy$ independent of x. Also,

$$p(x \mid y) = p(x,y) / p_2(y), \quad p_2(y) > 0$$

and

$$p(y \mid x) = p(x,y) / p_1(x), \quad p_1(x) > 0$$

are, respectively, the *conditional probability functions* such that $p(x|y_0)dx$ is the probability that the variate x lies between x and $x + dx$ given that $y = y_0$ and $p(y|x_0)dy$ is the probability that the variate y lies between y and $y + dy$ given that $x = x_0$.

Finally, two variates x and y are said to be *independent* if $p(x, y) = p_1(x)p_2(y)$ for all x and y.

MATHEMATICAL EXPECTATION

Various forms of mathematical expectations are used to describe the main features of a probability distribution. The mean and median of the distribution establish the center. The mean represents the center of gravity of the probability density function while the median divides that function into two equal parts. The root mean square, variance, standard deviation, and the mean absolute deviation are measures of the spread about the mean. The moments of order three and four about the mean describe the asymmetry and peakedness, respectively, of the probability density function.

The *expected value of a function* of a random variable can be written as

$$E[g(x_k)] = \sum_{\text{all } k} g(x_k) p_k$$

for the function $g(x_k)$ of the discrete random variable x_k, and

$$E[g(x)] = \int_{-\infty}^{\infty} g(x)p(x)dx$$

for the function $g(x)$ of the continuous random variable x.

Using the definition of the expected value, the various properties of a distribution could be obtained as follows.

The *mean* of a distribution is

$$\mu = E[x_k] = \sum_{\text{all } k} x_k p_k$$

for the discrete case

and

$$\mu = E[x] = \int_{-\infty}^{\infty} xp(x)dx$$

for the continuous case

For the discrete case, the *median* is a value m such that the variate x_k has equal probability of being larger or smaller than m. For the continuous case, it has a value such that the variate x satisfies

$$\int_{-\infty}^{m} p(x)dx = \int_{m}^{\infty} p(x)dx = \tfrac{1}{2}$$

The *mode* is a value of x_k (or x) where the probability density p_k (or $p(x)$) is the largest. Note that there may be more than one mode.

The *root mean square* is

$$r = \left[E[x_k^2]\right]^{1/2} = \left[\sum_{\text{all } k} x_k^2 p_k\right]^{1/2}$$

for the discrete case

and

$$r = \left[E[x^2]\right]^{1/2} = \left[\int_{-\infty}^{\infty} x^2 p(x)dx\right]^{1/2}$$

for the continuous case

The *moment of order r about the origin* is

$$\nu_r = E[x_k^r] = \sum_{\text{all } k} x_k^r p_k$$

for the discrete case

and

$$\nu_r = E[x^r] = \int_{-\infty}^{\infty} x^r p(x)dx$$

for the continuous case

Note that $\nu_1 = \mu$.

The *moment of order r about the mean* is

$$\mu_r = E[(x_k - \mu)^r] = \sum_{\text{all } k} (x_k - \mu)^r p_k$$

for the discrete case

and

$$\mu_r = E[(x - \mu)^r] = \int_{-\infty}^{\infty} (x - \mu)^r p(x)dx$$

for the continuous case

The *variance* is

$$\sigma^2 = \mu_2 = E[(x_k - \mu)^2] = \sum_{\text{all } k} (x_k - \mu)^2 p_k$$

for the discrete case

and

$$\sigma^2 = \mu_2 = E[(x - \mu)^2] = \int_{-\infty}^{\infty} (x - \mu)^2 p(x)dx$$

for the continuous case

The *standard deviation* (or the *root mean square deviation from the mean*) is

$$\sigma = \left\{E[(x_k - \mu)^2]\right\}^{1/2} = \left[\sum_{\text{all } k} (x_k - \mu)^2 p_k\right]^{1/2}$$

for the discrete case

and

$$\sigma = \left\{E[(x - \mu)^2]\right\}^{1/2} = \left[\int_{-\infty}^{\infty} (x - \mu)^2 p(x)dx\right]^{1/2}$$

for the continuous case

The *mean absolute deviation* (or the *mean absolute error*) is

$$mae = E[|x_k - \mu|] = \sum_{\text{all } k} |x_k - \mu| p_k$$

for the discrete case

and

$$mae = E[|x - \mu|] = \int_{-\infty}^{\infty} |x - \mu| p(x) dx$$

for the continuous case

IMPORTANT THEORETICAL PROBABILITY DISTRIBUTIONS

A probability distribution describes the behavior of a random variable. Often, the observations generated from many different statistical experiments behave in similar ways. This means that the random variables generated by the different experiments may be more or less explained by the same probability distribution and hence could be represented by a single mathematical expression. As it turns out, one requires only a few of the standard probability distributions to describe most types of random variables encountered in practice. Tables 1 and 2 present a summary of some common theoretical discrete and continuous probability distributions.

GOODNESS OF FIT

To determine whether the sample data fit a given theoretical distribution or not, a goodness of fit test is performed. One of the most widely used goodness of fit tests is the *chi-square test*. The chi-square test is based on comparing the probability density of the sample data with that of the theoretical distribution.

The first step is to divide the sample data into m disjoint sets. Let the number of sample points falling within the ith set be f_i. From the assumed theoretical distribution and the size of the sample, the expected number, g_i, of points in the ith set is computed. The deviation between this and the actual result is expressed by

$$D = \sum_{i=1}^{m} \frac{(f_i - g_i)^2}{g_i}$$

If the f_i are sufficiently large, D is approximately distributed according to the chi-square distribution with

TABLE 1. VARIOUS DISCRETE DISTRIBUTIONS AND THEIR PROPERTIES*

	Parameters	p_k	Mean	Variance
Bernoulli	$0 < p < 1$	$p^k q^{1-k}$, $k = 0, 1$	p	pq
Binomial	n $0 < p < 1$	$\binom{n}{k} p^k q^{n-k}$, $k = 0, 1, \ldots, n$	np	npq
Geometric	$0 < p < 1$	pq^k, $k = 0, 1, \ldots$	$\frac{q}{p}$	$\frac{q}{p^2}$
Hypergeometric	$N > 0$ $n, k \geq 0$	$\frac{\binom{r}{k}\binom{N-r}{n-k}}{\binom{N}{n}}$ $k = 0, 1, \ldots, \text{Min}(r, n)$	$\frac{nr}{N}$	$\frac{nr(N-r)(N-n)}{N^2(N-1)}$
Negative Binomial	$0 < p < 1$ r is positive integer	$\binom{r+k-1}{k} p^r q^k$, $k = 0, 1, \ldots$	$\frac{rq}{p}$	$\frac{rq}{p^2}$
Poisson	$\alpha > 0$	$e^{-\alpha} \frac{\alpha^k}{k!}$ $k = 0, 1, \ldots$	α	α

* $q = 1 - p$

TABLE 2. VARIOUS CONTINUOUS DISTRIBUTIONS AND THEIR PROPERTIES

	Parameters	$p(x)$	Mean	Variance
Chi-square	$n > 0$	$\frac{x^{n/2-1}}{2^{n/2}\Gamma(n/2)}e^{-x/2}$, $x > 0$	n	$2n$
Erlang-k	$k > 0, \mu > 0$	$\frac{\mu k(\mu k x)^{k-1}}{(k-1)!}e^{-\mu k x}$, $x > 0$	$\frac{1}{\mu}$	$\frac{1}{k\mu^2}$
Exponential	$\alpha > 0$	$\alpha e^{-\alpha x}, x \geq 0$	$\frac{1}{\alpha}$	$\frac{1}{\alpha^2}$
Gamma	$\alpha > 0, \beta > 0$	$\frac{\alpha(\alpha x)^{\beta-1}}{\Gamma(\beta)}e^{-\alpha x}$, $x > 0$	$\frac{\beta}{\alpha}$	$\frac{\beta}{\alpha^2}$
Normal	$\sigma > 0$	$\frac{1}{\sigma\sqrt{2\pi}}e^{\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right]}$	μ	σ^2
Uniform	$a < b$	$\frac{1}{b-a}$, $a \leq x \leq b$	$\frac{a+b}{2}$	$\frac{(b-a)^2}{12}$

$m - 1 - r$ degrees of freedom, where r is the number of parameters that are estimated from the sample data for use in defining the theoretical distribution.

To illustrate the application of the chi-square test, consider the following example. During three successive one-hour periods, the number of telephone calls received at a station was 11, 15, and 23, while during two nonoverlapping two-hour periods, it was 40 and 37. How does this agree with a Poisson process?

Since the number of calls per hour is not specified, it is estimated from the sample as

$$\frac{11+15+23+40+37}{7} = 18$$

The deviation from the expected number is

$$\frac{7^2}{18}+\frac{3^2}{18}+\frac{5^2}{18}+\frac{4^2}{36}+\frac{1^2}{36} = 5.1$$

For $5 - 1 - 1 = 3$ degrees of freedom, this deviation is exceeded about 15 percent of the time. The assumption of a Poisson process is therefore very good. It would have been significantly doubtful only if the deviation obtained was exceeded as rarely as 5 percent or less of the time, which corresponds to D larger than 7.8 in this application.

45 Reliability and Life Testing

Revised by
Douglas L. Marriott

DEFINITIONS AND TERMINOLOGY

Availability: Probability of a system subject to repair operating satisfactorily on demand.

Average Life: The mean value for a normal distribution of lives. Generally applied to mechanical failures resulting from "wear-out."

Burn-In (also *Initial Failure):* Initially high failure rate encountered on first placing a component on test. Burn-in failures are usually associated with manufacturing defects and the debugging phase of early service.

Component: (Normally used interchangeably with the term "unit.") A component is defined as an article which is normally a combination of parts, subassemblies, or assemblies, and is a self-contained element of a complete operating equipment and performs a function necessary to the operation of that equipment. *Examples:* indicator unit, power unit, receiver, transmitter, rotating antenna, modulator unit, amplifier unit.

Confidence Level (Coefficient): The degree of desired trust or assurance in a given result. A confidence level is always associated with some assertion and measures the probability that a given assertion is true. For example, it could be the probability that a particular characteristic will fall within specified limits, i.e., the chance that the true value of P lies between $P = a$ and $P = b$.

Configuration Management: Management of and knowledge of where all specifications, procedures, and associated test results are located and assigned, so that it is possible to produce these controlled items and all reliability evaluations and predictions pertaining to the system.

Cumulative Distribution Function: If x is a random variable, then the cumulative distribution function of x is defined to be the function F such that for every real number t, $F(t)$ is the probability that a given outcome of x will not exceed t; in symbols:

$$F(t) = \Pr(x \leq t)$$

Defect: Any deviation of a unit of product from specified requirements. A unit of product may contain more than one defect.

Degradation Failure: A failure that results from a gradual change in performance characteristics of an equipment or part with time.

Design Reviews:

(A) Preliminary design review: As soon as possible after a contract has been signed, a breadboard model should be built and its reliability estimated. Reliability engineering shall re-evaluate all parts and components and determine and recommend improvements in the design.

(B) Intermediate design reviews: While developing the system, conduct design reviews on a formal basis at all suppliers as well as at the prime contractor. This program should be coordinated with the reliability growth program. Account must be taken of the contract requirements for reliability goals at scheduled points in the production schedule.

(C) Critical design review: When engineering believes the design is ready to be "frozen" and also when a satisfactory prototype has met the qualification and other reliability tests, a final design review shall be scheduled. This formal review takes into account all contract demands as modified by the most recent changes in the contract. If the product is adjudged to be satisfactory, the final design may be approved for production. The block system should be used and authorization should be given to production to make x units per the specifications and blueprints without any change.

Downtime: Time during which equipments are not capable of doing useful work because of malfunction. This does not include preventive-maintenance time. In other words, downtime is measured from the occurrence of a malfunction to the correction of that malfunction.

Equipment: Material or articles (such as sets) comprising an outfit. The term "equipment" sometimes is used instead of "set," i.e., one or more assemblies or a combination of items capable of independently performing a complete function. *Examples:* Radio receiver, digital computer, automobile. An equipment may contain several sets as components. An example would be two radio receivers assembled for dual-diversity reception. The combination would constitute the equipment.

Failure: A failure is a detected cessation of ability to perform a specified function or functions within previously established limits on the area of interest. It is beyond adjustment by the operator by means of controls normally accessible to him during the routine operation of the device. This requires that measurable limits be established to define satisfactory performance of the function.

Failure Mode Analysis: Research, development, and production engineers as well as the reliability engineers analyze the basic design and determine by simulation and logistics what possible failures might occur. Corrective measures for eliminating and preventing failures are built into the basic design. Standard forms for the failure mode analysis are made available, and the results must be given to the prime contractors and production engineers for evaluation.

Failure Modes and Effects Analysis (FMEA): Extension of failure mode analysis which also considers the consequences of the failure mode, such as "revealed fault," "fail-safe," etc.

Failure Rate and Hazard Rate: Failure rate is generally the rate at which failure occurs during an interval of time (given that it has not occurred before the start of

that interval) as a function of the total interval length. Hazard rate is an instantaneous failure rate and is defined as the limit of the failure rate as the time interval approaches 0. An example might be: A family takes an automobile trip of 120 miles and completes the trip in three hours. The average rate was 40 mph, although they drove at various rates of speed. The rate at any given instant could be determined by reading the speedometer at that instant. Therefore, the 40 mph is equivalent to the failure rate and the speed at any instant of time equals the hazard rate.

Inherent Reliability: The basic or generic failure rates of components have often been compiled by several companies as well as by some government agencies. A library covering failure rates should be part of a good reliability program. Such a listing gives concretely the reliability that can be guaranteed.

Lot Size: A specific quantity of similar material or collection of similar units from a common source; in inspection work, the quantity offered for inspection and acceptance at any one time. It may be a collection of raw material, parts, subassemblies inspected during production, or a consignment of finished products to be sent out for service.

Maintainability: The maintainability of an equipment in a specified maintenance environment is the probability that a failure will be repaired within a specified time after the failure occurs.

Mean Time Before Failure (MTBF): The total measured operating time of a population of equipments divided by the total number of failures of a repairable equipment is defined as the ratio of the total operating time to the total number of failures. The measured operating time of the equipments of the population that did not fail must be included. This measurement is normally made during that period of time between the early life and wear-out failures. In the case of a constant hazard rate, this ratio is the reciprocal of the failure rate.

The MTBF can be determined by dividing the product of the number of equipments tested, N, and the test time, t, by the number of failures, f, which occur during that time; i.e., MTBF, or often just m, is equal to Nt/f. The quantity m is the reciprocal of λ, i.e., $m = 1/\lambda$, and is related to the probability of survival by the exponential law $P_s = e(-t/m)$. The figure of merit m (sometimes expressed as t) is convenient for use in determining if the reliability of an equipment is likely to be adequate for missions of specific lengths.

Mean Time to Failure (MTTF): The measured operating time of a single piece of equipment divided by the total number of failures of the equipment during the measured period of time. This measurement is normally made during that period of time between the early life and wear-out failures.

Mean Time to Repair (MTTR): The measured repair time divided by the total number of failures of the equipment.

Mission Success Rate: That percentage of the total missions uninterrupted by failure of the equipment. This figure of merit is more closely dependent on the reliability of the parts included in the system and on the design of the system than are either maintenance ratio or in-commission rate. However, this measure of reliability is valuable primarily to a using agency that has a regular schedule of missions. A mission success rate obtained by one agency is not typical of the equipment in general and will not necessarily apply for other agencies with different operating schedules.

Mode of Failure: The physical description of the manner in which a failure occurs and the operating condition of the equipment or part at the time of the failure.

Part Failure Rate: The rate at which a part fails to perform its intended function.

Probability: The limiting relative frequency in an infinite random series. If an event can occur in n ways and its failure in m ways, and if these $m + n$ ways are equally likely, then the mathematical probability that the event will occur in any one trial is the ratio $n/(n + m)$.

In other words, the probability of an event is the theoretical relative frequency with which it will occur, such relative frequency being the ratio of the number of times the event is observed under experimental conditions to the total of a great number of observations made under those conditions.

Common notation is:

$$\Pr(X) = \text{Probability of event } X$$

$$\Pr(X/Y) = \text{Probability of event } X$$

given Y has occurred

Probability Density Function (PDF): The relative frequency of a continuous random variable, obtained from the cumulative distribution function by differentiation.

$$f(t) = dF(t)/dt$$

Probability of Survival: A numerical expression of reliability with the accepted nomenclature of P_s and a range from 0 to 1.0 indicating the extremes of "impossibility" and "certainty."

In other words, the probability of a given equipment performing its intended function or the given use cycle is

$$R(t) = 1 - F(t)$$

Product Effectiveness: The entire reliability program must be tied in with the quality engineering programs for securing the most effective operation possible. Product effectiveness includes all the elements for

securing at minimum cost a product with maximum effectiveness. Programs for quality assurance contain schedules and procedures that encompass within them reliability, preventive maintenance, value engineering, human engineering, quality control, inspection, and tests that result in systems and products that will prove most effective when in operation.

Quality Assurance (QA): All those activities, including surveillance, inspection, control, and documentation, aimed at ensuring that the product will meet its performance specifications. Quality assurance generally has an independent role from production and reports directly to senior management.

Reliability Allocations: With an overall system reliability goal and where the confidence level is known, reliability values may be allocated to every component in the system by the use of available failure rates and weighting factors.

Reliability Demonstration: Critical tests must be programmed to provide sufficient valid data to determine the reliability of the system and all critical component parts. Provision should be made for processing all such data as expeditiously as possible to speed up all phases of the program with truly reliable materials and parts.

Reliability Goals: Requests for bids, specifications, and contracts requiring quality assurance and reliability generally describe completely the reliability goals. The reliability of the system with specified confidence levels is the principal goal. Values to be secured at specified points in time are listed on the growth curves. A reliability demonstration program is detailed to show that the reliability goals have been attained. How are such reliability goals expressed? The simplest statement covers only an expected value. The quality assurance paragraph in the specification will state simply: "The desired reliability is 99.7%." This is too simple, as the length of the mission or number of cycles of operation has not been detailed. The statement should be, "For 100 hours of operation the specified reliability is 99.7%."

Many contracts also introduce confidence levels. For example, after the initial design review, the reliability of the system must be 99% with a confidence level of 0.60. After qualifying, the system must have a reliability of 99.7% for a mission time of 10 hours with a confidence level of 0.99. Thus expressed, this goal has within it a final goal plus some information concerning the desired growth curve for reliability. In many programs, provision for the reliability demonstration program has not been made, or in making final arrangements for the finalized contract it is cancelled because of lack of funds. The reliability engineer should establish a very modest program to check the achievement of the reliability goals by means of an economic reliability demonstration program. Thus, it must be emphasized that the simplest possible reliability demonstration test should be made a part of the final program covered by contract and funds. This provides vital evidence that the reliability goals have been achieved and that the customer reliability requirements have been met.

Reliability Growth Curves: Periodic reports, such as monthly or quarterly, should be prepared containing up-to-date predictions of the system's reliability. These should be presented graphically on the reliability growth curves for this system and its various components and parts.

Reliability Predictions: Many agencies and companies have compiled failure rates for parts, components, subassemblies, assemblies, and systems. These generic failure rates are used as basic data to predict a value for reliability.

Sample: One or more sample units selected at random from a quantity of product to represent that quantity of product for inspection purposes.

Sequential Sampling: Sampling inspection in which, after each unit is inspected, the decision is made to accept, to reject, or to inspect another unit. *Note:* Sequential sampling as defined here is sometimes called "unit sequential sampling" or "multiple sampling." Multiple sampling is preferred, to differentiate from sequential testing.

Significance Level: The level of confidence (i.e., the probability of being correct) at which a hypothesis, such as "goodness of fit," is to be accepted or rejected.

Specification Limits: The specification limit(s) is the requirement that a quality characteristic should meet. This requirement may be expressed as an upper or a lower specification limit (called a single specification limit) or both upper and lower specification limits (called a double specification limit).

System (General): A combination of parts, assemblies, and sets joined together to perform a specific operational function or functions. *Examples:* Piping system, refrigeration system, air conditioning system.

Test to Failure: Testing conducted on one or more items until a predetermined number of failures have been observed. Failures are induced by increasing electrical, mechanical, and/or environmental stress levels, usually in contrast to life tests in which failures occur after extended exposure to predetermined stress levels. A life test can be considered a test to failure using age as the stress.

Value Engineering: One feature of a good reliability program is a concurrent value engineering program. Many programs include incentive provisions. If an operation is usually expensive, provisions should be made for a series of improvements that fall in with the value engineering and incentive programs. Provisions for successive cost reduction programs as well as basic value engineering improvements should be added to each contract. It may be made a part of the incentive programs that are now usually included in military and government contracts for procurement.

Weapon System: A missile and all the necessary support equipment (either ground or airborne) necessary to launch and properly operate a missile.

Wear-Out Period: The wear-out period of an equipment is that period of equipment life, following the normal operating period, during which the equipment failure rate increases above the normal rate.

RELIABILITY DEFINITIONS

Reliability is the probability that a given product, system, or action will achieve its designated goal successfully under the specified environmental conditions and for a prescribed period of time or for the number of cycles of operation required for the mission or task.

Reliability involves three distinct concepts:

1. Attaining a specified level of performance
2. The probability of achieving that level
3. Maintaining that level for a specified time

ORGANIZATION FOR RELIABILITY

Reliability is one of the disciplines that form the assurance sciences. These disciplines govern the quality, safety, and dependability of a product throughout its life cycle. Whereas many of the aspects of assurance science, such as quality control, are aimed at ensuring that a product has been manufactured within acceptable limits, reliability is also related to aspects of design and development, in that its objective is to predict and assure an acceptable level of performance in service. For this reason, provision must be made in the structure of any manufacturing organization to integrate reliability activities with the product evolution process.

There is no single answer to the question of where the reliability function should exist in any organization. To some extent, the solution depends on the form of product and the organization itself. Comprehensive discussions of organization for product assurance and reliability are contained in References 1 and 2. Guidance is also available from professional bodies. For instance, the Institute of Electrical and Electronics Engineers and the American Society for Quality Control have defined a structure as shown in Fig. 1.

Today, reliability seems to fit most naturally into the product-assurance or product-effectiveness section of major space equipment manufacturers.

The most important organizational aspect is the fact that reliability and well-versed quality personnel use one tool which, when shared jointly, adds to the "experience-retention" capability; that tool is statistics. If the intent of any organization is to get the most out of the "fall of data," the organization of Fig. 1 is effective. Because of the problem of decision making, reliability is best placed at the staff level.

In a small organization, reliability is usually shared by engineering and by quality assurance. Some firms, to better satisfy the requirements of the Department of Defense, put reliability in the quality organization spectrum of operations, viz.,

Quality and reliability assurance tasks
Data reduction
Planning
Inspection, etc.
Test plan
Vendor survey
Quality-control engineering

Reliability planning, to be effective, must fit into the total program. One of the best ways to gain acceptance of the reliability or maintainability effort is to establish

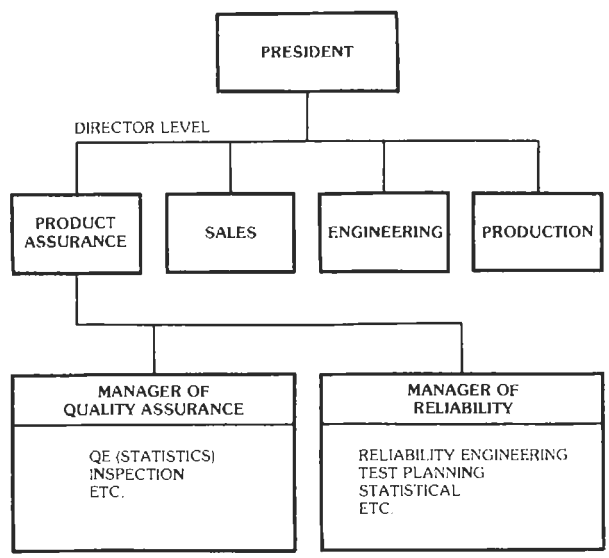

Fig. 1. Typical organization chart showing reliability chain of responsibility.

a proper sequence for its insertion into a master operating plan. For companies without a particular project, this plan usually is discussed with the engineering head and the production head. For corporations working on a program that requires reliability by specified intent, the customer invariably requires a reliability plan. The major items (or task delineators) in a reliability plan are noted in Chart 1.

In the plan itself, the time relationships of the tasks to reliability and overall project tasks are noted as milestones. Some of these milestones are then placed on more sophisticated PERT* or CPM† charts for management review of major effort.

The recognition of reliability as an integral part of product performance is more than simply a matter of early prediction of in-service behavior. It also identifies a number of major economic and safety implications. The realization that failures are inevitable adds an extra dimension to conventional design, consideration being given to the consequences of failures and actions which must be taken to mitigate them. One possible action, for instance, is to provide redundant or standby systems. Others are to give early attention to availability (the percentage of time a system is in a working state) and maintainability (the average time required to repair a system after failure).

Alternatively, potentially catastrophic failures can be prevented by designing in deliberate weak links, such as fuses or breakers that cause the system to fail prematurely in a safe manner ("fail-safe" design).

None of the above actions can be implemented unless product development and the reliability assessment program are closely coordinated. In the case of complex systems, for which high reliability must be achieved, the required performance in service may be impossible to obtain without conscious design for reliability.

ELEMENTS OF RELIABILITY ASSESSMENT

Reliability assessment, rather than occupying one place in product development, is involved in a more or less continuous basis from the early conceptual stages through to the monitoring of service performance. As a result, reliability analysts may be called on to take part in the following activities:

Design reviews
Failure mode analysis
Quantitative reliability assessment
Failure data collection and assessment

Design Reviews

Several reviews of a system design are performed, usually by an interdisciplinary team of designers, production engineers, safety and reliability analysts, and others. The objectives are generally to ensure that the product is capable of meeting performance requirements, conforms with necessary standards, optimizes production facilities, and contains no unanticipated flaws. Guidelines for performing a design review have been set out in Reference 2. These emphasize careful documentation and the use of check lists prepared from past experience to ensure coverage of all relevant factors. The list of reliability terms at the beginning of this chapter gives a brief description of three common design reviews.

Failure Mode Analysis

An essential step in controlling reliability is a full investigation of all potential failure mechanisms and their causes, effects, and possible consequences. This is largely a qualitative exercise aimed at finding out what may happen, rather than how often, but it forms an essential foundation for all subsequent quantitative analysis. In fact, there are many instances where it is more important to have all the failure modes identified than to make accurate analyses of some while neglecting others altogether. This task is known by a variety of titles, one alternative being cause and effects analysis, but the most frequently used name is failure modes and effects analysis (FMEA). As in the case of design reviews, FMEA is helped considerably by a systematic approach using check lists and analysis sheets (See Reference 2 for examples.) In addition, the sequential structure of many forms of failure can be used to identify the failure itself, using logic diagrams or

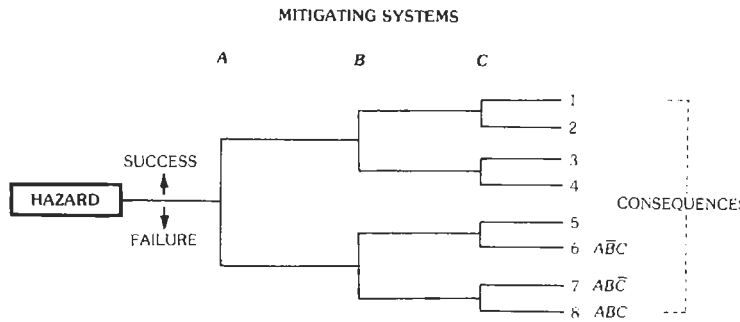

Fig. 2. A simple event tree.

decision trees. Two of the many variants available are shown in Figs. 2 and 3. Fig. 2 illustrates an event tree. This type of diagram is commonly used to map the end results of a sequence of safety device operations. Each branch point represents two possibilities, e.g., "device operates" or "device fails to operate." The event tree starts from an initiating event and progresses forward through subsequent events to a final state which may or may not be a significant failure state for the system. It is capable of pointing to undesirable event sequences which might not be identified by a less systematic approach. Unfortunately, event trees tend to generate many spurious branches and rapidly reach unmanageable proportions. Their main use is in mapping sequences where there is a clear chain of events, for instance, as in certain human operations (see Reference 3).

The most common form of diagram is the fault tree (Fig. 3). This diagram employs a top-down logic, expanding out from a known end result to identify events, or combinations of events, that lead to failure. Fault trees use the same conventions for logic gates that

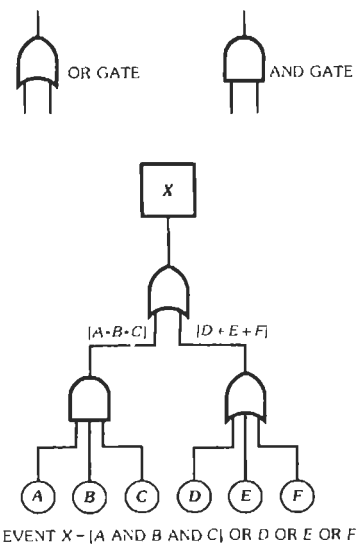

Fig. 3. A simple fault tree.

are used in logic-circuit theory. They are not confined to only two branches at each branch point as is normally the case in event-tree construction. In theory, there is a problem with fault-tree analysis, in that the top event must first be identified by some other means. In practice, it is usually possible to identify failure events at a sufficiently high level to ensure exhaustive coverage of all possibilities. For instance, the top events for reliability analysis of a radio receiver would include:

Fail to operate at all
Fail to receive any signal
Fading or hunting reception
Drift
Excessive interference and noise levels

More detailed failure mechanisms can then be identified within each category, on the next lower level of detail. Fig. 4 is a partially developed fault tree for the top event, "fail to operate." To illustrate the technique more fully, it has been assumed that the receiver is powered from a mains (power-line) supply with an automatic switching backup battery. This diagram is by no means complete.

Fault trees can grow rapidly beyond easy manipulation by hand, and, for formal analysis, it is advisable to resort to computer codes, of which several are currently available for fault tree analysis. (See Reference 4 for an extensive summary of currently available software.) On a less formal level, the fault tree is an extremely useful aid in that it imposes a disciplined approach to the problem of failure-mode identification and it provides a structure whereby details of potential failures can be recorded in a sequential manner, without getting lost in the process.

In addition to identifying individual events that lead to failure, a fault tree also contains the logic governing the necessary sequences of events that lead to failure. These sequences are known as "cut sets." In Fig. 5, any one of the combinations *A* and *D*, *B* and *C*, *D* and *G*, or *J* and *B* is a cut set. In more complicated problems, the cut sets may be very complex themselves, and not necessarily independent of one another. It can be shown that cut sets can be reduced to an equivalent set of minimal independent requirements for failure called "minimum cut sets." Two simple examples are shown in Fig. 5. In Fig. 5A, four events, *A*, *B*, *C*, and *D*

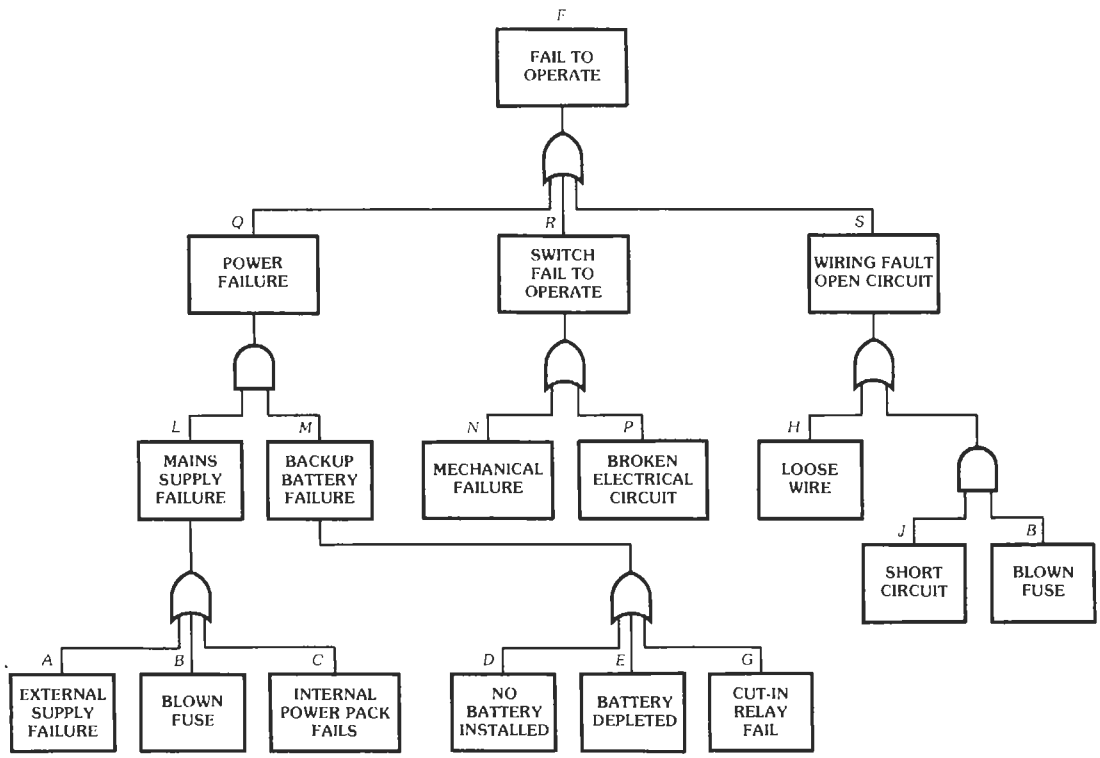

Fig. 4. Fault tree for radio-receiver failure mode "fail to operate on demand."

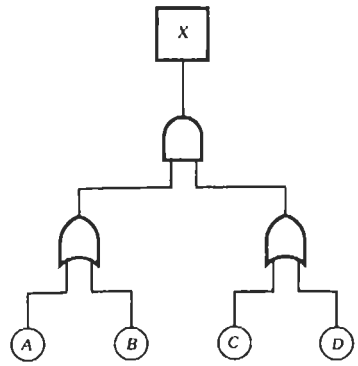
contribute to some failure event X. Combining these events by the rules of Boolean logic algebra, X occurs if A and C or A and D or B and C or B and D occur. These sequences are cut sets and, in this case, minimum cut sets. In Fig. 5B, a similar fault tree contains a common element B in both branches. In this case, the top event, Y, is only dependent on the occurrence of A and C or B. Here, B represents an important class of failures called "common mode" or "common cause" failures. It can be easily seen that if A, B, C, and D all have similar probabilities of occurrence, Y has a much higher probability of occurrence that X, because it only requires a single event instead of two simultaneous events. Failure to identify common modes or dependencies between different failure mechanisms is a frequent cause of excessively optimistic reliability predictions. It can be seen from the above simple example how fault tree analysis can be used to avoid this problem.

Quantitative Reliability Assessment

Quantitative reliability assessment is one of the most important tasks of the reliability analyst. Reliability quantification covers two dimensions—probability of occurrence and magnitude of the consequence of failure. Assessment of failure consequence is probably more the task of design. Nevertheless, it cannot be neglected in reliability assessment, particularly when assigning reliability targets, or allocating reliability to subsystems. Intuitively, it seems sensible to assign a higher reliability target to a subsystem with potentially catastrophic failure consequences than to one that involves only a degradation in performance.

Consequences of failure can be extremely difficult to estimate. In the preliminary stages of development, a useful technique is called worst-case analysis. It takes the most pessimistic values of all parameters, regardless of the likelihood of this occurring. In electronic circuits, for instance, all components are assumed to be at the extreme limits of their tolerance bands, including any drift due to environmental factors. By this procedure, it is possible to identify undesirable modes of operation that might not be considered possible otherwise. The detection of potentially catastrophic modes of failure is probably the most useful outcome of this type of analysis. Regardless of their likelihood, failures of this type may require designing out of the system completely. It is only in those cases where the cost of failure can be reasonably balanced against the cost of



EVENT X = (A AND C) OR (A AND D) OR (B AND C) OR (B AND D)

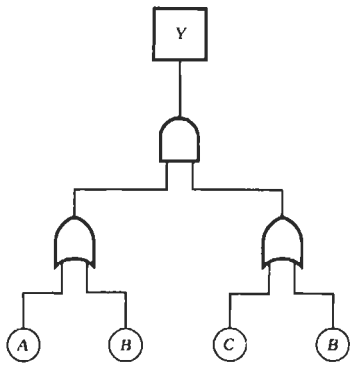
$Pr(A) = A \cdot C + A \cdot D + B \cdot C + B \cdot D$

IF $Pr(A) = Pr(B) = Pr(C) = Pr(D) = 0.01$

$Pr(X) = Pr(A) \cdot Pr(C) + Pr(A) \cdot Pr(D) + Pr(B) \cdot Pr(C) + Pr(B) \cdot Pr(D)$

$= 4 \times 10^{-4}$

(A) Independent events.



$Y = A \cdot B + A \cdot C \cdot B \cdot C \cdot B$

$= A \cdot C \cdot B$

$Pr(Y) = 2 \times 10^{-4} \cdot 10^{-2} = 10^{-2}$

$Pr(Y) >> Pr(X)$

(B) Dependent events.

Fig. 5. Calculation of event probability.

improved design that the question of probability of occurrence becomes important.

The area of quantification most closely identified with the reliability analyst is the assessment of failure probability. This is a natural result of defining reliability in probabilistic terms. A wide range of mathematical techniques have been developed in the general fields of probability and statistics, supplemented with methods specifically directed toward reliability modeling. These methods will be reviewed in a special section later in this chapter.

Failure Data Collection and Assessment

The collection of failure data is part of a continuous feedback loop that is essential to reliability growth. The process begins in the early stages of product development, where failures are likely to be common due to design faults and as yet uncontrolled production processes, and extends through to collection of data under normal service conditions. The reliability analyst should be closely involved in this process. In addition to receiving basic failure-rate data from this source, the reliability analyst also has an active role in evaluating failure reports, assessing whether the failures are random or represent a significant deviation from expected conditions, providing backup to quality control, and offering recommendations for remedial action.

For failure analysis to be successful, the data collection system must be carefully designed and controlled. Considerable thought has been given to this problem in recent years, and a number of reporting systems have been developed. A comprehensive review of data banks and their methods of operation is contained in Reference 4. Some of these are appropriate models for in-house reporting systems. This subject will be discussed further in a later section of this chapter on sources of data. One reporting system of particular relevance to integrated circuit reliability was developed by Lockheed Corporation on behalf of NASA (Reference 5). This report is both an excellent source of information and a model for setting up an in-house reporting and analysis system.

COMPONENT RELIABILITY

A population of components on test or in service under nominally similar conditions will decrease in time as a result of failures as shown in Fig. 6. The numbers failed and surviving after time t are $N_f(t)$ and $N_s(t)$, respectively. For a sufficiently large population number N, the relative frequencies represent the cumulative probability of failure and the probability of survival (i.e., the reliability), respectively:

$$\hat{F}(t) = N_f(t)/N$$

$$\hat{R}(t) = N_s(t)/N$$

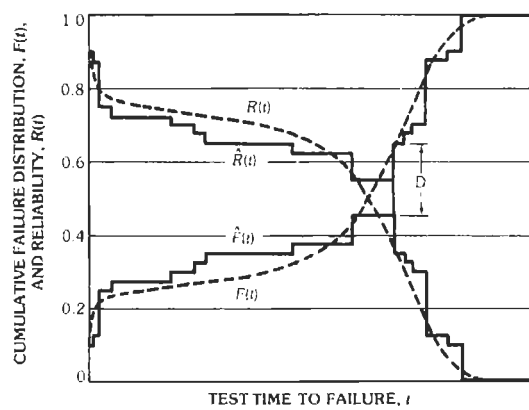


Fig. 6. Cumulative failure distribution and reliability plots for a test with 40 samples—experimental and theoretical curves shown.

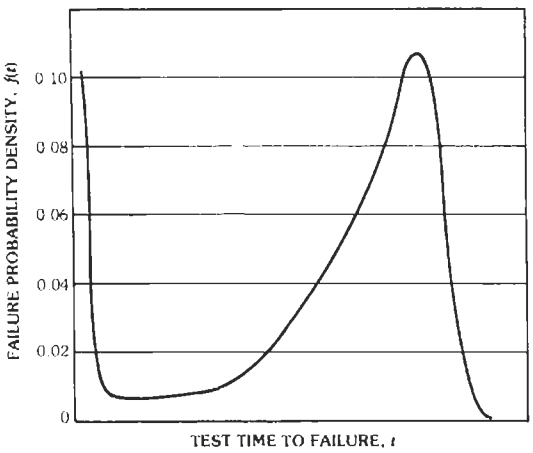

Fig. 7. Failure probability density derived from Fig. 6.

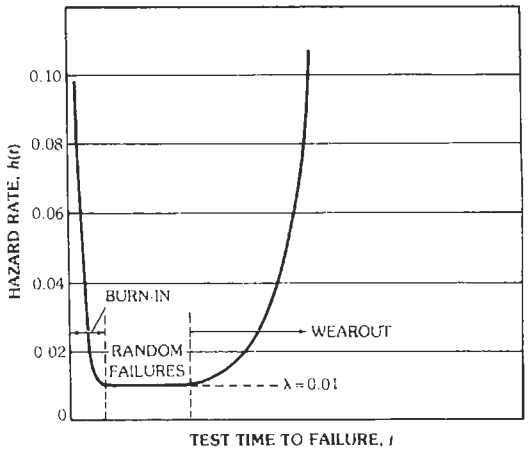

Fig. 8. Hazard rate for data given in Fig. 6.

As N tends to infinity, estimates $\hat{F}(t)$ and $\hat{R}(t)$ tend to the true failure and reliability functions, $F(t)$ and $R(t)$. Here, and subsequently in this chapter, a "hat" (ˆ) will be used to represent an estimate of a random variable. These functions are shown also in Fig. 6. By differentiating $F(t)$, the probability density function of failures, $f(t)$, is obtained (Fig. 7). This represents the relative frequency of failures with respect to the original population. Three zones can be identified in this figure. They are an initial period of high failure density, corresponding to initial manufacturing defects, an intermediate period of relatively low failure rate, where the only cause is external and random, and a final peak of high density corresponding to wearout or material deterioration. These zones can be more readily distinguished by calculating the instantaneous failure rate, or hazard rate, $h(t)$, which is the failure rate expressed as a proportion of the population surviving at time t.

$$h(t) = f(t)/[1 - F(t)]$$

The hazard rate has a characteristic shape, illustrated in Fig. 8, known as the "bathtub curve." Here, initial, or burn-in, failures; random failures; and wearout failures are clearly identified by having decreasing, constant, and increasing hazard rates, respectively. This characteristic of the hazard rate is an important diagnostic tool, as will be demonstrated later in this chapter.

It can be shown (see Reference 4 for details) that

$$F(t) = 1 - \exp\left[-\int_0^t h(t)dt\right]$$

$$R(t) = \exp\left[-\int_0^t h(t)dt\right]$$

Knowing the hazard rate, e.g., from life tests, permits the reliability function, $R(t)$, to be calculated.

In electronic components, it is common practice to require a burn-in test period that, as far as service performance is concerned, effectively removes the initial stage of the hazard rate. It is also generally assumed that stress levels have been so chosen in design that there is little likelihood of the occurrence of wearout failures. Under these conditions, it is reasonable to use a restricted version of reliability theory that assumes a constant hazard rate and is relatively easy to manipulate mathematically. In fact, the majority of formal reliability theory is based on the constant-hazard-rate model (sometimes referred to loosely and erroneously in much of the literature as a "constant-failure-rate" theory). In this model,

$$h(t) = \lambda = \text{constant}$$

$$R(t) = 1 - F(t) = \exp(-\lambda t)$$

This is the so-called exponential distribution, a special case of the Poisson distribution.

In many cases, one is interested only in high component reliabilities, in which case there is a simple approximation. That is,

$$\text{if } \lambda t \ll 1,\ 1 - F(t) = R(t) = 1 - \lambda t$$

Where the simple models discussed above are not valid, other more complex distributions must be used. Table 1 summarizes some of the more commonly used distributions. In choosing a particular distribution, there is sometimes a degree of rationale, based on the physics of the problem. More often, however, the choice is empirical so as to best fit the available data. One distribution of predominant interest in reliability studies is the Weibull distribution (see Table 1). This distribution has some justification in that it is one of a class of extreme distributions, i.e., distributions of extreme values of groups of components. Its main

TABLE 1. LIST OF COMMON FREQUENCY DISTRIBUTIONS

Name	Mass/Density Function		Mean	Variance
Binomial	$P_X(x) = \binom{n}{x}p^x(1-p)^{n-x}$	$x = 0, 1, 2, \ldots$	np	$np(1-p)$
Poisson	$p_X(x) = (\theta^x/x!)e^{-\theta}$	$x = 0, 1, 2, \ldots$	θ	θ
Normal	$f_X(x) = (1/\sqrt{2\pi}\sigma)\exp[(-1/2\sigma^2)(x-\mu)^2]$	$-\infty < x < \infty$	μ	σ^2
Lognormal	$f_X(x) = (1/\sqrt{2\pi}\sigma x)\exp[(-1/2\sigma^2)(\ln x - \mu)^2]$	$x > 0$	$\exp(\mu + \sigma^2/2)$	$\exp(2\mu + \sigma^2)[\exp(\sigma^2) - 1]$
Student-t	$f_X(t) = [\Gamma(m/2 + 1/2)/\sqrt{m\pi}\Gamma(m/2)](1 + t^2/m)^{-(m+1)/2}$	$-\infty < t < \infty$	0	$m/(m-2)$
Gamma	$f_X(x) = [\theta^n/\Gamma(n)]x^{n-1}e^{-\theta x}$	$x > 0$	n/θ	n/θ^2
Exponential	$f_X(x) = \theta e^{-\theta x}$	$x > 0$	$1/\theta$	$1/\theta^2$
Weibull	$f_X(x) = \beta(x^{\beta-1}/\eta^\beta)\exp[-(x/\eta)^\beta]$	$x > 0$	$\eta\Gamma(\beta + 1)/\beta$	$\eta^2\{\Gamma(\beta + 2)/\beta - [\Gamma(\beta + 1)/\beta]^2\}$
Chi-Square	$f_X(x) = [1/2^{n/2}\Gamma(n/2)]x^{n/2-1}e^{-x/2}$	$x > 0$	n	$2n$

attribute is its ability to represent any one of the three zones in the bathtub curve (Fig. 8) by choosing the shape parameter, β, to be less than, equal to, or greater than unity (see Fig. 9). This property of the Weibull distribution will be shown later to be a useful method of evaluating service data.

SYSTEM RELIABILITY

System reliability can be dealt with in two different ways, depending on the advancement of the project.

In the early stages of making a bid, the eventual configuration will not be known precisely, but a reliability estimate is required for the purpose of making the proposal. This estimate is inevitably crude and must draw on previous experience and generic data for its quantitative basis. The simplest approach, once the number and types of components are known approximately, is to assume the individual failure rates to be additive:

$$\lambda_s = \sum\lambda_i$$

The system reliability, $R_s(t)$, is obtained as

$$R_s(t) = \exp(-\lambda_s t)$$

This simple approach can also be used in reverse to assign component reliabilities so as to achieve a target system reliability that may have been set as a design requirement. Illustrating this simple method, if an assembly is made up of two components of equal weight and is to have an end reliability of 0.99, then each component should have a reliability of at least 0.995. The product $0.995 \times 0.995 = 0.990025$. If the assembly is made up of three units of equal weight, then each should have a reliability of 0.997, since $(0.997)^3 = 0.991026973$. The same procedure is used even if the parts have widely different importance and hence extremely different reliability values.

Formalized variants of this approach are given in the AGREE report (Reference 6) and in a more recent version in Military Handbook MIL-HDBK-217B (Reference 7).

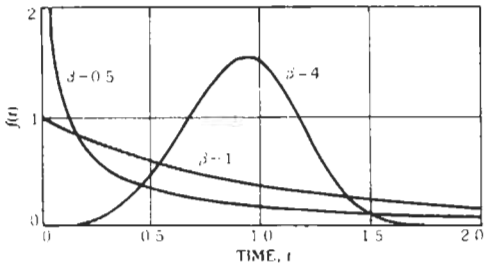
The AGREE report uses a more complex method, detailed on pages 192–195 of Reference 18. The AGREE report cautions against the use of its method for items of low importance. Its basis is the complexity of the units rather than their failure rates. Consideration is given to the number of hours the jth unit will be required to operate in T system hours and the total number of modules in the system. The importance factor of each unit must also be considered. All units do not operate the same length of time; hence, these times of operation must be considered, and many of these t_j values will be less than T hours. The AGREE report gives the allocated rate of the jth unit as

$$\tilde{\lambda}_j = n_j|-\log R^*(T)|/E_j t_j N$$

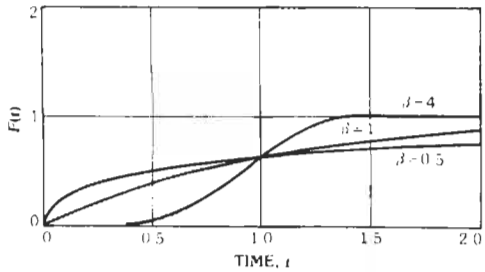
This is used in many instances to allocate reliabilities among the components.

