Reference Data For Engineers

Radio, Electronics, Computer, and Communications

NINTH EDITION

Reference Data for Engineers:

Radio, Electronics, Computer, and Communications

Reference Data for Engineers:

Radio, Electronics, Computer, and Communications

Ninth Edition

Mac E. Van Valkenburg, Editor-in-Chief, Eighth Edition
Wendy M. Middleton, Editor-in-Chief, Ninth Edition

Originally titled, *Reference Data for Radio Engineers*

Newnes

Boston Oxford Johannesburg Melbourne New Delhi

Newnes is an imprint of Butterworth–Heinemann.

A member of the Reed Elsevier group

Recognizing the importance of preserving what has been written, Butterworth–Heinemann prints its books on acid-free paper whenever possible.

Butterworth–Heinemann supports the efforts of American Forests and the Global ReLeaf program in its campaign for the betterment of trees, forests, and our environment.

ISBN: 0-7506-7291-9

The publisher offers special discounts on bulk orders of this book.

IN MEMORIAM
Edward C. Jordan
1910–1991

Preface

The ninth edition provides new knowledge in the fields of satellite technology, space communication, microwave science, telecommunication, global positioning systems, frequency data, and radar. Also revised and updated were the chapters on intellectual property and patents, probability and design, power electronics—rectifiers, filter, and power supplies, properties of materials, units, constants and conversion factors, active filter design, antennas, integrated circuits, digital signal processing, and surface acoustic wave devices.

I am sure that as you read this text you will also appreciate the hard work and expertise of these authors. This edition of *Reference Data for Electrical Engineers* will continue its tradition of being an important reference text for all electrical engineers.

Highlights of Updated Chapters

Chapter 1: Radio Frequency Spectrum Management and Time Frequency Standards - by F. Matos

- ITU information is available on the web for download.
- While the Omnibus Budget Reconciliation Act did open the door for auctions, it only authorized them for a short time. A better reference is: *Radiofrequency Spectrum Management: Background, Status, and Current Issues*, January 30, 2001, Richard M. Nunno, Congressional Research Service, Washington, DC Order Code RL30829.
- The GPS Time Scale began on January 6, 1980 and is not adjusted for leap seconds. Therefore, it differs from UTC by the number of leap seconds that have occurred January 6, 1980. As of June 2001, GPS Time is 13 seconds ahead of UTC.
- Much of the data in this chapter cross-references with Chapter 37 on GPS.
- The updates on GPS before and after S/A was turned off are quite good, as is the discussion of the merits of different types of atomic clocks.
- For up-to-date GPS information, the web address for the United States Coast Guard Navigation Center is: http://www.navcen.uscg.gov/
- For the readers' reference: A nanometer is 10-9 meter. The *meter* is defined as: the length of the path traveled by light in vacuum during a time interval of 1/299 792 458 of a second.
- The constant for the speed of light can be found at: http://www.physics.nist.gov/cgi-bin/cuu/Value?clsearch_for=light

Chapter 3: Units, Constants, and Conversion Factors - by E. Mechtly

- Temperatures are discussed in the context of Table 2, SI Base and Derived Units. See entries for *Kelvin* and for *degree Celsius* in Table 2.
- Many tables were updated. The style information on how to correctly express different units is a resource that many will be likely to use in the future.
- The values for constants have been updated and citations including worldwide web addresses have been added.

Chapter 4: Properties of Materials - by E. Mechtly

- The most current versions of the table of Superconducting Materials can be found at internet sources such as the NIST Superconducting Materials Database at http://www.ceramics.nist.gov/srd or by the "High-T (critical) Update," sponsored by the Argonne National Laboratory at http://www.iitap.iastate.edu.
- The tables on wires, gauges, and drills sizes lie on the interface between engineering and shop technology. Here, again, the internet offers a multitude of equivalent sources. For example, a web search for "wire gauge" or "AWG" yields many sources. Likewise, does a search for "drills."

Chapter 10: Active Filter Design - by R. Schaumann

- GHz applications and three amplifier filters sections have been updated.
- The chapter now has additional detail on switched filters.

Chapter 14: Power Electronics—Rectifiers, Filters, and Power Supplies - by O. Pauk

- Manufacturer's data sheets are now available for free download from the web as PDF files.
- Information on switching power supplies is of high quality and is up-to-date.

Chapter 16: Electron Tubes - by D. Abe, R. Abrams, B. Danly, H. Freund, K. Jensen, B. Levush, R. Myers, R. Parker, J. Shaw, A. Shih, and J. Yater

- For more than fifty years, the venerable vacuum tube has proved to be the technology of choice for many applications. The advent of solid-state power amplifiers has also made a profound impact. This healthy technological competition has no doubt

been to the benefit of both technologies, and the reader should not mistake the proud history of vacuum electronics as an indication of a technology at its sunset.

- This chapter describes the numerous advances in the area of vacuum electronics, which continue to make the technology the appropriate choice for many applications. Present-day applications for microwave tubes include satellite and terrestrial communications, industrial and scientific applications from heating materials to heating fusion reactors, and continuing military applications, such as radar and electronic warfare.
- Driven by these continuing needs, this technology area has continued to see impressive advances in recent times, as described in this chapter.

Chapter 20: Integrated Circuits - by H. Hosack

- Updated information and figures add to this essential chapter.
- New information has been added on MEM's and submicron topics.

Chapter 27: Satellite and Space Communications - by G. Hyde

- A discussion of Iridium is included in the chapter. However, Iridium's fate is far from clear.
- BSS definition: Broadcast Satellite Services.
- DARS definition: Digital Audio Radio System.
- ALOHA definition: A made-up name, not an acronym - made up by Prof. Abramson (of the University of Hawaii, of course) Somebody may have fitted words to the letters, but the author did not hear it defined by Abramson when he lectured on it at Comsat Labs many years ago.
- Multi-beam antennas of 15 meters diameter for MSS are mentioned at the end of the Spacecraft Antenna section.
- Note that 3G wireless is a future system and it is not clear when it will supersede 2.5G, which seems to be growing rapidly.

Chapter 28: Discrete-Time Signal Processing - by K. Jenkins and D. Jones

- The SAW filter data has been updated.
- Advances in Digital signal processing have been presented.
- Technological improvements in Surface Acoustic design techniques are covered.

Chapter 32: Antennas - by R. Hansen

- Updated data on antennas.

Chapter 36: Radar - by M. Skolnik

- Information of the newest advances in Radar.

Chapter 37: Radio Navigation Systems - by D. Jablonski

- The most recent data on GPS.
- Information on the remaining uses for LORAN.
- Insights into upcoming changes in the field.

Chapter 38: Common Carrier Transmission - by L. Sibley

- Provides good information on DSL.

Chapter 44: Probability and Statistics - by S. Gupta

- Gives concise clear data for design use.

Chapter 46: Cellular Telecommunications Systems - by W. Lee

- Updates on 3G and IMT-2000.

Chapter 49: Miscellaneous Data - by D. Bender

- Copyright law changes highlighted.
- Intellectual property protection strategies outlined.

Wendy M. Middleton
February 2001

Contents

Contributors

David K. Abe (Ch. 16)

Electronics Engineer, Vacuum Electronics Branch, Electronic Systems and Technology Division, Naval Research Laboratory.
Member IEEE, APS.

Richard H. Abrams, Jr. (Ch. 16)

Head, Emission Sources Section, Vacuum Electronics Branch, Naval Research Laboratory.
Member IEEE, APS, AAAS, AOC.

Richard W. Avery (Ch. 38)

Member of Technical Staff. AT&T - Bell Laboratories.

Fred J. Banzi (Ch. 13)

Member of Technical Staff. AT&T - Bell Laboratories.
Member IEEE.

Pier L. Bargellini (Ch. 27)

Senior Scientist (retired), COMSAT Laboratories.
Fellow IEEE.
Assoc. Fellow AIAA.

Stanley Baron (Ch. 35)

Managing Director Technical Development, National Broadcasting Co. (NBC).
Fellow SMPTE.
Member Royal Television Society.
Past Engineering Vice-President SMPTE.
Chair, CCIR TG 11/3 - Digital Terrestrial Television Broadcasting.
David Sarnoff Gold Medal.

David Bender (Ch. 49)

Counsel, White & Case (New York).
American Bar Assn.
Computer Law Assn. Board of Directors.
American Intellectual Property Law Assn.
Member ACM.

Richard E. Blahut (Ch. 25)

IBM Fellow, IBM Corporation.
Fellow IEEE.
Past-President IEEE/GIT.
National Academy of Engineering.

Robert Blaszczyk (Ch. 5)

Applications Engineer, VRN Division of Vernitron Corp.

John Bohrer (Ch. 5)

Consultant, Bohrcon.
Past-Chairman ECC.
Past-President AI Chem.

John F. X. Browne (Ch. 35)

President, John F. X. Browne and Associates.

Fellow SMPTE.

Governor SMPTE.

Senior Member IEEE.

Past-President Assn. of Federal Communications Consulting Engineers.

Charles A. Cain (Ch. 49)

Professor of Electrical Engineering and Bioengineering, University of Michigan.

Senior Member IEEE.

Member of Directors, Bioelectromagnetic Society.

Bernard B. Carnigila (Ch. 13)

Member of Technical Staff. AT&T - Bell Laboratories.

Dorothy H. Cerni (Ch. 2)

Technical Information Specialist, Institute for Telecommunication Sciences, National Telecommunications and Information Administration (NITA).

Pallab K. Chatterjee (Ch. 20)

Vice-President and Chief Technical Officer, Components Section, Director Research and Development, Texas Instruments, Inc.

Fellow IEEE.

Member APS.

Marvin Chodorow (Ch. 16 & 17)

Professor Emeritus of Applied Physics and Electrical Engineering, Ginzton Laboratory, Stanford University.

Fellow IEEE.

Lamme Medal (1982).

W. R. G. Baker Award (1962).

Erich Christian (Ch. 9)

Master of Advanced Engineering, ITT Telecom (retired).

Professor North Carolina State University.

Senior Member IEEE.

Robert Coakley (Ch. 12)

President, Elenex Corp.

Fellow (British) IEEE.

Douglass D. Crombie (Ch. 2 & 33)

Senior Editor, The Acrospace Corporation.

Former Director of the Institute of Telecommunication Science, National Telecommunications And Information Administration (NITA).

Chief Scientist (retired) NITA.

National Academy of Engineering.

Fellow IEEE.

Bruce G. Danly (Ch. 16)

Supervisory Research Physicist, Head, High Power Devices Section, Vacuum Electronics Branch, Naval Research Laboratory.

Member IEEE, APS.

Member of the Team awarded DoD Robert L. Woods Award for Development of the High-power 94 GHz Gyro-Klystron technology.

Thijs de Hass (Ch. 2)

Networks and Systems Division, ITS, National Telecommunications And Information Administration (NITA).

Georges A. Deschamps (Ch. 31 & 44)
Professor Emeritus of Electrical and Computer Engineering, UIUC.
National Academy of Engineering.
Fellow IEEE, AAAS.
Member APS.

Thomas DeTemple (Ch. 41)
Professor of Electrical and Computer Engineering, UIUC.
Senior Member IEEE.
Member APS.

Michiel deWitt (Ch. 20)
Senior Member, Technical Staff, Texas Instruments, Inc.
Member IEEE, APS.

John J. Dupre (Ch. 12)
R&D Section Manager, Lightwave Instruments, Hewlett-Packard Co.
Member IEEE.

John D. Dyson (Ch. 31)
Professor of Electrical and Computer Engineering, UIUC.
Fellow IEEE.
Member APS, MTT, I and M, EMC, Antenna Standards Committee.

Hermann Fickenscher (Ch. 13)
Supervisor, Magnetic Components Group, AT&T - Bell Laboratories.
Senior Member IEEE.
Member Electronics Transformers Technical Committee.

Arthur Fong (Ch. 12)
Manager (retired) Corporate Engineering Design, Hewlett-Packard Corp.
Fellow IEEE.

Henry P. Freund (Ch. 16)
Senior Research Physicist, Science Applications International Corp.
Member and Fellow APS.
New York Academy of Sciences.

Chester S. Gardner (Ch. 22)
Professor of Electrical and Computer Engineering, UIUC.
Fellow OSA, IEEE.
Vice-Chairman for Remote Sensing OS Technical Council.

Mario Gerla (Ch. 26)
Professor and Vice-Chair of Computer Science, University of California, Los Angeles.
Member IEEE.
Fulbright Fellow.

Stephen J. Greer (Ch. 12)
Interface Engineer, Hewlett-Packard Co.
Member IEEE.
Secretary IEC/SC/G5C Working Group.

Surendra M. Gupta (Ch. 44)

Director of Laboratory for Responsible Manufacturing. Northeastern University, Boston, MA.

Professor of Mechanical, Industrial and Manufacturing Engineering.

Member IIE, INFORMS, DSI, POMS, APICS.

Elected Member of Alpha Pi Mu Honor Society, Delta Mu Delta Honor Society, Sigma Xi Honor Society, Tau Beta Pi Honor Society.

2000 Outstanding Research Award, Northwestern University.

Registered Professional Engineer, MA.

Robert C. Hansen (Ch. 32)

President, R. C. Hansen, Inc.

Phi Kappa Phi, Tau Beta Pi, Eta Kappa Nu.

Fellow IEE and IEEE.

National Academy of Engineering.

Mark Harward (Ch. 20)

Member of Technical Staff, Texas Instruments, Inc.

Member IEEE.

Member Eta Kappa Nu.

Charles F. Hempstead (Ch. 13)

Supervisor (retired), Magnetics and Characterization, AT&T - Bell Laboratories.

Harold H. Hosack (Ch. 20)

Associate Director, Materials and Process Science, Semiconductor Research Corp.

Bill J. Hunsinger (Ch. 28)

Co-Chair, Comlinear Corp.

Fellow IEEE.

Geoffrey Hyde (Ch. 27)

Editor-in-Chief, Space Communications Journal (IOS Press).

Fellow and Life Fellow IEEE.

Member IEEE-USA APC, IEEE (AP-S, Comm. Soc.), USNC/URSI Comm. B and F, AIAA.

IEEE AP-S Best Paper Award 1967.

RCA Sarnoff Fellowships 1964. 1965.

Tatsuo Itoh (Ch. 29)

Hayden Head Professor in Engineering, University of Texas.

Fellow IEEE.

Editor IEEE Transactions, MMT.

Chairman Microwave Field Theory Comm.

Daniel G. Jablonski (Ch. 37)

Member Principal Professional Staff, Johns Hopkins University Applied Physics.

Instructor, Whiting School of Engineering, Johns Hopkins University.

Adjunct Professor, Capitol College, Laurel, MD.

Senior Member IEEE.

Member American Physical Society.

Licensed Professional Engineer, MD.

Horace G. Jackson (Ch. 19)

Lecturer, Dept. of Electrical Engineering and Computer Science, University of California, Berkeley.

W. Kenneth Jenkins (Ch. 28)

Head of Electrical Engineering, Pennsylvania State College.

Fellow IEEE.

IEEE Millenium Medal, 2000.

IEEE Circuits and Systems Society Golden Jubilee Medal, 2000.

Co-winner of the 2000 International Award of the George Montefiore Foundation (U. of Liege, Belgium) for outstanding career contributions to the field of Electrical Engineering.

Recipient of the IEEE Circuits and Systems Society Meritorious Service Award (1990).

Past President of IEEE Circuits and Systems Society (1985).

Kevin Lynn Jensen (Ch. 16)

Research Physicist, Electron Science and Technology Division, Naval Research Laboratory.

Member APS, IEEE, NYAS, MRS, ECS.

Amos E. Joel (Ch. 39)

Switching Consultant, Bell Telephone Laboratories (retired).

National Academy of Engineering.

Fellow IEEE.

IEEE Medal of Honor (1992).

ITU Centenary Award (1983).

Alexander Graham Bell Medal (1976).

Douglas L. Jones (Ch. 28)

Professor of Electrical and Computer Engineering, UIUC.

Fellow IEEE.

Fulbright Fellow (1987–88).

Durwood R. Kressler (Ch. 13)

Member of Technical Staff, AT&T - Bell Laboratories.

Kenneth R. Laker (Ch. 10)

Alfred Fitler Moore Professor of Electrical Engineering, University of Pennsylvania.

Formerly, Supervisor, Signal Processing Subsystems Group, AT&T - Bell Laboratories.

Fellow IEEE.

Past-President Circuits and Systems Society.

President, Division 1 of IEEE.

William C. Y. Lee (Ch. 46)

Chairman of LinkAir Communications, Inc. and developer of LAS-CDMA—a new patented technology for wireless telecom systems.

Baruch Levush (Ch. 16)

Head of Theory and Design Section, Vacuum Electronics Branch, Electronics Science and Technology division, Naval Research Laboratories.

Member IEEE, APS.

Fellow IEEE.

Member of the Team awarded DoD Robert L. Woods Award for Development of the High-power 94 GHz Gyro-Klystron technology.

Sigfried Linkwitz (Ch. 12)

EMC Specialist, Hewlett Packard Company.

Satwinder D. S. Malhi (Ch. 20)

Member Technical Staff, Texas Instruments, Inc.

Member IEEE.

Frederick Matos (Ch. 1)

Telecommunication policy analyst, National Telecommunications and Information Administration (NITA).
Former IEEE Congressional Fellow.

Edward McClusky (Ch. 43)

Professor and Director, Center for Reliable Computing, Stanford University.
Fellow IEEE.
Member ACM.
SIGARCH Director 1980–83.
Past-President IEEE Computer Society.

Eugene A. Mechtly (Ch. 3 & 4)

Professor, Former, 2-term, Assistant Dean College of Engineering, UIUC.
Member American Society for Testing and Materials.
Member National Conference on Weights and Measures.

Douglas L. Merriott (Ch. 45)

Associate Professor of Mechanical and Industrial Engineering, UIUC.

Edward Mette (Ch. 5)

Resistive Products Division, TRW, Inc.

Mehrdad Moslehi (Ch. 20)

Member of Technical Staff, Texas Instruments, Inc.
Member IEEE.

David C. Munson Jr. (Ch. 7)

Professor of Electrical and Computer Engineering, UIUC.
Member IEEE.

Robert E. Myers (Ch. 16)

Program Manager, Vacuum Electronics Branch, Vacuum Electronics Engineering Facility, Naval Research Laboratory.
Member IEEE, ASM.

Arthur Olsen Jr. (Ch. 13)

Supervisor, Magnetics and Data Group, AT&T - Bell Laboratories.

John R. Page Jr. (Ch. 12)

R&D Manager, RF and Microwave Instruments, Hewlett-Packard Company.
Member IEEE.

George Papen (Ch. 22)

Professor of Electrical and Computer Engineering, UIUC.
Fellow OSA.
Vice-Chairman for Remote Sensing OS Technical Council.
Fellow IEEE.

Robert K. Parker (Ch. 16)

Head, Vacuum Electronics Branch, Naval Research Laboratory.
Fellow IEEE, APS.

Ondrej Pauk (Ch. 14)

Applications Engineer, Motorola Transportation Systems Group, SMARTMOS Product Technology Center.

William R. Perkins (Ch. 15)

Professor of Electrical and Computer Engineering, UIUC.
Fellow IEEE.
Editor-in-Chief IEEE Press.
IEEE Centennial Medal.
Distinguished Member, IEEE Controls Systems Society (President 1985).
Halliburton Education Leadership Award.

Ronald E. Pratt (Ch. 12)

R&D Project Manager, Hewlett-Packard Company.
Manager IEEE.

Rick Price (Ch. 5)

Capacitor Division, TRW, Inc.

Donald H. Priest (Ch. 17)

Consultant.
Former Chief Advisory Engineer (retired), EIMAC Division of Varian Assoc.

Michael B. Pursley (Ch. 23 & 24)

Professor of Electrical and Computer Engineering, UIUC.
Fellow IEEE.
Past-President IEEE/GIT.

Frederick M. Remley Jr. (Ch. 35)

Staff Video Specialist, Center for Information Technology Integration, University of Michigan.
Fellow, Honorary Member SMPTE.
Chairman Working Group on Advanced Television Production.
Member IEEE.
Fellow SBE.

Eugene A. Robinson (Ch. 37)

Senior Fellow, Texas Instruments, Inc.
Engineering Director, Missile Systems.

Lawrence C. J. Roscoe (Ch. 38)

Department Head, AT&T - Bell Laboratories.
Member IEEE.

Douglas K. Rytting (Ch. 12)

R&D Section Manager, High Performance Network Analyzers, Hewlett-Packard Company.

Gary D. Sasaki (Ch. 12)

R&D Section Manager, Frequency and Time Instruments, Hewlett-Packard Company.
Member IEEE.

Rolf Schaumann (Ch. 10)

Professor Emeritus, Former Chair of Electrical and Computer Engineering at Portland State University.
Fellow IEEE.
Member HKN, TBP.
Millennium Medal, IEEE, 2000.
Golden Jubilee Medal, IEEE Circuits and Systems Society, 1999.
Meritorious Service Award, IEEE Circuits and Systems Society, 1993.

Paul D. Schomer (Ch. 40)

Team Leader - Acoustics, U. S. Army Construction Engineering Research Laboratory.

Fellow ASA.

Member IEEE, Institute of Noise Control Engineering.

Chairman, NAE.

U. S. National Counterpart Committee to CIB-W-51 Acoustics.

Jonathan Shaw (Ch. 16)

Electronics Engineer, Naval Research Laboratories.

Member AVS, MRS, IEEE.

W. Ford Shepherd (Ch. 8 & 9)

Director, R&D Network Systems Division, ITT Telecomm.

Arnold Shih (Ch. 16)

Research Physicist, Naval Research Laboratories.

Member APS.

Ludwell A Sibley (Ch. 38)

Consultant.

Formerly Director, Transmission Engineering and Network Technical Support, Telcordia Technologies, Inc.

Senior Member IEEE.

Merrill I. Skolnik (Ch. 36)

Superintendent Emeritus, Radar Division, Naval Research Laboratory.

Fellow IEEE.

Kent Sternstrom (Ch. 13)

Member of Technical Staff, AT&T - Bell Laboratories.

Gregory E. Stillman (Ch. 21)

Professor of Electrical and Computer Engineering UIUC.

Fellow IEEE.

Past-President Electron Device Society.

Jack Morton Award 1999.

Gallium Arsenide Society, Heinrich Welker Medal 1999.

Chairman, National Research Council, Center for Electronic Engineering Assessment, National Institute of Standards and Technology.

National Academy of Engineering.

Ben G. Streetman (Ch. 18)

Professor and J. S. Cockrell Centtenial Chair, Dept. of Electrical Engineering, University of Texas, Austin.

Fellow IEEE.

Member Electrochemical Society.

ASEE Terman Award.

George W. Swenson (Ch. 34 & 40)

Professor Emeritus of Electrical Engineering and Astronomy, UIUC.

Member of the Acoustics Team, Construction Engineering Research Laboratory, U. S. Army Corps. of Engineers.

Robert Symons (Ch. 16)

Technical Director, Litton Electron Device Division.

Fellow IEEE.

Former Associate Editor, IEEE Transactions on Electron Devices.

Richard Thomas (Ch. 34)
Senior Staff Scientist, National Radio Astronomy Observatory.
Fellow IEEE.

Fouad A. Tobagi (Ch. 26)
Associate of Electrical Engineering, Stanford University.
Fellow IEEE.
Member ACM.

Joseph A. Toro (Ch. 5)
Manager, Special Products, TWR Capacitor Division.
Member IEEE.

Fred G. Turnbull (Ch. 14)
Electronics Engineer, General Electric Co.
Fellow IEEE.

Joseph T. Verdeyen (Ch. 41)
Professor of Electrical and Computer Engineering, UIUC.
Senior Member IEEE.
Member APS.
Chairman, Gaseous Electronics Conference.

Theodore F. VonKampen (Ch. 5)
Engineering Manager, TWR Capacitor Division.

John Wakerly (Ch. 42)
Vice-President of Engineering, Alantec, San Jose, CA.
Consulting Associate Professor, Stanford University.
Member IEEE.
IEEE Centennial Award 1984.

Richard Walker (Ch. 13)
Member of Technical Staff, AT&T - Bell Laboratories.

Alva L. Wallis (Ch. 48)
Meteorologist, National Climatic Data Center, Asheville, NC.

Bruno Weinschel (Ch. 11)
Chief Engineer, Weinschel Associates.
Fellow and Past-President IEEE.
Past-Chairman CPEM.
Past-Chairman U. S. Commission I of URSI.
Fellow (British) IEE.

Joan E. Yater (Ch. 16)
Research Physicist, Naval Research Laboratories.
Member APS.

Acknowledgments

The search for new knowledge springs from current knowledge. When we have outgrown the current we look for new frontiers. The previous edition of *Reference Data for Electrical Engineers* has provided a foundation for this new edition and gave it the nutrients to grow. I would like to thank the Editor-in-Chief of the eighth edition, Mac E. Van Valkenburg for establishing a solid foundation for new growth.

The backbone of the ninth edition is comprised of authors from the eighth edition who revised and updated their chapters. This gives the ninth edition endurance and stability. I would like to thank Geoffrey Hyde, Merrill Skolnik, Ludwell Sibley, Rolf Schaumann, Fredrick Matos, Eugene Mechtly, Harold Hosack, David Bender, Kevin Jenkins, Douglas Jones, William Lee, and Robert Hansen for participating in this new edition and for their continuing generous sharing of knowledge. Their advice and assistance to me was of immeasurable value.

Adding to the expansion of our knowledge were several new authors. Ondrej Pauk wrote on power electronics—rectifiers, filters, and power supplies. Surendra Gupta provided a much-needed update of the probability and statistics chapter. Daniel Jablonski expanded upon the GPS chapter to give us an up-to-date direction for the ninth edition. Robert Parker, Kevin Jensen, and their associates collaborated to provide an excellent source of knowledge on microwave technology.

Finally, I would like to acknowledge the strength and support of my husband, James; my children, Rebecca and David; my granddaughter, Aislinn (who provided distraction when needed); and last but not least, my best friend, an electrical engineer and electronic journalist, Lee Goldberg.

Wendy M. Middleton

1 Radio Frequency Spectrum Management and Time and Frequency Standards

Revised by Fredrick Matos

WAVELENGTH–FREQUENCY CONVERSION

Fig. 1 permits conversion between frequency and wavelength. The f scale may be multiplied by a power of 10 if the λ scale is divided by the same power of 10.

Conversion Equations

Propagation velocity

$$c \approx 3 \times 10^8 \text{ meters/second}$$

Wavelength in meters

$$\lambda_m = \frac{300\,000}{f \text{ in kilohertz}} = \frac{300}{f \text{ in megahertz}}$$

Wavelength in centimeters

$$\lambda_{cm} = \frac{30}{f \text{ in gigahertz}}$$

Wavelength in feet

$$\lambda_{ft} = \frac{984\,000}{f \text{ in kilohertz}} = \frac{984}{f \text{ in megahertz}}$$

Wavelength in inches

$$\lambda_{in} = \frac{11.8}{f \text{ in gigahertz}}$$

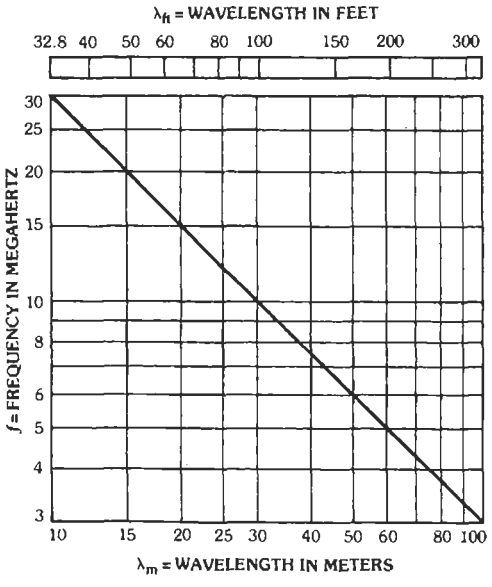

Fig. 1. Wavelength–frequency conversion.

1 angstrom unit, Å = 3.937×10^{-9} inch
= 1×10^{-10} meter
= 1×10^{-4} micrometer
1 micrometer, μm = 3.937×10^{-5} inch
= 1×10^{-6} meter
= 1×10^{4} angstrom units

(Note that the term "micrometer" has superceded the term "micron.")

Nomenclature of Radio Frequency Bands

Table 1 is adapted from the Radio Regulations of the International Telecommunication Union, Geneva, 1990. Table 2 shows an alternative and more widely used set of designations.

RADIO FREQUENCY SPECTRUM MANAGEMENT

International

The distribution of radio frequencies for various telecommunications services is established by international treaty by the International Telecommunication Union (ITU), an organ of the United Nations. Frequency allocations, procedures for international registration and coordination of frequencies and satellites, frequency sharing, and other regulations, procedures, and technical standards are contained in the ITU *Radio Regulations*. Copies of the *Radio Regulations*, technical standards, and related information may be obtained from the International Telecommunication Union, Place des Nations, CH-1211, Geneva 20, Switzerland.

The ITU *Radio Regulations* have the status of international law and are amended at a treaty conference referred to as a World Radiocommunication Conference (WRC), normally convened every two or three years to address various topics. The tables of frequency allocations, regulations, and procedures of individual nations generally follow the ITU *Radio Regulations* with nations amending their own domestic rules and regulations following those of the WRC.

US Radio Frequency Spectrum Management

The Communications Act of 1934 provides the foundation for US spectrum rules and regulations, management, and usage. The basic authority is delineated in Sections 303, 304, and 305 of the Act. Section 303 presents the general powers of the Federal Communications Commission (FCC) regarding transmitting stations; 304 deals with waiving frequency claims; and 305 provides that Federal Government owned stations shall be assigned frequencies by the President (delegated to the Department of Commerce National Telecommunications and Information Administration [NTIA]).

TABLE 1. NOMENCLATURE OF FREQUENCY BANDS

Band Number*	Frequency Range	Metric Subdivision	Adjectival Designation	
4	3 to 30 kilohertz	Myriametric waves	VLF	Very low frequency
5	30 to 300 kilohertz	Kilometric waves	LF	Low frequency
6	300 to 3000 kilohertz	Hectometric waves	MF	Medium frequency
7	3 to 30 megahertz	Decametric waves	HF	High frequency
8	30 to 300 megahertz	Metric waves	VHF	Very high frequency
9	300 to 3000 megahertz	Decimetric waves	UHF	Ultrahigh frequency
10	3 to 30 gigahertz	Centimetric waves	SHF	Superhigh frequency
11	30 to 300 gigahertz	Millimetric waves	EHF	Extremely high frequency
12	300 to 3000 gigahertz or 3 terahertz	Decimillimetric waves		

* "Band Number N" extends from 0.3×10^N to 3×10^N hertz. The upper limit is included in each band; the lower limit is excluded.

Based on ITU Radio Regulations, 1998.

TABLE 2. LETTER DESIGNATIONS FOR FREQUENCY BANDS

Letter	Frequency Band
L	1000–2000 MHz
S	2000–4000 MHz
C	4000–8000 MHz
X	8000–12 000 MHz
K_u	12–18 GHz
K	18–27 GHz
K_a	27–40 GHz
V	40–75 GHz
W	75–110 GHz

Source: IEEE Standard Letter Designations for Radar Frequency Bands, IEEE Std 521–1984, reaffirmed 1989.

Section 305 is particularly significant because it provides for the separation of authority between the Federal Government and the non-Federal Government, or private, sector. Section 305 has resulted in two US spectrum regulatory bodies: the FCC regulating the non-Federal Government sector, and the NTIA regulating the Federal Government sector. Section 305 has also resulted in agreements between the Federal Government and non-Government sectors that essentially divide the spectrum usage into three parts: exclusive Federal Government use, exclusive non-Federal Government use, and use shared between the two sectors.

The NTIA is aided by other federal agencies and departments through an advisory group, the Interdepartment Radio Advisory Committee (IRAC). IRAC carries out frequency coordination for the Federal Government agencies, recommends technical standards, and reviews major Federal Government systems to assure spectrum availability. The IRAC also provides advice to the NTIA on spectrum policy issues.

Although the NTIA and FCC generally operate independently of each other, they coordinate closely on spectrum matters. An FCC liaison representative participates in the IRAC, and the NTIA participates in the rule-making process of the FCC with the advice of the IRAC. FCC and NTIA spectrum sharing coordination is also carried out daily as required.

Spectrum Engineering Software

Spectrum engineering software is available free of charge from the National Telecommunications and Information Administration, Washington, DC. The Microcomputer Spectrum Analysis Models (MSAM) software contains 13 models, including models for intermodulation and propagation.

Frequency Allocations

Frequencies are allocated into tables via international treaty set by the ITU, and domestically in the United States by the Federal Communications Commission (FCC) and the National Telecommunications and Information Administration (NTIA). Many other nations have their own domestic tables. Table 3 presents the International Table of Frequency Allocations and the United States National Table of Frequency Allocations from the *Manual of Regulations and Procedures for Federal Radio Frequency Management* published by the NTIA or simply the *NTIA Manual.* (The latest edition of the NTIA Manual can be obtained from the Website www.ntia.doc.gov.) A very similar table is provided in Part 2 of the FCC Rules and Regulations. The international table contained in the following is obtained from the ITU's *Radio Regulations,* Edition of 1998.

The footnotes to the tables are important and need to be reviewed when considering frequency allocations. There are four different types of footnotes: 1) international;

2) United States comprehensive with the prefix "US;" 3) US Federal Government applying to only US Federal Government users, with the prefix "G;" and 4) Non-Federal-Government footnotes, applying to the US private sector, including state and local governments, abbreviated "NG."

ITU Table of Frequency Allocations—The ITU Table of Frequency Allocations (Table 3) is that table contained in Article S5 of the ITU Radio Regulations, Edition of 1998.

National Table of Frequency Allocations—The National Table of Frequency Allocations is comprised of the US Government Table of Frequency Allocations and the FCC Table of Frequency Allocations. The National Table indicates the normal national frequency allocation planning and the degree of conformity with the ITU Table. When required in the national interest and consistent with national rights, as well as obligations undertaken by the United States to other countries that may be affected, additional uses of frequencies in any band may be authorized to meet service needs other than those provided for in the National Table.

Specific exceptions to the National Table of Frequency Allocations are as follows:

A Government frequency assignment may be authorized in a non-Government band, as an exception, provided a) the assignment is coordinated with the FCC and b) no harmful interference will be caused to the service rendered by non-Government stations, present or future.

A non-Government frequency assignment may be authorized in a Government band, as an exception, provided a) the assignment is coordinated with the IRAC and b) no harmful interference will be caused to the service rendered by Government stations, present or future.

In the case of bands shared by Government and non-Government services, frequency assignments therein shall be subject to coordination between the IRAC and the FCC and no priority is recognized unless the terms of such priority are specifically defined in the National Table of Frequency Allocations or unless they are subject to mutually agreed arrangements in specific cases.

US Government Table of Frequency Allocations—The US Government Table of Frequency Allocations shall be used as a guide in the assignment of radio frequencies to Government radio stations in the United States and Possessions. Exceptions to the Table may be made by the IRAC after careful consideration to avoid harmful interference and to ensure compliance with the ITU Radio Regulations.

For the use of frequencies by Government radio stations outside the United States and Possessions, Government agencies shall be guided insofar as practicable by the ITU Table of Frequency Allocations and, where applicable, by the authority of the host government. Maximum practicable effort should be made to avoid the possibility of harmful interference to other authorized US operations. If harmful interference is considered likely, it is incumbent upon the agency conducting the operation to coordinate with other US Flag users, as provided for in Section 8.3.11 of the NTIA Manual.

Application of the US Government Table is subject to the recognition that:

below 25 000 kHz the Table is only applicable in the assignment of frequencies after 5 September 1961;

under Article 48 of the International Telecommunication Constitution, administrations "retain their entire freedom with regard to military radio installations of their army, naval and air forces;" and under No. S4.4 of the ITU Radio Regulations, administrations may assign frequencies in derogation of the ITU Table of Frequency Allocations "on the express condition that harmful interference shall not be caused to services carried on by stations operating in accordance with the provisions of the Convention and of these Regulations."

Some frequency assignments below 25 000 kHz that were made before 5 September 1961, are not in conformity with the Government Table. Because of the exception mentioned in the first subparagraph above, the status of these assignments can be determined only on a case-by-case basis. With this exception, the rules pertaining to the relative status between radio services are as follows:

Stations of secondary services are on a noninterference basis to the primary service; they

(a) shall not cause harmful interference to stations of primary services to which frequencies are already assigned or to which frequencies may be assigned at a later date;
(b) cannot claim protection from harmful interference from stations of a primary service to which frequencies are already assigned or may be assigned at a later date;
(c) can claim protection, however, from harmful interference from stations of the same or other secondary service(s) to which frequencies may be assigned at a later date.

Additional allocation—where a band is indicated in a footnote of the Table as "also allocated" to a service in an area smaller than a Region, or in a particular country. For example, an allocation which is added in this area or in this country to the service or services that are indicated in the Table.

Alternative allocation—where a band is indicated in a footnote of the Table as "allocated" to one or more services in an area smaller than a Region, or in a particular country. For example, an allocation that replaces, in this area or in this country, the allocation indicated in the Table.

Different category of service—where the allocation category (primary or secondary) of the service in

the Table is changed. For example, the Table reflects the allocation as Fixed, Mobile, and RADIOLOCATION, the category of these services are changed by the footnote to FIXED, MOBILE, and Radiolocation.

An allocation or a footnote to the Government Table denoting relative status between radio services automatically applies to each assignment in the band to which the footnote or allocation pertains, unless at the time of a particular frequency assignment action a different provision is decided upon for the assignment concerned.

A priority note reflecting the same provisions as an allocation or an applicable footnote to the Government Table is redundant and shall not be applied to frequency assignments.

An assignment that is in conformity with the service allocation (as amplified by pertinent footnotes) for the band in which it is contained takes precedence over assignments therein that are not in conformity unless, at the time of the frequency assignment action, a different provision is decided upon.

Where in this Table a band is indicated as allocated to more than one service, such services are listed in the following order:

(a) services, the names of which are printed in all capital letters (example: FIXED); these services are called "primary" services;
(b) services, the names of which are printed in "normal characters" (example: Mobile); these are "secondary" services.

The columns to the right of the double line show the national provisions; those to the left show the provisions of the ITU Table of Frequency Allocations.

Column 1 indicates the national band limits.

Column 2 indicates the Government allocation, including all "US" and "G" footnotes considered to be applicable to the Government nationally. Where the allocated service is followed by a function in parentheses, e.g., SPACE (space-to-Earth), the allocation is limited to the function shown.

Column 3 indicates the non-Government allocation including all "US" footnotes and certain "NG" footnotes as contained in Part 2 of the FCC Rules and Regulations. Where the allocated service is followed by a function in parentheses, e.g., SPACE (space-to-Earth), the allocation is limited to the function shown. These data have been included in the Government Table for information purposes only.