MIL-HDBK-217B describes two methods of failure-rate prediction, "part stress analysis" and "parts count." The latter is the simpler of the two, and more appropriate to early design and bidding. For full explanations, reference is made to the handbook itself and to an expanded explanation in Reference 1. A parts count failure rate prediction lumps components into generic part types and assigns part quality levels to each type. The inputs are therefore

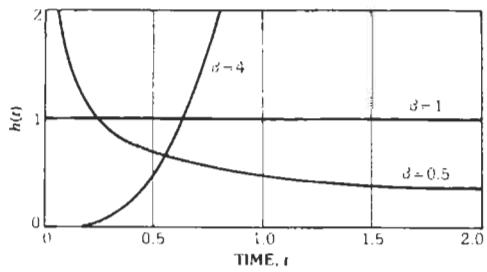
Generic part types
Quantities of parts in each type
Part quality levels
Equipment environment



(A) Probability density function.



(B) Probability distribution.



(C) Hazard function rate or instantaneous failure rate.

Fig. 9. The Weibull distribution, $F(t) = 1 - \exp[-(t/\eta)^{\beta}]$.

The total failure rate, λ_s, is then calculated from

$$\lambda_s = \sum_i (\lambda_{pc})_i$$

where $(\lambda_{pc})_i$ is the ith part category failure rate:

$$\lambda_{pc} = n \cdot \lambda_g \cdot \pi_Q$$

where,

n = number of parts in category i,
λ_g = generic failure rate, provided in MIL-HDBK-217B, for a range of components, taking into account environmental factors such as "ground, benign," "space, flight," "naval, unsheltered," up to the most severe, "missile, launch,"
π_Q = quality factor, specifying the standard of selection, e.g., "above spec.," "MIL-spec.," "below MIL-spec."

EXAMPLE 1. A preliminary design of an RC network for a ground mobile (G_M) environment gives the information shown in Table 2.

$$(\lambda_{pc})_1 = 32 \times 0.042 \times 10^{-6} \times 0.1/hr = 0.1344 \times 10^{-6}/\text{hr}$$

$$(\lambda_{pc})_2 = 5 \times 0.11 \times 10^{-6} \times 0.1/\text{hr} = 0.055 \times 10^{-6}/\text{hr}$$

$$(\lambda_{pc})_3 = 15 \times 0.044 \times 10^{-6} \times 0.1/\text{hr} = 0.066 \times 10^{-6}/\text{hr}$$

$$\lambda_s = 0.2554 \times 10^{-6}/\text{hr}$$

EXAMPLE 2. A system consisting of 1000 units as described in Example 1.

$$\lambda_{\text{system}} = 1000\lambda_s = 2.554 \times 10^{-4}/\text{hr}$$

The mean time between failures is

$$\text{MTBF} = 1/\lambda_{\text{system}} = 3915 \text{ hr}$$

The reliability at 1000 hours is

$$R(1000) = \exp(-2.554 \times 10^{-4} \times 10^{3}) = 0.775$$

The above approach assumes implicitly that all components in a system are connected in series and that a single failure causes system failure (weakest-link theory). This is conservative and unrealistic in large systems where backups are necessary if the system is to work at all. A more accurate assessment can be made once the system configuration has been finalized. In general, this may contain parallel, or redundant, elements in addition to series elements. A number of examples of redundant systems are given in Fig. 10. Note particularly that a series system is less reliable than its components, whereas a parallel system is more reliable. Series connections are generally forced on the designer by functional requirements, and redundancy is one method of retaining an acceptable level of reliability. Other techniques, such as standby and voting logic systems, are also possible (see Reference 4 for further details).

In practice, reliability of a system is not simply a function of the inherent failure rates of its components. The system will be subject to repair and scheduled maintenance. While periodic repair ensures that the reliability does not decay continuously to zero, the system will not be available on demand while it is being repaired. For complex systems with repair, therefore,

TABLE 2. DATA FOR EXAMPLE 1

Part Count	Generic Part Type*	Number of Parts	Generic Failure Rate, $\lambda_G/10^6$ hr*	Quality Factor, π_Q*
1	Film Resistor RNR 55182	32	0.042	0.1 (R)

* Data from MIL-HDBK-217B

it is more convenient to think in terms of "availability," A.

Product availability is defined as the probability that the system will operate satisfactorily at any point in time, where time includes not only operating life, but also active repair time and administrative and logistic time. An equation for availability is

$$A = \text{MTBF}/(\text{MTBF} + \text{MTTR})$$

where,

A = availability,
MTBF = mean time before failure,
MTTR = mean time to repair.

The calculation of MTTR is related to repair hours, while the calculation of MTBF is related to component operating hours. Fig. 11 is a graph of the above equation.

It is evident from the figure that the effect of maintainability on availability increases as the ratio of MTBF to MTTR decreases. If an item has an inherently low MTBF, the MTTR must be very low to sustain a good level of availability.

In the design of any complex system, an optimum relationship should be established between reliability and maintainability, so that reliability is not increased beyond the point where very little availability gain is obtained because of lack of consideration of the effect of maximum maintainability.

To look at this another way, manufacturers of microelectronic devices claim that MTBF is very high and repair time is nil or very low. Look again at Fig. 11 and the ratio of MTBF/MTTR in the region to the right of 100. Little is to be gained by designing a module that can be repaired extremely quickly, if to do the job special tools and costs are involved. In other words, the throwaway concept in this case is clearly justifiable. NOTE: There is some ambiguity in the use of the terms MTBF and MTTF. Some references use the same definitions as accepted in this chapter. Others, such as Reference 4, use MTTF as the inverse of failure rate, with MTBF to be given by

$$\text{MTBF} = \text{MTTF} + \text{MTTR}$$

Hence, by this convention, A = MTTF/MTBF

SOURCES OF RELIABILITY DATA

There are two sources of failure-rate data:

Generic data banks
Experimental determination by life testing

Generic Data Sources

Generic data are usually used for initial design and evaluation, whereas life testing is more appropriate to the latter stages of system development, where questions such as reliability growth and system substantiation are important.

Data banks and other sources of failure-rate data have grown considerably in recent years. A comprehensive review of existing data sources is given in Reference 4. Sources which are readily available are MIL-HDBK-217B (Reference 7), the results of the IEEE Project 500 on failure rates for electronic components (Reference 8), the Government/Industry Data Exchange Program (GIDEP) (Reference 9), and the Failure Data Handbook for Nuclear Facilities, available from NTIS (Reference 10). More detailed information can be obtained by subscribing to one of several data banks, such as the Nuclear Plant Reliability Data System (NPRDS) (Reference 11) or the System Reliability Service Data Bank (SYREL) (Reference 12), operated by the United Kingdom Atomic Energy Authority.

Life Testing

If it is possible to perform adequately, life testing of actual components is a more accurate method of determining failure rates, as long as testing conditions are chosen to simulate actual service conditions as realistically as possible.

Two basic methods are used in securing reliability data. In the first method, assume that 20 units are placed on test with the stipulation that each unit be operated 5000 hours, which requires over 200 days of continuous operation. During this period of operation, the time at which each of five failures occurs is recorded. If they occur at 4200, 4350, 4400, 4750, and 4900 hours, and if the test is stopped at the end of 5000 hours, the total time of operation is 100 000 − (800 + 650 + 600 + 250 + 100) = 97 600 hours. If the

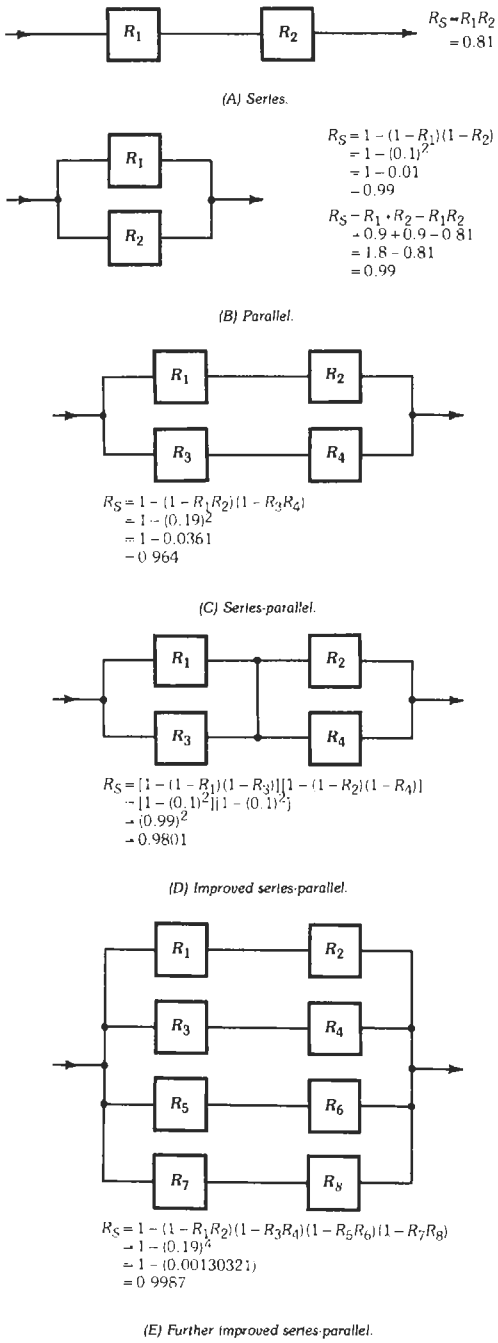

Fig. 10. Diagrams of redundant systems with relationships for computing system reliabilities. All parts are assumed to have equal reliability (R_C = 0.90).

technician making the test wishes to obtain the total operating time of 100 000 hours, then the remaining 15 units must operate 2400/15 = 160 hours each more

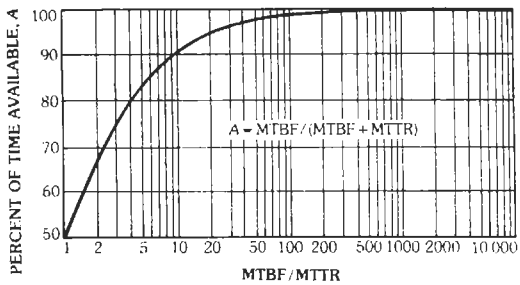

Fig. 11. Product availability.

than the original 5000 hours specified with no additional failures. Otherwise, the estimate of the failure rate should be r = 5/97 600 = 5.12/100 000 = 5.12%/1000 hours. The value of m = MTBF is m = 97 600/5 = 19 520 hours.

The second basic method for determining the failure rate is to operate all 20 units until they fail. This makes it difficult to plan a testing program, as some equipment may be tied up for two or even several times the period designated for the original test. However, failure rates found by the second method should be more representative of actual field failure rates. The data secured under these conditions for the 20 units might be as given in Chart 2.

This gives a failure rate much larger than the first estimate, i.e., r = 20/153 200 = 13.05%/1000 hours. If the 5% value is near the actual central value, then the total operating time should be about 400 000 hours, or 20 000 hours (833 days) on the average for each unit.

It is desirable to establish confidence levels for reliability values. A distribution of probability values is used to give either a one-sided confidence value or a two-sided confidence value with both upper and lower limits. When determining failure rates, a one-sided level applies. A confidence level of 0.95 might be stipulated for a reliability of 0.95 or better (the goal stipulated in the contract). In the first set of data, the rate of 5%/1000 hours may be expressed as a reliability of 95% where the mission time is 1000 hours. If the mission time is 10 hours, then the corresponding reliability is 99.95%. These values are associated with expected values rather than having a range of values associated with a designated confidence-level value. Where a confidence limit is used, a limit is established that is associated with this limit. It will be expressed as a failure rate or an MTBF value.

Fixed time testing is covered in a useful publication of the Department of Defense (DOD), Handbook H108 (Reference 13). Both fixed and sequential testing are covered by a military standard, MIL-STD-781B (Reference 14). These references and their applications are well illustrated in Reference 1.

CHART 2. TIME IN HOURS TO FAILURE FOR RELIABILITY TESTS (n = 20 UNITS)

	6500		8000		10200	5500	
	4200		7000		4750	8900

PROBABILITY AND STATISTICAL INFERENCE

Confidence Limits

If 100 components are tested and two fail, the failure probability can be estimated approximately as

$$\hat{P}_F = 0.02$$

The corresponding reliability is therefore

$$\hat{R} = 1 - P_F = 0.98$$

However, these are only estimates based on a single test. If the test is repeated, a different estimate will be obtained, as shown in Table 3, which summarizes 20 such tests, each of 100 components. Empirically, it can be determined that the mean observed reliability is $\bar{R}$ = 0.975, with a standard deviation of $\sigma_R = 0.01775$. By fitting a theoretical distribution such as a normal or Poisson distribution to this data, it is possible to determine the probability of the number of failures in some subsequent batch exceeding some value, say 6. The relative frequencies of different observed reliability estimates have been calculated in Table 4 using a normal distribution with sample mean and standard deviation, and using a Poisson distribution with the same observed overall failure rate, 0.025. Predictions are shown in Fig. 12. It appears that the normal distribution gives the better fit to the data.

This problem shows that the true reliability may be different from any observed estimate. However, it is possible to use the data summarized in Table 3 to calculate limits that will contain the true value a specified percentage of the time. These limits are known as *confidence limits*, and the percentage is called the *confidence level*.

In practice, the observed values of $\hat{R}$ will be dispersed around the true reliability, R, but R is unknown. If it can be assumed that R is normally distributed with a true standard deviation equal to the estimate from the 20 tests, then it can be shown that the mean of n tests, $\bar{R}$, will be normally distributed with a standard deviation $\sigma_R = \sigma_{\hat{R}}/\sqrt{n}$, where $n = 20$ in this case; furthermore $\bar{R}$ tends to the true reliability as n increases. If we imagine many sets of n tests to be performed, the results will be distributed around the true (unknown) reliability R, as shown in Fig. 13. The value $\bar{R} = 0.975$ obtained from Table 3 is also shown.

The probability that $\bar{R}$ is greater than some amount L larger than R is

$$\Pr(\bar{R} > R + L) = \int_{R+L}^{\infty} n(R;\ \sigma_{\hat{R}}/\sqrt{n})dR$$

where $n(R;\ \sigma_{\hat{R}}/\sqrt{n})$ is the normal distribution with mean R and standard deviation $\sigma_{\hat{R}}/\sqrt{n}$.

This can be expressed more conveniently in terms of the standard normal variate, Z_X.

$$Z_X = (X - R)/(\sigma_{\hat{R}}/\sqrt{n}),\ Z_L = L/(\sigma_{\hat{R}}/\sqrt{n})$$

$$\Pr[(\bar{R} - R)/(\sigma_{\hat{R}}/\sqrt{n}) > Z_L] = \int_{Z_L}^{\infty} n(0;1)dZ$$

If as is usual $\bar{R}$ is known and R is unknown, we need to determine the probability that R is less than $\bar{R}$ by some amount L. From the previous equation

$$\Pr(R < \hat{R} - Z_L/\sigma_{\hat{R}}/\sqrt{n}) = \int_{Z_L}^{\infty} n(0;1)dZ = \alpha$$

The quantity α can be expressed in terms of the error function that is tabulated in any standard text for the standardized normal distribution, $n(0;1)$.

The quantity $(\bar{R} - L)$ is the lower confidence limit (LCL) for a confidence level of $(1 - \alpha)$. Table 5 gives a short list of α against standardized L, derived from tables of the error function.

EXAMPLE 2 (*continued*). Find the 97.5% LCL for the reliability, $R_{L,97.5}$.

$$\alpha = 0.025$$

Hence,

$$L/(\sigma_{\hat{R}}/\sqrt{n}) = 1.96 \text{ (from Table 5)}$$

$$\sigma_{\hat{R}}/\sqrt{n} = 0.01775/\sqrt{20}$$

$$L = 1.96 \times 0.01775/\sqrt{20}$$

$$= 7.77 \times 10^{-3}$$

$$R_{L,97.5} = 0.975 - 7.77 \times 10^{-3} = 0.967$$

TABLE 3. RESULTS OF 20 LIFE TEST GROUPS OF 100 COMPONENTS EACH

20	100	4	96	0.960
Total	2000	50	1950	(0.975)

$m = 20$, $n = n_i = 100$, $\sum d_i = 50$, $\sum n_i = 2000$.

$$R = (\sum n_i - \sum d_i)/\sum n_i = \sum s_i/\sum n_i$$

Average: $\bar{R} = 19.500/20 = 0.9750$

$$\sigma_R^2 = (\sum f_j R_j^2/\sum f_j) - \bar{R}^2 = (19.0188/20) - (0.975)^2 = 0.950940 - 0.950625 = 0.000315.$$

Also $\sigma_R^2 = \sum f_j(\Delta R_j)^2/\sum f_j$ (where $\Delta R_j = R_j - \bar{R}_j$) and $\sigma_R = 0.017748$; hence

$$\sigma_R^2 = \tfrac{1}{20}(0.001225 + 0.001250 + 0.000675 + 0.000100 + 0.000100 + 0.000450 + 0.002500)$$

$= \frac{1}{20}(0.006300) = 0.000315$, or using relative weights, $w_j f_j = 1.00$, $\sigma_R^2 = w_j f_j(\Delta R_j)^2 = 0.000315$, given in last column above. Hence $\sigma_R = (0.000315)^{1/2} = 0.017748$.

Similarly, an upper confidence level can be obtained by postulating $\bar{R}$ to be to the left of R (see Fig. 14). Hence,

$$R_{U,97.5} = 0.975 + 7.77 \times 10^{-3} = 0.983$$

The above two quantities represent the one-sided LCL and UCL at the $(1 - \alpha)$ confidence level, respectively. Taken together, they constitute a two-sided confidence band at the $(1 - 2\alpha)$ confidence level. That is,

$$0.967 < R < 0.983 \text{ at } 95\% \text{ confidence level}$$

When the standard deviation of the population is unknown, it is no longer valid to use the above approach based on a normal distribution. Instead, the student-t distribution must be used. The t distribution is flatter than the normal and gives wider confidence limits for the same data.

Confidence limits are calculated from the following relation:

$$\text{UCL,LCL} = R \pm t_\alpha S/\sqrt{n}$$

where,

t_α = confidence coefficient for level $(1 - \alpha)$ (See Table 6),
S = sample standard deviation,
n = number of components in sample,
r = number of degrees of freedom $(= n - 1)$.

EXAMPLE 3. Same problem as example 1, but with no assumption on standard deviation. The number of components in the sample is 20; therefore the number of degrees of freedom is 19. From Table 6, $t_{0.025} = 2.09$.

$$\text{UCL} = 0.975 + 2.09 \times 0.01775/\sqrt{20} = 0.9833$$

$$\text{LCL} = 0.975 - 2.09 \times 0.01775/\sqrt{20} = 0.9667$$

There is not much difference between this result and the previous one. This is because the sample size is relatively large. In general, the t distribution need only be used if the sample is smaller than 30.

In calculating confidence limits for other quantities, such as the MTBF, neither the normal nor t distribution is valid because the distribution of the random variable differs too much from a normal distribution (exponential in the case of MTBF). In the case of the exponential distribution, the appropriate relation for determining confidence limits is the chi-squared distribution.

When it is desired to specify that the true mean time between failures must exceed a given minimum value with a confidence level of $(1 - \alpha)$, the procedure for a one-sided confidence limit is applied. This provides a tail area α and means there is a probability α that the m value actually observed by test will be smaller than the specified minimum and a probability of $1 - \alpha$ that it will be larger. Reference 15 denotes the one-sided confidence limit by the notation C_L to distinguish it from the two-sided lower limit L. Its value is given by

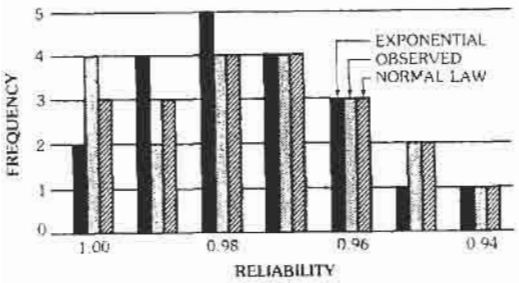
$$C_L = (2r/\chi^2_{\alpha;2r})\hat{m} = 2T/\chi^2_{\alpha;2r}$$

where,

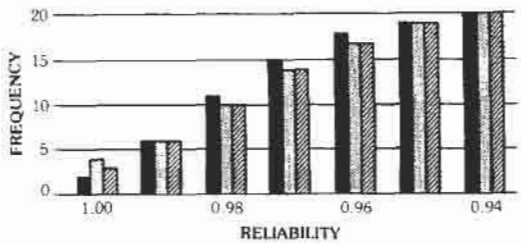
$\chi^2_{\alpha;2r}$ is the value of χ^2 at the $(1 - \alpha)$ confidence level for $2r$ degrees of freedom.
tests are continued until the rth failure occurs with $r = 1, 2, \cdots, d$,
T = accumulated test time = Σt_i,
m = T/r = an estimate of the mean time between failures,
$1 - \alpha$ = confidence level prescribed.

Note that in this case $2r$ = degrees of freedom (d.f.).

However, a test can also be terminated at some preselected test time without a failure occurring exactly at that time. For such a case, Reference 16 has shown that for the accumulated hours of operating time $T = \Sigma t_i$, then



(A) Individual failures.



(B) Cumulated failures.

Fig. 12. Observed reliability distributions of individual and cumulated failures for 20 sets with $n = 100$ on test for 1000 hours each. The corresponding theoretical frequencies for exponential and normal law are also shown. Failure rate $r = 0.025$ and $rn = 2.5$ for exponential; $\bar{R} = 0.975$ and $\sigma_R = 0.01775$ for normal law.

$$m \geq 2T/\chi^2_{\alpha;2r+2}$$

where d.f. $= 2r + 2$ and the case where $r = 0$ is covered. For $r = 0$, then

$$C_L = 2T/\chi^2_{\alpha;2}$$

In the percent survival method, the accumulated operating time T is not measured, and only the straight

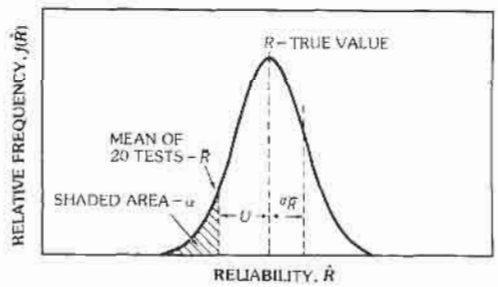
test duration time t_d is known, at which time r failures of n units on test are counted. In this method, confusion may exist between chance failures and failures due to actual wearout. The time to wearout must be known, and it is necessary to design and select parts from manufacturers that can be made so that their respective wearout time is many hours past the time of the mission. Again referring to both Reference 15 and to Epstein, for a one-sided confidence level of $1 - \alpha$, the lower-limit estimated reliability for t_d hours is

$$\hat{R}(t_d) = \frac{1}{1 + [(r + 1)/(n - r)]F_{\alpha;2r+2,2n-2r}}$$

where F is the upper α percentage point of the Fisher distribution (termed the F distribution) with the two corresponding degrees of freedom, $2r + 2$ and $2n - 2r$. For this estimate of reliability there is a probability of $1 - \alpha$ that the true reliability for t_d hours is equal to or larger than $R(t_d)$. It must be noted that this reliability estimate is nonparametric and is valid for the exponential as well as the nonexponential case.

A general mathematical approach is used in many cases to determine the confidence levels for either one-sided or two-sided distributions for various density functions. Confidence levels and reliability values are



$Z_U = U/\sigma_{\bar{R}} = U/(\sigma_{\hat{R}}/\sqrt{n})$

Fig. 14. Calculation of upper confidence limit when standard deviation of sample is known.

TABLE 6. SHORT LIST OF STUDENT-t DISTRIBUTION

r	$t_{0.1}$	$t_{0.05}$	$t_{0.025}$	$t_{0.01}$
1	3.078	6.314	12.706	31.82

29	1.311	1.699	2.045	2.462
∞	1.282	1.645	1.96	2.326

related by the two following general relations, where P_b = degree of belief, equivalent to the confidence level. One relation covers continuous distributions and makes use of the area under the density function secured by integration, while the second relation covers summations for integral values. These relations are

$$P_b = \int_0^{x^*} f(x)dx \Big/ \int_0^{x=\infty} f(x)dx$$

$$P_b = \sum_0^{x^*} F(x) / \sum_0^{x=\infty} F(x)$$

For the exponential density function, use of these relations gives

$$P_b = \int_0^{t^*} \lambda \exp(-\lambda t)dt \Big/ \int_0^{\infty} \lambda \exp(-\lambda t)dt$$

$$= -\exp(-\lambda t)_0^{t^*} / -\exp(-\lambda t)_0^{\infty}$$

$$= [-\exp(-\lambda t^*) + 1]/(0 + 1)$$

$$= 1 - \exp(-\lambda t^*)$$

The reliability $R(t)$ for time t for P_b (the one-sided confidence level) is derived from the term λt^*, where no failures have been observed in time $T = \Sigma t_i$. From an exponential table determine $\lambda t^* = a$, corresponding to $1 - P_b$. Then $\lambda = a/t^* = a/T$, since t^* corresponds to the total time required for the test. The final reliability value is determined from

$$R(t) = \exp(-\lambda t) = \exp(-at/T)$$

If a test is terminated when the rth failure has occurred, the ratio $2r(\hat{m}/m)$ has a chi-square distribution with $2r$ degrees of freedom. The two-sided confidence interval at a confidence level of $(1 - \alpha)$ is

$$\hat{m}(2r/\chi^2_{\alpha/2;2r}) \le m \le \hat{m}(2r/\chi^2_{1-\alpha/2;2r})$$

Here $\hat{m}$ represents the estimate of m derived from the samples tested and is the MTBF. The lower limit L is given by

$$L = (2r/\chi^2_{\alpha/2;2r})\hat{m} = 2T/\chi^2_{\alpha/2;2r}$$

while the upper confidence limit is given by

$$U = (2r/\chi^2_{1-\alpha/2;2r})\hat{m} = 2T/\chi^2_{1-\alpha/2;2r}$$

Herein $\hat{m} = T/r$ and can be derived from either a replacement or a nonreplacement test, while $T = \sum t_i$, the sum of the operating times accumulated by all the components during the test. When the test is terminated at time t_d without a failure occurring exactly at that time, then the degrees of freedom for the lower limit are changed from $2r$ to $2r + 2$. The upper and lower limits are given by

$$2T/\chi^2_{\alpha/2;2r+2} \le m \le 2T/\chi^2_{1-\alpha/2;2r}$$

From these limits giving lower and upper limits, L and U, in terms of mean time before failure, for any mission time t, then lower and upper limiting values for the reliability $R(t)$ may be readily computed from

$$L::R_L:R_L(t) = \exp(-t/L)$$

$$U::R_U:R_U(t) = \exp(-t/U)$$

When the Gaussian (normal law) distribution applies or is used as a means of determining upper and lower limits for either m or $R(t)$, where $\bar{m}$, σ_m and $\bar{R}$, σ_R are known, either symmetric or nonsymmetric confidence limits may be determined from

$$L:\bar{m} - z_\alpha\sigma_m;\ \bar{R} - z_\alpha\sigma_R$$

$$U:\bar{m} + z_\beta\sigma_m;\ \bar{R} + z_\beta\sigma_R$$

where $\alpha + \beta = \gamma$ = probability for the specified confidence band.

As an aid to the calculation of confidence bands under certain stated conditions, several of the military specifications listed in Table 7 allow an easy calculation of these limits. One specification to note is MIL-R-22973.

EXAMPLE 4. Estimation of reliability for times different from test time.

In most cases, reliability values are associated with life usage or with the time of storage. A mission may require t hours to be accomplished. For example, it may require 10 hours to drive an automobile from Los Angeles to San Francisco, a distance of approximately 420 miles. What is $R(10)$, the reliability of accomplishing this mission in 10 hours at any time? In a prior example, $p = 2.5\%$ where it was assumed that each unit was tested 1000 hours. The failure rate then may be expressed as 2.5%/1000 hours. If the mission time is 10 hours, the reliability $R(t)$, assumed to be based on the exponential, is determined as follows. For $t = 10$ hours, $\nu = 2.5\%/1000$ hours $= 0.000025$/hr, and for this case

$$R(10) = \exp[-0.000025(10)]$$

$$= \exp(-0.00025) = 0.99975$$

This value of reliability is based on the expected value. For the exponential, the variance is equal to the expected value. Hence, since for this 10-hour mission $t = 0.00025$, $\sigma_t = (0.00025)^{1/2} = 0.01581$. For a 90% confidence level using the proper multiplying factor based on the normal law

$$t_{0.90} = 0.00025 + 1.282(0.01581) = 0.00025 + 0.02026842 = 0.02051842$$

The corresponding reliability for $t = 10$ hours is $R_{0.90}(t = 10) = \exp(-0.02052)$, $R(10)_{0.90} = 0.97968$. For a 95% confidence level based on the normal law:

$$(\lambda t)_{0.95} = 0.00025 + 1.645(0.01581)$$

$$0.00025 + 0.0260075 = 0.0262575$$

For this expected value of λt with $t = 10$ hours, $R(10) = \exp(-0.02626) = 0.97408$. For a 99% confidence level based on the normal law:

$$(\lambda t)_{0.99} = 0.00025 + 2.326(0.01581)$$

$$= 0.00025 + 0.03677406 = 0.03702406$$

Hence $R(t = 10)_{0.99} = \exp(-0.03702) = 0.96366$. For the six confidence levels often used, the reliability values for a one-tailed confidence level may be obtained from Table 8.

According to the data in Table 3, there existed only one set of 100 units = n out of 10 000 that had a reliability observed of 0.94. Associated with this value is a confidence level of (10 000 − 100)/10 000 = 9900/10 000 = 0.99 (Table 9). This reliability value is determined for an assumed operating period of 1000

TABLE 8. RELIABILITY VALUES FOR A MISSION OF t = 10 HOURS FOR λ = 2.5%/1000 HOURS FOR 6 ONE-TAILED CONFIDENCE LEVELS FOR EXPONENTIAL: $R(\lambda t) = R[\lambda t + z(\lambda t)^{1/2}]$, z GIVEN IN NORMAL LAW (GAUSSIAN) TABLES FOR P_z TABULATED FOR CONFIDENCE LEVEL

Confidence Level	Normal Law z Values	Upper Limit for $(\lambda t)_z = 0.00025 + z(0.00025)^{1/2}$	$R(\lambda t)_z = \exp[-(\lambda t)_z]$
0.90	1.282	0.02052	0.97968
0.95	1.645	0.02626	0.97408
0.96	1.751	0.02794	0.97245
0.97	1.881	0.02999	0.97045
0.98	2.054	0.03272	0.96780
0.99	2.326	0.03702	0.96366

hours. Hence this gives $R(1000) = 0.94$ when the confidence level $P_C = 0.99$. Hence the value of λ is thus computed

$$R(1000) = 0.94 = \exp[-\lambda(1000)] = \exp(-0.0619)$$

Then $1000\lambda = 0.0619$, and $\lambda = 6.19\%/1000$ hours. For $t = 10$ hours, then

$$R(10) = \exp(-\lambda t) = \exp[-0.0619(10)/1000]$$

$$= \exp(-0.000619) = 0.99938$$

Thus the actual data provide more optimistic estimates of the reliability based on field test results. Since the distribution as graphed appears to be almost rectangular in Fig. 12, the assumption of normality is pessimistic.

In these life tests, each failure must be carefully analyzed to determine whether it is a *chance* failure or a *wearout* failure. These results must be fed back to the design engineers to make certain that corrective measures for improving the life characteristics are taken and established as standard procedures.

Fitting a Distribution Using Chi-Squared Test

In a sample of n observed values of a random variable, $n_1, n_2, \ldots, n_k$ frequencies are observed in each of k intervals (Fig. 12). An assumed distribution predicts $e_1, e_2, \ldots, e_k$ for the same intervals. The goodness-of-fit is tested by the criterion

$$\sum(n_i - e_i)^2/e_i < \chi^2_{1-\alpha;r}$$

In this expression, $\chi^2_{1-\alpha;r}$ is the value of the χ^2 distribution at the cumulative probability level $(1 - \alpha)$ and with degrees of freedom $r = k - 1$ if the mean is known independently and $r = k - 2$ if the sample mean is used.

EXAMPLE 5. Using data from example 1, test the goodness of fit for normal and Poisson distributions.

From Table 4 for $k = 7$, obtain the data in Table 10. For the normal distribution,

$$\chi^2 = (1/3 + 1/3 + 0 + 0 + 0 + 0 + 0) = 0.667$$

For $\alpha = 0.05$ significance level and $r = k - 2 = 5$, standard tables of χ^2, $\chi^2_{0.95;5} = 11.1$, which is greater than χ^2 for the normal distribution. Hence the normal distribution is a valid model at the 5% level.

For the Poisson distribution,

$$\chi^2 = (4/2 + 4/4 + 1/5 + 0 + 0 + 1/1 + 0) = 4.2$$

Hence, the Poisson distribution is also valid at the 5% significance level, but it is a poorer fit to the data than the normal distribution.

TABLE 9. RELIABILITIES ASSOCIATED WITH ONE-TAILED CONFIDENCE LEVELS

Confidence Level	Multiplying Factor for Normal Law, z	n = 10 000 units: Observed Reliability	Normal Law Theoretical Reliability
0.90	1.282	95.07%	95.69%
0.95	1.645	94.50%	95.18%
0.96	1.751	94.38%	95.03%
0.97	1.881	94.25%	94.85%
0.98	2.054	94.12%	94.60%
0.99	2.326	94.00%	94.22%

5	3	3	3
6	2	2	1
7	1	1	1

Probability Paper

An alternative method of fitting a distribution is to use probability plotting paper. This procedure attempts to produce the best fit to the cumulative distribution rather than the probability density function. A number of results obtained in a life test are tabulated in Table 11. The cumulative failure distribution, $F(t)$, can be approximated by

$$F(t_i) = i/n$$

where i is the number of failures at time t_i.

The principle in using probability paper is to transform the axes of the cumulative plot to give a straight line if the data conform with the assumed theoretical distribution. For instance, an exponential distribution gives a straight line if log $[F(t)]$ is plotted against t, with a slope equal to the hazard rate, λ. In other cases, such as the normal distribution, special plotting papers must be prepared. These can be obtained for the more common distributions from suppliers of drawing materials.

Weibull Analysis

By far the most commonly used plotting paper in reliability studies is Weibull paper (see Fig. 15). A

TABLE 11. RESULTS OF COMPONENT LIFE TEST ON 15 UNITS

Test Number	Time to Failure (Hours)
1	8.35×10^4
2	2.24×10^4
3	4.84×10^4
4	0.33×10^4
5	9.90×10^4
6	8.85×10^4
7	0.83×10^4
8	10.60×10^4
9	6.55×10^4
10	1.80×10^4
11	4.30×10^4
12	8.45×10^4
13	9.27×10^4
14	3.15×10^4
15	6.02×10^4

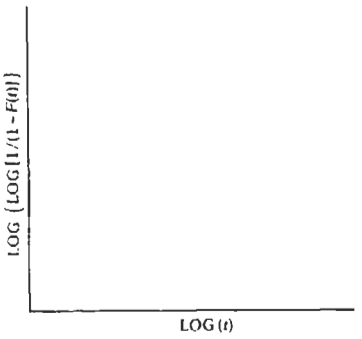

Fig. 15. Weibull plotting transformation.

Weibull distribution has the attribute that it can describe distributions with decreasing, constant, or increasing hazard rate, simply by appropriate choice of the shape parameter, β. Furthermore, the slope of the Weibull plot gives β directly.

EXAMPLE 6. Use of Weibull paper to analyze the data in Table 11. It is first necessary to place the results in increasing rank order m. Next the cumulative failure distribution $F(t)$ is approximated by the median rank

$$\hat{F}_n(t) = m/(n + 1) \fallingdotseq F(t)$$

This is slightly different from the approximation to $F(t)$ quoted earlier, i.e., $F(t_i) = m/n$. The difference is that the median rank is a minimally biased estimate of $F(t)$ and avoids some plotting problems near $m = 1$ and $m = n$ as well. Similarly, the reliability $R(t)$ can be estimated by

$$\hat{R}_n(t) = (n - m)/(n + 1)$$

Table 12 shows the ordered list with the median ranks calculated. The results are plotted in Fig. 16. Note the following:

1. Fitting a distribution using probability paper requires relatively few points compared with the number needed to produce a histogram to approximate a probability density function. As few as five or six can be used to fit a cumulative distribution, whereas more than 20 are needed for a histogram.
2. The data in the Weibull plot clearly indicate three distinct zones, suggesting that three modes of failure are occurring.
3. From the estimates of the shape parameter, it can be deduced that the first two or three failures are burn-in ($\beta = 0.6$), the last five are clearly wearout ($\beta = 3.6$, which is incidentally very close to a normal distribution in shape), while the remainder are random failures with external cause ($\beta = 1.08$, approximately 1).

TABLE 12. CALCULATION OF MEDIAN RANKS FOR WEIBULL ANALYSIS OF DATA IN TABLE 11

Rank Order, m	Median Rank, $m/(n+1)$	Time to Failure, (10^4 hr)
1	0.0625	0.33
2	0.125	0.83
3	0.1875	1.80
4	0.25	2.24
5	0.3125	3.15
6	0.375	4.30
7	0.4375	4.84
8	0.50	6.02
9	0.5625	6.55
10	0.625	8.35
11	0.6875	8.45
12	0.75	8.85
13	0.8125	9.27
14	0.875	9.90
15	0.9375	10.60

The Weibull plot is therefore not just a means of fitting a distribution to data. It is also a useful diagnostic tool, indicating the number and nature of failure modes present.

Distribution-Free Tests of Goodness of Fit

As with all data-fitting procedures, probability-paper plots provide only an estimate of the true distribution. Confidence limits should be placed on any parameter estimates made. This is more difficult to do for several parameters simultaneously than for a single variable such as failure rate. Further details of this type of analysis are to be found in any standard text on statistics, e.g., Reference 17. One technique that will be illustrated here is a check to find out whether a set of data belongs to an already known and characterized population. This test is known as the Smirnov-Kolmogorov test. The procedure is illustrated in Fig. 6, which shows the actual $F(t)$ of the population and a median-rank plot for a typical sample of data. It is required to test whether the data is a member of the population. The test requires that the maximum deviation between $F(t)$ and $F_n(t)$, D_n, must be less than some specified value, D_n^α which depends on the number of data points, n, and the desired significance level, $(1-\alpha)$. The value for D_n^α is found in tables, e.g., in Reference 17. A short version of D_n^α values is given in Table 13.

EXAMPLE 7. Given a test $n = 40$, $D_n = 0.2$ (see Fig. 6), determine the appropriateness of the theoretical model at the 10% significance level.

From Table 13, $D_{40}^{0.1} = 0.19 < D_n$. Model rejected at 10% level.

NOTE. For more information on estimation and confidence limits, consult the references at the end of this chapter. Chapters 44 and 47 give additional statistical and mathematical information.

Bayesian Statistics

Previous discussion has been confined to the classical approach to estimation, which implicitly assumes no information other than the immediately acquired test data. Since 1964, increased interest has been expressed in the so-called Bayesian approach.

Bayes' theorem is an early result in probability theory which states that, if the occurrences of two events A and B are dependent, then

$$\Pr(A \text{ and } B) = \Pr(A/B) \cdot \Pr(B) = \Pr(B/A) \cdot \Pr(A)$$

This can be re-expressed as

$$\Pr(A/B) = \Pr(A) \cdot \Pr(B/A)/\Pr(B)$$

This equation can be used to infer a result using both test data and previous experience. For instance,

$A = \lambda$, the actual (unknown) failure rate
$B = \hat{\lambda}$, the observed failure rate in a test

The question is posed, what is the actual failure rate given the observed rate in the test?

The focal point of the method is the so-called "prior" distribution, $\Pr(A)$. In classical statistics, A

TABLE 13. SHORT LIST OF CRITICAL VALUES OF D_n FOR THE SMIRNOV-KOLMOGOROV TEST

n	$D_n^{0.1}$	$D_n^{0.05}$	$D_n^{0.01}$
5	0.51	0.56	0.67
10	0.37	0.41	0.49
20	0.26	0.29	0.36
30	0.22	0.24	0.29
40	0.19	0.21	0.25
50 and more	$1.22/\sqrt{n}$	$1.36/\sqrt{n}$	$1.63/\sqrt{n}$

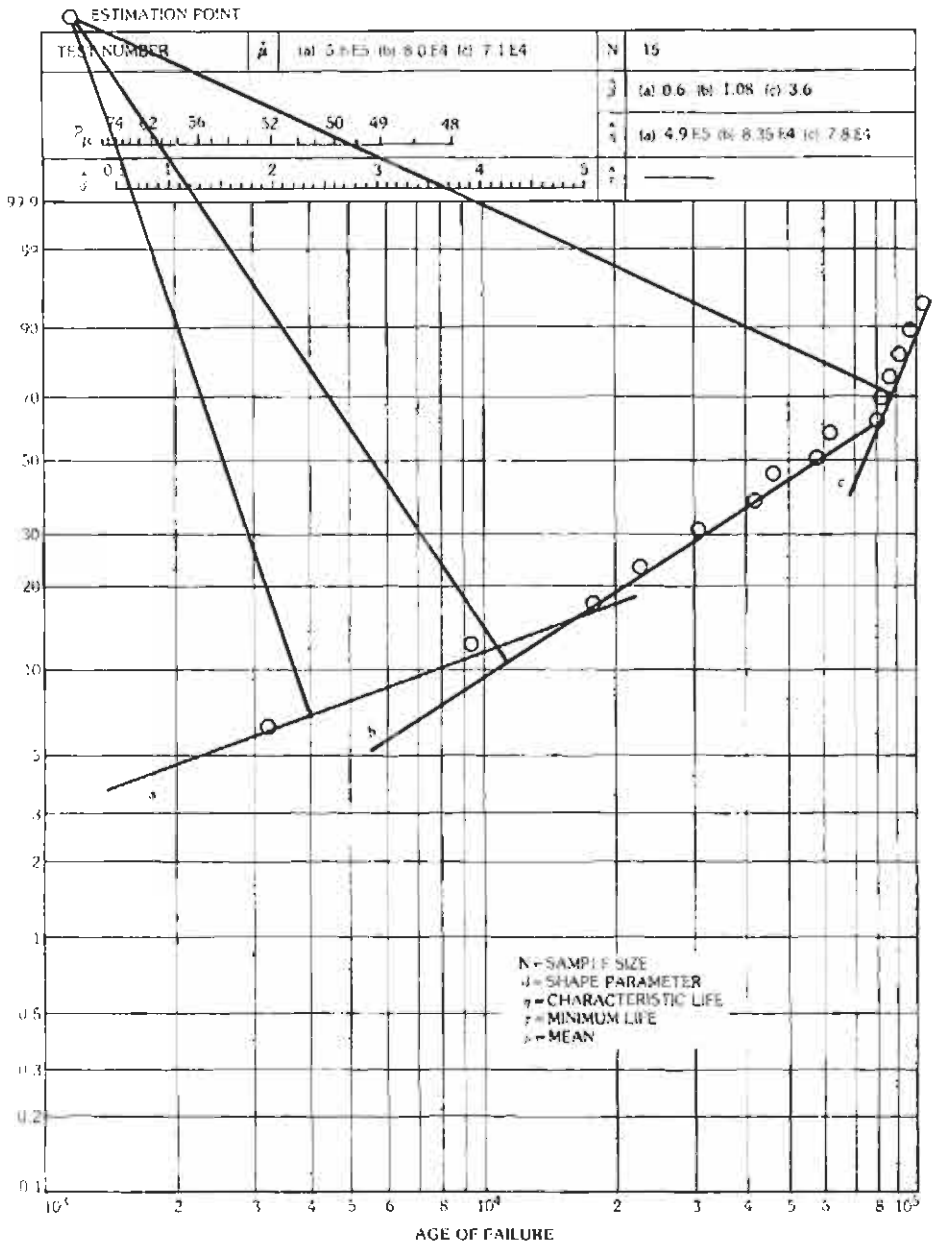

Fig. 16. Standardized Weibull paper with example.

would be considered a constant, but unknown. In Bayesian statistics, A is considered to be a random variable, and use is made of previous experience, or even subjective judgement, to choose an appropriate distribution for $\Pr(A)$. The Bayesian approach, therefore, has some appeal in engineering applications, where reasonable estimations based on previous experience are not only common but absolutely necessary in some cases, if a decision is to be made at all. On the other hand, there is some controversy over the validity of the reasoning behind the Bayesian approach that should be explored before it is used, although most of the concern appears to be over points that do not affect the practical use of the approach. A readable introduction to Bayesian statistics is given in Reference 17. Applications to problems in reliability are given in

References 4 and 15. Generally, Bayesian estimates tend to be more optimistic than those derived from classical statistical methods.

CODES AND STANDARDS

Practically all military contracts contain clauses under quality assurance requiring reliability programs. This is becoming increasingly true in other fields as well, particularly civil aviation, nuclear power, and industries where equipment failure is potentially hazardous. Many contracts include provisions for a preliminary design review and also a critical design review before qualification tests. In addition, some contracts require a reliability demonstration test. Use is made in this latter case of all the engineering data that might be obtained in the qualification tests, if they precede the reliability demonstration test.

Table 7 presents a family tree of US Government documents establishing and supporting reliability requirements. New specifications are added frequently to build up the reliability factors and requirements. One area (not listed in the table) that is expanding steadily is special parts reliability specifications such as the MIL-R-38000 series. These specifications cover the acceptance and qualification testing of high-reliability parts.

THE USE OF COMPUTERS IN RELIABILITY

Most organizations today have extensive computing facilities. Invariably, such a facility will include software packages for performing statistical calculations. Even the most modest of desk-top computers has a package of this type, or one can be obtained as an option. The majority of standard calculations, such as curve fitting, evaluation of confidence limits, etc., can be done as a routine exercise, and cumbersome, error-prone tasks like referring to sets of tables for values of chi-square and the t distribution are now obsolete, except for educational demonstration.

Of particular interest to reliability analysts is an ongoing series in *Quality Progress*, the journal of the American Society for Quality Control, which offers computer programs for use on small desk-top models and hand-held programmable calculators, covering a range of reliability-related topics.

Several large computer codes are now generally available for various aspects of reliability analysis of complex systems. These are reviewed in Reference 4. Many of the codes described in Reference 4 are available from the authors of the reference. Some examples of the range of capabilities are

KITT — Fault-tree analysis of complex systems (several versions).

BACFIRE — Search routine for common-mode failures.

FAMULS — Calculates cut sets for systems with multiple control loops given signal flow graph representation of system.

SCHE — Converts reliability block diagrams (see Fig. 10) into fault trees.

HEUR — Reliability optimization under constraints of cost, weight, etc.

46 Cellular Telecommunications Systems

William C. Y. Lee

GENERAL DESCRIPTION

History

The cellular telecommunications system was developed by AT&T Bell Laboratories. It was called the Advanced Mobile Phone Service (AMPS) System. The first AMPS system was deployed in Japan with a slight change in 1979. In 1983, the first cellular telecommunications system was operated in Chicago. Each city has two cellular system operators licensed by the FCC for achieving a duopoly competition policy. In 1984, one cellular system operator in each of the first thirty largest cities was in operation.

Since the cellular industry was growing very fast, the system capacity became a challenge and needed to be resolved. The answer was to go digital. In 1989, the first cellular digital standard (IS-54), called North American TDMA (Time Division Multiple Access), was issued. In 1991, the second digital cellular digital standard (IS-95), called CDMA (Code Division Multiple Access), was issued. In 1994, the standard IS-54 had a major modification and was renamed as IS-136. The capacity of IS-95 can be ten times that of AMPS, and the IS-136 is three times that of the AMPS. Both systems were commercialized in 1995 and both are mainly for voice.

In 1998, the Internet industry started to grow rapidly and transmitted data became important for wireless communication. The ITU (International Telecommunication Union) then issued an IMT-2000 standard also called the third-generation (3G) standard. There were three modes: WCDMA (Direct Sequence (DS) CDMA) developed by a standard group named 3GPP (Third Generation Partnership Project); CDMA 2000 (or multi-carrier (MC) CDMA developed by 3GPP2); and TDD (Time Division Duplexing). In TDD, there were UTRA-TDD developed by European community, and TD-SCDMA developed by Chinese standard. TDD system is used for a small-area system such as on a campus or in a shopping mall. There is a new large-area TDD system called LAS-TDD using a smart code technology. It will be described later in this chapter. Both CDMA 2000 (its 1X version, i.e., 1.25 MHz bandwidth), and WCDMA will be commercialized in 2003. The maximum data rate can be 2Mbps.

In the future, wireless communications and the Internet will be merged to become a wireless-Internet industry carrying both voice and data services.

Allocated Frequency Spectrum

In 1983, the FCC allocated a spectrum of 40 MHz to analog cellular systems. In 1986, another 10 MHz of spectrum was added. The total spectrum is 50 MHz. The same 50 MHz spectrum is operated in every city. Since there are two operators in each city, the 50 MHz spectrum is divided into two 25 MHz bands denoted Band A and Band B. Each operator may operate only in its own band, either A or B, as licensed by the FCC.

In 1996, the PCS (personal communications service) spectrum was auctioned. There were six bands: A, B, C, D, E, F as shown in Table 1. Each market can have all of the six bands in operation. Each band can choose its own standard system among three: CDMA, TDMA, or DCS 1900 (a GSM version). A non-standard system called iDEN, invented by Motorola and operated by Nextel, also serves to the public at its SMR spectrum. The IMT-2000 system allocated spectrum issued by ITU is also shown in Table 1. The U.S. PCS bands for base transmit are overlayed on the IMT-2000 band for mobile transmit also shown in Table 1. Therefore, a new IMT-2000 spectrum is needed.

A Duplexed System

FDD System: A cellular system is a frequency division duplexed (FDD) system. In an analog system, a 25 MHz spectrum, 12.5 MHz is for base transmit and 12.5 MHz is for mobile transmit. In the North American system there are 832 frequency channels. Since this is a duplexed system, a frequency channel consists of a pair of two frequencies, forward link and reverse link. The forward link is from the cell to the mobile unit, and the reverse link is from the mobile unit to the cell site. The allocation of Band A and Band B is shown in Chart 1. In each band, Band A and Band B, there are 416 channels. Among them, 21 channels are setup channels (sometimes called control channels). The remaining 395 channels in each band are voice channels. Neither Band A nor Band B has a continuous spectrum, as shown in Chart 1.

In 1991, a European standard digital system called GSM was deployed in Germany. In 1994, the North American digital TDMA system was deployed in the United States and in 1995, the CDMA was deployed in Hong Kong and in the United States. The three systems' descriptions are shown in the digital cellular systems section. The two modes of third-generation (3G) systems, DS and MC, are also FDD-CDMA systems that we will mention later.

TDD system: The Time Division Duplex systems in 3G such as UTRA-TDD and TD-SCDMA are using a single frequency band for both transmitting and receiving. The current 3G TDD systems are developed for campus or small area communications. There is a new TDD system called the LAS-CDMA system, which uses a smart code, called LAS code, to isolate interference. The LAS-CDMA system is a large area synchronous (LAS) system. With its efficient spectrum by using smart code, the LAS-CDMA system could be a candidate for the future high capacity and high-speed data system. The system specification will be mentioned later.

CELLULAR SYSTEM ELEMENTS

The cellular system consists of a switch, a number of cell sites, a data-link network, enhancers and converters, and mobile subscribers' units. The general view of cellular telecommunications systems is shown in Fig. 1.

Cell Site (or Base Station)

The cell site consists of a cell-site antenna with a height of about 30 m (100 ft) to 45 m (150 ft), a controller, and a number of transceivers. The controller is used to handle the call process between the switch and the mobile unit or handset via a setup channel. For an analog system, each cell site is assigned a different setup channel from the 21 setup channels. Also, each cell site is assigned one of three SATs (Supervisory Audio Tones). The three SATs are 5970 Hz, 6000 Hz, and 6030 Hz. The cell-site transceivers modulate the assigned SATs on all the forward voice channels from each cell site. Also, the cell-site transceivers are able to detect the SATs on the reverse voice channels sent back by the mobile unit. The choice of a proper cell site is dependent upon the planned signal coverage area, which is determined by the ERP (Effective Radiated Power), the antenna patterns, and the antenna height. In addition, a permit from the local unit of government is required.

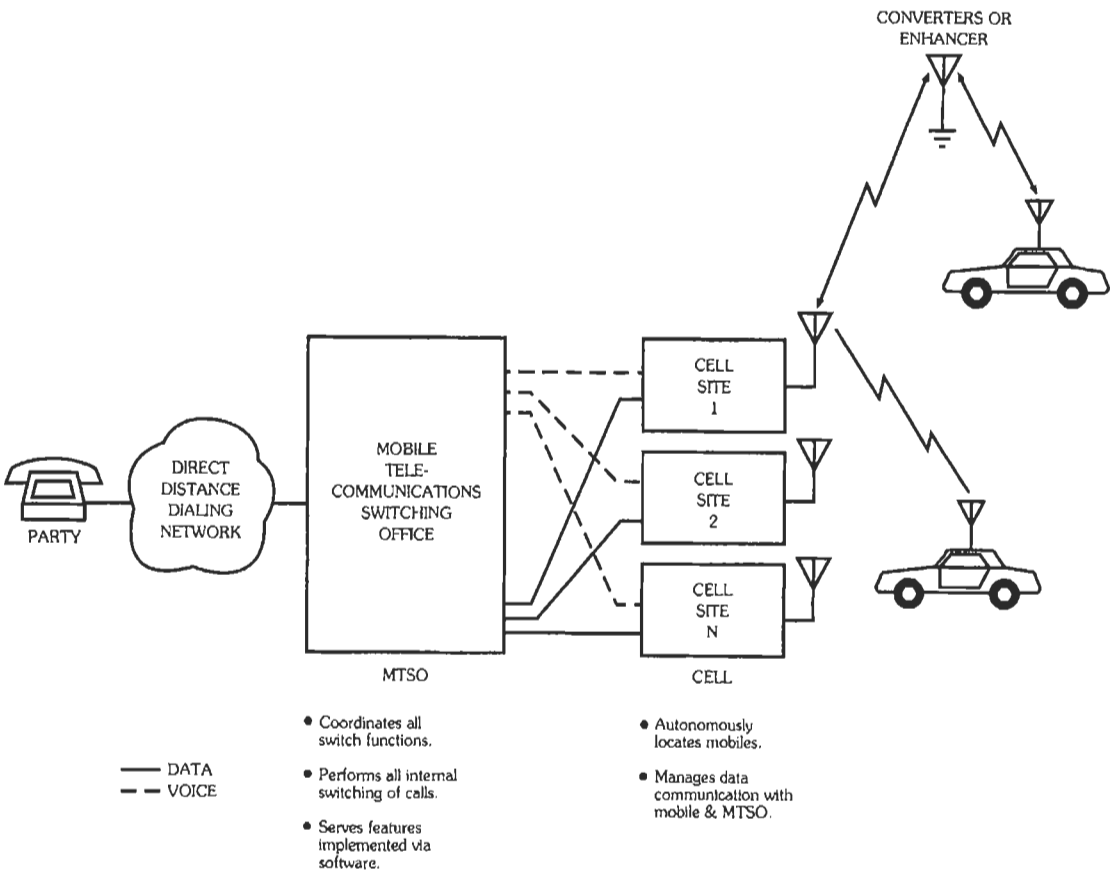

Fig. 1. A general view of cellular telecommunications systems.

In digital systems,

TDMA Systems (GSM or North American TDMA)—In these systems, there is a frequency correction channel (FCCH), a synch channel (SCH), a broadcast control channel (BCCH), a paging and access grant channel (PAGCH), a call broadcast channel (CBCH), and a traffic channel (TCH).

CDMA System—In this system, there is a pilot channel, a synch channel, a paging channel, and a traffic channel. In the pilot channel, an unmodulated, direct-sequence (DS) signal is transmitted continuously by each CDMA BS.

3G Systems—3G systems are wideband CDMA systems, which have 5MHz bandwidth. The European and Japanese standards bodies have developed WCDMA (DS) and the North American standards body developed CDMA 2000 (MC). These two are FDD systems. The TDD mode has two versions: TD-SCDMA, developed by China, and UTRA-TDD, developed by Europe. The differences among these systems are shown in Table 2.

The Switch and BSC

In analog systems, the Mobile Telephone Switching Office (MTSO) is a special-purpose switch that connects the call between mobile units and between the mobile unit and the landline telephone via the PSTN (Public Service Telephone Network). The function of the MTSO is to assign the voice channel to each cell, perform the handoffs (this operation will be described later) and the vertical service features, and monitor the calling information for billing.

In digital systems, the base station controller (BSC) was developed to handle all the control functions of the system, including handoffs. The transcoder and mobility management reside in the BSC. Therefore, in the advanced network, the switch and control are separated.

Data-Link Network

In analog systems, the data-link network carries the data between the cell sites and the MTSO. Each data link can carry multiple-channel data (10 kb/s data

transmitted per channel). The data link can also carry PCM voice (64 kb/s per voice channel). There are generally three means of implementing the data links: 1) use TI-carrier wire lines; 2) use microwave radio links; and 3) use optical fibers.

In digital systems, the functional architecture and principal interfaces are shown in Fig. 2. The HLR (home location register) is a permanent database that contains subscriber information and is related to the subscriber's current location. VLR (visitor location register) is linking to one or more MSC's temporarily storing subscription data. OAM (operation, administration, and maintenance) is collecting the operational

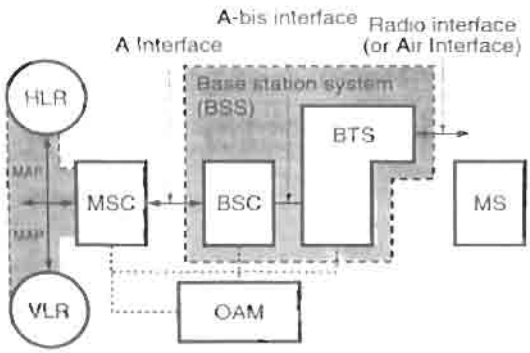

Fig. 2. Functional architecture and principal interfaces.

data for troubleshooting and statistical analysis for performance. The architecture shown in Fig. 2 is mainly for voice communication using circuit switches which provide dedicated lines. The general packet radio system (GPRS) is called 2.5G and is used for packet transmission. Every packet has its sending address for delivery. The packet switch would not hold the line until the call termination. The packet transmission link is called the virtue connection or the connectionless transmission.

In 3G systems, there are two lagacy networks, GSM MAP and ANSI 4, shown in Fig. 3. In order to have network-to-network interface (NNI) between two networks, the standards bodies (3GPP and 3GPP2) are developing new standards for hooks and extensions, as shown in Fig 3. The hooks provide the specified functionality. The extensions provide the additional functions needed to meet the specified requirements. Also, in 3G system networks, two industry alliances were formed, 3GIP and MWiF (mobile wireless IP forum). These two forums are developing the wireless Internet network. The IP (Internet protocol) network can be the future 3G network, which is migrated from today's lagacy network.

Enhancers and Converters

The enhancer is a repeater with amplification. It operates at the same cellular bandwidth. The signal range can be extended by the enhancer.

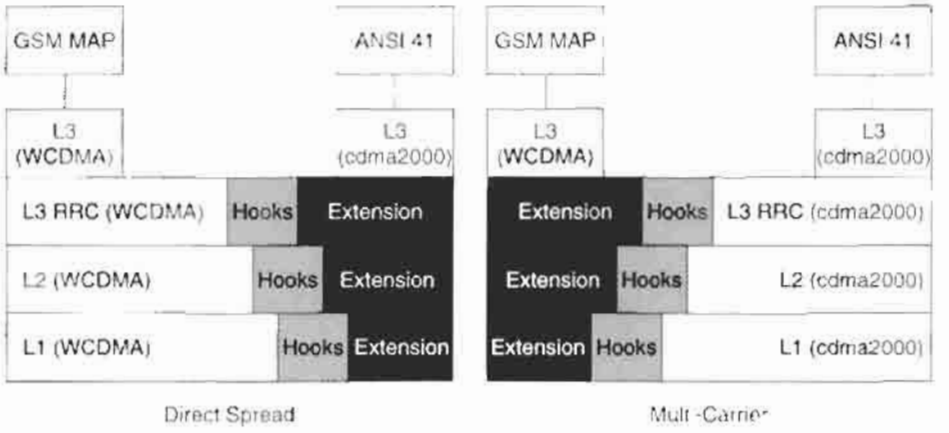

Fig. 3. Hooks and extensions.

If the converter changes the cellular frequency to a microwave frequency, it is called a microwave converter. If it converts the cellular frequency to an optical frequency, it is called an optical converter. If it down-converts to baseband frequency, it is called a baseband converter. The converted signal can be delivered to any destination without interference, then converted back to the cellular frequency at the destination.

Mobile Subscribers' Units

The mobile subscribers' units consist of three parts: the transceiver, the logic unit (handles signal processes), and the control unit (indicators). The mobile subscribers' units can be classified into two kinds, mobile units and handsets. Mobile units are mounted in vehicles; handsets are carried by the users.

OPERATION OF CELLULAR SYSTEMS

The cellular systems does not require the user to touch any adjustment buttons during a call. The operation can be described in seven different stages, plus a handoff procedure.

Mobile-Unit Initialization

In analog systems, when the mobile unit is turned on, the receiver scans the 21 setup channels, selects the strongest, and locks on for a certain time. Since each cell site is assigned a different setup channel, locking onto the strongest one means choosing the nearest cell site. This scheme is called a self-location scheme and is used at the idle stage. Every 60 seconds, the self-location procedure is repeated. This repetition is necessary due to the motion of the vehicle. A new nearest cell site can be determined after 60 seconds.

In digital systems,

For TDMA Systems—The mobile station (MS) guides the FCCH burst, then looks for an SCH burst on the same frequency to achieve synchronization. The MS then receives BCCH on several time slots and selects a proper cell, remaining for a period in the idle mode. The random-access channel (RACH) is the only common uplink channel that the MS chooses to access the calls.

For CDMA Systems—This allows the MS to acquire the timing of the forward CDMA channel, provides a phase reference for coherent demodulation, and provides a means for signal strength comparisons between base stations for determining when to hand off.

Mobile-Originated Call

In analog systems, when the user wants to make a call, a number is placed into an originating register in the mobile unit. When the "send" button is pushed, a request for service is sent on a preselected setup channel. The receiver has to check whether the setup channel is idle or not by examining the "busy" or "idle" bit in the forward setup channel. The cell site receives the request and in turn sends a request to the MTSO via a data link. The MTSO selects an appropriate voice channel from a group of allocated voice channels and notifies the cell site; then the cell site informs the mobile unit. At the same time, the MTSO also connects the wire-line telephone party through the telephone company central office.

In digital systems, the base station receives the signal from the RACH, an assigned traffic channel to the MS, informing MS through the PAGCH (paging ch.).

Network-Originated Call

In analog systems, a land-line party dials a mobile-unit number. The telephone company recognizes the

mobile number and forwards it to the MTSO. The MTSO then sends a paging message to certain cell sites depending on the mobile number. Paging is needed at the cell site because the MTSO does not know where the mobile unit is due to the self-location scheme being used by the mobile unit. Each cell site transmits the paging signal on its own assigned setup channel. The mobile unit recognizes its number on the strongest setup channel during the idle stage and responds to the particular cell site. The mobile unit also follows the message to tune to an assigned voice channel, at this time, the mobile unit alerts the user.

In digital systems, PAGCH is used to page the MS, and the MS will respond to the PAGCH message through RACH. As soon as the base station receives the response, it assigns a traffic channel to MS through PAGCH.

Call Termination

When the analog mobile user terminates a call, a special signal tone (10 kHz) is transmitted to the cell site to free the voice channel. The mobile unit resumes its initialization stage. In the digital mobile system, the functions are handled by different information bits.

Call Blocking

If during a mobile-originated call stage all the voice channels assigned to the nearest cell site are busy, then the analog mobile-originated call is repeated every 100 ms. After ten tries, a busy tone is turned on to inform the user. In digital systems, the operations can be changed dynamically depending on the demand.

Call Completion

After the mobile-originated call or network-originated call is completed, the voice channel is assigned to make a call connection. This process is called "call completion."

Call Drops

During a conversation, because of interference or weak-signal spots in certain areas, if the analog system cell site cannot receive an assigned SAT (generated at the cell site and sent back by the mobile unit) in 5 seconds, the cell site will turn off the transceiver. In digital systems, no SAT tone is needed. There are 256 digital color codes to assign to different cells and sectors. The call drops can be reduced.

Handoff Procedure

When a mobile unit moves out of the range of one cell and enters the range of another cell during a conversation on a voice channel, that voice channel has to change from one frequency channel to another. The system can make this handoff procedure without either interrupting the call or alerting the user. The handoff process is a unique function in cellular-system operation. The signal threshold level setting for a handoff request cannot be too high, or there will be many unnecessary handoffs. However, if the threshold level is set too low, this will cause dropped calls.

In digital systems, TDMA is using hard handoff (break before make) but with a MAHO (mobile assisted handoff). The level of signal strengths of neighboring cells, measured by MS, will send back to the home base station for it to make the handoff decision.

CDMA is using soft handoff (make before break). In the handoff region, two cells (one home cell, one new cell) will simultaneously receive the MS signals. Also, many other potential cells will be considered (up to six cell fingers) by their pilot signal, to choose dynamically the new candidate cell in the soft handoff process.

MOBILE RADIO ENVIRONMENT

Uniqueness of the Mobile Radio Environment

Effect of the Natural Terrain Configuration—Due to the strong ground-reflected wave at the vehicle, both the direct wave and the reflected wave will be received. Since the ground-reflected wave has a 180° phase shift after reflection from the ground, the two waves tend to cancel and result in an excessive signal loss that is dependent on the natural terrain configuration.

Effect of Man-Made Structures—Because the mobile antenna is lower than most man-made structures, the multipath phenomenon prevails. Multipath waves arriving at the mobile unit cause signal fading called multipath fading or Rayleigh fading.

Effect of Man-Made Noise—Due to automobile ignition noise on the cellular frequency, the noise floor is much higher in the city than in a suburban area. Due to unintentional interference from signal sources such as government or military communications equipment or industrial machines, the noise floor can also be different in different areas.

Effect of Vehicle Motion—Different speeds of the vehicle cause different signal fading characteristics. When the speed is high, the fading is rapid; when the speed is low, the fading becomes slow. Also, the duration of the fading is short when the speed is high and is long when the speed is slow.

A Model of a Mobile-Radio Path Loss

A mobile-radio signal can be artificially separated into two parts as shown in Fig. 4. The first part is the radio-path propagation loss due to the terrain configu-

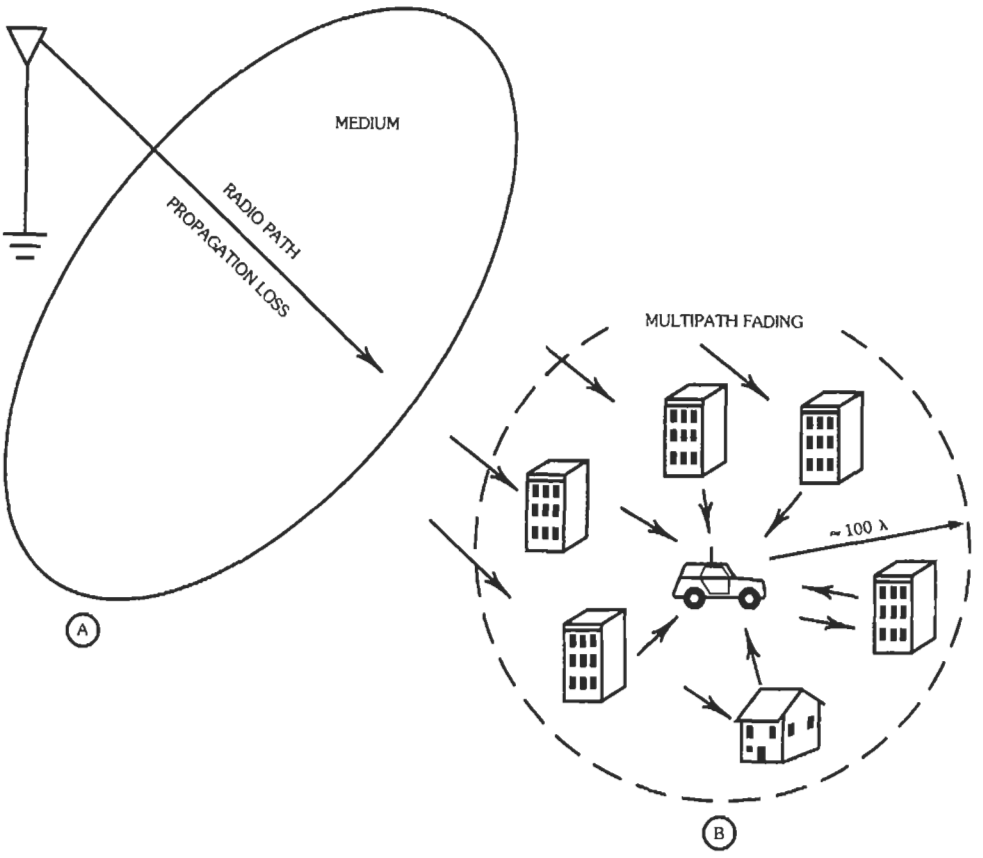

Fig. 4. Two parts of a mobile-radio environment: (A) propagation loss, (B) multipath fading.

ration, and the second part is the multipath fading due to the man-made structures.

Radio-Path Propagation Loss—The path-loss curve follows a log-normal distribution with a standard deviation of ± 8 dB. In theory:

$$\Delta P = 40 \log (d_1/d_0) \quad \text{(A 40 dB/decade path loss)} \qquad \text{(Eq. 1)}$$

$$\Delta G = 20 \log (h_1'/h_1) \quad \text{(A base-station antenna-height gain of 6 dB/octave)} \qquad \text{(Eq. 2)}$$

where ΔP is the difference in two received signal strengths based on the two different path lengths d_1 and d_0, and ΔG is the difference in two received signal strengths based on the two different antenna heights h_1 and h_1'.

Local Mean Prediction from a Prediction Tool—The Lee model* can predict the local mean on each individual road provided that the geographical terrain data is available for that location. This model combines the effects of man-made structures, which are different in different cities, and the natural terrain configuration. The received signal in decibels can be expressed as follows:

P_r = received signal (due to the man-made structure + due to the natural terrain configuration) + correction factor

The received predicted signal P_r in dBm can be obtained as follows for the indicated conditions.

For a nonobstructive path:

$$P_r = P_{ro} - \gamma \log (r/r_o) + 20 \log (h_e'/h_1) + \alpha \qquad \text{(Eq. 3a)}$$

For an obstructive path:

$$P_r = P_{ro} - \gamma \log (r/r_o) - L + \alpha \qquad \text{(Eq. 3b)}$$

For land-to-mobile path over water:

Use free-space formula.

For land-to-boat path on the water:

Use open-area formula.

* Reference 1.

In equations 3a and 3b,

r is the distance between the base and the mobile unit in miles or kilometers,
h_e' is the effective antenna height shown in Fig. 5,
L is the shadow loss shown in Fig. 6.
P_{ro} is the received signal at a reference distance r_o; r_o is usually equal to 1 mile (1.6 km),
α is a correction factor which will be described later.

Typical values of P_{ro} and γ are listed in Table 3. If the area of interest is similar to an area listed in the table, the corresponding data from the table can be used for prediction purposes. The suburban data can be used generally for most areas. The values of P_{ro} and γ

TABLE 3. TYPICAL VALUES OF P_{ro} AND γ

	P_{ro} (dBm)		
Area	1 mi	1 km	γ (dB/dec)
Free Space	–45	–40	20
Open Area	–49	–40	43.5
Suburban	–61.7	–54	38.4
Philadelphia	–70	–62.5	36.8
Newark (Urban)	–64	–55	43.1
Tokyo	–84	–78	30.5
New York	–77	–67	48

also can be obtained very easily by taking the average values of five or more local mean data points at 1 mile and 10 miles. The averaging process attempts to make a real nonflat area into an imaginary flat area. Since the area becomes flat, the different average values of P_{r0} and γ shown for each city are caused solely by the man-made structures. Then the additional changes of the signal strength due to the variation of the terrain configuration in each area can be added back to the first predicted signal obtained from a flat man-made area. For mobile units traveling along paths in a non-flat area with the terrain contour information provided, the additional effect due to the terrain variation can be predicted according to one of the four conditions listed above. Therefore, in equations 3a and 3b, the first and second parts are due to the man-made structures, and

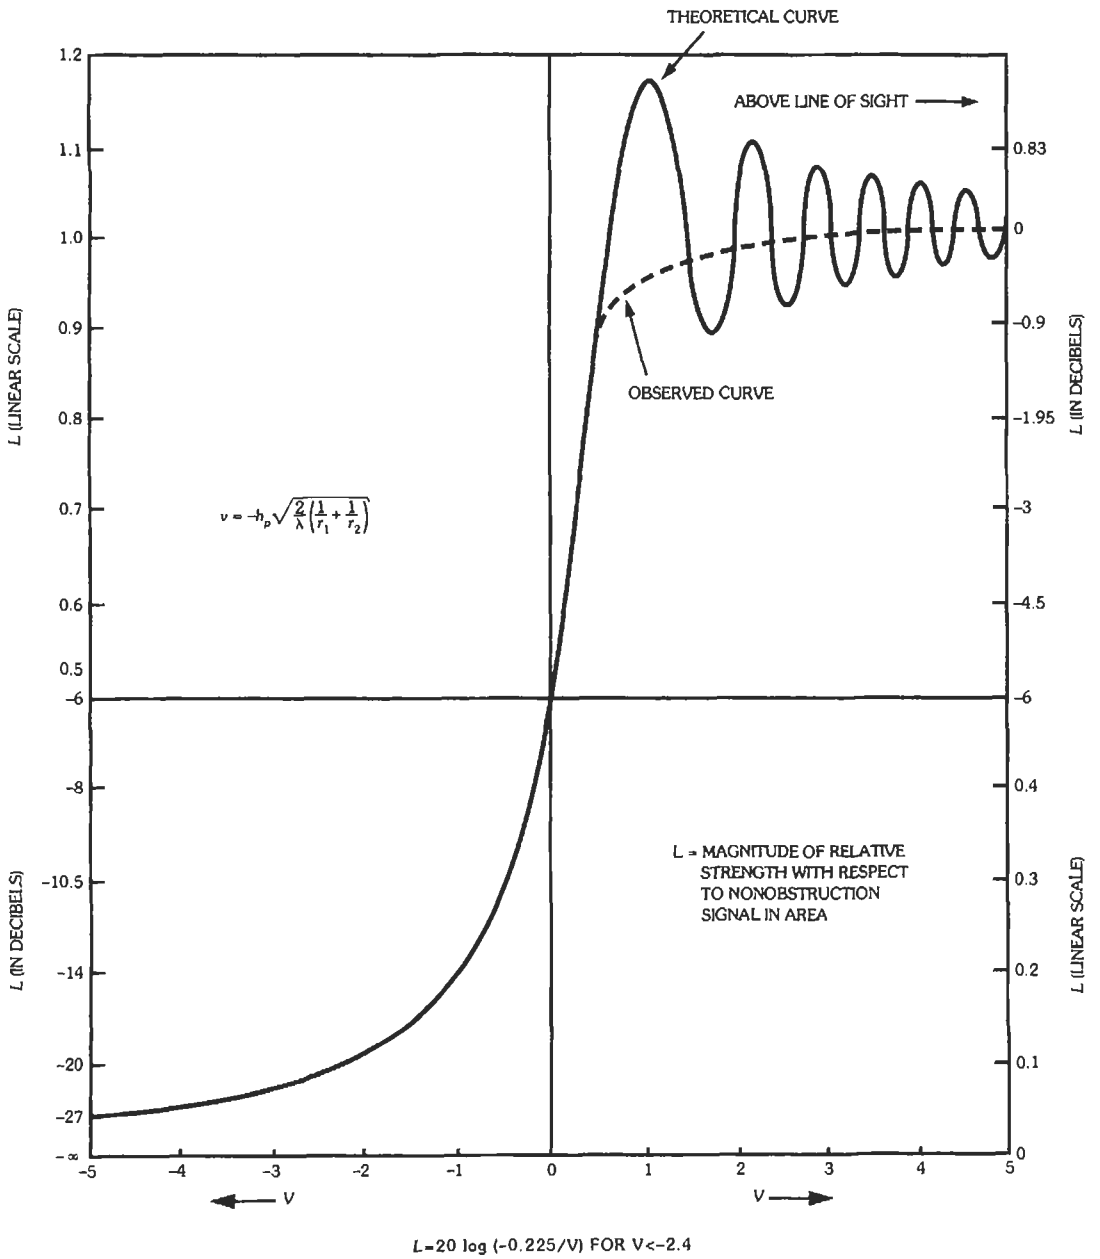

Fig 6B. Shadow-loss prediction. (B) Prediction curve.

the third part is due to the terrain-contour variation. This model can be run on a computer.

Standard Condition: This model can predict the power level in dBm that compares directly with experimental data. For achieving this capability, a standard condition has to be set, as follows:

Frequency f_0 = 900 MHz
Base-station antenna height (h_1) = 30.48 m (100 ft)
Base-station power at the antenna = 10 watts (40 dBm)
Base-station antenna gain G_t = 6 dB above dipole gain (6 dBd)
Mobile-unit antenna height = 3 m (10 ft)
r_o = 1.6 km (or 1 mi)
Mobile-unit antenna gain G_m = 0 dB above dipole gain (0 dBd)

Correction Factor: For a condition in an actual environment that is different from the standard condition, the following correction factor is used:

$$\alpha = \sum_{i=1}^{5} \alpha_i$$

where

$\alpha_1 = 20 \log (h_1'/30{,}48)$

$\alpha_2 = 10 \log (h_2'/3)$

$\alpha_2 = 10 \log (P_1/10)$ (P_t is the transmit power)

α_4 = Base-station antenna gain in dBd, $G_t - 6$

α_5 = Mobile-unit antenna gain in dBd, G_m

In the above equations, the heights are in meters, and the power is in watts.

General Formula for Mobile Radio Propagation Path Loss: Based on the suburban-area formula with correction factors inserted, the general formula can be expressed as

$$P_r = P_t - 134.4 - 38.4 \log r_1 + 20 \log h_1 + 10 \log h_2 + G_t + G_m \quad \text{(Eq. 4)}$$

where P_r and P_t are in decibels above 1 mW, r_1 is in kilometers, h_1 and h_2 are in meters, and G_t and G_m are in decibels.

Characteristics of Multipath and Selective Fading

Cumulative Distribution Function (CDF)—The CDF of a multipath fading signal follows the Rayleigh statistics shown in Fig. 7 when no line-of-sight (LOS) path condition is present and follows Rician statistics if an LOS path condition is present. Both conditions are shown in Fig. 8. The normalized amplitude of an LOS path is defined as

$$\frac{a_o}{\sqrt{2}} = \frac{\text{amplitude of LOS path}}{\text{rms of the received signal}}$$

The Rayleigh fading condition occurs when $a_0 = 0$, i.e., no LOS is present.

Level-Crossing Rate (LCR) and Average Duration of Fades (ADF)—These two statistical parameters are second-order statistics. They involve time, which is a function of the vehicle speed. When the vehicle travels fast, more level crossing and shorter average duration of fades can be seen in the received signal plot.

The LCR curve shown in Fig. 9 normalizes to n_R with the factor.

$$n_0 = \sqrt{2\pi}(V/\lambda)$$

where

V is the vehicle speed in meters/second,
λ is the wavelength in meters.

Therefore, after normalization the curve shown in Fig. 9 is independent of the frequency and the vehicle speed. For example, at a level of –10 dB, $n_R = 0.3$ from Fig. 9. Assume that a signal of 850 MHz is received at a mobile unit with a vehicle speed of 24 km/h (15 mi/h). Then $n_0 \approx 50$. The LCR $\bar{n}$ equals

$$\bar{n}(-10 \text{ dB}) = 0.3 \times 50 = 15 \text{ crossings/second}$$

The average duration of fades is shown in Fig. 10, For example, at a level of –10 dB, $t_R = 0.33$, With the same assumption as was used in calculating LCR above, $t_0 = 1/n_0$, and ADF, $\bar{t}$ is:

$$\bar{t}(-10 \text{ dB}) = 0.33/50 = 0.0066 \, s = 6.6 \text{ ms}$$

Distribution of Duration of Fades—The distribution of duration of fades $F_\tau(U, R)$ is shown in Fig. 11, where $U = \tau/\bar{t}$. The distribution function $F_\tau(U, R)$ can be interpreted as the probability $P(t > \tau, R(t) < R)^2$ that $R(t) < R$ for an interval lasting longer than τ. The average duration of fades is $\bar{t}$, and R is the envelope with respect to its rms values. Furthermore, the vehicle speed V can be related to $\bar{t}$, which is a normalized factor for U. The probability $P(t) > \tau$, $R(t) < R$ is shown in Fig. 11 as a family of curves for different values of envelope levels. From the curves, we can find that the probability of occurrence of a fade whose duration is greater than twice that of an average duration of fades (ADF) at a level of 3 dB below its rms value, is 10%.

Selective Fading and Time Delay Spread—Selective fading is due to the time-dispersive medium. When an impulse (short pulse) is sent out from the base-station antenna, due to man-made structures the reflected waves travel in different paths and arrive at the mobile-unit antenna at different times. They form a signal $e(t)$. The delay spread (Δ) can be obtained from $e(t)$ as follows:

$$\Delta^2 = \int_0^\infty t^2 \cdot e(t)\, dt - \int_0^\infty t \cdot e(t)\, dt$$

In general, the delay spread is measured from the strongest received level to the range which is at its –20-dB

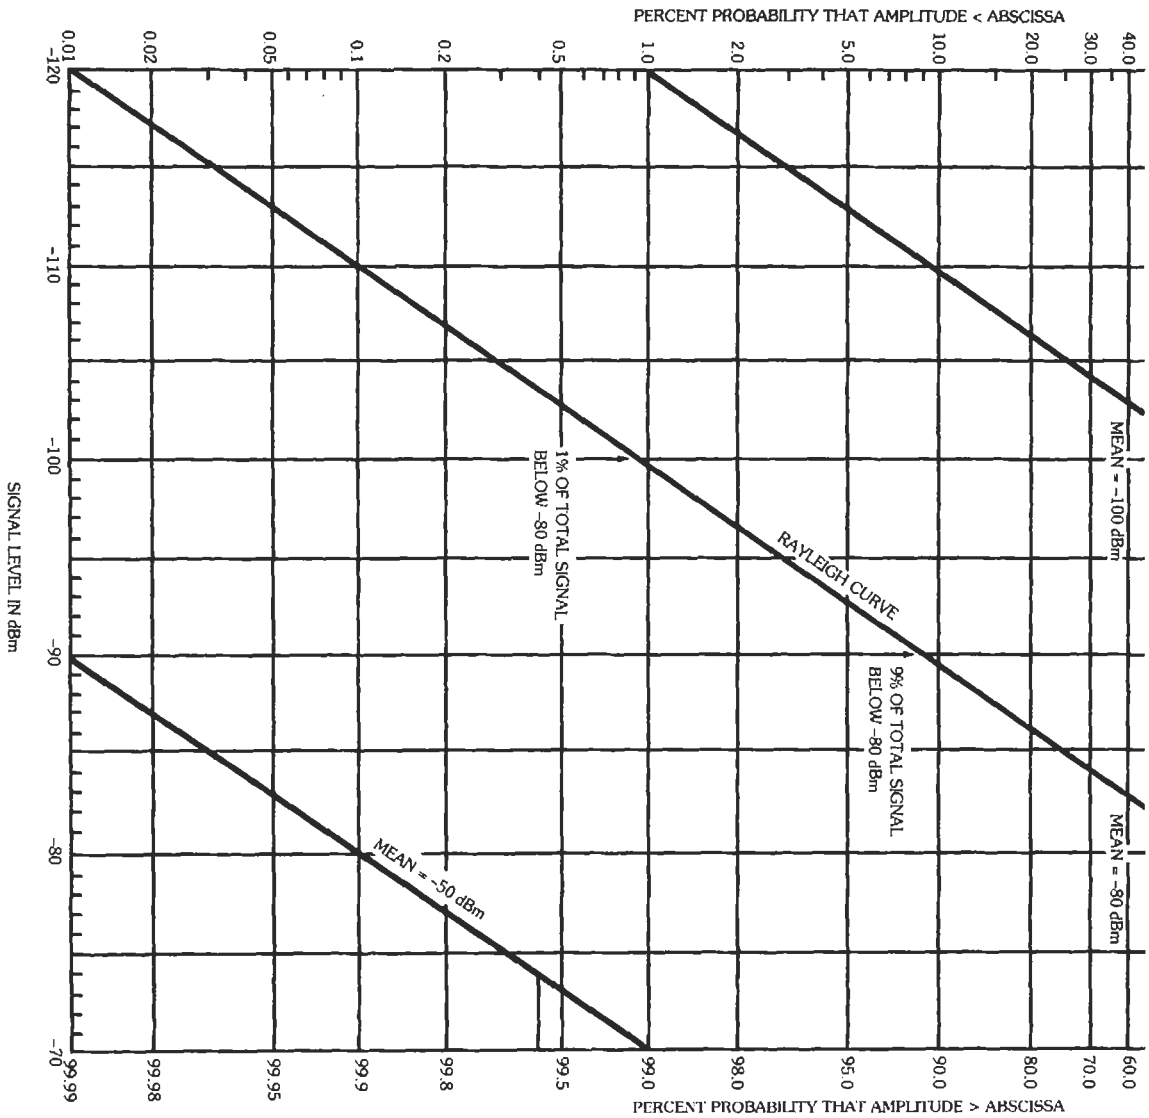

Fig. 7. Cumulative distribution function.

level. Mean time delay spreads ($\bar{\Delta}$) are shown in Table 4. This data does not include the possibility of reflections from high-rise buildings or nearby mountains, which would generate more time delay spread due to the late arrival of the reflected waves. Sometimes a time delay caused by a mountain reflection can be up to 100 μs.

TABLE 4. MEAN TIME DELAY SPREADS

Type of Environment	Mean Delay Spread ($\bar{\Delta}$)

Metropolitan area	0.35 μs
In building	<0.1 μs

FREQUENCY REUSE AND DESIGN ASPECT FOR FDMA AND TDMA

The frequency reuse concept is used in the cellular system to achieve spectrum efficiency and serve a high volume of calls. The frequency reuse concept can be used in the time domain and the space domain. The cellular system applies frequency reuse in the space domain. In many cities, the same frequency is being reused in a general geographical area more than 30 times.

Frequency Reuse Distance

When the same channel is to be reused in two cells, the two cells are called cochannel cells. The distance D is the separation of the two cochannel cells. The smaller the D, the greater the spectrum efficiency would be. The key parameter, a ratio of D/R, where R is the cell radius, is used to measure the spectrum efficiency.

Cellular Design Aspect

The cellular system is a high-capacity and spectrum-efficient system. In the AMPS system, it was found from subjective tests that 75% of the people grade the system voice quality as "good" or "excellent" at the system's required carrier-to-interference ratio (C/I), $\geq$ 18 dB (which is 63 in a linear scale). The level of C/I = 18 dB will be set at the boundary of the cell as shown in Fig. 12. The D/R ratio is obtained based on the six cochannel cells surrounding the cell of interest, and the mobile radio propagation rule of 40 dB/decade. Furthermore, assume for simplicity that all the Ds are equal. Then

$$(C/I)_s = 63 = \frac{R^{-4}}{\sum_{i=1}^{6} D_i^{-4}} \approx \frac{R^{-4}}{6D^{-4}} = \frac{(D/R)^4}{6} \quad \text{(Eq. 5)}$$

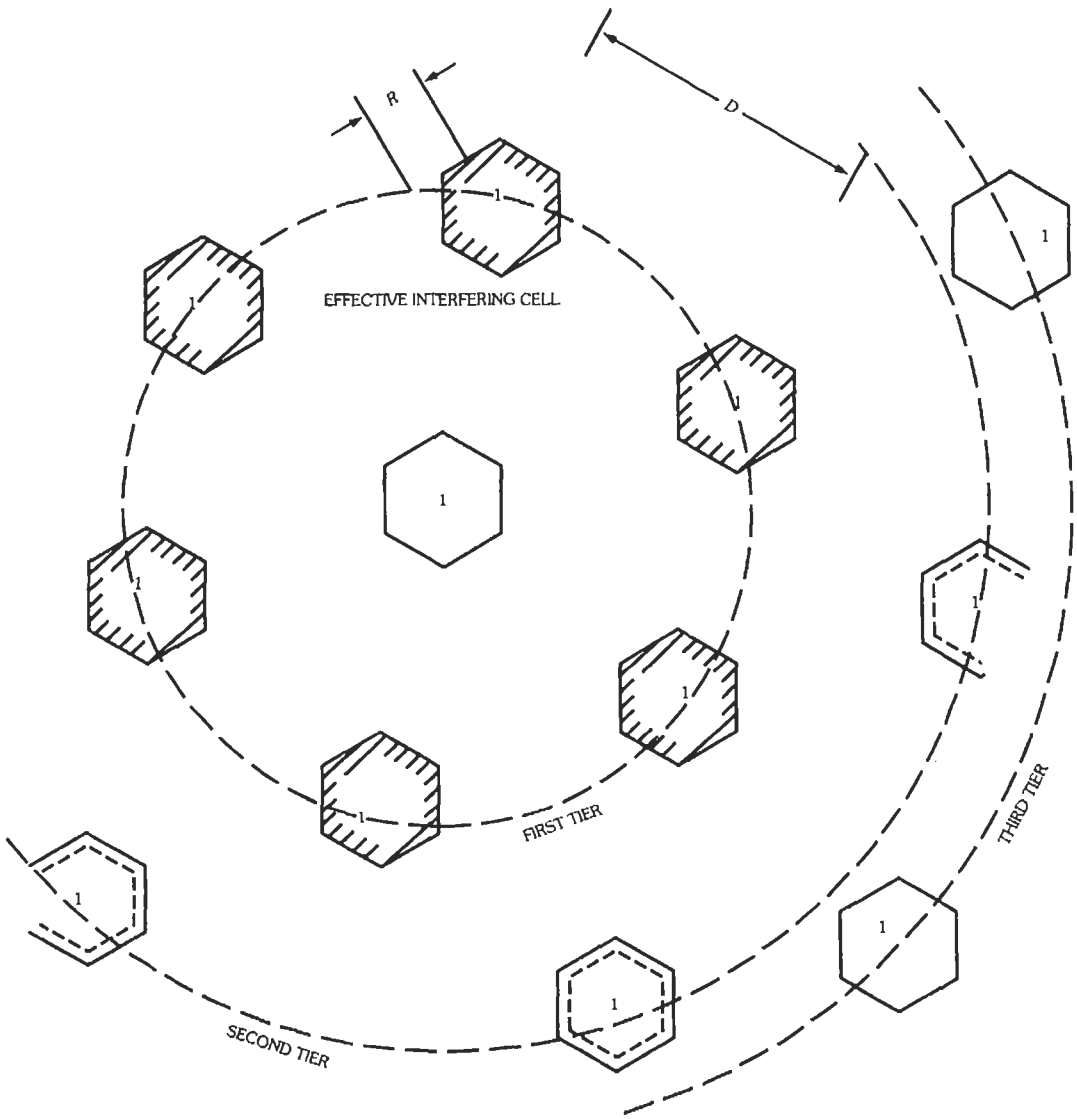

Fig. 12. Six effective interfering cells of cell 1.

or

$$(D/R)_s \approx 4.4$$

The computer simulation finds a required value of $(D/R)_s = 4.6$, which is slightly different from the value of 4.4 which was generated from Eq. 5. The $(D/R)_s$ ratio can be called Cochannel Interference Reduction Factor (CIRF), q,

$$q = (D/R)_s \qquad \text{(Eq. 6)}$$

In designing a cellular system, the key factor is q.

Frequency Reuse Factor, *K*

The factor q can be related to a finite set of cells in a frequency reuse pattern. K is a frequency reuse factor calculated in a hexagonal-shaped cellular system by

$$q = \sqrt{3K} \quad \text{or} \quad K = q^2/3 \qquad \text{(Eq. 7)}$$

For $q = 4.6$, $K = 7$. This indicates seven frequency reuse patterns (Fig. 13). This means that the total voice channels, say 395 channels, should be divided by seven. Then the number of voice channels per cell is 57.

RADIO CAPACITY*

The radio capacity, m, is used to measure the spectrum efficiency.

$$m = B_t \Big/ \left[B_c \sqrt{\tfrac{2}{3}(C/I)_s}\right] \quad \begin{matrix}\text{(for FDMA}\\ \text{and TDMA)}\end{matrix} \qquad \text{(Eq. 8a)}$$

$$= M/K \quad \begin{matrix}\text{number of voice channels/cell}\\ \text{(for CDMA, } K \approx 1\text{)}\end{matrix} \qquad \text{(Eq. 8b)}$$

where

B_t = total allocated spectrum,
B_c = channel bandwidth,
M = total number of voice channels,
K = frequency reuse factor,
$(C/I)_s$ = required carrier-to-interference ratio in linear values.

In an analog cellular system, B_c and $(C/I)_s$ are related. For example, to keep an accepted voice quality, B_c = 30 kHz and $(C/I)_s$ = 18 dB. If B_c is reduced to 15 kHz, then $(C/I)_s$ has to be increased to 24 dB in order to maintain the same voice quality. Then the radio capacity (m) does not change. Equation 8a is used in analog, frequency division multiple access (FDMA), and time division multiple access (TDMA) cellular systems. Equation 8b is used in code division multiple access (CDMA) cellular systems.

* Reference 2.

Increase Capacity

Increase Radio Capacity—Try to increase capacity by designing a new digital system the voice quality of which can cope with a narrow bandwidth and a low required $(C/I)_s$. The radio capacity of Eq. 8 can be used to compare the spectrum efficiencies of any two different systems.

Increase System Capacity: Cell Splitting—The system capacity is measured by the total calling channels in a given geographical area. One physical frequency channel can become ten calling channels if the frequency is reused ten times. The system capacity can be increased without increasing radio capacity. Cell splitting uses this type of approach. When a cell radius is reduced to one-half the original radius, four small cells can be created. Each small cell has the same radio capacity as the original one. The system capacity then increases by four times. When a cell is small, the effect of interference on the performance becomes greater. Splitting cells will not achieve four times system capacity.

Microcells—A cell of radius less than 1 mile or 1 kilometer is called a microcell. A conventional microcell system can still increase system capacity based on cell splitting, but only by two or three times; it cannot increase the radio capacity. Also, a conventional microcell system may not be able to provide the fast handoffs required for small-cell operation. A newly invented microcell system† cannot only increase the system capacity but can also increase the radio capacity by reducing the frequency reuse factor K from 7 to 3. The key factor in increasing the radio capacity is to reduce the interference by simply aiming the signal at the mobile unit.

Diversity Schemes and Combining Techniques

General Description—In a mobile radio environment, the multipath fading and the time delay spread generate major problems for cellular communications. Diversity schemes provide the means to generate two or more uncorrelated fading signals at the mobile reception point. The information carried by the two different received signals is the same, but the multipath fading, at any given time, is different for the two signals. The cross correlation coefficient ρ, where $\rho \leq 1$, is used to measure their correlation. If $\rho = 1$, then the two fading signals are totally correlated. If $\rho = 0$, then the two fading signals are uncorrelated. The ideal reduction of signal fading at reception, after combining two fading signals, occurs when ρ approaches zero.

† Reference 3.

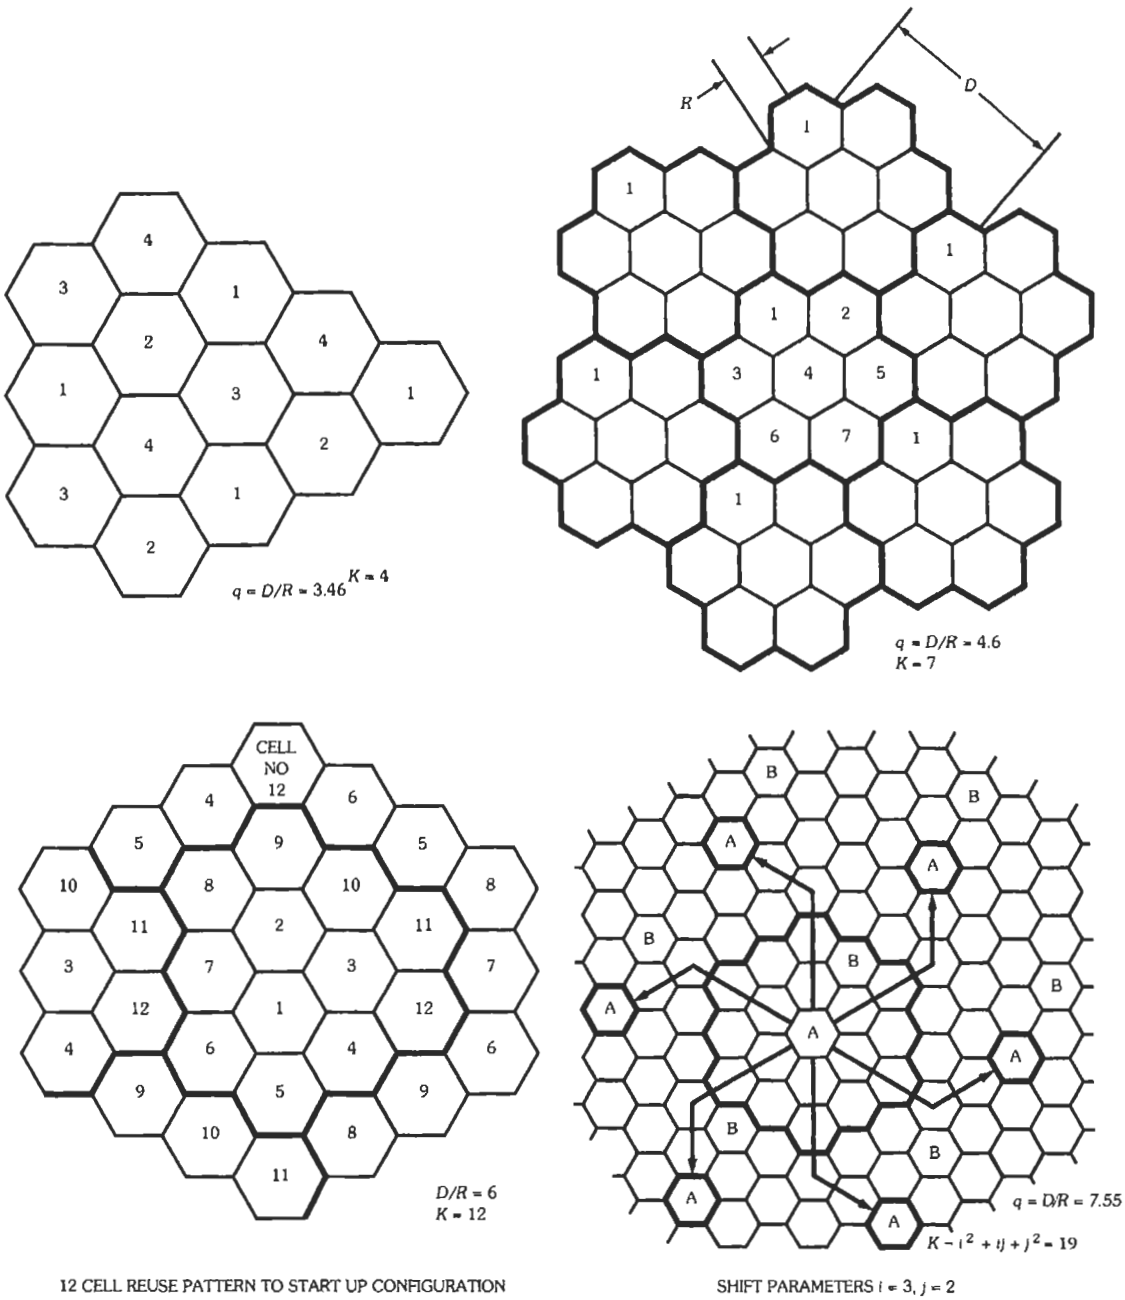

Fig. 13. *N*-cell reuse patterns.