Column 4 contains such remarks as serve to amplify the Government and non-Government allocations or point to an understanding between the FCC and IRAC/NTIA in respect thereof.

The international footnotes shown in the columns to the left of the double line are applicable only in the relationships between the United States and other countries. An international footnote is applicable to the US Table of Allocations if the number also appears in Columns 2 and 3 of the US Table. The international footnote is then applicable to both Government and non-Government use.

The texts of footnotes in this Table are listed in numerical order at the end of the Table, in sections headed Government Footnotes, US Footnotes, International Footnotes, and NG Footnotes.

Chart of Regions as Defined in Table of Frequency Allocations—For the allocation of frequencies the world has been divided into three Regions* as shown in Fig. 2 and described in Nos. S5.3 to S5.9.

Government (G) Footnotes

(These footnotes, each consisting of the letter "G" followed by one or more digits, denote stipulations applicable only to the Government.)

G2—In the bands 216–225, 420–450 (except as provided by US217), 890–902, 928–942. 1300–1400, 2310–2390, 2417–2450, 2700–2900, 5650–5925, and 9000–9200 MHz, the Government radiolocation is limited to the military services.

G5—In the bands 162.0125–173.2, 173.4–174, 406.1–410, and 410–420 MHz, the fixed and mobile services are all allocated on a primary basis to the Government nonmilitary agencies.

G6—Military tactical fixed and mobile operations may be conducted nationally on a secondary basis; (1) to the meteorological aids service in the band 403–406 MHz; and (2) to the radio astronomy service in the band 406.1–410 MHz. Such fixed and mobile operations are subject to local coordination to ensure that harmful interference will not be caused to the services to which the bands are allocated.

G8—Low-power Government radio control operations are permitted in the band 420–450 MHz.

G11—Government fixed and mobile radio services including low power radio control operations are permitted in the band 902–928 MHz on a secondary basis.

G15—Use of the band 2700–2900 MHz by the military fixed and shipborne air defense radiolocation installations will be fully coordinated with the meteorological aids and aeronautical radionavigation services. The military air defense installations will be moved from the band 2700–2900 MHz at the earliest practicable date. Until such time as military air defense installations can be accommodated satisfactorily elsewhere in the spectrum, such operations will, insofar as practicable, be adjusted to meet the requirements of the aeronautical radionavigation service.

G19—Use of the band 9000–9200 MHz by military fixed and shipborne air defense radiolocation installations will be fully coordinated with the aeronautical radionavigation service, recognizing fully the safety aspects of the latter. Military air defense installations will be accommodated ultimately outside this band. Until such time as military defense installations can be accommodated satisfactorily elsewhere in the spectrum, such operations will, in-so-far as practicable, be adjusted to meet the requirements of the aeronautical radionavigation service.

---

* It should be noted that where the words "regions" or "regional" are without a capital "R" in these Regulations, they do not relate to the three Regions here defined for purposes of frequency allocation.

* From *Manual of Regulations and Procedures for Federal Radio Frequency Management*, January 2000 Edition, as revised May and September 2000, US Department of Commerce, National Telecommunications and Information Administreation, Washington, DC.

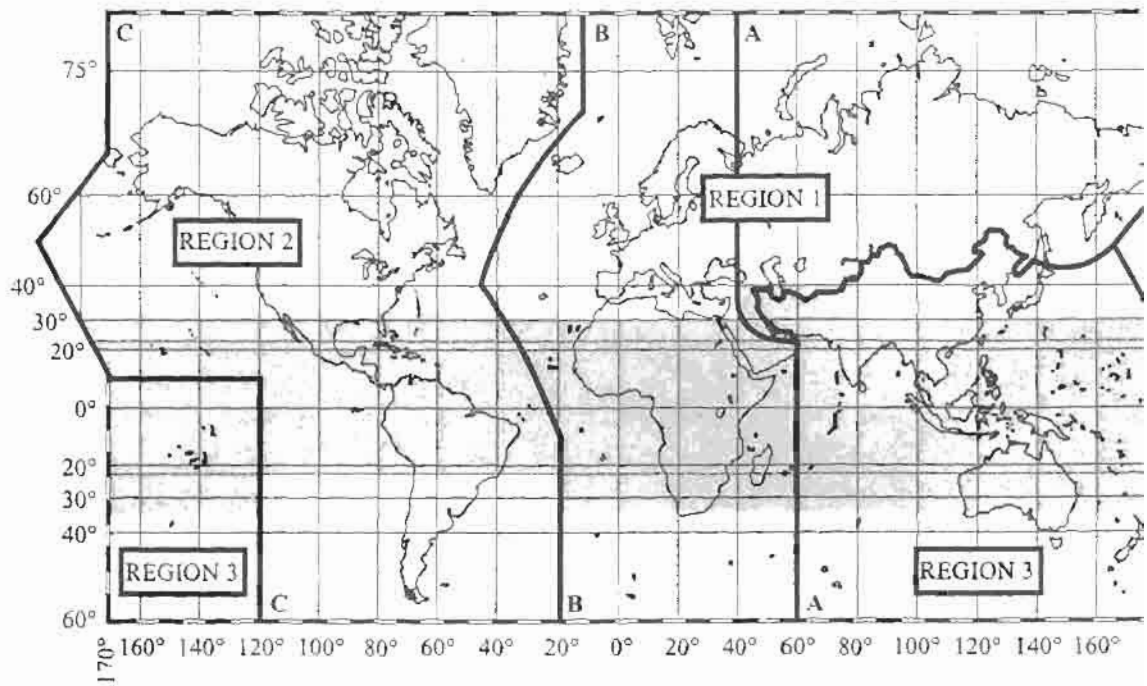

Fig. 2. The shaded part represents the Tropical Zones as defined in Nos. **S5.16** to **S5.20** and **S5.21.**

G27—In the bands 225–328.6, 335.4–399.9, and 1350–1400 MHz, the fixed and mobile services are limited to the military services.

G30—In the bands 138–144, 148–149.9, 150.05–150.8, 1427–1429, and 1429–1435 MHz, the fixed and mobile services are limited primarily to operations by the military services.

G31—In the bands 3300–3500 MHz, the Government radiolocation is limited to the military services, except as provided by footnote US108.

G32—Except for weather radars on meteorological-satellites in the band 9975–10025 MHz and for Government survey operations (see footnote US-108), Government radiolocation in the band 10000–10500 MHz is limited to the military services.

G34—In the band 34.4–34.5 GHz, weather radars on board meteorological satellites for cloud detection are authorized to operate on the basis of equality with military radiolocation devices. All other nonmilitary radiolocation in the band 33.4–36.0 GHz shall be secondary to the military services.

G42—Space command, control, range, and range rate systems for earth station transmission only (including installations on certain Navy ships) may be accommodated on a co-equal basis with the fixed and mobile services in the band 1761–1842 MHz. Specific frequencies required to be used at any location will be satisfied on a coordinated case-by-case basis.

G56—Government radiolocation in the bands 1215–1300, 2900–3100, 5350–5650, and 9300–9500 MHz is primarily for the military services; however, limited secondary use is permitted by other Government agencies in support of experimentation and research programs. In addition, limited secondary use is permitted for survey operations in the band 2900–3100 MHz.

G59—In the bands 902–928 MHz, 3100–3300 MHz, 3500–3700 MHz, 5250–5350 MHz, 8500–9000 MHz, 9200–9300 MHz, 13.4–14.0 GHz, 15.7–17.7 GHz, and 24.05–24.25 GHz, all Government nonmilitary radiolocation shall be secondary to military radiolocation, except in the subband 15.7–16.2 GHz airport surface detection equipment (ASDE) is permitted on a co-equal basis subject to coordination with the military departments.

G100—The bands 235–322 MHz and 335.4–399.9 MHz are also allocated on a primary basis to the mobile-satellite service, limited to military operations.

G104—In the bands 7450–7550 and 8175–8215 MHz, it is agreed that although the military space radio communication systems, which include earth stations near the proposed meteorological-satellite, installations will precede the meteorological-satellite installations; engineering adjustments to either the military or the meteorological-satellite systems or both will be made as mutually required to assure compatible operations of the systems concerned.

G106—The bands 2501–2502 kHz, 5003–5005 kHz, 10003–10005 kHz, 15005–15010 kHz, 19990–19995 kHz, 20005–20010 kHz, and 25005–25010 kHz are also allocated, on a secondary basis, to the space research service. The space research transmissions are subject to immediate temporary or permanent shutdown in the event of interference to the reception of the standard frequency and time broadcasts.

G109—All assignments in the band 157.0375–157.1875 MHz are subject to adjustment to other frequencies in this band as long-term US maritime VHF planning develops, particularly that planning incident to support the National VHF-FM Radiotelephone Safety and Distress System (see Doc. 15624/1–1.9.111/1.9.125).

G110—Government ground-based stations in the aeronautical radionavigation service may be authorized between 3500 and 3700 MHz where accommodation in the 2700–2900 MHz band is not technically and/or economically feasible.

G114—In the band 1350–1400 MHz, the frequency 1381.05 MHz with emissions limited to ± 12 MHz is also allocated to Fixed and Mobile-Satellite Services (space-to-Earth) for the relay of nuclear burst data.

G115—In the band 13360–13410 kHz, the fixed service is allocated on a primary basis outside the conterminous United States. Within the conterminous United States, assignments in the fixed service are permitted, and will be protected for national defense purposes or if they are to be used only in an emergency jeopardizing life, public safety, or important property under conditions calling for immediate communication where other means of communication do not exist.

G116—The band 7125–7155 MHz is also allocated for Earth-to-space transmission in the Space Operations Service at a limited number of sites (not to exceed two), subject to established coordination procedures.

G117—In the bands 7250–7750 and 7900–8400 MHz, and 17.8–21.2, 30–31, 39.5–40.5, 43.5–45.5, and 50.4–51.4 GHz the Government fixed-satellite and mobile-satellite services are limited to military systems.

G118—Government fixed stations may be authorized in the band 1700–1710 MHz only if spectrum is not available in the band 1710–1850 MHz.

G120—Development of airborne primary radars in the band 2310–2390 MHz with peak transmitter power in excess of 250 watts for use in the United States is not permitted.

G121—In the band 285–325 kHz, the Maritime Radionavigation Service may also be used on a primary basis by Maritime Radionavigation Land Stations, and on a secondary basis by Radionavigation Land Stations, to transmit differential global positioning satellite (DGPS) information.

G122—The bands 2390–2400, 2402–2417, and 4660–4685 MHz were identified for immediate reallocation, effective 10 August 1994, for exclusive non-Government use under Title VI of the Omnibus Budget Reconciliation Act of 1993. Effective 10 August 1994, any Government operations in these bands are on a noninterference basis to authorized non-Government operations and shall not hinder the implementation of any non-Government operations.

G123—The bands 2300–2310 and 2400–2402 MHz were identified for reallocation, effective 10 August 1995, for exclusive non-Government use under Title VI of the Omnibus Budget Reconciliation Act of 1993. Effective 10 August 1995, any Government operations in these bands are on a noninterference basis to authorized non-Government operations and shall not hinder the implementation of any non-Government operations.

G124—The band 2417–2450 MHz was identified for reallocation, effective August 10, 1995, for mixed Government and non-Government use under Title VI of the Omnibus Budget Reconciliation Act of 1993.

G125—The 4635–4660 MHz band was identified for reallocation, effective January 1, 1997, for exclusive non-Government use under Title VI of the Omnibus Budget Reconciliation Act of 1993. Effective January 1, 1997, any Government operations in this band are on a noninterference basis to authorized non-Government operations and shall not hinder the implementation of any non-Government operations. However, Government operation of mobile (including airborne) systems authorized as of March 22, 1995, within 80 km of Pico Del Este, PR (18°16′ N, 65°46′ W), Dam Neck, VA (36°46′ N, 75°57′ W), and St. Thomas, VI (18°21′ N, 64°55′ W) will be permitted on a fully protected basis until January 1, 2009.

G126—Differential-Global-Positioning-System (DGPS) Stations may be authorized on a primary basis in the bands 108–117.975 MHz, 1559–1610 MHz, and 5000–5150 MHz for the specific purpose of transmitting DGPS information intended for aircraft navigation.

G127—Federal Travelers Information Stations (TIS) on 1610 kHz have co-primary status with AM Broadcast assignments. Federal TIS authorized as of August 4, 1994, preclude subsequent assignment for conflicting allotments.

US Footnotes

(These footnotes, each consisting of the letters US followed by one or more digits, denote stipulations applicable to both Government and non-Government stations.)

US7—In the band 420–450 MHz and within the following areas, the peak envelope power output of a transmitter employed in the amateur service shall not exceed 50 watts, unless expressly authorized by the Commission after mutual agreement, on a case-by-case basis, between the Federal Communications Commission Engineer in Charge at the applicable district office and the military area frequency coordinator at the applicable military base. For areas (e) through (j), the appropriate military coordinator is located at Peterson AFB, CO.

(a) Those portions of Texas and New Mexico bounded on the south by latitude 31°45′ N, on the east by 104°00′ W, on the north by latitude 34°30′ N, and on the west by longitude 107°30′ W.

(b) The entire State of Florida including the Key West area and the areas enclosed within a 322-kilometer (200-mile) radius of Patrick Air Force Base, Florida (latitude 28°21′ N, longitude 80°43′ W), and within a 322-kilometer (200-mile) radius of Eglin Air Force Base, Florida (latitude 30°30′ N, longitude 86°30′ W).

(c) The entire State of Arizona.

(d) Those portions of California and Nevada south of latitude 37°10′ N, and the areas enclosed within a 322-kilometer (200–mile) radius of the Pacific Missile Test Center, Point Mugu, California (latitude 34°09′ N, longitude 119°11′ W).

(e) In the State of Massachusetts within a 160-kilometer (100-mile) radius around locations at Otis Air Force Base, Massachusetts (latitude 41°45′ N, longitude 70°32′ W).

(f) In the State of California within a 240-kilometer (150-mile) radius around locations at Beale Air Force Base, California (latitude 39°08′ N, longitude 121°26′ W).

(g) In the State of Alaska within a 160-kilometer (100-mile) radius of Clear, Alaska (latitude 64°17′ N, longitude 149°10′ W).

(h) In the State of North Dakota within a 160-kilometer (100-mile) radius of Concrete, North Dakota (latitude 48°43′ N, longitude 97°54′ W).

(i) In the States of Alabama, Florida, Georgia, and South Carolina within a 200-kilometer (124-mile) radius of Warner Robins Air Force Base, Georgia (latitude 32°38′ N, longitude 83°35′ W).

(j) In the State of Texas within a 200-kilometer (124-mile) radius of Goodfellow Air Force Base, Texas (latitude 31°25′ N, longitude 100°24′ W).

US8—The use of frequencies 170.475, 171.425, 171.575, and 172.275 MHz east of the Mississippi River and 170.425, 170.575, 171.475, 172.225, and 172.375 MHz west of the Mississippi River may be authorized to fixed, land, and mobile stations operated by non-Federal forest firefighting agencies. In addition, land stations and mobile stations operated by non-Federal conservation agencies, for mobile relay operation only, may be authorized to use the frequency 172.275 MHz east of the Mississippi River and the frequency 171.475 MHz west of the Mississippi River. The use of any of the foregoing nine frequencies shall be on the condition that no harmful interference will be caused to Government stations.

US10—The use of the frequencies 26.62, 143.75, 143.90, and 148.15 MHz may be authorized to Civil Air Patrol land stations and Civil Air Patrol mobile stations.

US11—The use of the frequencies 166.250 and 170.150 MHz may be authorized to non-Government remote pickup broadcast base and land mobile stations and to non-Government base, fixed, and land mobile stations in the public safety radio services (the sum of the bandwidth of emission and tolerance is not to exceed 25 kHz, except that authorizations in existence as of December 20, 1974, using a larger bandwidth are permitted to continue in operation until December 20, 1979) in the continental United States (excluding Alaska) only, except within the area bounded on the west by the Mississippi River, on the north by the parallel of latitude 37°30′ N, and on the east and south by that arc of the circle with centre at Springfield, Illinois, and radius equal to the airline distance between Springfield, Illinois, and Montgomery, Alabama, subtended between the foregoing west and north boundaries, on the conditions that harmful interference will not be caused to Government stations present or future in the Government band 162–174 MHz. The use of these frequencies by remote pickup broadcast stations will not be authorized for locations within 240 kilometers (150 miles) of New York City; and use of these frequencies by the public safety radio services will not be authorized except for locations within 240 kilometers (150 miles) of New York City.

US13—For the specific purpose of transmitting hydrological and meteorological data in cooperation with agencies of the Federal Government, the following frequencies may be authorized to non-Government fixed stations on the condition that harmful interference will not be caused to Government stations:

MHz	MHz	MHz	MHz
169.425	170.275	171.125	406.175
169.450	170.300	171.825	409.675
169.475	170.325	171.850	409.725
169.500	171.025	171.875	412.625
169.525	171.050	171.900	412.675
170.225	171.075	171.925	412.725
170.250	171.100	406.125	412.775

Licensees holding a valid authorization on June 11, 1962, to operate on the frequencies 169.575, 170.375, or 171.975 MHz may continue to be authorized for such operations on the condition that harmful interference will not be caused to Government stations.

US14—When 500 kHz is being used for distress purposes, ship and coast stations using morse telegraphy may use 512 kHz for calling.

US18—Navigation aids in the United States and possessions in the bands 9–14 kHz, 90–110 kHz, 190–415 kHz, 510–535 kHz, and 2700–2900 MHz are normally operated by the US Government. However, authorizations may be made by the FCC for non-Government operation in these bands subject to the conclusion of appropriate arrangements between the FCC and the Government agencies concerned and upon special showing of need for service which the Government is not yet prepared to render.

US25—The use of frequencies in the band 25.85–26.1 MHz may be authorized in any area to non-Government remote pickup broadcast base and mobile stations on the condition that harmful interference is not caused to stations in the broadcasting service.

US26—The bands 117.975–121.4125 MHz, 123.5875–128.8125 MHz, and 132.0125–136 MHz are for air traffic control communications.

US28—The band 121.5875–121.9375 MHz is for use by aeronautical utility land and mobile stations, and for air traffic control communications.

US30—The band 121.9375–123.0875 MHz is available to FAA aircraft for communications pursuant to flight inspection functions in accordance with the Federal Aviation Act of 1958.

US31—Except as provided below the band 121.9375–123.0875 MHz is for use by private aircraft stations.

The frequencies 122.700, 122.725, 122.750, 122.800, 122.950, 122.975, 123.000, 123.050, and 123.075 MHz may be assigned to aeronautical advisory stations. In addition, at landing areas having a part-time or no airdrome control tower or FAA flight service station, these frequencies may be assigned on a secondary noninterference basis to aeronautical utility mobile stations and may be used by FAA ground vehicles for safety related communications during inspections conducted at such landing areas.

The frequencies 122.850, 122.900, and 122.925 MHz may be assigned to aeronautical multicom stations. In addition, 122.850 MHz may be assigned on a secondary noninterference basis to aeronautical utility mobile stations. In case of 122.925 MHz, US213 applies.

Air carrier aircraft stations may use 122.000 and 122.050 MHz for communication with aeronautical stations of the Federal Aviation Administration and 122.700, 122.800, 122.900, and 123.000 MHz for communications with aeronautical stations pertaining to safety of flight with and in the vicinity of landing areas not served by a control tower.

Frequencies in the band 121.9375–122.6875 MHz may be used by aeronautical stations of the Federal Aviation Administration for communication with private aircraft stations only, except that 122.000 and 122.050 MHz may also be used for communication with air carrier aircraft stations concerning weather information.

US32—Except for the frequencies 123.3 and 123.5 MHz, which are not authorized for Government use, the band 123.1125–123.5875 MHz is available for FAA Communications incident to flight test and inspection activities pertinent to aircraft and facility certification on a secondary noninterference basis.

US33—The band 123.1125–123.5875 MHz is for use by flight test and aviation instructional stations. The frequency 121.950 MHz is available for aviation instructional stations.

US41—The Government radiolocation service is permitted in the band 2450–2500 MHz on the condition that harmful interference is not caused to non-Government services.

US44—The non-Government radiolocation service may be authorized in the band 2900–3100 MHz on the condition that no harmful interference is caused to Government services.

US48—The non-Government radiolocation service may be authorized in the bands 5350–5460 MHz and 9000–9200 MHz on the condition that it does not cause harmful interference to the aeronautical radionavigation service or to the Government radiolocation service.

US49—The non-Government radiolocation service may be authorized in the band 5460–5470 MHz on the condition that it does not cause harmful interference to the aeronautical or maritime radionavigation services or to the Government radiolocation service.

US50—The non-Government radiolocation service may be authorized in the band 5470–5600 MHz on the condition that it does not cause harmful interference to the maritime radionavigation service or to the Government radiolocation service.

US51—In the bands 5600–5650 MHz and 9300–9500 MHz, the non-Government radiolocation service shall not cause harmful interference to the Government radiolocation service.

US53—In view of the fact that the band 13.25–13.4 GHz is allocated to doppler navigation aids, Government and non-Government airborne doppler radars in the aeronautical radionavigation service are permitted in the band 8750–8850 MHz only on the condition that they must accept any interference that may be experienced from stations in the radiolocation service in the band 8500–10000 MHz.

US54—Temporarily, and until certain operations of the radiolocation service in the band 9000–9200 MHz can be transferred to other appropriate frequency bands, the aeronautical radionavigation service may, in certain geographical areas, be subject to receiving some degree of interference from the radiolocation service.

US58—In the band 10000–10500 MHz, pulsed emissions are prohibited, except for weather radars on board meteorological-satellites in the band 10000–10025 MHz. The amateur service and the non-Government radiolocation service, which shall not cause harmful interference to the Government radiolocation service, are the only non-Government services permitted in this band. The non-Government radiolocation service is limited to survey operations as specified in footnote US108.

US59—The band 10.5–10.55 GHz is restricted to systems using type N0N emission with a power not to exceed 40 watts into the antenna.

US65—The use of the band 5460–5650 MHz by the maritime radionavigation service is limited to shipborne radars.

US66—The use of the band 9300–9500 MHz by the aeronautical radionavigation service is limited to airborne radars and associated airborne beacons. In addition, ground-based radar beacons in the aeronautical radionavigation service are permitted in the band 9300–9320 MHz on condition that harmful interference is not caused to the maritime radionavigation service.

US67—The use of the band 9300–9500 MHz by the meteorological aids service is limited to ground-based radars. Radiolocation installations will be coordinated with the meteorological aids service and, insofar as practicable, will be adjusted to meet the requirements of the meteorological aids service.

US69—In the band 31.8–33.4 GHz, ground-based radionavigation aids are not permitted except where they operate in cooperation with airborne or shipborne radionavigation devices.

US70—The meteorological aids service allocation in the band 400.15–406 MHz does not preclude the operation therein of associated ground transmitters.

US71—In the band 9300–9320 MHz, low-powered maritime radionavigation stations shall be protected from harmful interference caused by the operation of land-based equipment.

US74—In the bands 25.55–25.67, 73–74.6, 406.1–410, 608–614, 1400–1427, 1660.5–1670, 2690–2700, and 4990–5000 MHz and in the bands 10.68–10.7, 15.35–15.4, 23.6–24, 31.3–31.8, 86–92, 105–116, and 217–231 GHz, the radio astronomy service shall be protected from extraband radiation only to the extent such radiation exceeds the level that would be present if the offending station were operating in compliance with the technical standards or criteria applicable to the service in which it operates.

US77—Government stations may also be authorized for:

(a) port operations use on a simplex basis by coast and ship stations on the frequencies 156.6 and 156.7 MHz;

(b) duplex port operations use of the frequency 157.0 MHz for ship stations and 161.6 MHz for coast stations;

(c) intership use of 156.3 MHz on a simplex basis; and

(d) vessel traffic services under the control of the US Coast Guard on a simplex basis by coast and ship stations on the frequencies 156.25, 156.55, 156.6, and 156.7 MHz.

(e) navigational bridge-to-bridge and navigational communications on a simplex basis by coast and ship stations on the frequencies 156.375 and 156.65 MHz.

US78—In the mobile service, the frequencies between 1435 and 1535 MHz will be assigned for aeronautical telemetry and associated telecommand operations for flight testing of manned or unmanned aircraft and missiles or for their major components. Permissible usage includes telemetry associated with launching and reentry into the earth's atmosphere as well as any incidental orbiting prior to reentry of manned objects undergoing flight tests. The following frequencies are shared with flight telemetering mobile stations: 1444.5, 1453.5, 1501.5, 1515.5, 1524.5, and 1525.5 MHz.

US80—Government stations may use the frequency 122.9 MHz subject to the following conditions:

(a) All operations by Government stations shall be restricted to the purpose for which the frequency is authorized to non-Government stations and shall be in accordance with the appropriate provisions of the Commission's rules and regulations, Part 87, Aviation Services.

(b) Use of the frequency is required for coordination of activities with Commission licensees operating on this frequency.

(c) Government stations will not be authorized for operations at fixed locations.

US81—The band 38–38.25 MHz is used by both Government and non-Government radio astronomy observatories. No new fixed or mobile assignments are to be made and Government stations in the band 38–38.25 MHz will be moved to other bands on a case-by-case basis, as required, to protect radio astronomy observations from harmful interference. As an exception however, low-powered military transportable and mobile stations used for tactical and training purposes will continue to use the band. To the extent practicable, the latter operations will be adjusted to relieve such interference as may be caused to radio astronomy observations. In the event of harmful interference from such local operations, radio astronomy observatories may contact local military commands directly, with a view to effecting relief. A list of military commands, areas of coordination, and points of contact for purposes of relieving interference may be obtained upon request from the Office of the Chief Scientist, Federal Communications Commission, Washington, DC 20554.

US82—Until July 1, 1991, the assignable frequencies in the bands 4143.6–4146.6 kHz, 6218.6–6224.6 kHz, 8291.1–8297.3 kHz, 12429.2–12439.5 kHz, 16587.1–16596.4 kHz, and 22124–22139.5 kHz may be authorized on a shared nonpriority basis to Government and non-Government ship and coast stations (SSB telephony, with peak envelope power not to exceed 1 kW). Effective July 1, 1991, the assignable frequencies in the bands 4146–4152 kHz, 6224–6233 kHz, 8294–8300 kHz, 12353–12368 kHz, 16528–16549 kHz, 18825–18846 kHz, 22159–22180 kHz, and 25100–25121 kHz may be authorized on a shared nonpriority basis to Government and non-Government ship and coast stations (SSB telephony, with peak envelope power not to exceed 1 kW).

US87—The frequency 450 MHz, with maximum emission bandwidth of 500 kHz, may be used by Government and non-Government stations for space telecommand at specific locations, subject to such conditions as may be applied on a case-by-case basis.

US90—In the band 2025–2110 MHz Earth-to-space and space-to-space transmissions may be authorized in the space research and earth exploration-satellite services subject to such conditions as may be applied on a case-by-case basis. Such transmissions shall not cause harmful interference to non-Government stations operating in accordance with the Table of Frequency Allocations. All space-to-space transmission reaching the earth's surface shall adhere to a power flux density of between -144 and -154 dBW/m^2/4 kHz depending on the angle of arrival per ITU Radio Regulation 2557 and shall not cause harmful interference to the other space services.

US93—In the conterminous United States, the frequency 108.0 MHz may be authorized for use by VOR test facilities, the operation of which is not essential for the safety of life or property, subject to the condition that no interference is caused to the reception of FM broadcasting stations operating in the band 88–108 MHz. In the event that such interference does occur, the licensee or other agency authorized to operate the facility shall discontinue operation on 108 MHz and shall not resume operation until the interference has been eliminated or the complaint otherwise satisfied. VOR test facilities operating on 108 MHz will not be protected against interference caused by FM broadcasting stations operating in the band 88–108 MHz nor shall the authorization of a VOR test facility on 108 MHz preclude the Commission from authorizing additional FM broadcasting stations.

US99—In the band 1668.4–1670 MHz, the meteorological aids service (radiosonde) will avoid operations to the maximum extent practicable. Whenever it is necessary to operate radiosondes in the band 1668.4–1670 MHz within the United States, notification of the operations shall be sent as far in advance as possible to the Electromagnetic Spectrum Management Unit, National Science Foundation, Washington, DC 20550.

US102—In Alaska only, the frequency 122.1 MHz may also be used for air carrier air traffic control purposes at locations where other frequencies are not available to air carrier aircraft stations for air traffic control.

US104—The LORAN Radionavigation System has priority in the band 90–110 kHz in the United States and Possessions. Radiolocation land stations making use of LORAN type equipment may be authorized to both Government and non-Government on a Secondary Service basis for offshore radiolocation activities only at specific locations and subject to such technical and operational conditions (e.g., power, emission, pulse rate and phase code, hours of operation), including on-the-air testing, as may be required on a case-by-case basis to ensure protection of the LORAN Radionavigation System from harmful interference and to ensure mutual compatibility among radiolocation operators. Such authorizations to stations in the radiolocation service are further subject to showing of need for service which is not currently provided and which the Government is not yet prepared to render by way of the radionavigation service.

US106—The frequency 156.75 MHz is available for assignment to non-Government and Government stations for environmental communications in accordance with an agreed plan.

US107—The frequency 156.8 MHz is the international distress, safety and calling frequency for the maritime mobile VHF radiotelephone service for use by Government and non-Government ship and coast stations. Guard bands of 156.7625–156.7875 and 156.8125–156.8375 MHz are maintained.

US108—Within the bands 3300–3500 MHz and 10000–10500 MHz, survey operations, using transmitters with a peak power not to exceed 5 watts into the antenna, may be authorized for Government and non-Government use on a secondary basis to other Government radiolocation operations.

US110—In the frequency bands 3100–3300 MHz, 3500–3700 MHz, 5250–5350 MHz, 8500–9000 MHz, 9200–9300 MHz, 9500–10000 MHz, 13.4–14.0 GHz, 15.7–17.3 GHz, 24.05–24.25 GHz, and 33.4–36 GHz, the non-Government radiolocation service shall be secondary to the Government radiolocation service and to airborne doppler radars at 8800 MHz and shall provide protection to airport surface detection equipment (ASDE) operating between 15.7 and 16.2 GHz.

US111—In the band 1990–2120 MHz, Government space research earth stations may be authorized to use specific frequencies at specific locations for earth-to-space transmissions. Such authorizations shall be secondary to non-Government use of this band and subject to such other conditions as may be applied on a case-by-case basis.

Corpus Christi, TX, 27°39′N, 097°23′ W
Fairbanks, AK, 64°59′ N, 147°53′ W
Goldstone, CA, 35°18′ N, 116°54′ W
Greenbelt, MD, 39°00′ N, 076°50′ W
Guam, Mariana Is., 13°19′ N, 144°44′ E
Kauai, HI, 22°08′ N, 159°40′ W
Merritt Is., FL, 28°29′ N, 080°35′ W
Roseman, NC, 35°12′ N, 082°52′ W
Wallops Is., VA, 37°57′ N, 075°28′ W

US112—The frequency 123.1 MHz is for search and rescue communications. This frequency may be assigned for air traffic control communications at special aeronautical events on the condition that no harmful interference is caused to search and rescue communications during any period of search and rescue operations in the locale involved.

US116—In the bands 890–902 MHz, 928–932 MHz, and 935–941 MHz, no new assignments are to be made to Government radio stations after July 10, 1970, except, on a case-by-case basis, to experimental stations and to additional stations of existing networks in Alaska. Government assignments existing prior to July 10, 1970, to stations in Alaska may be continued. All other existing Government assignments shall be on a secondary basis to stations in the non-Government land mobile service and shall be subject to adjustment or removal from the bands 890–902 MHz, 928–932 MHz, and 935–941 MHz, at the request of the FCC.

US117—In the band 406.1–410 MHz, all new authorizations will be limited to a maximum 7 watts per kHz of necessary bandwidth; existing authorizations as of November 30, 1970, exceeding this power are permitted to continue in use.

New authorizations in this band for stations, other than mobile and transportable stations, within the following areas are subject to prior coordination by the applicant through the Electromagnetic Spectrum Management Unit, National Science Foundation, Washington, DC 20550 (202-357-9696):

Arecibo Observatory: Rectangle between latitudes 17°30′ N and 19°00′ N and between longitudes 65°10′ W and 68°00′ W.

Owens Valley Radio Observatory: Two contiguous rectangles, one between latitudes 36° N and 37° N and longitudes 117°40′ W and 118°30′ W and the second between latitudes 37° N and 38° N and longitudes 118° W and 118°50′ W.

Sagamore Hill Radio Observatory: Rectangle between latitudes 42°10′ N and 43°00′ N and longitudes 70°31′ W and 71°31′ W.

Table Mountain Solar Observatory (NOAA) Boulder, Colorado (407–409 MHz only): Rectangle between latitudes 39°30′ N and 40° 30′ N and longitudes 104°30′ W and 106°00′ W or the Continental Divide whichever is farther east.

The non-Government use of this band is limited to the radio astronomy service and as provided by footnote US13.

US201—In the band 460–470 MHz, space stations in the earth exploration-satellite service may be authorized for space-to-Earth transmission on a secondary basis with respect to the fixed and mobile services. When operating in the meteorological-satellite service such stations shall be protected from harmful interference from other applications of the earth exploration-satellite service. The power flux density produced at the earth's surface by any space station in this band shall not exceed – 152 dBW/m^2/4 kHz.

US203—Radio astronomy observations of the formaldehyde line frequencies 4825–4835 MHz and 14.470–14.500 GHz may be made at certain radio astronomy observatories as indicated below:

Bands to be Observed		Observatory
4 GHz	14 GHz	
X		National Astronomy and Ionosphere Center, Arecibo, Puerto Rico
X	X	National Radio Astronomy Observatory, Green Bank, West Virginia
X	X	National Radio Astronomy Observatory, Socorro, New Mexico
X	X	Hat Creek Observatory (U. of CA), Hat Creek, California
X	X	Haystack Radio Observatory (MIT-Lincoln Lab) Tyngsboro, Massachusetts
X	X	Owens Valley Radio Observatory (Cal. Tech.), Big Pine, California
	X	Five College Radio Astronomy Observatory, Quabbin Reservoir (near Amherst) Massachusetts

Every practicable effort will be made to avoid the assignment of frequencies to stations in the fixed or mobile services in these bands. Should such assignments result in harmful interference to these observations, the situation will be remedied to the extent practicable.

US205—Tropospheric scatter systems are prohibited in the band 2500–2690 MHz.

US208—Planning and use of the band 1559–1626.5 MHz necessitate the development of technical and/or operational sharing criteria to ensure the maximum degree of electromagnetic compatibility with existing and planned systems within the band.

US209—The use of frequencies 460.6625, 460.6875, 460.7125, 460.7375, 460.7625, 460.7875, 460.8125, 460.8375, 460.8625, 465.6625, 465.6875, 465.7125, 465.7375, 465.7625, 465.7875, 465.8125, 465.8375, and 465.8625 MHz may be authorized with 100 mW or less output power, to Government and non-Government radio stations for one-way, nonvoice biomedical telemetry operations in hospitals or in medical or convalescent centres.

US210—Use of frequencies in the bands 40.66–40.70 and 216–220 MHz may be authorized to Government and non-Government stations on a secondary basis for the tracking of, and telemetering of scientific data from, ocean buoys and wildlife. Airborne wildlife telemetry in the 216–220 MHz band will be limited to the 216.000–216.100 MHz portion of the band. Operation in these two bands is subject to the technical standards specified in (a) Section 8.2.42 of the NTIA Manual for Government use or in (b) Section 5.108 of the Commission's Rules for non-Government.

US211—In the bands 1670–1690 and 5000–5250 MHz and 10.7–11.7, 15.1365–15.35, 15.4–15.7, 22.5–22.55, 24–24.05, 31.0–31.3, 31.8–32, 40.5–42.5, 84–86, 102–105, 116–126, 151–164, 176.5–182, 185–190, 231–235, 252–265 GHz, applicants for airborne or space station assignments are urged to take all practicable steps to protect radio astronomy observations in the adjacent bands from harmful interference; however, US74 applies.

US212—In the State of Alaska, the carrier frequency 5167.5 kHz (assigned frequency 5168.9 kHz) is designated for emergency communications. This frequency may also be used in the Alaska-Private Fixed Service for calling and listening, but only for establishing communications before switching to another frequency. The maximum power is limited to 150 watts peak envelope power (PEP).

US213—The frequency 122.925 MHz is for use only for communications with or between aircraft when coordinating natural resources programs of Federal or State natural resources agencies, including forestry management and fire suppression, fish and game management and protection, and environmental monitoring and protection.

US214—The frequency 157.100 MHz is the primary frequency for liaison communications between ship stations and stations of the United States Coast Guard.

US215—Emissions from microwave ovens manufactured on and after January 1, 1980, for operation on the frequency 915 MHz, must be confined within the band 902–928 MHz. Emissions from microwave ovens manufactured prior to January 1, 1980, for operation on the frequency 915 MHz, must be confined within the band 902–940 MHz. Radiocommunications services operating within the band 928–940 MHz must accept any harmful interference that may be experienced from the operation of microwave ovens manufactured before January 1, 1980.

US216—The frequencies 150.775 and 150.790 and the bands 152–152.0150, 163.2375–163.2625, 462.9375–463.1875, and 467.9375–468.1875 MHz are authorized for Government and non-Government operations in medical radio communications systems.

US217—Pulse-ranging radiolocation systems may be authorized for Government and non-Government use in the 420–450 MHz band along the shorelines of Alaska and the contiguous 48 states. Spread-spectrum radiolocation systems may be authorized in the 420–435 MHz portion of the band for operation within the contiguous 48 states and Alaska. Authorizations will be granted on a case-by-case basis; however, operations proposed to be located within the zones set forth in US228 should not expect to be accommodated. All stations operating in accordance with this provision will be secondary to stations operating in accordance with the Table of Frequency Allocations.

US218—The band 902–928 MHz is available for Location and Monitoring Service (LMS) systems subject to their not causing harmful interference to the operation of all Government stations authorized in these bands. These systems must tolerate interference from the operation of industrial, scientific, and medical (ISM) devices and the operation of Government stations authorized in these bands.

US219—In the band 2025–2110 MHz Government Earth Resources Satellite Earth Stations in the Earth Exploration-Satellite Service may be authorized to use the frequency 2106.4 MHz for Earth-to-space transmissions for tracking, telemetry, and telecommand at the sites listed below. Such transmissions shall not cause harmful interference to non-Government operations:

Sioux Falls, SD, 43°32′03.1″ N, 96°45′42.8″ W
Fairbanks, AK, 64°58′36.6″ N, 147°30′54.2″ W

US220—The frequencies 36.25 and 41.71 MHz may be authorized to Government stations and non-Government stations in the Petroleum Radio Service, for oil spill containment and cleanup operations. The use of these frequencies for oil spill containment or cleanup operations is limited to the inland and coastal waterways regions.