Diversity Schemes—There are six common diversity schemes, as follows:

1. Space diversity (receives two fading signals from two separate antennas)
2. Field component diversity (receives E field and H field)
3. Polarization diversity (receives vertically and horizontally polarized waves, or left-hand and right-hand circularly polarized waves)

4. Time diversity (repeats the same signal more than once)
5. Frequency diversity (receives two fading signals on two different frequencies)
6. Angle diversity (receives two fading signals from two different directions)

Combining Techniques—There are three general techniques for combining two or more uncorrelated or partially correlated received fading signals. The signal fading is reduced after combination. The best method is the maximum-ratio combiner, which combines the signals to achieve the maximum signal-to-noise ratio. The next best technique is the equal-gain combiner. It combines the two fading signals in phase to reduce the signal fading. The third technique is the selective combiner. This technique always selects the strongest signal from among the received fading signals. The difference in performance between the maximum-ratio technique and the selective-combiner technique is 2 dB. The switched combined technique which switches the signal when it is below a threshold level is not applicable in cellular systems.

Antenna Separation Requirement—*At the Base Station:* The antenna separation for cellular systems is determined by the formula

$$h/d = 11$$

where

h is the antenna height,
d is the spacing between two antennas.

If h = 30 m, then d = 2.72 m. The formula does not apply if the location of a mobile unit is in line with the two base-station antennas. Therefore, the orientation of two antennas mounted on a mast has to be carefully determined to obtain the maximum diversity gain in the cell.

At the Mobile Unit: A separation of a half wavelength between two mobile antennas is required at 850 MHz. Therefore, the separation between two antennas needs to be only 0.18 m (about 6 inches) at the cellular frequency of 850 MHz.

Diversity Scheme Reduces Time Delay Spread—The diversity scheme not only reduces the signal fading, it also reduces the time delay spread. Time delay spread does not affect an analog system, but it does affect a digital system. The time delay spread in a mobile radio environment always exists at the reception point whether the mobile unit is standing still or moving. Signal fading occurs only when the mobile unit is moving. In a digital system, an equalizer is normally used to reduce the intersymbol interference which is caused by the time delay spread. The strength of the equalizer equipment is based on the severity of the mobile radio environment. When the diversity scheme has been implemented, the equalizer design requirement can be relaxed or removed.

SWITCHING EQUIPMENT AND TRAFFIC MODELS

Analog Switching Equipment

The analog switch is usually a circuit switch which must hold a call throughout the duration of the call. The analog switching equipment consists of processor, memory, switching network, trunk circuitry, and miscellaneous service circuitry as shown in Fig. 14. The switching of a Class 5 telephone central office is switching from trunk frame to line frame. The difference in this cellular switching equipment is the switching from trunk frame to trunk frame via the switch network. One trunk side is connected to the mobile calls because the mobile unit does not have a fixed frequency channel associated with a mobile unit. The other trunk side is connected to PSTN.

Cellular Digital Switching Equipment

The digital switch is usually a message switch handling digitized messages. The digital switch can send the message or transmit the voice in digital form. Therefore, the digital signal format permits breaking a message into small pieces for faster transmission. Also, it can handle other calls while the switch alternates between the "on" and "off" modes periodically. Hence, the call-processing efficiency of digital switching is higher than that of analog switching. The other advantages of using a digital switch are small size, less power consumption, less human effort required to operate, and ease of maintenance. Digital switching equipment can be modular and is very flexible. Often, capacity can be increased simply by adding modules. Digital equipment can be either a centralized system (Fig. 15A) or a decentralized system (Fig. 15B).

Traffic Models

There are three telephone traffic models (see Chapter 39):

Erlang B—Blocked calls clear condition specified blocking probability
Erlang C—Blocked calls delay condition specified delay probability
Poisson—Blocked calls held condition specified the held probability at a time period equal to an average holding time.

In the cellular industry, the system operators usually specify the blocking probability for designing the system and calculate the number of radios in each cell site to meet this requirement based on the Erlang B formula. Some operators are more conservative and use the Erlang C formula to calculate the number of radios. However, they have to substitute the value of the specified blocking probability into the delay proba-

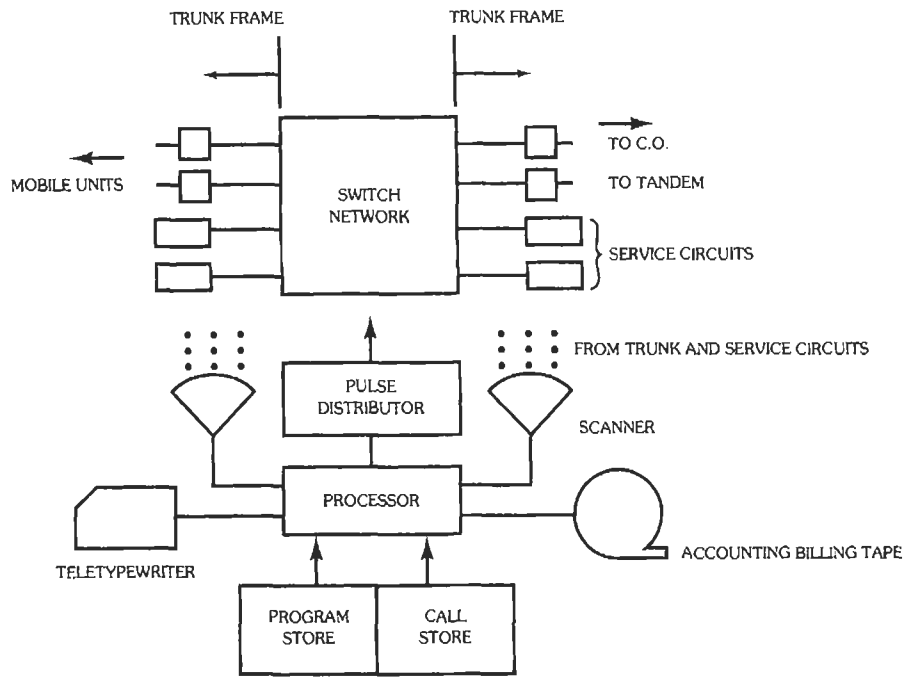

Fig. 14. A modified analog switching system for cellular mobile systems.

bility in the Erlang C formula. Also, by substituting the specified blocking probability into the held probability of the Poisson formula, another different number of radios would be required. Among the three formulas, any one can be used within an error in general less than 15%. In the future, a cellular traffic model will be generated based on the past traffic data in cellular telecommunication systems.

EXAMPLE: A cell site has 57 voice channels. Assume a blocking probability of 2%. From the Erlang B table, the offered load A = 46.8 erlangs. Assume the average talking time per call is 100 s; then the number of calls per busy hour, Q_1, is

$$Q_1 = (46.8 \times 3600)/100 = 1685 \text{ calls/busy hour}$$

and the number of calls per radio, Q_2, becomes

$$Q_2 = 1685/57 = 29.5 \text{ calls/radio}$$

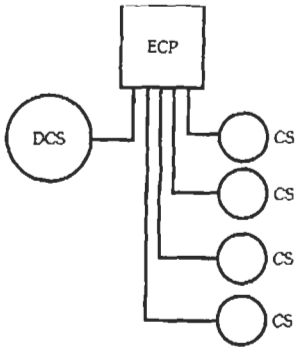
DIGITAL CELLULAR SYSTEMS

Digital AMPS (or North America Digital Cellular, NADC)

- Voted cellular digital standard at TIA
- Allocated the same spectrum as analog cellular system
- Requires a dual-mode (analog/digital) subscriber's unit
- Handoff requirements—analog to digital, digital to digital, digital to analog
- Number of channels—416 channels for Band A and 416 channels for Band B
- 21 analog setup channels are used for digital system
- Channel bandwidth—30 kHz
- Multiple access method—TDMA (3 time slots per channel)
- Modulation— $\frac{\pi}{4}$-*DQPSK*
- Detection—differential detection
- Speed coding—VSELP (vector sum excited LPC)
- Speech frame—20 ms/frame
- Speech code rate—8 kbps
- Channel coding—interleaving convolutional code
- Equalizer—equalize the time delay spread up to 60 μs
- Duration of slots—6.6 ms

GSM (Special Mobile Group) System

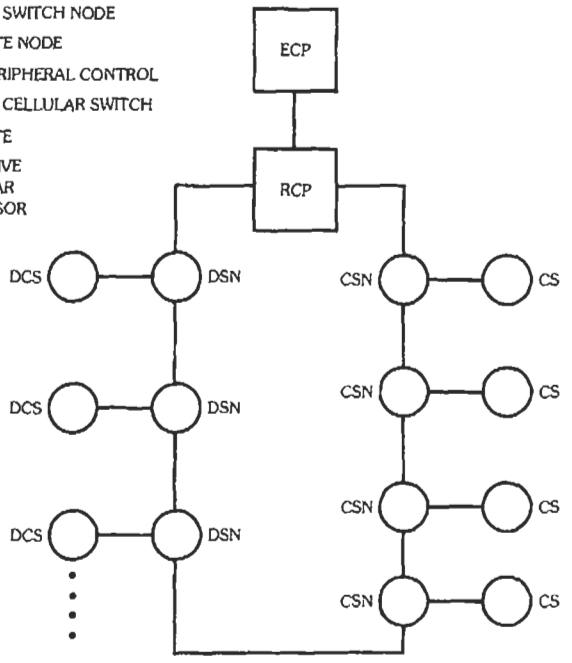
- GSM is a European digital cellular standard.
- GSM is allocated a spectrum exclusively.
- Frequency
  935–960 MHz base-to-mobile
  890–915 MHz mobile-to-base
- Number of channels—124 radio carriers



CS: CELL SITE
ECP: EXECUTIVE CELLULAR PROCESSOR
DCS: DIGITAL CELLULAR SWITCH

(A) Centralized system.

DSN: DIGITAL SWITCH NODE
CSN: CELL SITE NODE
RPC: RING PERIPHERAL CONTROL
DCS: DIGITAL CELLULAR SWITCH
CS: CELL SITE
ECP: EXECUTIVE CELLULAR PROCESSOR



(B) Decentralized system.

Fig. 15. Cellular switching equipment.

- Channel bandwidth—200 kHz
- Multiple access method—TDMA (8 time slots per channel)
- Modulation—GMSK
- Detection—coherent detection
- Speech coding—RPE-LPC (regular pulse excited-LPC)
- Speech frame—20 ms/frame

- Speech coding rate—13 kbps
- Channel coding—convolutional code
- Equalizer—equalize the time delay spread up to 16 μs
- Transmission rate—270 kbps
- Duration of slots—0.557 ms (the frame of 8 slots is 4.615 ms)

Cellular CDMA System

- This is a code division multiple access (CDMA) system.
- CDMA is in the process of being standardized by TIA.
- Bandwidth—1.23 MHz
- Modulation—BPSK
- $E_b/I_0 = 7$ dB
- Speech coding rate—8 kbps (variable rate for nonvoice conditions)
- Power control increment—0.5 dB
- Channel coding—convolutional code
- Detection—Forward channel uses coherent detection; reverse channel uses noncoherent detection.
- Transmit power
  cell site—1.25 W
  mobile—300 mW
- Range—13 miles

3G Systems

Three modes are FDD direct spread, FDD multicarrier, and TDD as listed in Table 2.

In FDD modes, several high-speed data channel systems have been introduced as shown in Table 5. Depending on different modulations, the peak data rate can be from a range of 2.4 to 5.2 Mbps.

4G System

A TDD system with a set of smart code (LAS code)[4] can reduce the multiuser access interference and the multi-path interference along a single-spectrum band transmission. It brings a high hope that using a code technology to change the system environment from an interference environment to a noise environment is a winner for the 4G system.

Other Personal Communication Systems

PCN (Personal Communication Network)

- Three licenses in UK
- Frequency—50–100 MHz band in 1.8 GHz range
- System—modified GSM

DECT (Digital European Cordless Telephone)

- Frequency—1880–1900 MHz
- Multiple access—TDMA/TDD
- Transmission rate—38.8 kbps/slot channel
- Modulation—GFSK
- Channel bandwidth—1.728 MHz/channel
- TDD (Time division duplex)
  12 slots (base-to-portable)
  12 slots (portable-to-base)
- Frame length—10 ms/24 time slots
- Number of channels—5
- Transmit power—10 mW

CT-2 (Cordless Telephone—2)
This system acts as a "portable payphone booth"

- Applied country—four licenses issued in UK
- Transmission signal format—TDD (time division duplexing)
- Number of channels—40
- Channel bandwidth—100 kHz/TDD channel
- No call delivery capability
- No handoffs

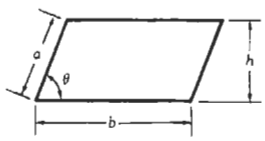
47 Mathematical Equations

MENSURATION EQUATIONS

Areas and Lengths Associated With Plane Figures

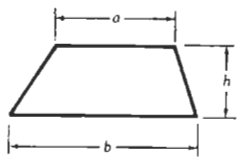
Parallelogram:



$$\text{Area} = bh$$

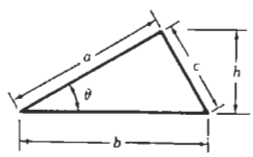
$$= ab \sin\theta$$

Trapezoid:



$$\text{Area} = \tfrac{1}{2}h(a + b)$$

Triangle:



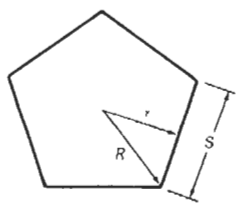
$$\text{Area} = \tfrac{1}{2}bh$$

$$= \tfrac{1}{2}ab \sin\theta$$

$$= [s(s - a)(s - b)(s - c)]^{1/2}$$

where $s = \tfrac{1}{2}(a + b + c)$

Regular Polygon:



$$\text{Area} = \tfrac{1}{2}nrS$$

$$= nr^2 \tan(180°/n)$$

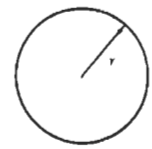
$$= \tfrac{1}{4}nS^2 \cot(180°/n)$$

$$= \tfrac{1}{2}nR^2 \sin(360°/n)$$

where,

n = number of sides,
S = length of one side,
R = long radius,
r = short radius = $R \cos(180°/n)$ = $\tfrac{1}{2}S \cot(180°/n)$.

Circle:



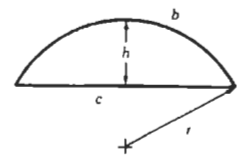
$$\text{Area} = \pi r^2$$

$$\text{Circumference} = 2\pi r$$

where,

r = radius,
$\pi = 3.1416$.

Segment of Circle:

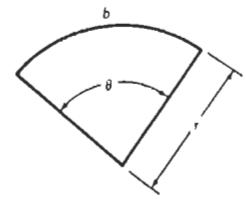


$$\text{Area} = \tfrac{1}{2}[br - c(r - h)]$$

where,

b = length of arc,
c = length of chord = $[4(2hr - h^2)]^{1/2}$.

Sector of Circle:

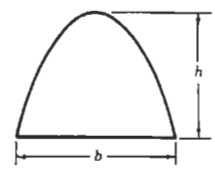


$$\text{Area} = br/2 = \pi r^2(\theta/360°)$$

where,

$b = (\pi r\theta/180°)$,
θ is in degrees.

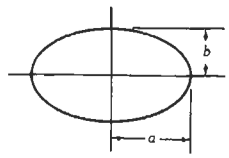
Parabola:



$$\text{Area} = \tfrac{2}{3}bh$$

$$\text{Arc length} = [4h^2 + (b^2/4)]^{1/2} + (b^2/8h) \ln\{4h + 2[4h^2 + (b^2/4)]^{1/2}/b\}$$

Ellipse:

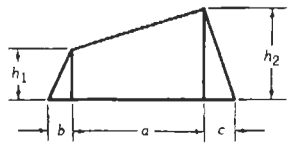


$$\text{Area} = \pi ab$$

$$\text{Circumference} = 4aE(k)$$

where $E(k)$ is a complete elliptic integral with $k = (a^2 - b^2)^{1/2}/a$ of the second kind, $a > b$.

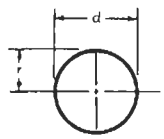
Trapezium:



$$\text{Area} = \tfrac{1}{2}[a(h_1 + h_2) + bh_1 + ch_2]$$

Surface Areas and Volumes of Solid Figures

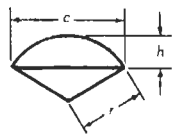
Sphere:



$$\text{Surface} = 4\pi r^2 = 12.5664r^2 = \pi d^2$$

$$\text{Volume} = (4\pi r^3/3) = 4.1888r^3$$

Sector of Sphere:



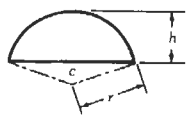
$$\text{Total surface} = (\pi r/2)(4h + c)$$

$$\text{Volume} = (2\pi r^2 h/3) = 2.0944r^2 h$$

$$= (2\pi r^2/3)[r - (r^2 - \tfrac{1}{4}c^2)^{1/2}]$$

$$c = [4(2hr - h^2)]^{1/2}$$

Segment of Sphere:



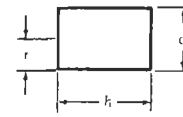
$$\text{Spherical surface} = 2\pi rh = \tfrac{1}{4}\pi(c^2 + 4h^2)$$

$$\text{Volume} = \pi h^2(r - \tfrac{1}{3}h)$$

$$= \pi h^2[(c^2 + 4h^2)/8h - \tfrac{1}{3}h]$$

$$c = [4(2hr - h^2)]^{1/2}$$

Cylinder:



$$\text{Cylindrical surface} = \pi dh = 3.1416dh$$

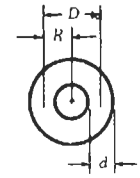
$$\text{Total surface} = 2\pi r(r + h)$$

$$\text{Volume} = \pi r^2 h = 0.7854d^2 h$$

$$= c^2 h/4\pi = 0.0796c^2 h$$

$$c = \text{circumference}$$

Torus or Ring of Circular Cross Section:



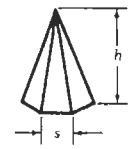
$$\text{Surface} = 4\pi^2 Rr = 39.4784Rr = 9.8696Dd$$

$$\text{Volume} = 2\pi^2 Rr^2 = 19.74Rr^2 = 2.467Dd^2$$

where,

$D = 2R$ = diameter to centers of cross-section of torus,
$r = d/2$.

Pyramid:



$$\text{Volume} = Ah/3$$

When base is a regular polygon

$$\text{Volume} = \tfrac{1}{3}h\{nr^2[\tan(360°/2n)]\}$$

$$= \tfrac{1}{3}h\{\tfrac{1}{4}(ns^2)[\cot(360°/2n)]\}$$

where,

A = area of base,
n = number of sides,
r = short radius of base.

See "Regular Polygon" in subsection on plane figures.

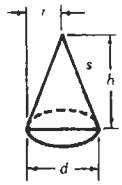
Pyramidal frustum:

$$\text{Volume} = \tfrac{1}{3}h[a + A + (aA)^{1/2}]$$

where,

A = area of base,
a = area of top.

Cone With Circular Base:

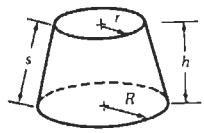


$$\text{Conical area} = \pi rs = \pi r(r^2 + h^2)^{1/2}$$

$$\text{Volume} = \pi r^2 h/3 = 1.047r^2h = 0.2618d^2h$$

where s = slant height.

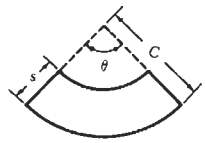
Conic Frustum:



$$\text{Volume} = (\pi h/3)(R^2 + Rr + r^2)$$

$$\text{Area of conic surface} = \pi s(R + r)$$

Development of Conic Surface:

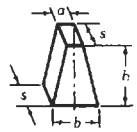


$$C = sR/(R - r)$$

$$\theta = 360R/C$$

where θ is in degrees.

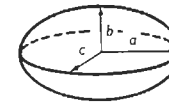
Wedge Frustum:



$$\text{Volume} = \tfrac{1}{2}hs(a + b)$$

where h = height between parallel bases.

Ellipsoid:



$$\text{Volume} = (4\pi abc/3)$$

$$\text{Surface} = 2\pi\{c^2 + [b/(a^2 - c^2)^{1/2}][c^2F(\phi,k) + (a^2 - c^2)E(\phi,k)]\} \quad \text{if } a > b > c$$

$$= 2\pi a\{a + [c^2/(a^2 - c^2)^{1/2}] \times \ln[a + (a^2 - c^2)^{1/2}]/c\} \quad \text{if } a = b > c \quad \text{(oblate ellipsoid)}$$

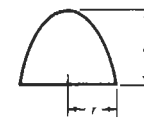
$$= 2\pi c\{c + a^2(a^2 - c^2)^{-1/2} \arcsin[(a^2 - c^2)^{1/2}/a]\} \quad \text{if } a > b = c \quad \text{(prolate ellipsoid)}$$

$F(\phi, k)$ and $E(\phi, k)$ are incomplete elliptic integrals of the first and second kinds, respectively.

$$\phi = \arcsin[(a^2 - c^2)^{1/2}/a]$$

$$k = (a/b)[(b^2 - c^2)/(a^2 - c^2)]^{1/2}$$

Paraboloid:



$$\text{Volume} = (\pi r^2 h/2)$$

$$\text{Curved surface} = (\pi r/6h^2)[(r^2 + 4h^2)^{3/2} - r^3]$$

ALGEBRAIC AND TRIGONOMETRIC EQUATIONS (INCLUDING COMPLEX QUANTITIES)

Quadratic Equation

If $ax^2 + bx + c = 0$, then

$$x = [-b \pm (b^2 - 4ac)^{1/2}]/2a$$

$$= 2c/[-b \mp (b^2 - 4ac)^{1/2}]$$

Solution of Cubic Equations*

Given $z^3 + a_2z^2 + a_1z + a_0 = 0$, let

$$q = \tfrac{1}{3}a_1 - \tfrac{1}{9}a_2^2; \quad r = \tfrac{1}{6}(a_1a_2 - 3a_0) - \tfrac{1}{27}a_2^3$$

* Abramovitz, M. and Stegun, I. A. *Handbook of Mathematical Functions*, Washington, D. C.: National Bureau of Standards; p. 17.

If $q^3 + r^2 > 0$, one real root and a pair of complex conjugate roots
$q^3 + r^2 = 0$, all roots real and at least two are equal
$q^3 + r^2 < 0$, all roots real (irreducible case)

Let

$$s_1 = [r + (q^3 + r^2)^{1/2}]^{1/3}$$

$$s_2 = [r - (q^3 + r^2)^{1/2}]^{1/3}$$

then

$$z_1 = (s_1 + s_2) - (a_2/3)$$

$$z_2 = -\tfrac{1}{2}(s_1 + s_2) - (a_2/3) + (j\sqrt{3}/2)(s_1 - s_2)$$

$$z_3 = -\tfrac{1}{2}(s_1 + s_2) - (a_2/3) - (j\sqrt{3}/2)(s_1 - s_2)$$

If z_1, z_2, z_3 are the roots of the cubic equation

$$z_1 + z_2 + z_3 = -a_2$$

$$z_1z_2 + z_1z_3 + z_2z_3 = a_1$$

$$z_1z_2z_3 = -a_0$$

Solution of Quartic Equations*

Given $z^4 + a_3z^3 + a_2z^2 + a_1z + a_0 = 0$, find the real root u_1 of the cubic equation

$$u^3 - a_2u^2 + (a_1a_3 - 4a_0)u - ({a_1}^2 + a_0{a_3}^2 - 4a_0a_2) = 0$$

and determine the four roots of the quartic as solutions of the two quadratic equations

$$v^2 + \{(a_3/2) \mp [({a_3}^2/4) + u_1 - a_2]^{1/2}\}v + (u_1/2) \mp [(u_1/2)^2 - a_0]^{1/2} = 0$$

If all roots of the cubic equation are real, use the value of u_1 that gives real coefficients in the quadratic equation.

Complex Quantities

In the following equations, all quantities are real except $j = (-1)^{1/2}$.

$$(A + jB) + (C + jD) = (A + C) + j(B + D)$$

$$(A + jB)(C + jD) = (AC - BD) + j(BC + AD)$$

$$\frac{A + jB}{C + jD} = \frac{AC + BD}{C^2 + D^2} + j\frac{BC - AD}{C^2 + D^2}$$

$$\frac{1}{A + jB} = \frac{A}{A^2 + B^2} - j\frac{B}{A^2 + B^2}$$

Polar Form:

$$A + jB = \rho(\cos\theta + j\sin\theta) = \rho e^{j\theta}$$

De Moivre's Equation:

$$(A + jB)^v = \rho^v(\cos v\theta + j\sin v\theta)$$

where,

$\rho = (A^2 + B^2)^{1/2} > 0$,
$\cos\theta = A/\rho$,
$\sin\theta = B/\rho$.

For nonintegral v, this quantity is many-valued.

Complex Conjugate:

$$A + jB = (A + jB)^* = A - jB$$

Analytic Function: Let $f(z)$ be a function of the complex variable $z = x + jy$. Function $f(z)$ is analytic at a point $z = z_0$, if

$$\lim_{\Delta z \to 0} [f(z_0 + \Delta z) - f(z_0)]/\Delta z$$

exists independent of the manner in which Δz approaches zero. Analyticity is equivalent to the existence of a Taylor series about the point in question. In addition, $f(z)$ is analytic if and only if the Cauchy-Riemann equations hold:

$$\partial u/\partial x = \partial v/\partial y$$

$$\partial v/\partial x = -\partial u/\partial y$$

where,

$u = \mathrm{Re}f(z)$,
$v = \mathrm{Im}f(z)$.

If $f(z)$ is analytic for all z, it is called an entire function.

Properties of *e*

$$e = \lim_{n \to \infty} (1 + n^{-1})^n = \sum_{k=0}^{\infty} (k!)^{-1} = 2.71828$$

$$e^{\pm jx} = \cos x \pm j\sin x = \exp(\pm jx)$$

Properties of Logarithms

If $\log_a x = N$, then $a^N = x$

$$\log_a x = \log_a b \log_b x$$

$$\log_a xy = \log_a x + \log_a y$$

$$\log_a x/y = \log_a x - \log_a y$$

* Abramovitz, M. and Stegun, I. A. *Handbook of Mathematical Functions*. Washington, D. C.: National Bureau of Standards.

$$\log_a x^y = y \log_a x$$

$$\log_a b = 1/\log_b a$$

$$a^{\log_a x} = x$$

$$\log_a 1 = 0$$

$$\log_a a = 1$$

$$\log_e x = \ln x = \log_e 10 \log_{10} x = 2.30259 \log_{10} x$$

$$\log_{10} x = \log_{10} e \log_e x = 0.43429 \log_e x$$

Sums

In this subsection, the following symbols will be used:

$\Gamma(\alpha)$ = Gamma function of α

$\binom{n}{k} = \dfrac{n!}{k!(n-k)!}$ in which n and k are positive integers, $n \geq k$, and

$\binom{n}{0} = 1$

Arithmetic Progression:

$$\sum_{k=0}^{n-1} (a + kd) = a + (a + d) + (a + 2d) + \cdots + [a + (n-1)d]$$

$$= \tfrac{1}{2}n[2a + (n-1)d]$$

Geometric Progression:

$$\sum_{k=0}^{n-1} ar^k = a + ar + ar^2 + \cdots + ar^{n-1}$$

$$= [a(r^n - 1)/(r-1)], \quad \text{for } r \neq 1$$

$$= na, \quad \text{for } r = 1$$

Sums of Powers of Integers:

$$\sum_{k=1}^{n} k^2 = 1^2 + 2^2 + 3^2 + \cdots + n^2$$

$$= [n(n+1)(2n+1)/6]$$

$$\sum_{k=1}^{n} k^3 = 1^3 + 2^3 + 3^3 + \cdots + n^3$$

$$= [n^2(n+1)^2/4]$$

$$\sum_{k=1}^{n} k^4 = 1^4 + 2^4 + 3^4; \cdots + n^4$$

$$= \tfrac{1}{30} n(n+1)(2n+1)(3n^2 + 3n - 1)$$

$$\sum_{k=1}^{n} k^r = 1^r + 2^r + 3^r + \cdots + n^r$$

$$= \frac{n^{r+1}}{r+1} + \tfrac{1}{2}n^r + \sum_{k=1}^{[r/2]} (2k)^{-1} \binom{r}{2k-1} B_{2k} n^{r-2k+1}$$

where,

r is a positive integer,
$[r/2]$ is the largest integer less than or equal to $r/2$,
B_{2k} is the $2k$th Bernoulli number.

These sums are tabulated for $n = 1, 2, 3, \cdots, 100$ and for $r = 1, 2, 3, \cdots, 10$.*

Sums of integral powers of odd integers may be obtained from the above. For example,

$$\sum_{k=0}^{n} (2k+1)^2 = 1^2 + 3^2 + 5^2 + \cdots + (2n+1)^2$$

$$= 1^2 + 2^2 + 3^2 + \cdots + (2n+1)^2 - 2^2 - 4^2 - 6^2 - \cdots - (2n)^2$$

$$= \sum_{k=1}^{2n+1} k^2 - 2^2 \sum_{k=1}^{n} k^2$$

$$= \tfrac{1}{3}(n+1)(2n+1)(2n+3)$$

Sums of Powers of Reciprocals of Integers:

$$\zeta(z) = \sum_{k=1}^{\infty} (1/k^z) = (1/1^z) + (1/2^z) + (1/3^z) + \cdots$$

For Rez > 1, $\zeta(z)$ is the Riemann zeta function of z

$$\sum_{k=1}^{\infty} (1/k^2) = (1/1^2) + (1/2^2) + (1/3^2) + \cdots$$

$$= \pi^2/6 = 1.64493$$

$$\sum_{k=1}^{\infty} (1/k^3) = (1/1^3) + (1/2^3) + (1/3^3) + \cdots$$

$$= 1.20206$$

$$\sum_{k=1}^{\infty} (1/k^4) = (1/1^4) + (1/2^4) + (1/3^4) + \cdots$$

$$= \pi^4/90 = 1.08232$$

$$\sum_{k=1}^{\infty} (1/k^{2r}) = (1/1^{2r}) + (1/2^{2r}) + (1/3^{2r}) + \cdots$$

$$= [2^{2r-1}\pi^{2r}|B_{2r}|/(2r)!], \quad r \text{ integral}$$

---

* Abramovitz, M. and Stegun, I. A. *Handbook of Mathematical Functions*. Washington, D. C.: National Bureau of Standards.

where B_{2r} is the $2r$th Bernoulli number. Values of $\zeta(z)$ are tabulated for $z = 2, 3, 4, \cdots, 42$, to 20 decimal places in the *Handbook of Mathematical Functions*. The truncated sums

$$\sum_{k=1}^{n} (1/k^r)$$

are related to the polygamma functions.

Finite Sums of Binomial Coefficients:

$$\sum_{k=0}^{n} \binom{m+k}{m} = \binom{m}{m} + \binom{m+1}{m} + \cdots + \binom{m+n}{m} = \binom{m+n+1}{m+1}$$

$$\sum_{k=0}^{n} \binom{r}{k}\binom{s}{n-k} = \binom{r}{0}\binom{s}{n} + \binom{r}{1}\binom{s}{n-1} + \cdots + \binom{r}{n}\binom{s}{0} = \binom{r+s}{n} \quad (r \geq n \text{ and } s \geq n)$$

Binomial Theorem:
Nonnegative integral exponent:

$$(a+b)^n = a^n + na^{n-1}b + \tfrac{1}{2}[n(n-1)]a^{n-2}b^2 + \cdots + b^n = \sum_{k=0}^{n} \binom{n}{k} a^{n-k}b^k$$

For other n, integral negative and nonintegral, the series will be infinite. For convergence it is assumed $|a| > |b|$. (If $|a| < |b|$, interchange a and b.)

Negative integral exponent:

$$(a+b)^{-n} = a^{-n} - na^{-n-1}b + \tfrac{1}{2}[n(n+1)]a^{-n-2}b^2 - \cdots = \sum_{k=0}^{\infty} (-1)^k \binom{n+k-1}{k} a^{-n-k}b^k$$

Nonintegral exponent:

$$(a+b)^{\alpha} = a^{\alpha} + \alpha a^{\alpha-1}b + \tfrac{1}{2}\alpha(\alpha-1)a^{\alpha-2}b^2 + \cdots = \sum_{k=0}^{\infty} \frac{\Gamma(\alpha+1)}{k!\Gamma(\alpha-k+1)} a^{\alpha-k}b^k$$

Multinomial Series:

$$(x_1 + x_2 + \cdots + x_r)^n = \sum_{n_1=0}^{n} \sum_{n_2=0}^{n-n_1} \sum_{n_3=0}^{n-n_1-n_2} \cdots \sum_{n_{r-1}=0}^{n-n_1-n_2-\cdots-n_{r-2}} n! \prod_{k=1}^{r} \frac{x_k^{n_k}}{n_k!}$$

where the interpretation $n_r = n - n_1 - n_2 - \cdots - n_{r-1}$ is to be used in the final product.

Combinations and Permutations

A combination is a selection from a number of things in which the order of the selected objects is disregarded, whereas a permutation is a selection in which the order is taken into consideration. For example, if from the letters a, b, and c a group of two is selected, then ab, bc, ac are the combinations and ab, ba, bc, cb, ac, ca are the permutations.

The number of different combinations of n (dissimilar) things taken r at a time is

$$\binom{n}{r} = C_r^n = \frac{n!}{r!(n-r)!}$$

The number of different permutations of n (dissimilar) things taken r at a time is

$$P_r^n = n!/(n-r)! = n \times (n-1) \times \cdots \times (n-r+1)$$

Bernoulli Numbers

Definition:

$$B_n = (d^n/dx^n)[x/(e^x - 1)]\big|_{x=0}$$

Values for Small n:

$$B_0 = 1,\ B_1 = -\tfrac{1}{2},\ B_2 = \tfrac{1}{6},\ B_4 = -\tfrac{1}{30},$$

$$B_6 = \tfrac{1}{42},\ B_8 = -\tfrac{1}{30},\ B_{10} = \tfrac{5}{66},$$

$$B_{2n+1} = 0, \text{ for all integral } n > 0$$

Identities:

$$B_{2n} = (-1)^{n-1}\frac{2 \cdot (2n)!}{(2\pi)^{2n}} \sum_{k=1}^{\infty} \frac{1}{k^{2n}},\ n \geq 1$$

$$B_n = \sum_{k=0}^{n} \binom{n}{k} B_k,\ n > 1$$

The latter identity may be used for recursive calculation of the B_n's.

Trigonometric Identities

$$1 = \sin^2 A + \cos^2 A = \sin A \csc A = \tan A \cot A = \cos A \sec A$$

$$\sin A = \cos A/\cot A = 1/\csc A = \cos A \tan A$$
$$= \pm(1 - \cos^2 A)^{1/2}$$
$$\cos A = \sin A/\tan A = 1/\sec A = \sin A \cot A$$
$$= \pm(1 - \sin^2 A)^{1/2}$$
$$\tan A = \sin A/\cos A = 1/\cot A = \sin A \sec A$$
$$\sin A = (e^{jA} - e^{-jA})/2j$$

Approximations for Small Angles

$$\left.\begin{aligned}\sin\theta &= (\theta - \theta^3/6\cdots)\\ \tan\theta &= (\theta + \theta^3/3\cdots)\\ \cos\theta &= (1 - \theta^2/2\cdots)\end{aligned}\right\}\ \theta \text{ in radians}$$

$\sin\theta = \theta$

with less than 1-percent error up to $\theta = 0.24$ radian $= 14.0°$
with less than 10-percent error up to $\theta = 0.78$ radian $= 44.5°$

$\tan\theta = \theta$

with less than 1-percent error up to $\theta = 0.17$ radian $= 10.0°$
with less than 10-percent error up to $\theta = 0.54$ radian $= 31.0°$

Inequalities

$\sin x \le x \le \tan x$, for $0 \le x < \pi/2$

$\sin x \ge (2/\pi)x$, for $0 \le x \le \pi/2$

$\cos x < \sin x/x \le 1$, for $0 < x \le \pi$

where x is in radians.

PLANE TRIGONOMETRY

Right Triangles

Refer to Fig. 1.

$$C = 90°$$

$$B = 90° - A$$

$$\sin A = \cos B = a/c$$

$$\tan A = a/b$$

$$c^2 = a^2 + b^2$$

$$\text{area} = \tfrac{1}{2}ab$$

Oblique Triangles

Refer to Fig. 2.

Sum of Angles:

$$A + B + C = 180° \qquad \text{(Eq. 1)}$$

Law of Cosines:

$$a^2 = b^2 + c^2 - 2bc,\cos A \qquad \text{(Eq. 2)}$$

Law of Sines:

$$a/\sin A = b/\sin B = c/\sin C \qquad \text{(Eq. 3)}$$

Law of Tangents:

$$\frac{a-b}{a+b} = \frac{\tan\frac{1}{2}(A-B)}{\tan\frac{1}{2}(A+B)} \qquad \text{(Eq. 4)}$$

Half-Angle Equation (Fig. 3):

$$\tan\tfrac{1}{2}A = r/(p-a) \qquad \text{(Eq. 5)}$$

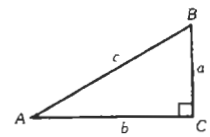

Fig. 1. Right triangle.

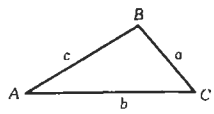

Fig. 2. Oblique triangle.

where,

$$2p = a + b + c$$

$$r = [(p - a)(p - b)(p - c)/p]^{1/2}$$

Solving an Oblique Triangle:

Given	Use Eq.	To Obtain
aBC	(1) (3)	*A* *bc*
Abc	(1) (4)	$B + C$ hence $B - C$ B,C
abc	(5) or (2)	*ABC*
abA ambiguous case	(3) and (1)	*BCc*

SPHERICAL TRIGONOMETRY

Spherical triangles are bounded by the arcs of great circles. These are circles formed by the intersection of a sphere with planes passing through the center of the sphere. In the following equations, α, β, γ are the angles, and a, b, c are the corresponding opposite sides, respectively. The sides are measured by the angles subtended by the arcs; for example, a side extending from the Equator to the North Pole is a 90° side.

Right Spherical Triangles ($\gamma = 90°$)

Refer to Fig. 4.

$$\cos c = \cos a \cos b = \cot\alpha \cot\beta$$

$$\cos\alpha = \sin\beta \cos a = \tan b \cot c$$

$$\cos\beta = \sin\alpha \cos b = \tan a \cot c$$

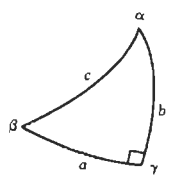

Fig. 4. Right spherical triangle.

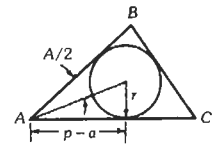

Fig. 3. Half angle.

$$\sin a = \sin c \sin\alpha = \tan b \cot\beta$$

$$\sin b = \sin c \sin\beta = \tan a \cot\alpha \quad \text{(Eq. 6)}$$

Oblique Triangles

Refer to Fig. 5.

Law of Cosines for Sides:

$$\cos a = \cos b \cos c + \sin b \sin c \cos\alpha$$

$$\cos b = \cos c \cos a + \sin c \sin a \cos\beta$$

$$\cos c = \cos a \cos b + \sin a \sin b \cos\gamma \quad \text{(Eq. 7a)}$$

Law of Cosines for Angles:

$$\cos\alpha = -\cos\beta \cos\gamma + \sin\beta \sin\gamma \cos a$$

$$\cos\beta = -\cos\gamma \cos\alpha + \sin\gamma \sin\alpha \cos b$$

$$\cos\gamma = -\cos\alpha \cos\beta + \sin\alpha \sin\beta \cos c \quad \text{(Eq. 7b)}$$

Law of Sines:

$$\sin a/\sin\alpha = \sin b/\sin\beta = \sin c/\sin\gamma \quad \text{(Eq. 8)}$$

Napier's Analogies:

$$\frac{\sin\frac{1}{2}(\alpha - \beta)}{\sin\frac{1}{2}(\alpha + \beta)} = \frac{\tan\frac{1}{2}(a - b)}{\tan\frac{1}{2}c} \quad \text{(Eq. 9a)}$$

$$\frac{\cos\frac{1}{2}(\alpha - \beta)}{\cos\frac{1}{2}(\alpha + \beta)} = \frac{\tan\frac{1}{2}(a + b)}{\tan\frac{1}{2}c} \quad \text{(Eq. 9b)}$$

$$\frac{\sin\frac{1}{2}(a - b)}{\sin\frac{1}{2}(a + b)} = \frac{\tan\frac{1}{2}(\alpha - \beta)}{\cot\frac{1}{2}\gamma} \quad \text{(Eq. 9c)}$$

$$\frac{\cos\frac{1}{2}(a - b)}{\cos\frac{1}{2}(a + b)} = \frac{\tan\frac{1}{2}(\alpha + \beta)}{\cot\frac{1}{2}\gamma} \quad \text{(Eq. 9d)}$$

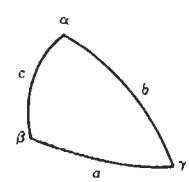

Fig. 5. Oblique spherical triangle.

Half-Angle Equations:

$$\tan\tfrac{1}{2}\alpha = \tan r/\sin(p-a)$$

$$\tan\tfrac{1}{2}\beta = \tan r/\sin(p-b)$$

$$\tan\tfrac{1}{2}\gamma = \tan r/\sin(p-c) \qquad \text{(Eq. 10a)}$$

where $2p = a + b + c$ and

$$\tan^2 r = \frac{\sin(p-a)\sin(p-b)\sin(p-c)}{\sin p}$$

$$\sin^2\tfrac{1}{2}\alpha = [\sin(p-b)\sin(p-c)/\sin b \sin c]$$

$$\cos^2\tfrac{1}{2}\alpha = [\sin p \sin(p-a)/\sin b \sin c]$$

$$\tan^2\tfrac{1}{2}\alpha = [\sin(p-b)\sin(p-c)/\sin p \sin(p-a)] \qquad \text{(Eq. 10b)}$$

and equations obtained by cyclical permutation for β and γ.

Half-Side Equations:

$$\tan\tfrac{1}{2}a = \tan R \sin(\alpha - E)$$

$$\tan\tfrac{1}{2}b = \tan R \sin(\beta - E)$$

$$\tan\tfrac{1}{2}c = \tan R \sin(\gamma - E) \qquad \text{(Eq. 11a)}$$

where $2E = \alpha + \beta + \gamma - \pi$ is the spherical excess and

$$\tan^2 R = \frac{\sin E}{\sin(\alpha - E)\sin(\beta - E)\sin(\gamma - E)}$$

$$\sin^2\tfrac{1}{2}a = -[\sin E \sin(E-\alpha)/\sin\beta \sin\gamma]$$

$$\cos^2\tfrac{1}{2}a = [\sin(E-\beta)\sin(E-\gamma)/\sin\beta \sin\gamma]$$

$$\tan^2\tfrac{1}{2}a = -[\sin E \sin(E-\alpha)/\sin(E-\beta)\sin(E-\gamma)] \qquad \text{(Eq. 11b)}$$

and equations obtained by cyclical permutation for b and c.

Area: On a sphere of radius one, the area of a triangle is equal to the spherical excess

$$2E = \alpha + \beta + \gamma - \pi$$

L'Huilier's Theorem:

$$\tan^2\tfrac{1}{2}E = \tan\tfrac{1}{2}p \tan\tfrac{1}{2}(p-a) \times \tan\tfrac{1}{2}(p-b)\tan\tfrac{1}{2}(p-c) \qquad \text{(Eq. 12)}$$

Solving an Oblique Triangle:*

Given	Use Eq.	To Obtain
abc	(10)	$\alpha\beta\gamma$
$\alpha\beta\gamma$	(11)	abc
$ab\gamma$	(9)	$\alpha \pm \beta$, hence α,β, then c
$\alpha\beta c$	(9)	$a \pm b$, hence a,b, then γ
$ab\alpha$ ambiguous	(8)	β
case	(9)	$c\gamma$
$\alpha\beta a$ ambiguous	(8)	b
case	(9)	$c\gamma$

HYPERBOLIC FUNCTIONS*

$$\sinh x = (e^x - e^{-x})/2$$

$$\cosh x = (e^x + e^{-x})/2$$

$$\tanh x = \sinh x/\cosh x = [1 - \exp(-2x)]/[1 + \exp(-2x)] = 1/\coth x$$

$$\operatorname{sech} x = 1/\cosh x$$

$$\operatorname{csch} x = 1/\sinh x$$

$$\sinh(-x) = -\sinh x$$

$$\cosh(-x) = \cosh x$$

$$\tanh(-x) = -\tanh x$$

$$\coth(-x) = -\coth x$$

$$\sinh jx = j \sin x$$

$$\cosh jx = \cos x$$

$$\tanh jx = j \tan x$$

$$\coth jx = -j \cot x$$

$$\cosh^2 x - \sinh^2 x = 1$$

$$1 - \tanh^2 x = 1/\cosh^2 x$$

$$\coth^2 x - 1 = 1/\sinh^2 x$$

$$\sinh 2x = 2 \sinh x \cosh x$$

$$\cosh 2x = \cosh^2 x + \sinh^2 x$$

$$\sinh(x \pm jy) = \sinh x \cos y \pm j \cosh x \sin y$$

$$\cosh(x \pm jy) = \cosh x \cos y \pm j \sinh x \sin y$$

* See also great-circle calculations in Chapter 33.

* Tables of hyperbolic functions appear in Chapter 48.

$$\tanh(x \pm y) = (\tanh x \pm \tanh y)/(1 \pm \tanh x \tanh y)$$

If $y = \mathrm{gd}x$ (gudermannian of x) is defined by

$$x = \log_e \tan(\tfrac{1}{4}\pi + \tfrac{1}{2}y)$$

then

$$\sinh x = \tan y$$

$$\cosh x = \sec y$$

$$\tanh x = \sin y$$

$$\tanh(x/2) = \tan(y/2)$$

HYPERBOLIC TRIGONOMETRY

Hyperbolic (or pseudospherical) trigonometry applies to triangles drawn in the hyperbolic type of non-Euclidean space. Reflection charts, used in transmission-line theory and waveguide analysis, are models of this hyperbolic space.*

Conformal Model

The space is limited to the inside of a unit circle, Γ. Geodesics (or "straight lines" for the model) are arcs of circle orthogonal to Γ as shown in Fig. 6. The hyperbolic distance between two points A and B is defined by

$$[AB] = \log_e[(BI/BJ):(AI/AJ)]$$

where I and J are the intersections with Γ of geodesic AB. The distance $[AB]$ is expressed in nepers. For engineering purposes, a unit corresponding to the decibel and equal to 1/8.686 neper is sometimes used.

As this model is conformal, the angle between two lines is the ordinary angle between the tangents at their common point.

* G. A. Deschamps, *Hyperbolic Protractor for Microwave Impedance Measurements and Other Purposes*. New York: International Telephone and Telegraph Corp., 1953.

Projective Model

The space is again composed of the points inside a circle, Γ. Geodesics are straight-line segments limited to the inside of Γ (JI in Fig. 7).

The hyperbolic distance AB is defined by

$$\langle AB \rangle = \tfrac{1}{2}\log_e[(BI/BJ):(AI/AJ)]$$

and can be measured directly by means of a hyperbolic protractor. The angles for this model do not appear in true size except when at the center of Γ. An angle such as BAC, when it is considered in reference to the projective model, will be called an *elliptic* angle. It can be evaluated, as shown in Fig. 8, by projecting B and C through the hyperbolic midpoint of OA onto B' and C' on circle Γ, then measuring $B'OC'$ as in Euclidean geometry.

The two models in Fig. 9 drawn inside the same circle Γ can be set into a distance-preserving correspondence by the transformation: $\mathfrak{B}(M) = M'$ defined by

$$[OM] = \langle OM' \rangle$$

or in terms of ordinary distances

$$OM' = 2OM/(1 + OM^2)$$

The hyperbolic distance to the center O being denoted by u

$$OM = \tanh(u/2)$$

and

$$OM' = \tanh u$$

The points on Γ are at an infinite distance from any point inside Γ.

In the following equations, the sides are expressed in nepers, the angles in radians. The three points A,B,C are assumed to be inside circle Γ.

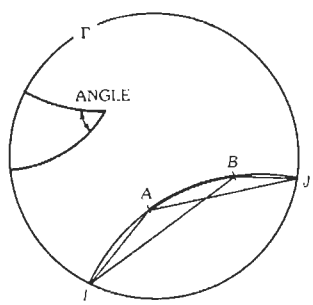

Fig. 6. Conformal model.

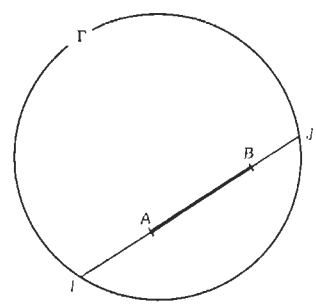

Fig. 7. Projective model.

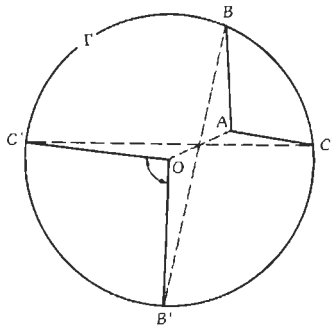

Fig. 8. Construction of angle on projective model.

Right Hyperbolic Triangles ($\gamma = 90°$)

Refer to Figs. 10 and 11.

$$\cosh c = \cosh a \cosh b$$

$$= \cot\alpha \cot\beta$$

$$\cos\alpha = \sin\beta \cosh a$$

$$= \tanh b \coth c$$

$$\cos\beta = \sin\alpha \cosh b$$

$$= \tanh a \coth c$$

When B is at infinity, i.e., on Γ

$$\cos A = \tanh b$$

$$\cot A = \sinh b$$

$$\csc A = \cosh b$$

$$\tan\tfrac{1}{2}A = \exp b$$

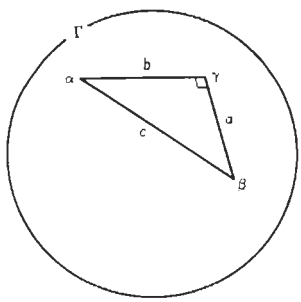

Fig. 10. Projective representation of right hyperbolic triangle.

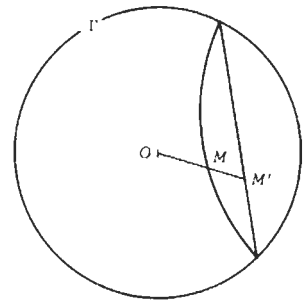

Fig. 9. Correspondence between the two models.

or

$$(\pi/2) - A = \mathrm{gd}b$$

(See definition of gd in section "Hyperbolic Functions.")

CB and AB are "parallel." A is also called angle of parallelism and is noted by

$$A = \Pi(b)$$

$$= \pi/2 - \mathrm{gd}b$$

Oblique Hyperbolic Triangles

Law of Cosines:

$$\cosh a = \cosh b \cosh c - \sinh b \sinh c \cos\alpha$$

and permutations (Eq. 13a)

$$\cos\alpha = -\cos\beta \cos\gamma + \sin\beta \sin\gamma \cosh a$$

and permutations (Eq. 13b)

Law of Sines (Fig. 12):

$$\sinh a/\sin\alpha = \sinh b/\sin\beta = \sinh c/\sin\gamma \quad \text{(Eq. 14)}$$

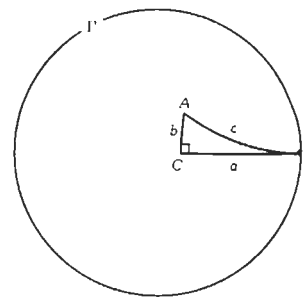

Fig. 11. Conformal representation of right hyperbolic triangle with B at infinity.

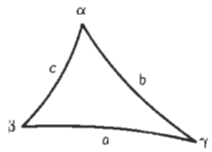

Fig. 12. Oblique hyperbolic triangle.

Napier's Analogies:

$$\frac{\sin\frac{1}{2}(\alpha-\beta)}{\sin\frac{1}{2}(\alpha+\beta)}=\frac{\tanh\frac{1}{2}(a-b)}{\tanh\frac{1}{2}c} \quad \text{(Eq. 15a)}$$

$$\frac{\cos\frac{1}{2}(\alpha-\beta)}{\cos\frac{1}{2}(\alpha+\beta)}=\frac{\tan\frac{1}{2}(a+b)}{\tanh\frac{1}{2}c} \quad \text{(Eq. 15b)}$$

$$\frac{\sinh\frac{1}{2}(a-b)}{\sinh\frac{1}{2}(a+b)}=\frac{\tan\frac{1}{2}(\alpha-\beta)}{\cot\frac{1}{2}\gamma} \quad \text{(Eq. 15c)}$$

$$\frac{\cosh\frac{1}{2}(a-b)}{\cosh\frac{1}{2}(a+b)}=\frac{\tan\frac{1}{2}(\alpha+\beta)}{\cot\frac{1}{2}\gamma} \quad \text{(Eq. 15d)}$$

Half-Angle Equations:

$$\tan\tfrac{1}{2}\alpha=\tanh r/\sinh(p-\alpha)$$

and permutations where $2p=a+b+c$ and

$$\tanh^2 r=\frac{\sinh(p-a)\sinh(p-b)\sinh(p-c)}{\sinh p} \quad \text{(Eq. 16a)}$$

$$\sin^2\tfrac{1}{2}\alpha=\frac{\sinh(p-b)\sinh(p-c)}{\sinh b\sinh c}$$

$$\cos^2\tfrac{1}{2}\alpha=\frac{\sinh p\sinh(p-a)}{\sinh b\sinh c}$$

$$\tan^2\tfrac{1}{2}\alpha=\frac{\sinh(p-b)\sinh(p-c)}{\sinh p\sin(p-a)} \quad \text{(Eq. 16b)}$$

Half-Side Equations:

$$\coth\tfrac{1}{2}a=\coth R/\sin(\Delta+\alpha)$$

and permutations where $2\Delta=\pi-\alpha-\beta-\gamma$ is the hyperbolic defect and

$$\tanh^2 R=\frac{\sin\Delta}{\sin(\Delta+\alpha)\sin(\Delta+\beta)\sin(\Delta+\gamma)} \quad \text{(Eq. 17a)}$$

$$\sinh^2\tfrac{1}{2}a=\frac{\sin\Delta\sin(\Delta+\alpha)}{\sin\beta\sin\gamma}$$

$$\cosh^2\tfrac{1}{2}a=\frac{\sin(\Delta+\beta)\sin(\Delta+\gamma)}{\sin\beta\sin\gamma}$$

$$\tanh^2\tfrac{1}{2}a=\frac{\sin\Delta\sin(\Delta+\alpha)}{\sin(\Delta+\beta)\sin(\Delta+\gamma)} \quad \text{(Eq. 17b)}$$

Area: The hyperbolic area of a triangle is equal to the hyperbolic defect.

$$2\Delta=\pi-(\alpha+\beta+\gamma) \quad \text{(Eq. 18)}$$

Solving an Oblique Hyperbolic Triangle: Solution of an oblique hyperbolic triangle is analogous to that for an oblique spherical triangle, as follows.

Given	Use Eq.	To Obtain
abc	(16)	$\alpha\beta\gamma$
$\alpha\beta\gamma$	(17)	abc
$ab\gamma$	(15)	$\alpha \pm \beta$, hence α, β, then c
$\alpha\beta c$	(15)	$a \pm b$, hence a, b, then γ
$ab\alpha$ ambiguous case	(14) (15)	β $c\gamma$
$\alpha\beta a$ ambiguous case	(14) (15)	b $c\gamma$

PLANE ANALYTIC GEOMETRY

In the following, x and y are coordinates of a variable point in a rectangular-coordinate system.

Straight Line

General Equation:

$$Ax+By+C=0$$

A, B, and C are constants.

Slope-Intercept Form (Fig. 13):

$$y=sx+b$$

b = y-intercept

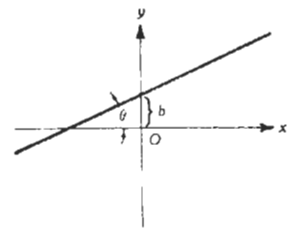

Fig. 13. Slope-intercept.

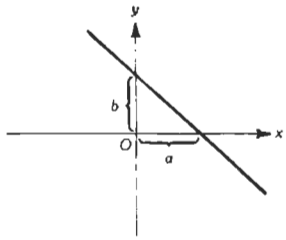

Fig. 14. Intercept-intercept.

$$s = \tan\theta$$

$$= \text{slope}$$

Intercept-Intercept Form (Fig. 14):

$$(x/a) + (y/b) = 1$$

a = x-intercept

b = y-intercept

Point-Slope Form (Fig. 15):

$$y - y_1 = s(x - x_1)$$

$$s = \tan\theta$$

(x_1, y_1) = coordinates of known point on line.

Point-Point Form:

$$(y - y_1)/(y_1 - y_2) = (x - x_1)/(x_1 - x_2)$$

where (x_1, y_1) and (x_2, y_2) are coordinates of two different points on the line.

Normal Form:

$$\frac{A}{\pm(A^2 + B^2)^{1/2}}x + \frac{B}{\pm(A^2 + B^2)^{1/2}}y + \frac{C}{\pm(A^2 + B^2)^{1/2}} = 0$$

The sign of the radical is chosen so that

$$\frac{C}{\pm(A^2 + B^2)^{1/2}} < 0$$

Distance From Point (x_1, y_1) to a Line: Substitute coordinates of the point in the normal form of the line. Thus

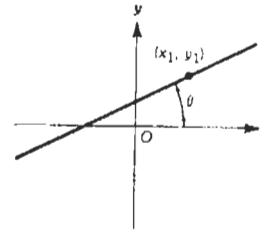

Fig. 15. Point-slope.

$$\text{distance} = \frac{A}{\pm(A^2 + B^2)^{1/2}}x_1 + \frac{B}{\pm(A^2 + B^2)^{1/2}}y_1 + \frac{C}{\pm(A^2 + B^2)^{1/2}}$$

Angle Between Two Lines:

$$\tan\phi = (s_1 - s_2)/(1 + s_1 s_2)$$

where,

ϕ = angle between the lines,
s_1 = slope of one line,
s_2 = slope of other line.

When the lines are mutually perpendicular, $\tan\phi = \pm\infty$, whence

$$s_1 = -1/s_2$$

Transformation of Rectangular Coordinates

Translation:

$$x_1 = h + x_2$$

$$y_1 = k + y_2$$

$$x_2 = x_1 - h$$

$$y_2 = y_1 - k$$

(h, k) = coordinates of new origin referred to old origin

Rotation (Fig. 16):

$$x_1 = x_2\cos\theta - y_2\sin\theta$$

$$y_1 = x_2\sin\theta + y_2\cos\theta$$

$$x_2 = x_1\cos\theta + y_1\sin\theta$$

$$y_2 = -x_1\sin\theta + y_1\cos\theta$$

(x_1, y_1) = "old" coordinates

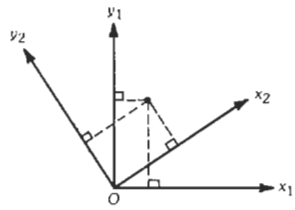

Fig. 16. Rotation of axes.

(x_2, y_2) = "new" coordinates

θ = counterclockwise angle of rotation of axes

Circle

The equation of a circle of radius r with center at (m, n) is

$$(x - m)^2 + (y - n)^2 = r^2$$

Tangent Line to a Circle: At (x_1, y_1) is

$$y - y_1 = -[(x_1 - m)/(y_1 - n)](x - x_1)$$

Normal Line to a Circle: At (x_1, y_1) is

$$y - y_1 = [(y_1 - n)/(x_1 - m)](x - x_1)$$

Parabola

Fig. 17 shows an x-parabola centered at the origin open to the right.

Focus: F
Directrix: D
Vertex: O
Latus rectum: AA'
e = eccentricity = 1
$MP/FP = 1$ for any point P on the parabola

x-Parabola:

$$(y - k)^2 = \pm 2p(x - h)$$

where (h, k) are the coordinates of the vertex, and the sign used is plus or minus when the parabola is open to the right or to the left, respectively. The semilatus rectum is p.

y-Parabola:

$$(x - h)^2 = \pm 2p(y - k)$$

where (h, k) are the coordinates of the vertex. Use plus sign if parabola is open above, and minus sign if open below.

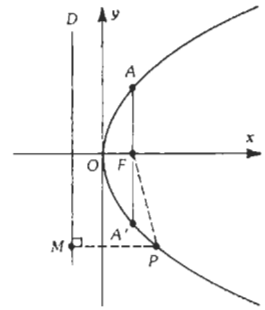

Fig. 17. Parabola.

Tangent Lines to a Parabola:

(x_1, y_1) = point of tangency

For x-parabola

$$y - y_1 = \pm[p/(y_1 - k)](x - x_1)$$

Use plus sign if parabola is open to the right, minus sign if open to the left.

For y-parabola

$$y - y_1 = \pm[(x_1 - h)/p](x - x_1)$$

Use plus sign if parabola is open above, minus sign if open below.

Normal Lines to a Parabola:

(x_1, y_1) = point of contact

For x-parabola

$$y - y_1 = \mp[(y_1 - k)/p](x - x_1)$$

Use minus sign if parabola is open to the right, plus sign if open to the left.

For y-parabola

$$y - y_1 = \mp[p/(x_1 - h)](x - x_1)$$

Use minus sign if parabola is open above, plus sign if open below.

Ellipse

Fig. 18 shows an ellipse centered at the origin. If the ellipse is centered at (h, k) instead, the equations that follow must be modified by replacing x, x_1, y, y_1 by $x - h$, $x_1 - h$, $y - k$, $y_1 - k$, respectively.

Foci: F, F'
Directrices: D, D'

e = eccentricity < 1

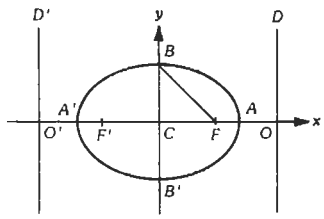

Fig. 18. Ellipse.

$2a = A'A$ = major axis

$2b = BB'$ = minor axis

$2c = FF'$ = focal distance

Then

$$OC = a/e$$

$$BF = a$$

$$FC = ae$$

$$1 - e^2 = b^2/a^2$$

Equation of Ellipse:

$$(x^2/a^2) + (y^2/b^2) = 1$$

Sum of the Focal Radii:

To any point on ellipse $= 2a$

Equation of Tangent Line to Ellipse:

(x_1, y_1) = point of tangency

$$(xx_1/a^2) + (yy_1/b^2) = 1$$

Equation of Normal Line to an Ellipse:

$$y - y_1 = (a^2y_1/b^2x_1)(x - x_1)$$

Hyperbola

Fig. 19 shows an x-hyperbola centered at the origin. If the hyperbola is centered at (h, k) instead, the equations that follow must be modified by replacing x, x_1, y, y_1 by $x - h$, $x_1 - h$, $y - k$, $y_1 - k$, respectively.

Foci: F, F'
Directrices: D, D'

e = eccentricity > 1

$2a$ = transverse axis $= A'A$

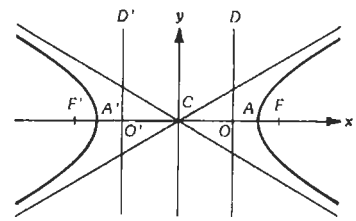

Fig. 19. Hyperbola.

$$CO = a/e$$

$$CF = ae$$

Equation of x-Hyperbola:

$$(x^2/a^2) - (y^2/b^2) = 1$$

where,

$$b^2 = a^2(e^2 - 1)$$

Equation of Conjugate (y-) Hyperbola:

$$(y^2/b^2) - (x^2/a^2) = 1$$

Tangent Line to x-Hyperbola:

(x_1, y_1) = point of tangency

$$a^2y_1y - b^2x_1x = -a^2b^2$$

Normal Line to x-Hyperbola:

$$y - y_1 = -(a^2y_1/b^2x_1)(x - x_1)$$

Asymptotes to Hyperbola:

$$y = \pm(b/a)x$$

SOLID ANALYTIC GEOMETRY

In the following, x, y, and z are the coordinates of a variable point in space in a right-handed rectangular-coordinate system. See Fig. 20.

Coordinates

The coordinates of a point are given by a triplet, e.g., (x_0, y_0, z_0).

Direction Cosines and Numbers

In Fig. 20, α, β, and γ are the angles line OP makes with the x, y, and z axes, respectively. Cosα, cosβ, and cosγ are the direction cosines of line OP. Numbers

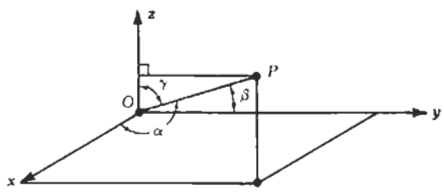

Fig. 20. Coordinates of point P.

proportional to the direction cosines are called direction numbers.

Distance Between Two Points

$$d = [(x_1 - x_0)^2 + (y_1 - y_0)^2 + (z_1 - z_0)^2]^{1/2}$$

Equations of a Plane

General Form:

$$Ax + By + Cz + D = 0$$

Three-Point Form:

$$\begin{vmatrix} x - x_0 & y - y_0 & z - z_0 \\ x_1 - x_0 & y_1 - y_0 & z_1 - z_0 \\ x_2 - x_0 & y_2 - y_0 & z_2 - z_0 \end{vmatrix} = 0$$

where (x_0, y_0, z_0), (x_1, y_1, z_1), and (x_2, y_2, z_2) are three points on the plane.

Intercept Form:

$$(x/a) + (y/b) + (z/c) = 1$$

where a, b, and c are the intercepts on the x, y, and z axes, respectively.

Point-Direction Form:

$$A(x - x_1) + B(y - y_1) + C(z - z_1) = 0$$

where,

A, B, and C are the direction numbers of a normal to the plane,

(x_1, y_1, z_1) is a point on the plane.

Normal Form:

$$x\cos\alpha + y\cos\beta + z\cos\gamma - p = 0$$

where,

$\cos\alpha$, $\cos\beta$, and $\cos\gamma$ are the direction cosines of a normal to the plane,

p is the distance of the plane to the origin.

Equations of a Straight Line

Point-Direction Form:

$$(x - x_1)/A = (y - y_1)/B = (z - z_1)/C$$

or

$$x = At + x_1$$

$$y = Bt + y_1$$

$$z = Ct + z_1 \text{ (parametric)}$$

where,

A, B, and C are direction numbers of the line, (x_1, y_1, z_1) is a point on the line.

Two-Point Form:

$$(x - x_1)/(x_1 - x_0) = (y - y_1)/(y_1 - y_0) = (z - z_1)/(z_1 - z_0)$$

or

$$x = x_0 + (x_1 - x_0)t$$

$$y = y_0 + (y_1 - y_0)t$$

$$z = z_0 + (z_1 - z_0)t \text{ (parametric)}$$

where (x_0, y_0, z_0) and (x_1, y_1, z_1) are two points on the line.

Ellipsoid

$$(x^2/a^2) + (y^2/b^2) + (z^2/c^2) = 1$$

where a, b, c are the semiaxes of the ellipsoid or the intercepts on the x, y, and z axes, respectively.

Prolate Spheroid

$$a^2(y^2 + z^2) + b^2x^2 = a^2b^2$$

where $a > b$, and x-axis = axis of revolution.

Oblate Spheroid

$$b^2(x^2 + z^2) + a^2y^2 = a^2b^2$$

where $a > b$, and y-axis = axis of revolution.

Paraboloid of Revolution

$$y^2 + z^2 = 2px$$

x-axis = axis of revolution

Hyperboloid of Revolution

Revolving an x-hyperbola about the x-axis results in the hyperboloid of two sheets

$$a^2(y^2 + z^2) - b^2x^2 = -a^2b^2$$

Revolving an x-hyperbola about the y-axis results in the hyperboloid of one sheet

$$b^2(x^2 + z^2) - a^2y^2 = a^2b^2$$

DIFFERENTIAL CALCULUS

List of Derivatives

In the following, u, v, w are differentiable functions of x, and c is a constant.

General Equations:

$$dc/dx = 0$$

$$dx/dx = 1$$

$$(d/dx)(u + v - w) = (du/dx) + (dv/dx) - (dw/dx)$$

$$(d/dx)(cv) = c(dv/dx)$$

$$(d/dx)(uv) = u(dv/dx) + v(du/dx)$$

$$(d/dx)(v^c) = cv^{c-1}(dv/dx)$$

$$\frac{d}{dx}\left(\frac{u}{v}\right) = \frac{v(du/dx) - u(dv/dx)}{v^2}$$

$$dy/dx = (dy/dv)(dv/dx), \qquad \text{if } y = y(v)$$

$$dy/dx = (dx/dy)^{-1}, \qquad \text{if } dx/dy \neq 0$$

Transcendental Functions:

$$(d/dx)\ \ln v = v^{-1}(dv/dx)$$

$$(d/dx)\ (c^v) = c^v \ln c(dv/dx)$$

$$(d/dx)\ (e^v) = e^v(dv/dx)$$

$$(d/dx)\ (u^v) = vu^{v-1}(du/dx) + (\ln u)u^v(dv/dx)$$

$$(d/dx)\ (\sin v) = \cos v(dv/dx)$$

$$(d/dx)\ (\cos v) = -\sin v(dv/dx)$$

$$(d/dx)\ (\tan v) = \sec^2 v(dv/dx)$$

$$(d/dx)\ (\cot v) = -\csc^2 v(dv/dx)$$

$$(d/dx)\ (\sec v) = \sec v \tan v(dv/dx)$$

$$(d/dx)\ (\csc v) = \csc v \cot v(dv/dx)$$

$$(d/dx)\ (\arcsin v) = (1 - v^2)^{-1/2}(dv/dx)$$

$$(d/dx)\ (\arccos v) = -(1 - v^2)^{-1/2}(dv/dx)$$

$$(d/dx)\ (\arctan v) = (1 + v^2)^{-1}(dv/dx)$$

$$(d/dx)\ (\operatorname{arc\,cot} v) = -(1 + v^2)^{-1}(dv/dx)$$

$$(d/dx)\ (\operatorname{arc\,sec} v) = [v(v^2 - 1)^{1/2}]^{-1}(dv/dx)$$

$$(d/dx)\ (\operatorname{arc\,csc} v) = -[v(v^2 - 1)^{1/2}]^{-1}(dv/dx)$$

$$(d/dx)\ (\sinh v) = \cosh v(dv/dx)$$

$$(d/dx)\ (\cosh v) = \sinh v(dv/dx)$$

$$(d/dx)\ (\tanh v) = \operatorname{sech}^2 v(dv/dx)$$

TABLE OF INTEGRALS

Indefinite Integrals

General Equations:

$$\int af(x)dx = a\int f(x)dx$$

$$\int [f(x) + g(x)]dx = \int f(x)dx + \int g(x)dx$$

$$(d/dx)\int f(x)dx = f(x)$$

$$(d/dx)\int_u^v f(y, x)dy$$

$$= f(v, x) \cdot (dv/dx) - f(u, x) \cdot (du/dx) + \int_u^v \frac{\partial f(y, x)}{\partial x}dy$$

$$\int f'(x)\, g(x)dx = f(x)\, g(x) - \int f(x)\, g'(x)dx$$

$$\int f(x)dx = \int f[h(y)]h'(y)dy$$

$$\int_{x_1}^{x_2} f(x)dx = \int_{-x_1}^{-x_2} f(-x)dx$$

$$\int \frac{x^m R^n}{(R)^{1/2}}\,dx = \frac{x^{m-1}R^n(R)^{1/2}}{(2n+m)a} - \frac{(2n+2m+1)b}{2a(2n+m)}\int \frac{x^{m-1}R^n dx}{(R)^{1/2}} - \frac{(m-1)c}{(2n+m)a}\int \frac{x^{m-2}R^n dx}{(R)^{1/2}}$$

$$\int \frac{dx}{x^m R^n(R)^{1/2}} = -\frac{(R)^{1/2}}{(m-1)cx^{m-1}R^n} - \frac{(2n+2m-3)b}{2c(m-1)}\int \frac{dx}{x^{m-1}R^n(R)^{1/2}} - \frac{(2n+m-2)a}{(m-1)c}\int \frac{dx}{x^{m-2}R^n(R)^{1/2}}$$

$$\int \frac{R^n dx}{x^m(R)^{1/2}} = -\frac{R^{n-1}(R)^{1/2}}{(m-1)x^{m-1}} + \frac{(2n-1)b}{2(m-1)}\int \frac{R^{n-1}dx}{x^{m-1}(R)^{1/2}} + \frac{(2n-1)a}{m-1}\int \frac{R^{n-1}dx}{x^{m-2}(R)^{1/2}}$$

Logarithmic Integrands

$$\int \ln ax\,dx = x(\ln ax - 1)$$

$$\int \log_b x\,dx = \log_b e(\ln x - 1)x = [(\ln x - 1)x/\ln b]$$

$$\int (\ln x)^n dx = x(\ln x)^n - n\int (\ln x)^{n-1}dx$$

$$\int x^m \ln x\,dx = x^{m+1}[(m+1)^{-1}\ln x - (m+1)^{-2}],\ m \neq -1$$

$$\int \frac{\ln x}{x}dx = \tfrac{1}{2}(\ln x)^2$$

$$\int x^m(\ln x)^n dx = [x^{m+1}(\ln x)^n/(m+1)] - [n/(m+1)]\int x^m(\ln x)^{n-1}dx,\ m \neq -1$$

$$\int [(\ln x)^n/x]dx = (\ln x)^{n+1}/(n+1),\ n \neq -1$$

$$\int dx/(x \ln x) = \ln|\ln x|$$

$$\int \frac{x^m dx}{(\ln x)^n} = -\frac{x^{m+1}}{(n-1)(\ln x)^{n-1}} + \frac{m+1}{n-1}\int \frac{x^m dx}{(\ln x)^{n-1}},\ n \neq 1$$

$$\int (x^m/\ln x)dx = \mathrm{Ei}[(n+1)\ln x],\quad m \neq -1$$

Exponential Integrands

$$\int a^{bx}dx = a^{bx}/(b \ln a)$$

$$\int x^m e^x dx = x^m e^x - m\int x^{m-1} e^x\,dx$$

$$\int dx/(a + be^{mx}) = (x/a) - (am)^{-1}\ln|a + be^{mx}|,\quad a \text{ and } m \neq 0$$

$$\int \frac{dx}{(a+be^{mx})^{1/2}} = [m(a)^{1/2}]^{-1}\ln\frac{(a+be^{mx})^{1/2} - (a)^{1/2}}{(a+be^{mx})^{1/2} + (a)^{1/2}},\quad a > 0$$

$$= \{2/[m(-a)^{1/2}]\}\arctan[(a+be^{mx})^{1/2}/(-a)^{1/2}],\quad a < 0$$

Trigonometric Integrands

$$\int \sin^2 x dx = \tfrac{1}{2}(x - \sin x \cos x)$$

$$\int \sin^n x dx = -[(\sin^{n-1}x \cos x)/n] + (n-1)/n\int \sin^{n-2}x dx$$

$$\int \cos^2 x dx = \tfrac{1}{2}(x + \sin x \cos x)$$

$$\int \cos^n x dx = [(\cos^{n-1}x \sin x)/n] + (n-1)/n\int \cos^{n-2}x dx$$

$$\int \sin x \cos^m x dx = -\cos^{m+1} x/(m+1)$$

$$\int \sin^m x \cos x dx = \sin^{m+1} x/(m+1)$$

$$\int \sin^n x \cos^m x = \frac{\cos^{m-1} x \sin^{n+1} x}{m+n} + \frac{m-1}{m+n}\int \cos^{m-2} x \sin^n x dx$$

$$= -\frac{\sin^{n-1} x \cos^{m+1} x}{m+n} + \frac{n-1}{m+n}\int \cos^m x \sin^{n-2} x dx$$

$$\int \frac{\sin^n x dx}{\cos^m x} = (m-1)^{-1}\left[\frac{\sin^{n-1} x}{\cos^{m-1} x} - (n-1)\int \frac{\sin^{n-2} x dx}{\cos^{m-2} x}\right]$$

$$\int \frac{\cos^m x}{\sin^n x} dx = -(n-1)^{-1}\left[\frac{\cos^{m-1} x}{\sin^{n-1} x} - (m-1)\int \frac{\cos^{m-2} x dx}{\sin^{n-2} x}\right]$$

$$\int \frac{dx}{\sin^m x \cos^n x} = [(n-1)\sin^{m-1} x \cos^{n-1} x]^{-1} + \frac{m+n-2}{n-1}\int \frac{dx}{\sin^m x \cos^{n-2} x}$$

$$= -[(m-1)\sin^{m-1} x \cos^{n-1} x]^{-1} + \frac{m+n-2}{m-1}\int \frac{dx}{\sin^{m-2} x \cos^n x}$$

$$\int \tan^n x dx = [\tan^{n-1} x/(n-1)] - \int \tan^{n-2} x dx$$

$$\int \cot^n x dx = -[\cot^{n-1} x/(n-1)] - \int \cot^{n-2} x dx$$

$$\int \sec^2 x dx = \tan x$$

$$\int \sec^n x dx = [\sin x/(n-1)\cos^{n-1} x] + [(n-2)/(n-1)]\int \sec^{n-2} x dx,\ n \neq 1$$

$$\int \frac{dx}{a + b\cos x + c\sin x} = \frac{2}{(a^2 - b^2 - c^2)^{1/2}} \tan^{-1} \frac{(a-b)\tan(x/2) + c}{(a^2 - b^2 - c^2)^{1/2}},\ a^2 > b^2 + c^2$$

$$= (b^2 + c^2 - a^2)^{-1/2} \ln \left| \frac{(a-b)\tan(x/2) + c - (b^2 + c^2 - a^2)^{1/2}}{(a-b)\tan(x/2) + c + (b^2 + c^2 - a^2)^{1/2}} \right|,\ a^2 < b^2 + c^2,\ a \neq b$$

$$= c^{-1} \ln|a + c\tan(x/2)|,\ a = b$$

$$= \frac{-2}{c + (a-b)\tan(x/2)},\quad a^2 = b^2 + c^2$$

$$\int x^n \sin ax dx = -\sum_{k=0}^{n} k! \binom{n}{k} \frac{x^{n-k}}{a^{k+1}} \cos[ax + (k\pi/2)],\ n \text{ nonnegative integer}$$

$$\int x^n \cos ax dx = \sum_{k=0}^{n} k! \binom{n}{k} \frac{x^{n-k}}{a^{k+1}} \sin[ax + (k\pi/2)],\ n \text{ nonnegative integer}$$

Inverse Trigonometric Integrals, x and $a > 0$:

$$\int \sin^{-1}(x/a)dx = x \sin^{-1}(x/a) + (a^2 - x^2)^{1/2}$$

$$\int \cos^{-1}(x/a)dx = x \cos^{-1}(x/a) - (a^2 - x^2)^{1/2}$$

$$\int \tan^{-1}(x/a)dx = x \tan^{-1}(x/a) - \tfrac{1}{2}a \ln(a^2 + x^2)$$

$$\int \cot^{-1}(x/a)dx = x \cot^{-1}(x/a) + \tfrac{1}{2}a \ln(a^2 + x^2)$$

$$\int \sec^{-1}(x/a)dx = x \sec^{-1}(x/a) - a \ln[x + (x^2 - a^2)^{1/2}]$$

$$\int \csc^{-1}(x/a)dx = x \csc^{-1}(x/a) + a \ln[x + (x^2 - a^2)^{1/2}]$$

$$\int x \sin^{-1}x dx = \tfrac{1}{4}[(2x^2 - 1)\sin^{-1}x + x(1 - x^2)^{1/2}]$$

$$\int x \cos^{-1}x dx = \tfrac{1}{4}[(2x^2 - 1)\cos^{-1}x - x(1 - x^2)^{1/2}]$$

$$\int x^n \sin^{-1}x dx = [x^{n+1}\sin^{-1}x/(n + 1)] - (n + 1)^{-1}\int [x^{n+1}/(1 - x^2)^{1/2}]dx$$

$$\int x^n \cos^{-1}x dx = [x^{n+1}\cos^{-1}x/(n + 1)] + (n + 1)^{-1}\int [x^{n+1}/(1 - x^2)^{1/2}]dx$$

Miscellaneous Integrals:

$$\int \frac{dx}{ax^3 + b} = \frac{p}{3b}\left[\tfrac{1}{2}\ln\frac{(x + p)^2}{x^2 - px + p^2} + \sqrt{3}\arctan\frac{x\sqrt{3}}{2p - x}\right], \quad p = (b/a)^{1/3}$$

$$\int \frac{dx}{x^4 + a^4} = (4a^3\sqrt{2})^{-1}\left[\ln\left(\frac{x^2 + ax\sqrt{2} + a^2}{x^2 - ax\sqrt{2} + a^2}\right) + 2\tan^{-1}\left(\frac{ax\sqrt{2}}{a^2 - x^2}\right)\right]$$

$$\int \frac{dx}{x^4 - a^4} = (1/4a^3)\left[\ln\left(\frac{x - a}{x + a}\right) - 2\tan^{-1}(x/a)\right]$$

Definite Integrals

$$\int_0^1 x^u(1 - x)^v dx = [\Gamma(u + 1)\Gamma(v + 1)/\Gamma(u + v + 2)], \quad u > -1, \; v > -1$$

$$= [u!v!/(u + v + 1)!], \text{ if } u, v \text{ nonnegative integers}$$

$$\int_0^{\pi} \ln(a + b\cos x)dx = \pi \ln \tfrac{1}{2}[a + (a^2 - b^2)^{1/2}],\ a \geq b$$

SERIES

Taylor's Series for a Single Variable

$$f(z) = f(a) + f'(a)(z-a) + \tfrac{1}{2}[f''(a)](z-a)^2 + \cdots + [f^{(n)}(a)/n!](z-a)^n + R_n$$

$$= \sum_{k=0}^{n} (k!)^{-1} f^{(k)}(a)(z-a)^k + R_n$$

where the remainder is bounded by $|R_n| \leq [M/(n+1)!]\,|z-a|^{n+1}$ in which

$$M = \max_{0 \leq \theta \leq 1} |f^{(n+1)}[a + \theta(z-a)]|$$

If a, z, and f are real, then there exists a real θ, $0 < \theta < 1$, such that the remainder is

$$R_n = \{f^{(n+1)}[a + \theta(z-a)]/(n+1)!\}(z-a)^{n+1}$$

When $a = 0$, this series is often called MacLaurin's series.

Taylor's Series for Two Variables

$$f(x, y) = f(a, b) + \left[\left.\frac{\partial f(x, y)}{\partial x}\right|_{x=a,y=b}(x - a) + \left.\frac{\partial f(x, y)}{\partial y}\right|_{x=a,y=b}(y - b)\right]$$

$$+ \tfrac{1}{2}\left[\left.\frac{\partial^2 f(x, y)}{\partial x^2}\right|_{x=a,y=b}(x - a)^2 + 2\left.\frac{\partial^2 f(x, y)}{\partial x \partial y}\right|_{x=a,y=b}(x - a)(y - b) + \left.\frac{\partial^2 f(x, y)}{\partial y^2}\right|_{x=a,y=b}(y - b)^2\right] + \cdots$$

$$= \sum_{k=0}^{n} (k!)^{-1}\{[(x - a)(\partial/\partial\xi) + (y - b)(\partial/\partial\eta)]^k f(\xi, \eta)\}_{\xi=a,\eta=b} + R_n$$

where the remainder is bounded by $|R_n| \leq [M/(n + 1)!](|x - a| + |y - b|)^{n+1}$ in which

$$M = \max_{\substack{k=0,1,2,\cdots,n+1 \\ 0\leq\theta\leq 1}} |\partial^{n+1} f(\xi, \eta)/\partial^k \xi \partial^{n+1-k}\eta|, \quad \xi = a + \theta(x - a), \quad \eta = b + \theta(y - b)$$

If $f(x, y)$ is a real function of two variables, there exists a number θ, $0 < \theta < 1$ such that the remainder is

$$R_n = [(n + 1)!]^{-1}\{[(x - a)(\partial/\partial\xi) + (y - b)(\partial/\partial\eta)]^{n+1} f(\xi, \eta)\}, \quad \xi = a + \theta(x - a), \quad \eta = b + \theta(y - b)$$

Miscellaneous Series

$$\ln(1 + x) = x - \tfrac{1}{2}x^2 + \tfrac{1}{3}x^3 - \tfrac{1}{4}x^4 + \cdots = -\sum_{k=1}^{\infty} (-1)^k \frac{x^k}{k}, \quad |x| < 1$$

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots = \sum_{k=0}^{\infty} \frac{x^k}{k!}, \quad |x| < \infty$$

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \cdots = \sum_{k=0}^{\infty} (-1)^k \frac{x^{2k+1}}{(2k + 1)!}, \quad |x| < \infty$$

$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \cdots = \sum_{k=0}^{\infty} (-1)^k \frac{x^{2k}}{(2k)!}, \quad |x| < \infty$$

$$\sinh x = x + \frac{x^3}{3!} + \frac{x^5}{5!} + \frac{x^7}{7!} + \cdots = \sum_{k=0}^{\infty} \frac{x^{2k+1}}{(2k + 1)!}, \quad |x| < \infty$$

$$\cosh x = 1 + \frac{x^2}{2!} + \frac{x^4}{4!} + \frac{x^6}{6!} + \cdots = \sum_{k=0}^{\infty} \frac{x^{2k}}{(2k)!}, \quad |x| < \infty$$

$$\tan x = x + \frac{x^3}{3} + \frac{2x^5}{15} + \frac{17x^7}{315} + \frac{62x^9}{2835} + \cdots, \quad |x| < \tfrac{1}{2}\pi$$

$$\cot x = \frac{1}{x} - \frac{x}{3} - \frac{x^3}{45} - \frac{2x^5}{945} - \frac{x^7}{4725} - \cdots, \quad |x| < \pi$$

$$\text{arc } \sin x = x + \frac{1}{2}\frac{x^3}{3} + \frac{1 \cdot 3}{2 \cdot 4}\frac{x^5}{5} + \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6}\frac{x^7}{7} + \cdots, \quad |x| < 1$$

$$\text{arc } \tan x = x - \tfrac{1}{3}x^3 + \tfrac{1}{5}x^5 - \tfrac{1}{7}x^7 + \cdots, \quad |x| < 1$$

$$\text{arc } \sinh x = x - \frac{1}{2}\frac{x^3}{3} + \frac{1 \cdot 3}{2 \cdot 4}\frac{x^5}{5} - \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6}\frac{x^7}{7} + \cdots, \quad |x| < 1$$

$$\text{arc } \tanh x = x + \tfrac{1}{3}x^3 + \tfrac{1}{5}x^5 + \tfrac{1}{7}x^7 + \cdots, \quad |x| < 1$$

MATRIX ALGEBRA

Notation

A matrix of order $m \times n$ is a rectangular array of numbers, real or complex, consisting of m rows and n columns:

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} & a_{13} & \cdots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \cdots & a_{2n} \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ a_{m1} & a_{m2} & a_{m3} & \cdots & a_{mn} \end{bmatrix} = [a_{ij}]$$

A row (column) vector is a $1 \times n$ ($n \times 1$) matrix. An $n \times n$ matrix is called a square matrix. A matrix with all entries equal to zero is called a zero matrix; it is denoted by $\mathbf{0}$. A square zero matrix with the elements on the main diagonal, that is, the diagonal extending from the upper left corner to the lower right corner, replaced by ones is called an identity matrix. It is denoted by $\mathbf{I}_n$ *or* $\mathbf{I}$. A square matrix with all entries zero above or below the main diagonal is called triangular. For example,

$$(1,2,5), \quad \begin{bmatrix} 2 \\ 3 \end{bmatrix}, \quad \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{bmatrix},$$

$$\begin{bmatrix} 1 & 4 & 3 & 4 \\ 0 & 3 & -1 & 5 \\ 0 & 0 & 4 & -2 \\ 0 & 0 & 0 & 2 \end{bmatrix}, \quad \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

are row, column, zero, triangular, and identity matrices, respectively.

Operations

Addition and Subtraction: If $\mathbf{A}$ and $\mathbf{B}$ are matrices of the same order with elements a_{ij} and b_{ij}, respectively, the matrix

$$\mathbf{C} = \mathbf{A} \pm \mathbf{B}$$

has elements

$$c_{ij} = a_{ij} \pm b_{ij}, \quad i = 1, 2, \cdots, m; j = 1, 2, \cdots, n$$

Multiplication by a Number: If k is a number, real or complex, the matrix

$$\mathbf{C} = k\mathbf{A}$$

has elements

$$c_{ij} = ka_{ij}, \quad i = 1, 2, \cdots, m; j = 1, 2, \cdots, n$$

Multiplication of Two Matrices: Let $\mathbf{A}$ and $\mathbf{B}$ be two matrices of orders $m \times n$ and $n \times p$, respectively. The matrix

$$\mathbf{C} = \mathbf{AB}$$

will have elements

$$c_{ij} = \sum_{k=1}^{n} a_{ik} b_{kj}, \quad i = 1, 2, \cdots, m; j = 1, 2, \cdots, p$$

Matrix $\mathbf{C}$ has order $m \times p$. Note that the product $\mathbf{BA}$ is defined only when $m = p$. In general $\mathbf{AB} \neq \mathbf{BA}$ even when $m = n = p$, so it is necessary to distinguish between premultiplication and postmultiplication.

For a square matrix $\mathbf{A}$ of order n, powers are defined

$$\mathbf{A}^0 = \mathbf{I}, \mathbf{A}^1 = \mathbf{A}, \mathbf{A}^2 = \mathbf{A} \cdot \mathbf{A}, \mathbf{A}^3 = \mathbf{A} \cdot \mathbf{A}^2, \text{ etc.}$$

A polynomial function of $\mathbf{A}$ is a square matrix of order n given by

$$P(\mathbf{A}) = a_n\mathbf{A}^n + a_{n-1}\mathbf{A}^{n-1} + \cdots + a_1\mathbf{A}^1 + a_0\mathbf{A}^0$$

where the a_i are real or complex numbers.

Division of Two Matrices: Not defined.

Determinant

Definition: The determinant of a square matrix $\mathbf{A}$ of order n is usually defined

$$|\mathbf{A}| = \sum \pm a_{1i}a_{2j} \cdots a_{nr}$$

where the second subscripts $i, j, \cdots, r$ form a permutation (rearrangement) of the integers $1, 2, \cdots, n$. The sum is taken over all permutations with a plus (minus) sign if the permutation is even (odd). A permutation is called even (odd) if an even (odd) number of inversions is necessary to attain the natural or ascending order. For example, 4132→1432→1342→1324→1234; therefore, 4132 is an even permutation.

A square matrix is said to be singular if its determinant is zero and nonsingular otherwise.

Laplace's Development: By an expansion known as Laplace's development, the determinant of a matrix $\mathbf{A}$ of order n can be expressed in terms of determinants of matrices of order $n - 1$.

$$|\mathbf{A}| = \sum_{j=1}^{n} (-1)^{i+j} a_{ij} M_{ij}$$

(expansion by the ith row)

$$= \sum_{i=1}^{n} (-1)^{i+j} a_{ij} M_{ij}$$

(expansion by the jth column)

The notation M_{ij} represents the determinant of the matrix formed by deleting the ith row and jth column of $\mathbf{A}$. Expanding by any row or column will lead to the

same value of $|\mathbf{A}|$. The M_{ij} are in turn evaluated in terms of determinants of order $n - 2$. This process is continued until, say, second-order determinants are obtained.

$$\begin{vmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{vmatrix} = b_{11}b_{22} - b_{12}b_{21}$$

A first-order determinant has a value equal to its only entry. M_{ij} is called the minor and $(-1)^{i+j} \times M_{ij} = A_{ij}$ is called the cofactor of the element a_{ij}.

Laplace's development is valuable for a literal expansion. For numerical evaluation of determinants of large order, say greater than four, the Gauss algorithm described in the next subsection requires less effort.

Linear Transformations

The linear transformation or set of equations

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + \cdots + a_{1n}x_n &= y_1 \\ a_{21}x_1 + a_{22}x_2 + \cdots + a_{2n}x_n &= y_2 \\ \vdots \\ a_{m1}x_1 + a_{m2}x_2 + \cdots + a_{mn}x_n &= y_m \end{aligned}$$

may be compactly written in matrix form

$$\mathbf{AX} = \mathbf{Y}$$

where $\mathbf{A} = [a_{ij}]$ is a matrix of order $m \times n$, and $\mathbf{X}$ and $\mathbf{Y}$ are column vectors.

Inverse Matrix: If $m = n$ and $|\mathbf{A}| \neq 0$, then there exists an inverse matrix denoted by $\mathbf{A}^{-1}$ such that $\mathbf{AA}^{-1} = \mathbf{A}^{-1}\mathbf{A} = \mathbf{I}$. The inverse transformation expressing the x's in terms of the y's may then be compactly written

$$\mathbf{X} = \mathbf{A}^{-1}\mathbf{Y}$$

This inverse transformation may be effected using *Cramer's rule*

$$x_i = (1/|\mathbf{A}|) \sum_{k=1}^{n} A_{ki}\, y_k,\ i = 1, 2, \cdots, n$$

where A_{ki} denotes the cofactor associated with the element a_{ki} in the original matrix $\mathbf{A}$. Cramer's rule provides a useful literal expansion of the solution. However, numerical evaluation of the determinants involved, say Laplace's development, requires of the order of $n!$ operations.

The following *Gauss algorithm* requires only of the order of n^3 operations and is therefore preferred for numerical evaluation when n is large: Renumber the x_k's if necessary to make $a_{11} \neq 0$. Normalize the first equation by dividing it by a_{11}. If $a_{21} = 0$, leave the second equation intact. If $a_{21} \neq 0$, eliminate x_1 by subtracting the normalized first equation multiplied by a_{21} from the second equation. Similarly, eliminate x_1 from the remaining $n - 2$ equations. The result is

$$\begin{aligned} x_1 + (a_{12}/a_{11})x_2 + (a_{13}/a_{11})x_3 + \cdots + (a_{1n}/a_{11})x_n &= (y_1/a_{11}) \\ [a_{22} - a_{21}(a_{12}/a_{11})]x_2 + [a_{23} - a_{21}(a_{13}/a_{11})]x_3 + \cdots + [a_{2n} - a_{21}(a_{1n}/a_{11})]x_n &= y_2 - a_{21}(y_1/a_{11}) \\ \vdots \\ [a_{n2} - a_{n1}(a_{12}/a_{11})]x_2 + [a_{n3} - a_{n1}(a_{13}/a_{11})]x_3 + \cdots + [a_{nn} - a_{n1}(a_{1n}/a_{11})]x_n &= y_n - a_{n1}(y_1/a_{11}) \end{aligned}$$

The entire process is now repeated with the first equation omitted. There then results a set of the form

$$\begin{aligned} x_1 + b_{12}x_2 + b_{13}x_3 + \cdots + b_{1n}x_n &= c_{11}y_1 \\ x_2 + b_{23}x_3 + \cdots + b_{2n}x_n &= c_{21}y_1 + c_{22}y_2 \\ b_{33}x_3 + \cdots + b_{3n}x_n &= c_{31}y_1 + c_{32}y_2 + c_{33}y_3 \\ \vdots \\ b_{n3}x_3 + \cdots + b_{nn}x_n &= c_{n1}y_1 + c_{n2}y_2 + c_{nn}y_n \end{aligned}$$

Again the process is repeated with the first two equations omitted. Continuing in this manner yields a triangular form

$$\begin{aligned} x_1 + b_{12}x_2 + b_{13}x_3 + b_{14}x_4 + \cdots + b_{1n}x_n &= c_{11}y_1 \\ x_2 + b_{23}x_3 + b_{24}x_4 + \cdots + b_{2n}x_n &= c_{21}y_1 + c_{22}y_2 \\ x_3 + d_{34}x_4 + \cdots + d_{3n}x_n &= e_{31}y_1 + e_{32}y_2 + e_{33}y_3 \\ x_4 + \cdots + d_{4n}x_n &= e_{41}y_1 + e_{42}y_2 + e_{43}y_3 + e_{44}y_4 \\ \vdots \\ x_n &= e_{n1}y_1 + e_{n2}y_2 + e_{n3}y_3 + \cdots + e_{nn}y_n \end{aligned}$$

Note that the last equation gives the value of x_n. This may be substituted in the next to the last equation to obtain x_{n-1} and so on. If the y's are literal as shown above, the process will yield the inverse transformation

$$\mathbf{X} = \mathbf{A}^{-1}\mathbf{Y}$$

where $\mathbf{A}^{-1}$ is the inverse of the original matrix. If the y's are numerical, labor is saved by combining the values on the right side of each equation at each step of the algorithm.