US221—Use of the mobile service in the bands 525–535 kHz and 1605–1615 kHz is limited to distribution of public service information from Travelers Information stations operating on 530 kHz or 1610 kHz.

US222—In the band 2025–2035 MHz Geostationary Operational Environmental Satellite earth stations in the Space Research and Earth Exploration-Satellite Services may be authorized on a co-equal basis to use the frequency band 2025–2035 MHz for Earth-to-space transmissions for tracking, telemetry, and telecommand at the sites listed below:

Wallops Is., VA, 37°50′48″ N, 75°27′33″ W
Seattle, WA, 47°34′15″ N, 122°33′10″ W
Honolulu, HI, 21°21′12″ N, 157°52′36″ W

US223—Within 120 kilometers (75 miles) of the United States/Canada border on the Great Lakes, the Saint Lawrence Seaway, and the Puget Sound and the Strait of Juan de Fuca and its approaches, use of coast transmit frequency 162.025 MHz and ship station transmit frequency 157.425 MHz (VHF maritime mobile service channel 88) may be authorized by the maritime mobile service for public correspondence.

US224—Government systems utilizing spread-spectrum techniques for terrestrial communication, navigation, and identification may be authorized to operate in the band 960–1215 MHz on the condition that harmful interference will not be caused to the aeronautical radionavigation service. These systems will be handled on a case-by-case basis. Such systems shall be subject to a review at the national level for operational requirements and electromagnetic compatibility prior to development, procurement, or modification.

US225—In addition to its present Government use, the frequency band 510–525 kHz is available to Government and non-Government aeronautical radionavigation stations inland of the Territorial Base Line as coordinated with the military services. In addition, the frequency 510 kHz is available for non-Government ship-helicopter operations when beyond 185 kilometers (100 nautical miles) from shore and required for aeronautical radionavigation.

US226—In the State of Hawaii, stations in the aeronautical radionavigation service shall not cause harmful interference to US Navy reception from its station at Honolulu on 198 kHz.

US228—Applicants of operation in the band 420 to 450 MHz under the provisions of US217 should not expect to be accommodated if their area of service is within the following geographic areas:

(a) Those portions of Texas and New Mexico bounded on the south by latitude 31°45′ N, on the east by longitude 104°00′ W, on the north by latitude 34°30′ N, and on the west by longitude 107°30′ W.

(b) The entire State of Florida including the Key West area and the areas enclosed within a 322-kilometer (200-mile) radius of Patrick Air Force Base, Florida (latitude 28°21′ N, longitude 80°43′ W), and within a 322-kilometer (200-mile) radius of Eglin Air Force Base, Florida (latitude 30°30′ N, longitude 86°30′ W).

(c) The entire State of Arizona.

(d) Those portions of California and Nevada south of latitude 37°10′ N, and the areas enclosed within a 322-kilometer (200-mile) radius of the Pacific Missile Test Center, Point Mugu, California (latitude 34°09′ N, longitude 119°11′ W).

(e) In the State of Massachusetts within a 160-kilometer (100-mile) radius around locations at Otis Air Force Base, Massachusetts (latitude 41°45′ N, longitude 70°32′ W).

(f) In the State of California within a 240-kilometer (150-mile) radius around locations at Beale Air Force Base, California (latitude 39°08′ N, longitude 121°26′ W).

(g) In the State of Alaska within a 160-kilometer (100-mile) radius of Clear, Alaska (latitude 64°17′ N, longitude 149°10′ W).

(h) In the State of North Dakota within a 160-kilometer (100-mile) radius of Concrete, North Dakota (latitude 48°43′ N, longitude 97°54′ W).

(i) In the States of Alabama, Florida, Georgia, and South Carolina within a 200-kilometer (124-mile) radius of Warner Robins Air Force Base, Georgia (latitude 32°38′ N, longitude 83°35′ W).

(j) In the State of Texas within a 200-kilometer (124-mile) radius of Goodfellow Air Force Base, Texas (latitude 31°25′ N, longitude 100°24′ W).

US229—Assignments to stations in the fixed and mobile services may be made on the condition that no harmful interference is caused to the Navy SPASUR system currently operating in the southern United States in the frequency band 216.88–217.08 MHz.

US230—Non-Government land mobile service is allocated on a primary basis in the bands 422.1875–425.4875 and 427.1875–429.9875 MHz within 80 kilometers (50 statute miles) of Detroit, MI, and Cleveland, OH, and in the bands 423.8125–425.4875 and 428.8125–429.9875 MHz within 80 kilometers (50 statute miles) of Buffalo, NY.

US231—When an assignment cannot be obtained in the bands between 200 and 525 kHz, which are allocated to aeronautical radionavigation, assignments may be made to aeronautical radiobeacons in the maritime mobile band 435–490 kHz, on a secondary basis, subject to the coordination and agreement of those agencies having assignments within the maritime mobile band that may be affected. Assignments to aeronautical radionavigation radiobeacons in the band 435–490 kHz shall not be a bar to any required changes to the Maritime Mobile Radio Service and shall be limited to Government not employing voice emissions.

US235—Until implementation procedures and schedules are determined by future conferences of the International Telecommunication Union, the bands 9775–9900, 11650–11700, 11975–12050, 13600–13800, 15450–15600, 17550–17700, and 21750–21850 kHz to be implemented by the broadcasting service are allocated as an alternative allocation to the fixed service. The bands 12230–12330, 16360–16460, 17360–17410, 18780–18900, 19680–19800, 22720–22855, 25110–25210, and 26100–26175 kHz to be implemented by the maritime mobile service are also allocated as an alternative allocation to the fixed service until July 1, 1991, when these bands are to be allocated exclusively to the maritime mobile service.

US236—Until implementation procedures and schedules are determined by future conferences of the International Telecommunication Union (see Resolution 319), the bands 4000–4063 and 8100–8195 kHz are also allocated on a primary basis to the fixed service.

US237—Until implementation procedures and schedules are determined by a future Regional Conference of the International Telecommunication Union, the band 1615–1625 kHz is also allocated on a primary basis to the radiolocation service.

US238—Until implementation procedures and schedules are determined by a future Regional Conference of the International Telecommunication Union, the band 1625–1705 kHz

is allocated to the radiolocation service on a primary basis as a different category of service.

US239—Aeronautical radionavigation stations (radiobeacons) may be authorized, primarily for offshore use, in the band 525–535 kHz on a noninterference basis to Travelers Information Stations.

US240—The bands 1715–1725 kHz and 1740–1750 kHz are allocated on a primary basis and the bands 1705–1715 kHz and 1725–1740 kHz on a secondary basis to the aeronautical radionavigation service (radiobeacons).

US244—The band 136–137 MHz is allocated to the non-Government aeronautical mobile (R) service on a primary basis and is subject to pertinent international treaties and agreements. The frequencies 136.000 MHz, 136.025 MHz, 136.050 MHz, 136.075 MHz, 136.125 MHz, 136.150 MHz, 136.175 MHz, 136.225 MHz, 136.250 MHz, 136.300 MHz, 136.325 MHz, 136.350 MHz, 136.400 MHz, 136.425 MHz, and 136.450 MHz are available on a shared basis to the Federal Aviation Administration for air traffic control purposes, such as automatic weather observation services, automatic terminal information services, and airport control tower communications. Stations licensed prior to January 2, 1990, using the 136–137 MHz band for space operations (space-to-Earth), meteorological-satellite service (space-to-Earth), and the space research service (space-to-Earth) may continue to use this band on a secondary basis to aeronautical mobile (R) service stations. No new assignments will be made to stations in the above space services.

US245—The Fixed-Satellite Service is limited to international intercontinental systems and subject to case-by-case electromagnetic compatibility analysis.

US246—No stations will be authorized to transmit in the bands 608–614 MHz, 1400–1427 MHz, 1660.5–1668.4 MHz, 2690–2700 MHz, 4990–5000 MHz, 10.68–10.70 GHz, 15.35–15.40 GHz, 23.6–24.0 GHz, 31.3–31.8 GHz, 51.4–54.25 GHz, 58.2–59.0 GHz, 64–65 GHz, 86–92 GHz, 100–102 GHz, 105–116 GHz, 164–168 GHz, 182–185 GHz, and 217–231 GHz.

US247—The band 10100–10150 kHz is allocated to the fixed service on a primary basis outside the United States and Possessions. Transmissions of stations in the amateur service shall not cause harmful interference to this fixed service use and stations in the amateur service shall make all necessary adjustments (including termination of transmission) if harmful interference is caused.

US251—The band 12.75–13.25 GHz is also allocated to the Space Research Service (Deep Space) (space-to-Earth) for reception only at Goldstone, California, 35°18′ N, 116°54′ W.

US252—The bands 2110–2120 MHz, 7145–7190 MHz, and 34.2–34.7 GHz are also allocated for Earth-to-space transmissions in the Space Research Service, limited to deep space communications at Goldstone, California.

US253—In the band 2300–2310 MHz, the fixed and mobile services shall not cause harmful interference to the amateur service.

US254—In the band 18.6–18.8 GHz, the fixed and mobile services shall be limited to a maximum equivalent isotopically radiated power of +35 dBW and the power delivered to the antenna shall not exceed –3 dBW.

US255—In the band 18.6–18.8 GHz, the fixed-satellite service shall be limited to a power flux density at the Earth's surface of – 101 dBW/in^2 in a 200 MHz band for all angles of arrival.

US256—Radio astronomy observations may be made in the band 1718.8–1722.2 MHz on an unprotected basis. Agencies providing other services in this band in the geographic areas listed below should bear in mind that their operations may affect those observations, and those agencies are encouraged to minimize potential interference to the observations insofar as it is practicable.

Hat Creek Observatory, Hat Creek, California	Rectangle between latitudes 40°00′N and 42°00′N and between latitudes 120°15′W and 122°15′W.
Owens Valley Radio Observatory, Big Pine, California	Two contiguous rectangles, one between 36°00′N and 37°00′N and between longitudes 117°40′W and 118°30′W and the second between latitudes 37°00 N and 30°00′N and between longitudes 118°00′W and 118°50′W.
Haystack Radio Observatory, Tyngsboro, Massachusetts	Rectangle between latitudes 41°00′N and 43°00′N and between longitudes 71°00′W and 73°00′W.
National Astronomy and Ionosphere Center, Arecibo, Puerto Rico	Rectangle between latitudes 17°30′N and 19°00′N and between longitudes 65°10′W and 68°00′W.
National Radio Astronomy Observatory, Green Bank, West Virginia	Rectangle between latitudes 37°30′N and 39°15′N and between longitudes 78°30′W and 80°30′W.

US257—Radio astronomy observations may be made in the 4950–4990 MHz band at certain Radio Astronomy Observatories indicated below:

National Astronomy and Ionosphere Center, Arecibo, Puerto Rico	Rectangle between latitudes 17°30′n and 19°00′N and between latitudes 65°10′W and 68°00′W.
Haystack Radio Observatory, Tyngsboro, Massachusetts	Rectangle between latitudes 41°00′N and 43°00′N and between longitudes 71°00′W and 73°00′W.
National Radio Astronomy Observatory, Green Bank, West Virginia	Rectangle between latitudes 37°00′N and 39°15′N and between longitudes 78°30′N and 80°30′W.
National Radio Astronomy Observatory, Socorro, New Mexico	Rectangle between latitudes 32°30′N and 35°30′N and between longitudes 106°00′W and 109°00′W.

Owens Valley Radio Observatory, Big Pine, California	Two contiguous rectangles, one between latitudes 36°00′N and 37°00′N and between longitudes 117°40′W and 118°30′W and the second between latitudes 37°00′N and 38°00′N and between longitudes 118°00′W and 118°50′W.
Hat Creek Observatory, Hat Creek, California	Rectangle between latitudes 40°00′N and 42°00′N and between longitudes 120°15′W and 122°15′W.

Every practicable effort will be made to avoid the assignment of frequencies in the band 4950–4990 MHz to stations in the fixed and mobile services within the geographic areas given above. In addition, every practicable effort will be made to avoid the assignment of frequencies in this band to stations in the aeronautical mobile service that operate outside of those geographic areas, but which may cause harmful interference to the listed observatories. Should such assignments result in harmful interference to these observatories, the situation will be remedied to the extent practicable.

US258—In the band 8025–8400 MHz, the non-Government earth exploration-satellite service (space-to-Earth) is allocated on a primary basis. Authorizations are subject to a case-by-case electromagnetic compatibility analysis.

US259—Stations in the radiolocation service in the band 17.3–17.7 GHz shall be restricted to operating powers of less than 51 dBW effective isotropic radiated power (eirp) after feeder link stations for the broadcasting-satellite service are authorized and brought into use.

US260—Aeronautical mobile communications that are an integral part of aeronautical radionavigation systems may be satisfied in the bands 1559–1626.5 MHz, 5000–5250 MHz, and 15.4–15.7 GHz.

US261—The use of the band 4200–4400 MHz by the Aeronautical Radionavigation service is reserved exclusively for airborne radio altimeters. Experimental stations will not be authorized to develop equipment for operational use in this band other than equipment related to altimeter stations. However, passive sensing in the Earth Exploration-Satellite and Space Research services may be authorized in this band on a secondary basis (no protection is provided from the radio altimeters).

US262—The band 31.8–32.3 GHz is also allocated for space-to-Earth transmissions in the Space Research Service, limited to deep space communications at Goldstone, California.

US263—In the frequency bands 21.2–21.4, 22.21–22.5, 36–37, 50.2–50.4, 54.25–58.2, 116–126, 150–151, 174.5–176.5, 200–202, and 235–238 GHz, the Space Research and the Earth Exploration-Satellite Services shall not receive protection from the Fixed and Mobile Services operating in accordance with the Table of Frequency Allocations.

US264—In the band 48.94–49.04 GHz, airborne stations shall not be authorized.

US265—In the band 10.6–10.68 GHz, the fixed service shall be limited to a maximum equivalent isotopically radiated power of 40 dBW and the power delivered to the antenna shall not exceed –3 dBW, per 250 kHz.

US266—Licensees in the Public Safety Radio Services holding a valid authorization on June 30, 1958, to operate in the frequency band 156.27–157.47 MHz or on the frequencies of 161.85, 161.91, or 161.97 MHz may, upon proper application, continue to be authorized for such operation, including expansion of existing systems, until such time as harmful interference is caused to the operation of any authorized station other than those licensed in the Public Safety Radio Service.

US267—In the band 902–928 MHz, amateur radio stations shall not operate within the States of Colorado and Wyoming, bounded by the area of: latitude 39° N to 42° N and longitude 103° W to 108° W.

US268—The bands 890–902 MHz and 928–942 MHz are also allocated to the radiolocation service for Government ship stations (offshore ocean areas) on the condition that harmful interference is not caused to non-Government land mobile stations. The provisions of footnote US116 apply.

US269—In the band 2500–2690 MHz, applicants for space station assignments are urged to take all practicable steps to protect radio astronomy observations in the adjacent band, 2690–2700 MHz, from harmful interference. Further, all applicants are urged to coordinate their proposed systems through the Electromagnetic Spectrum Management Unit, National Science Foundation, Washington, DC 20550, prior to systems development.

US270—The band 72.77–72.91 GHz is also allocated to the radio astronomy service. Applicants for frequency assignments in this band are urged to take all practicable steps to protect radio astronomy observations from harmful interference.

US271—The use of the band 17.3–17.8 GHz by the Fixed-Satellite Service (Earth-to-space) is limited to feeder links for Broadcasting-Satellite Service.

US273—In the 74.6–74.8 MHz and 75.2–75.4 MHz bands, stations in the fixed and mobile services are limited to a maximum power of 1 watt from the transmitter into the antenna transmission line.

US274—In the 216–220 MHz band, fixed, aeronautical mobile, and land mobile stations are limited to telemetering and associated telecommand operations.

US275—The band 902–928 MHz is allocated on a secondary basis to the amateur service subject to not causing harmful interference to the operations of Government stations authorized in this band or to Location and Monitoring Service (LMS) systems. Stations in the amateur service must tolerate any interference from the operations of industrial, scientific, and medical (ISM) devices, LMS systems, and the operations of Government stations authorized in this band. Further, the amateur service is prohibited in those portions of Texas and New Mexico bounded on the south by latitude 31°41′ N, on the east by longitude 104°11′ W, on the north by latitude 34°30′ N, and on the west by longitude 107°30′ W; in addition, outside this area but within 240 kilometers (150 miles) of these boundaries of White Sands Missile Range the service is

restricted to a maximum transmitter peak envelope power output of 50 watts.

US276—Except as otherwise provided for herein, use of the band 2310–2390 MHz by the mobile service is limited to aeronautical telemetering and associated telecommand operations for flight testing of manned or unmanned aircraft, missiles, or major components thereof. The following six frequencies are shared on a co-equal basis by Government and non-Government stations for telemetering and associated telecommand operations of expendable and reusable launch vehicles whether or not such operations involve flight testing: 2312.5, 2332.5, 2352.5, 2364.5, 2370.5, and 2382.5 MHz. All other mobile telemetering uses shall be secondary to the above uses.

US277—The band 10.6–10.68 GHz is also allocated on a primary basis to the radio astronomy service. However, the radio astronomy service shall not receive protection from stations in the Fixed Service, which is licensed to operate in the 100 most populous urbanized areas as defined by the US Census Bureau. The following radio astronomy sites have been coordinated for observations in this band: National Radio Astronomy Observatory, Green Bank, West Virginia (38°26′08″ N; 79°49′42″ W); National Radio Astronomy Observatory, Socorro, New Mexico (34°04′43″ N; 107°37′04″ W); Harvard Radio Astronomy Station, Fort Davis, Texas (30°38′08″ N); 103°56′42″ W); Hat Creek Observatory, Hat Creek, California (40°49′03″ N; 121°28′24″ W); Owens Valley Radio Observatory, Big Pine, California (37°13′54″ N; 118°17′36″ W); Naval Research Laboratory, Maryland Point, Maryland (38°22′26″ N; 77°14′00″ W).

US278—In the 22.55–23.55 and 32–33 GHz bands, non-geostationary inter-satellite links may operate on a secondary basis to geostationary inter-satellite links.

US279—The frequency 2182 kHz may be authorized to fixed stations associated with the maritime mobile service for the sole purpose of transmitting distress calls and distress traffic and urgency and safety signals and messages.

US281—In the band 25.07–25.11 MHz, non-Government stations in the Industrial Radio Services shall not cause harmful interference to, and must accept interference from, stations in the Maritime Mobile Service operating in accordance with the International Table of Frequency Allocations.

US282—In the band 4650–4700 kHz, frequencies may be authorized for non-Government communication with helicopters in support of offshore drilling operations on the condition that harmful interference will not be caused to services operating in accordance with the Table of Frequency Allocations.

US283—In the bands 2850–3025 kHz, 3400–3500 kHz, 4650–4700 kHz, 5450–5680 kHz, 6525–6685 kHz, 10005–10100 kHz, 11275–11400 kHz, 13260–13360 kHz, and 17900–17970 kHz frequencies in these bands may be authorized for non-Government flight test purposes on the condition that harmful interference will not be caused to services operating in accordance with the Table of Frequency Allocations.

US285—Under exceptional circumstances, the carrier frequencies 2635, 2638, and 2738 kHz may be authorized to coast stations.

US287—The band 14–14.5 GHz is also allocated to the non-Government land mobile-satellite service (Earth-to-space) on a secondary basis.

US290—In the band 1900–2000 kHz, amateur stations may continue to operate on a secondary basis to the Radiolocation Service, pending a decision as to their disposition through a future rule making proceeding in conjunction with implementation of the Standard Broadcasting Service in the 1625–1705 kHz band.

US291—Television pickup stations in the mobile service may be authorized to use frequencies in the band 38.6–40 GHz on a secondary basis to stations operating in accordance with the Table of Frequency Allocations.

US292—In the band 14.0–14.2 GHz, stations in the radionavigation service shall operate on a secondary basis to the fixed-satellite service.

US294—In the spectrum below 490 kHz electric utilities operate Power Line Carrier (PLC) systems on power transmission lines for communications important to the reliability and security of electric service to the public. These PLC systems operate under the provisions of Part 15 of the Federal Communication Commission's Rules and Regulations or Chapter 7 of the National Telecommunications and Information Administration's Manual of Regulations and Procedures for Federal Radio Frequency Management, on an unprotected and noninterference basis with respect to authorized radio users. Notification of intent to place new or revised radio frequency assignments or PLC frequency uses in the bands below 490 kHz is to be made in accordance with the Rules and Regulations of the FCC and NTIA, and users are urged to minimize potential interference to the degree practicable. This footnote does not provide any allocation status to PLC radio frequency uses.

US296—In the bands designated for ship wide-band telegraphy, facsimile, and special transmission systems, the following assignable frequencies are available to non-Federal Government stations on a shared basis with Government stations: 2070.5, 2072.5, 2074.5, 2076.5, 4154, 4170, 6235, 6259, 8302, 8338, 12370, 12418, 16551, 16615, 18848, 18868, 22182, 22238, 25123, and 25159 kHz.

US297—The bands 47.2–49.2 GHz and 74.0–75.5 GHz are also available for feeder links for the broadcasting-satellite service.

US298—Channels 27555, 27615, 27635, 27655, 27765, and 27860 KHz are available to eligibles in the Forest Products Radio Service on a secondary basis to Government operations including experimental stations. Operations in the Forest Products Radio Service on these channels will not exceed 150 watts and are limited to the States of Washington, Oregon, Maine, North Carolina, South Carolina, Tennessee, Georgia, Florida, Alabama, Mississippi, Louisiana, and Texas (eastern portion).

US299—Until implementation procedures and schedules are determined by a future Regional Conference of the International Telecommunication Union the frequency bands 1615–1625 and 1625–1705 kHz in Alaska are also allocated to the maritime mobile services and the Alaska fixed service.

US300—The frequencies 169.445, 169.505, 170.245, 170.305, 171.045, 171.105, 171.845, and 171.905 MHz are

available for wireless microphone operations on a secondary basis to Government and non-Government operations.

US301—Except as provided in US302, broadcast auxiliary stations licensed as of November 21, 1984, to operate in the band 942–944 MHz may continue to operate on a co-equal primary basis to other stations and services operating in the band in accordance with the Table of Frequency Allocations.

US302—The band 942–944 MHz in Puerto Rico is allocated as an alternative allocation to the fixed service for broadcast auxiliary stations only.

US303—In the band 2285–2290 MHz, non-Federal government space stations in the space research, space operations, and earth exploration-satellite services may be authorized to transmit to the Tracking and Data Relay Satellite System subject to such conditions as may be applied on a case-by-case basis. Such transmissions shall not cause harmful interference to authorized Federal Government stations. The power flux density at the Earth's surface from such non-Government stations shall not exceed – 144 to – 154 dBW/m^2/4 kHz, depending on angle of arrival, in accordance with ITU Radio Regulation S21.16.

US307—The sub-band 5150–5216 MHz is also allocated for space-to-Earth transmissions in the fixed-satellite service for feeder links in conjunction with the radiodetermination-satellite service operating in the bands 1610–1626.5 MHz and 2483.5–2500 MHz. The total power flux density at the earth's surface shall in no case exceed – 159 dBW/m^2/4 kHz for all angles of arrival.

US308—In the frequency bands 1549.5–1558.5 MHz and 1651–1660 MHz, the Aeronautical Mobile-Satellite (R) requirements that cannot be accommodated in the 1545–1549.5 MHz, 1558.5–1559 MHz, 1646.5–1651 MHz, and 1660–1660.5 MHz bands shall have priority access with real-time preemptive capability for communications in the mobile-satellite service. Systems not interoperable with the aeronautical mobile-satellite (R) service shall operate on a secondary basis. Account shall be taken of the priority of safety-related communications in the mobile-satellite service.

US309—Transmissions in the bands 1545–1559 MHz from terrestrial aeronautical stations directly to aircraft stations, or between aircraft stations, in the aeronautical mobile (R) service are also authorized when such transmissions are used to extend or supplement the satellite-to-aircraft links. Transmissions in the band 1646.5–1660.5 MHz from aircraft stations in the aeronautical mobile (R) service directly to terrestrial aeronautical stations, or between aircraft stations, are also authorized when such transmissions are used to extend or supplement the aircraft-to-satellite links.

US310—In the band 14.896–15.121 GHz, non-Federal Government space stations in the space research service may be authorized on a secondary basis to transmit to Tracking and Data Relay Satellites subject to such conditions as may be applied on a case-by-case basis. Such transmissions shall not cause harmful interference to authorized Federal Government stations. The power flux density at the earth's surface from such non-Government stations shall not exceed – 138 to – 148 dBW/m^2/4 kHz, depending on the angle of arrival, in accordance with Recommendation ITU-R SA510-1(1994).

US311—Radio astronomy observations may be made in the 1350–1400 MHz band on an unprotected basis at certain radio astronomy observatories indicated below:

National Astronomy and Ionosphere Center, Arecibo, Puerto Rico	Rectangle between latitudes 17°30′N and 19°00′N and between longitudes 65°10′W and 68°00′W.	
National Radio Astronomy Observatory, Socorro, New Mexico	Rectangle between latitudes 32°30′N and 35°30′N and between longitudes 106°00′W and 109°00′W.	
National Radio Astronomy Observatory, Green Bank, West Virginia	Rectangle between latitudes 37°30′N and 39°15′N and between longitudes 78°30′W and 80°30′W.	
National Radio Astronomy Observatory, very Long Baseline Array Stations	80-kilometer (50-mile) radius centered on:	
	Latitude (North)	Longitude (West)
Pie Town, NM	34°18′	108°07′
Kitt Peak, AZ	31°57′	111°37′
Los Alamos, NM	35°47′	106°15′
Fort Davis, TX	30°38′	103°57′
North Liberty, IA	41°46′	91°34′
Brewster, WA	48°08′	119°41′
Owens Valley, CA	37°14′	118°17′
Saint Croix, VI	17°46′	64°35′
Mauna Kea, HI	19°48′	155°27′
Hancock, NH	42°56′	71°59′

Every practicable effort will be made to avoid the assignment of frequencies in the band 1350–1400 MHz to stations in the fixed and mobile services that could interfere with radio astronomy observations within the geographic areas given above. In addition, every practicable effort will be made to avoid assignment of frequencies in this band to stations in the aeronautical mobile service that operate outside of those geographic areas, but which may cause harmful interference to the listed observatories. Should such assignments result in harmful interference to these observatories, the situation will be remedied to the extent practicable.

US312—The frequency 173.075 MHz may also be authorized on a primary basis to non-Government stations in the Police Radio Service (with a maximum authorized bandwidth of 20 kHz) for stolen vehicle recovery systems.

US315—In the frequency bands 1530–1544 MHz and 1626.5–1645.5 MHz maritime mobile-satellite distress and safety communications, e.g., GMDSS, shall have priority access with real-time preemptive capability in the mobile-satellite service. Communications of mobile-satellite system stations not participating in the GMDSS shall operate on a secondary basis to distress and safety communications of sta-

tions operating in the GMDSS. Account shall be taken of the priority of safety-related communications in the mobile-satellite service.

US316—The band 2900–3000 MHz is also allocated on a primary basis to the Meteorological Aids Service. Operations in this service are limited to Government Next Generation Weather Radar (NEXRAD) systems where accommodation in the 2700–2900 MHz band is not technically practical and are subject to coordination with existing authorized stations.

US317—The band 218.0–219.0 MHz is allocated on a primary basis to the Interactive Video and Data Operations.

US318—Until January 1, 2000, the use of the 137–138 MHz band by the mobile-satellite service will be secondary to Government operations within the sub-bands: 137.333–137.367, 137.485–137.515, 137.605–137.635, and 137.753–137.787 MHz.

US319—In the 137–138, 148–149.9, 149.9–150.05, 399.9–400.05, 400.15–401, 1610–1626.5, and 2483.5–2500 MHz bands, Federal Government stations in the mobile-satellite service shall be limited to earth stations operating with non-Federal Government space stations.

US320—Use of the 137–138, 148–149.9, and 400.15–401 MHz bands by the mobile-satellite service is limited to non-voice, nongeostationary satellite systems and may include satellite links between land earth stations at fixed locations.

US322—Use of bands 149.9–150.05 MHz and 399.9–400.05 MHz by the mobile-satellite service (Earth-to-space) is limited to nonvoice, nongeostationary satellite systems, including satellite links between land earth stations.

US323—In the 148–149.9 MHz band, no individual mobile earth station shall transmit on the same frequency being actively used by fixed and mobile stations and shall transmit no more than 1% of the time during any 15 minute period; except, individual mobile earth stations in this band that do not avoid frequencies actively being used by the fixed and mobile services shall not exceed a power density of –16 dBW/4 kHz and shall transmit no more than 0.25% of the time during any 15 minute period. Any single transmission from any individual mobile earth station operating in this band shall not exceed 450 ms in duration and consecutive transmissions from a single mobile earth station on the same frequency shall be separated by at least 15 seconds. Land earth stations in this band shall be subject to electromagnetic compatibility analysis and coordination with fixed and mobile stations.

US324—Government and non-Government satellite systems in the 400.15–401 MHz band shall be subject to electromagnetic compatibility analysis and coordination.

US325—In the band 148–149.9 MHz fixed and mobile stations shall not claim protection from land earth stations in the mobile-satellite service that have been previously coordinated; Government fixed and mobile stations exceeding 27 dBW eirp, or an emission bandwidth greater than 38 kHz, will be coordinated with existing mobile-satellite service space stations.

US326—The 399.9–400.05 MHz band is allocated to the mobile-satellite service (Earth-to-space) on a primary basis after January 1, 1997, and shall be limited to nonvoice, nongeostationary satellite systems, including satellite links between land earth stations.

US327—The band 2310–2360 MHz is allocated to the broadcasting-satellite service (sound) and complementary terrestrial broadcasting service on a primary basis. Such use is limited to digital audio broadcasting and is subject to the provisions of Resolution 528.

US328—In the band 2310–2360 MHz, the mobile and radiolocation services are allocated on a primary basis until 1 January 1997 or until broadcasting-satellite (sound) service has been brought into use in such a manner as to affect or be affected by the mobile and radiolocation services in those service areas, whichever is later. The broadcasting-satellite (sound) service during implementation should also take cognizance of the expendable and reusable launch vehicle frequencies 2312.5, 2332.5, and 2352.5 MHz, to minimize the impact on this mobile service use to the extent possible.

US334—In the band 17.8–20.2 GHz, Government space stations and associated earth stations in the fixed-satellite (space-to-Earth) service may be authorized on a primary basis. For a Government geostationary satellite network to operate on a primary basis, the space station shall be located outside the arc measured from East to West, 70° W to 120° W. Coordination between Government fixed-satellite systems and non-Government systems operating in accordance with the US Table of Frequency Allocations is required.

US335—The primary Government and non-Government allocations for the various segments of the 220–222 MHz band are divided as follows:

(1) The 220.0–220.55/221.0–221.55, 220.6–220.8/221.6–221.8, 220.85–220.90/221.85–221.90, and 220.925–221.0/221.925–222.0 MHz bands (Channels 1–110, 121–160, 171–180, and 186–200, respectively) are available for exclusive non-Government use.

(2) The 220.55–220.60/221.55–221.60 MHz bands (Channels 111–120) are available for exclusive Government use.

(3) The 220.80–220.85/221.80–221.85 and 220.900–220.925/221.900–221.925 MHz bands (Channels 161–170 and 181–185, respectively) are available for shared Government and non-Government use. The exclusive non-Government band segments are also available for temporary fixed geophysical telemetry operations on a secondary basis to the fixed and mobile services.

US337—In the band 13.75–13.80 GHz, earth stations in the fixed-satellite service shall be coordinated on a case-by-case basis through the frequency assignment subcommittee to minimize harmful interference to the Tracking and Data Relay Satellite System's forward space-to-space link (TDRSS forward link-to-LEO).

US338—In the 2305–2310 MHz band, space-to-Earth operations are prohibited. Additionally, in the 2305–2320 MHz band, all Wireless Communications Service (WCS) operations within 50 kilometers of 35°20″ N and 116°53″ W shall be coordinated through the Frequency Assignment Subcommittee of the Interdepartment Radio Advisory Committee to minimize harmful interference to NASA's Goldstone Deep Space facility.

US339—The bands 2310–2320 and 2345–2360 MHz are also available for aeronautical telemetering and associated telecommand operations for flight testing of manned or unmanned aircraft, missiles, or major components thereof on a secondary basis to the Wireless Communications Service. The following two frequencies are shared on a co-equal basis by Government and non-Government stations for telemetering and associated telecommand operations of expendable and reusable launch vehicles whether or not such operations involve flight testing: 2312.5 and 2352.5 MHz. Other mobile telemetering uses may be provided on a noninterference basis to the above uses. The broadcasting-satellite (sound) service during implementation should also take cognizance of the expendable and reusable launch vehicle frequencies 2312.5 and 2352.5 MHz, to minimize the impact on this mobile service use to the extent possible.

US340—The 2–30 MHz band is available on a secondary noninterference basis to Government and non-Government maritime and aeronautical stations for the purposes of measuring the quality of reception on radio channels. See 47 C.F.R. Sec. 87.149 for the list of protected frequencies and bands within this frequency range. Actual communications shall be limited to those frequencies specifically allocated to the maritime mobile and aeronautical mobile services.

US342—In making assignments to stations of other services to which are allocated the following bands:

13360–13410 kHz
37.5–38.25 MHz
322–328.6 MHz*
1330–1400 MHz*
1610.6–1613.8 MHz*
1660–1670 MHz
3260–3267 MHz*
3332–3339 MHz*
3345.8–3352.5 MHz*
4825–4835 MHz*
14.47–14.5 GHz*
22.01–22.21 GHz*
22.21–22.5 GHz
22.81–22.86 GHz*
23.07–23.12 GHz*
31.2–31.3 GHz
36.43–36.5 GHz*
42.5–43.5 GHz
48.94–49.04 GHz*
97.88–98.08 GHz*
140.69–140.98 GHz*
144.68–144.98 GHz*
145.45–145.75 GHz*
146.82–147.12 GHz*
262.24–262.76 GHz*
265–275 GHz

(* indicates radio astronomy use for spectral line observations), all practicable steps shall be taken to protect the radio astronomy service from harmful interference. Emissions from spaceborne or airborne stations can be particularly serious sources of interference to the radio astronomy service (see Nos. 343/S4.5 and 344/S4.6 and Article 36/S29 of the ITU Radio Regulations).

International Footnotes

(These footnotes come from the ITU Radio Regulations, Geneva, 1998.)

Until such time as the FCC has considered the substantively revised international footnotes that have previously been adopted domestically, the old international footnotes shall apply in the United States. These old footnotes appear immediately after S5.565.

S5.3—*Region 1:* Region 1 includes the area limited on the east by line A (lines A, B, and C are defined below) and on the west by line B, excluding any of the territory of the Islamic Republic of Iran which lies between these limits. It also includes the whole of the territory of Armenia, Azerbaijan, Russian Federation, Georgia, Kazakstan, Mongolia, Uzbekistan, Kyrgyzstan, Tajikistan, Turkmenistan, Turkey, and Ukraine and the area to the north of Russian Federation that lies between lines A and C.

S5.4—*Region 2:* Region 2 includes the area limited on the east by line B and on the west by line C.

S5.5—*Region 3:* Region 3 includes the area limited on the east by line C and on the west by line A, except any of the territory of Armenia, Azerbaijan, Russian Federation, Georgia, Kazakstan, Mongolia, Uzbekistan, Kyrgyzstan, Tajikistan, Turkmenistan, Turkey, and Ukraine and the area to the north of Russian Federation. It also includes that part of the territory of the Islamic Republic of Iran lying outside of those limits.

S5.6—The lines A, B, and C are defined as follows:

S5.7—*Line A:* Line A extends from the North Pole along meridian 40° East of Greenwich to parallel 40° North; thence by great circle arc to the intersection of meridian 60° East and the Tropic of Cancer; thence along the meridian 60° East to the South Pole.

S5.8—*Line B:* Line B extends from the North Pole along meridian 10° West of Greenwich to its intersection with parallel 72° North; thence by great circle arc to the intersection of meridian 50° West and parallel 40° North; thence by great circle arc to the intersection of meridian 20° West and parallel 10° South; thence along meridian 20° West to the South Pole.

S5.9—*Line C:* Line C extends from the North Pole by great circle arc to the intersection of parallel 65°30′ North with the international boundary in Bering Strait; thence by great circle arc to the intersection of meridian 165° East of Greenwich and parallel 50° North; thence by great circle arc to the intersection of meridian 170° West and parallel 10° North; thence along parallel 10° North to its intersection with meridian 120° West; thence along meridian 120° West to the South Pole.

S5.53—Administrations authorizing the use of frequencies below 9 kHz shall ensure that no harmful interference is caused thereby to the services to which the bands above 9 kHz are allocated.

S5.54—Administrations conducting scientific research using frequencies below 9 kHz are urged to advise other administrations that may be concerned so that such research may be afforded all practicable protection from harmful interference.

S5.55—*Additional allocation:* in Armenia, Azerbaijan, Bulgaria, Russian Federation, Georgia, Kazakstan, Kyrgyzstan, Tajikistan, Turkmenistan, and Ukraine, the band 14–

17 kHz is also allocated to the radionavigation service on a primary basis (WRC-97).

S5.56—The stations of services to which the bands 14–19.95 kHz and 20.05–70 kHz and in Region 1 also the bands 72–84 kHz and 86–90 kHz are allocated may transmit standard frequency and time signals. Such stations shall be afforded protection from harmful interference. In Armenia, Azerbaijan, Belarus, Bulgaria, Georgia, Kazakstan, Mongolia, Uzbekistan, Kyrgyzstan, Slovakia, the Czech Republic, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the frequencies 25 kHz and 50 kHz will be used for this purpose under the same conditions (WRC-97).

S5.57—The use of the bands 14–19.95 kHz, 20.05–70 kHz, and 70–90 kHz (72–84 kHz and 86–90 kHz in Region 1) by the maritime mobile service is limited to coast radiotelegraph stations (A1A and F1B only). Exceptionally, the use of class J2B or J7B emissions is authorized subject to the necessary bandwidth not exceeding that normally used for class A1A or F1B emissions in the band concerned.

S5.58—*Additional allocation:* in Armenia, Azerbaijan, Bulgaria, Georgia, Kazakstan, Kyrgyzstan, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the band 67–70 kHz is also allocated to the radionavigation service on a primary basis (WRC-97).

S5.59—*Different category of service:* in Bangladesh, the Islamic Republic of Iran, and Pakistan, the allocation of the bands 70–72 kHz and 84–86 kHz to the fixed and maritime mobile services is on a primary basis (see No. **S5.33**).

S5.60—In the bands 70–90 kHz (70–86 kHz in Region 1) and 110–130 kHz (112–130 kHz in Region 1), pulsed radionavigation systems may be used on condition that they do not cause harmful interference to other services to which these bands are allocated.

S5.61—In Region 2, the establishment and operation of stations in the maritime radionavigation service in the bands 70–90 kHz and 110–130 kHz shall be subject to agreement obtained under No. **S9.21** with administrations whose services, operating in accordance with the Table, may be affected. However, stations of the fixed, maritime mobile, and radiolocation services shall not cause harmful interference to stations in the maritime radionavigation service established under such agreements.

S5.62—Administrations that operate stations in the radionavigation service in the band 90–110 kHz are urged to coordinate technical and operating characteristics in such a way as to avoid harmful interference to the services provided by these stations.

S5.63—(SUP – WRC-97).

S5.64—Only classes A1A, F1B, A2C, A3C, F1C, or F3C emissions are authorized for stations of the fixed service in the bands allocated to this service between 90 kHz and 160 kHz (148.5 kHz in Region 1) and for stations of the maritime mobile service in the bands allocated to this service between 110 kHz and 160 kHz (148.5 kHz in Region 1). Exceptionally, class J2B or J7B emissions are also authorized in the bands between 110 kHz and 160 kHz (148.5 kHz in Region 1) for stations of the maritime mobile service.

S5.65—*Different category of service:* in Bangladesh, the Islamic Republic of Iran, and Pakistan, the allocation of the bands 112–117.6 kHz and 126–129 kHz to the fixed and maritime mobile services is on a primary basis (see No. **S5.33**).

S5.66—*Different category of service:* in Germany, the allocation of the band 115–117.6 kHz to the fixed and maritime mobile services is on a primary basis (see No. **S5.33**) and to the radionavigation service on a secondary basis (see No. **S5.32**).

S5.67—*Additional allocation:* in Azerbaijan, Bulgaria, Mongolia, Kyrgyzstan, Romania, Turkmenistan, and Ukraine, the band 130–148.5 kHz is also allocated to the radionavigation service on a secondary basis. Within and between these countries this service shall have an equal right to operate (WRC-97).

S5.68—*Alternative allocation:* in Angola, Botswana, Burundi, the Congo, Malawi, Dem. Rep. of the Congo, Rwanda, and South Africa, the band 160–200 kHz is allocated to the fixed service on a primary basis.

S5.69—*Additional allocation:* in Somalia, the band 200–255 kHz is also allocated to the aeronautical radionavigation service on a primary basis.

S5.70—*Alternative allocation:* in Angola, Botswana, Burundi, Cameroon, the Central African Republic, the Congo, Ethiopia, Kenya, Lesotho, Madagascar, Malawi, Mozambique, Namibia, Nigeria, Oman, Democratic Republic of the Congo, Rwanda, South Africa, Swaziland, Tanzania, Chad, Zambia, and Zimbabwe, the band 200–283.5 kHz is allocated to the aeronautical radionavigation service on a primary basis.

S5.71—*Alternative allocation:* in Tunisia, the band 255–283.5 kHz is allocated to the broadcasting service on a primary basis.

S5.72—Norwegian stations of the fixed service situated in northern areas (north of 60° N) subject to auroral disturbances are allowed to continue operation on four frequencies in the bands 283.5–490 kHz and 510–526.5 kHz.

S5.73—The band 285–325 kHz (283.5–325 kHz in Region 1) in the maritime radionavigation service may be used to transmit supplementary navigational information using narrow-band techniques, on condition that no harmful interference is caused to radiobeacon stations operating in the radionavigation service (WRC-97).

S5.74—*Additional allocation:* in Region 1, the frequency band 285.3–285.7 kHz is also allocated to the maritime radionavigation service (other than radiobeacons) on a primary basis.

S5.75—*Different category of service:* in Armenia, Azerbaijan, Belarus, Georgia, Kazakstan, Moldova, Kyrgyzstan, Russian Federation, Tajikistan, Turkmenistan, Ukraine, and the Black Sea areas of Bulgaria and Romania, the allocation of the band 315–325 kHz to the maritime radionavigation service is on a primary basis under the condition that in the Baltic Sea area, the assignment of frequencies in this band to new stations in the maritime or aeronautical radionavigation services shall be subject to prior consultation between the administrations concerned.

S5.76—The frequency 410 kHz is designated for radio direction-finding in the maritime radionavigation service. The other radionavigation services to which the band 405–415 kHz is allocated shall not cause harmful interference to radio direction-finding in the band 406.5–413.5 kHz.

S5.77—*Different category of service:* in Australia, China, the French Overseas Territories of Region 3, India, Indonesia, the Islamic Republic of Iran, Japan, Pakistan, Papua New Guinea, and Sri Lanka, the allocation of the band 415–495 kHz to the aeronautical radionavigation service is on a primary basis. Administrations in these countries shall take all practical steps necessary to ensure that aeronautical radionavigation stations in the band 435–495 kHz do not cause interference to reception by coast stations of ship stations transmitting on frequencies designated for ship stations on a worldwide basis (see No. **S52.39**).

S5.78—*Different category of service:* in Cuba, the United States of America, and Mexico, the allocation of the band 415–435 kHz to the aeronautical radionavigation service is on a primary basis.

S5.79—The use of the bands 415–495 kHz and 505–526.5 kHz (505–510 kHz in Region 2) by the maritime mobile service is limited to radiotelegraphy.

S5.79A—When establishing coast stations in the NAVTEX service on the frequencies 490 kHz, 518 kHz, and 4209.5 kHz, administrations are strongly recommended to coordinate the operating characteristics in accordance with the procedures of the International Maritime Organization (IMO) (see Resolution **339 (Rev.WRC-97)**) (WRC-97).

S5.80—In Region 2, the use of the band 435–495 kHz by the aeronautical radionavigation service is limited to nondirectional beacons not employing voice transmission.

S5.81—The bands 490–495 kHz and 505–510 kHz shall be subject to the provisions of Appendix **S13**, § 15-1, Part A2 (WRC-97).

S5.82—In the maritime mobile service, the frequency 490 kHz is, from the date of full implementation of the GMDSS (see Resolution **331 (Rev.WRC-97)**), to be used exclusively for the transmission by coast stations of navigational and meteorological warnings and urgent information to ships, by means of narrow-band direct-printing telegraphy. The conditions for use of the frequency 490 kHz are prescribed in Articles **S31** and **S52**. In using the band 415–495 kHz for the aeronautical radionavigation service, administrations are requested to ensure that no harmful interference is caused to the frequency 490 kHz (WRC-97).

S5.83—The frequency 500 kHz is an international distress and calling frequency for Morse radiotelegraphy. The conditions for its use are prescribed in Articles **S31** and **S52** and in Appendix **S13**.

S5.84—The conditions for the use of the frequency 518 kHz by the maritime mobile service are prescribed in Articles **S31** and **S52** and in Appendix **S13** (WRC-97).

S5.85—Not used.

S5.86—In Region 2, in the band 525–535 kHz the carrier power of broadcasting stations shall not exceed 1 kW during the day and 250 W at night.

S5.87—*Additional allocation:* in Angola, Botswana, Lesotho, Malawi, Mozambique, Namibia, South Africa, Swaziland, Zambia, and Zimbabwe, the band 526.5–535 kHz is also allocated to the mobile service on a secondary basis.

S5.87A—*Additional allocation:* in Uzbekistan, the band 526.5–1606.5 kHz is also allocated to the radionavigation service on a primary basis. Such use is subject to agreement obtained under No. **S9.21** with administrations concerned and limited to ground-based radiobeacons in operation on 27 October 1997 until the end of their lifetime (WRC-97).

S5.88—*Additional allocation:* in China, the band 526.5–535 kHz is also allocated to the aeronautical radionavigation service on a secondary basis.

S5.89—In Region 2, the use of the band 1605–1705 kHz by stations of the broadcasting service is subject to the Plan established by the Regional Administrative Radio Conference (Rio de Janeiro, 1988).

The examination of frequency assignments to stations of the fixed and mobile services in the band 1625–1705 kHz shall take account of the allotments appearing in the Plan established by the Regional Administrative Radio Conference (Rio de Janeiro, 1988).

S5.90—In the band 1605–1705 kHz, in cases where a broadcasting station of Region 2 is concerned, the service area of the maritime mobile stations in Region 1 shall be limited to that provided by ground-wave propagation.

S5.91—*Additional allocation:* in the Philippines and Sri Lanka, the band 1606.5–1705 kHz is also allocated to the broadcasting service on a secondary basis (WRC-97).

S5.92—Some countries of Region 1 use radiodetermination systems in the bands 1606.5–1625 kHz, 1635–1800 kHz, 1850–2160 kHz, 2194–2300 kHz, 2502–2850 kHz, and 3500–3800 kHz, subject to agreement obtained under No. **S9.21**. The radiated mean power of these stations shall not exceed 50 W.

S5.93—*Additional allocation:* in Angola, Armenia, Azerbaijan, Belarus, Bulgaria, Georgia, Hungary, Kazakstan, Latvia, Lithuania, Moldova, Mongolia, Nigeria, Uzbekistan, Poland, Kyrgyzstan, Slovakia, the Czech Republic, Russian Federation, Tajikistan, Chad, Turkmenistan, and Ukraine, the bands 1625–1635 kHz, 1800–1810 kHz, and 2160–2170 kHz are also allocated to the fixed and land mobile services on a primary basis, subject to agreement obtained under No. **S9.21**.

S5.94 and **S5.95**—Not used.

S5.96—In Germany, Armenia, Azerbaijan, Belarus, Denmark, Estonia, Finland, Georgia, Hungary, Ireland, Israel, Jordan, Kazakstan, Latvia, Lithuania, Malta, Moldova, Norway, Uzbekistan, Poland, Kyrgyzstan, Slovakia, the Czech Republic, the United Kingdom, Russian Federation, Sweden, Tajikistan, Turkmenistan, and Ukraine, administrations may allocate up to 200 kHz to their amateur service in the bands 1715–1800 kHz and 1850–2000 kHz. However, when allocating the bands within this range to their amateur service, administrations shall, after prior consultation with administrations of neighbouring countries, take such steps as may be necessary to prevent harmful interference from their amateur service to the fixed and mobile services of other countries. The mean power of any amateur station shall not exceed 10 W.

S5.97—In Region 3, the Loran system operates either on 1850 kHz or 1950 kHz, the bands occupied being 1825–1875 kHz and 1925–1975 kHz respectively. Other services to which the band 1800–2000 kHz is allocated may use any frequency therein on condition that no harmful interference is caused to the Loran system operating on 1850 kHz or 1950 kHz.

S5.98—*Alternative allocation:* in Angola, Armenia, Austria, Azerbaijan, Belarus, Belgium, Bulgaria, Cameroon, the Congo, Denmark, Egypt, Eritrea, Spain, Ethiopia, Georgia, Greece, Italy, Kazakstan, Lebanon, Lithuania, Moldova, the

Netherlands, Syria, Kyrgyzstan, Russian Federation, Somalia, Tajikistan, Tunisia, Turkmenistan, Turkey, and Ukraine, the band 1810–1830 kHz is allocated to the fixed and mobile, except aeronautical mobile, services on a primary basis (WRC-97).

S5.99—*Additional allocation:* in Saudi Arabia, Bosnia and Herzegovina, Iraq, Libya, Uzbekistan, Slovakia, the Czech Republic, Romania, Slovenia, Chad, Togo, and Yugoslavia, the band 1810–1830 kHz is also allocated to the fixed and mobile, except aeronautical mobile, services on a primary basis (WRC-97).

S5.100—In Region 1, the authorization to use the band 1810–1830 kHz by the amateur service in countries situated totally or partially north of 40° N shall be given only after consultation with the countries mentioned in Nos. **S5.98** and **S5.99** to define the necessary steps to be taken to prevent harmful interference between amateur stations and stations of other services operating in accordance with Nos. **S5.98** and **S5.99**.

S5.101—*Alternative allocation:* in Burundi and Lesotho, the band 1810–1850 kHz is allocated to the fixed and mobile, except aeronautical mobile, services on a primary basis.

S5.102—*Alternative allocation:* in Argentina, Bolivia, Chile, Mexico, Paraguay, Peru, Uruguay and Venezuela, the band 1850–2000 kHz is allocated to the fixed, mobile, except aeronautical mobile, radiolocation, and radionavigation services on a primary basis.

S5.103—In Region 1, in making assignments to stations in the fixed and mobile services in the bands 1850–2045 kHz, 2194–2498 kHz, 2502–2625 kHz, and 2650–2850 kHz, administrations should bear in mind the special requirements of the maritime mobile service.

S5.104—In Region 1, the use of the band 2025–2045 kHz by the meteorological aids service is limited to oceanographic buoy stations.

S5.105—In Region 2, except in Greenland, coast stations and ship stations using radiotelephony in the band 2065–2107 kHz shall be limited to class J3E emissions and to a peak envelope power not exceeding 1 kW. Preferably, the following carrier frequencies should be used: 2065.0 kHz, 2079.0 kHz, 2082.5 kHz, 2086.0 kHz, 2093.0 kHz, 2096.5 kHz, 2100.0 kHz, and 2103.5 kHz. In Argentina and Uruguay, the carrier frequencies 2068.5 kHz and 2075.5 kHz are also used for this purpose, while the frequencies within the band 2072–2075.5 kHz are used as provided in No. **S52.165.**

S5.106—In Regions 2 and 3, provided no harmful interference is caused to the maritime mobile service, the frequencies between 2065 kHz and 2107 kHz may be used by stations of the fixed service communicating only within national borders and whose mean power does not exceed 50 W. In notifying the frequencies, the attention of the Bureau should be drawn to these provisions.

S5.107—*Additional allocation:* in Saudi Arabia, Botswana, Eritrea, Ethiopia, Iraq, Lesotho, Libya, Somalia, Swaziland and Zambia, the band 2160–2170 kHz is also allocated to the fixed and mobile, except aeronautical mobile (R), services on a primary basis. The mean power of stations in these services shall not exceed 50 W (WRC-97).

S5.108—The carrier frequency 2182 kHz is an international distress and calling frequency for radiotelephony. The conditions for the use of the band 2173.5–2190.5 kHz are prescribed in Articles **S31** and **S52** and in Appendix **S13**.

S5.109—The frequencies 2187.5 kHz, 4207.5 kHz, 6312 kHz, 8414.5 kHz, 12577 kHz, and 16804.5 kHz are international distress frequencies for digital selective calling. The conditions for the use of these frequencies are prescribed in Article **S31**.

S5.110—The frequencies 2174.5 kHz, 4177.5 kHz, 6268 kHz, 8376.5 kHz, 12520 kHz, and 16695 kHz are international distress frequencies for narrow-band direct-printing telegraphy. The conditions for the use of these frequencies are prescribed in Article **S31**.

S5.111—The carrier frequencies 2182 kHz, 3023 kHz, 5680 kHz, and 8364 kHz and the frequencies 121.5 MHz, 156.8 MHz, and 243 MHz may also be used, in accordance with the procedures in force for terrestrial radiocommunication services, for search and rescue operations concerning manned space vehicles. The conditions for the use of the frequencies are prescribed in Article **S31** and in Appendix **S13**.

The same applies to the frequencies 10003 kHz, 14993 kHz, and 19993 kHz, but in each of these cases emissions must be confined in a band of 3 kHz about the frequency.

S5.112—*Alternative allocation:* in Bosnia and Herzegovina, Cyprus, Denmark, France, Greece, Iceland, Italy, Malta, Norway, Sri Lanka, Turkey, and Yugoslavia, the band 2194–2300 kHz is allocated to the fixed and mobile, except aeronautical mobile, services on a primary basis (WRC-97).

S5.113—For the conditions for the use of the bands 2300–2495 kHz (2498 kHz in Region 1), 3200–3400 kHz, 4750–4995 kHz, and 5005–5060 kHz by the broadcasting service, see Nos. **S5.16** to **S5.20, S5.21** and **S23.3** to **S23.10**.

S5.114—*Alternative allocation:* in Bosnia and Herzegovina, Cyprus, Denmark, France, Greece, Iraq, Italy, Malta, Norway, Turkey, and Yugoslavia, the band 2502–2625 kHz is allocated to the fixed and mobile, except aeronautical mobile, services on a primary basis (WRC-97).

S5.115—The carrier (reference) frequencies 3023 kHz and 5680 kHz may also be used, in accordance with Article **S31** and Appendix **S13** by stations of the maritime mobile service engaged in coordinated search and rescue operations.

S5.116—Administrations are urged to authorize the use of the band 3155–3195 kHz to provide a common worldwide channel for low-power wireless hearing aids. Additional channels for these devices may be assigned by administrations in the bands between 3155 kHz and 3400 kHz to suit local needs. It should be noted that frequencies in the range 3000 kHz to 4000 kHz are suitable for hearing aid devices, which are designed to operate over short distances within the induction field.

S5.117—*Alternative allocation:* in Bosnia and Herzegovina, Cyprus, Côte d'Ivoire, Denmark, Egypt, France, Greece, Iceland, Italy, Liberia, Malta, Norway, Sri Lanka, Togo, Turkey, and Yugoslavia, the band 3155–3200 kHz is allocated to the fixed and mobile, except aeronautical mobile, services on a primary basis (WRC-97).

S5.118—*Additional allocation:* in the United States, Japan, Mexico, Peru, and Uruguay, the band 3230–3400 kHz is also allocated to the radiolocation service on a secondary basis.

S5.119—*Additional allocation:* in Honduras, Mexico, Peru, and Venezuela, the band 3500–3750 kHz is also allocated to the fixed and mobile services on a primary basis.

S5.120—For the use of the bands allocated to the amateur service at 3.5 MHz, 7.0 MHz, 10.1 MHz, 14.0 MHz, 18.068 MHz, 21.0 MHz, 24.89 MHz, and 144 MHz in the event of natural disasters, see Resolution 640.

S5.121—Not used.

S5.122—*Alternative allocation:* in Argentina, Bolivia, Chile, Ecuador, Paraguay, Peru, and Uruguay, the band 3750–4000 kHz is allocated to the fixed and mobile, except aeronautical mobile, services on a primary basis.

S5.123—*Additional allocation:* in Botswana, Lesotho, Malawi, Mozambique, Namibia, South Africa, Swaziland, Zambia, and Zimbabwe, the band 3900–3950 kHz is also allocated to the broadcasting service on a primary basis, subject to agreement obtained under No. **S9.21**.

S5.124—*Additional allocation:* in Canada, the band 3950–4000 kHz is also allocated to the broadcasting service on a primary basis. The power of broadcasting stations operating in this band shall not exceed that necessary for a national service within the frontier of this country and shall not cause harmful interference to other services operating in accordance with the Table.

S5.125—*Additional allocation:* in Greenland, the band 3950–4000 kHz is also allocated to the broadcasting service on a primary basis. The power of the broadcasting stations operating in this band shall not exceed that necessary for a national service and shall in no case exceed 5 kW.

S5.126—In Region 3, the stations of those services to which the band 3995–4005 kHz is allocated may transmit standard frequency and time signals.

S5.127—The use of the band 4000–4063 kHz by the maritime mobile service is limited to ship stations using radiotelephony (see No. **S52.220** and Appendix **S17**).

S5.128—In Afghanistan, Argentina, Armenia, Azerbaijan, Belarus, Botswana, Burkina Faso, Central African Republic, China, Georgia, India, Kazakstan, Mali, Niger, Kyrgyzstan, Russian Federation, Tajikistan, Chad, Turkmenistan, and Ukraine, in the bands 4063–4123 kHz, 4130–4133 kHz, and 4408–4438 kHz, stations of limited power in the fixed service that are situated at least 600 km from the coast may operate on condition that harmful interference is not caused to the maritime mobile service (WRC-97).

S5.129—On condition that harmful interference is not caused to the maritime mobile service, the frequencies in the bands 4063–4123 kHz and 4130–4438 kHz may be used exceptionally by stations in the fixed service communicating only within the boundary of the country in which they are located with a mean power not exceeding 50 W.

S5.130—The conditions for the use of the carrier frequencies 4125 kHz and 6215 kHz are prescribed in Articles **S31** and **S52** and in Appendix **S13**.

S5.131—The frequency 4209.5 kHz is used exclusively for the transmission by coast stations of meteorological and navigational warnings and urgent information to ships by means of narrow-band direct-printing techniques (WRC-97).

S5.132—The frequencies 4210 kHz, 6314 kHz, 8416.5 kHz, 12579 kHz, 16806.5 kHz, 19680.5 kHz, 22376 kHz, and 26100.5 kHz are the international frequencies for the transmission of maritime safety information (MSI) (see Appendix **S17**).

S5.133—*Different category of service:* in Armenia, Azerbaijan, Belarus, Georgia, Kazakstan, Latvia, Lithuania, Moldova, Uzbekistan, Kyrgyzstan, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the allocation of the band 5130–5250 kHz to the mobile, except aeronautical mobile, service is on a primary basis (see No.**S5.33**).

S5.134—The use of the bands 5900–5950 kHz, 7300–7350 kHz, 9400–9500 kHz, 11600–11650 kHz, 12050–12100 kHz, 13570–13600 kHz, 13800–13870 kHz, 15600–15800 kHz, 17480–17550 kHz, and 18900–19020 kHz by the broadcasting service is limited to single-sideband emissions with the characteristics specified in Appendix **S11** or to any other spectrum-efficient modulation techniques recommended by ITU-R. Access to these bands shall be subject to the decisions of a competent conference (WRC 97).

S5.135—SUP-WRC-97.

S5.136—The band 5900–5950 kHz is allocated, until 1 April 2007, to the fixed service on a primary basis, as well as to the following services: in Region 1 to the land mobile service on a primary basis, in Region 2 to the mobile, except aeronautical mobile (R), service on a primary basis, and in Region 3 to the mobile, except aeronautical mobile (R), service on a secondary basis, subject to application of the procedure referred to in Resolution 21 (Rev.WRC-95). After 1 April 2007, frequencies in this band may be used by stations in the above-mentioned services, communicating only within the boundary of the country in which they are located, on the condition that harmful interference is not caused to the broadcasting service. When using frequencies for these services, administrations are urged to use the minimum power required and to take account of the seasonal use of frequencies by the broadcasting service published in accordance with the Radio Regulations.

S5.137—On condition that harmful interference is not caused to the maritime mobile service, the bands 6200–6213.5 kHz and 6220.5–6525 kHz may be used exceptionally by stations in the fixed service, communicating only within the boundary of the country in which they are located, with a mean power not exceeding 50 W. At the time of notification of these frequencies, the attention of the Bureau will be drawn to the above conditions.

S5.138—The following bands:

6765–6795 kHz (centre frequency 6780 kHz),
433.05–434.79 MHz (centre frequency 433.92 MHz) in Region 1 except in the countries mentioned in No. **S5.280**,
61–61.5 GHz (centre frequency 61.25 GHz),
122–123 GHz (centre frequency 122.5 GHz), and
244–246 GHz (centre frequency 245 GHz)

are designated for industrial, scientific, and medical (ISM) applications. The use of these frequency bands for ISM applications shall be subject to special authorization by the administration concerned, in agreement with other administrations whose radiocommunication services might be affected. In applying this provision, administrations shall have due regard to the latest relevant ITU-R Recommendations.

S5.139—*Different category of service:* in Armenia, Azerbaijan, Belarus, Georgia, Kazakstan, Latvia, Lithuania, Moldova, Mongolia, Uzbekistan, Kyrgyzstan, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the allocation of the band 6765–7000 kHz to the land mobile service is on a primary basis (see No. **S5.33**).

S5.140—*Additional allocation:* in Angola, Iraq, Rwanda, Somalia, and Togo, the band 7000–7050 kHz is also allocated to the fixed service on a primary basis.

S5.141—*Alternative allocation:* in Egypt, Eritrea, Ethiopia, Guinea, Libya, and Madagascar, the band 7000–7050 kHz is allocated to the fixed service on a primary basis (WRC-97).

S5.142—The use of the band 7100–7300 kHz in Region 2 by the amateur service shall not impose constraints on the broadcasting service intended for use within Region 1 and Region 3.

S5.143—The band 7300–7350 kHz is allocated, until April 1, 2007, to the fixed service on a primary basis and to the land mobile service on a secondary basis, subject to application of the procedure referred to in Resolution 21 (Rev.WRC-95). After 1 April 2007, frequencies in this band may be used by stations in the above-mentioned services, communicating only within the boundary of the country in which they are located, on condition that harmful interference is not caused to the broadcasting service. When using frequencies for these services, administrations are urged to use the minimum power required and to take account of the seasonal use of frequencies by the broadcasting service published in accordance with the Radio Regulations.

S5.144—In Region 3, the stations of those services to which the band 7995–8005 kHz is allocated may transmit standard frequency and time signals.

S5.145—The conditions for the use of the carrier frequencies 8291 kHz, 12290 kHz, and 16420 kHz are prescribed in Articles **S31** and **S52** and in Appendix **S13**.

S5.146—The bands 9400–9500 kHz, 11600–11650 kHz, 12050–12100 kHz, 15600–15800 kHz, 17480–17550 kHz, and 18900–19020 kHz are allocated to the fixed service on a primary basis until 1 April 2007, subject to application of the procedure referred to in Resolution 21 (Rev.WRC-95). After 1 April 2007, frequencies in these bands may be used by stations in the fixed service, communicating only within the boundary of the country in which they are located, on condition that harmful interference is not caused to the broadcasting service. When using frequencies in the fixed service, administrations are urged to use the minimum power required and to take account of the seasonal use of frequencies by the broadcasting service published in accordance with the Radio Regulations.

S5.147—On condition that harmful interference is not caused to the broadcasting service, frequencies in the bands 9775–9900 kHz, 11650–11700 kHz, and 11975–12050 kHz may be used by stations in the fixed service communicating only within the boundary of the country in which they are located, each station using a total radiated power not exceeding 24 dBW.

S5.148—SUP - WRC-97.

S5.149—In making assignments to stations of other services to which the bands are allocated:

13360–13410 kHz,
25550–25670 kHz,
37.5–38.25 MHz,
73–74.6 MHz in Regions 1 and 3,
150.05–153 MHz in Region 1,
322–328.6 MHz*,
406.1–410 MHz,
608–614 MHz in Regions 1 and 3,
1330–1400 MHz*,
1610.6–1613.8 MHz*,
1660–1670 MHz,
1718.8–1722.2 MHz*,
2655–2690 MHz,
3260–3267 MHz*,
3332–3339 MHz*,
3345.8–3352.5 MHz*,
4825–4835 MHz*,
4950–4990 MHz,
4990–5000 MHz,
6650–6675.2 MHz*,
10.6–10.68 GHz,
14.47–14.5 GHz*,
22.01–22.21 GHz*,
22.21–22.5 GHz,
22.81–22.86 GHz*,
23.07–23.12 GHz*,
31.2–31.3 GHz,
31.5–31.8 GHz in Regions 1 and 3,
36.43–36.5 GHz*,
42.5–43.5 GHz,
42.77–42.87 GHz*,
43.07–43.17 GHz*,
43.37–43.47 GHz*,
48.94–49.04 GHz*,
72.77–72.91 GHz*,
93.07–93.27 GHz*,
97.88–98.08 GHz*,
140.69–140.98 GHz*,
144.68–144.98 GHz*,
145.45–145.75 GHz*,
146.82–147.12 GHz*,
150–151 GHz*,
174.42–175.02 GHz*,
177–177.4 GHz*,
178.2–178.6 GHz*,
181–181.46 GHz*,
186.2–186.6 GHz*,
250–251 GHz*,
257.5–258 GHz*,
261–265 GHz,
262.24–262.76 GHz*,
265–275 GHz,
265.64–266.16 GHz*,
267.34–267.86 GHz*,
271.74–272.26 GHz*

(* indicates radio astronomy use for spectral line observations), administrations are urged to take all practicable steps to protect the radio astronomy service from harmful interference. Emissions from spaceborne or airborne stations can be particularly serious sources of interference to the radio

astronomy service (see Nos. **S4.5** and **S4.6** and Article **S29**) (WRC-97).

S5.150—The following bands:

13553–13567 kHz (centre frequency 13560 kHz),
26957–27283 kHz (centre frequency 27120 kHz),
40.66–40.70 MHz (centre frequency 40.68 MHz),
902–928 MHz in Region 2 (centre frequency 915 MHz),
2400–2500 MHz (centre frequency 2450 MHz),
5725–5875 MHz (centre frequency 5800 MHz),
and
24–24.25 GHz (centre frequency 24.125 GHz)

are also designated for industrial, scientific, and medical (ISM) applications. Radiocommunication services operating within these bands must accept harmful interference that may be caused by these applications. ISM equipment operating in these bands is subject to the provisions of No. **S15.13**.

S5.151—The bands 1570–13 600 kHz and 13 800–13 870 kHz are allocated, until 1 April 2007, to the fixed service on a primary basis and to the mobile, except aeronautical mobile (R), service on a secondary basis, subject to application of the procedure referred to in Resolution 21 (Rev.WRC-95). After 1 April 2007, frequencies in these bands may be used by stations in the above-mentioned services, communicating only within the boundary of the country in which they are located, on the condition that harmful interference is not caused to the broadcasting service. When using frequencies in these services, administrations are urged to use the minimum power required and to take account of the seasonal use of frequencies by the broadcasting service published in accordance with the Radio Regulations.

S5.152—*Additional allocation:* in Armenia, Azerbaijan, China, Côte d'Ivoire, Georgia, the Islamic Republic of Iran, Kazakstan, Moldova, Uzbekistan, Kyrgyzstan, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the band 14 250–14 350 kHz is also allocated to the fixed service on a primary basis. Stations of the fixed service shall not use a radiated power exceeding 24 dBW (WRC-97).

S5.153—In Region 3, the stations of those services to which the band 15 995–16 005 kHz is allocated may transmit standard frequency and time signals.

S5.154—*Additional allocation:* in Armenia, Azerbaijan, Georgia, Kazakstan, Moldova, Uzbekistan, Kyrgyzstan, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the band 18068–18168 kHz is also allocated to the fixed service on a primary basis for use within their boundaries, with a peak envelope power not exceeding 1 kW (WRC-97).

S5.155—*Additional allocation:* in Armenia, Azerbaijan, Belarus, Bulgaria, Georgia, Hungary, Kazakstan, Moldova, Mongolia, Uzbekistan, Kyrgyzstan, Slovakia, the Czech Republic, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the band 21 850–21 870 kHz is also allocated to the aeronautical mobile (R) services on a primary basis.

S5.155A—In Armenia, Azerbaijan, Belarus, Bulgaria, Georgia, Hungary, Kazakstan, Moldova, Mongolia, Uzbekistan, Kyrgyzstan, Slovakia, the Czech Republic, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the use of the band 21 850–21 870 kHz by the fixed service is limited to provision of services related to aircraft flight safety.

S5.155B—The band 21 870–21 924 kHz is used by the fixed service for provision of services related to aircraft flight safety.

S5.156—*Additional allocation:* in Nigeria, the band 22 720–23 200 kHz is also allocated to the meteorological aids service (radiosondes) on a primary basis.

S5.156A—The use of the band 23 200–23 350 kHz by the fixed service is limited to provision of services related to aircraft flight safety.

S5.157—The use of the band 23 350–24 000 kHz by the maritime mobile service is limited to inter-ship radiotelegraphy.

S5.158 and **S5.159**—Not used.

S5.160—*Additional allocation:* in Botswana, Burundi, Lesotho, Malawi, Namibia, Democratic Republic of the Congo, Rwanda, and Swaziland, the band 41–44 MHz is also allocated to the aeronautical radionavigation service on a primary basis (WRC-97).

S5.161—*Additional allocation:* in the Islamic Republic of Iran and Japan, the band 41–44 MHz is also allocated to the radiolocation service on a secondary basis.

S5.162—*Additional allocation:* in Australia and New Zealand, the band 44–47 MHz is also allocated to the broadcasting service on a primary basis.

S5.162A—*Additional allocation:* in Germany, Austria, Belgium, Bosnia and Herzegovina, China, Vatican, Denmark, Spain, Estonia, Finland, France, Ireland, Iceland, Italy, Latvia, the former Yugoslav Republic of Macedonia, Liechtenstein, Lithuania, Luxembourg, Moldova, Monaco, Norway, the Netherlands, Poland, Portugal, Slovakia, the Czech Republic, the United Kingdom, Russian Federation, Sweden, Switzerland, and Turkey, the band 46–68 MHz is also allocated to the radiolocation service on a secondary basis. This use is limited to the operation of wind profiler radars in accordance with Resolution 217 (WRC-97). (WRC-97).

S5.163—*Additional allocation:* in Armenia, Azerbaijan, Belarus, Estonia, Georgia, Hungary, Kazakstan, Latvia, Lithuania, Moldova, Mongolia, Uzbekistan, Kyrgyzstan, Slovakia, the Czech Republic, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the bands 47–48.5 MHz and 56.5–58 MHz are also allocated to the fixed and land mobile services on a secondary basis.

S5.164—*Additional allocation:* in Albania, Germany, Austria, Belgium, Bosnia and Herzegovina, Bulgaria, Côte d'Ivoire, Denmark, Spain, Finland, France, Gabon, Greece, Ireland, Israel, Italy, Jordan, Lebanon, Libya, Liechtenstein, Luxembourg, Madagascar, Mali, Malta, Morocco, Mauritania, Monaco, Nigeria, Norway, the Netherlands, Poland, Syria, the United Kingdom, Senegal, Slovenia, Sweden, Switzerland, Swaziland, Togo, Tunisia, Turkey, and Yugoslavia the band 47–68 MHz, in Romania the band 47–58 MHz, and in the Czech Republic the band 66–68 MHz are also allocated to the land mobile service on a primary basis. However, stations of the land mobile service in the countries mentioned in connection with each band referred to in this footnote shall not cause harmful interference to, or claim protection from, existing or planned broadcasting stations of countries other than those mentioned in connection with the band (WRC-97).

S5.165—*Additional allocation:* in Angola, Cameroon, the Congo, Madagascar, Mozambique, Somalia, Sudan, Tanzania,

and Chad, the band 47–68 MHz is also allocated to the fixed and mobile, except aeronautical mobile, services on a primary basis.

S5.166—*Alternative allocation:* in New Zealand, the band 50–51 MHz is allocated to the fixed, mobile, and broadcasting services on a primary basis; the band 53–54 MHz is allocated to the fixed and mobile services on a primary basis.

S5.167—*Alternative allocation:* in Bangladesh, Brunei Darussalam, India, Indonesia, the Islamic Republic of Iran, Malaysia, Pakistan, Singapore, and Thailand, the band 50–54 MHz is allocated to the fixed, mobile, and broadcasting services on a primary basis.

S5.168—*Additional allocation:* in Australia, China, and the Democratic People's Republic of Korea, the band 50–54 MHz is also allocated to the broadcasting service on a primary basis.

S5.169—*Alternative allocation:* in Botswana, Burundi, Lesotho, Malawi, Namibia, Democratic Republic of the Congo, Rwanda, South Africa, Swaziland, Zambia, and Zimbabwe, the band 50–54 MHz is allocated to the amateur service on a primary basis.

S5.170—*Additional allocation:* in New Zealand, the band 51–53 MHz is also allocated to the fixed and mobile services on a primary basis.

S5.171—*Additional allocation:* in Botswana, Burundi, Lesotho, Malawi, Mali, Namibia, Democratic Republic of the Congo, Rwanda, South Africa, Swaziland, and Zimbabwe, the band 54–68 MHz is also allocated to the fixed and mobile, except aeronautical mobile, services on a primary basis.

S5.172—*Different category of service:* in the French Overseas Departments in Region 2, Guyana, Jamaica, and Mexico, the allocation of the band 54–68 MHz to the fixed and mobile services is on a primary basis (see No. **S5.33**).

S5.173—*Different category of service:* in the French Overseas Departments in Region 2, Guyana, Jamaica, and Mexico, the allocation of the band 68–72 MHz to the fixed and mobile services is on a primary basis (see No. **S5.33**).

S5.174—*Alternative allocation:* in Bulgaria, Hungary, Poland, and Romania, the band 68–73 MHz is allocated to the broadcasting service on a primary basis and used in accordance with the decisions in the Final Acts of the Special Regional Conference (Geneva, 1960) (WRC-97).

S5.175—*Alternative allocation:* in Armenia, Azerbaijan, Belarus, Estonia, Georgia, Kazakstan, Latvia, Lithuania, Moldova, Mongolia, Uzbekistan, Kyrgyzstan, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the bands 68–73 MHz and 76–87.5 MHz are allocated to the broadcasting service on a primary basis. The services to which these bands are allocated in other countries and the broadcasting service in the countries listed above are subject to agreements with the neighbouring countries concerned.

S5.176—*Additional allocation:* in Australia, China, the Republic of Korea, the Philippines, the Democratic People's Republic of Korea, and Western Samoa, the band 68–74 MHz is also allocated to the broadcasting service on a primary basis.

S5.177—*Additional allocation:* in Armenia, Azerbaijan, Belarus, Bulgaria, Estonia, Georgia, Kazakstan, Latvia, Lithuania, Moldova, Mongolia, Uzbekistan, Poland, Kyrgyzstan, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the band 73–74 MHz is also allocated to the broadcasting service on a primary basis, subject to agreement obtained under No. **S9.21** (WRC-97).

S5.178—*Additional allocation:* in Colombia, Costa Rica, Cuba, El Salvador, Guatemala, Guyana, Honduras, and Nicaragua, the band 73–74.6 MHz is also allocated to the fixed and mobile services on a secondary basis.

S5.179—*Additional allocation:* in Armenia, Azerbaijan, Belarus, Bulgaria, China, Georgia, Kazakstan, Latvia, Lithuania, Moldova, Mongolia, Kyrgyzstan, Slovakia, the Czech Republic, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the bands 74.6–74.8 MHz and 75.2–75.4 MHz are also allocated to the aeronautical radionavigation service, on a primary basis, for ground-based transmitters only.

S5.180—The frequency 75 MHz is assigned to marker beacons. Administrations shall refrain from assigning frequencies close to the limits of the guardband to stations of other services that, because of their power or geographical position, might cause harmful interference or otherwise place a constraint on marker beacons.

Every effort should be made to improve further the characteristics of airborne receivers and to limit the power of transmitting stations close to the limits 74.8 MHz and 75.2 MHz.

S5.181—*Additional allocation:* in Germany, Austria, Cyprus, Denmark, Egypt, France, Greece, Israel, Italy, Japan, Jordan, Lebanon, Malta, Morocco, Monaco, Norway, Syria, Sweden, and Switzerland, the band 74.8–75.2 MHz is also allocated to the mobile service on a secondary basis, subject to agreement obtained under No. **S9.21**. To ensure that harmful interference is not caused to stations of the aeronautical radionavigation service, stations of the mobile service shall not be introduced in the band until it is no longer required for the aeronautical radionavigation service by any administration that may be identified in the application of the procedure invoked under No. **S9.21** (WRC-97).

S5.182—*Additional allocation:* in Western Samoa, the band 75.4–87 MHz is also allocated to the broadcasting service on a primary basis.