Since the determinant of a triangular matrix is equal to the product of the elements on the main diagonal

$$|\mathbf{A}| = a_{11}a_{22}'a_{33}' \cdots a_{nn}'$$

where a_{kk}' is the quantity the kth equation is divided by in the above Gauss algorithm. This is useful for evaluating determinants of large order since it requires only of the order of n^3 operations.

A matrix $\mathbf{A}$ may be viewed as consisting of column or row vectors. The largest number of linearly independent column vectors (which is the same as the largest number of linearly independent row vectors) is called the *rank* of the matrix, $\rho(\mathbf{A})$. A set of vectors $\mathbf{V}_i$ is linearly independent if

$$\sum_i a_i\mathbf{V}_i = \mathbf{0}$$

implies that $a_i = 0$ for $i = 1, 2, \cdots$.

The rank is equal to the order of the largest nonvanishing determinant of the submatrix by deleting rows and columns of the original matrix. Consider the matrices

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ & & \vdots & \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{bmatrix}$$

and

$$\mathbf{B} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} & y_1 \\ a_{21} & a_{22} & \cdots & a_{2n} & y_2 \\ & & \vdots & & \\ a_{m1} & a_{m2} & \cdots & a_{mn} & y_m \end{bmatrix}$$

The equations

$$\mathbf{AX} = \mathbf{Y}$$

have a solution if and only if

$$\rho(\mathbf{A}) = \rho(\mathbf{B})$$

in which case the equations are said to be consistent.

If $\rho(\mathbf{A}) < n = m$, that is, $|\mathbf{A}| = 0$, and if the equations are consistent, then the Gauss algorithm will terminate before n steps. That is, the coefficients of all the x_k's will be zero in the remaining $n - \rho(\mathbf{A})$ equations. Therefore, among the x_k's there will be certain ones, $n - \rho(\mathbf{A})$ in number, which may be assigned arbitrary values. Similarly, if $m \neq n$, the Gauss algorithm will yield an equivalent set of $\rho(\mathbf{A})$ equations that has the same solution as the original set. Again $n - \rho(\mathbf{A})$ (possibly zero) of the x_k's may be assigned arbitrary values.

It is not necessary to know beforehand whether the equations are inconsistent. If they are inconsistent, the algorithm will yield an "equation" in which the coefficients of the x_k's on the left side are zero but there is a nonzero combination of the y_k's on the right side. Since the right side of the "equation" may contain accumulated round-off errors, an analysis of the error propagation in the Gauss algorithm may be necessary to determine whether a small right side is caused by inconsistent equations or by round-off errors.

Eigenvectors and Eigenvalues

An eigenvector of the square matrix $\mathbf{A}$ of order n is nonzero vector $\mathbf{X}$ such that

$$\mathbf{AX} = \lambda\mathbf{X}$$

The scalar λ is called an eigenvalue of $\mathbf{A}$, and $\mathbf{X}$ is called an eigenvector corresponding to or associated with λ. The eigenvalues may be determined from the characteristic equation

$$|\mathbf{A} - \lambda\mathbf{I}| = 0$$

The corresponding eigenvectors $\mathbf{X}$ may then be found by solving

$$(\mathbf{A} - \lambda\mathbf{I})\mathbf{X} = \mathbf{0}$$

The solution may be obtained by the Gauss algorithm. If the eigenvalues λ are distinct, an explicit solution may be obtained by taking a nontrivial row of cofactors from $\mathbf{A} - \lambda_i\mathbf{I}$. This is possible since the rank of $\mathbf{A} - \lambda_i\mathbf{I}$ is $n - 1$ and, therefore, there exists a nonvanishing subdeterminant of order $n - 1$.

Note that eigenvectors are determined only to within a multiplicative constant.

Further Definitions and Properties

The matrix whose elements are a_{ji}^* is called the conjugate transpose of $\mathbf{A} = [a_{ij}]$; it is denoted by $\mathbf{A}\dagger$. The conjugate transpose of a product is

$$(AB)\dagger = B\dagger A\dagger$$

If $\mathbf{A} = \mathbf{A}\dagger$ ($\mathbf{A} = -\mathbf{A}\dagger$), $\mathbf{A}$ is said to be Hermitian

(skew-Hermitian). If $\mathbf{A}\dagger\mathbf{A} = \mathbf{I}$, $\mathbf{A}$ is called unitary. If $\mathbf{A}\dagger\mathbf{A} = \mathbf{A}\mathbf{A}\dagger$, $\mathbf{A}$ is called normal. Diagonal, unitary, Hermitian, and skew-Hermitian matrices are special cases of normal matrices. If the matrix $\mathbf{A}$ is real (that is, all entries are real), the terms Hermitian, skew-Hermitian, and unitary are usually replaced by symmetric, skew-symmetric, and unitary, respectively. The eigenvalues of Hermitian, skew-Hermitian, and unitary matrices are real, pure imaginary, and of unit absolute value, respectively.

The inner product of vectors x and y is

$$\mathbf{X}\dagger\mathbf{Y} = \sum_{i=1}^{n} x_i^* y_i$$

where x_i^* is the complex conjugate of x_i. (A square matrix of order one is considered here as a scalar.)

The length of a vector is given by

$$\|\mathbf{X}\| = (\mathbf{X}\dagger\mathbf{X})^{1/2} = \left(\sum_{i=1}^{n} |x_i|^2\right)^{1/2}$$

Two vectors are said to be orthogonal if

$$\mathbf{x}\dagger\mathbf{Y} = 0$$

Orthogonality corresponds to perpendicularity in two and three dimensions. Inner products obey the following inequalities

$$|\mathbf{X}\dagger\mathbf{Y}| \leq \|\mathbf{X}\|\|\mathbf{Y}\| \text{ (Schwarz)}$$

$$\|\mathbf{X} + \mathbf{Y}\| \leq \|\mathbf{X}\| + \|\mathbf{Y}\| \text{ (Triangle)}$$

Two matrices $\mathbf{A}$ and $\mathbf{B}$ are called similar if there exists a nonsingular matrix $\mathbf{C}$ such that

$$\mathbf{B} = \mathbf{C}\mathbf{A}\mathbf{C}^{-1}$$

Of particular interest is the case in which matrix $\mathbf{B}$ is diagonal

$$\mathbf{B} = \begin{bmatrix} \lambda_1 & 0 & 0 & \cdots & 0 \\ 0 & \lambda_2 & 0 & \cdots & 0 \\ 0 & 0 & \lambda_3 & \cdots & 0 \\ & & & \vdots & \\ 0 & 0 & 0 & \cdots & \lambda_n \end{bmatrix}$$

The diagonal elements λ_i are the eigenvalues of the matrix $\mathbf{A}$. Not all matrices are similar to diagonal ones. However, if a matrix of order n has n linearly independent eigenvectors, as is the case with normal matrices or when all its eigenvalues are distinct, it can be diagonalized. This may be done as follows: Let

$$\mathbf{A}\begin{bmatrix} x_{1i} \\ x_{2i} \\ \vdots \\ x_{ni} \end{bmatrix} = \lambda_i \begin{bmatrix} x_{1i} \\ x_{2i} \\ \vdots \\ x_{ni} \end{bmatrix}$$

Then

$$\mathbf{A}\begin{bmatrix} x_{11} & x_{12} & \cdots & x_{1n} \\ x_{21} & x_{22} & \cdots & x_{2n} \\ & & \vdots & \\ x_{n1} & x_{n2} & \cdots & x_{nn} \end{bmatrix}$$

$$= \begin{bmatrix} x_{11} & x_{12} & \cdots & x_{1n} \\ x_{21} & x_{22} & \cdots & x_{2n} \\ & & \vdots & \\ x_{n1} & x_{n2} & \cdots & x_{nn} \end{bmatrix} \begin{bmatrix} \lambda_1 & 0 & 0 & \cdots & 0 \\ 0 & \lambda_2 & 0 & \cdots & 0 \\ & & & \vdots & \\ 0 & 0 & 0 & \cdots & \lambda_n \end{bmatrix}$$

The matrix formed from the eigenvectors is nonsingular since the eigenvectors are linearly independent. Hence

$$\mathbf{C}^{-1} = \begin{bmatrix} x_{11} & x_{12} & \cdots & x_{1n} \\ x_{21} & x_{22} & \cdots & x_{2n} \\ & & \vdots & \\ x_{n1} & x_{n2} & \cdots & x_{nn} \end{bmatrix}$$

If a matrix $\mathbf{A}$ is reducible to diagonal form, polynomial functions of $\mathbf{A}$ are readily calculated

$$f(\mathbf{A}) = f(\mathbf{C}^{-1}\mathbf{B}\mathbf{C})$$

$$= \mathbf{C}^{-1}\begin{bmatrix} f(\lambda_1) & 0 & 0 & \cdots & 0 \\ 0 & f(\lambda_2) & 0 & \cdots & 0 \\ & & & \vdots & \\ 0 & 0 & 0 & \cdots & f(\lambda_n) \end{bmatrix}\mathbf{C}$$

Matrices can always be reduced to the Jordan canonical form, in which the eigenvalues are on the main diagonal and there are ones in certain places just above the main diagonal, and zeros elsewhere. In this form, operations such as polynomial functions are simplified.

Hermitian Forms

A Hermitian form is a polynomial

$$\mathbf{X}\dagger\mathbf{A}\mathbf{X} = \sum_{j=1}^{n}\sum_{i=1}^{n} a_{ij} x_i^* x_j$$

where $\mathbf{A}$ is a Hermitian matrix. Hermitian forms are real-valued and satisfy the inequality

$$\lambda_n\|\mathbf{X}\|^2 \leq \mathbf{X}\dagger\mathbf{A}\mathbf{X} \leq \lambda_1\|\mathbf{X}\|^2$$

in which λ_1 and λ_n are the largest and smallest eigenvalues of $\mathbf{A}$. By a suitable change of variable

$$\mathbf{Y} = \mathbf{T}\mathbf{X}$$

any Hermitian form $\mathbf{X}\dagger\mathbf{A}\mathbf{X}$ may be reduced.

$$\mathbf{X}^{\dagger}\mathbf{A}\mathbf{X} = \mathbf{Y}^{\dagger}\mathbf{T}\mathbf{A}\mathbf{T}^{\dagger}\mathbf{Y} = \sum_{i=1}^{n} \lambda_i |y_i|^2$$

by choosing $\mathbf{T}$ to be that unitary matrix which diagonalizes $\mathbf{A}$.

The maximum value of $\mathbf{X}^{\dagger}\mathbf{A}\mathbf{X}$ for all unit vectors $\mathbf{X}$, that is, $\|\mathbf{X}\| = 1$, is the largest eigenvalue of $\mathbf{A}$, say λ_1. A vector yielding this largest value will be a corresponding eigenvector, say $\mathbf{X}_1$. The maximum of $\mathbf{X}^{\dagger}\mathbf{A}\mathbf{X}$ overall unit vectors orthogonal to $\mathbf{X}_1$ will be another eigenvalue, say λ_2. A vector yielding λ_2 will be a corresponding eigenvector, say $\mathbf{X}_2$. The process is repeated considering unit vectors orthogonal to both $\mathbf{X}_1$ and $\mathbf{X}_2$. In this way, the eigenvalues of any Hermitian matrix may be found.

VECTOR-ANALYSIS EQUATIONS

Rectangular Coordinates

(In the following, vectors are indicated in bold-faced type.)

Notation:

$\mathbf{a} = a\hat{\mathbf{a}}$
a = magnitude of $\mathbf{a}$
$\hat{\mathbf{a}}$ = unit vector in direction of $\mathbf{a}$

Associative Law: For addition

$$\mathbf{a} + (\mathbf{b} + \mathbf{c}) = (\mathbf{a} + \mathbf{b}) + \mathbf{c} = \mathbf{a} + \mathbf{b} + \mathbf{c}$$

Commutative Law: For addition

$$\mathbf{a} + \mathbf{b} = \mathbf{b} + \mathbf{a}$$

Scalar or "Dot" Product (Fig. 21):

$$\mathbf{a} \cdot \mathbf{b} = \mathbf{b} \cdot \mathbf{a}$$

$$= ab\cos\theta$$

where θ = angle included by $\mathbf{a}$ and $\mathbf{b}$.

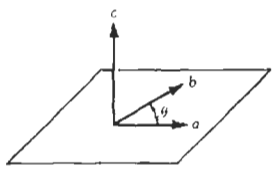

Fig. 21. "Dot" product.

Vector or "Cross" Product:

$$\mathbf{a} \times \mathbf{b} = -\mathbf{b} \times \mathbf{a}$$

$$= ab\sin\theta\hat{\mathbf{c}}$$

where,

θ = smallest angle swept in rotating $\mathbf{a}$ into $\mathbf{b}$,
$\hat{\mathbf{c}}$ = unit vector perpendicular to plane of $\mathbf{a}$ and $\mathbf{b}$, and directed in the sense of travel of a right-hand screw rotating from $\mathbf{a}$ to $\mathbf{b}$ through the angle θ.

Distributive Law for Scalar Multiplication:

$$\mathbf{a} \cdot (\mathbf{b} + \mathbf{c}) = \mathbf{a} \cdot \mathbf{b} + \mathbf{a} \cdot \mathbf{c}$$

Distributive Law for Vector Multiplication:

$$\mathbf{a} \times (\mathbf{b} + \mathbf{c}) = \mathbf{a} \times \mathbf{b} + \mathbf{a} \times \mathbf{c}$$

Scalar Triple Product:

$$\mathbf{a} \cdot (\mathbf{b} \times \mathbf{c}) = (\mathbf{a} \times \mathbf{b}) \cdot \mathbf{c} = \mathbf{c} \cdot (\mathbf{a} \times \mathbf{b}) = \mathbf{b} \cdot (\mathbf{c} \times \mathbf{a})$$

Vector Triple Product:

$$\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = (\mathbf{a} \cdot \mathbf{c})\mathbf{b} - (\mathbf{a} \cdot \mathbf{b})\mathbf{c}$$

$$(\mathbf{a} \times \mathbf{b}) \cdot (\mathbf{c} \times \mathbf{d}) = (\mathbf{a} \cdot \mathbf{c})(\mathbf{b} \cdot \mathbf{d}) - (\mathbf{a} \cdot \mathbf{d})(\mathbf{b} \cdot \mathbf{c})$$

$$(\mathbf{a} \times \mathbf{b}) \times (\mathbf{c} \times \mathbf{d}) = (\mathbf{a} \times \mathbf{b} \cdot \mathbf{d})\mathbf{c} - (\mathbf{a} \times \mathbf{b} \cdot \mathbf{c})\mathbf{d}$$

Del Operator:

$$\nabla \equiv \mathbf{i}(\partial/\partial x) + \mathbf{j}(\partial/\partial y) + \mathbf{k}(\partial/\partial z)$$

where $\mathbf{i}$, $\mathbf{j}$, $\mathbf{k}$ are unit vectors in the directions of the x, y, z coordinate axes, respectively.

Gradient:

$$\text{grad}\phi = \nabla\phi$$

$$= \mathbf{i}(\partial\phi/\partial x) + \mathbf{j}(\partial\phi/\partial y) + \mathbf{k}(\partial\phi/\partial z),$$

in Cartesian coordinates

$$\text{grad}(\phi + \psi) = \text{grad}\phi + \text{grad}\psi$$

$$\text{grad}(\phi\psi) = \phi\,\text{grad}\psi + \psi\,\text{grad}\phi$$

Divergence:

$$\text{div}\mathbf{a} = \nabla \cdot \mathbf{a} = (\partial a_x/\partial x) + (\partial a_y/\partial y) + (\partial a_z/\partial z),$$

in Cartesian coordinates

where a_x, a_y, a_z are components of $\mathbf{a}$ in the directions of the x, y, z coordinate axes, respectively.

$$\text{div}(\mathbf{a} + \mathbf{b}) = \text{div}\mathbf{a} + \text{div}\mathbf{b}$$

$$\text{div}(\phi\mathbf{a}) = \phi\,\text{div}\mathbf{a} + \mathbf{a} \cdot \text{grad}\phi$$

Curl:

$$\text{curl}\mathbf{a} = \nabla \times \mathbf{a}$$

$$= \mathbf{i}\left(\frac{\partial a_z}{\partial_y} - \frac{\partial a_y}{\partial z}\right) + \mathbf{j}\left(\frac{\partial a_x}{\partial z} - \frac{\partial a_z}{\partial x}\right) + \mathbf{k}\left(\frac{\partial a_y}{\partial x} - \frac{\partial a_x}{\partial y}\right)$$

$$= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ a_x & a_y & a_z \end{vmatrix}, \quad \text{in Cartesian coordinates}$$

$$\text{curl}(\mathbf{a} + \mathbf{b}) = \text{curl}\mathbf{a} + \text{curl}\mathbf{b}$$

$$\text{curl}(\phi\mathbf{a}) = \text{grad}\phi \times \mathbf{a} + \phi\text{curl}\mathbf{a}$$

$$\text{curl grad}\phi = 0$$

$$\text{div curl}\mathbf{a} = 0$$

$$\text{div}(\mathbf{a} \times \mathbf{b}) = \mathbf{b} \cdot \text{curl}\mathbf{a} - \mathbf{a} \cdot \text{curl}\mathbf{b}$$

$$\text{Laplacian} \equiv \nabla^2 = \nabla \cdot \nabla$$

$$\nabla^2\phi = (\partial^2\phi/\partial x^2) + (\partial^2\phi/\partial y^2) + (\partial^2\phi/\partial z^2), \quad \text{in Cartesian coordinates}$$

$$\text{curl curl}\mathbf{a} = \text{grad div}\mathbf{a} - (\mathbf{i}\nabla^2 a_x + \mathbf{j}\nabla^2 a_y + \mathbf{k}\nabla^2 a_z)$$

$$= \nabla(\nabla \cdot \mathbf{a}) - \nabla^2\mathbf{a}$$

Directional Derivative: Derivative of ϕ in the direction of $\mathbf{s}$

$$d\phi/ds = \hat{\mathbf{s}} \cdot \nabla\phi$$

Integral Relations: In the following equations, τ is a volume bounded by a closed surface, S. The unit vector $\mathbf{n}$ is normal to the surface and is directed outward. The symbol dS represents an element of surface area. If the surface is represented by $z = f(x, y)$ then

$$dS = [1 + (\partial f/\partial x)^2 + (\partial f/\partial x)^2 +]^{1/2}\, dx\, dy$$

$$\int_\tau \nabla\phi d\tau = \int_S \phi\mathbf{n}dS$$

$$\int_\tau \nabla \cdot \mathbf{a}d\tau = \int_S \mathbf{a} \cdot \mathbf{n}dS \text{ (Gauss' theorem)}$$

$$\int_\tau \nabla \times \mathbf{a}d\tau = \int_S \mathbf{n} \times \mathbf{a}dS$$

$$\int_\tau (\psi\nabla^2\phi - \phi\nabla^2\psi)d\tau, \int_S [\psi(\partial\phi/\partial n) - \phi(\partial\psi/\partial n)]dS$$

where $\partial/\partial n$ is the derivative in the direction of $\mathbf{n}$ (Green's theorem).

In the two following equations, S is an open surface bounded by a contour C, with distance along C represented by s.

$$\int_S \mathbf{n} \times \nabla\phi dS = \int_C \phi d\mathbf{s}$$

$$\int_S (\nabla \times \mathbf{a}) \cdot \mathbf{n}dS = \int_C \mathbf{a} \cdot ds \text{ (Stokes' theorem)}$$

where,

$\mathbf{s} = s\hat{\mathbf{s}}$,

$\hat{\mathbf{s}}$ is the unit tangent vector along C.

Gradient, Divergence, Curl, and Laplacian in Coordinate Systems Other Than Rectangular

Cylindrical Coordinates: (ρ, ϕ, z), unit vectors $\hat{\boldsymbol{\rho}}$, $\hat{\boldsymbol{\phi}}$, $\mathbf{k}$, respectively

$$\text{grad}\psi = \nabla\psi = (\partial\psi/\partial\rho)\hat{\boldsymbol{\rho}} + \rho^{-1}(\partial\psi/\partial\phi)\hat{\boldsymbol{\phi}} + (\partial\chi/\partial z)\mathbf{k}$$

Let $\mathbf{a} = a_\rho\hat{\boldsymbol{\rho}} + a_\phi\hat{\boldsymbol{\phi}} + a_z\mathbf{k}$. Then

$$\text{div}\mathbf{a} = \nabla \cdot \mathbf{a} = \rho^{-1}(\partial/\partial\rho)(\rho a_\rho) + \rho^{-1}(\partial a_\phi/\partial\phi) + (\partial a_z/\partial z)$$

$$\text{curl}\mathbf{a} = \nabla \times \mathbf{a} = [\rho^{-1}(\partial a_z/\partial\phi) - (\partial a_\phi/\partial z)]\hat{\boldsymbol{\rho}} + [(\partial a_\rho/\partial z) - (\partial a_z/\partial\rho)]\hat{\boldsymbol{\phi}} + [\rho^{-1}(\partial/\partial\rho)(\rho a_\phi) - \rho^{-1}(\partial a_\rho/\partial\phi)]\mathbf{k}$$

$$\nabla^2\psi = \rho^{-1}(\partial/\partial\rho)[\rho(\partial\psi/\partial\rho)] + \rho^{-2}(\partial^2\psi/\partial\phi^2) + (\partial^2\psi/\partial z^2)$$

Spherical Coordinates: (r, θ, ϕ), unit vectors $\hat{\mathbf{r}}$, $\hat{\boldsymbol{\theta}}$, $\hat{\boldsymbol{\phi}}$

r = distance to origin

θ = polar angle

ϕ = azimuthal angle

$$\text{grad}\psi = \nabla\psi = (\partial\psi/\partial r)\hat{\mathbf{r}} + r^{-1}(\partial\psi/\partial\theta)\hat{\boldsymbol{\theta}} + (r\sin\theta)^{-1}(\partial\psi/\partial\phi)\hat{\boldsymbol{\phi}}$$

Let $\mathbf{a} = a_r\hat{\mathbf{r}} + a_\theta\hat{\boldsymbol{\theta}} + a_\phi\hat{\boldsymbol{\phi}}$. Then

$$\text{div}\mathbf{a} = \nabla\cdot\mathbf{a} = r^{-2}(\partial/\partial r)(r^2a_r) + (r\sin\theta)^{-1}(\partial/\partial\theta)(a_\theta\sin\theta) + (r\sin\theta)^{-1}(\partial a_\phi/\partial\phi)$$

$$\text{curl}\mathbf{a} = \nabla\times\mathbf{a} = (r\sin\theta)^{-1}[(\partial/\partial\theta)(a_\phi\sin\theta) - (\partial a_\theta/\partial\phi)]\hat{\mathbf{r}} + r^{-1}[(\sin\theta)^{-1}(\partial a_r/\partial\phi) - (\partial/\partial r)(ra_\phi)]\hat{\boldsymbol{\theta}} + r^{-1}[(\partial/\partial r)(ra_\theta) - (\partial a_r/\partial\theta)]\hat{\boldsymbol{\phi}}$$

$$\nabla^2\psi = r^{-2}(\partial/\partial r)[r^2(\partial\psi/\partial r)] + (r^2\sin\theta)^{-1}(\partial/\partial\theta)[\sin\theta(\partial\psi/\partial\theta)] + (r^2\sin^2\theta)^{-1}(\partial^2\psi/\partial\phi^2)$$

Orthogonal Curvilinear Coordinates:

Coordinates: u_1, u_2, u_3

Metric coefficients: h_1, h_2, h_3 $(ds^2 = h_1^2du_1^2 + h_2^2du_2^2 + h_3^2du_3^2)$

Unit vectors: $\mathbf{i}_1, \mathbf{i}_2, \mathbf{i}_3$ $(d\mathbf{s} = \mathbf{i}_1h_1du_1 + \mathbf{i}_2/i_2du_2 + \mathbf{i}_3h_3du_3)$

$$\text{grad}\psi = \nabla\psi = h_1^{-1}(\partial\psi/\partial u_1)\mathbf{i}_1 + h_2^{-1}(\partial\psi/\partial u_2)\mathbf{i}_2 + h_3^{-1}(\partial\psi/\partial u_3)\mathbf{i}_3$$

$$\text{div}\mathbf{a} = \nabla\cdot\mathbf{a} = (h_1h_2h_3)^{-1}[(\partial/\partial u_1)(h_2h_3a_1) + (\partial/\partial u_2)(h_3h_1a_2) + (\partial/\partial u_3)(h_1h_2a_3)]$$

$$\text{curl}\mathbf{a} = \nabla\times\mathbf{a} = (h_2h_3)^{-1}[(\partial/\partial u_2)(h_3a_3) - (\partial/\partial u_3)(h_2a_2)]\mathbf{i}_1 + (h_3h_1)^{-1}[(\partial/\partial u_3)(h_1a_1) - (\partial/\partial u_1)(h_3a_3)]\mathbf{i}_2 + (h_1h_2)^{-1}[(\partial/\partial u_1)(h_2a_2) - (\partial/\partial u_2)(h_1a_1)]\mathbf{i}_3$$

$$= (h_1h_2h_3)^{-1}\begin{vmatrix} h_1\mathbf{i}_1 & h_2\mathbf{i}_2 & h_3\mathbf{i}_3 \\ \partial/\partial u_1 & \partial/\partial u_2 & \partial/\partial u_3 \\ h_1a_1 & h_2a_2 & h_3a_3 \end{vmatrix}$$

$$\nabla^2\psi = (h_1h_2h_3)^{-1}\left[\frac{\partial}{\partial u_1}\left(\frac{h_2h_3}{h_1}\frac{\partial}{\partial u_1}\right) + \frac{\partial}{\partial u_2}\left(\frac{h_3h_1}{h_2}\frac{\partial\psi}{\partial u_2}\right) + \frac{\partial}{\partial u_3}\left(\frac{h_1h_2}{h_3}\frac{\partial\psi}{\partial u_3}\right)\right]$$

Space Curves

A curve may be represented vectorially as $\mathbf{r} = \mathbf{r}(s)$. See Fig. 22.

A unit tangent $\mathbf{t}$ is then given by

$$\mathbf{t} = d\mathbf{r}/ds$$

The principal normal $\mathbf{n}$ is given by

$$\mathbf{n} = (1/k)(d\mathbf{t}/ds)$$

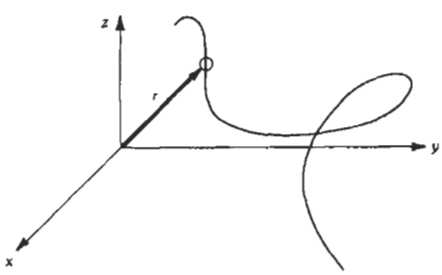

Fig. 22. Space curve.

where k is the curvature. The radius of curvature $R = 1/k$. For a plane curve $y = f(x)$, the curvature may be computed from

$$k = |y''|/[1 + (y')^2]^{3/2}$$

The binormal is defined by

$$\mathbf{b} = \mathbf{t}\times\mathbf{n}$$

These vectors satisfy Frenet's equations

$$d\mathbf{n}/ds = -k\mathbf{t} + \tau\mathbf{b}$$

$$d\mathbf{b}/ds = -\tau\mathbf{n}$$

where τ is the torsion. The torsion is zero everywhere if and only if the curve lies in a plane.

LAPLACE TRANSFORM

The Laplace transform of a function $f(t)$ is defined by the expression

$$F(p) = \int_0^\infty f(t)e^{-pt}dt$$

If this integral converges for some $p = p_0$, real or complex, then it will converge for all p such that $\mathrm{Re}p > \mathrm{Re}p_0$.

The inverse transform may be found by

$$f(t) = (j2\pi)^{-1}\int_{c-j\infty}^{c+j\infty} F(z)e^{tz}dz, \quad t > 0$$

where there are no singularities to the right of the path of integration.

TABLE OF LAPLACE TRANSFORMS

General Equations

	Function	Transform*
Shifting theorem	$f(t-a), \quad f(t) = 0, \quad t < 0$	$e^{-ap}F(p), \quad a > 0$
Convolution	$\int_0^t f_1(\lambda)f_2(t-\lambda)d\lambda$	$F_1(p)F_2(p)$
Linearity	$a_1f_1(t) + a_2f_2(t), \quad (a_1, a_2 \text{ const})$	$a_1F_1(p) + a_2F_2(p)$
Derivative	$df(t)/dt$	$-f(0) + pF(p)$
Integral	$\int f(t)dt$	$p^{-1}\left[\int f(t)dt\right]_{t=0} + [f(p)/p], \quad \mathrm{Re}p > 0$
Periodic function	$f(t) = f(t+r)$	$\int_0^r f(\lambda)e^{-p\lambda}\,d\lambda/(1-e^{-pr}), \quad r > 0$
	$f(t) = -f(t+r)$	$\int_0^r f(\lambda)e^{-\lambda}\,d\lambda/(1+e^{-pr}), \quad r > 0$
	$f(at), \quad a > 0$	$F(p/a)/a$
	$e^{at}f(t)$	$F(p-a), \quad \mathrm{Re}p > \mathrm{Re}a$
	$t^nf(t)$	$(-1)^n[d^nF(p)/dp^n]$
Final-value theorem	$f(\infty)$	$\lim_{p\to 0} pF(p)$
Initial-value theorem	$f(0+)$	$\lim_{p\to\infty} pF(p)$

* $F(p)$ denotes the Laplace transform of $f(t)$.

Miscellaneous Functions*

SELECTED FUNCTIONS

Exponential Integrals

Definitions:

$$E_1(z) = \int_z^\infty (e^{-t}/t)dt, \quad |\arg z| < \pi$$

in which the path of integration does not cross the negative t-axis and also excludes the origin. For $\arg z = \pi$ the following function is used:

$$E_i(x) = -\mathrm{pv}\int_{-x}^{\infty} (e^{-t}/t)dt, \quad x > 0$$

where pv stands for the Cauchy principal value.

$$E_1(-x \pm j0) = E_i(x) \mp j\pi$$

Series Expansions:

$$E_1(z) = -\gamma - \ln z - \sum_{n=1}^{\infty} [(-1)^n z^n/(n \cdot n!)], \quad |\arg z| < \pi$$

$$Ei(x) = \gamma + \ln x + \sum_{n=1}^{\infty} x^n/(n \cdot n!)$$

in which γ is Euler's constant, $\gamma = 0.57722$.

Asymptotic Expansions:

$$E_1(z) \sim (e^{-z}/z)[1 - z^{-1} + (2!/z^2) - (3!/z^3) + \cdots], \quad |\arg z| < \pi$$

$$Ei(x) \sim (e^x/x)[1 + x^{-1} + (2!/x^2) + (3!/x^3) + \cdots]$$

Cosine and Sine Integrals

Definitions:

$$Si(z) = \int_0^z (\sin t/t)dt$$

$$Ci(z) = \gamma + \ln z + \int_0^z [(\cos t - 1)/t]dt, \quad |\arg z| < \pi$$

where γ is Euler's constant, $\gamma = 0.57722$.

Series Expansions:

$$Si(z) = \sum_{n=0}^{\infty} \frac{(-1)^n z^{2n+1}}{(2n + 1)(2n + 1)!}$$

$$Ci(z) = \gamma + \ln z + \sum_{n=1}^{\infty} \frac{(-1)^n z^{2n}}{2n(2n)!}$$

Asymptotic Expansions:

$$Si(z) \sim \tfrac{1}{2}\pi - \left(1 - \frac{2!}{z^2} + \frac{4!}{z^4} - \frac{6!}{z^6} + \cdots\right)\frac{\cos z}{z} - \left(1 - \frac{3!}{z^2} + \frac{5!}{z^4} - \frac{7!}{z^6} + \cdots\right)\frac{\sin z}{z^2}$$

$$Ci(z) \sim \left(1 - \frac{2!}{z^2} + \frac{4!}{z^4} - \frac{6!}{z^6} + \cdots\right)\frac{\sin z}{z} - \left(1 - \frac{3!}{z^2} + \frac{5!}{z^4} - \frac{7!}{z^6} + \cdots\right)\frac{\cos z}{z^2}$$

Gamma Function

Definition:

$$\Gamma(z) = \int_0^\infty t^{z-1}e^{-t}dt$$

$$\Gamma(-z) = -\pi/[\Gamma(z+1)\sin\pi z], \quad \mathrm{Re}\, z > 0$$

The function $\Gamma(z)$ is an analytic function everywhere except at the negative integers.

Identities:

$$z\Gamma(z) = \Gamma(z+1)$$

$$\Gamma(\tfrac{1}{2}+z)\Gamma(\tfrac{1}{2}-z) = \pi\sec\pi z$$

Special Values:

$$\Gamma(z) = (z-1)! \quad z = 1, 2, 3, \cdots$$

$$\Gamma(z+\tfrac{1}{2}) = [(2z)!/2^{2z}z!](\pi)^{1/2}$$

n	1	2	3	4	5	6	7	8	9	10
$\Gamma(n) = (n-1)!$	1	1	2	6	24	120	720	5040	40 320	362 880

Asymptotic Expansion (Stirling's Equation):

$$\Gamma(z) \sim e^{-z}z^{z-1/2}(2\pi)^{1/2}[1 + (1/12z) + (1/288z^2) + \cdots]$$

$$\text{Note } z! = z\Gamma(z) \sim e^{-z}z^{z+1/2}(2\pi)^{1/2}[1 + (1/12z) + (1/288z^2) + \cdots]$$

Psi and Polygamma Functions

Definitions:

$$\psi^{(n)}(z) = \frac{d^{n+1}}{dz^{n+1}}[\ln\Gamma(z)] \quad n = 0, 1, 2, \cdots$$

$\psi^{(0)}(z) = \psi(z)$ is known as the psi function, and $\psi^{(n)}(z)$ as the polygamma function of order n, $n = 1, 2, \cdots$

Special Values:

$$\psi^{(n)}(1) = (-1)^{n+1}n!\zeta(n+1), \quad n = 1, 2, \cdots$$

$$\psi(1) = -\gamma$$

$$\psi^{(n)}(\tfrac{1}{2}) = (-1)^{n+1}n!(2^{n+1}-1)\zeta(n+1), \quad n = 1, 2, \cdots$$

$$\psi(\tfrac{1}{2}) = -\gamma - 2\ln 2$$

in which $\zeta(n+1)$ is the Riemann zeta function of $n+1$.

Series Expansions:

$$\psi^{(n)}(1+z) = \sum_{k=0}^{\infty}\frac{(-1)^{n+k+1}(n+k)!\zeta(n+k+1)z^k}{k!}, \quad |z| < 1, n = 1, 2, \cdots$$

$$\psi(1+z) = -\gamma - \sum_{k=1}^{\infty}(-1)^k\zeta(k+1)z^k, \quad |z| < 1$$

Asymptotic Expansions:

$$\psi^{(n)}(z) \sim [(-1)^n(n-1)!/z^n][1 + (n/2z) + \cdots], \quad \text{as } z\to\infty, |\arg z| < \pi, n = 1, 2, \cdots$$

$$\psi(z) \sim \ln z - (1/2z) + \cdots$$

Error Function

Definitions:

$$\mathrm{erf}z = (2/\pi^{1/2})\int_0^z \exp(-t^2)dt$$

$$\mathrm{erfc}z = (2/\pi^{1/2})\int_z^\infty \exp(-t^2)dt$$

$$= 1 - \mathrm{erf}z$$

The path of integration for large t must remain within $|\arg t| < \pi/4$ in the latter integral.

Series Expansion:

$$\operatorname{erf} z = (2/\pi^{1/2}) \sum_{n=0}^{\infty} [(-1)^n z^{2n+1}/n!(2n+1)], \quad |z| < \infty$$

Asymptotic Expansion:

$$\operatorname{erf} z \sim 1 - [\exp(-z^2)/z\pi^{1/2}] \times [1 - (1/2z^2) + (3/4z^4) - \cdots], \quad \text{as } z \to \infty, \ |\arg z| < 3\pi/4$$

Inequality:

$$\frac{(2/\pi^{1/2}) \exp(-x^2)}{x + (x^2 + 2)^{1/2}} < \operatorname{erfc} x \leq \frac{(2/\pi^{1/2}) \exp(-x^2)}{x + [x^2 + (4/\pi)]^{1/2}}, \quad x \geq 0$$

Derivatives:

$$(d^{(n+1)}/dz^{(n+1)}) \operatorname{erf} z = (-1)^n (2/\pi^{1/2}) H_n(z) e^{-z^2}, \quad n = 0, 1, 2, \cdots$$

where $H_n(z)$ is the Hermite polynomial of order n.

Relation to Gaussian Distribution:

$$\text{Prob}(x \leq x) = [\sigma(2\pi)^{1/2}]^{-1} \int_{-\infty}^{x} \exp\left(-\frac{(t-\mu)^2}{2\sigma^2}\right) dt = \tfrac{1}{2}\left[1 + \operatorname{erf}\left(\frac{x-\mu}{\sigma\sqrt{2}}\right)\right]$$

Fresnel Integrals

Definitions:

$$C(z) = \int_0^z \cos[(\pi/2)t^2]\,dt$$

$$S(z) = \int_0^z \sin[(\pi/2)t^2]\,dt$$

Series Expansions:

$$C(z) = \sum_{n=0}^{\infty} \frac{(-1)^n (\pi/2)^{2n}}{(2n)!(4n+1)} z^{4n+1}$$

$$S(z) = \sum_{n=0}^{\infty} \frac{(-1)^n (\pi/2)^{2n+1}}{(2n+1)!(4n+3)} z^{4n+3}, \quad |z| < \infty$$

Asymptotic Expansions:

$$C(z) \sim \tfrac{1}{2} + \left(1 - \frac{1 \cdot 3}{(\pi z^2)^2} + \frac{1 \cdot 3 \cdot 5 \cdot 7}{(\pi z^2)^4} - \cdots\right) \frac{\sin \frac{1}{2}\pi z^2}{\pi z} - \left[(1/\pi z^2) - \frac{1 \cdot 3 \cdot 5}{(\pi z^2)^3} + \frac{1 \cdot 3 \cdot 5 \cdot 7 \cdot 9}{(\pi z^2)^5} - \cdots\right] \frac{\cos \frac{1}{2}\pi z^2}{\pi z}$$

$$S(z) \sim \tfrac{1}{2} - \left[1 - \frac{1 \cdot 3}{(\pi z^2)^2} + \frac{1 \cdot 3 \cdot 5 \cdot 7}{(\pi z^2)^4} - \cdots\right] \frac{\cos \frac{1}{2}\pi z^2}{\pi z} - \left[(1/\pi z^2) - \frac{1 \cdot 3 \cdot 5}{(\pi z^2)^3} + \frac{1 \cdot 3 \cdot 5 \cdot 7 \cdot 9}{(\pi z^2)^5} - \cdots\right] \frac{\sin \frac{1}{2}\pi z^2}{\pi z}$$

Elliptic Integrals

First Kind:

$$F(\phi, k) = \int_0^{\phi} \frac{d\theta}{(1 - k^2 \sin^2\theta)^{1/2}}$$

Second Kind:

$$E(\phi, k) = \int_0^{\phi} (1 - k^2 \sin^2\theta)^{1/2} d\theta$$

If $\phi = \pi/2$, the elliptic integrals are said to be complete, and they are denoted by K or $K(k)$ and E or $E(k)$.

Bessel Functions*

Refer to Fig. 23.

Definitions: Bessel functions are solutions to Bessel's differential equation

$$z^2(d^2w/dz^2) + z(dw/dz) + (z^2 - \nu^2)w = 0$$

They are divided into

First kind

$$J_\nu(z) = (z/2)^\nu \sum_{k=0}^{\infty} \frac{(-1)^k (z/2)^{2k}}{k!\Gamma(k + \nu + 1)}$$

Second kind

$$Y_\nu(z) = \frac{J_\nu(z) \cos\nu\pi - J_{-\nu}(z)}{\sin\pi\nu}, \quad \nu \text{ not an integer}$$

* For an extensive treatment of Bessel functions, see G. N. Watson, *A Treatise on the Theory of Bessel Functions*, New York: Cambridge University Press, 1943.

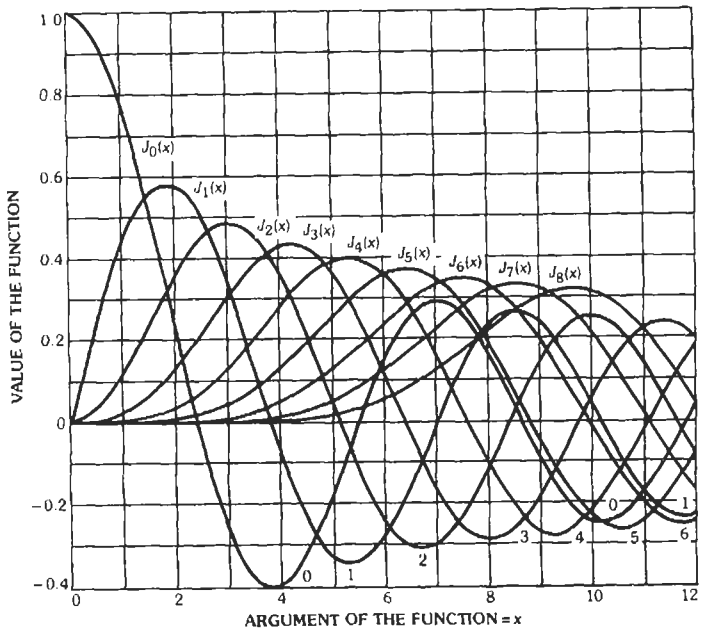

Fig. 23. Bessel functions for the first eight orders.

$$Y_n(z) = \lim_{\nu \to n} Y_\nu(z), \; n \text{ integral}$$

Third kind

$$H_\nu^{(1)}(z) = J_\nu(z) + jY_\nu(z)$$

$$H_\nu^{(2)}(z) = J_\nu(z) - jY_\nu(z)$$

The second and third kinds are sometimes called Neumann and Hankel functions, respectively.

The modified Bessel functions are solutions to Bessel's differential equation with z replaced by jz.

$$I_\nu(z) = \exp(-j\pi\nu/2)J_\nu\,[z\exp(j\pi/2)], \quad -\pi < \arg z \le \pi/2$$

$$= \exp(j3\pi\nu/2)J_\nu[z\exp(-j3\pi/2)], \quad \pi/2 < \arg z \le \pi$$

$$K_\nu(z) = (j\pi/2)\exp(j\pi\nu/2)H_\nu^{(1)}\,[z\exp(j\pi/2)], \quad -\pi < \arg z \le \pi/2$$

$$= -(j\pi/2)\exp(-j\pi\nu/2) \times H_\nu^{(2)}[z\exp(-j\pi/2)], \quad -\pi/2 < \arg z \le \pi$$

Integral Representations:

$$J_\nu(z) = \frac{2(z/2)^\nu}{\Gamma(\nu + \frac{1}{2})\pi^{1/2}} \int_0^{\pi/2} \cos(z\sin\phi)(\cos\phi)^{2\nu}d\pi, \quad \mathrm{Re}\nu > -\tfrac{1}{2}$$

$$H_\nu^{(1)}(z) = -(j/\pi)e^{-j\pi\nu/2} \int_{-\infty}^{\infty} \exp(jz\cosh t - \nu t)dt, \quad 0 < \arg z < \pi$$

$$H_\nu^{(2)}(z) = (j/\pi)e^{j\pi\nu/2} \int_{-\infty}^{\infty} \exp(-jz\cosh t - \nu t)dt, \quad -\pi < \arg z < 0$$

Asymptotic Expressions: For $|z| \to \infty$

$$J_\nu(z) \sim [(2/\pi z)]^{1/2}\cos(z - \nu\pi/2 - \pi/4), \; |\arg z| < \pi$$

$$Y_\nu(z) \sim [(2/\pi z)]^{1/2}\sin(z - \nu\pi/2 - \pi/4), \; |\arg z| < \pi$$

$$H_\nu^{(1)}(z) \sim [(2/\pi z)]^{1/2}\exp[j(z - \nu\pi/2 - \pi/4)], \quad -\pi < \arg z < 2\pi$$

$$H_\nu^{(2)}(z) \sim [(2/\pi z)]^{1/2}\exp[-j(z - \nu\pi/2 - \pi/4)], \quad -2\pi < \arg z < \pi$$

Recurrence Relations:

$$C_{\nu-1}(z) + C_{\nu+1}(z) = (2\nu/z)C_\nu(z)$$

$$C_{\nu-1}(z) - C_{\nu+1}(z) = 2C_\nu'(z)$$

where C denotes J, Y, $H^{(1)}$ or $H^{(2)}$

Series Containing Bessel Functions:

$$\exp(-ju\sin x) = \sum_{n=-\infty}^{\infty} J_n(u)\exp(-jnx)$$

$$\cos(u\sin x) = J_0(u) + 2\sum_{n=1}^{\infty} J_{2n}(u)\cos 2nx$$

$$\sin(u\sin x) = 2\sum_{n=1}^{\infty} J_{2n-1}(u)\sin(2n-1)x$$

$$\cos(u\cos x) = J_0(u) + 2\sum_{n=1}^{\infty}(-1)^n J_{2n}(u)\cos 2nx$$

$$\sin(u\cos x) = 2\sum_{n=1}^{\infty}(-1)^{n+1}J_{2n-1}(u) \times \cos(2n-1)x$$

$$1 = \sum_{n=-\infty}^{\infty} J_n^2(x)$$

Orthogonal Polynomials

Any set of polynomials $\{f_n(x)\}$ with the property

$$\int_a^b w(x)f_n(x)f_m(x)dx = 0, \text{ for } m \neq n$$

$$= h_n, \text{ for } m = n$$

is called a set of orthogonal polynomials on the interval (a, b) with respect to the weight function $w(x)$. These functions occur in the Gauss quadrature equations among other places. Chebishev polynomials are involved in the theory of the Chebishev filter; Hermite polynomials arise in the refinements of the central limit theorem, the so-called Edgeworth series, etc. The important properties are summarized in Table 1.

NUMERICAL ANALYSIS

Algorithms for Solving $F(x) = 0$

Bisection Method and Regula Falsi (Rule of False Position): First determine x_1 and x_2 such that $F(x_1)F(x_2) < 0$, i.e., x_1 and x_2 are points at which the function has opposite signs.

Bisection Method: Calculate

$$x_3 = (x_1 + x_2)/2$$

Regula Falsi: Calculate

$$x_3 = [x_1F(x_2) - x_2F(x_1)]/[F(x_2) - F(x_1)]$$

To obtain the next approximation, take x_3 and x_i, $i = 1$ or 2, such that $F(x_3)F(x_i) < 0$, and repeat the procedure.

Newton-Raphson: Take some initial value x_1 and calculate successively

$$x_{n+1} = x_n - [F(x_n)/F'(x_n)],\ n = 1, 2, 3 \cdots$$

This method may not converge. When it converges, the rate of convergence is generally faster than the bisection method or the regula falsi.

Algorithm for Solving $F(x, y) = G(x, y) = 0$

The following is an extension of the Newton-Raphson method described above. Take some initial values x_1 and y_1 and calculate successively

TABLE 1. PROPERTIES OF ORTHOGONAL POLYNOMIALS

$f_n(x)$	Name	a	b	$w(x)$	h_n	Explicit Expression*
$T_n(x)$	Chebishev	-1	$+1$	$(1-x^2)^{-1/2}$	$\frac{1}{2}\pi,\ n \neq 0;\ \pi,\ n = 0$	$\frac{1}{2}n\sum_{m=0}^{[n/2]}(-1)^m\frac{(n-m-1)!}{m!(n-2m)!}(2x)^{n-2m}$
$H_n(x)$	Hermite	$-\infty$	∞	e^{-x^2}	$2^n n!\pi^{1/2}$	$n!\sum_{m=0}^{[n/2]}(-1)^m\frac{(2x)^{n-2m}}{m!(n-2m)!}$
$L_n(x)$	Laguerre	0	∞	e^{-x}	1	$\sum_{m=0}^{n}(-1)^m\binom{n}{m}\frac{x^m}{m!}$
$P_n(x)$	Legendre	-1	1	1	$2/(2n+1)$	$2^{-n}\sum_{m=0}^{[n/2]}(-1)^m\binom{n}{m}\binom{2n-2m}{n}x^{n-2m}$

* $[n/2]$ denotes the largest integer less than or equal to $n/2$.

$$x_{n+1} = x_n + \left[\left(\frac{\partial F}{\partial y}G - F\frac{\partial G}{\partial y}\right) \Big/ \left(\frac{\partial F}{\partial x}\frac{\partial G}{\partial y} - \frac{\partial F}{\partial y}\frac{\partial G}{\partial x}\right)\right]\Bigg|_{(x,y)=(x_n,y_n)}$$

$$y_{n+1} = y_n + \left[\left(F\frac{\partial G}{\partial x} - \frac{\partial F}{\partial x}G\right) \Big/ \left(\frac{\partial F}{\partial x}\frac{\partial G}{\partial y} - \frac{\partial F}{\partial y}\frac{\partial G}{\partial x}\right)\right]\Bigg|_{(x,y)=(x_n,y_n)}$$

for $n = 1, 2, 3, \cdots$.