S5.183—*Additional allocation:* in China, the Republic of Korea, Japan, the Philippines, and the Democratic People's Republic of Korea, the band 76–87 MHz is also allocated to the broadcasting service on a primary basis.

S5.184—*Additional allocation:* in Bulgaria and Romania, the band 76–87.5 MHz is also allocated to the broadcasting service on a primary basis and used in accordance with the decisions contained in the Final Acts of the Special Regional Conference (Geneva, 1960) (WRC-97).

S5.185—*Different category of service:* in the United States, the French Overseas Departments in Region 2, Guyana, Jamaica, Mexico, and Paraguay, the allocation of the band 76–88 MHz to the fixed and mobile services is on a primary basis (see No. **S5.33**).

S5.186—SUP - WRC-97.

S5.187—*Alternative allocation:* in Albania, the band 81–87.5 MHz is allocated to the broadcasting service on a primary basis and used in accordance with the decisions contained in the Final Acts of the Special Regional Conference (Geneva, 1960).

S5.188—*Additional allocation:* in Australia, the band 85–87 MHz is also allocated to the broadcasting service on a primary basis. The introduction of the broadcasting service in Australia is subject to special agreements between the administrations concerned.

S5.189—Not used.

S5.190—*Additional allocation:* in Monaco, the band 87.5–88 MHz is also allocated to the land mobile service on a primary basis, subject to agreement obtained under No. **S9.21** (WRC-97).

S5.191—Not used.

S5.192—*Additional allocation:* in China and the Republic of Korea, the band 100–108 MHz is also allocated to the fixed and mobile services on a primary basis (WRC-97).

S5.193—Not used.

S5.194—*Additional allocation:* in Azerbaijan, Lebanon, Syria, Kyrgyzstan, Somalia, and Turkmenistan, the band 104–108 MHz is also allocated to the mobile, except aeronautical mobile (R), service on a secondary basis (WRC-97).

S5.195 and **S5.196**—Not used.

S5.197—*Additional allocation:* in Germany, Austria, Cyprus, Denmark, Egypt, France, Italy, Japan, Jordan, Lebanon, Malta, Morocco, Monaco, Norway, Pakistan, Syria, and Sweden, the band 108–111.975 MHz is also allocated to the mobile service on a secondary basis, subject to agreement obtained under No. **S9.21**. To ensure that harmful interference is not caused to stations of the aeronautical radionavigation service, stations of the mobile service shall not be introduced in the band until it is no longer required for the aeronautical radionavigation service by any administration that may be identified in the application of the procedures invoked under No. **S9.21** (WRC-97).

S5.198—*Additional allocation:* The band 117.975–136 MHz is also allocated to the aeronautical mobile-satellite (R) service on a secondary basis, subject to agreement obtained under No. **S9.21** (WRC-97).

S5.199—The bands 121.45–121.55 MHz and 242.95–243.05 MHz are also allocated to the mobile-satellite service for the reception on board satellites of emissions from emergency position-indicating radiobeacons transmitting at 121.5 MHz and 243 MHz (see Appendix **S13**).

S5.200—In the band 117.975–136 MHz, the frequency 121.5 MHz is the aeronautical emergency frequency and, where required, the frequency 123.1 MHz is the aeronautical frequency auxiliary to 121.5 MHz. Mobile stations of the maritime mobile service may communicate on these frequencies under the conditions laid down in Article **S31** and Appendix **S13** for distress and safety purposes with stations of the aeronautical mobile service.

S5.201—*Additional allocation:* in Angola, Armenia, Azerbaijan, Belarus, Bulgaria, Estonia, Georgia, Hungary, the Islamic Republic of Iran, Iraq, Japan, Kazakstan, Latvia, Moldova, Mongolia, Mozambique, Uzbekistan, Papua New Guinea, Poland, Kyrgyzstan, Slovakia, the Czech Republic, Romania, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the band 132–136 MHz is also allocated to the aeronautical mobile (OR) service on a primary basis. In assigning frequencies to stations of the aeronautical mobile (OR) service, the administration shall take account of the frequencies assigned to stations in the aeronautical mobile (R) service (WRC-97).

S5.202—*Additional allocation:* in Saudi Arabia, Armenia, Azerbaijan, Belarus, Bulgaria, United Arab Emirates, Georgia, the Islamic Republic of Iran, Jordan, Kazakstan, Latvia, Moldova, Oman, Uzbekistan, Poland, Syria, Kyrgyzstan, Slovakia, the Czech Republic, Romania, Russian Federation, Tajikistan, Turkmenistan, Turkey, and Ukraine, the band 136–137 MHz is also allocated to the aeronautical mobile (OR) service on a primary basis. In assigning frequencies to stations of the aeronautical mobile (OR) service, the administration shall take account of the frequencies assigned to stations in the aeronautical mobile (R) service (WRC-97).

S5.203—In the band 136–137 MHz, existing operational meteorological satellites may continue to operate, under the conditions defined in No. **S4.4** with respect to the aeronautical mobile service, until January 1, 2002. Administrations shall not authorize new frequency assignments in this band to stations in the meteorological-satellite service (WRC-97).

S5.203A—*Additional allocation:* in Israel, Mauritania, Qatar, and Zimbabwe, the band 136–137 MHz is also allocated to the fixed and mobile, except aeronautical mobile (R), services on a secondary basis until January 1, 2005, (WRC-97).

S5.203B—*Additional allocation:* in Saudi Arabia, United Arab Emirates, Jordan, Oman, and Syria, the band 136–137 MHz is also allocated to the fixed and mobile, except aeronautical mobile, services on a secondary basis until January 1, 2005 (WRC-97).

S5.204—*Different category of service:* in Afghanistan, Saudi Arabia, Bahrain, Bangladesh, Bosnia and Herzegovina, Brunei Darussalam, China, Cuba, the United Arab Emirates, India, Indonesia, the Islamic Republic of Iran, Iraq, Malaysia, Oman, Pakistan, Philippines, Qatar, Singapore, Sri Lanka, Thailand, Yemen, and Yugoslavia, the band 137–138 MHz is allocated to the fixed and mobile, except aeronautical mobile (R), services on a primary basis (see No. **S5.33**).

S5.205—*Different category of service:* in Israel and Jordan, the allocation of the band 137–138 MHz to the fixed and mobile, except aeronautical mobile, services is on a primary basis (see No. **S5.33**).

S5.206—*Different category of service:* in Armenia, Austria, Azerbaijan, Belarus, Bulgaria, Egypt, Finland, France, Georgia, Greece, Hungary, Kazakstan, Lebanon, Moldova, Mongolia, Uzbekistan, Poland, Kyrgyzstan, Syria, Slovakia, the Czech Republic, Romania, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the allocation of the band 137–138 MHz to the aeronautical mobile (OR) service is on a primary basis (see No. **S5.33**).

S5.207—*Additional allocation:* in Australia, the band 137–144 MHz is also allocated to the broadcasting service on a primary basis until that service can be accommodated within regional broadcasting allocations.

S5.208—The use of the band 137–138 MHz by the mobile-satellite service is subject to coordination under No. **S9.11A** (WRC-97).

S5.208A—In making assignments to space stations in the mobile-satellite service in the bands 137–138 MHz, 387–390 MHz, and 400.15–401 MHz, administrations shall take all practicable steps to protect the radio astronomy service in the

bands 150.05–153 MHz, 322–328.6 MHz, 406.1–410 MHz, and 608–614 MHz from harmful interference from unwanted emissions. The threshold levels of interference detrimental to the radio astronomy service are shown in Table 1 of Recommendation ITU-R RA. 769-1 (WRC-97).

S5.209—The use of the bands 137–138 MHz, 148–150.05 MHz, 399.9–400.05 MHz, 400.15–401 MHz, 454–456 MHz, and 459–460 MHz by the mobile-satellite service is limited to nongeostationary-satellite systems (WRC-97).

S5.210—*Additional allocation:* in Austria, France, Italy, Liechtenstein, Slovakia, the Czech Republic, the United Kingdom, and Switzerland, the bands 138–143.6 MHz and 143.65–144 MHz are also allocated to the space research service (space-to-Earth) on a secondary basis (WRC-97).

S5.211—*Additional allocation:* in Germany, Saudi Arabia, Austria, Bahrain, Belgium, Bosnia and Herzegovina, Denmark, the United Arab Emirates, Spain, Finland, Greece, Ireland, Israel, Kenya, Kuwait, the former Yugoslav Republic of Macedonia, Liechtenstein, Luxembourg, Mali, Malta, Norway, the Netherlands, Qatar, the United Kingdom, Slovenia, Somalia, Sweden, Switzerland, Tanzania, Tunisia, Turkey, and Yugoslavia, the band 138–144 MHz is also allocated to the maritime mobile and land mobile services on a primary basis.

S5.212—*Alternative allocation:* in Angola, Botswana, Burundi, Cameroon, the Central African Republic, the Congo, Gabon, Gambia, Ghana, Guinea, Iraq, Jordan, Lesotho, Liberia, Libya, Malawi, Mozambique, Namibia, Nigeria, Oman, Democratic Republic of the Congo, Rwanda, Sierra Leone, South Africa, Swaziland, Chad, Togo, Zaire, Zambia, and Zimbabwe, the band 138–144 MHz is allocated to the fixed and mobile services on a primary basis.

S5.213—*Additional allocation:* in China, the band 138–144 MHz is also allocated to the radiolocation service on a primary basis.

S5.214—*Additional allocation:* in Bosnia and Herzegovina, Croatia, Eritrea, Ethiopia, Kenya, the former Yugoslav Republic of Macedonia, Malta, Slovenia, Somalia, Sudan, Tanzania, and Yugoslavia, the band 138–144 MHz is also allocated to the fixed service on a primary basis.

S5.215—Not used.

S5.216—*Additional allocation:* in China, the band 144–146 MHz is also allocated to the aeronautical mobile (OR) service on a secondary basis.

S5.217—*Alternative allocation:* in Afghanistan, Bangladesh, Cuba, Guyana, and India, the band 146–148 MHz is allocated to the fixed and mobile services on a primary basis.

S5.218—*Additional allocation:* The band 148–149.9 MHz is also allocated to the space operation service (Earth-to-space) on a primary basis, subject to agreement obtained under No. **S9.21**. The bandwidth of any individual transmission shall not exceed ± 25 kHz.

S5.219—The use of the band 148–149.9 MHz by the mobile-satellite service is subject to coordination under No. **S9.11A**. The mobile-satellite service shall not constrain the development and use of the fixed, mobile, and space operation services in the band 148–149.9 MHz.

S5.220—The use of the bands 149.9–150.05 MHz and 399.9–400.05 MHz by the mobile-satellite service is subject to coordination under No. **S9.11A**. The mobile-satellite service shall not constrain the development and use of the radionavigation-satellite service in the bands 149.9–150.05 MHz and 399.9–400.05 MHz (WRC-97).

S5.221—Stations of the mobile-satellite service in the band 148–149.9 MHz shall not cause harmful interference to, or claim protection from, stations of the fixed or mobile services operating in accordance with the Table of Frequency Allocations in the following countries: Albania, Algeria, Germany, Saudi Arabia, Australia, Austria, Bahrain, Bangladesh, Barbados, Belarus, Belgium, Benin, Bosnia and Herzegovina, Brunei Darussalam, Bulgaria, Cameroon, China, Cyprus, Congo, the Republic of Korea, Croatia, Cuba, Denmark, Egypt, the United Arab Emirates, Eritrea, Spain, Estonia, Ethiopia, Finland, France, Gabon, Ghana, Greece, Guinea, Guinea Bissau, Hungary, India, the Islamic Republic of Iran, Ireland, Iceland, Israel, Italy, Jamaica, Japan, Jordan, Kazakstan, Kenya, Kuwait, Latvia, The Former Yugoslav Republic of Macedonia, Lebanon, Libya, Liechtenstein, Luxembourg, Malaysia, Mali, Malta, Mauritania, Moldova, Mongolia, Mozambique, Namibia, Norway, New Zealand, Oman, Uganda, Uzbekistan, Pakistan, Panama, Papua New Guinea, Paraguay, the Netherlands, the Philippines, Poland, Portugal, Qatar, Syria, Kyrgyzstan, Slovakia, Romania, the United Kingdom, Russian Federation, Senegal, Sierra Leone, Singapore, Slovenia, Sri Lanka, South Africa, Sweden, Switzerland, Swaziland, Tanzania, Chad, Thailand, Togo, Tonga, Trinidad and Tobago, Tunisia, Turkey, Ukraine, Viet Nam, Yemen, Yugoslavia, Zambia, and Zimbabwe (WRC-97).

S5.222—Emissions of the radionavigation-satellite service in the bands 149.9–150.05 MHz and 399.9–400.05 MHz may also be used by receiving earth stations of the space research service.

S5.223—Recognizing that the use of the band 149.9–150.05 MHz by the fixed and mobile services may cause harmful interference to the radionavigation-satellite service, administrations are urged not to authorize such use in application of No. **S4.4**.

S5.224—SUP-WRC-97.

S5.224A—The use of the bands 149.9–150.05 MHz and 399.9–400.05 MHz by the mobile-satellite service (Earth-to-space) is limited to the land mobile-satellite service (Earth-to-space) until January 1, 2015 (WRC-97).

S5.224B—The allocation of the bands 149.9–150.05 MHz and 399.9–400.05 MHz to the radionavigation-satellite service shall be effective until January 1, 2015 (WRC-97).

S5.225—*Additional allocation:* in Australia and India, the band 150.05–153 MHz is also allocated to the radio astronomy service on a primary basis.

S5.226—The frequency 156.8 MHz is the international distress, safety, and calling frequency for the maritime mobile VHF radiotelephone service. The conditions for the use of this frequency are contained in Article **S31** and Appendix **S13**.

In the bands 156–156.7625 MHz, 156.8375–157.45 MHz, 160.6–160.975 MHz, and 161.475–162.05 MHz, each administration shall give priority to the maritime mobile service on only such frequencies as are assigned to stations of the maritime mobile service by the administration (see Articles **S31** and **S52** and Appendix **S13**).

Any use of frequencies in these bands by stations of other services to which they are allocated should be avoided in areas

where such use might cause harmful interference to the maritime mobile VHF radiocommunication service.

However, the frequency 156.8 MHz and the frequency bands in which priority is given to the maritime mobile service may be used for radiocommunications on inland waterways subject to agreement between interested and affected administrations and taking into account current frequency usage and existing agreements.

S5.227—In the maritime mobile VHF service the frequency 156.525 MHz is to be used exclusively for digital selective calling for distress, safety, and calling. The conditions for the use of this frequency are prescribed in Articles **S31** and **S52** and in Appendices **S13** and **S18**.

S5.228—Not used.

S5.229—*Alternative allocation:* in Morocco, the band 162–174 MHz is allocated to the broadcasting service on a primary basis. The use of this band shall be subject to agreement with administrations having services, operating or planned, in accordance with the Table which are likely to be affected. Stations in existence on 1 January 1981, with their technical characteristics as of that date, are not affected by such agreement.

S5.230—*Additional allocation:* in China, the band 163–167 MHz is also allocated to the space operation service (space-to-Earth) on a primary basis, subject to agreement obtained under No. **S9.21**.

S5.231—*Additional allocation:* in Afghanistan, China, and Pakistan, the band 167–174 MHz is also allocated to the broadcasting service on a primary basis. The introduction of the broadcasting service into this band shall be subject to agreement with the neighbouring countries in Region 3 whose services are likely to be affected.

S5.232—*Additional allocation:* in Japan, the band 170–174 MHz is also allocated to the broadcasting service on a primary basis.

S5.233—*Additional allocation:* in China, the band 174–184 MHz is also allocated to the space research (space-to-Earth) and the space operation (space-to-Earth) services on a primary basis, subject to agreement obtained under No. **S9.21**. These services shall not cause harmful interference to, or claim protection from, existing or planned broadcasting stations.

S5.234—*Different category of service:* in Mexico, the allocation of the band 174–216 MHz to the fixed and mobile services is on a primary basis (see No. **S5.33**).

S5.235—*Additional allocation:* in Germany, Austria, Belgium, Denmark, Spain, Finland, France, Israel, Italy, Liechtenstein, Malta, Monaco, Norway, the Netherlands, the United Kingdom, Sweden, and Switzerland, the band 174–223 MHz is also allocated to the land mobile service on a primary basis. However, the stations of the land mobile service shall not cause harmful interference to, or claim protection from, broadcasting stations, existing or planned, in countries other than those listed in this footnote.

S5.236—Not used.

S5.237—*Additional allocation:* in the Congo, Eritrea, Ethiopia, Gambia, Guinea, Libya, Malawi, Mali, Senegal, Sierra Leone, Somalia, Tanzania, and Zimbabwe, the band 174–223 MHz is also allocated to the fixed and mobile services on a secondary basis, (WRC-97).

S5.238—*Additional allocation:* in Bangladesh, India, Pakistan, and the Philippines, the band 200–216 MHz is also allocated to the aeronautical radionavigation service on a primary basis.

S5.239—Not used.

S5.240—*Additional allocation:* in China and India, the band 216–223 MHz is also allocated to the aeronautical radionavigation service on a primary basis and to the radiolocation service on a secondary basis.

S5.241—In Region 2, no new stations in the radiolocation service may be authorized in the band 216–225 MHz. Stations authorized prior to 1 January 1990 may continue to operate on a secondary basis.

S5.242—*Additional allocation:* in Canada, the band 216–220 MHz is also allocated to the land mobile service on a primary basis.

S5.243—*Additional allocation:* in Somalia, the band 216–225 MHz is also allocated to the aeronautical radionavigation service on a primary basis, subject to not causing harmful interference to existing or planned broadcasting services in other countries.

S5.244—SUP-WRC-97.

S5.245—*Additional allocation:* in Japan, the band 222–223 MHz is also allocated to the aeronautical radionavigation service on a primary basis and to the radiolocation service on a secondary basis.

S5.246—*Alternative allocation:* in Spain, France, Israel, and Monaco, the band 223–230 MHz is allocated to the broadcasting and land mobile services on a primary basis (see No. **S5.33**) on the basis that, in the preparation of frequency plans, the broadcasting service shall have prior choice of frequencies; and allocated to the fixed and mobile, except land mobile, services on a secondary basis. However, the stations of the land mobile service shall not cause harmful interference to, or claim protection from, existing or planned broadcasting stations in Morocco and Algeria.

S5.247—*Additional allocation:* in Saudi Arabia, Bahrain, the United Arab Emirates, Jordan, Oman, Qatar, and Syria, the band 223–235 MHz is also allocated to the aeronautical radionavigation service on a primary basis.

S5.248 and **S5.249**—Not used.

S5.250—*Additional allocation:* in China, the band 225–235 MHz is also allocated to the radio astronomy service on a secondary basis.

S5.251—*Additional allocation:* in Nigeria, the band 230–235 MHz is also allocated to the aeronautical radionavigation service on a primary basis, subject to agreement obtained under No. **S9.21**.

S5.252—*Alternative allocation:* in Botswana, Lesotho, Malawi, Mozambique, Namibia, South Africa, Swaziland, Zambia, and Zimbabwe, the bands 230–238 MHz and 246–254 MHz are allocated to the broadcasting service on a primary basis, subject to agreement obtained under No. **S9.21**.

S5.253—Not used.

S5.254—The bands 235–322 MHz and 335.4–399.9 MHz may be used by the mobile-satellite service, subject to agreement obtained under No. **S9.21**, on condition that stations in this service do not cause harmful interference to those of other services operating or planned to be operated in accordance with the Table of Frequency Allocations.

S5.255—The bands 312–315 MHz (Earth-to-space) and 387–390 MHz (space-to-Earth) in the mobile-satellite service may also be used by nongeostationary-satellite systems. Such use is subject to coordination under No. **S9.11A**.

S5.256—The frequency 243 MHz is the frequency in this band for use by survival craft stations and equipment used for survival purposes (see Appendix **S13**).

S5.257—The band 267–272 MHz may be used by administrations for space telemetry in their countries on a primary basis, subject to agreement obtained under No. **S9.21**.

S5.258—The use of the band 328.6–335.4 MHz by the aeronautical radionavigation service is limited to Instrument Landing Systems (glide path).

S5.259—*Additional allocation:* in Germany, Austria, Cyprus, the Republic of Korea, Denmark, Egypt, Spain, France, Greece, Israel, Italy, Japan, Jordan, Malta, Morocco, Monaco, Norway, the Netherlands, Syria, and Sweden, the band 328.6–335.4 MHz is also allocated to the mobile service on a secondary basis, subject to agreement obtained under No. **S9.21**. To ensure that harmful interference is not caused to stations of the aeronautical radionavigation service, stations of the mobile service shall not be introduced in the band until it is no longer required for the aeronautical radionavigation service by any administration that may be identified in the application of the procedure invoked under No. **S9.21** (WRC-97).

S5.260—Recognizing that the use of the band 399.9–400.05 MHz by the fixed and mobile services may cause harmful interference to the radionavigation satellite service, administrations are urged not to authorize such use in application of No. **S4.4**.

S5.261—Emissions shall be confined in a band of ± 25 kHz about the standard frequency 400.1 MHz.

S5.262—*Additional allocation:* in Saudi Arabia, Armenia, Azerbaijan, Bahrain, Belarus, Bosnia and Herzegovina, Bulgaria, Colombia, Costa Rica, Cuba, Egypt, the United Arab Emirates, Ecuador, Estonia, Georgia, Hungary, Indonesia, the Islamic Republic of Iran, Iraq, Israel, Jordan, Kazakstan, Kuwait, Liberia, Malaysia, Moldova, Nigeria, Uzbekistan, Pakistan, the Philippines, Qatar, Syria, Kyrgyzstan, Slovakia, Romania, Russian Federation, Singapore, Somalia, Sri Lanka, Tajikistan, Turkmenistan, Ukraine, and Yugoslavia, the band 400.05–401 MHz is also allocated to the fixed and mobile services on a primary basis.

S5.263—The band 400.15–401 MHz is also allocated to the space research service in the space-to-space direction for communications with manned space vehicles. In this application, the space research service will not be regarded as a safety service.

S5.264—The use of the band 400.15–401 MHz by the mobile-satellite service is subject to coordination under No. **S9.11A**. The power flux-density limit indicated in Annex 1 of Appendix **S5** shall apply until such time as a competent world radiocommunication conference revises it.

S5.265—Not used.

S5.266—The use of the band 406–406.1 MHz by the mobile-satellite service is limited to low-power satellite emergency position-indicating radiobeacons (see also Article **S31** and Appendix **S13**).

S5.267—Any emission capable of causing harmful interference to the authorized uses of the band 406–406.1 MHz is prohibited.

S5.268—Use of the band 410–420 MHz by the space research service is limited to communications within 5 km of an orbiting, manned space vehicle. The power flux-density at the surface of the Earth produced by emissions from extra-vehicular activities shall not exceed -153 dB(W/m^2) for $0° \le \delta \le 5°$, $-153 + 0.077\,(\delta - 5)$ dB(W/m^2) for $5° \le \delta \le 70°$ and -148 dB(W/m^2) for $70° \le \delta \le 90°$, where δ is the angle of arrival of the radio-frequency wave and the reference bandwidth is 4 kHz. No. **S4.10** does not apply to extra-vehicular activities. In this frequency band the space research (space-to-space) service shall not claim protection from, nor constrain the use and development of, stations of the fixed and mobile services (WRC-97).

S5.269—*Different category of service:* in Australia, the United States, India, Japan, and the United Kingdom, the allocation of the bands 420–430 MHz and 440–450 MHz to the radiolocation service is on a primary basis (see No. **S5.33**).

S5.270—*Additional allocation:* in Australia, the United States, Jamaica, and the Philippines, the bands 420–430 MHz and 440–450 MHz are also allocated to the amateur service on a secondary basis.

S5.271—*Additional allocation:* in Azerbaijan, Belarus, China, Estonia, India, Latvia, Lithuania, Kyrgyzstan, Turkmenistan, and Ukraine, the band 420–460 MHz is also allocated to the aeronautical radionavigation service (radio altimeters) on a secondary basis (WRC-97).

S5.272—*Different category of service:* in France, the allocation of the band 430–434 MHz to the amateur service is on a secondary basis (see No. S5.32).

S5.273—*Different category of service:* in Denmark, Libya, and Norway, the allocation of the bands 430–432 MHz and 438–440 MHz to the radiolocation service is on a secondary basis (see No. **S5.32**).

S5.274—*Alternative allocation:* in Denmark, Norway, and Sweden, the bands 430–432 MHz and 438–440 MHz are allocated to the fixed and mobile, except aeronautical mobile, services on a primary basis.

S5.275—*Additional allocation:* in Bosnia and Herzegovina, Croatia, Estonia, Finland, Latvia, the former Yugoslav Republic of Macedonia, Libya, Slovenia, and Yugoslavia, the bands 430–432 MHz and 438–440 MHz are also allocated to the fixed and mobile, except aeronautical mobile, services on a primary basis (WRC-97).

S5.276—*Additional allocation:* in Afghanistan, Algeria, Saudi Arabia, Bahrain, Bangladesh, Brunei Darussalam, Burkina Faso, Burundi, Egypt, the United Arab Emirates, Ecuador, Eritrea, Ethiopia, Greece, Guinea, India, Indonesia, the Islamic Republic of Iran, Iraq, Israel, Italy, Jordan, Kenya, Kuwait, Lebanon, Libya, Liechtenstein, Malaysia, Malta, Nigeria, Oman, Pakistan, the Philippines, Qatar, Syria, Democratic People's Republic of Korea, Singapore, Somalia, Switzerland, Tanzania, Thailand, Togo, Turkey, and Yemen, the band 430–440 MHz is also allocated to the fixed service on a primary basis and the bands 430–435 MHz and 438–440 MHz are also allocated to the mobile, except aeronautical mobile, service on a primary basis (WRC-97).

S5.277—*Additional allocation:* in Angola, Armenia, Azerbaijan, Belarus, Cameroon, the Congo, Djibouti, Gabon, Georgia, Hungary, Kazakstan, Latvia, Mali, Moldova, Mongolia, Uzbekistan, Pakistan, Poland, Kyrgyzstan, Slovakia, the Czech Republic, Romania, Russian Federation, Rwanda, Tajikistan, Chad, Turkmenistan, and Ukraine, the band 430–440 MHz is also allocated to the fixed service on a primary basis (WRC-97).

S5.278—*Different category of service:* in Argentina, Colombia, Costa Rica, Cuba, Guyana, Honduras, Panama, and Venezuela, the allocation of the band 430–440 MHz to the amateur service is on a primary basis (see No. **S5.33**).

S5.279—*Additional allocation:* in Mexico, the bands 430–435 MHz and 438–440 MHz are also allocated on a primary basis to the land mobile service, subject to agreement obtained under No. **S9.21**.

S5.280—In Germany, Austria, Bosnia and Herzegovina, Croatia, The Former Yugoslav Republic of Macedonia, Liechtenstein, Portugal, Slovenia, Switzerland, and Yugoslavia, the band 433.05–434.79 MHz (centre frequency 433.92 MHz) is designated for industrial, scientific, and medical (ISM) applications. Radiocommunication services of these countries operating within this band must accept harmful interference which may be caused by these applications. ISM equipment operating in this band is subject to the provisions of No. **S15.13**.

S5.281—*Additional allocation:* in the French Overseas Departments in Region 2 and India, the band 433.75–434.25 MHz is also allocated to the space operation service (Earth-to-space) on a primary basis. In France and in Brazil, the band is allocated to the same service on a secondary basis.

S5.282—In the bands 435–438 MHz, 1260–1270 MHz, 2400–2450 MHz, 3400–3410 MHz (in Regions 2 and 3 only), and 5650–5670 MHz, the amateur-satellite service may operate subject to not causing harmful interference to other services operating in accordance with the Table (see No. **S5.43**). Administrations authorizing such use shall ensure that any harmful interference caused by emissions from a station in the amateur-satellite service is immediately eliminated in accordance with the provisions of No. **S25.11**. The use of the bands 1260–1270 MHz and 5650–5670 MHz by the amateur-satellite service is limited to the Earth-to-space direction.

S5.283—*Additional allocation:* in Austria, the band 438–440 MHz is also allocated to the fixed and mobile, except aeronautical mobile, services on a primary basis.

S5.284—*Additional allocation:* in Canada, the band 440–450 MHz is also allocated to the amateur service on a secondary basis.

S5.285—*Different category of service:* in Canada, the allocation of the band 440–450 MHz to the radiolocation service is on a primary basis (see No. **S5.33**).

S5.286—The band 449.75–450.25 MHz may be used for the space operation service (Earth-to-space) and the space research service (Earth-to-space), subject to agreement obtained under No. **S9.21**.

S5.286A—The use of the bands 454–456 MHz and 459–460 MHz by the mobile-satellite service is subject to coordination under No. **S9.11A** (WRC-97).

S5.286B—The use of the band 454–455 MHz in the countries listed in No. **S5.286D**, 455–456 MHz and 459–460 MHz in Region 2, and 454–456 MHz and 459–460 MHz in the countries listed in No. **S5.286E**, by stations in the mobile-satellite service, shall not cause harmful interference to, or claim protection from, stations of the fixed or mobile services operating in accordance with the Table of Frequency Allocations (WRC-97).

S5.286C—The use of the band 454–455 MHz in the countries listed in No. **S5.286D**, 455–456 MHz and 459–460 MHz in Region 2, and 454–456 MHz and 459–460 MHz in the countries listed in No. S5.286E, by stations in the mobile-satellite service, shall not constrain the development and use of the fixed and mobile services operating in accordance with the Table of Frequency Allocations (WRC-97).

S5.286D—*Additional allocation:* in Canada, the United States, Mexico, and Panama, the band 454–455 MHz is also allocated to the mobile-satellite service (Earth-to-space) on a primary basis (WRC-97).

S5.286E—*Additional allocation:* in Cape Verde, Indonesia, Nepal, Nigeria, and Papua New Guinea, the bands 454–456 MHz and 459–460 MHz are also allocated to the mobile-satellite (Earth-to-space) service on a primary basis (WRC-97).

S5.287—In the maritime mobile service, the frequencies 457.525 MHz, 457.550 MHz, 457.575 MHz, 467.525 MHz, 467.550 MHz, and 467.575 MHz may be used by on-board communication stations. Where needed, equipment designed for 12.5 kHz channel spacing using also the additional frequencies 457.5375 MHz, 457.5625 MHz, 467.5375 MHz, and 467.5625 MHz may be introduced for on-board communications. The use of these frequencies in territorial waters may be subject to the national regulations of the administration concerned. The characteristics of the equipment used shall conform to those specified in Recommendation ITU-R M.1174 (see Resolution 341 (WRC-97)) (WRC-97).

S5.288—In the territorial waters of the United States and the Philippines, the preferred frequencies for use by on-board communication stations shall be 457.525 MHz, 457.550 MHz, 457.575 MHz, and 457.600 MHz paired, respectively, with 467.750 MHz, 467.775 MHz, 467.800 MHz, and 467.825 MHz. The characteristics of the equipment used shall conform to those specified in Recommendation ITU-R M.1174.

S5.289—Earth exploration-satellite service applications, other than the meteorological-satellite service, may also be used in the bands 460–470 MHz and 1690–1710 MHz for space-to-Earth transmissions subject to not causing harmful interference to stations operating in accordance with the Table.

S5.290—*Different category of service:* in Afghanistan, Armenia, Azerbaijan, Belarus, China, Japan, Kazakstan, Mongolia, Uzbekistan, Kyrgyzstan, Slovakia, the Czech Republic, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the allocation of the band 460–470 MHz to the meteorological-satellite service (space-to-Earth) is on a primary basis (see No. **S5.33**), subject to agreement obtained under No. **S9.21** (WRC-97).

S5.291—*Additional allocation:* in China, the band 470–485 MHz is also allocated to the space research (space-to-Earth) and the space operation (space-to-Earth) services on a primary basis subject to agreement obtained under No. **S9.21**

and subject to not causing harmful interference to existing and planned broadcasting stations.

S5.291A—*Additional allocation:* in Germany, Austria, Denmark, Estonia, Finland, Liechtenstein, Norway, the Netherlands, the Czech Republic and Switzerland, the band 470–494 MHz is also allocated to the radiolocation service on a secondary basis. This use is limited to the operation of wind profiler radars in accordance with Resolution 217 (WRC-97) (WRC-97).

S5.292—*Different category of service:* in Mexico, and Venezuela, the allocation of the band 470–512 MHz to the fixed and mobile services, and in Argentina and Uruguay to the mobile service, is on a primary basis (see No. **S5.33**), subject to agreement obtained under No. **S9.21**.

S5.293—*Different category of service:* in Chile, Colombia, Cuba, the United States, Guyana, Honduras, Jamaica, Mexico, and Panama, the allocation of the bands 470–512 MHz and 614–806 MHz to the fixed and mobile services is on a primary basis (see No. **S5.33**), subject to agreement obtained under No. **S9.21**.

S5.294—*Additional allocation:* in Burundi, Cameroon, the Congo, Ethiopia, Israel, Kenya, Lebanon, Libya, Malawi, Senegal, Sudan, Syria, and Yemen, the band 470–582 MHz is also allocated to the fixed service on a secondary basis.

S5.295—Not used.

S5.296—*Additional allocation:* in Germany, Austria, Belgium, Cyprus, Denmark, Spain, Finland, France, Ireland, Israel, Italy, Libya, Malta, Morocco, Monaco, Norway, the Netherlands, Portugal, Syria, the United Kingdom, Sweden, Switzerland, Swaziland, and Tunisia, the band 470–790 MHz is also allocated on a secondary basis to the land mobile service, intended for applications ancillary to broadcasting. Stations of the land mobile service in the countries listed in this footnote shall not cause harmful interference to existing or planned stations operating in accordance with the Table of Frequency Allocations in countries other than those listed in this footnote (WRC-97).

S5.297—*Additional allocation:* in Costa Rica, Cuba, El Salvador, the United States, Guatemala, Guyana, Honduras, Jamaica, Mexico and Venezuela, the band 512–608 MHz is also allocated to the fixed and mobile services on a primary basis, subject to agreement obtained under No. **S9.21**.

S5.298—*Additional allocation:* in India, the band 549.75–550.25 MHz is also allocated to the space operation service (space-to-Earth) on a secondary basis.

S5.299—Not used.

S5.300—*Additional allocation:* in Israel, Libya, Syria, and Sudan, the band 582–790 MHz is also allocated to the fixed and mobile, except aeronautical mobile, services on a secondary basis.

S5.301—Not used.

S5.302—*Additional allocation:* in the United Kingdom, the band 590–598 MHz is also allocated to the aeronautical radionavigation service on a primary basis. All new assignments to stations in the aeronautical radionavigation service, including those transferred from the adjacent bands, shall be subject to coordination with the Administrations of the following countries: Germany, Belgium, Denmark, Spain, France, Ireland, Luxembourg, Morocco, Norway, and the Netherlands.

S5.303—Not used.

S5.304—*Additional allocation:* in the African Broadcasting Area (see Nos. **S5.10** to **S5.13**), the band 606–614 MHz is also allocated to the radio astronomy service on a primary basis.

S5.305—*Additional allocation:* in China, the band 606–614 MHz is also allocated to the radio astronomy service on a primary basis.

S5.306—*Additional allocation:* in Region 1, except in the African Broadcasting Area (see Nos. **S5.10** to **S5.13**), and in Region 3, the band 608–614 MHz is also allocated to the radio astronomy service on a secondary basis.

S5.307—*Additional allocation:* in India, the band 608–614 MHz is also allocated to the radio astronomy service on a primary basis.

S5.308—Not used.

S5.309—*Different category of service:* in Costa Rica, El Salvador, and Honduras, the allocation of the band 614–806 MHz to the fixed service is on a primary basis (see No. **S5.33**), subject to agreement obtained under No. **S9.21**.

S5.310—SUP-WRC-97.

S5.311—Within the frequency band 620–790 MHz, assignments may be made to television stations using frequency modulation in the broadcasting-satellite service subject to agreement between the administrations concerned and those having services, operating in accordance with the Table, which may be affected (see Resolutions 33 (Rev. WRC-97) and 507). Such stations shall not produce a power flux-density in excess of the value -129 dB(W/m^2) for angles of arrival less than 20° (see Recommendation 705) within the territories of other countries without the consent of the administrations of those countries.

S5.312—*Additional allocation:* in Armenia, Azerbaijan, Belarus, Bulgaria, Georgia, Hungary, Kazakstan, Latvia, Moldova, Mongolia, Uzbekistan, Poland, Kyrgyzstan, Slovakia, the Czech Republic, Romania, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the band 645–862 MHz is also allocated to the aeronautical radionavigation service on a primary basis (WRC-97).

S5.313—SUP - WRC-97.

S5.314—*Additional allocation:* in Austria, Italy, Uzbekistan, the United Kingdom, and Swaziland, the band 790–862 MHz is also allocated to the land mobile service on a secondary basis (WRC-97).

S5.315—*Alternative allocation:* in Greece, Italy, Morocco, and Tunisia, the band 790–838 MHz is allocated to the broadcasting service on a primary basis.

S5.316—*Additional allocation:* in Germany, Bosnia and Herzegovina, Burkina Faso, Cameroon, Côte d'Ivoire, Croatia, Denmark, Egypt, Finland, Israel, Kenya, the former Yugoslav Republic of Macedonia, Libya, Liechtenstein, Monaco, Norway, the Netherlands, Portugal, Syria, Sweden, Switzerland, and Yugoslavia, the band 790–830 MHz, and in these same countries and in Spain, France, Gabon, and Malta, the band 830–862 MHz, are also allocated to the mobile, except aeronautical mobile, service on a primary basis. However, stations of the mobile service in the countries mentioned in connection with each band referred to in this footnote shall not cause harmful interference to, or claim protection from, stations of services operating in accordance with the Table in

countries other than those mentioned in connection with the band (WRC-97).

S5.317—*Additional allocation:* in Region 2 (except Brazil and the United States), the band 806–890 MHz is also allocated to the mobile-satellite service on a primary basis, subject to agreement obtained under No. **S9.21**. The use of this service is intended for operation within national boundaries.

S5.318—*Additional allocation:* in Canada, the United States, and Mexico, the bands 849–851 MHz and 894–896 MHz are also allocated to the aeronautical mobile service on a primary basis, for public correspondence with aircraft. The use of the band 849–851 MHz is limited to transmissions from aeronautical stations and the use of the band 894–896 MHz is limited to transmissions from aircraft stations.

S5.319—*Additional allocation:* in Belarus, Russian Federation, and Ukraine, the bands 806–840 MHz (Earth-to-space) and 856–890 MHz (space-to-Earth) are also allocated to the mobile-satellite, except aeronautical mobile-satellite (R), service. The use of these bands by this service shall not cause harmful interference to, or claim protection from, services in other countries operating in accordance with the Table of Frequency Allocations and is subject to special agreements between the administrations concerned.

S5.320—*Additional allocation:* in Region 3, the bands 806–890 MHz and 942–960 MHz are also allocated to the mobile-satellite, except aeronautical mobile-satellite (R), service on a primary basis, subject to agreement obtained under No. **S9.21**. The use of this service is limited to operation within national boundaries. In seeking such agreement, appropriate protection shall be afforded to services operating in accordance with the Table, to ensure that no harmful interference is caused to such services.

S5.321—*Alternative allocation:* in Italy, the band 838–854 MHz is allocated to the broadcasting service on a primary basis as from January 1, 1995.

S5.322—In Region 1, in the band 862–960 MHz, stations of the broadcasting service shall be operated only in the African Broadcasting Area (see Nos. **S5.10** to **S5.13**) excluding Algeria, Egypt, Spain, Libya, Morocco, Nigeria, South Africa, Tanzania, and Zimbabwe, subject to agreement obtained under No. **S9.21** (WRC-97).

S5.323—*Additional allocation:* in Armenia, Azerbaijan, Belarus, Bulgaria, Hungary, Kazakstan, Latvia, Moldova, Mongolia, Uzbekistan, Poland, Kyrgyzstan, Slovakia, the Czech Republic, Romania, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the band 862–960 MHz is also allocated to the aeronautical radionavigation service on a primary basis. Such use is subject to agreement obtained under No. **S9.21** with administrations concerned and limited to ground-based radiobeacons in operation on 27 October 1997 until the end of their lifetime (WRC-97).

S5.324—Not used.

S5.325—*Different category of service:* in the United States, the allocation of the band 890–942 MHz to the radiolocation service is on a primary basis (see No. **S5.33**), subject to agreement obtained under No. **S9.21**.

S5.326—*Different category of service:* in Chile, the band 903–905 MHz is allocated to the mobile, except aeronautical mobile, service on a primary basis, subject to agreement obtained under No. **S9.21**.

S5.327—*Different category of service:* in Australia, the allocation of the band 915–928 MHz to the radiolocation service is on a primary basis (see No. **S5.33**).

S5.328—The band 960–1215 MHz is reserved on a worldwide basis for the use and development of airborne electronic aids to air navigation and any directly associated ground-based facilities.

S5.329—Use of the radionavigation-satellite service in the band 1215–1260 MHz shall be subject to the condition that no harmful interference is caused to the radionavigation service authorized under No. **S5.331**.

S5.330—*Additional allocation:* in Angola, Saudi Arabia, Bahrain, Bangladesh, Cameroon, China, the United Arab Emirates, Eritrea, Ethiopia, Guyana, India, Indonesia, the Islamic Republic of Iran, Iraq, Israel, Japan, Jordan, Kuwait, Lebanon, Libya, Morocco, Mozambique, Nepal, Nigeria, Pakistan, the Philippines, Qatar, Syria, Somalia, Sudan, Sri Lanka, Chad, Togo, and Yemen, the band 1215–1300 MHz is also allocated to the fixed and mobile services on a primary basis (WRC-97).

S5.331—*Additional allocation:* in Algeria, Germany, Austria, Bahrain, Belgium, Benin, Bosnia and Herzegovina, Burundi, Cameroon, China, Croatia, Denmark, the United Arab Emirates, France, Greece, India, the Islamic Republic of Iran, Iraq, Kenya, the former Yugoslav Republic of Macedonia, Liechtenstein, Luxembourg, Mali, Mauritania, Norway, Oman, Pakistan, the Netherlands, Portugal, Qatar, Senegal, Slovenia, Somalia, Sudan, Sri Lanka, Sweden, Switzerland, Turkey, and Yugoslavia, the band 1215–1300 MHz is also allocated to the radionavigation service on a primary basis.

S5.332—In the band 1215–1300 MHz, active spaceborne sensors in the earth exploration-satellite and space research services shall not cause harmful interference to, claim protection from, or otherwise impose constraints on operation or development of the radiolocation service, the radionavigation-satellite service, and other services allocated on a primary basis (WRC-97).

S5.333—SUP - WRC-97.

S5.334—*Additional allocation:* in Canada and the United States, the bands 1240–1300 MHz and 1350–1370 MHz are also allocated to the aeronautical radionavigation service on a primary basis.

S5.335—In Canada and the United States in the band 1240–1300 MHz, active spaceborne sensors in the earth exploration-satellite and space research services shall not cause interference to, claim protection from, or otherwise impose constraints on operation or development of the aeronautical radionavigation service (WRC-97).

S5.336—Not used.

S5.337—The use of the bands 1 300–1350 MHz, 2700–2900 MHz, and 9000–9200 MHz by the aeronautical radionavigation service is restricted to ground-based radars and to associated airborne transponders which transmit only on frequencies in these bands and only when actuated by radars operating in the same band.

S5.338—In Azerbaijan, Bulgaria, Mongolia, Poland, Kyrgyzstan, Slovakia, the Czech Republic, Romania, Turkmenistan, and Ukraine, existing installations of the radionavigation

service may continue to operate in the band 1350–1400 MHz (WRC-97).

S5.339—The bands 1370–1400 MHz, 2640–2655 MHz, 4950–4990 MHz, and 15.20–15.35 GHz are also allocated to the space research (passive) and earth exploration-satellite (passive) services on a secondary basis.

S5.340—All emissions are prohibited in the following bands:

1400–1427 MHz,
2690–2700 MHz, except those provided for by Nos. **S5.421** and **S5.422**,
10.68–10.7 GHz, except those provided for by No. **S5.483**,
15.35–15.4 GHz, except those provided for by No. **S5.511**,
23.6–24 GHz,
31.3–31.5 GHz,
31.5–31.8 GHz, in Region 2,
48.94–49.04 GHz, from airborne stations, 50.2–50.4 GHz,* except those provided for by No. **S5.555A**,
52.6–54.25 GHz,
86–92 GHz,
105–116 GHz,
140.69–140.98 GHz, from airborne stations and from space stations in the space-to-Earth direction,
182–185 GHz, except those provided for by No. **S5.563**,
217–231 GHz

S5.341—In the bands 1400–1727 MHz, 101–120 GHz, and 197–220 GHz, passive research is being conducted by some countries in a program for the search for intentional emissions of extraterrestrial origin.

S5.342—*Additional allocation:* in Belarus, Russian Federation, and Ukraine, the band 1429–1535 MHz is also allocated to the aeronautical mobile service on a primary basis exclusively for the purposes of aeronautical telemetry within the national territory. As of April 1, 2007, the use of the band 1452–1492 MHz is subject to agreement between the administrations concerned.

S5.343—In Region 2, the use of the band 1435–1535 MHz by the aeronautical mobile service for telemetry has priority over other uses by the mobile service.

S5.344—*Alternative allocation:* in the United States, the band 1452–1525 MHz is allocated to the fixed and mobile services on a primary basis (see also No. **S5.343**).

S5.345—Use of the band 1452–1492 MHz by the broadcasting-satellite service, and by the broadcasting service, is limited to digital audio broadcasting and is subject to the provisions of Resolution 528 (WARC-92).

S5.346—Not used.

S5.347—*Different category of service:* in Bangladesh, Bosnia and Herzegovina, Botswana, Bulgaria, Burkina Faso, Cuba, Denmark, Egypt, Greece, Ireland, Italy, Jordan, Kenya, Mozambique, Portugal, Sri Lanka, Swaziland, Yemen, Yugoslavia, and Zimbabwe, the allocation of the band 1452–1492 MHz to the broadcasting-satellite service and the broadcasting service is on a secondary basis until April 1, 2007 (WRC-97).

S5.348—The use of the band 1492–1525 MHz by the mobile-satellite service is subject to coordination under No. **S9.11A**. However, no coordination threshold in Article **S21** for space stations of the mobile-satellite service with respect to terrestrial services shall apply to the situation referred to in No. **S5.343**. With respect to the situation referred to in No. **S5.343**, the requirement for coordination in the band 1492–1525 MHz will be determined by band overlap.

S5.348A—In the band 1492–1525 MHz, the coordination threshold in terms of the power flux-density levels at the surface of the Earth in application of No. **S.9.11A** for space stations in the mobile-satellite (space-to-Earth) service, with respect to the land mobile service use for specialized mobile radios or used in conjunction with public switched telecommunication networks (PSTN) operating within the territory of Japan, shall be -150 dB(W/m^2) in any 4 kHz band for all angles of arrival, instead of those given in Table S5-2 of Appendix **S5**. The above threshold level of the power flux-density shall apply until it is changed by a competent world radiocommunication conference.

S5.349—*Different category of service:* in Saudi Arabia, Azerbaijan, Bahrain, Bosnia, and Herzegovina, Cameroon, Egypt, the United Arab Emirates, France, the Islamic Republic of Iran, Iraq, Israel, Kazakstan, Kuwait, the former Yugoslav Republic of Macedonia, Lebanon, Morocco, Mongolia, Oman, Qatar, Syria, Kyrgyzstan, Romania, Turkmenistan, Ukraine, Yemen, and Yugoslavia, the allocation of the band 1525–1530 MHz to the mobile, except aeronautical mobile, service is on a primary basis (see No. **S5.33**) (WRC-97).

S5.350—*Additional allocation:* in Azerbaijan, Kyrgyzstan, Turkmenistan, and Ukraine, the band 1525–1530 MHz is also allocated to the aeronautical mobile service on a primary basis (WRC-97).

S5.351—The bands 1525–1544 MHz, 1545–1559 MHz, 1626.5–1645.5 MHz, and 1646.5–1660.5 MHz shall not be used for feeder links of any service. In exceptional circumstances, however, an earth station at a specified fixed point in any of the mobile-satellite services may be authorized by an administration to communicate via space stations using these bands.

S5.352—SUP - WRC-97.

S5.352A—In the band 1525–1530 MHz, stations in the mobile-satellite service, except stations in the maritime mobile-satellite service, shall not cause harmful interference to, or claim protection from, stations of the fixed service in France and French Overseas Territories in Region 3, Algeria, Saudi Arabia, Egypt, Guinea, India, Israel, Italy, Jordan, Kuwait, Mali, Malta, Morocco, Mauritania, Nigeria, Oman, Pakistan, Philippines, Qatar, Syria, Tanzania, Viet Nam, and Yemen notified prior to 1 April 1998 (WRC-97).

S5.353—SUP - WRC-97.

S5.353A—In applying the procedures of No. **S9.11A** to the mobile-satellite service in the bands 1530–1544 MHz and 1626.5–1645.5 MHz, priority shall be given to accommodating the spectrum requirements for distress, urgency, and safety communications of the Global Maritime Distress and

* The allocation to the earth exploration-satellite service (passive) and the space research service (passive) in the band 50.2–50.4 GHz should not impose undue constraints on the use of the adjacent bands by the primary allocated services in those bands (WRC-97).

Safety System (GMDSS). Maritime mobile-satellite distress, urgency, and safety communications shall have priority access and immediate availability over all other mobile satellite communications operating within a network. Mobile-satellite systems shall not cause unacceptable interference to, or claim protection from, distress, urgency, and safety communications of the GMDSS. Account shall be taken of the priority of safety-related communications in the other mobile-satellite services (WRC-97). (See Resolution 218 (WRC-97).)

S5.354—The use of the bands 1525–1559 MHz and 1626.5–1660.5 MHz by the mobile-satellite services is subject to coordination under No. **S9.11A**.

S5.355—*Additional allocation:* in Bahrain, Bangladesh, the Congo, Egypt, the United Arab Emirates, Eritrea, Ethiopia, the Islamic Republic of Iran, Iraq, Israel, Jordan, Kuwait, Lebanon, Malta, Morocco, Oman, Qatar, Syria, Somalia, Sudan, Sri Lanka, Chad, Togo, Yemen, and Zambia, the bands 1540–1645.5 MHz and 1646.5–1660 MHz are also allocated to the fixed service on a secondary basis (WRC-97).

S5.356—The use of the band 1544–1545 MHz by the mobile-satellite service (space-to-Earth) is limited to distress and safety communications (see Article **S31**).

S5.357—Transmissions in the band 1545–1555 MHz from terrestrial aeronautical stations directly to aircraft stations, or between aircraft stations, in the aeronautical mobile (R) service are also authorized when such transmissions are used to extend or supplement the satellite-to-aircraft links.

S5.357A—In applying the procedures of No. **S9.11A** to the mobile-satellite service in the bands 1545–1555 MHz and 1646.5–1656.5 MHz, priority shall be given to accommodating the spectrum requirements of the aeronautical mobile-satellite (R) service providing transmission of messages with priority 1 to 6 in Article **S44**. Aeronautical mobile-satellite (R) service communications with priority 1 to 6 in Article **S44** shall have priority access and immediate availability, by preemption if necessary, over all other mobile-satellite communications operating within a network. Mobile-satellite systems shall not cause unacceptable interference to, or claim protection from, aeronautical mobile-satellite (R) service communications with priority 1 to 6 in Article **S44**. Account shall be taken of the priority of safety-related communications in the other mobile-satellite services (WRC-97) (See Resolution 218 (WRC-97)); (WRC-97).

S5.358—SUP-WRC-97.

S5.359—*Additional allocation:* in Germany, Saudi Arabia, Armenia, Austria, Azerbaijan, Belarus, Benin, Bulgaria, Cameroon, Spain, France, Gabon, Georgia, Greece, Guinea, Guinea-Bissau, Hungary, Jordan, Kazakstan, Kuwait, Latvia, Libya, Mali, Mauritania, Moldova, Mongolia, Nigeria, Uganda, Uzbekistan, Pakistan, Poland, Syria, Kyrgyzstan, the Democratic People's Republic of Korea, Romania, Russian Federation, Senegal, Swaziland, Tajikistan, Tanzania, Turkmenistan, Ukraine, Zambia, and Zimbabwe the bands 1550–1645.5 MHz and 1646.5–1660 MHz are also allocated to the fixed service on a primary basis. Administrations are urged to make all practicable efforts to avoid the implementation of new fixed-service stations in the bands 1550–1555 MHz, 1610–1645.5 MHz, and 1646.5–1660 MHz.

S5.360 to **S5.362**–SUP-WRC-97.

S5.362A—In the United States, in the bands 1555–1559 MHz and 1656.5–1660.5 MHz, the aeronautical mobile-satellite (R) service shall have priority access and immediate availability, by preemption if necessary, over all other mobile-satellite communications operating within a network. Mobile-satellite systems shall not cause unacceptable interference to, or claim protection from, aeronautical mobile-satellite (R) service communications with priority 1 to 6 in Article **S44**. Account shall be taken of the priority of safety-related communications in the other mobile-satellite services (WRC-97).

S5.363—*Alternative allocation:* in Sweden, the band 1590–1626.5 MHz is allocated to the aeronautical radionavigation service on a primary basis.

S5.364—The use of the band 1610–1626.5 MHz by the mobile-satellite service (Earth-to-space) and by the radiodetermination-satellite service (Earth-to-space) is subject to coordination under No. **S9.11A**. A mobile earth station operating in either of the services in this band shall not produce a peak eirp density in excess of –15 dB(W/4 kHz) in the part of the band used by systems operating in accordance with the provisions of No. **S5.366** (to which No. **S4.10** applies), unless otherwise agreed by the affected administrations. In the part of the band where such systems are not operating, the mean eirp density of a mobile earth station shall not exceed –3 dB(W/4 kHz). Stations of the mobile-satellite service shall not claim protection from stations in the aeronautical radionavigation service, stations operating in accordance with the provisions of No. **S5.366**, and stations in the fixed service operating in accordance with the provisions of No. **S5.359**. Administrations responsible for the coordination of mobile-satellite networks shall make all practicable efforts to ensure protection of stations operating in accordance with the provisions of No. **S5.366**.

S5.365—The use of the band 1613.8–1626.5 MHz by the mobile-satellite service (space-to-Earth) is subject to coordination under No. **S9.11A**.

S5.366—The band 1610–1626.5 MHz is reserved on a worldwide basis for the use and development of airborne electronic aids to air navigation and any directly associated ground-based or satellite-borne facilities. Such satellite use is subject to agreement obtained under No. **S9.21**.

S5.367—*Additional allocation:* The bands 1610–1626.5 MHz and 5000–5150 MHz are also allocated to the aeronautical mobile-satellite (R) service on a primary basis, subject to agreement obtained under No. **S9.21**.

S5.368—With respect to the radiodetermination-satellite and mobile-satellite services the provisions of No. **S4.10** do not apply in the band 1610–1626.5 MHz, with the exception of the aeronautical radionavigation-satellite service.

S5.369—*Different category of service:* in Angola, Australia, Burundi, China, Côte d'Ivoire, Eritrea, Ethiopia, India, the Islamic Republic of Iran, Israel, Jordan, Lebanon, Liberia, Libya, Madagascar, Mali, Pakistan, Papua New Guinea, Dem. Rep. of the Congo, Syria, Senegal, Sudan, Swaziland, Togo, and Zambia, the allocation of the band 1610–1626.5 MHz to the radiodetermination-satellite service (Earth-to-space) is on a primary basis (see No. **S5.33**), subject to agreement obtained under No. **S9.21** from countries not listed in this provision (WRC-97).

S5.370—*Different category of service:* in Venezuela, the allocation to the radiodetermination-satellite service in the band 1610–1626.5 MHz (Earth-to-space) is on a secondary basis.

S5.371—*Additional allocation:* in Region 1, the bands 1610–1626.5 MHz (Earth-to-space) and 2483.5–2500 MHz (space-to-Earth) are also allocated to the radiodetermination-satellite service on a secondary basis, subject to agreement obtained under No. **S9.21**.

S5.372—Harmful interference shall not be caused to stations of the radio astronomy service using the band 1610.6–1613.8 MHz by stations of the radiodetermination-satellite and mobile-satellite services (No. **S29.13** applies).

S5.373—Not used.

S5.373A—SUP-WRC-97.

S5.374—Mobile earth stations in the mobile-satellite service operating in the bands 1631.5–1634.5 MHz and 1656.5–1660 MHz shall not cause harmful interference to stations in the fixed service operating in the countries listed in No. **S5.359** (WRC-97).

S5.375—The use of the band 1645.5–1646.5 MHz by the mobile-satellite service (Earth-to-space) and for inter-satellite links is limited to distress and safety communications (see Article **S31**).

S5.376—Transmissions in the band 1646.5–1656.5 MHz from aircraft stations in the aeronautical mobile (R) service directly to terrestrial aeronautical stations, or between aircraft stations, are also authorized when such transmissions are used to extend or supplement the aircraft-to-satellite links.

S5.376A—Mobile earth stations operating in the band 1660–1660.5 MHz shall not cause harmful interference to stations in the radio astronomy service (WRC-97).

S5.377—In the band 1675–1710 MHz, stations in the mobile-satellite service shall not cause harmful interference to, nor constrain the development of, the meteorological-satellite and meteorological aids services (see Resolution 213 (Rev. WRC-95)) and the use of this band shall be subject to coordination under No. **S9.11A**.

S5.378—Not used.

S5.379—*Additional allocation:* in Bangladesh, India, Indonesia, Nigeria, and Pakistan, the band 1660.5–1668.4 MHz is also allocated to the meteorological aids service on a secondary basis.

S5.379A—Administrations are urged to give all practicable protection in the band 1660.5–1668.4 MHz for future research in radio astronomy, particularly by eliminating air-to-ground transmissions in the meteorological aids service in the band 1664.4–1668.4 MHz as soon as practicable.

S5.380—The bands 1670–1675 MHz and 1800–1805 MHz are intended for use, on a worldwide basis, by administrations wishing to implement aeronautical public correspondence. The use of the band 1670–1675 MHz by stations in the systems for public correspondence with aircraft is limited to transmissions from aeronautical stations and the use of the band 1800–1805 MHz is limited to transmissions from aircraft stations.

S5.381—*Additional allocation:* in Afghanistan, Costa Rica, Cuba, India, the Islamic Republic of Iran, Malaysia, Pakistan, and Sri Lanka, the band 1690–1700 MHz is also allocated to the fixed and mobile, except aeronautical mobile, services on a primary basis (WRC-97).

S5.382—*Different category of service:* in Saudi Arabia, Armenia, Austria, Azerbaijan, Bahrain, Belarus, Bosnia and Herzegovina, Bulgaria, the Congo, Egypt, the United Arab Emirates, Eritrea, Ethiopia, Guinea, Hungary, Iraq, Israel, Jordan, Kazakstan, Kuwait, the former Yugoslav Republic of Macedonia, Lebanon, Mauritania, Moldova, Mongolia, Oman, Uzbekistan, Poland, Qatar, Syria, Kyrgyzstan, Romania, Russian Federation, Somalia, Tajikistan, Tanzania, Turkmenistan, Ukraine, Yemen and Yugoslavia, the allocation of the band 1690–1700 MHz to the fixed and mobile, except aeronautical mobile, services is on a primary basis (see No. **S5.33**), and in the Democratic People's Republic of Korea, the allocation of the band 1690–1700 MHz to the fixed service is on a primary basis (see No. **S5.33**) and to the mobile, except aeronautical mobile, service on a secondary basis (WRC-97).

S5.383—Not used.

S5.384—*Additional allocation:* in India, Indonesia, and Japan, the band 1700–1710 MHz is also allocated to the space research service (space-to-Earth) on a primary basis (WRC-97).

S5.385—*Additional allocation:* The bands 1718.8–1722.2 MHz, 150–151 GHz, 174.42–175.02 GHz, 177–177.4 GHz, 178.2–178.6 GHz, 181–181.46 GHz, 186.2–186.6 GHz, and 257.5–258 GHz are also allocated to the radio astronomy service on a secondary basis for spectral line observations.

S5.386—*Additional allocation:* The band 1750–1850 MHz is also allocated to the space operation (Earth-to-space) and space research (Earth-to-space) services in Region 2, in Australia, India, Indonesia, and Japan on a primary basis, subject to agreement obtained under No. **S9.21**, having particular regard to troposcatter systems.

S5.387—*Additional allocation:* in Armenia, Azerbaijan, Belarus, Georgia, Kazakstan, Mali, Mongolia, Uzbekistan, Kyrgyzstan, Slovakia, the Czech Republic, Romania, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the band 1770–1790 MHz is also allocated to the meteorological-satellite service on a primary basis, subject to agreement obtained under No. **S9.21** (WRC-97).

S5.388—The bands 1885–2025 MHz and 2110–2200 MHz are intended for use, on a worldwide basis, by administrations wishing to implement International Mobile Telecommunications-2000 (IMT-2000). Such use does not preclude the use of these bands by other services to which they are allocated. The bands should be made available for IMT-2000 in accordance with Resolution 212 (Rev. WRC-97) (WRC-97).

S5.389—Not used.

S5.389A—The use of the bands 1980–2010 MHz and 2170–2200 MHz by the mobile-satellite service is subject to coordination under No. **S9.11A** and to the provisions of Resolution 716 (WRC-95). The use of these bands shall not commence before January 1, 2000; however, the use of the band 1980–1990 MHz in Region 2 shall not commence before January 1, 2005.

S5.389B—The use of the band 1980–1990 MHz by the mobile-satellite service shall not cause harmful interference to or constrain the development of the fixed and mobile services in Argentina, Brazil, Canada, Chile, Ecuador, the United

States, Honduras, Jamaica, Mexico, Peru, Suriname, Trinidad and Tobago, Uruguay, and Venezuela.

S5.389C—The use of the bands 2010–2025 MHz and 2160–2170 MHz in Region 2 by the mobile-satellite service shall not commence before January 1, 2002 and is subject to coordination under No. **S9.11A** and to the provisions of Resolution 716 (WRC-95) (WRC-97).

S5.389D—In Canada and the United States the use of the bands 2010–2025 MHz and 2160–2170 MHz by the mobile-satellite service shall not commence before January 1, 2000.

S5.389E—The use of the bands 2010–2025 MHz and 2160–2170 MHz by the mobile-satellite service in Region 2 shall not cause harmful interference to or constrain the development of the fixed and mobile services in Regions 1 and 3.

S5.389F—In Algeria, Benin, Cape Verde, Egypt, Mali, Syria, and Tunisia, the use of the bands 1980–2010 MHz and 2170–2200 MHz by the mobile-satellite service shall neither cause harmful interference to the fixed and mobile services nor hamper the development of those services prior to January 1, 2005, nor shall the former service request protection from the latter services.

S5.390—In Argentina, Brazil, Chile, Colombia, Cuba, Ecuador, and Suriname, the use of the bands 2010–2025 MHz and 2160–2170 MHz by the mobile-satellite services shall not cause harmful interference to stations in the fixed and mobile services before January 1, 2005. After this date, the use of these bands is subject to coordination under No. **S9.11A** and to the provisions of Resolution 716 (WRC-95) (WRC-97).

S5.391—In making assignments to the mobile service in the bands 2025–2110 MHz and 2200–2290 MHz, administrations shall not introduce high-density mobile systems, as described in Recommendation ITU-R SA.1154, and shall take that Recommendation into account for the introduction of any other type of mobile system (WRC-97).

S5.392—Administrations are urged to take all practicable measures to ensure that space-to-space transmissions between two or more nongeostationary satellites, in the space research, space operations, and Earth exploration-satellite services in the bands 2025–2110 MHz and 2200–2290 MHz, shall not impose any constraints on Earth-to-space, space-to-Earth, and other space-to-space transmissions of those services and in those bands between geostationary and nongeostationary satellites.

S5.392A—*Additional allocation:* in Russian Federation, the band 2160–2200 MHz is also allocated to the space research service (space-to-Earth) on a primary basis until 1 January 2005. Stations in the space research service shall not cause harmful interference to, or claim protection from, stations in the fixed and mobile services operating in this frequency band.

S5.393—*Additional allocation:* in the United States, India, and Mexico, the band 2310–2360 MHz is also allocated to the broadcasting-satellite service (sound) and complementary terrestrial sound broadcasting service on a primary basis. Such use is limited to digital audio broadcasting and is subject to the provisions of Resolution 528(WARC-92) (WRC-97).

S5.394—In the United States, the use of the band 2300–2390 MHz by the aeronautical mobile service for telemetry has priority over other uses by the mobile services. In Canada, the use of the band 2300–2483.5 MHz by the aeronautical mobile service for telemetry has priority over other uses by the mobile services.

S5.395—In France, the use of the band 2310–2360 MHz by the aeronautical mobile service for telemetry has priority over other uses by the mobile service.

S5.396—Space stations of the broadcasting-satellite service in the band 2310–2360 MHz operating in accordance with No. **S5.393** that may affect the services to which this band is allocated in other countries shall be coordinated and notified in accordance with Resolution 33 (Rev. WRC-97). Complementary terrestrial broadcasting stations shall be subject to bilateral coordination with neighbouring countries prior to their being brought into use.

S5.397—*Different category of service:* in France, the band 2450–2500 MHz is allocated on a primary basis to the radiolocation service (see No. **S5.33**). Such use is subject to agreement with administrations having services operating or planned to operate in accordance with the Table of Frequency Allocations which may be affected.

S5.398—In respect of the radiodetermination-satellite service in the band 2483.5–2500 MHz, the provisions of No. **S4.10** do not apply.

S5.399—In Region 1, in countries other than those listed in No. **S5.400**, harmful interference shall not be caused to, or protection shall not be claimed from, stations of the radiolocation service by stations of the radiodetermination-satellite service.

S5.400—*Different category of service:* in Angola, Australia, Bangladesh, Burundi, China, Eritrea, Ethiopia, India, the Islamic Republic of Iran, Jordan, Lebanon, Liberia, Libya, Madagascar, Mali, Pakistan, Papua New Guinea, Democratic Republic of the Congo, Syria, Sudan, Swaziland, Togo, and Zambia, the allocation of the band 2483.5–2500 MHz to the radiodetermination-satellite service (space-to-Earth) is on a primary basis (see No. **S5.33**), subject to agreement obtained under No. **S9.21** from countries not listed in this provision (WRC-97).

S5.401—Not used.

S5.402—The use of the band 2483.5–2500 MHz by the mobile-satellite and the radiodetermination-satellite services is subject to the coordination under No. **S9.11A**. Administrations are urged to take all practicable steps to prevent harmful interference to the radio astronomy service from emissions in the 2483.5–2500 MHz band, especially those caused by second-harmonic radiation that would fall into the 4990–5000 MHz band allocated to the radio astronomy service worldwide.

S5.403—Subject to agreement obtained under No. **S9.21**, the band 2520–2535 MHz (until 1 January 2005 the band 2500–2535 MHz) may also be used for the mobile-satellite (space-to-Earth), except aeronautical mobile-satellite, service for operation limited to within national boundaries. The provisions of No. **S9.11A** apply.

S5.404—*Additional allocation:* in India and the Islamic Republic of Iran, the band 2500–2516.5 MHz may also be used for the radiodetermination-satellite service (space-to-Earth) for operation limited to within national boundaries, subject to agreement obtained under No. **S9.21**.

S5.405—*Additional allocation:* in France, the band 2500–2550 MHz is also allocated to the radiolocation service on a

primary basis. Such use is subject to agreement with the administrations having services operating or planned to operate in accordance with the Table which may be affected.

S5.406—Not used.

S5.407—In the band 2500–2520 MHz, the power flux-density at the surface of the Earth from space stations operating in the mobile-satellite (space-to-Earth) service shall not exceed –152 dB(W/m^2/4 kHz) in Argentina, unless otherwise agreed by the administrations concerned.

S5.408—*Additional allocation:* in the United Kingdom, the band 2500–2600 MHz is also allocated to the radiolocation service on a secondary basis.

S5.409—Administrations shall make all practicable efforts to avoid developing new tropospheric scatter systems in the band 2500–2690 MHz.

S5.410—The band 2500–2690 MHz may be used for tropospheric scatter systems in Region 1, subject to agreement obtained under No. **S9.21**.

S5.411—When planning new tropospheric scatter radio-relay links in the band 2500–2690 MHz, all possible measures shall be taken to avoid directing the antennas of these links toward the geostationary-satellite orbit.

S5.412—*Alternative allocation:* in Azerbaijan, Bulgaria, Kyrgyzstan, Turkmenistan, and Ukraine, the band 2500–2690 MHz is allocated to the fixed and mobile, except aeronautical mobile, services on a primary basis (WRC-97).

S5.413—In the design of systems in the broadcasting-satellite service in the bands between 2500 MHz and 2690 MHz, administrations are urged to take all necessary steps to protect the radio astronomy service in the band 2690–2700 MHz.

S5.414—The allocation of the frequency band 2500–2520 MHz to the mobile-satellite service (space-to-Earth) shall be effective on January 1, 2005 and is subject to coordination under No. **S9.11A**.

S5.415—The use of the bands 2500–2690 MHz in Region 2 and 2500–2535 MHz and 2655–2690 MHz in Region 3 by the fixed-satellite service is limited to national and regional systems, subject to agreement obtained under No. **S9.21**, giving particular attention to the broadcasting-satellite service in Region 1. In the direction space-to-Earth, the power flux-density at the Earth's surface shall not exceed the values given in Article **S21**, Table **S21-4**.

S5.415A—*Additional allocation:* in Japan, subject to agreement obtained under No. **S9.21**, the band 2515–2535 MHz may also be used for the aeronautical mobile-satellite service (space-to-Earth) for operation limited to within its national boundary from January 1, 2000 (WRC-97).

S5.416—The use of the band 2520–2670 MHz by the broadcasting-satellite service is limited to national and regional systems for community reception, subject to agreement obtained under No. **S9.21**. The power flux-density at the Earth's surface shall not exceed the values given in Article **S21**, Table **S21-4**.

S5.417—*Alternative allocation:* in Germany and Greece, the band 2520–2670 MHz is allocated to the fixed service on a primary basis.

S5.418—*Additional allocation:* in Bangladesh, Belarus, China, Rep. of Korea, India, Japan, Pakistan, Russian Federation, Singapore, Sri Lanka, Thailand, and Ukraine the band 2535–2655 MHz is also allocated to the broadcasting-satellite service (sound) and complementary terrestrial broadcasting service on a primary basis. Such use is limited to digital audio broadcasting and is subject to provisions of Resolution 528 (WARC-92). The provisions of No. **S5.416** and Article **S21**, Table **S21-4**, do not apply to this additional allocation.

S5.419—The allocation of the frequency band 2670–2690 MHz to the mobile-satellite service shall be effective from January 1, 2005. When introducing systems of the mobile-satellite service in this band, administrations shall take all necessary steps to protect the satellite systems operating in this band prior to 3 March 1992. The coordination of mobile-satellite systems in the band shall be in accordance with No. **S9.11A**.

S5.420—The band 2655–2670 MHz (until January 1, 2005 the band 2655–2690 MHz) may also be used for the mobile-satellite (Earth-to-space), except aeronautical mobile-satellite, service for operation limited to within national boundaries, subject to agreement obtained under No. **S9.21**. The coordination under No. **S9.11A** applies.

S5.420A—*Additional allocation:* in Japan, subject to agreement obtained under No. **S9.21**, the band 2670–2690 MHz may also be used for the aeronautical mobile-satellite service (Earth-to-space) for operation limited to within its national boundary from January 1, 2000 (WRC-97).

S5.421—*Additional allocation:* in Germany and Austria, the band 2690–2695 MHz is also allocated to the fixed service on a primary basis. Such use is limited to equipment in operation by 1 January 1985.

S5.422—*Additional allocation:* in Saudi Arabia, Armenia, Azerbaijan, Bahrain, Belarus, Bosnia and Herzegovina, Brunei Darussalam, the Central African Republic, the Congo, Côte d'Ivoire, Cuba, Egypt, the United Arab Emirates, Eritrea, Ethiopia, Gabon, Georgia, Guinea, Guinea-Bissau, the Islamic Republic of Iran, Iraq, Israel, Jordan, Kazakstan, Lebanon, Malaysia, Mali, Morocco, Mauritania, Moldova, Mongolia, Nigeria, Oman, Uzbekistan, Pakistan, the Philippines, Qatar, Syria, Kyrgyzstan, Dem. Rep. of the Congo, Romania, Russian Federation, Somalia, Tajikistan, Tunisia, Turkmenistan, Ukraine, Yemen, Yugoslavia, and Zambia, the band 2690–2700 MHz is also allocated to the fixed and mobile, except aeronautical mobile, services on a primary basis. Such use is limited to equipment in operation by 1 January 1985 (WRC-97).

S5.423—In the band 2700–2900 MHz, ground-based radars used for meteorological purposes are authorized to operate on a basis of equality with stations of the aeronautical radionavigation service.

S5.424—*Additional allocation:* in Canada, the band 2850–2900 MHz is also allocated to the maritime radionavigation service, on a primary basis, for use by shore-based radars.

S5.425—In the band 2900–3100 MHz, the use of the ship-borne interrogator-transponder system (SIT) shall be confined to the sub-band 2930 –2950 MHz.

S5.426—The use of the band 2900–3100 MHz by the aeronautical radionavigation service is limited to ground-based radars.

S5.427—In the bands 2900–3100 MHz and 9300–9500 MHz, the response from radar transponders shall not be capable of being confused with the response from radar beacons (racons) and shall not cause interference to ship or aeronauti-

cal radars in the radionavigation service, having regard, however, to No. **S4.9**.

S5.428—*Additional allocation:* in Azerbaijan, Bulgaria, Cuba, Kazakstan. Mongolia, Poland, Kyrgyzstan, Romania, Turkmenistan, and Ukraine, the band 3100–3300 MHz is also allocated to the radionavigation service on a primary basis (WRC-97).

S5.429—*Additional allocation:* in Saudi Arabia, Bahrain, Bangladesh, Brunei Darussalam, China, the Congo, the Republic of Korea, the United Arab Emirates, India, Indonesia, the Islamic Republic of Iran, Iraq, Israel, Japan, Jordan, Kuwait, Lebanon, Libya, Malaysia, Oman, Pakistan, Qatar, Syria, Democratic People's Republic of Korea and Yemen, the band 3300–3400 MHz is also allocated to the fixed and mobile services on a primary basis. The countries bordering the Mediterranean shall not claim protection for their fixed and mobile services from the radiolocation service (WRC-97).

S5.430—*Additional allocation:* in Azerbaijan, Bulgaria, Cuba, Mongolia, Poland, Kyrgyzstan, Romania, Turkmenistan, and Ukraine, the band 3300–3400 MHz is also allocated to the radionavigation service on a primary basis (WRC-97).

S5.431—*Additional allocation:* in Germany, Israel, Nigeria, and the United Kingdom, the band 3400–3475 MHz is also allocated to the amateur service on a secondary basis.

S5.432—*Different category of service:* in the Republic of Korea, Indonesia, Japan and Pakistan, the allocation of the band 3400–3500 MHz to the mobile, except aeronautical mobile, service is on a primary basis (see No. **S5.33**) (WRC-97).

S5.433—In Regions 2 and 3, in the band 3400–3600 MHz the radiolocation service is allocated on a primary basis. However, all administrations operating radiolocation systems in this band are urged to cease operations by 1985. Thereafter, administrations shall take all practicable steps to protect the fixed-satellite service and coordination requirements shall not be imposed on the fixed-satellite service.

S5.434—SUP-WRC-97.

S5.435—In Japan, in the band 3620–3700 MHz, the radiolocation service is excluded.

S5.436—Not used.

S5.437—*Additional allocation:* in Germany and Norway, the band 4200–4210 MHz is also allocated to the fixed service on a secondary basis (WRC-97).

S5.438—Use of the band 4200–4400 MHz by the aeronautical radionavigation service is reserved exclusively for radio altimeters installed on board aircraft and for the associated transponders on the ground. However, passive sensing in the earth exploration-satellite and space research services may be authorized in this band on a secondary basis (no protection is provided by the radio altimeters).

S5.439—*Additional allocation:* in China, the Islamic Republic of Iran, and Libya, the band 4200–4400 MHz is also allocated to the fixed service on a secondary basis (WRC-97).

S5.440—The standard frequency and time signal-satellite service may be authorized to use the frequency 4202 MHz for space-to-Earth transmissions and the frequency 6427 MHz for Earth-to-space transmissions. Such transmissions shall be confined within the limits of 2 MHz of these frequencies, subject to agreement obtained under No. **S9.21**.

S5.441—The use of the bands 4500–4800 MHz (space-to-Earth), 6725–7025 MHz (Earth-to-space) by the fixed-satellite service shall be in accordance with the provisions of Appendix **S30B**. The use of the bands 10.7–10.95 GHz (space-to-Earth), 11.2–11.45 GHz (space-to-Earth), and 12.75–13.25 GHz (Earth-to-space) by geostationary-satellite systems in the fixed-satellite service shall be in accordance with the provisions of Appendix **S30B**. The use of the bands 10.7–10.95 GHz (space-to-Earth), 11.2–11.45 GHz (space-to-Earth), and 12.75–13.25 GHz (Earth-to-space) by nongeostationary-satellite systems in the fixed-satellite service shall be in accordance with the provisions of Resolution 130 (WRC-97) (WRC-97).

S5.442—In the bands 4825–4835 MHz and 4950–4990 MHz, the allocation to the mobile service is restricted to the mobile, except aeronautical mobile, service.