By using Taylor's series to first derivatives and Cramer's rule, this algorithm may be further extended to the case of m simultaneous equations in m variables.

Interpolation Polynomial

The polynomial of lowest degree that passes through n points (x_i, y_i), $i = 1, 2, \cdots, n$, is given by

$$P(x) = \sum_{i=1}^{n}\left(y_i \prod_{k=1\,k\neq i}^{n}\frac{x - x_k}{x_i - x_k}\right)$$

where $x_i \neq x_k$ for $i \neq k$.

Interpolation at Equidistant Points

Let

$$f_i = f(x_0 + ih)$$

$$g_{ij} = g(x + ih, y + jk)$$

Then $f(x_0 + ph)$ may be approximated by

$(1 - p)f_0 + pf_1$, given two points

$[p(p - 1)/2]f_{-1} + (1 - p^2)f_0 + [p(p + 1)/2]f_1$, given three points

$[-p(p - 1)(p - 2)/6]f_{-1} + [(p^2 - 1)(p - 2)/2]f_0 - [p(p + 1)(p + 2)/2]f_1 + [p(p^2 - 1)/6]f_2$, given four points

$g(x_0 + ph, y_0 + qk)$ may be approximated by

$(1 - p - q)g_{00} + pg_{10} + qg_{01}$, given three points

$(1 - p)(1 - q)g_{00} + p(1 - q)g_{10} + q(1 - p)g_{01} + pqg_{11}$, given four points

Integration

Refer to Fig. 24. Let

$$f_i = f(x_0 + ih)$$

$$\int_{x_0}^{x_0+mh} f(x)dx \approx h(\tfrac{1}{2}f_0 + f_1 + f_2 + \cdots + f_{n-1} + \tfrac{1}{2}f_n)$$

(Trapezoidal Rule)

$$\int_{x_0}^{x_0+2nh} f(x)dx \approx \tfrac{1}{3}h(f_0 + 4f_1 + 2f_2 + 4f_3 + 2f_4 + \cdots + 2f_{2n-2} + 4f_{2n-1} + f_{2n})$$ (Simpson's Rule)

Differentiation

If a function $f(x)$ is known at two points a and b, then

$$f'(a) \approx [f(b) - f(a)]/(b - a)$$

If $f(x)$ is given at a discrete set of points, one may differentiate the interpolation polynomial stated above. The equation simplifies when the derivative is calculated at interpolation points that are equidistant, for example

$$f_{-1}' \approx (1/2h)(-3f_{-1} + 4f_0 - f_1)$$

$$f_0' \approx (1/2h)(-f_{-1} + f_1)$$

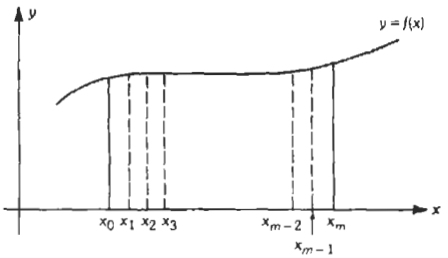
$$f_1' \approx (1/2h)(f_{-1} - 4f_0 + 3f_1)$$

where,

$$f_i = f(x_0 + ih),\ i = -1, 0, 1$$

Error in Arithmetic Operations

Let the quantities A and B be known to within errors of a and b, respectively, where a and b are small relative to A and B. Then



For Simpson's rule, m must be even.

Fig. 24. Integration.

Operation	Maximum Error (to first order in a and b)
$A \pm B$	$a + b$
$A \cdot B$	$\lvert AB\rvert(\lvert a/A\rvert + \lvert b/B\rvert)$
A/B	$\lvert A/B\rvert(\lvert a/A\rvert + \lvert b/B\rvert)$

The magnitude, q, of small random errors often has a normal distribution

$$(h/\pi^{1/2}) \exp(-h^2q^2)$$

where h is called the index of precision. The rms of q, denoted by σ, is, in terms of h

$$\sigma = 1/h\sqrt{2}$$

Let $f(x_1, x_2, \cdots, x_n)$ be a function of n variables x_i, which have normally distributed independent errors q_i with indices of precision h_i. Then $f(x_1, x_2, \cdots, x_n)$ will have an error Q, which is also normally distributed with index of precision H. For small errors

$$H \approx \{[h_1^{-1}(\partial f/\partial q_1)]^2 + [h_2^{-1}(\partial f/\partial q_2)]^2 + \cdots + [h_n^{-1}(\partial f/\partial q_n)]^2\}^{-1/2}$$

49 Miscellaneous Data

EFFECT OF ALTITUDE ON BREAKDOWN VOLTAGES

Pressure-Altitude Graph

Design of electrical equipment for aircraft is somewhat complicated by the requirement of additional insulation for high voltages as a result of the decrease in atmospheric pressure. The extent of this effect may be determined from Figs. 1 and 2 and Table 1. (1 inch mercury = 25.4 millimeters mercury = 0.4912 pound/inch^2 = 3.38 × 10^3 pascals.)

Spark-Gap Breakdown Voltages

Fig. 2 is for a voltage that is continuous or at a frequency low enough to permit complete deionization between cycles, between needle points or clean smooth spherical surfaces (electrodes ungrounded) in dust-free dry air. Temperature is 25 degrees Celsius and pressure is 760 millimeters (29.9 inches) of mercury. Peak kilovolts shown in the figure should be multiplied by the factors given in Table 1 for atmospheric conditions other than the above.

An approximate rule for uniform fields at all frequencies up to at least 300 megahertz is that the breakdown gradient of air is 30 peak kilovolts/centimeter or 75 peak kilovolts/inch at sea level (760 millimeters of mercury) and normal temperature (25 degrees Celsius). The breakdown voltage is approximately proportional to pressure and inversely proportional to absolute (Kelvin) temperature.

Certain synthetic gases have higher dielectric strengths than air. Two such gases that appear to be useful for electrical insulation are sulfur hexafluoride (SF_6) and Freon 12 (CCl_2F_2), which both have about

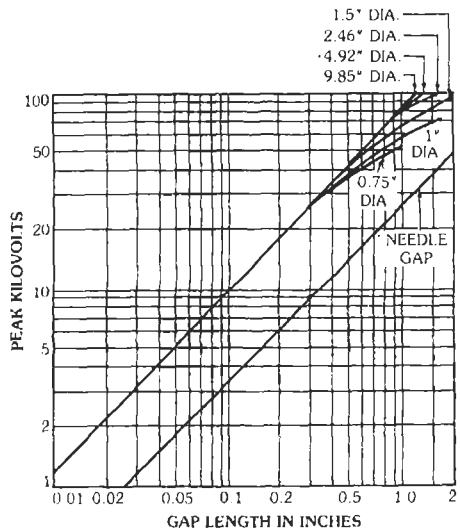

Fig. 1. Pressure as a function of altitude.

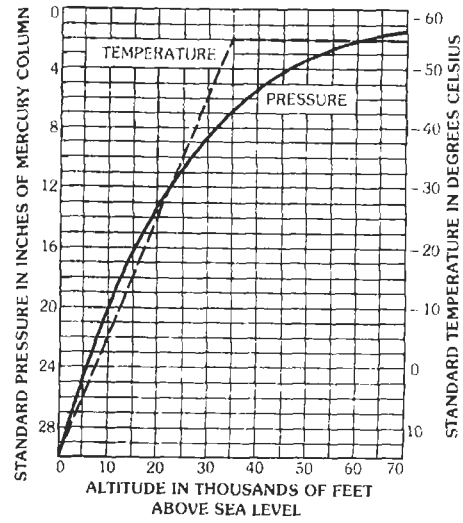

Fig. 2. Spark-gap breakdown voltages.

2.5 times the dielectric strength of air. Mixtures of sulfur hexafluoride with helium and of perfluoromethylcyclohexane (C_7F_{14}) with nitrogen have good dielectric strength as well as other desirable properties.

WEATHER DATA*

Temperature Extremes

United States (contiguous):

Lowest temperature:
Rodgers Pass, Montana (January 20, 1954)—−57 °C (−70 °F).

Highest temperature:
Greenland Ranch, Death Valley, California (July 10, 1913)—57 °C (134 °F).

Alaska:

Lowest temperature:
Prospect Creek Camp (January 23, 1971)—−62 °C (−79.8 °F).

Highest temperature:
Fort Yukon (June 27, 1915)—38 °C (100 °F).

Precipitation Extremes

United States:

Wettest state:
Louisiana—average annual rainfall 57.34 inches.
Driest state:
Nevada—average annual rainfall 8.60 inches.
Maximum recorded:
Camp Leroy, California (January 22–23, 1943)—26.12 inches in 24 hours.
Minimums recorded:
Bagdad, California (1909–1913)—3.93 inches in 5 years.

Greenland Ranch, California—1.76 inches annual average.

World:

Maximums recorded:
Cherrapunji, India (July, 1861)--366 inches in 1 month. (Average annual rainfall of Cherrapunji is 450 inches).
Baguio, Luzon, Philippines, July 14–15, 1911—46 inches in 24 hours.

Minimums recorded:
Wadi Halfa (Sudan) and Aswan (Egypt) are in the "rainless" area; average annual rainfall is too small to be measured.

Wind-Velocity and Temperature Extremes in North America

Data regarding extremes of temperature and wind velocity for several locations in North America may be found in Table 2.

Celsius Table of Relative Humidity or Percent of Saturation

To find the relative humidity when the wet-bulb and dry-bulb temperatures are known, consult Table 3.

WORLD TIME CHART

Time differences between selected major world cities may be determined from Chart 1.

MATERIALS AND FINISHES FOR TROPICAL AND MARINE USE

Corrosion

Ordinary finishing of equipment fails to meet satisfactorily conditions encountered in tropical and marine use. Under these conditions, corrosive influences are greatly aggravated by prevailing higher relative humidi-

Notes:

(1) Lightface figures designate am, bold figures pm.

(2) Time is that used at places indicated. In general, this is standard time, but for places marked with asterisks it is permanent daylight saving time. Temporary daylight saving time is commonplace but not indicated above.

(3) When passing the heavy line going down or to the right, add 1 day. When passing the heavy line going up or to the left, subtract 1 day.

ties, and temperature cycling causes alternate condensation on and evaporation of moisture from finished surfaces. Useful equipment life under adverse atmospheric influences depends largely on proper choice of base materials and finishes applied. Especially important in tropical and marine applications is avoidance of electrical contact between dissimilar metals.

Dissimilar metals widely separated in the galvanic series should not be bolted, riveted, etc., without separation by insulating material at the facing surfaces. The only exception occurs when both surfaces have been coated with the same protective metal, e.g., electroplating, hot dipping, galvanizing, etc.

Aluminum, steel, zinc, and cadmium should never be used bare. Electrical contact surfaces should be given copper-nickel-chromium or copper-nickel finish, and, in addition, they should be silver plated. Adjustable-capacitor plates should be silver plated.

An additional 0.000015-inch to 0.000020-inch electroplating of hard, bright gold over the silver greatly improves resistance to tarnish and oxidation and to attack by most chemicals, lowers electrical resistance, and provides long-term solderability.

Fungus and Decay

The value of fungicidal coatings or treatments is controversial. If equipment is to operate under tropical conditions, greater success can be achieved by the use of materials that do not provide a nutrient medium for fungus and insects. The following types or kinds of materials are examples of nonnutrient mediums that are generally considered acceptable.

Metals
Glass
Ceramics (steatite, glass-bonded mica)
Mica
Polyamide
Cellulose acetate
Rubber (natural or synthetic)
Plastic materials using glass, mica, or asbestos as a filler
Polyvinylchloride
Polytetrafluoroethylene
Monochlortrifluoroethylene

The following types or kinds of materials should not be used, except where such materials are fabricated into completed parts and their use is acceptable to the customer.

Linen
Cellulose nitrate
Regenerated cellulose
Wood
Jute
Leather
Cork
Paper and cardboard
Organic fiberboard
Hair or wool felts
Plastic materials using cotton, linen, or wood flour as a filler

Wood should not be used as an electrical insulator, and its use for other purposes should be restricted to those parts for which a superior substitute is not known. When used, it should be pressure-treated and impregnated to resist moisture, insects, and decay with a waterborne preservative (as specified in Federal Specification TT-W-571), and it should also be treated with a suitable fire-retardant chemical.

Finish Application Table

For information regarding the application of finishes, see Table 4.

PRINCIPAL LOW-VOLTAGE POWER SUPPLIES IN THE WORLD

Territory (Frequency) Voltage

North America:

Alaska (60) 120/240
Belize (60) 110/220
Bermuda (60) 115/230; some 120/208
Canada (60) 120/240; some 115/230
Costa Rica (60) 110/220
El Salvador (60) 110/220
Guatemala (60) 110/240; some 220, 120/208
Honduras (60) 110/220
Mexico (50, 60) 127/220 and other voltages Mexico City (50) 125/216
Nicaragua (60) 120
Panama (60) 110/220; some 120/240, 115/230
United States (60) 120/240 and 120/208

West Indies:

Antigua (60) 230/400
Bahamas (60) 115/200; some 115/220
Barbados (50) 120/208; some 110/200
Cuba (60) 115/230; some 120/208
Dominican Republic (60) 115/230
Guadeloupe (50) 127/220
Jamaica (50, some 60) 110/220
Martinique (50) 127/220
Puerto Rico (60) 120/240
Trinidad (50) 115/230
Virgin Islands (60) 120/240

South America:

Argentina (50) 220/380; also 220/440 dc
Bolivia (50, also 60) 220 and other voltages
Brazil (50, 60) 110, 220; also other voltages and dc Rio de Janeiro (50) 125/216
Chile (50) 220/380; some 220 dc
Colombia (60) 110/220; also 120/240 and others

TABLE 4. FINISH APPLICATION TABLE*

Material	Finish	Remarks
Aluminum alloy	Anodizing	An electrochemical-oxidation surface treatment, for improving corrosion resistance; not an electroplating process. For riveted or welded assemblies, specify chromic acid anodizing. Do not anodize parts with nonaluminum inserts. Colors vary: yellow-green, gray, or black.
	"Alrok"	Chemical-dip oxide treatment. Cheap. Inferior in abrasion and corrosion resistance to the anodizing process, but applicable to assemblies of aluminum and nonaluminum materials.
Copper and zinc alloys	Bright acid dip	Immersion of parts in acid solution. Clear lacquer applied to prevent tarnish.
Brass, bronze, zinc die-casting alloys	Brass, chrome, nickel, tin	As discussed under steel.
Magnesium alloy	Dichromate treatment	Corrosion-preventive dichromate dip. Yellow color.
Stainless steel	Passivating treatment	Nitric-acid immunizing dip.
Steel	Cadmium	Electroplate, dull white color, good corrosion resistance, easily scratched, good thread antiseize. Poor wear and galling resistance.
	Chromium	Electroplate, excellent corrosion resistance and lustrous appearance. Relatively expensive. Specify hard chrome plate for exceptionally hard abrasion-resistive surface. Has low coefficient of friction. Used to some extent on nonferrous metals particularly when die-cast. Chrome-plated objects usually receive a base electroplate of copper, then nickel, followed by chromium. Used for buildup of parts that are undersized. Do not use on parts with deep recesses.
	Blueing	Immersion of cleaned and polished steel into heated saltpeter or carbonaceous material. Part then rubbed with linseed oil. Cheap. Poor corrosion resistance.
	Silver plate	Electroplate, frosted appearance; buff to brighten. Tarnishes readily. Good bearing lining. For electrical contacts, reflectors.
	Zinc plate	Dip in molten zinc (galvanizing) or electroplate of low-carbon or low-alloy steels. Low cost. Generally inferior to cadmium plate. Poor appearance. Poor wear resistance: Electroplate has better adherence to base metal than hot-dip coating. For improving corrosion resistance, zinc-plated parts are given special inhibiting treatments.
	Nickel plate	Electroplate, dull white. Does not protect steel from galvanic corrosion. If plating is broken, corrosion of base metal will be hastened. Finishes in dull white, polished, or black. Do not use on parts with deep recesses.
	Black-oxide dip	Nonmetallic chemical black oxidizing treatment for steel, cast iron, and wrought iron. Inferior to electroplate. No buildup. Suitable for parts with close dimensional requirements as gears, worms, and guides. Poor abrasion resistance.
	Phosphate treatment	Nonmetallic chemical treatment for steel and iron products. Suitable for protection of internal surfaces of hollow parts. Small amount of surface buildup. Inferior to metallic electroplate. Poor abrasion resistance. Good paint base.

Continued on next page.

TABLE 4 (CONT.) FINISH APPLICATION TABLE*

Material	Finish	Remarks
Steel (cont.)	Tin plate	Hot dip or electroplate. Excellent corrosion resistance, but if broken will not protect steel from galvanic corrosion. Also used for copper, brass, and bronze parts that must be soldered after plating. Tin-plated parts can be severely worked and deformed without rupture of plating.
	Brass plate	Electroplate of copper and zinc. Applied to brass and steel parts where uniform appearance is desired. Applied to steel parts when bonding to rubber is desired.
	Copper plate	Electroplate applied before nickel or chrome plates. Also for parts to be brazed or protected against carburization. Tarnishes readily.

Notes:

1. Abstracted from *Electric Power Abroad*, issued 1963 by the Bureau of International Commerce of the US Department of Commerce. This pamphlet is obtainable from the Superintendent of Documents, US Government Printing Office, Washington, D.C. 20402.
2. The listings show electric (residential) power supplied in each country; as indicated, in very many cases other types of supply also exist to a greater or lesser extent. Therefore, for specific characteristics of the power supply of particular cities, reference should be made to *Electric Power Abroad*. This pamphlet also gives additional details such as number of phases, number of wires to the residence, frequency stability, grounding regulations, and some data on types of commercial service.
3. In the United States in urban areas, the usual supply is 60-hertz 3-phase 120/208 volts; in less densely populated areas, it is usually 120/240 volts, single phase, to each customer. Any other supplies, including dc, are rare and are becoming more so. Additional information for the US is given in the current edition of *Directory of Electric Utilities*, published by McGraw-Hill Book Co., New York, N.Y.
4. All voltages in the table are ac except where specifically stated as dc. The latter are infrequent and in most cases are being replaced by ac. The lower voltages shown for ac, wye or delta ac, or for dc distribution lines, are used mostly for lighting and small appliances; the higher voltages are used for larger appliances.

POWER SUPPLY WIRING

Electric power supply (mains) wiring is usually controlled for public safety by local or state government boards, based in the USA primarily on the National Electrical Code (NEC)* and the National Electric Safety Codes.† Brief extracts from some NEC requirements are given here for convenient reference.

Many products such as wire and cable, fuses, outlet boxes, appliances, etc., are governed within the USA by Underwriters Laboratories (UL) Standards, which specify the terminology used for the various classes of an item as well as the safety requirements that must be met by UL approved items. Note that the overall performance of assemblies such as appliances, motors, radio equipment, or television equipment is not covered by NEC or UL standards, which are primarily for personnel safety.

The following tables are provided.

Tables 5 and 6: NEC standard types of insulated wires and cables.

Tables 7 and 8: Allowable currents for conductors.

Table 8: Derating factors to be applied for ambient temperatures above 30 °C (86 °F) and for more than three conductors in a cable or conduit.

Table 9: Motor starting currents, which determine the overcurrent protection requirements during the starting period.

Table 10: Motor full-load operating currents for usual conditions and speeds.

Guide to Use of Tables

Determine the total equipment load by adding the loads of the various individual items, estimating motor currents according to Table 10 if specific operating-current information is not otherwise available. Any load substantially bigger than this should be interrupted by an overload protective device; normally the next-larger standard fuse or circuit breaker is considered satisfactory.

Determine the total starting load by using the locked-rotor currents computed from Table 9 and the steady-state currents for resistive devices. Make an additional allowance for any large quantities of tungsten lamps, starting transients, and high-inertia loads that will increase the duration of the starting period. The circuit overload protection must be designed to carry this load for the entire starting period. Time-lag fuses or time-delay circuit breakers are usually desirable.

Using the starting currents, determine the voltage drops in the supply circuit; thus be sure that the terminal voltage of the motor or other device will be adequate at start. Increase the size of the supply conductor or reduce the source impedance if necessary. From the starting and running currents, determine the required size of supply conductors.

WIRING OF ELECTRONIC EQUIPMENT AND CHASSIS

There are few official standards for the internal wiring of electronic equipment and chassis. Nevertheless, the following points should be considered.

(A) Probable maximum continuous ambient temperature where the wiring is located.
(B) Allowable temperature rise of conductor surface under full-load conditions (determines minimum wire size).
(C) Maximum voltage to ground or to surrounding metal parts (determines required insulation thickness).
(D) Possibility of corona on high-voltage leads; some insulating materials deteriorate rapidly under corona conditions.
(E) Need for shield braid on some conductors to reduce noise pickup. Shields must be insulated if positive single-point grounding is to be attained.
(F) Skin effect on conductors carrying high radio-frequency currents.
(G) Vibration, shock, or relative motion of conductors during normal use of the equipment. Stranded or flexible conductors and adequate clamping or other tie-down of conductors and cables may be essential.

3. Derating factors—more than three conductors in raceway or cable:

Number of conductors	4–6	7–24	25–42	>42
% of current capacity	80	70	60	50

(H) Wiring should be shielded from the direct heat radiation of high-temperature parts such as electron tubes and power resistors.

(I) Wire identification may be required for convenience in manufacture, installation, or servicing.

As a matter of expediency, most electronic equipment employs the smallest conveniently handled wire size (usually 20 to 24 AWG) for most wiring, with the larger conductors being installed only for circuits carrying currents greater than that permitted for the "general-use" wire size. With the trend toward compact solid-state integrated-circuit equipment, smaller wire sizes are being used. However, the reduction in wiring bundle size may be small unless the conductor insulation thickness (determined by voltage considerations) can be reduced.

Table 11 gives recommended current ratings for copper and some aluminum based on a 45 °C (40 °C for wires smaller than 22 AWG) conductor temperature rise due to load current. Table 11 may be used for the temperature conditions given in Table 12.

A 60 °C ambient temperature around the wiring (20 °C internal temperature rise from 40 °C [104 °F]

* Locked-rotor currents of motors are useful in determining branch-circuit overcurrent protection requirements and voltage drop at start. These values are indicated by code letters on motor nameplate. Note NEMA standard.

ambient around the equipment) is typical of some electronic equipment. If higher ambient temperatures, high power, or compact designs with electron tubes or magnetic-core components (except for very low power) are a factor, the temperature in the wiring space should be specifically determined.

"Wiring confined" ratings are based on 15 or more wires in a bundle, with the sum of all the actual load currents of the bundled wires not exceeding 20% of the permitted "wiring confined" sum total carrying capacity of the bundled wires. These ratings approximate 60% of the free-air ratings (with some variations due to rounding). They should be used for wire in harnesses, cable, conduit, and general chassis conditions. Bundles of fewer than 15 wires may have the allowable sum of the load currents increased as the bundle approaches the single-wire condition.

RESISTANCE CHANGE WITH TEMPERATURE

The resistance of most conductor materials changes with temperature. Table 11 shows the copper-wire resistance at 100 °C. Correction factors must be applied to determine the resistance at other temperatures, or for other materials. Thus, from Table 11 determine the copper-wire resistance at 100 °C (multiply by conversion factor m of Table 13 for other materials). Use the equation

$$R_t = R_r m[1 + K(t - 100)]$$

where,

R_t = resistance at desired temperature t,
R_r = resistance at 100 °C for copper (Table 11),

K = correction factor (Table 13),
t = desired temperature (°C).

WIRE IDENTIFICATION

In a complex wiring assembly, or if both ends of a wire cannot be seen from one station, a means of identifying each lead simplifies manufacture, installation, and servicing. Common identification methods are:

(A) Tag each end of a lead with an assigned designation (an alternative method is to print the designation at frequent intervals along the wire insulation).

(B) Color code the wires. The wire insulation may be a solid color, color stripes may be spiraled around the wire, or the name of the color (or its numerical code equivalent) may be stamped at frequent intervals along the wire.

TABLE 12. TEMPERATURE CONDITIONS FOR TABLE 11

Maximum Allowable Conductor Temperature °C	Maximum Ambient Temperature Around Wire °C	Typical Conductor and Insulation
105	60	Bare or tinned copper or aluminum; polyvinyl-chloride insulation
200	155	Silver-coated copper; FEP or PTFE with FEP jacket insulation*
260	215	Nickel-coated copper; PTFE insulation*

* FEP = Fluorinated ethylene propylene.
PTFE = Polytetrafluoroethylene.

TABLE 13. TEMPERATURE AND MATERIALS CORRECTION FACTORS

Conductor Material	Material Factor m	Correction Factor K
Soft copper	1.00	0.0039
Hard copper	1.03	0.0038
Copper-clad steel:		
30% conductivity	3.47	0.0044
40% conductivity	2.56	0.0041
Aluminum	1.64	0.0039
Nickel	5.28	0.0047
Nickel-clad copper:		
10%	1.07	0.0038
30%	1.35	0.0036
Silver	0.94	0.0038

Color Coding

The commonly used colors and their numerical codes are:

0	Black	5	Green
1	Brown	6	Blue
2	Red	7	Violet (purple)
3	Orange	8	Gray (slate)
4	Yellow	9	White

While spiral stripes can be applied on top of any basic insulation color, under less favorable viewing conditions it is difficult to distinguish some colors from the basic insulation color. Identification may be slow and subject to error. The preferred combination consists of one or two (sometimes three) colored stripes on a white basic insulation. To minimize identification errors, the first stripe is made wider than the second (or third), and some rules require that the second stripe be of higher numerical code than the first stripe. If the required variety of wire color codes is not great, the preceding guides should be followed.

Table 14 gives a standard color code used to distinguish by function the various leads in electronic circuits.

In manufacturing practice, it is preferred that, at any harness breakout point, all wires of the same color code be connected to the same terminal at that location. When this rule and the wire color coding of Table 14 are both applicable, additional tracers may be used to supplement the primary coding of Table 14.

TABLE 14. COLORS FOR WIRE IDENTIFICATION BY FUNCTION

Function	Color	Identification No.
Grounds, grounded elements	Black	0

* Applies to diodes, semiconductor elements, photoelectric cells, mercury-arc rectifiers, and other elements with operation similar to vacuum tubes and transistors.

† Applies to all types of gas tubes with operation similar to vacuum tubes.

DIAMETER OF CIRCLE ENCLOSING A GIVEN NUMBER OF SMALLER CIRCLES*

Four of many possible compact arrangements of circles within a circle are shown in Fig. 3. To determine the diameter of the smallest enclosing circle for a particular number of enclosed circles all of the same size, three factors that influence the size of the enclosing circle should be considered, as follows.

Arrangement of Center or Core Circles

The four most common arrangements of center or core circles are shown in cross section in Fig. 3. It may seem that Fig. 3A would require the smallest enclosing circle for a given number of enclosed circles, but this is not always the case since the most compact arrangement will depend in part on the number of circles to be enclosed.

Diameter of Enclosing Circle When Outer Layer of Circles Is Complete

Successive, complete "layers" of circles may be placed around each of the central cores of 1, 2, 3, or 4 circles. The number of circles contained in arrangements of complete "layers" around a central core of circles, as well as the diameter of the enclosing circle, may be obtained from Table 15. Thus, for example, Fig. 3A has a total of 18 circles arranged in two complete "layers" around a central core consisting of one circle; this agrees with the data shown in the left half of Table 15 for $n = 2$.

To determine the diameter of the enclosing circle, the data in the right half of Table 15 are used. Thus, for $n = 2$ and an "A" pattern, diameter D is 5 times the diameter, d, of the enclosed circles.

Diameter of Enclosing Circle When Outer Layer of Circles Is Not Complete

In most cases, it is possible to reduce the size of the enclosing circle from that required if the outer layer

n	†	†	†	†	†	†	†	†

* Diameter D is given in terms of d, the diameter of the enclosed circles.

† For n complete layers over core, the number of enclosed circles N for "A" center pattern is $3n^2 + 3n + 1$; for "B," $3n^2 + 5n + 2$; for "C," $3n^2 + 6n + 3$; for "D," $3n^2 + 7n + 4$; while the diameter D of the enclosing circle for "A" center pattern is $(2n + 1)d$; for "B," $(2n + 2)d$; for "C," $[1 + 2(n^2 + n + \frac{1}{3})^{1/2}]d$; and for "D," $[1 + (4n^2 + 5.644n + 2)^{1/2}]d$.

Reprinted with permission from *Machinery's Handbook*, 17th edition. New York: Industrial Press, Inc.

were complete. Thus, for example, Fig. 3B shows that the central core consisting of two circles is surrounded by one complete layer of eight circles and one partial outer layer of four circles so that the total number of circles enclosed is 14. If the outer layer were complete, then (from Table 15) the total number of enclosed circles would be 24 and the diameter of the enclosing circle would be $6d$; however, since the outer layer is composed of only four circles out of a possible 14 for a complete second layer, a smaller diameter of enclosing circle may be used. Table 16 shows that for a total of 14 enclosed circles arranged in a "B" pattern with the outer layer of circles incomplete, the diameter for the enclosing circle is $4.606d$.

Table 16 can be used to determine the smallest enclosing circle for a given number of circles to be enclosed by direct comparison of the "A," "B," and "C" columns. For data outside the range of Table 16, use the equations in Dr. Dutka's article.*

Approximate Equation When Number of Enclosed Circles is Large

When a large number of circles is to be enclosed, the arrangement of the center circles has little effect on the diameter of the enclosing circle. For numbers of circles greater than 10 000, the diameter of the enclosing circle may be calculated within 2 percent from the equation

$$D = d[1 + (N/0.907)^{1/2}]$$

where,

D = diameter of enclosing circle,
d = diameter of enclosed circles,
N = number of enclosed circles.

TORQUE AND HORSEPOWER

Torque varies directly with power and inversely with rotating speed of the shaft, or

$$T = KP/N$$

where,

T = torque in pound-inches,
P = horsepower,
N = revolutions/minute,
K = 63 000 (constant).

TRANSMISSION-LINE SAG CALCULATIONS*

For transmission-line work, with towers on the same or slightly different levels, the cables are assumed to

* The diameter, D, of the enclosing circle is equal to the diameter factor, K, multiplied by d, the diameter of the enclosed circles, or $D = K \times d$. For example, if the number of circles to be enclosed, N, is 12, and the center circle arrangement is "C," then for $d = 1\frac{1}{2}$ inches, $D = 4.005 \times 1\frac{1}{2} = 6.083$ inches. Reprinted with permission from *Machinery's Handbook*, 17th Edition. New York: Industrial Press, Inc.

take the form of a parabola instead of their actual form of a catenary. The error is negligible, and the computations are much simplified. In calculating sags, the changes in cables due to variations in load and temperature must be considered.

Supports at Same Level

Refer to Fig. 4. The equations used in calculating sags are

$$H = WL^2/8S$$

$$S = WL^2/8H = [(L_c - L)3L/8]^{1/2}$$

$$L_c = L + 8S^2/3L$$

where,

L = length of span in feet,
L_c = length of cable in feet,
S = sag of cable at center of span in feet,

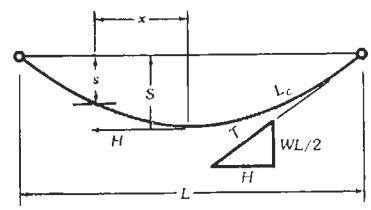

Fig. 4. Supports at same elevation.

H = tension in cable at center of span in pounds = horizontal component of the tension at any point,
W = weight of cable in pounds per lineal foot.

If cables are subject to wind and ice loads, W = the algebraic sum of the loads. That is, for ice on cables, W = weight of cables plus weight of ice; for wind on bare or ice-covered cables, W = the square root of the sum of the squares of the vertical and horizontal loads.

For any intermediate point at a distance x from the center of the span, the sag is

$$S_x = S(1 - 4x^2/L^2)$$

Supports at Different Levels

Refer to Fig. 5.

$$S = S_0 = WL_0^2 \cos a/8T$$

$$= WL^2/8T \cos a$$

$$S_1 = WL_1^2/8H$$

$$S_2 = WL_2^2/8H$$

$$L_1/2 = L/2 - (hH \cos a/WL)$$

$$L_2/2 = L/2 + (hH \cos a/WL)$$

$$L_c = L + \tfrac{4}{3}[(S_1^2/L_1) + (S_2^2/L_2)]$$

where,

W = weight of cable in pounds per lineal foot between supports or in direction of L_0,
T = tension in cable direction parallel with line between supports.

The change, l, in length of cable, L_c, for varying temperature is found by multiplying the number of degrees, n, by the length of the cable in feet times the coefficient of linear expansion per foot per degree Fahrenheit, c. This is

$$l = L_c \times n \times c$$

A short approximate method for determining sags under varying temperatures and loadings that is close enough for all ordinary line work is as follows:

(A) Determine sag of cable with maximum stress under maximum load of lowest temperature occurring at the time of maximum load, and find length of cable with this sag.

(B) Find length of cable at the temperature for which the sag is required.

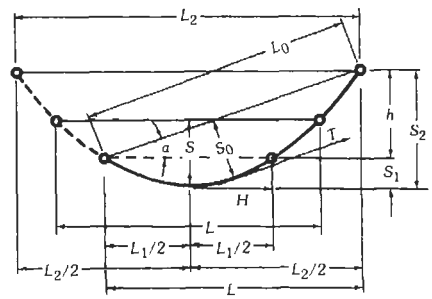

Fig. 5. Supports at different elevations.

(C) Assume a certain reduced tension in the cable at the temperature and under the loading combination for which the sag is required; then find the decrease in length of the cable due to the decrease of the stress from its maximum.

(D) Combine the algebraic sum of **(B)** and **(C)** with **(A)** to get the length of the cable under the desired conditions; from this length, the sag and tension can be determined.

(E) If this tension agrees with that assumed in **(C)**, the sag in **(D)** is correct. If it does not agree, another assumption of tension in **(C)** must be made and the process repeated until **(C)** and **(D)** agree.

STRUCTURAL STANDARDS FOR STEEL RADIO TOWERS*

Material

(A) Structural steel shall conform to American Society for Testing Materials *Standard Specifications for Steel for Bridges and Buildings*, Serial Designation A-7, as amended to date.

(B) Steel pipe shall conform to American Society for Testing Materials standard specifications either for electric-resistance welded steel pipe, Grade A or Grade B, Serial Designation A-135, or for welded and seamless steel pipe, Grade A or Grade B, Serial Designation A-53, each as amended to date.

Loading

(A) 20-pound design: Structures up to 600 feet in height (unless they are to be located within city limits) shall be designed for a horizontal wind pressure of 20

* Abstracted from *American Standard Minimum Design Loads in Buildings and Other Structures*, A58.1-1955. New York: American National Standards Institute, Inc. Also from Electronic Industries Association Standard TR-116, October 1949. Sections on manufacture and workmanship, finish, and plans and marking of the standard are not reproduced here. The section "Wind Velocities and Pressures" is not part of the standard.

pounds/foot^2 on flat surfaces and 13.3 pounds/foot^2 on cylindrical surfaces.

(B) 30-pound design: Structures more than 600 feet in height and those of any height to be located within city limits shall be designed for a horizontal wind pressure of 30 pounds/foot^2 on flat surfaces and 20 pounds/foot^2 on cylindrical surfaces.

(C) Other designs: Certain structures may be designed to resist loads greater than those described in **(A)** and **(B)**. Figure 1 of American Standard A58.1-1955 shows sections of the United States where greater wind pressures may occur. In all such cases, the pressure on cylindrical surfaces shall be computed as being $\frac{2}{3}$ of that specified for flat surfaces.

(D) For open-face (latticed) structures of square cross section, the wind pressure normal to one face shall be applied to 2.20 times the normal projected area of all members in one face, or 2.40 times the normal projected area of one face for wind applied to one corner. For open-face (latticed) structures of triangular cross section, the wind pressure normal to one face shall be applied to 2.00 times the normal projected area of all members in one face, or 1.50 times the normal projected area for wind parallel to one face. For closed-face (solid) structures, the wind pressure shall be applied to 1.00 times the normal projected area for square or rectangular shape, 0.80 for hexagonal or octagonal shape, and 0.60 for round or elliptical shape.

(E) Provisions shall be made for all supplementary loadings caused by the attachment of guys, antennas, transmission and power lines, ladders, etc. The pressure shall be as described for the respective designs and shall be applied to the projected area of the construction.

(F) The total load specified above shall be applied to the structure in the directions that will cause the maximum stress in the various members.

(G) The dead weight of the structure, and all materials attached thereto, shall be included.

Unit Stresses

(A) All parts of the structure shall be so designed that the unit stresses resulting from the specified loads shall not exceed the following values:

Axial tension on net section = 20 000 pounds/inch^2

Axial compression on gross section:

For members with values of L/R not greater than 120,

$$= 17\,000 - 0.485L^2/R^2 \text{ pounds/inch}^2$$

For members with values of L/R greater than 120,

$$= \frac{18\,000}{1 + L^2/18\,000R^2} \text{ pounds/inch}^2$$

where L = unbraced length of the member, and

R = corresponding radius of gyration, both in inches.

Maximum L/R for main leg members = 140

Maximum L/R for other compression members with calculated stress = 200

Maximum L/R for members with no calculated stress = 250

Bending on extreme fibres = 20 000 pounds/inch^2

Single shear on bolts = 13 500 pounds/inch^2

Double shear on bolts = 27 000 pounds/inch^2

Bearing on bolts (single shear) = 30 000 pounds/inch^2

Bearing on bolts (double shear) = 30 000 pounds/inch^2

Tension on bolts and other threaded parts, on nominal area at root of thread = 16 000 pounds/inch^2

Members subject to both axial and bending stresses shall be so designed that the calculated unit axial stress divided by the allowable unit axial stress, plus the calculated unit bending stress, divided by the allowable unit bending stress, shall not exceed unity.

(B) Minimum thickness of material for structural members:

Pinted structural angles and plates = $\frac{3}{16}$ inch

Hot-dip galvanized structural angles and plates = $\frac{1}{8}$ inch

Other structural members to mill minimum for standard shapes.

(C) Where materials of higher quality than specified under "Material" above are used, the above unit stresses may be modified. The modified unit stresses must provide the same factor of safety based on the yield point of the materials.

Foundations

(A) Standard foundations shall be designed for a soil pressure not to exceed 4000 pounds/foot^2 under the specified loading. In uplift, the foundations shall be designed to resist 100 percent more than the specified loading, assuming that the base of the pier will engage the frustum of an inverted pyramid of earth whose sides form an angle of 30 degrees with the vertical. Earth shall be considered to weigh 100 pounds/foot^3 and concrete 140 pounds/foot^3.

(B) Foundation plans shall ordinarily show standard foundations as defined in **(A)**. Where the actual soil conditions are not normal, requiring some modification in the standard design, and complete soil information is provided to the manufacturer by the purchaser, the foundation plan shall show the required design.

(C) Under conditions requiring special engineering such as pile construction, roof installations, etc., the manufacturer shall provide the necessary information so

that proper foundations can be designed by the purchaser's engineer or architect.

(D) In the design of guy anchors subject to submersion, the upward pressure of the water should be taken into account.

Wind Velocities and Pressures

Data regarding wind velocities and pressures are contained in Table 17.

VIBRATION AND SHOCK ISOLATION

Symbols

b = damping factor
d = static deflection in inches
E = relative transmissibility
= (force transmitted by isolators)/(force transmitted by rigid mountings)
F = force in pounds
F_0 = peak force in pounds
f = frequency in hertz
f_0 = resonant frequency of system in hertz
G = acceleration of gravity
≈ 386 inches per second^2
g = peak acceleration in dimensionless gravitational units
$= \ddot{X}_0/G$
$j = (-1)^{1/2}$, vector operator
k = stiffness constant; force required to compress or extend isolators unit distance in pounds per inch
r = coefficient of viscous damping in pounds per inch per second
t = time in seconds
W = weight in pounds
x = displacement from equilibrium position in inches
X_0 = peak displacement in inches
$\dot{x}$ = velocity in inches per second
$= dx/dt$
$\dot{X}_0$ = peak velocity in inches per second
$\ddot{x}$ = acceleration in inches per second^2
$= d^2x/dt^2$
$\ddot{X}_0$ = peak acceleration in inches per second^2
ϕ = phase angle in radians
ω = angular velocity in radians per second
$= 2\pi f$

Equations

The following relations apply to simple harmonic motion in systems with one degree of freedom. Although actual vibration is usually more complex, the equations provide useful approximations for practical purposes.

TABLE 17. WIND VELOCITIES AND PRESSURES

Actual Velocity V_a* (miles/hour)	Indicated Velocity V_i (miles/hour)		Pressure P (pounds/foot^2) Projected Areas†	
	3-cup Anemometer	4-cup Anemometer	Cylindrical Surfaces ($P = 0.0025V_a^2$)	Flat Surfaces ($P = 0.0042V_a^2$)

150	167	201	56.3	94.5

* Although wind velocities are measured with cup anemometers, all data published by the US Weather Bureau since January 1932 include instrumental corrections and are actual velocities. Prior to 1932, indicated velocities were published.

In calculating pressures on structures, the "fastest-single-mile velocities" published by the Weather Bureau should be multiplied by a gust factor of 1.3 to obtain the maximum instantaneous actual velocities. See "Wind-Velocity and Temperature Extremes in North America" in this chapter for fastest-single-mile records at various places in the United States and Canada.

† The American Bridge Company equations given here are based on a ratio of 25/42 for pressures on cylindrical and flat surfaces, respectively, while the Electronic Industries Association specifies a ratio of 2/3. The actual ratio varies in a complex manner with Reynolds number, shape, and size of the exposed object.

$$F = W(\ddot{x}/G) \quad \text{(Eq. 1)}$$

$$F_0 = Wg \quad \text{(Eq. 2)}$$

$$x = X_0 \sin(\omega t + \phi) \quad \text{(Eq. 3)}$$

$$X_0 = 9.77\ g/f^2 \quad \text{(Eq. 4)}$$

$$\dot{X}_0 = \omega X_0 = 6.28 f X_0 = 61.4 g/f \quad \text{(Eq. 5)}$$

$$\ddot{X}_0 = \omega^2 X_0 = 39.5 f^2 X_0 = 386 g \quad \text{(Eq. 6)}$$

$$E = \left| \frac{r - j(k/\omega)}{r + j[(\omega W/G) - k/\omega]} \right| \quad \text{(Eq. 7)}$$

$$f_0 = 3.13\ (k/W)^{1/2} \quad \text{(Eq. 8)}$$

$$b = 9.77 r/(kW)^{1/2} \quad \text{(Eq. 9)}$$

For critical damping, $b = 1$.

Neglecting dissipation ($b = 0$), or at $f/f_0 = (2)^{1/2}$ for any degree of damping

$$E = \left| \frac{1}{(f/f_0)^2 - 1} \right| \quad \text{(Eq. 10)}$$

When damping is neglected

$$k = W/d \quad \text{(Eq. 11)}$$

$$f_0 = 3.13/d^{1/2} \quad \text{(Eq. 12)}$$

$$E = 9.77/(df^2 - 9.77) \quad \text{(Eq. 13)}$$

Acceleration

The intensity of vibratory forces is often defined in terms of g values. From Eq. 2, it is apparent, for example, that a peak acceleration of $10g$ on a body will result in a reactionary force by the body equal to 10 times its weight.

If an object is mounted on vibration isolators, the accelerations of the vehicle are transmitted to the object (or vice versa) in an amplitude and phase that depend on the elastic flexing of the isolators in the direction in which the accelerations (dynamic forces) are applied.

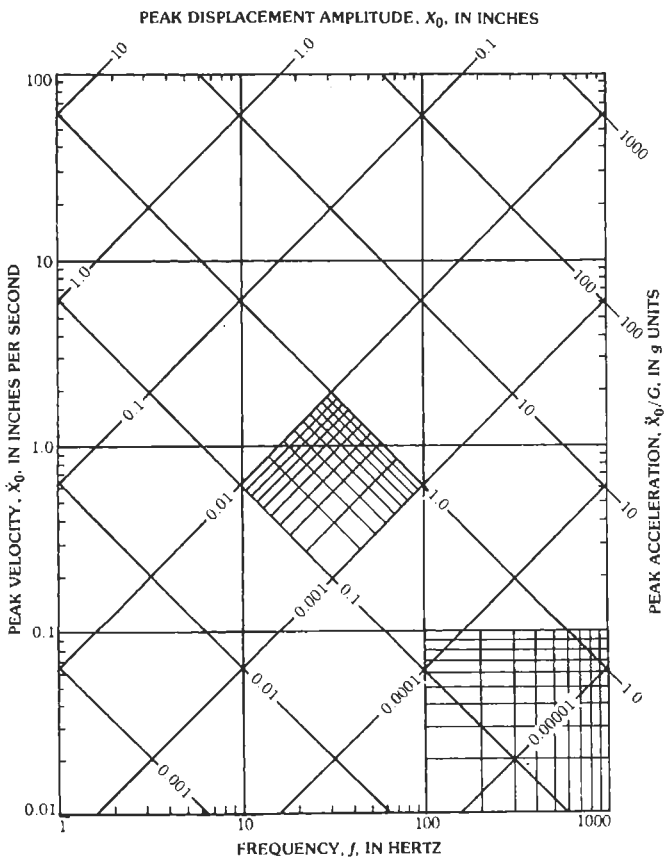

Fig. 6. Relation of frequency and peak values of velocity, displacement, and acceleration.

Magnitudes

The relations among X_0, $\dot{X}_0$, $\ddot{X}_0$, and f are shown in Fig. 6. Any two of these parameters applied to the graph locate the other two. For example, suppose $f = 10$ hertz and peak displacement $X_0 = 1$ inch. From Fig. 6, peak velocity $\dot{X}_0 = 63$ inches per second and peak acceleration $\ddot{X}_0 = 10g$.

Natural Frequency

If damping is neglected, the natural frequency, f_0, of vibration of an isolated system in the vertical direction can be calculated from Eq. 12 from the static deflection of the mounts. For example, suppose an object at rest causes a 0.25-inch deflection of its supporting springs. Then

$$f_0 = 3.13/(0.25)^{1/2} = 6.3 \text{ hertz}$$

Resonance

In Fig. 7, E is plotted against f/f_0 for various damping factors. Note that resonance occurs when $f_0 \approx f$ and that the vibratory forces are then increased by the isolators. To reduce vibration, f_0 must be less than $0.7f$, and it should be as small as $0.3f$ for good isolation.

It is not possible to secure good isolation at all vibrational frequencies in vehicles and similar environments where several different and varying exciting frequencies are present and where the isolators may have to withstand shock as well as vibration. In such cases, f_0 is often selected as about 1.5 to 2 times the predominant f. Information regarding vibration in typical vehicles is shown in Table 18.

Although all supporting structures have compliance and may reduce the effects of vibration and shock, the apparent stiffness of many "rigid" mountings is merely a matter of degree, and in conjunction with the supported mass, they can also give rise to resonance effects, thus magnifying the amplitude of certain vibrations.

Damping

Damping is desirable to reduce vibration amplitude when the exciting frequency is in the vicinity of f_0. This occurs occasionally in most installations. Any isolator that absorbs energy provides damping.

It is seldom practical to introduce damping as an independent variable in the design of vibration isolators for relatively small objects. The usual practice is to rely on the inherent damping characteristics of the rubber or other elastic material employed in the mounting. Damping achieved in this way seldom exceeds 5 percent of the amount needed to produce a critically damped system. In vibration isolators for large objects, such as variable-speed engines, the system often can be designed to produce nearly critical damping by employing fluid dashpots or similar devices.