S5.443—*Different category of service:* in Argentina, Australia, and Canada, the allocation of the bands 4825–4835 MHz and 4950–4990 MHz to the radio astronomy service is on a primary basis (see No. **S5.33**).

S5.444—The band 5000–5150 MHz is to be used for the operation of the international standard system (microwave landing system) for precision approach and landing. The requirements of this system shall take precedence over other uses of this band. For the use of this band, No. **S5.444A** and Resolution 114 (WRC-95) apply.

S5.444A—*Additional allocation:* The band 5091–5150 MHz is also allocated to the fixed-satellite service (Earth-to-space) on a primary basis. This allocation is limited to feeder links of nongeostationary mobile-satellite systems and is subject to coordination under No. **S9.11A**. In the band 5091–5150 MHz, the following conditions also apply:

- Prior to January 1, 2010, the use of the band 5091–5150 MHz by feeder links of non-geostationary-satellite systems in the mobile-satellite service shall be made in accordance with Resolution 114 (WRC-95).
- Prior to January 1, 2010, the requirements of existing and planned international standard systems for the aeronautical radionavigation service which cannot be met in the 5000–5091 MHz band shall take precedence over other uses of this band.
- After January 1, 2008, no new assignments shall be made to stations providing feeder links of nongeostationary mobile-satellite systems.
- After January 1, 2010, the fixed-satellite service will become secondary to the aeronautical radionavigation service.

S5.445—Not used.

S5.446—*Additional allocation:* in the countries listed in Nos. **S5.369** and **S5.400**, the band 5150–5216 MHz is also allocated to the radiodetermination-satellite service (space-to-Earth) on a primary basis, subject to agreement obtained under No. **S9.21**. In Region 2, the band is also allocated to the radiodetermination-satellite service (space-to-Earth) on a primary basis. In Regions 1 and 3, except those countries listed in Nos. **S5.369** and **S5.400**, the band is also allocated to the radiodetermination-satellite service (space-to-Earth) on a secondary basis. The use by the radiodetermination-satellite service is limited to feeder links in conjunction with the radiodetermina-

tion-satellite service operating in the bands 1610–1626.5 MHz and/or 2483.5–2500 MHz. The total power flux-density at the Earth's surface shall in no case exceed –159 dBW/m^2 in any 4 kHz band for all angles of arrival.

S5.447—*Additional allocation:* in Germany, Austria, Belgium, Denmark, Spain, Finland, France, Greece, Israel, Italy, Japan, Jordan, Lebanon, Liechtenstein, Luxembourg, Malta, Morocco, Norway, Pakistan, the Netherlands, Portugal, Syria, the United Kingdom, Sweden, Switzerland, and Tunisia, the band 5150–5250 MHz is also allocated to the mobile service, on a primary basis, subject to agreement obtained under No. **S9.21**.

S5.447A—The allocation to the fixed-satellite service (Earth-to-space) is limited to feeder links of nongeostationary-satellite systems in the mobile-satellite service and is subject to coordination under No. **S9.11A**.

S5.447B—*Additional allocation:* The band 5150–5216 MHz is also allocated to the fixed-satellite service (space-to-Earth) on a primary basis. This allocation is limited to feeder links of nongeostationary-satellite systems in the mobile-satellite service and is subject to provisions of No. **S9.11A**. The power flux-density at the Earth's surface produced by space stations of the fixed-satellite service operating in the space-to-Earth direction in the band 5150–5216 MHz shall in no case exceed –164 dB(W/m^2) in any 4 kHz band for all angles of arrival.

S5.447C—Administrations responsible for fixed-satellite service networks in the band 5150–5250 MHz operated under Nos. **S5.447A** and **S5.447B** shall coordinate on an equal basis in accordance with No. **S9.11A** with administrations responsible for nongeostationary-satellite networks operated under No. **S5.446** and brought into use prior to 17 November 1995. Satellite networks operated under No. **S5.446** brought into use after 17 November 1995 shall not claim protection from, and shall not cause harmful interference to, stations of the fixed-satellite service operated under Nos. **S5.447A** and **S5.447B.**

S5.447D—The allocation of the band 5250–5255 MHz to the space research service on a primary basis is limited to active spaceborne sensors. Other uses of the band by the space research service are on a secondary basis (WRC-97).

S5.448—*Additional allocation:* in Austria, Azerbaijan, Bulgaria, Libya, Mongolia, Kyrgyzstan, Slovakia, the Czech Republic, Romania, Turkmenistan and Ukraine, the band 5250–5350 MHz is also allocated to the radionavigation service on a primary basis (WRC-97).

S5.448A—The use of the frequency band 5250–5350 MHz by the earth exploration-satellite (active) and space research (active) services shall not constrain the future development and deployment of the radiolocation service (WRC-97).

S5.448B—The earth exploration-satellite (active) service operating in the band 5350–5460 MHz shall not cause harmful interference to, or constrain the use and development of, the aeronautical radionavigation service (WRC-97).

S5.449—The use of the band 5350–5470 MHz by the aeronautical radionavigation service is limited to airborne radars and associated airborne beacons.

S5.450—*Additional allocation:* in Austria, Azerbaijan, Bulgaria, the Islamic Republic of Iran, Mongolia, Kyrgyzstan, Slovakia, the Czech Republic, Romania, Turkmenistan, and Ukraine, the band 5470–5650 MHz is also allocated to the aeronautical radionavigation service on a primary basis (WRC-97).

S5.451—*Additional allocation:* in the United Kingdom, the band 5470–5850 MHz is also allocated to the land mobile service on a secondary basis. The power limits specified in Nos. **S21.2**, **S21.3, S21.4,** and **S21.5** shall apply in the band 5725–5850 MHz.

S5.452—Between 5600 MHz and 5650 MHz, ground-based radars used for meteorological purposes are authorized to operate on a basis of equality with stations of the maritime radionavigation service.

S5.453—*Additional allocation:* in Saudi Arabia, Bahrain, Bangladesh, Brunei Darussalam, Cameroon, the Central African Republic, China, the Congo, the Republic of Korea, Egypt, the United Arab Emirates, Gabon, Guinea, India, Indonesia, the Islamic Republic of Iran, Iraq, Israel, Japan, Jordan, Kuwait, Lebanon, Libya, Madagascar, Malaysia, Nigeria, Oman, Pakistan, the Philippines, Qatar, Syria, Democratic People's Republic of Korea, Singapore, Swaziland, Tanzania, Chad, and Yemen, the band 5650–5850 MHz is also allocated to the fixed and mobile services on a primary basis (WRC-97).

S5.454—*Different category of service:* in Armenia, Azerbaijan, Belarus, Bulgaria, Georgia, Kazakstan, Mongolia, Uzbekistan, Kyrgyzstan, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the allocation of the band 5670–5725 MHz to the space research service is on a primary basis (see No. **S5.33**) (WRC-97).

S5.455—*Additional allocation:* in Armenia, Azerbaijan, Belarus, Bulgaria, Cuba, Georgia, Hungary, Kazakstan, Latvia, Moldova, Mongolia, Uzbekistan, Poland, Kyrgyzstan, Slovakia, Russian Federation, Tajikistan, Turkmenistan and Ukraine, the band 5670–5850 MHz is also allocated to the fixed service on a primary basis.

S5.456—*Additional allocation:* in Germany and in Cameroon, the band 5755–5850 MHz is also allocated to the fixed service on a primary basis.

S5.457—Not used.

S5.458—In the band 6425–7075 MHz, passive microwave sensor measurements are carried out over the oceans. In the band 7075–7250 MHz, passive microwave sensor measurements are carried out. Administrations should bear in mind the needs of the Earth exploration-satellite (passive) and space research (passive) services in their future planning of the bands 6425–7025 MHz and 7075–7250 MHz.

S5.458A—In making assignments in the band 6700–7075 MHz to space stations of the fixed-satellite service, administrations are urged to take all practicable steps to protect spectral line observations of the radio astronomy service in the band 6650–6675.2 MHz from harmful interference from unwanted emissions.

S5.458B—The space-to-Earth allocation to the fixed-satellite service in the band 6700–7075 MHz is limited to feeder links for nongeostationary satellite systems of the mobile-satellite service and is subject to coordination under No. **S9.11A**. The use of the band 6700–7075 MHz (space-to-Earth) by feeder links for nongeostationary satellite systems in the mobile-satellite service is not subject to No. **S22.2.**

S5.458C—Administrations making submissions in the band 7025–7075 MHz (Earth-to-space) for geostationary-satellite systems in the fixed-satellite service after 17 November

1995 shall consult on the basis of relevant ITU-R Recommendations with the administrations that have notified and brought into use nongeostationary-satellite systems in this frequency band before 18 November 1995 upon request of the latter administrations. This consultation shall be with a view to facilitating shared operation of both geostationary-satellite systems in the fixed-satellite service and nongeostationary-satellite systems in this band.

S5.459—*Additional allocation:* in Russian Federation, the frequency bands 7100–7155 MHz and 7190–7235 MHz are also allocated to the space operation service (Earth-to-space) on a primary basis, subject to agreement obtained under No. **S9.21** (WRC-97).

S5.460—*Additional allocation:* The band 7145–7235 MHz is also allocated to the space research (Earth-to-space) service on a primary basis, subject to agreement obtained under No. **S9.21**. The use of the band 7145–7190 MHz is restricted to deep space; no emissions to deep space shall be effected in the band 7190–7235 MHz.

S5.461—*Additional allocation:* The bands 7250–7375 MHz (space-to-Earth) and 7900–8025 MHz (Earth-to-space) are also allocated to the mobile-satellite service on a primary basis, subject to agreement obtained under No. **S9.21**.

S5.461A—The use of the band 7450–7550 MHz by the meteorological-satellite service (space-to-Earth) is limited to geostationary-satellite systems. Nongeostationary meteorological-satellite systems in this band notified before 30 November 1997 may continue to operate on a primary basis until the end of their lifetime (WRC-97).

S5.461B—The use of the band 7750–7850 MHz by the meteorological-satellite service (space-to-Earth) is limited to nongeostationary satellite systems (WRC-97).

S5.462—SUP - WRC-97.

S5.462A—In Regions 1 and 3 (except for Japan), in the band 8025–8400 MHz, the earth exploration-satellite service using geostationary satellites shall not produce a power flux-density in excess of the following provisional values for angles of arrival (q), without the consent of the affected administration:

-174 dB(W/m^2) in a 4 kHz band for $0° \le \theta < 5°$

$-174 + 0.5\,(\theta - 5)$ dB(W/m^2) in a 4 kHz band for $5° \le \theta < 25°$

-164 dB(W/m^2) in a 4 kHz band for $25° \le \theta \le 90°$

These values are subject to study under Resolution 124 (WRC-97) (WRC-97).

S5.463—Aircraft stations are not permitted to transmit in the band 8025–8400 MHz (WRC-97).

S5.464—SUP - WRC-97.

S5.465—In the space research service, the use of the band 8400–8450 MHz is limited to deep space.

S5.466—*Different category of service:* in Israel, Malaysia, Singapore, and Sri Lanka, the allocation of the band 8400–8500 MHz to the space research service is on a secondary basis (see No. **S5.32**) (WRC-97).

S5.467—*Alternative allocation:* in the United Kingdom, the band 8400–8500 MHz is allocated to the radiolocation and space research services on a primary basis.

S5.468—*Additional allocation:* in Saudi Arabia, Bahrain, Bangladesh, Brunei Darussalam, Burundi, Cameroon, China, the Congo, Costa Rica, Egypt, the United Arab Emirates, Gabon, Guyana, Indonesia, the Islamic Republic of Iran, Iraq, Jamaica, Jordan, Kuwait, Lebanon, Libya, Malaysia, Mali, Morocco, Mauritania, Nepal, Nigeria, Oman, Pakistan, Qatar, Syria, Democratic People's Republic of Korea, Senegal, Singapore, Somalia, Swaziland, Tanzania, Chad, Togo, Tunisia, and Yemen, the band 8500–8750 MHz is also allocated to the fixed and mobile services on a primary basis (WRC-97).

S5.469—*Additional allocation:* in Armenia, Azerbaijan, Belarus, Bulgaria, Georgia, Hungary, Kazakstan, Lithuania, Moldova, Mongolia, Uzbekistan, Poland, Kyrgyzstan, Slovakia, the Czech Republic, Romania, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the band 8500–8750 MHz is also allocated to the land mobile and radionavigation services on a primary basis.

S5.469A—In the band 8550–8650 MHz, stations in the earth exploration-satellite service (active) and space research service (active) shall not cause harmful interference to, or constrain the use and development of, stations of the radiolocation service (WRC-97).

S5.461B—The use of the band 7750–7850 MHz by the meteorological-satellite service (space-to-Earth) is limited to nongeostationary satellite systems (WRC-97).

S5.462—SUP - WRC-97.

S5.462A—In Regions 1 and 3 (except for Japan), in the band 8025–8400 MHz, the earth exploration-satellite service using geostationary satellites shall not produce a power flux-density in excess of the following provisional values for angles of arrival (q), without the consent of the affected administration:

-174 dB(W/m^2) in a 4 kHz band for $0° \le \theta < 5°$

$-174 + 0.5\,(\theta - 5)$ dB(W/m^2) in a 4 kHz band for $5° \le \theta < 25°$

-164 dB(W/m^2) in a 4 kHz band for $25° \le \theta \le 90°$

These values are subject to study under Resolution 124 (WRC-97), (WRC-97).

S5.463—Aircraft stations are not permitted to transmit in the band 8025–8400 MHz (WRC-97).

S5.464—SUP - WRC-97.

S5.465—In the space research service, the use of the band 8400–8450 MHz is limited to deep space.

S5.466—*Different category of service:* in Israel, Malaysia, Singapore and Sri Lanka, the allocation of the band 8400–8500 MHz to the space research service is on a secondary basis (see No. **S5.32**) (WRC-97).

S5.467—*Alternative allocation:* in the United Kingdom, the band 8400–8500 MHz is allocated to the radiolocation and space research services on a primary basis.

S5.468—*Additional allocation:* in Saudi Arabia, Bahrain, Bangladesh, Brunei Darussalam, Burundi, Cameroon, China, the Congo, Costa Rica, Egypt, the United Arab Emirates, Gabon, Guyana, Indonesia, the Islamic Republic of Iran, Iraq, Jamaica, Jordan, Kuwait, Lebanon, Libya, Malaysia, Mali, Morocco, Mauritania, Nepal, Nigeria, Oman, Pakistan, Qatar, Syria, Democratic People's Republic of Korea, Senegal, Singapore, Somalia, Swaziland, Tanzania, Chad, Togo, Tunisia, and Yemen, the band 8500–8750 MHz is also allocated to the fixed and mobile services on a primary basis (WRC-97).

S5.469—*Additional allocation:* in Armenia, Azerbaijan, Belarus, Bulgaria, Georgia, Hungary, Kazakstan, Lithuania, Moldova, Mongolia, Uzbekistan, Poland, Kyrgyzstan, Slovakia, the Czech Republic, Romania, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the band 8500–8750 MHz is also allocated to the land mobile and radionavigation services on a primary basis.

S5.469A—In the band 8550–8650 MHz, stations in the earth exploration-satellite service (active) and space research service (active) shall not cause harmful interference to, or constrain the use and development of, stations of the radiolocation service (WRC-97).

S5.470—The use of the band 8750–8850 MHz by the aeronautical radionavigation service is limited to airborne Doppler navigation aids on a centre frequency of 8800 MHz.

S5.471—*Additional allocation:* in Algeria, Germany, Bahrain, Belgium, China, the United Arab Emirates, France, Greece, Indonesia, the Islamic Republic of Iran, Libya, the Netherlands, Qatar, and Sudan, the bands 8825–8850 MHz and 9000–9200 MHz are also allocated to the maritime radionavigation service, on a primary basis, for use by shore-based radars only.

S5.472—In the bands 8850–9000 MHz and 9200–9225 MHz, the maritime radionavigation service is limited to shore-based radars.

S5.473—*Additional allocation:* in Armenia, Austria, Azerbaijan, Belarus, Bulgaria, Cuba, Georgia, Hungary, Kazakstan, Moldova, Mongolia, Uzbekistan, Poland, Kyrgyzstan, Slovakia, the Czech Republic, Romania, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the bands 8850–9000 MHz and 9200–9300 MHz are also allocated to the radionavigation service on a primary basis.

S5.474—In the band 9200–9500 MHz, search and rescue transponders (SART) may be used, having due regard to the appropriate ITU-R Recommendation (see also Article **S31**).

S5.475—The use of the band 9300–9500 MHz by the aeronautical radionavigation service is limited to airborne weather radars and ground-based radars. In addition, ground-based radar beacons in the aeronautical radionavigation service are permitted in the band 9300–9320 MHz on condition that harmful interference is not caused to the maritime radionavigation service. In the band 9300–9500 MHz, ground-based radars used for meteorological purposes have priority over other radiolocation devices.

S5.476—In the band 9300–9320 MHz in the radionavigation service, the use of shipborne radars, other than those existing on 1 January 1976, is not permitted until 1 January 2001.

S5.476A—In the band 9500–9800 MHz, stations in the earth exploration-satellite service (active) and space research service (active) shall not cause harmful interference to, or constrain the use and development of, stations of the radionavigation and radiolocation services (WRC-97).

S5.477—*Different category of service:* in Algeria, Saudi Arabia, Austria, Bahrain, Bangladesh, Brunei Darussalam, Cameroon, the Republic of Korea, Egypt, the United Arab Emirates, Eritrea, Ethiopia, Guyana, India, Indonesia, the Islamic Republic of Iran, Iraq, Jamaica, Japan, Jordan, Kuwait, Lebanon, Liberia, Malaysia, Nigeria, Oman, Pakistan, Qatar, Democratic People's Republic of Korea, Singapore, Somalia, Sudan, Sweden, Trinidad and Tobago, and Yemen, the allocation of the band 9800–10000 MHz to the fixed service is on a primary basis (see No. **S5.33**) (WRC-97).

S5.478—*Additional allocation:* in Azerbaijan, Bulgaria, Kazakstan, Mongolia, Kyrgyzstan, Slovakia, the Czech Republic, Romania, Turkmenistan, and Ukraine, the band 9800–10000 MHz is also allocated to the radionavigation service on a primary basis (WRC-97).

S5.479—The band 9975–10025 MHz is also allocated to the meteorological-satellite service on a secondary basis for use by weather radars.

S5.480—*Additional allocation:* in Brazil, Costa Rica, Ecuador, Guatemala, Honduras, and Mexico, the band 10–10.45 GHz is also allocated to the fixed and mobile services on a primary basis (WRC-97).

S5.481—*Additional allocation:* in Germany, Angola, China, Ecuador, Spain, Japan, Morocco, Nigeria, Oman, Democratic People's Republic of Korea, Sweden, Tanzania, and Thailand, the band 10.45–10.5 GHz is also allocated to the fixed and mobile services on a primary basis.

S5.482—In the band 10.6–10.68 GHz, stations of the fixed and mobile, except aeronautical mobile, services shall be limited to a maximum equivalent isotropically radiated power of 40 dBW and the power delivered to the antenna shall not exceed –3 dBW. These limits may be exceeded subject to agreement obtained under No. **S9.21**. However, in Saudi Arabia, Armenia, Azerbaijan, Bahrain, Bangladesh, Belarus, China, the United Arab Emirates, Georgia, India, Indonesia, the Islamic Republic of Iran, Iraq, Japan, Kazakstan, Kuwait, Latvia, Lebanon, Moldova, Nigeria, Uzbekistan, Pakistan, the Philippines, Qatar, Syria, Kyrgyzstan, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the restrictions on the fixed and mobile, except aeronautical mobile, services are not applicable.

S5.483—*Additional allocation:* in Saudi Arabia, Armenia, Azerbaijan, Bahrain, Belarus, Bosnia and Herzegovina, China, Colombia, the Republic of Korea, Costa Rica, Egypt, the United Arab Emirates, Georgia, the Islamic Republic of Iran, Iraq, Israel, Japan, Jordan, Kazakstan, Kuwait, Latvia, Lebanon, Moldova, Mongolia, Uzbekistan, Pakistan, Qatar, Kyrgyzstan, Democratic People's Republic of Korea, Romania, Russian Federation, Tajikistan, Turkmenistan, Ukraine, Yemen, and Yugoslavia, the band 10.68–10.7 GHz is also allocated to the fixed and mobile, except aeronautical mobile, services on a primary basis. Such use is limited to equipment in operation by 1 January 1985 (WRC-97).

S5.484—In Region 1, the use of the band 10.7–11.7 GHz by the fixed-satellite service (Earth-to-space) is limited to feeder links for the broadcasting-satellite service.

S5.484A—The use of the bands 10.95–11.2 GHz (space-to-Earth), 11.45–11.7 GHz (space-to-Earth), 11.7–12.2 GHz (space-to-Earth) in Region 2, 12.2–12.75 GHz (space-to-Earth) in Region 3, 12.5–12.75 GHz (space-to-Earth) in Region 1, 13.75–14.5 GHz (Earth-to-space), 17.8–18.6 GHz (space-to-Earth), 19.7–20.2 GHz (space-to-Earth), 27.5–28.6 GHz (Earth-to-space), and 29.5–30 GHz (Earth-to-space) by nongeostationary and geostationary-satellite systems in the fixed-satellite service is subject to the provisions of Resolution 130 (WRC-97). The use of the band 17.8–18.1 GHz (space-to-Earth) by nongeostationary fixed-satellite service

systems is also subject to the provisions of Resolution 538 (WRC-97) (WRC-97).

S5.485—In Region 2, in the band 11.7–12.2 GHz, transponders on space stations in the fixed-satellite service may be used additionally for transmissions in the broadcasting-satellite service, provided that such transmissions do not have a maximum eirp greater than 53 dBW per television channel and do not cause greater interference or require more protection from interference than the coordinated fixed-satellite service frequency assignments. With respect to the space services, this band shall be used principally for the fixed-satellite service.

S5.486—*Different category of service:* in Mexico and the United States, the allocation of the band 11.7–12.1 GHz to the fixed service is on a secondary basis (see No. **S5.32**).

S5.487—In the band 11.7–12.5 GHz in Regions 1 and 3, the fixed, fixed-satellite, mobile, except aeronautical mobile, and broadcasting services, in accordance with their respective allocations, shall not cause harmful interference to broadcasting-satellite stations operating in accordance with the provisions of Appendix **S30**.

S5.487A—*Additional allocation:* in Region 1, the band 11.7–12.5 GHz, in Region 2, the band 12.2–12.7 GHz and, in Region 3, the band 11.7–12.2 GHz are also allocated to the fixed-satellite service (space-to-Earth) on a primary basis, limited to nongeostationary systems and subject to the provisions of Resolution 538 (WRC-97) (WRC-97).

S5.488—The use of the bands 11.7–12.2 GHz by the fixed-satellite service in Region 2 and 12.2–12.7 GHz by the broadcasting-satellite service in Region 2 is limited to national and subregional systems. The use of the band 11.7–12.2 GHz by the fixed-satellite service in Region 2 is subject to previous agreement between the administrations concerned and those having services, operating or planned to operate in accordance with the Table, that may be affected (see Articles **S9** and **S11**). For the use of the band 12.2–12.7 GHz by the broadcasting-satellite service in Region 2, see Appendix **S30**.

S5.489—*Additional allocation:* in Peru, the band 12.1–12.2 GHz is also allocated to the fixed service on a primary basis.

S5.490—In Region 2, in the band 12.2–12.7 GHz, existing and future terrestrial radiocommunication services shall not cause harmful interference to the space services operating in conformity with the broadcasting-satellite Plan for Region 2 contained in Appendix **S30**.

S5.491—*Additional allocation:* in Region 3, the band 12.2–12.5 GHz is also allocated to the fixed-satellite (space-to-Earth) service on a primary basis, limited to national and subregional systems. The power flux-density limits in Article **S21**, Table **S21-4** shall apply to this frequency band. The introduction of the service in relation to the broadcasting-satellite service in Region 1 shall follow the procedures specified in Article 7 of Appendix **S30**, with the applicable frequency band extended to cover 12.2–12.5 GHz.

S5.492—Assignments to stations of the broadcasting-satellite service in conformity with the appropriate regional Plan in Appendix **S30** may also be used for transmissions in the fixed-satellite service (space-to-Earth), provided that such transmissions do not cause more interference or require more protection from interference than the broadcasting-satellite service transmissions operating in conformity with this Plan. With respect to the space services, this band shall be used principally for the broadcasting-satellite service (WRC-97).

S5.493—The broadcasting-satellite service in the band 12.5–12.75 GHz in Region 3 is limited to a power flux-density not exceeding –111 dB(W/m^2)/27 MHz for all conditions and for all methods of modulation at the edge of the service area (WRC-97).

S5.494—*Additional allocation:* in Algeria, Angola, Saudi Arabia, Bahrain, Cameroon, the Central African Republic, the Congo, Côte d'Ivoire, Egypt, the United Arab Emirates, Eritrea, Ethiopia, Gabon, Ghana, Guinea, Iraq, Israel, Jordan, Kuwait, Lebanon, Libya, Madagascar, Mali, Morocco, Mongolia, Nigeria, Qatar, Democratic Republic of the Congo, Syria, Senegal, Somalia, Sudan, Chad, Togo, and Yemen, the band 12.5–12.75 GHz is also allocated to the fixed and mobile, except aeronautical mobile, services on a primary basis (WRC-97).

S5.495—*Additional allocation:* in Bosnia and Herzegovina, Croatia, Denmark, France, Greece, Liechtenstein, Monaco, Norway, Uganda, Portugal, Romania, Slovenia, Switzerland, Tanzania, Tunisia, and Yugoslavia, the band 12.5–12.75 GHz is also allocated to the fixed and mobile, except aeronautical mobile, services on a secondary basis (WRC-97).

S5.496—*Additional allocation:* in Austria, Azerbaijan, Kyrgyzstan, Turkmenistan, and Ukraine, the band 12.5–12.75 GHz is also allocated to the fixed service and the mobile, except aeronautical mobile, service on a primary basis. However, stations in these services shall not cause harmful interference to fixed-satellite service earth stations of countries in Region 1 other than those listed in this footnote. Coordination of these earth stations is not required with stations of the fixed and mobile services of the countries listed in this footnote. The power flux-density limit at the Earth's surface given in Article **S21**, Table **S21-4**, for the fixed-satellite service shall apply on the territory of the countries listed in this footnote (WRC-97).

S5.497—The use of the band 13.25–13.4 GHz by the aeronautical radionavigation service is limited to Doppler navigation aids.

S5.498—SUP - WRC-97.

S5.498A—The Earth exploration-satellite (active) and space research (active) services operating in the band 13.25–13.4 GHz shall not cause harmful interference to, or constrain the use and development of, the aeronautical radionavigation service (WRC-97).

S5.499—*Additional allocation:* in Bangladesh, India, and Pakistan, the band 13.25–14 GHz is also allocated to the fixed service on a primary basis.

S5.500—*Additional allocation:* in Algeria, Angola, Saudi Arabia, Bahrain, Brunei Darussalam, Cameroon, the Republic of Korea, Egypt, the United Arab Emirates, Gabon, Indonesia, the Islamic Republic of Iran, Iraq, Israel, Jordan, Kuwait, Lebanon, Madagascar, Malaysia, Mali, Malta, Morocco, Mauritania, Nigeria, Pakistan, Qatar, Syria, Senegal, Singapore, Sudan, Chad, and Tunisia, the band 13.4–14 GHz is also allocated to the fixed and mobile services on a primary basis (WRC-97).

S5.501—*Additional allocation:* in Austria, Azerbaijan, Bulgaria, Hungary, Japan, Mongolia, Kyrgyzstan, Romania, the United Kingdom, Turkmenistan, and Ukraine, the band 13.4–14 GHz is also allocated to the radionavigation service on a primary basis (WRC-97).

S5.501A—The allocation of the band 13.4–13.75 GHz to the space research service on a primary basis is limited to active spaceborne sensors. Other uses of the band by the space research service are on a secondary basis (WRC-97).

S5.501B—In the band 13.4–13.75 GHz, the Earth exploration-satellite (active) and space research (active) services shall not cause harmful interference to, or constrain the use and development of, the radiolocation service (WRC-97).

S5.502—In the band 13.75–14 GHz, the eirp of any emission from an earth station in the fixed-satellite service shall be at least 68 dBW, and should not exceed 85 dBW, with a minimum antenna diameter of 4.5 m. In addition the eirp, averaged over one second, radiated by a station in the radiolocation or radionavigation services toward the geostationary-satellite orbit shall not exceed 59 dBW.

S5.503—In the band 13.75–14 GHz, geostationary space stations in the space research service for which information for advance publication has been received by the Bureau prior to 31 January 1992 shall operate on an equal basis with stations in the fixed-satellite service; after that date, new geostationary space stations in the space research service will operate on a secondary basis. The eirp density of emissions from any earth station in the fixed-satellite service shall not exceed 71 dBW in any 6 MHz band in the frequency range 13.772–13.778 GHz until those geostationary space stations in the space research service for which information for advance publication has been received by the Bureau prior to 31 January 1992 cease to operate in this band. Automatic power control may be used to increase the eirp density above 71 dBW in any 6 MHz band in this frequency range to compensate for rain attenuation, to the extent that the power-flux density at the fixed-satellite service space station does not exceed the value resulting from use of an eirp of 71 dBW in any 6 MHz band in clear sky conditions.

S5.503A—Until January 1, 2000, stations in the fixed-satellite service shall not cause harmful interference to nongeostationary space stations in the space research and Earth exploration-satellite services. After that date, these nongeostationary space stations will operate on a secondary basis in relation to the fixed-satellite service. Additionally, when planning earth stations in the fixed-satellite service to be brought into service between January 1, 2000 and January 1, 2001, in order to accommodate the needs of spaceborne precipitation radars operating in the band 13.793–13.805 GHz, advantage should be taken of the consultation process and the information given in Recommendation ITU-R SA.1071.

S5.504—The use of the band 14–14.3 GHz by the radionavigation service shall be such as to provide sufficient protection to space stations of the fixed-satellite service.

S5.505—*Additional allocation:* in Algeria, Angola, Saudi Arabia, Australia, Bahrain, Bangladesh, Botswana, Brunei Darussalam, Cameroon, China, the Congo, the Republic of Korea, Egypt, the United Arab Emirates, Gabon, Guatemala, Guinea, India, Indonesia, the Islamic Republic of Iran, Iraq, Israel, Japan, Jordan, Kuwait, Lesotho, Lebanon, Malaysia, Mali, Morocco, Mauritania, Oman, Pakistan, the Philippines, Qatar, Syria, the Democratic People's Republic of Korea, Senegal, Singapore, Somalia, Sudan, Swaziland, Tanzania, Chad, and Yemen, the band 14–14.3 GHz is also allocated to the fixed service on a primary basis (WRC-97).

S5.506—The band 14–14.5 GHz may be used, within the fixed-satellite service (Earth-to-space), for feeder links for the broadcasting-satellite service, subject to coordination with other networks in the fixed-satellite service. Such use of feeder links is reserved for countries outside Europe.

S5.507—Not used.

S5.508—*Additional allocation:* in Germany, Austria, Bosnia and Herzegovina, France, Greece, Ireland, Iceland, Italy, the former Yugoslav Republic of Macedonia, Libya, Liechtenstein, Portugal, the United Kingdom, Slovenia, Switzerland, Turkey, and Yugoslavia, the band 14.25–14.3 GHz is also allocated to the fixed service on a primary basis (WRC-97).

S5.509—*Additional allocation:* in Japan and Pakistan the band 14.25–14.3 GHz is also allocated to the mobile, except aeronautical mobile, service on a primary basis.

S5.510—The use of the band 14.5–14.8 GHz by the fixed-satellite service (Earth-to-space) is limited to feeder links for the broadcasting-satellite service. This use is reserved for countries outside Europe.

S5.511—*Additional allocation:* in Saudi Arabia, Bahrain, Bosnia and Herzegovina, Cameroon, Egypt, the United Arab Emirates, Guinea, the Islamic Republic of Iran, Iraq, Israel, Kuwait, Lebanon, Libya, Pakistan, Qatar, Syria, Slovenia, Somalia, and Yugoslavia, the band 15.35–15.4 GHz is also allocated to the fixed and mobile services on a secondary basis (WRC-97).

S5.511A—Use of the band 15.43–15.63 GHz by the fixed-satellite service (space-to-Earth (see Resolution 123 (WRC-97)) and Earth-to-space) is limited to feeder links of nongeostationary systems in the mobile-satellite service, subject to coordination under No. **S9.11A**. In the space-to-Earth direction, the minimum earth station elevation angle above and gain toward the local horizontal plane and the minimum coordination distances to protect an earth station from harmful interference shall be in accordance with Recommendation ITU-R S.1341. Also in the space-to-Earth direction, harmful interference shall not be caused to stations of the radio astronomy service using the band 15.35–15.4 GHz. The threshold levels of interference and associated power flux-density limits that are detrimental to the radio astronomy service are given in Recommendation ITU-R RA.769–1. Special measures will need to be employed to protect the radio astronomy service in the band 15.35–15.4 GHz (WRC-97).

S5.511B—SUP – WRC-97.

S5.511C—Stations operating in the aeronautical radionavigation service shall limit the effective eirp in accordance with Recommendation ITU-R S.1340. The minimum coordination distance required to protect the aeronautical radionavigation stations (No. **S4.10** applies) from harmful interference from feeder-link earth stations and the maximum eirp transmitted toward the local horizontal plane by a feeder-link earth station shall be in accordance with Recommendation ITU-R S.1340 (WRC-97).

S5.511D—Fixed-satellite service systems for which complete information for advance publication has been received by the Bureau by 21 November 1997 may operate in the bands 15.4–15.43 GHz and 15.63–15.7 GHz in the space-to-Earth direction and 15.63–15.65 GHz in the Earth-to-space direction. In the bands 15.4–15.43 GHz and 15.65–15.7 GHz, emissions from a nongeostationary space station shall not exceed the power flux-density limits at the Earth's surface of –146 dB(W/m^2/MHz) for any angle of arrival. In the band 15.63–15.65 GHz, where an administration plans emissions from a nongeostationary space station that exceed –146 dB(W/m^2/MHz) for any angle of arrival, it shall coordinate under No. **S9.11A** with the affected administrations. Stations in the fixed-satellite service operating in the band 15.63–15.65 GHz in the Earth-to-space direction shall not cause harmful interference to stations in the aeronautical radionavigation service (No. **S4.10** applies) (WRC-97).

S5.512—*Additional allocation:* in Algeria, Angola, Saudi Arabia, Austria, Bahrain, Bangladesh, Bosnia and Herzegovina, Brunei Darussalam, Cameroon, the Congo, Costa Rica, Egypt, El Salvador, the United Arab Emirates, Finland, Guatemala, India, Indonesia, the Islamic Republic of Iran, Jordan, Kuwait, Libya, Malaysia, Morocco, Mozambique, Nepal, Nicaragua, Oman, Pakistan, Qatar, Singapore, Slovenia, Somalia, Sudan, Swaziland, Tanzania, Chad, Yemen, and Yugoslavia, the band 15.7–17.3 GHz is also allocated to the fixed and mobile services on a primary basis (WRC-97).

S5.513—*Additional allocation:* in Israel, the band 15.7–17.3 GHz is also allocated to the fixed and mobile services on a primary basis. These services shall not claim protection from, or cause harmful interference to, services operating in accordance with the Table in countries other than those included in No. **S5.512**.

S5.513A—Spaceborne active sensors operating in the band 17.2–17.3 GHz shall not cause harmful interference to, or constrain the development of, the radiolocation and other services allocated on a primary basis (WRC-97).

S5.514—*Additional allocation:* in Algeria, Germany, Angola, Saudi Arabia, Austria, Bahrain, Bangladesh, Bosnia and Herzegovina, Cameroon, Costa Rica, El Salvador, the United Arab Emirates, Finland, Guatemala, Honduras, India, the Islamic Republic of Iran, Iraq, Israel, Japan, Jordan, Kuwait, Libya, Nepal, Nicaragua, Oman, Pakistan, Qatar, Slovenia, Sudan, Sweden, and Yugoslavia, the band 17.3–17.7 GHz is also allocated to the fixed and mobile services on a secondary basis. The power limits given in Nos. **S21.3** and **S21.5** shall apply (WRC-97).

S5.515—In the band 17.3–17.8 GHz, sharing between the fixed-satellite service (Earth-to-space) and the broadcasting-satellite service shall also be in accordance with the provisions of §1 of Annex 4 of Appendix **S30A/30A**.

S5.516—The use of the band 17.3–18.1 GHz by geostationary-satellite systems in the fixed-satellite service (Earth-to-space) is limited to feeder links for the broadcasting-satellite service. For the use of the band 17.3–17.8 GHz in Region 2 by feeder links for the broadcasting-satellite service in the band 12.2–12.7 GHz, see Article **S11**. The use of the bands 17.3–18.1 GHz (Earth-to-space) in Regions 1 and 3 and 17.8–18.1 GHz (Earth-to-space) in Region 2 by nongeostationary-satellite systems in the fixed-satellite service is subject to the provisions of Resolution 538 (WRC-97) (WRC-97).

S5.517—In Region 2, the allocation to the broadcasting-satellite service in the band 17.3–17.8 GHz shall come into effect on April 1, 2007. After that date, use of the fixed-satellite (space-to-Earth) service in the band 17.7–17.8 GHz shall not claim protection from and shall not cause harmful interference to operating systems in the broadcasting-satellite service.

S5.518—*Different category of service:* in Region 2, the allocation of the band 17.7–17.8 GHz to the mobile service is on a primary basis until March 31, 2007.

S5.519—*Additional allocation:* The band 18.1–18.3 GHz is also allocated to the meteorological-satellite service (space-to-Earth) on a primary basis. Its use is limited to geostationary satellites and shall be in accordance with the provisions of Article **S21**, Table **S21–4**.

S5.520—The use of the band 18.1–18.4 GHz by the fixed-satellite service (Earth-to-space) is limited to feeder links for the broadcasting-satellite service.

S5.521—*Alternative allocation:* in Germany, Denmark, the United Arab Emirates, Greece, Slovakia, and the Czech Republic, the band 18.1–18.4 GHz is allocated to the fixed, fixed-satellite (space-to-Earth), and mobile services on a primary basis (see No. **S5.33**). The provisions of No. **S5.519** also apply (WRC-97).

S5.522—In making assignments to stations in the fixed and mobile services, administrations are invited to take account of passive sensors in the Earth-exploration satellite and space research services operating in the band 18.6–18.8 GHz. In this band, administrations should endeavour to limit as far as possible both the power delivered by the transmitter to the antenna and the eirp to reduce the risk of interference to passive sensors to a minimum.