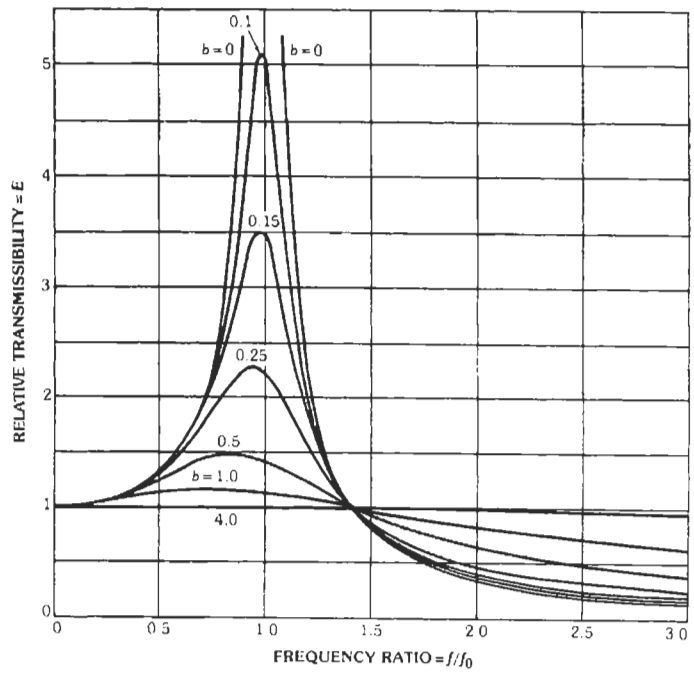

Fig. 7. Relative transmissibility E as a function of frequency ratio f/f_0 for various amounts of damping b. (*By permission from* Vibration Analysis, *by N. O. Myklestad. ©1944, McGraw-Hill Book Co.*)

TABLE 18. VIBRATION IN TYPICAL VEHICLES

Vehicle	Range of Frequencies (hertz)	Approximate Peak Amplitude (inches)	Nature of Excitation	Usual Choice of Isolator Resonant Frequency
Ships	0 to 15	0.02	Engine vibration in diesel or reciprocating steam drive	6 hertz for vibration isolation in commercial vessels. 27 to 30 hertz for shock isolation on naval vessels. These latter mounts amplify most vibrations to some extent.
	0 to 33	0.01	Propeller-blade frequency = (propeller rpm) × (number of blades)/60	
Piston-engine aircraft	0 to 60	0.01	Engine vibrations	Above 20 hertz. Amplitude of vibrations varies with location in aircraft. Landing shock can be neglected.
	0 to 100	0.01	Propeller vibrations. Aerodynamic vibrations due to buffeting	
Turboprop aircraft	0 to 60	0.01	Engine vibrations = (engine rpm)/60 Also aerodynamic vibrations due to buffeting and turbulence	9 hertz
	0 to 100	0.01	Propeller vibrations	
Jet aircraft	Up to 500	0.001	Audible noise frequencies due to jet wake and combustion turbulence; very little engine vibration	9 hertz
Passenger automobiles	1	6	Suspension resonance	25 hertz will usually avoid resonance with wheel hop and suspension resonant frequencies.
	8 to 12	0.02	Unsprung weight resonance (wheel hop)	
	20+	0.002	Irregular transient vibrations due to resonances of structural members with road roughnesses	
Automobile trucks	4	5	Suspension resonance	Above 20 hertz and should not correspond with any structural resonance. It is not advisible to attempt to isolate suspension and unsprung weight resonances.
	20	0.05	Unsprung weight resonance	
	80+	0.005	Structural resonances	
Military tanks	1 to 3	2	Suspension resonance	Similar to automobile truck
	Depends on speed	—	Track-laying frequency ≈17.6 (speed in mph)/(tread spacing in inches)	
	100+	0.001	Structural resonances	
Railroad trains	Broad and erratic		Similar to automobiles with additional excitations from rail joints and from side slop in rail trucks and draft gear	20 hertz has been successful in railroad applications. Shock with velocity changes up to 100 inches/second in direction of train occurs when coupling cars or starting freight trains.

Practical Application

Vibration can be accurately precalculated only for the simplest systems. In other cases, the actual vibration should be measured on experimental assemblies by using electrical vibration pickups. Complex vibration is often described by a plot of the g values against frequency. These plots usually show several frequencies at which the largest accelerations are present. The patterns will vary from place to place in a complicated structure and will also depend on the direction in which the acceleration is measured.

After vibration has been measured and plotted in this way, attention can be devoted to reduction of the predominant components. The equations and principles given above are used as guides in selecting the size, stiffness, damping characteristics, and location of isolators.

Shock

In many practical situations, vibration and shock occur simultaneously. The design of isolators for vibration should anticipate the effects of shock and vice versa.

When heavy shock is applied to a system using vibration isolators, there is usually a definite deflection at which the isolators snub or at which their stiffness suddenly becomes much greater. These actions may amplify the shock forces. To reduce this effect, it is generally desirable to use isolators that have smoothly increasing stiffness with increasing deflection.

Shock protection is improved by isolators that permit large deflections in all directions before the protected equipment is snubbed or strikes neighboring apparatus. The amplitude of vibration resulting from shock can be reduced by employing isolators that absorb energy and thus damp oscillatory movement.

Probabilities of damage to the apparatus itself from impact shock can be minimized by:

(A) Making the weight of equipment components as small as possible and the strength of structural members as great as possible.
(B) Distributing rather than concentrating the weights of equipment components and avoiding rigid connections between components.
(C) Employing structural members that have high ratios of stiffness to weight, such as tubes, I beams, etc.
(D) Avoiding, so far as is practical, stress concentrations at joints, supports, discontinuities, etc.
(E) Using materials such as steel that yield rather than rupture under high stress.

US GRAPHIC SYMBOLS

The USA standard graphic symbols for electrical and electronics diagrams cover both the communication and power fields. Symbols of primary interest to communications workers are in Fig. 8. They have been abstracted from IEEE Standard 315-1975.* Symbols that also agree with Recommendation No. 117 of the International Electrotechnical Commission are indicated by "*IEC*."

Diagram Types

Block diagrams consist of simple rectangles and circles with names or other designations within or adjacent to them to show the general arrangement of apparatus to perform desired functions. The direction of power or signal flow is often indicated by arrows near the connecting lines or arrowheads on the lines.

Schematic diagrams show all major components and their interconnections. A single-line diagram, as indicated by that name, uses single lines to interconnect components even though two or more conductors are actually required. It is a shorthand form of schematic diagram. It is always used for waveguide diagrams.

Wiring diagrams are complete in that all conductors are shown and all terminal identifications are included. The contact numbers on electron-tube sockets, colors of transformer leads, rotors of adjustable capacitors, and other terminal markings are shown so that a workman having no knowledge of the operation of the equipment can wire it properly.

Orientation

Graphic symbols are not considered to be coarse pictures of specific pieces of equipment but are true symbols representing the functions of parts in the circuit. Consequently, they may be rotated to any orientation with respect to each other without changing their meanings. Ground, chassis, and antenna symbols, for instance, may "point" in any direction that is convenient for drafting purposes.

Graphic symbols may be correlated with parts lists, descriptions, or instructions by means of reference designations (MIL-STD-16).

Detached Elements

Switches and relays often have many sets of contacts, and these sets may be separated and placed in the parts of the drawing to which they apply. Each separated element should be clearly labeled as part of the basic switch or relay.

Terminals

The terminal symbol need not be used unless it is needed. Thus, it may be omitted from relay and switch symbols. In particular, the terminal symbol often shown at the end of the movable element of a relay or

* Published by the Institute of Electrical and Electronics Engineers, 345 East 47th Street, New York, N.Y.

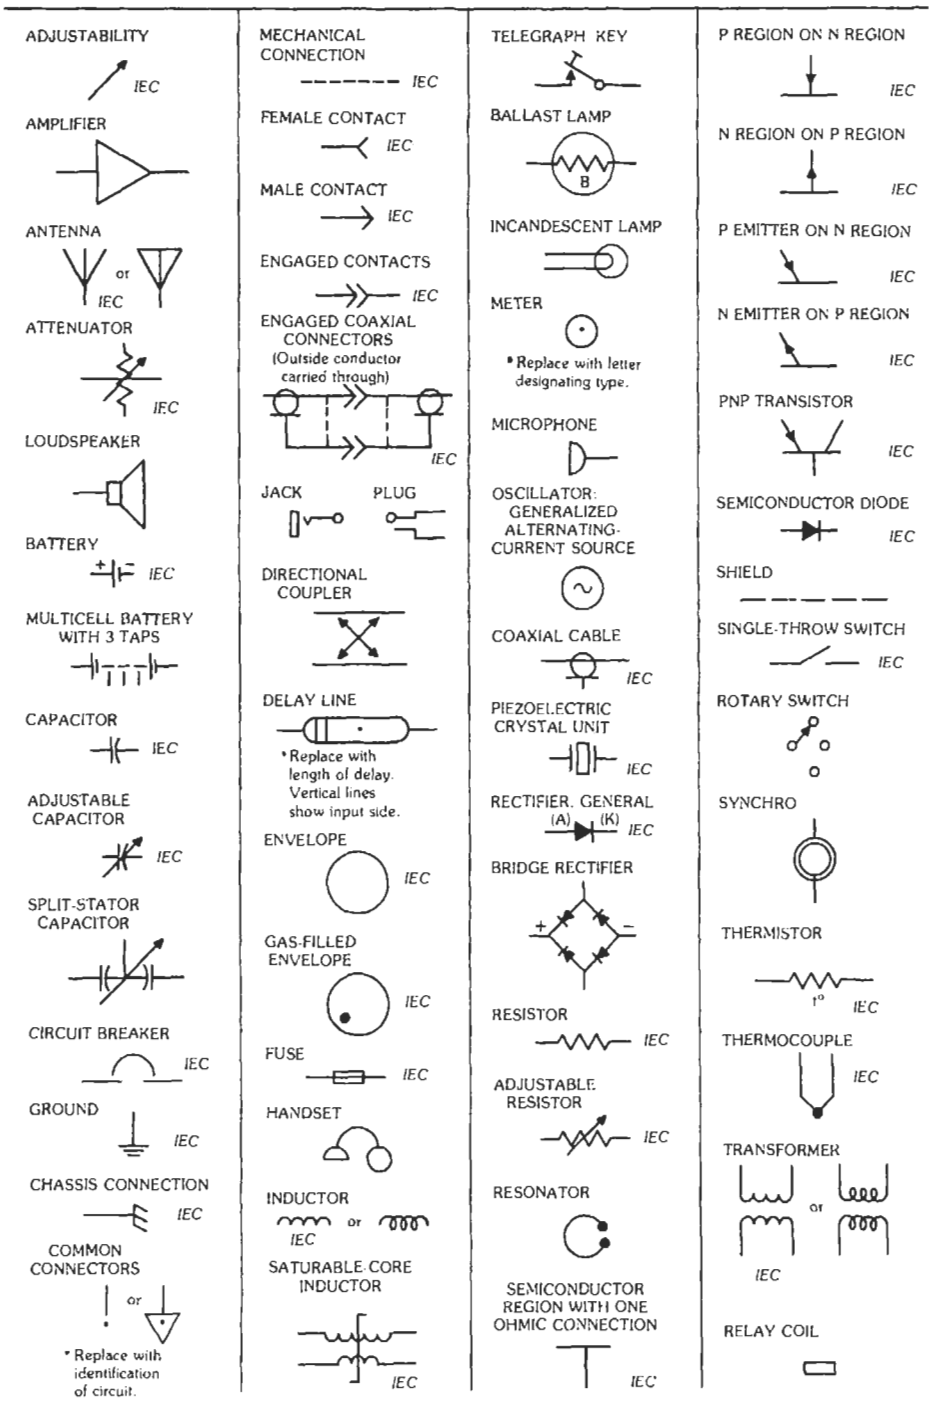

Fig. 8. Selected graphic symbols from IEEE Standard 315-1975.

switch should not be considered as the fulcrum or bearing but only as a terminal.

Associated or Future Equipment

Associated equipment, such as for measurement purposes, or additions that may be made later are identified as such by using broken lines for both symbols and connections.

BRITISH GRAPHIC SYMBOLS

Commonly used British block-diagram graphic symbols are in Fig. 9. They have been abstracted with permission from British Standard 530: 1948 and Supplement No. 5 (1962), and superseding BS 3939 (1966–1969). The issuing organization is the British Standards Institution, British Standards House, 2 Park Street, London, W. 1, England.

STANDARDIZED GRAPHIC SYMBOLS FOR LOGIC DESIGN

Symbols for logic design are so varied and in such a state of flux that many authors use their own symbols. Fig. 10 shows a short set of standardized graphic symbols for logic design selected from a revised draft of ANSI/IEEE Standard 91-1982.

SAFETY LEVELS FOR EXPOSURE TO EM FIELDS*

The American National Standards Institute (ANSI) has published recommendations concerning safety levels with respect to human exposure to electromagnetic fields in the frequency range from 300 kHz to 100 GHz.† The ANSI radio-frequency protection guides

* This section contributed by Charles A. Cain.
† Reference 1.

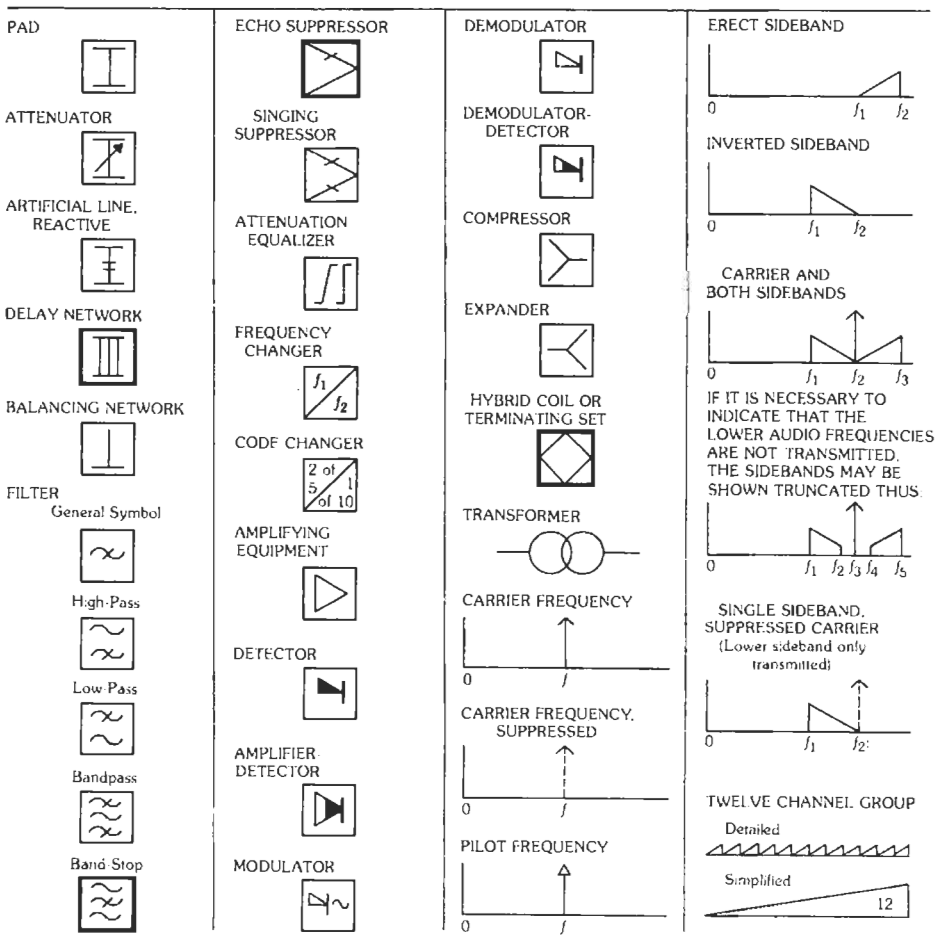

Fig. 9. Selected British block-diagram graphic symbols.

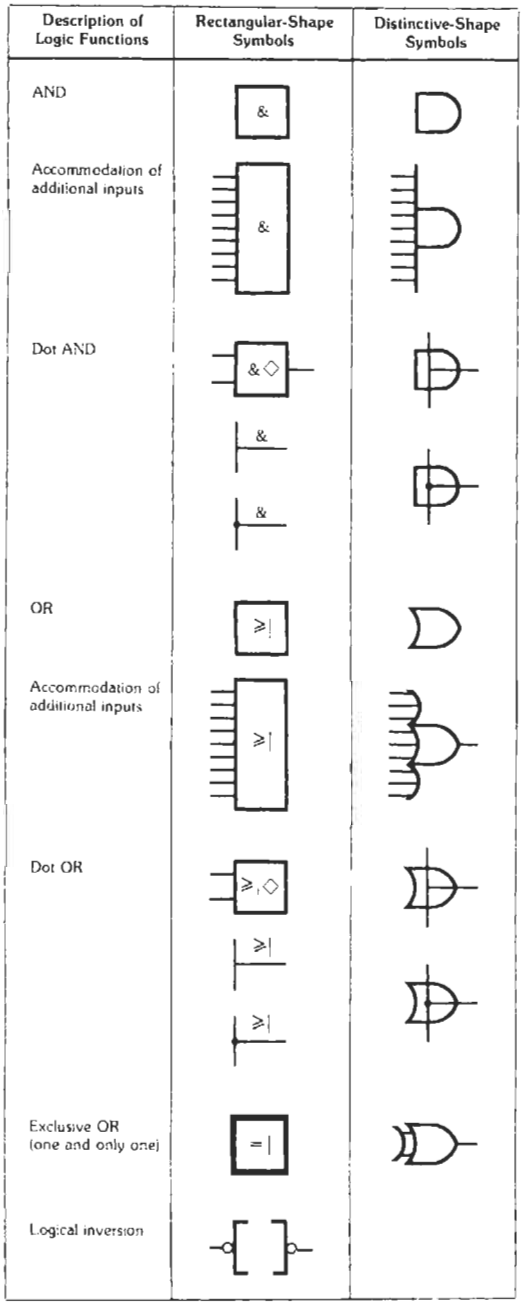

Fig. 10. Selected standardized graphic symbols for logic diagrams. (*Excerpted with permission from the revised draft of* IEEE Standard Graphic Symbols for Logic Diagrams (Two State Devices). *For a complete listing of all standardized symbols for logic diagrams, including the relationship between the new and superseded standards, see ANSI/IEEE Std. 91-1982, Appendix C.)*

(RFPG) are intended to apply to both occupational and nonoccupational exposure, but not to exposure of patients for medical purposes. These guides specify maximum allowable levels as a function of frequency in terms of the mean squared electric and magnetic fields, E and H, respectively, and the equivalent free-space plane-wave power density. To determine adherence to this RFPG, the power density or squares of the field strengths should be averaged over any 0.1-h period with all measurements to be made at a distance 5 cm or greater from any object. Table 19 is a summary of the ANSI C95.1-1982 RFPG.

A detailed rationale for the ANSI C95.1-1982 RFPG is given in reference 1. The frequency dependency of the maximum allowable equivalent plane-wave power density and of the mean squared field strengths is based on research results which show that the whole-body-average specific absorption rates* approach maximum values when the long axis of the body is parallel to the E-field vector and is approximately 0.4λ in length where λ is the free-space wavelength of the incident field.† This resonance occurs at a frequency of about 70 MHz for a man of average size. To account for the range of body dimensions from small infants to large adults, the RFPG specifies a maximum allowable power density of 1 mW/cm^2 over the frequency range from 30 MHz to 300 MHz. As indicated in Table 19, the allowable incident intensities increase below 30 MHz and above 300 MHz.

The ANSI C95.1-1982 standard specifies an exclusion from the recommended protection guides for low-power devices. The levels in Table 19 may be exceeded if the input power to a radiating device at radio frequencies between 300 kHz and 1 GHz is seven watts or less. The RFPG may also be exceeded between 300 kHz and 100 GHz if the exposure conditions result in specific absorption rates below 0.4 W/kg as averaged over the whole body and spatial peak specific absorption rates below 8 W/kg as averaged over any one gram of tissue for any 0.1-h time interval.

The type of situation that this exclusion is meant to address is illustrated by Table 20, which shows the field strengths and power densities in the near field of a 50-cm monopole antenna radiating at 150 MHz and 2 W of input power. It is clear from these data that the RFPG maximum recommended limits of field strength or of plane-wave equivalent power density are exceeded at locations near the antenna. However, this device radiates less than 7 watts and may be excluded.

Lerner: "Biological Effects of Electromagnetic Fields." *IEEE Spectrum*, May 1984, pp. 57–69; "The Drive to Regulate Electromagnetic Fields." *IEEE Spectrum*, March 1984, pp. 6370.

PATENT, COPYRIGHT, AND TRADE SECRET PROTECTION OF INVENTIONS

Intellectual Property Protection of Technology in the United States*

Depending on the nature of the invention or other development, the owner may seek protection in the United States by means of trade secret, patent, or copyright law.† Each nation is responsible for its own intellectual property laws, and on various points the law in many nations differs from that in the United States.

Trade Secret Protection of Inventions

What Is a Trade Secret?—One widely used definition is that a trade secret is "information, including a formula, pattern, computation, program, device, method, technique, or process, that: (i) derives independent economical value, actual or potential, from not being generally known to, and not being readily ascertainable by proper means, by other persons who can obtain economic value from its disclosure or use, and (ii) is the subject of efforts that are reasonable under the circumstances to maintain its secrecy." Basically, when a business has secret information giving it a commercial edge over competitors who don't have it, the business may seek to protect the information as a trade secret. Although trade secret protection often extends to such commercial items as customer lists and cost data, much of the information protected by trade secret law is technological.

For example, one may maintain as trade secrets chemical processes used in the trade secret owner's plant, or the structure and functioning of machines used by the owner's licensees who have agreed to keep these items confidential. And, along with copyright protection, trade secret law is quite commonly used to protect computer programs. However, a device marketed to consumers and embodying a "trade secret" whose characteristics are obvious from a casual inspection, would not be a good candidate for trade secret protection after marketing commenced, because there would then be no secret. Any person who lawfully comes into possession of a product embodying a trade secret, and is not contractually precluded from doing so, is entitled (if clever enough) to "reverse engineer" the product and learn the trade secret.

The Law of Trade Secrets—The basic rule of trade secret law is as easy to state as it is difficult to apply: a person may not make unauthorized access to, or use or disclosure of, another's trade secret. Such conduct constitutes misappropriation of the trade secret. It is not necessary that any tangible object be taken for misappropriation to occur; rather, misappropriation can occur on the basis of use or disclosure of information existing in a person's memory.

Unlike patent and copyright law, trade secrets are governed largely by state (rather than federal) law. One result of this is that trade secret law often differs from state to state, although in recent years some 42 states have enacted the "Uniform Trade Secret Act," which has introduced more uniformity into trade secret law. Under certain circumstances, in many states trade secret misappropriation may constitute a crime, and it does constitute a federal crime.

However, unlike patent rights, trade secret rights do not extend to preclude another from use or disclosure of information independently developed or otherwise lawfully acquired free of restrictions. Accordingly, a trade secret owner is continually subject to loss of the trade secret through the lawful conduct of others.

General Requirements for a Trade Secret—In many lawsuits, the following six factors have been viewed as important in determining whether a trade secret exists:

(1) The extent to which the information is known outside the owner's business. Obviously, if everyone in the industry knows it, there is no secret. But if one or two others know it, and maintain it as a secret, it may still be a trade secret.
(2) The extent to which it is known by employees and others involved in the owner's business. A business that restricts internal proliferation of its secrets on a "need to know" basis is in a better posture to claim that it has trade secrets.
(3) The extent of measures taken by the owner to guard the secrecy of the information. The owner will rarely be required to duplicate the security features of Fort Knox. But if the owner permits people to walk in off the street and roam around in areas where this information is available, it will be difficult to convince a court that it constitutes a trade secret.
(4) The value of the information to the owner and his competitors. Value embodies the commercial importance and desirability of the information.

---

* This section contributed by David Bender, White & Case, LLP.

† In addition, a special type of protection, known as semiconductor mask work protection, is available for protecting the structure and design of semiconductor integrated circuits.

Without such value, it is difficult to see how the information gives its owner an advantage over competitors.

(5) The amount of money or effort expended by the owner in developing the information. This may be looked to as one indicator of value. Moreover, as an equitable matter, a court or jury may be reluctant to permit a defendant to reap where he or she has not sown.

(6) The ease or difficulty with which the information could be properly acquired or duplicated by others. If it is a trivial matter for another to acquire it, it should not be protected.

Relationships Giving Rise to Trade Secret Relationship—The owner of a trade secret has rights, not against the world, but only against one who unlawfully acquires, uses, or discloses the trade secret. Typically, the owner's right to restrain use or disclosure arises from a "confidential relationship" that exists between the owner and the other party, whereby the other agrees to maintain the information as confidential. This confidential relationship may arise from a contract expressly creating it, or it may be implied from the relationship of the parties. For example, a confidential relationship arises generally from the owner's employment of an employee to work on developing a process or product.

Also, employers sometimes require certain key employees to sign a "covenant not to compete." In such a covenant, the employee agrees that for a specified period following employment by the employer, he or she will not, perhaps in a particular geographic region, undertake activities of the type in which he or she engaged for the present employer.

Who Owns Rights in a Trade Secret?—It is not always easy to determine who owns rights to a trade secret. For example, in the employer-employee situation, some factors that a court would look to in adjudicating that issue might be: the terms of any contract between the two; whether the employee was hired to do research and/or development work; whether the secrets in question are the result only of the employee's efforts; whether the work resulting in the trade secret was assigned to the employee by the employer; and whether the work done by the employee was done on the employer's premises, during normal working hours, and with the use of the employer's facilities and materials.

Patent Protection of Inventions

Nature of the Patent Grant—A United States patent grants to its owner the right to exclude others from making, using, selling, offering for sale, or importing the claimed invention in the United States for the term of that patent.* A patent can be asserted even against one who invents independently and without copying from the patent owner. Patents issuing on applications filed today will expire twenty years after the filing date.† Most importantly, a patent does not confer on its owner the right to practice that invention, for one or more other patents may also cover the invention. So, for example, if a patent for a carburetor coexisted with a patent for a dual-barrelled carburetor (an improvement on the basic carburetor), the owner of the latter could not lawfully manufacture his or her invention without a license from the owner of the former. However, when the patent expires, the owner loses all right to exclude. Once an application for a patent is filed, it is freely assignable as an item of personal property, as is an issued patent.

What Can be Protected by Patent?—A patent may be obtained on any new and useful process, machine, manufacture, or composition of matter, or any new and useful improvement thereof. The patent standard of novelty is a strict one.‡ One novelty requirement is that the inventor must have made the invention before it was used or known by others in the United States, and before it was patented or described by others in a printed publication anywhere on earth. Even beyond novelty itself, the claimed invention must be nonobvious, when made, to a person of ordinary skill in the area of technology to which it pertains.

Computer Programs and Methods of Doing Business—In recent years, many inventors of program-related inventions, and of methods of doing business, have obtained patents on them. Since at least 1981, it has been clear that the US Patent and Trademark Office (the PTO) will issue patents for program-related inventions. An important court case in 1998 has made it clear that a business method, at least when implemented by computer, is patentable subject matter. Since that case was decided, there has been a huge surge of patent applications from the financial services sector and others.

Recognizing Inventions—If an original development appears to be of commercial significance (or if there is some other reason why a patent is desired), the

---

* There are other less commonly exercised rights as well, including the right to preclude importation into, or sale, offering for sale or use in, the United States of a product made abroad by a process patented in the United States.

† Patents on applications filed prior to June 9, 1985 generally expire on the later of twenty years after the filing date or seventeen years after the issue date.

‡ The following hypothetical example shows just how strict the standard is. Suppose a person makes a simple, mechanical invention, yet one so ingenious that no person alive has contemplated it before. The inventor obtains a patent. A year later a cave is discovered in Massachusetts with wall paintings indicating that in 1795 the local tribe of native Americans publicly used that invention. Under this set of facts, the patent would be invalid.

inventor may wish to transmit the pertinent details to a patent attorney or patent agent in order to have a patent search done to assess whether the invention meets the patent standards of novelty and nonobviousness. The attorney or agent will generally compare the invention with issued U.S. patents and other items of "prior art" in reaching this determination.

Who Is the Inventor?—Patent law recognizes that invention comprises two stages: (1) conception of the idea, and (2) its reduction to practice (which amounts to either constructing the invention or making a detailed written description in a patent application). The person(s) actually responsible for the conception and reduction to practice is (are) the inventor(s). If a person's contribution to an invention does not rise above the level of ordinary mechanical skill, that person is not an inventor. Supervisors should not, as a matter of course, be named on patent applications as inventors. They (and anyone else) should be named only where they actually participated in the invention.

The Inventive Process—The question of whether an invention is patentable does not depend on the manner in which it is made. In particular, the fact that an invention is made by accident, or serendipity, will not negate patentability. Often the inventive process comprises the following steps: someone identifies either a problem to be solved or a result to be achieved; the inventor conceives a way of solving the problem or effecting the result; and the inventor reduces the conception to reality, either by actually building or practicing the invention, or by making a detailed written description of it.

Obtaining a Patent—One seeks a patent by filing and prosecuting a patent application with the PTO. There are many requirements that must be met in the application. The application must include: a written description of the invention, and the manner and process of making and using it, in such full, clear, concise, and exact terms as to enable any person skilled in the appropriate technology to make and use it; a statement of the best mode contemplated by the inventor at the time of filing; and one or more "claims" distinctly pointing out the subject matter regarded as the invention. The preparation and prosecution of a patent application is a very technical and detailed task. By law, an application can be filed and prosecuted only by the inventor or by a registered patent attorney or patent agent. Each year, over 200,000 patent applications are filed in the United States, and some 140,000 patents issued. The time between filing of the application and issuance of the patent varies considerably from application to application and currently averages between 1 1/2 and 2 years.

Interferences—On occasion, different inventors independently file patent applications claiming the same invention. (The PTO maintains all patent applications in secrecy for at least eighteen months, so that when an application is filed, the applicant may be unaware of other applications.) In the United States, the first person to invent is entitled to any resulting patent. When the PTO identifies applications by different inventors claiming substantially the same invention, the PTO declares an "interference" proceeding to determine the first to invent. Similarly, if two interfering patents inadvertently issue, the first inventor may be determined by suit in federal court. In most foreign countries, the first inventor to file a patent application is entitled to any resulting patent. Thus, the US patent owner may be a different person than the owner of foreign patents.

Publication—For a valid United States patent to issue, an application must be filed within one year of publication or public use of the invention. However, it is generally unwise publicly to disclose an invention before a patent application is filed. The law in some foreign countries is such that publication before filing for a patent will extinguish the right to obtain a patent there.

Importance of Records—In certain instances, the patent owner may be called upon to prove various facts associated with his or her patent rights. In an interference, he or she will be expected to prove when the invention was conceived, when it was reduced to practice, and perhaps that due diligence was exercised in the interim. In licensing negotiations, the owner may be challenged to show similar facts. And in litigation, the owner will be expected to show these and other facts relating to the invention. Interferences, licensing negotiations, or litigation may occur years—even decades—after the invention was made. Memories dim and witnesses die. With clear and detailed contemporaneous documents and models, it is less difficult to reconstruct precisely what happened and when.

Such documents may consist of the lab or engineering notebooks of the inventors and others, memoranda, and sketches. The notebooks in particular are often of prime importance, and certain characteristics may render them more credible as evidence:

(1) They should be bound, rather than loose-leaf.
(2) Entries should be in chronological order, written clearly and completely in ink, without blank pages or spaces.
(3) Changes should be made by drawing one line through material to be deleted (but not obliterating it).
(4) Erasures and removal of pages should be avoided.
(5) Where other materials must be included in the notebook (e.g., small lab samples, graphs), these should be fastened securely to the appropriate page, referenced on that page, dated, signed, and witnessed.
(6) Each entry should be made at or shortly after the events recorded and should be dated and signed when made.

(7) When an event of perceived significance is recorded, the entry should be shown to someone of discretion who will understand it. This person should then write the date and his or her signature below the entry, subscribing above the signature, "read and understood."

Copyright Protection of Inventions

Copyright law protects the expression of an "original work of authorship," as opposed to the tangible embodiment of a concept or idea. For this reason, copyright is not generally an appropriate vehicle for protecting technology. The single major exception to this generality occurs in connection with the computer program. Copyright springs into being automatically as soon as the work achieves fixed tangible form, without the necessity of filing any application. The copyright may be registered with the US Copyright Office, but registration is not a requirement for protection (although it offers certain advantages and is generally necessary in order to sue for infringement). Copyright provides protection against the unauthorized copying and distribution of programs. A copyright precludes only one who copies the owner's work, and not one who independently developed a similar (or even identical) work.

SUMMARY OF MILITARY NOMENCLATURE SYSTEM*

In the Joint Electronics Type Designation System (JETDS), formerly called the "AN" system, nomenclature for electronic equipment consists of a name, followed by a type number.

A type designation assignment for equipment such as a definitive system, subsystem, center, central, set, etc., shall consist of at least an AN, a slant bar, a three-letter equipment designation (see Table 21), a dash, and a number. Example: AN/VRC-12 would be a radio communication set installed in a vehicle designed for functions other than carrying electronic equipment.

All groups, including commercial off-the-shelf equipment, are identified by a two-letter indicator from Table 22. Applicable equipment indicator letters (see Table 21) follow the slant bar to indicate the potential of the group for multiple or peculiar application. Example: OE-162/ARC indicates an antenna for aircraft radiocommunication equipment. Equipment indicators with a specific model number (e.g., OK-450/TRC-26) are used following the slant bar when the group is peculiar to specific equipment (e.g., AN/TRC-26) with no known potential for other use.

The type designation for units having one end use consists of an indicator (Table 23), a dash, a number, a slant bar, and the equipment the unit is a part of or used with. Example: the receiver portion of the AN/VRC-12 is identified as R-40/VRC-12. If the unit has multiple usage, only those indicators that are common or appropriate are included after the slant bar.

Examples: A power supply, part of or used with the AN/VRC-12 and AN/VRC-19 would be identified as PP-50/VRC. A power supply, "part of" the AN/VRC-12 and "used with" the AN/VRR-40 would be identified as PP-60/ VR.

The system indicator (AN) does not mean that the Army, Navy, and Air Force use the equipment, but simply that the type number was assigned in the JETDS system.

Nomenclature Policy

JETDS nomenclature will be assigned to:

(A) Complete systems, subsystems, centers, centrals, sets, groups, kits, and units of military design, either definitive or variable in configuration.
(B) Groups of articles of either commercial or military design that are grouped for a military purpose.
(C) Electronic articles of military design that are part of or used with an item not identified in the JETDS.
(D) Commercial articles requiring military identification for use by US Government.
(E) Electronic materials of military design which are not part of or used with a set.

JETDS nomenclature will not be assigned to:

(A) Articles cataloged commercially except in accordance with paragraph (D) above.
(B) Minor components of military design for which other adequate means of identification are available.
(C) Small parts such as capacitors and resistors.
(D) Articles having other adequate identification in joint military specifications.

Nomenclature assignments will remain unchanged regardless of later changes in installation and/or application.

Modification Letters

Component modification suffix letters will be assigned for each modification of a component when detail parts and subassemblies used therein are no longer interchangeable, but the component itself is interchangeable physically, electrically, and mechanically.

* Adapted from MIL-STD-196C, Joint Electronics Type Designation System, 22 April 197 1; Notice 1, 20 April 1972; Notice 2, 8 June 1972: Notice 3, 14 November 1972; and Notice 4, 17 July 1977. Available from the Superintendent of Documents, Washington, DC 20402.

TABLE 21. SET OR EQUIPMENT INDICATOR LETTERS

1st Letter (Type of Installation)	2nd Letter (Type of Equipment)	3rd Letter (Purpose)
A Piloted aircraft	**A** Invisible light, heat radiation	**A** Auxiliary assemblies (not complete operating sets used with or part of two or more sets or sets series) (inactivated, do not use)
B Underwater mobile submarine	**B** Pigeon (do not use)	**B** Bombing
C Air transportable (inactivated, do not use)	**C** Carrier	**C** Communications (receiving and transmitting)
D Pilotless carrier	**D** Radiac	**D** Direction finder, reconnaissance, and/or surveillance
	E Nupac (inactivated, do not use)	**E** Ejection and/or release
F Fixed ground	**F** Photographic*	
G General ground use (includes two or more ground-type installations)	**G** Telegraph or Teletype	**G** Fire control or searchlight directing
		H Recording and/or reproducing (graphic meteorological and sound)
	I Interphone and public address	
	J Electromechanical or inertial wire covered	
K Amphibious	**K** Telemetering	**K** Computing
	L Countermeasures	**L** Searchlight control (inactivated, use **G**)
M Ground, mobile (installed as operating unit in a vehicle which has no function other than transporting the equipment)	**M** Meteorological	**M** Maintenance and/or test assemblies (including tools)
	N Sound in air	**N** Navigational aids (including altimeters, beacons, compasses, beacons, depth sounding, approach, and landing)
P Pack or portable (animal or man)	**P** Radar	**P** Reproducing (inactivated, use **H**)
	Q Sonar and underwater sound	**Q** Special, or combination of purposes
	R Radio	**R** Receiving, passive detecting
S Water surface craft	**S** Special types, magnetic, etc., or combinations of types	**S** Detecting and/or range and bearing, search
T Ground, transportable	**T** Telephone (wire)	**T** Transmitting
U General utility (includes two or more general installation classes, airborne, shipboard, and ground)		
V Ground, vehicular (installed in vehicle designed for functions other than carrying electronic equipment, etc., such as tanks)	**V** Visual and visible light	
W Water surface and underwater combination	**W** Armament (peculiar to armament, not otherwise covered)	**W** Automatic flight or remote control
	X Facsimile or television	**X** Identification and recognition
		Y Data processing surveillance (search, detect, and multiple target tracking) and control (both fire control and air control)
Z Piloted and pilotless airborne vehicle combination		

* Not for US use except for assigning suffix letters to previously nomenclatured items.

TABLE 22. GROUP INDICATORS

Indicator	Family Name	Indicator	Family Name
OA	Miscellaneous groups	**ON**	Interconnecting groups
OB	Multiplexer and/or demultiplexer groups	**OP**	Power supply groups
OD	Indicator groups	**OQ**	Test set groups
OE	Antenna groups	**OR**	Receiver groups
OF	Adapter groups	**OT**	Transmitter groups
OG	Amplifier groups	**OU**	Converter groups
OH	Simulator groups	**OV**	Generator groups
OI	Consoles and console groups	**OW**	Terminal groups
OK	Control groups	**OX**	Coder, decoder, interrogator, transponder groups
OL	Data analysis and data processing groups	**OY**	Radar set groups
OM	Modulator and/or demodulator groups	**OZ**	Radio set groups

Set modification letters will be assigned for each modification not affecting interchangeability of the sets or equipment as a whole, except that in some special cases these will be assigned to indicate functional interchangeability and not necessarily complete electrical and mechanical interchangeability. Modification letters will only be assigned if the frequency coverage of the unmodified equipment is maintained.

The suffix letters X, Y, and Z will be used only to designate a set or equipment modified by changing the power input voltage, phase, or frequency. They will be used as follows: X will indicate the first change, Y the second, Z the third, XX the fourth, etc. These letters will be in addition to other modification letters applicable.

Developmental Indicators

Experimental Sets—To identify a set or equipment of an experimental nature with the development organization concerned, the following indicators are used within the parentheses:

XA Aeronautical Systems Division, Wright-Patterson Air Force Base, OH.
XB Naval Research Laboratory, Washington, DC.
XC US Army Signal Engineering Laboratories, The Hexagon, Fort Monmouth, NJ (inactivated, use **XE**).
XD Electronic Systems Division, Laurence G. Hanscom Field, Bedford, MA.
XE US Army Electronics Laboratories, Fort Monmouth, NJ.
XF Frankford Arsenal, Philadelphia, PA.
XG USN Electronics Laboratory, San Diego, CA.
***XH** Aerial Reconnaissance Laboratory, Wright-Patterson Air Force Base, OH.
XI Air Force Armament Laboratory, Eglin Air Force Base, FL.
XJ Naval Air Development Center, Johnsville, PA.
***XK** Flight Control Laboratory, Wright-Patterson Air Force Base, OH.
XL US Army Signal Electronics Research Unit, Mountain View, CA.
XM US Army Signal Engineering Laboratories, The Hexagon, Fort Monmouth, NJ (inactivated, use **XE**).
XN Department of the Navy, Washington, DC.
XO US Army Missile Command, Redstone Arsenal, AL.
XP Canadian Department of National Defence, Ottawa, Ontario, Canada.
***XQ** Aeronautical Accessories Laboratory, Wright-Patterson Air Force Base, OH.
XR National Security Agency, Fort George G. Meade, MD.
***XS** Electronic Components Laboratory Wright-Patterson Air Force Base, OH.
XT US Army Security Agency, Arlington Hall Station, Arlington, VA.
XU USN Underwater Sound Laboratory, Fort Trumbull, New London, CT.
XV Air Force Weapons Laboratory, Kirtland Air Force Base, NM.
XW Rome Air Development Center, Rome, NY.
***XY** Weapons Guidance Laboratory, Wright-Patterson Air Force Base, OH.

* Not for Air Force use except for assigning additional developmental designations to previously type-designated items. Use XA for all new equipment.

XZ USN Bureau of Naval Weapons Activities.
XAA Air Force Ballistic Systems Division, Norton Air Force Base, CA.
XAE US Army Electronics Research and Development Activity, Fort Huachuca, AZ.
XAN Naval Avionics Facility, Indianapolis, IN.
XBB US Army Electronics Command, Proc and Prod Div., Fort Monmouth, NJ.
XCA US Naval Ammunition Depot, Crane, IN.
XCC Air Force Missile Test Center, Patrick Air Force Base, FL.
XCL Naval Weapons Center, China Lake, CA.
XCR Naval Weapons Center, Corona Laboratory, Corona, CA.
XDD US Army Signal Air Defense Engineering Agency, Fort George G. Meade, MD.
XDV US Naval Weapons Laboratory, Dahlgren, VA.
XGS Grand Support Equipment Division, Naval Air Engineering Center, Philadelphia, PA.
XIH US Naval Ordnance Station, Indianhead, MD.
XLW US Army Limited War Laboratory, Aberdeen Proving Ground, MD.
XMG Naval Missile Center, Point Mugu, CA.
XPM US Army, Project Michigan, Ypsilanti, MI.
XSC US Army Satellite Communications Agency, Fort Monmouth, NJ.
XWH US Naval Weapons Handling Laboratory, Naval Weapons Station Earle, Colts Neck, NJ.
XWO Naval Ordnance Laboratory, White Oak, Silver Spring, MD.

Example: Radio Set AN/ARC-3 might be assigned for a new airborne radio communication set under development. The cognizant development organization might then assign AN/ARC-3(XA-1), AN/ARC3(XA-2), etc., type numbers to the various sets developed for test. When the set was considered satisfactory for use, the experimental indicator would be dropped, and procurement nomenclature **AN/ARC-3** would be officially assigned thereto.

(A) A set to train for a specific basic set will be assigned the basic-set type number followed by a dash, the letter T, and a number. Example: Radio Training Set AN/ARC-6A-T1 would be the first training set for Radio Set AN/ARC-6A.
(B) A set to train for general types of sets will be assigned the usual set indicator letters followed by a dash, the letter T, and a number. Example: Radio Training Set AN/ARC-T1 would be the first training set for general airborne radio communication sets.

Parenthesis Indicators: A series of a basic item, i.e., all production and/or nonproduction versions, may be identified by a type designation with an empty parenthesis. Examples: AN/APS-25 ( ) or R-275( )/APS-25. Such an assignment is all inclusive and does not refer to any specific version within the series.

Systems, subsystems, centers, centrals, sets, groups, or units with variable parts lists are assigned type designations in the same manner, except a parenthetical V expressed as (V) is added to the type designation. Units designed to accept plug-ins that change the function, frequency, or technical characteristics of the type-designated unit are designated with a (P) preceding the slant bar. The plug-in is not considered a part of the unit.

Examples of JETDS Type Numbers

AN/SRC-3( ) General reference set nomenclature for water surface craft radio communication set number 3.
AN/SRC-3 Original procurement set nomenclature applied against AN/ SRC-3( ).
AN/SRC-3A Modification set nomenclature applied against AN/SRC-3.
AN/APQ-13-TI( ) General reference training set nomenclature for the AN/APQ-13 set.
AN/APQ-13-TI Original procurement training set nomenclature applied against AN/APQ-13-TI( ).
AN/APQ-13-TIA Modification training set nomenclature applied against AN/APQ-13-TI.
AN/UPT-T3( ) General reference training set nomenclature for general utility radar transmitting training set number 3.
AN/UPT-T3 Original procurement training set nomenclature applied against AN/UPT-T3( ).
AN/UPT-T3A Modification training set nomenclature applied against AN/ UPT-T3.
T-51( )/ARQ-8 General reference component nomenclature for transmitter number 51, part of or used with airborne radio special set 8.
T-51/ARQ-8 Original procurement component nomenclature applied against T-51( )/ARQ-8.
T-51A/ARQ-8 Modification component nomenclature applied against T51/ARQ-8.
RD-31( )/U General reference component nomenclature for recorder-reproducer number 31 for general utility use, not part of a specific set.
RD-31/U Original procurement component nomenclature applied against RD-31( )/U.
RD-31A/U Modification component nomenclature applied against RD31/U.

TABLE 23. UNIT INDICATORS

Indicator	Family Name	Indicator	Family Name
AB	Supports, antenna	**MF***	Magnets or magnetic-field generators
AM	Amplifiers	**MK**	Miscellaneous kits
AS	Antennas, complex and simple	**ML**	Meteorological devices
AT*	Antennas, simple	**MT**	Mountings
BA	Batteries, primary type	**MU**	Memory units
BB	Batteries, secondary type	**MX**	Miscellaneous
BZ	Alarm units	**O**	Oscillators
C	Controls	**OC***	Oceanographic devices
CA*	Commutator assemblies, sonar	**OS**	Oscilloscopes, test
CB*	Capacitor banks	**PD***	Prime drivers
CG	Cable assemblies, RF	**PF***	Fittings, pole
CK*	Crystal kits	**PG***	Pigeon articles
CM	Comparators	**PH***	Photographic articles
CN	Compensators	**PL**	Plug-in units
CP	Computers	**PP**	Power supplies
CR*	Crystals	**PT**	Mapping and plotting units
CU	Couplers	**PU**	Power equipments
CV	Converters (electronic)	**R**	Receivers
CW	Radomes	**RC***	Reels
CX	Cable assemblies, non-RF	**RD**	Recorder-reproducers
CY	Cases and cabinets	**RE**	Relay assemblies
D	Dispensers	**RF***	Radio-frequency components
DA	Loads, dummy	**RG***	Cables, RF bulk
DT	Detecting heads	**RL**	Reeling machines
DY*	Dynamotors	**RO**	Recorders
E*	Hoists	**RP**	Reproducers
F	Filter units	**RR**	Reflectors
FN*	Furniture	**RT**	Receiver and transmitter
FR	Frequency-measuring devices	**S**	Shelters
G	Generators, power	**SA**	Switching units
GO*	Goniometers	**SB**	Switchboards
GP*	Ground rods	**SG**	Generators, signal
H	Head, hand, and chest sets	**SM**	Simulators
HC*	Crystal holders	**SN**	Synchronizers
HD	Environmental apparatus (heating, cooling, etc.)	**ST***	Straps
ID	Indicators, noncathode-ray tube	**SU**	Optical devices
IL*	Insulators	**T**	Transmitters
IM	Intensity-measuring devices	**TA**	Telephone apparatus
IP	Indicators, cathode-ray tube	**TB**	Towed bodies
I	Interface units	**TC***	Towed cables
KY	Keying devices	**TD**	Timing devices
LC*	Tools, line-construction	**TF**	Transformers
LS	Loudspeakers	**TG**	Positioning devices
M	Microphones	**TH**	Telegraph apparatus
MA*	Magazines	**TK***	Tool kits
MD	Modulators, demodulators, and discriminators	**TL***	Tools
ME	Meters	**TN**	Tuning units

TABLE 23 (CONT). UNIT INDICATORS

Indicator	Family Name	Indicator	Family Name
TR	Transducers	**VS***	Signaling equipment, visual
TS	Test units	**WD***	Cables, two-conductor
TT	Teletypewriter and facsimile apparatus	**WF***	Cables, four-conductor
TV*	Testers, tube	**WM***	Cables, multiple-conductor
TW	Tape units	**WS***	Cables, single-conductor
U*	Connectors, audio and power	**WT***	Cables, three-conductor
UG*	Connectors, RF	**ZM**	Impedance-measuring devices
V	Vehicles		

* Not for US use except for assigning suffix letters to previously nomenclatured items.

Professional Reference

Reference Data for Engineers

Radio, Electronics, Computer, and Communications

NINTH EDITION

- **For Engineers, Scientists, and Technologists**
- **Features contributions from 96 professionals**
- **Recommends additional sources of information**

Reference Data for Engineers, Ninth Edition is the most respected, reliable, and indispensable information tool for technical professionals around the globe today. Written by professionals *for* professionals, this unique reference is the combined effort of ninety-six licensed engineers, scientists, educators and other recognized specialists in the fields of electronics, radio, computer, and communications technology.

By providing an abundance of information on essential, need-to-know topics without heavy emphasis on complicated mathematics, ***Reference Data for Engineers*** is an absolute "must-have" for every engineer who requires comprehensive electrical, electronics, and communications data at his or her fingertips. Featured in the Ninth Edition is updated coverage on intellectual property and patents, probability and design, antennas, power electronics, rectifiers, power supplies, and properties of materials. Useful information on units, constants and conversion factors, active filter design, antennas, integrated circuits, surface acoustic wave design, and digital signal processing is also included. The Ninth Edition also offers new knowledge in the fields of satellite technology, space communication, microwave science, telecommunication, global positioning systems, frequency data, and radar.

- Widely acclaimed as the most practical reference ever published for electronics and computer professionals, technicians and engineers.
- First revision in a decade brings the material completely up-to-date.
- Contributors represent some of the leading technology companies, organizations and universities throughout the world.