S5.523—In assigning frequencies to stations in the fixed-satellite service in the direction space-to-Earth, administrations are requested to limit as far as practicable the power flux-density at the Earth's surface in the band 18.6–18.8 GHz, to reduce the risk of interference to passive sensors in the earth exploration-satellite and space research services.

S5.523A—The use of the bands 18.8–19.3 GHz (space-to-Earth) and 28.6–29.1 GHz (Earth-to-space) by geostationary and nongeostationary fixed-satellite service networks is subject to the application of the provisions of No. **S9.11A**, and No. **S22.2** does not apply. Administrations having geostationary-satellite networks under coordination prior to 18 November 1995 shall cooperate to the maximum extent possible to coordinate pursuant to No. **S9.11A** with nongeostationary-satellite networks for which notification information has been received by the Bureau prior to that date, with a view to reaching results acceptable to all the parties concerned. Nongeostationary-satellite networks shall not cause unacceptable interference to geostationary fixed-satellite service networks for which complete Appendix **S4** notification information is considered as having been received by the Bureau prior to 18 November 1995 (WRC-97).

S5.523B—The use of the band 19.3–19.6 GHz (Earth-to-space) by the fixed-satellite service is limited to feeder links for nongeostationary-satellite systems in the mobile-satellite service. Such use is subject to the application of the provisions of No. **S9.11A**, and No. **S22.2** does not apply.

S5.523C—No. **S22.2** of the Radio Regulations shall continue to apply in the bands 19.3–19.6 GHz and 29.1–29.4 GHz, between feeder links of nongeostationary mobile-satellite service networks and those fixed-satellite service networks for which complete Appendix **S4** coordination information, or notification information, is considered as having been received by the Bureau prior to 18 November 1995 (WRC-97).

S5.523D—The use of the band 19.3–19.7 GHz (space-to-Earth) by geostationary fixed-satellite service systems and by feeder links for nongeostationary-satellite systems in the mobile-satellite service is subject to the application of the provisions of No. **S9.11A**, but not subject to the provisions of No. **S22.2**. The use of this band for other nongeostationary fixed-satellite service systems, or for the cases indicated in Nos. **S5.523C** and **S5.523E**, is not subject to the provisions of No. **S9.11A** and shall continue to be subject to Articles **S9** (except No. **S9.11A**) and **S11** procedures, and to the provisions of No. **S22.2** (WRC-97).

S5.523E—No. **S22.2** of the Radio Regulations shall continue to apply in the bands 19.6–19.7 GHz and 29.4–29.5 GHz, between feeder links of nongeostationary mobile-satellite service networks and those fixed-satellite service networks for which complete Appendix **S4** coordination information, or notification information, is considered as having been received by the Bureau by 21 November 1997 (WRC-97).

S5.524—*Additional allocation:* in Afghanistan, Algeria, Angola, Saudi Arabia, Bahrain, Bangladesh, Brunei Darussalam, Cameroon, China, the Congo, the Republic of Korea, Costa Rica, Egypt, the United Arab Emirates, Gabon, Guatemala, Guinea, India, Islamic Republic of Iran, Iraq, Israel, Japan, Jordan, Kuwait, Lebanon, Malaysia, Mali, Morocco, Mauritania, Nepal, Nigeria, Oman, Pakistan, the Philippines, Qatar, Dem. Rep. of the Congo, Syria, Democratic People's Republic of Korea, Singapore, Somalia, Sudan, Tanzania, Chad, Togo, and Tunisia, the band 19.7–21.2 GHz is also allocated to the fixed and mobile services on a primary basis. This additional use shall not impose any limitation on the power flux-density of space stations in the fixed-satellite service in the band 19.7–21.2 GHz and of space stations in the mobile-satellite service in the band 19.7–20.2 GHz where the allocation to the mobile-satellite service is on a primary basis in the latter band (WRC-97).

S5.525—To facilitate interregional coordination between networks in the mobile-satellite and fixed-satellite services, carriers in the mobile-satellite service that are most susceptible to interference shall, to the extent practicable, be located in the higher parts of the bands 19.7–20.2 GHz and 29.5–30 GHz.

S5.526—In the bands 19.7–20.2 GHz and 29.5–30 GHz in Region 2, and in the bands 20.1–20.2 GHz and 29.9–30 GHz in Regions 1 and 3, networks which are both in the fixed-satellite service and in the mobile-satellite service may include links between earth stations at specified or unspecified points or while in motion, through one or more satellites for point-to-point and point-to-multipoint communications.

S5.527—In the bands 19.7–20.2 GHz and 29.5–30 GHz, the provisions of No. **S4.10** do not apply with respect to the mobile-satellite service.

S5.528—The allocation to the mobile-satellite service is intended for use by networks that use narrow spot-beam antennas and other advanced technology at the space stations. Administrations operating systems in the mobile-satellite service in the band 19.7–20.1 GHz in Region 2 and in the band 20.1–20.2 GHz shall take all practicable steps to ensure the continued availability of these bands for administrations operating fixed and mobile systems in accordance with the provisions of No. **S5.524**.

S5.529—The use of the bands 19.7–20.1 GHz and 29.5–29.9 GHz by the mobile-satellite service in Region 2 is limited to satellite networks that are both in the fixed-satellite service and in the mobile-satellite service as described in No. **S5.526**.

S5.530—In Regions 1 and 3, the allocation to the broadcasting-satellite service in the band 21.4–22 GHz shall come into effect on April 1, 2007. The use of this band by the broadcasting-satellite service after that date and on an interim basis prior to that date is subject to the provisions of Resolution 525 (WARC-92).

S5.531—*Additional allocation:* in Japan, the band 21.4–22 GHz is also allocated to the broadcasting service on a primary basis.

S5.532—The use of the band 22.21–22.5 GHz by the Earth exploration-satellite (passive) and space research (passive) services shall not impose constraints upon the fixed and mobile, except aeronautical mobile, services.

S5.533—The intersatellite service shall not claim protection from harmful interference from airport surface detection equipment stations of the radionavigation service.

S5.534—*Additional allocation:* in Japan, the band 24.65–25.25 GHz is also allocated to the radionavigation service on a primary basis until 2008.

S5.535—In the band 24.75–25.25 GHz, feeder links to stations of the broadcasting-satellite service shall have priority over other uses in the fixed-satellite service (Earth-to-space). Such other uses shall protect and shall not claim protection from existing and future operating feeder-link networks to such broadcasting satellite stations.

S5.535A—The use of the band 29.1–29.5 GHz (Earth-to-space) by the fixed-satellite service is limited to geostationary-satellite systems and feeder links to nongeostationary-satellite systems in the mobile-satellite service. Such use is subject to the application of the provisions of No. **S9.11A**, but not subject to the provisions of No. **S22.2**, except as indicated in Nos. **S5.523C** and **S5.523E** where such use is not subject to the provisions of No. **S9.11A** and shall continue to be subject to Articles **S9** (except No. **S9.11A**) and **S11** procedures, and to the provisions of No. **S22.2** (WRC-97).

S5.536—Use of the 25.25–27.5 GHz band by the intersatellite service is limited to space research and Earth exploration-satellite applications, and also transmissions of data originating from industrial and medical activities in space.

S5.536A—Administrations installing earth exploration-satellite earth stations cannot claim protection from fixed and mobile stations operated by neighbouring administrations. In addition, earth stations operating in the earth exploration-satellite service should take into account Recommendation ITU-R SA. 1278 (WRC-97).

S5.536B—In Germany, Saudi Arabia, Austria, Belgium, Brazil, Bulgaria, China, the Republic of Korea, Denmark,

Egypt, United Arab Emirates, Spain, Estonia, Finland, France, Hungary, India, Islamic Republic of Iran, Ireland, Israel, Italy, Jordan, Kenya, Kuwait, Lebanon, Libya, Liechtenstein, Lithuania, Moldova, Norway, Oman, Uganda, Pakistan, the Philippines, Poland, Portugal, Syria, Slovakia, Czech Republic, Romania, the United Kingdom, Singapore, Sweden, Switzerland, Tanzania, Turkey, Viet Nam, and Zimbabwe, earth stations operating in the Earth exploration-satellite service in the band 25.5–27 GHz shall not claim protection from, or constrain the use and deployment of, stations of the fixed and mobile services (WRC-97).

S5.537—Space services using nongeostationary satellites operating in the intersatellite service in the band 27–27.5 GHz are exempt from the provisions of No. **S22.2**.

S5.538—*Additional allocation:* The bands 27.500–27.501 GHz and 29.999–30.000 GHz are also allocated to the fixed-satellite service (space-to-Earth) on a primary basis for the beacon transmissions intended for uplink power control. Such space-to-Earth transmissions shall not exceed an equivalent isotropically radiated power (eirp) of 10 dBW in the direction of adjacent satellites on the geostationary-satellite orbit. In the band 27.500–27.501 GHz, such space-to-Earth transmissions shall not produce a power flux-density in excess of the values specified in Article **S21**, Table **S21–4** on the Earth's surface.

S5.539—The band 27.5–30 GHz may be used by the fixed-satellite service (Earth-to-space) for the provision of feeder links for the broadcasting-satellite service.

S5.540—*Additional allocation:* The band 27.501–29.999 GHz is also allocated to the fixed-satellite service (space-to-Earth) on a secondary basis for beacon transmissions intended for uplink power control.

S5.541—In the band 28.5–30 GHz, the earth exploration-satellite service is limited to the transfer of data between stations and not to the primary collection of information by means of active or passive sensors.

S5.541A—Feeder links of nongeostationary networks in the mobile-satellite service and geostationary networks in the fixed-satellite service operating in the band 29.1–29.5 GHz (Earth-to-space) shall employ uplink adaptive power control or other methods of fade compensation, such that the earth station transmissions shall be conducted at the power level required to meet the desired link performance while reducing the level of mutual interference between both networks. These methods shall apply to networks for which Appendix **S4** coordination information is considered as having been received by the Bureau after 17 May 1996 and until they are changed by a future competent world radiocommunication conference. Administrations submitting Appendix **S4** information for coordination before this date are encouraged to utilize these techniques to the extent practicable. These methods are also subject to review by ITU-R (see Resolution 121 (Rev. WRC-97)) (WRC-97).

S5.542—*Additional allocation:* in Algeria, Saudi Arabia, Bahrain, Bangladesh, Brunei Darussalam, Cameroon, China, the Congo, the Republic of Korea, Egypt, the United Arab Emirates, Eritrea, Ethiopia, Guinea, India, the Islamic Republic of Iran, Iraq, Japan, Jordan, Kuwait, Lebanon, Malaysia, Mali, Morocco, Mauritania, Nepal, Pakistan, the Philippines, Qatar, Syria, Democratic People's Republic of Korea, Somalia, Sudan, Sri Lanka, and Chad, the band 29.5–31 GHz is also allocated to the fixed and mobile services on a secondary basis. The power limits specified in Nos. **S21.3** and **S21.5** shall apply (WRC-97).

S5.543—The band 29.95–30 GHz may be used for space-to-space links in the Earth exploration-satellite service for telemetry, tracking, and control purposes, on a secondary basis.

S5.544—In the band 31–31.3 GHz the power flux-density limits specified in Article **S21**, Table **S21–4** shall apply to the space research service.

S5.545—*Different category of service:* in Armenia, Azerbaijan, Belarus, Bulgaria, Georgia, Kazakstan, Mongolia, Kyrgyzstan, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the allocation of the band 31–31.3 GHz to the space research service is on a primary basis (see No. **S5.33**) (WRC-97).

S5.546—*Different category of service:* in Saudi Arabia, Armenia, Azerbaijan, Belarus, Bulgaria, Egypt, United Arab Emirates, Spain, Estonia, Finland, Georgia, Hungary, the Islamic Republic of Iran, Israel, Jordan, Kazakstan, Latvia, Lebanon, Moldova, Mongolia, Uzbekistan, Poland, Syria, Kyrgyzstan, Romania, the United Kingdom, Russian Federation, Tajikistan, Turkmenistan, Turkey, and Ukraine, the allocation of the band 31.5–31.8 GHz to the fixed and mobile, except aeronautical mobile, services is on a primary basis (see No. **S5.33**) (WRC-97).

S5.547—The bands 31.8–33.4 GHz, 51.4–52.6 GHz, 55.78–59 GHz, and 64–66 GHz are available for high-density applications in the fixed service (see Resolution 726 (WRC-97)) (WRC-97).

S5.547A—Use of the band 31.8–33.4 GHz by the fixed service shall be in accordance with Resolution 126 (WRC-97) (WRC-97).

S5.547B—*Alternative allocation*: in the United States, the band 31.8–32 GHz is allocated to the radionavigation and space research (deep space) (space-to-Earth) services on a primary basis (WRC-97).

S5.547C—*Alternative allocation*: in the United States, the band 32–32.3 GHz is allocated to the intersatellite, radionavigation, and space research (deep space) (space-to-Earth) services on a primary basis (WRC-97).

S5.547D—*Alternative allocation*: in the United States, the band 32.3–33 GHz is allocated to the intersatellite and radionavigation services on a primary basis (WRC-97).

S5.547E—*Alternative allocation*: in the United States, the band 33–33.4 GHz is allocated to the radionavigation service on a primary basis (WRC-97).

S5.548—In designing systems for the intersatellite and radionavigation services in the band 32–33 GHz, and for the space research service (deep space) in the band 31.8–32.3 GHz, administrations shall take all necessary measures to prevent harmful interference between these services, bearing in mind the safety aspects of the radionavigation service (see Recommendation 707).

S5.549—*Additional allocation:* in Saudi Arabia, Bahrain, Bangladesh, Egypt, the United Arab Emirates, Gabon, Indonesia, the Islamic Republic of Iran, Iraq, Israel, Jordan, Kuwait, Lebanon, Libya, Malaysia, Mali, Malta, Morocco, Mauritania, Nepal, Nigeria, Oman, Pakistan, the Philippines,

Qatar, Democratic Republic of the Congo, Syria, Senegal, Singapore, Somalia, Sudan, Sri Lanka, Togo, Tunisia, and Yemen, the band 33.4–36 GHz is also allocated to the fixed and mobile services on a primary basis (WRC-97).

S5.550—*Different category of service:* in Armenia, Azerbaijan, Belarus, Bulgaria, Georgia, Kazakstan, Mongolia, Uzbekistan, Kyrgyzstan, Russian Federation, Tajikistan, Turkmenistan, and Ukraine, the allocation of the band 34.7–35.2 GHz to the space research service is on a primary basis (see No. **S5.33**) (WRC-97).

S5.551—SUP - WRC-97.

S5.551A—In the band 35.5–36.0 GHz, active spaceborne sensors in the earth exploration-satellite and space research services shall not cause harmful interference to, claim protection from, or otherwise impose constraints on operation or development of the radiolocation service, the meteorological aids service and other services allocated on a primary basis (WRC-97).

S5.551B—The use of the band 41.5–42.5 GHz by the fixed-satellite service (space-to-Earth) is subject to Resolution 128 (WRC-97) (WRC-97).

S5.551C—*Alternative allocation:* in the French overseas territories in Regions 2 and 3, the Republic of Korea and India, the band 40.5–42.5 GHz is allocated to the broadcasting, broadcasting-satellite, and fixed services on a primary basis (WRC-97).

S5.551D—*Additional allocation:* in Algeria, Saudi Arabia, Bahrain, Benin, Cameroon, Egypt, United Arab Emirates, Israel, Jordan, Kuwait, Lebanon, Libya, Mali, Morocco, Mauritania, Nigeria, Oman, Qatar, Syria, Tunisia, and Yemen, the band 40.5–42.5 GHz is also allocated to the fixed-satellite service (space-to-Earth) on a primary basis. The use of this band by the fixed-satellite service shall be in accordance with Resolution 134 (WRC-97) (WRC-97).

S5.551E—Use of the band 40.5–42.5 GHz by the fixed-satellite service shall be in accordance with Resolution 134 (WRC-97) (WRC-97).

S5.551F—*Different category of service*: in Japan, the allocation of the band 41.5–42.5 GHz to the mobile service is on a primary basis (see No. **S5.33**) (WRC-97).

S5.552—The allocation of the spectrum for the fixed-satellite service in the bands 42.5–43.5 GHz and 47.2–50.2 GHz for Earth-to-space transmission is greater than that in the band 37.5–39.5 GHz for space-to-Earth transmission in order to accommodate feeder links to broadcasting satellites. Administrations are urged to take all practicable steps to reserve the band 47.2–49.2 GHz for feeder links for the broadcasting-satellite service operating in the band 40.5–42.5 GHz.

S5.552A—The allocation to the fixed service in the bands 47.2–47.5 GHz and 47.9–48.2 GHz is designated for use by high-altitude platform stations. The use of the bands 47.2–47.5 GHz and 47.9–48.2 GHz is subject to the provisions of Resolution 122 (WRC-97) (WRC-97).

S5.553—In the bands 43.5–47 GHz, 66–71 GHz, 95–100 GHz, 134–142 GHz, 190–200 GHz, and 252–265 GHz, stations in the land mobile service may be operated subject to not causing harmful interference to the space radiocommunication services to which these bands are allocated (see No. **S5.43**).

S5.554—In the bands 43.5–47 GHz, 66–71 GHz, 95–100 GHz, 134–142 GHz, 190–200 GHz, and 252–265 GHz, satellite links connecting land stations at specified fixed points are also authorized when used in conjunction with the mobile-satellite service or the radionavigation-satellite service.

S5.555—*Additional allocation:* The bands 48.94–49.04 GHz, 97.88–98.08 GHz, 140.69–140.98 GHz, 144.68–144.98 GHz, 145.45–145.75 GHz, 146.82–147.12 GHz, 250–251 GHz, and 262.24–262.76 GHz are also allocated to the radio astronomy service on a primary basis.

S5.555A—The band 50.2–50.4 GHz is also allocated, on a primary basis, to the fixed and mobile services until July 1, 2000 (WRC-97).

S5.556—In the bands 51.4–54.25 GHz, 58.2–59 GHz, 64–65 GHz, 72.77–72.91 GHz, and 93.07–93.27 GHz, radio astronomy observations may be carried out under national arrangements.

S5.556A—Use of the bands 54.25–56.9 GHz, 57–58.2 GHz, and 59–59.3 GHz by the intersatellite service is limited to satellites in the geostationary-satellite orbit. The single-entry power flux-density at all altitudes from 0 km to 1000 km above the Earth's surface produced by a station in the intersatellite service, for all conditions and for all methods of modulation, shall not exceed –147 dB(W/m^2/100 MHz) for all angles of arrival (WRC-97).

S5.556B—*Additional allocation:* in Japan, the band 54.25–55.78 GHz is also allocated to the mobile service on a primary basis for low-density use (WRC-97).

S5.557—*Additional allocation:* in Japan, the band 55.78–58.2 GHz is also allocated to the radiolocation service on a primary basis (WRC-97).

S5.558—In the bands 55.78–58.2 GHz, 59–64 GHz, 66–71 GHz, 116–134 GHz, 170–182 GHz, and 185–190 GHz, stations in the aeronautical mobile service may be operated subject to not causing harmful interference to the intersatellite service (see No. **S5.43**) (WRC-97).

S5.558A—Use of the band 56.9–57 GHz by intersatellite systems is limited to links between satellites in geostationary-satellite orbit and to transmissions from nongeostationary satellites in high-Earth orbit to those in low-Earth orbit. For links between satellites in the geostationary-satellite orbit, the single-entry power flux-density at all altitudes from 0 km to 1000 km above the Earth's surface, for all conditions and for all methods of modulation, shall not exceed –147 dB(W/m^2/100 MHz) for all angles of arrival (WRC-97).

S5.559—In the bands 59–64 GHz and 126–134 GHz, airborne radars in the radiolocation service may be operated subject to not causing harmful interference to the intersatellite service (see No. **S5.43**).

S5.560—In the band 78–79 GHz radars located on space stations may be operated on a primary basis in the Earth exploration-satellite service and in the space research service.

S5.561—In the band 84–86 GHz, stations in the fixed, mobile and broadcasting services shall not cause harmful interference to broadcasting-satellite stations operating in accordance with the decisions of the appropriate frequency assignment planning conference for the broadcasting-satellite service.

S5.562—The use of the band 94–94.1 GHz by the Earth exploration-satellite (active) and space research (active) services is limited to spaceborne cloud radars (WRC-97).

S5.563—*Additional allocation:* in the United Kingdom, the band 182–185 GHz is also allocated to the fixed and mobile services on a primary basis.

S5.564—*Additional allocation:* in Germany, Argentina, Spain, Finland, France, India, Italy, and the Netherlands, the band 261–265 GHz is also allocated to the radio astronomy service on a primary basis (WRC-97).

S5.565—The frequency band 275–400 GHz may be used by administrations for experimentation with, and development of, various active and passive services. In this band a need has been identified for the following spectral line measurements for passive services:

radio astronomy service: 278–280 GHz and 343–348 GHz;

Earth exploration-satellite service (passive) and space research service (passive): 275–277 GHz, 300–302 GHz, 324–326 GHz, 345–347 GHz, 363–365 GHz, and 379–381 GHz.

Future research in this largely unexplored spectral region may yield additional spectral lines and continuum bands of interest to the passive services. Administrations are urged to take all practicable steps to protect these passive services from harmful interference until the next competent world radiocommunication conference.

Old Numbering Scheme

459—In the Region 2 polar areas (north of 60°N and south of 60°S), which are subject to auroral disturbances, the aeronautical fixed service is the primary service in the band 160–190 kHz.

471—The bands 490–495 kHz and 505–510 kHz shall be subject to the provisions of No. 3018 until the entry into force of the reduced guardband in accordance with Resolution 210 (Mob-87).

472—The frequency 500 kHz is the international distress and calling frequency for Morse radiotelegraphy. The conditions for its use are prescribed in Articles 37, 38, N 38 and 60.

472A—In the maritime mobile service, the frequency 490 kHz is, from the date of full implementation of the GMDSS (see Resolution 331 (Mob-87)), to be used exclusively for the transmission by coast stations of navigational and meteorological warnings and urgent information to ships, by means of narrow-band direct-printing telegraphy. The conditions for use of the frequency 490 kHz are prescribed in Articles N 38 and 60 and Resolution 329 (Mob-87). In using the band 415–495 kHz for the aeronautical radionavigation service, administrations are requested to ensure that no harmful interference is caused to the frequency 490 kHz.

474—The conditions for the use of frequency 518 kHz by the maritime mobile service are prescribed in Articles 38, N38 and 60 (see Resolution 324 (Mob-87) and Article 14A).

480—In Region 2, the use of the band 1605–1705 kHz by stations of the broadcasting service is subject to the plan established by the Regional Administrative Radio Conference (Rio de Janeiro, 1988.)

In Region 2, in the band 1625–1705 kHz, the relationship between the broadcasting, fixed, and mobile services is shown in No. 419. However, the examination of frequency assignments to stations of the fixed and mobile services in the band 1625–1705 kHz under No. 1241 shall take account of the allotments appearing in the Plan established by the Regional Administrative Radio Conference (Rio de Janeiro, 1988).

591—Subject to agreement obtained under the procedure set forth in Article 14, the band 117.975–137 MHz is also allocated to the aeronautical mobile-satellite (R) service on a secondary basis and on the condition that harmful interference is not caused to the aeronautical mobile (R) service.

599A—The use of the band 137–138 MHz by the mobile-satellite service is subject to the application of the coordination and notification procedures set forth in Resolution 46. However, coordination of a space station of the mobile-satellite service with respect to terrestrial services is required only if the power flux-density produced by the station exceeds –125 dB(W/m^2/4 kHz) at the Earth's surface. The above power flux-density limit shall apply until such time as a competent world administrative radio conference revises it. In making assignments to the space stations in the mobile-satellite service in the above band, administrations shall take all practicable steps to protect the radio astronomy service in the 150.05–153 MHz band from harmful interference from unwanted emissions.

599B—The use of the bands 137–138 MHz, 148–149.9 MHz, and 400.15–401 MHz by the mobile-satellite service and the band 149.9–150.05 MHz by the land mobile-satellite service is limited to nongeostationary-satellite systems.

608A—The use of the band 148–149.9 MHz by the mobile-satellite service is subject to the application of the coordination and notification procedures set forth in Resolution 46 (WARC-92). The mobile-satellite service shall not constrain the development and use of fixed, mobile, and space operation services in the band 148–149.9 MHz. Mobile earth stations in the mobile-satellite service shall not produce a power flux-density in excess of –150 dB(W/m^2/4 kHz) outside national boundaries.

608B—The use of the band 149.9–150.05 MHz by the land mobile-satellite service is subject to the application of the coordination and notification procedures set forth in Resolution 46 (WARC-92). The land mobile-satellite service shall not constrain the development and use of the radionavigation-satellite service in the band 149.9–150.05 MHz. Land mobile earth stations of the land mobile-satellite service shall not produce power flux-density in excess of –150 dB(W/m^2/4 kHz) outside national boundaries.

647B—The use of the band 400.15–401 MHz by the mobile-satellite service is subject to the application of the coordination and notification procedures set forth in Resolution 46. However, coordination of a space station of the mobile-satellite service with respect to terrestrial services is required only if the power flux-density produced by the station exceeds –125 dB(W/m^2/4 kHz) at the Earth's surface. The above power flux-density limit shall apply until such time as a competent world administrative radio conference revises it. In making assignments to the space stations in the mobile-satellite service in the above band, administrations shall take all practicable steps to protect the radio astronomy service in the

band 406.1–410 MHz from harmful interference from unwanted emissions.

669—In the maritime mobile service, the frequencies 457.525 MHz, 457.550 MHz, 457.575 MHz, 467.525 MHz, 467.550 MHz, and 467.575 MHz may be used by on-board communication stations. The use of these frequencies in territorial waters may be subject to the national regulations of the administration concerned. The characteristics of the equipment used shall conform to those specified in Appendix 20.

733—The bands 1610–1626.5 MHz, 5000–5250 MHz, and 15.4–15.7 GHz are also allocated to the aeronautical mobile-satellite (R) service on a primary basis. Such use is subject to agreement obtained under the procedure set forth in Article 14.

753F—The use of the band 2483.5–2500 MHz by the mobile-satellite and the radiodetermination-satellite services is subject to the application of the coordination and notification procedures set forth in Resolution 46 (WARC-92). Coordination of space stations of the mobile-satellite and radiodetermination-satellite services with respect to terrestrial services is required only if the power flux-density produced at the Earth's surface exceeds the limits in No. 2566. In respect of assignments operating in this band, the provisions of Section II, paragraph 2.2 of Resolution 46 (WARC-92) shall also be applied to geostationary transmitting space stations with respect to terrestrial stations.

792A—The use of the bands 4500–4800 MHz, 6725–7025 MHz, 10.7–10.95 GHz, 11.2–11.45 GHz, and 12.75–13.25 GHz by the fixed-satellite service shall be in accordance with the provisions of Appendix 30B.

796—The band 5000–5250 MHz is to be used for the operation of the international standard system (microwave landing system) for precision approach and landing. The requirements of this system shall take precedence over other uses of this band.

797—The bands 5000–5250 MHz and 15.4–15.7 GHz are also allocated to the fixed-satellite service and the intersatellite service, for connection between one or more earth stations at specified fixed points on the Earth and space stations, when these services are used in conjunction with the aeronautical radionavigation and/or aeronautical mobile (R) service. Such use shall be subject to agreement obtained under the procedure set forth in Article 14.

909—In the bands 54.25–58.2 GHz, 59–64 GHz, 116–134 GHz, 170–182 GHz, and 185–190 GHz, stations in the aeronautical mobile service may be operated subject to not causing harmful interference to the intersatellite service (see No. 435).

917—In the bands 140.69–140.98 GHz all emissions from airborne stations, and from space stations in the space-to-Earth direction, are prohibited.

Non-Government (NG) Footnotes

NG2—Facsimile broadcasting stations may be authorized in the band 88–108 MHz.

NG3—Control stations in the domestic public mobile radio service may be authorized frequencies in the bands 72–73 and 75.4–76 MHz on the condition that harmful interference will not be caused to operational fixed stations.

NG4—The use of the frequencies in the band 152.84–153.38 MHz may be authorized, in any area, to remote pickup broadcast base and mobile stations on the condition that harmful interference will not be caused to stations operating in accordance with the Table of Frequency Allocations.

NG6—Stations in the public safety radio services authorized as of June 30, 1958, to use frequencies in the band 159.51–161.79 MHz in areas other than Puerto Rico and the Virgin Islands may continue such operation, including expansion of existing systems, on the condition that harmful interference will not be caused to stations in the services to which these bands are allocated. In Puerto Rico and the Virgin Islands this authority is limited to frequencies in the band 160.05–161.37 MHz. No new public radio service system will be authorized to operate on these frequencies.

NG12—Frequencies in the bands 454.40–455 MHz and 459.40–460 MHz may be assigned to domestic public land and mobile stations to provide a two-way air–ground public radiotelephone service.

NG17—Stations in the land transportation radio services authorized as of May 15, 1958 to operate on the frequency 161.61 MHz may, upon proper application, continue to be authorized for such operation, including expansion of existing systems, on the condition that harmful interference will not be caused to the operation of any authorized station in the maritime mobile service. No new land transportation radio service system will be authorized to operate on 161.61 MHz.

NG19—Fixed stations associated with the maritime mobile service may be authorized, for purposes of communication with coast stations, to use frequencies assignable to ship stations in this band on the condition that harmful interference will not be caused to services operating in accordance with the Table of Frequency Allocations.

NG23—Frequencies in the band 2100–2200 MHz may also be assigned to stations in the international fixed public radio service located south of latitude 25°30′ N in the State of Florida and in US Possessions in the Caribbean area, provided, however, no new assignments in the band 2150–2162 MHz will be made to such stations after February 25, 1974.

NG28—The frequency band 160.86–161.40 MHz is available for assignment to remote pickup base and remote pickup mobile stations in Puerto Rico and the Virgin Islands only on a shared basis with the land transportation radio service.

NG31—Stations in the Rural Radio Service licensed for Basic Exchange Telecommunications Radio Service may be authorized to use some frequencies in the bands 816–820 MHz (fixed subscriber) and 861–865 MHz (central office or base), on a co-primary basis with private land mobile radio licensees, pursuant to part 22 subpart H.

NG41—Frequencies in the bands 3700–4200 MHz, 5925–6425 MHz, and 10.7–11.7 GHz may also be assigned to stations in the international fixed public and international control services located in US Possessions in the Caribbean area.

NG42—Non-Government stations in the radiolocation service shall not cause harmful interference to the amateur service.

NG47—In Alaska frequencies within the band 2655–2690 MHz are not available for assignment to terrestrial stations.

NG49—The following frequencies may be authorized for mobile operations in the Manufacturers Radio Service subject

to the condition that no interference is caused to the reception of television stations operating on Channels 4 and 5 and that their use is limited to a manufacturing facility:

72.02, 72.04, 72.06, 72.08, 72.10, 72.12, 72.14, 72.16, 72.18, 72.20, 72.22, 72.24, 72.26, 72.28, 72.30, 72.32, 72.34, 72.36, 72.38, and 72.40 MHz.

Further, the following frequencies may be authorized for mobile operations in the Special Industrial Radio Service, Manufacturers Radio Service, Railroad Radio Service, and Forest Products Radio Service subject to the condition that no interference is caused to the reception of television stations operating on Channels 4 and 5 and that their use is limited to a railroad yard, manufacturing plant, logging site, mill, or similar industrial facility.

72.44, 72.48, 72.52, 72.56, 72.60, 75.44, 75.48, 75.52, 75.56, and 75.60 MHz.

NG51—In Puerto Rico and the Virgin Islands only, the bands 150.8–150.98 MHz and 150.98–151.49 MHz are allocated exclusively to the business radio service.

NG53—In the band 12.7–13.15 GHz, television pickup stations and CARS pickup stations shall be assigned channels on a co-equal basis and shall operate on a secondary basis to fixed stations operating in accordance with the Table of Frequency Allocations. In the 13.15–13.20 GHz band television pickup stations and CARS pickup stations shall be assigned on an exclusive basis in the top 100 markets, as set out in Section 76.51.

NG56—In the bands 72.0–73.0 and 75.4–76.0 MHz, the use of mobile radio remote control of models is on a secondary basis to all other fixed and mobile operations. Such operations are subject to the condition that interference will not be caused to common carrier domestic public stations, to remote control of industrial equipment operating in the 72–76 MHz band, or to the reception of television signal on Channels 4 (66–72 MHz) or 5 (76–82 MHz). Television interference shall be considered to occur whenever reception of regularly used television signals is impaired or destroyed, regardless of the strength of the television signal or the distance to the television station.

NG59—The frequencies 37.60 and 37.85 MHz may be authorized only for use by base, mobile, and operational fixed stations participating in an interconnected or coordinated power service utility system.

NG63—Television Broadcast translator stations holding valid licenses on November 15, 1971, to operate in the frequency band 806–890 MHz (Channels 70–83), may continue to operate in this band, pursuant to periodic license renewals, on a secondary basis to the land mobile radio service.

NG66—The frequency band 470–512 MHz is allocated for use in the broadcasting and land mobile radio services. In the land mobile services, it is available for assignment in the domestic public, public safety, industrial, and land transportation radio services at, or in the vicinity of, 11 urbanized areas of the United States, as set forth in the following table. Additionally, in the land mobile services, TV Channel 16 is available for assignment in the public safety radio services at, or in the vicinity of, Los Angeles. Such use in the land mobile services is subject to the conditions set forth in Parts 22 and 90 of this chapter.

Urbanized Area	TV Channel
New York, NY–Northeastern New Jersey	14, 15
Los Angeles, CA	14, 20
Chicago, IL–Northwestern Indiana	14, 15
Philadelphia, PA–New Jersey	19, 20
San Francisco–Oakland, CA	16, 17
Boston, MA	14, 16
Washington, DC–Maryland-Virginia	17, 18
Pittsburgh, PA	14, 18
Miami, FL	14
Houston, TX	17
Dallas, TX	16

NG70—In Puerto Rico and the Virgin Islands only, the bands 159.240–159.435 and 160.410–160.620 MHz are also available for assignment to base stations and mobile stations in the special industrial radio service.

NG101—The use of the band 2500–2690 MHz by the broadcasting-satellite service is limited to domestic and regional systems for community reception of educational television programming and public service information. Such use is subject to agreement among administrations concerned and those having services operating in accordance with the table, which may be affected. Unless such agreement includes the use of higher values, the power flux-density at the earth's surface produced by emissions from a space station in this service shall not exceed those values set forth in Part 73 of the rules for this frequency band.

NG102—Use of the fixed-satellite service in the bands 2500–2655 MHz (space-to-earth) and 2655–2690 MHz (Earth-to-space) is limited as follows:

(a) For common carrier use in Alaska, for intra-Alaska service only, and in the mid- and western Pacific areas including American Samoa, Guam, the Northern Mariana Islands, and Hawaii;

(b) for educational use in the contiguous United States, Alaska, and the mid- and western Pacific areas including American Samoa, Guam, the Northern Mariana Islands, and Hawaii.

Such use is subject to agreement with administrations having services operating in accordance with the Table, which may be affected. In the band 2500–2655 MHz, unless such agreement includes the use of higher values, the power flux-density at the Earth's surface produced by emissions from a space station in this service shall not exceed the values set forth in Part 25 of the Rules for this frequency band.

NG104—The use of the bands 10.7–11.7 and 12.75–13.25 GHz in the fixed-satellite service is limited to international systems, i.e., other than domestic systems.

NG111—The band 157.4375–157.4625 MHz may be used for one-way paging operations in the special emergency radio service.

NG112—The frequencies 25.04, 25.08, 150.980, 154.585, 158.445, 159.480, 454.000, and 459.000 MHz may be authorized to stations in the petroleum radio service for use primarily in oil spill containment and cleanup operations and secondarily in regular land mobile communication.

NG114—In the Gulf of Mexico offshore from the Louisiana–Texas coast, the frequency band 476–494 MHz (TV Channels 15, 16, and 17) is allocated to the Domestic Public and Private Land Mobile Radio Services in accordance with the regulations set forth in parts 22 and 90 respectively.

NG115—In the 174 to 216 MHz band wireless microphones may be authorized to operate on a secondary, noninterfering basis, subject to terms and conditions set forth in Part 74 of these Rules and Regulations.

NG117—The frequencies 156.050 and 156.175 MHz may be assigned to stations in the maritime mobile service for commercial and port operations in the New Orleans Vessel Traffic Service (VTS) area and the frequency 156.250 MHz may be assigned to stations in the maritime mobile service for port operating in the New Orleans and Houston VTS areas.

NG118—Television translator relay stations may be authorized to use frequencies in the 2025–2130 MHz band on a secondary basis to stations operating in accordance with the Table of Frequency Allocations.

NG120—Frequencies in the band 928–960 MHz may be assigned for multiple address systems and mobile operations on a primary basis as specified in 47 C.F.R Part 101.

NG124—Within designated segments of the bands that comprise 30.85–47.41 MHz, 150.8–159.465 MHz, and 453.0125–467.9875 MHz, police licensees are authorized to operate low-power radio transmitters on a secondary, noninterference basis in accordance with the provisions of 47 C.F.R. §§ 2.803 and 90.20(e)(5).

NG127—In Hawaii, the frequency band 488–494 MHz is allocated exclusively to the fixed service for use by common carrier control and repeater stations for point-to-point interisland communications only.

NG128—In the band 535–1705 kHz, AM broadcast licensees or permittees may use their AM carrier on a secondary basis to transmit signals intended for both broadcast and nonbroadcast purposes. In the band 88–108 MHz, FM broadcast licensees or permittees are permitted to use subcarriers on a secondary basis to transmit signals intended for both broadcast and nonbroadcast purposes. In the bands 54–72, 76–88, 174–216, 470–608, and 614–806 MHz, TV broadcast licensees or permittees are permitted to use subcarriers on a secondary basis for both broadcast and nonbroadcast purposes.

NG129—In Alaska, the bands 76–88 MHz and 88–100 MHz are also allocated to the Fixed service on a secondary basis. Broadcast stations operating in these bands shall not cause interference to non-Government fixed operations authorized prior to January 1, 1982.

NG133—Stations authorized in the band 73–74.6 MHz as of December 1, 1961 may continue to operate until December 31, 1985. Such stations shall not be required to afford protection to radio astronomy observations within the United States and possessions; however, such stations must afford protection to the observatories of other countries.

NG134—In the band 10.45–10.5 GHz non-Government stations in the radiolocation service shall not cause harmful interference to the amateur and amateur-satellite services.

NG135—In the 420–430 MHz band the amateur service is not allocated north of line A (def. Sec. 2.1).

NG139—Pending the adoption of further specific rules concerning usage of the band 12.2–12.7 GHz by the fixed and broadcasting-satellite services, systems in these services may be authorized subject to the condition that adjustments in certain systems design or technical parameters may become necessary during the system lifetime. The necessity for such adjustments, and their extent, will be dependent upon the Final Acts of the 1983 Regional Administrative Radio Conference and subsequent Commission decisions.

NG140—Pending the adoption of further specific rules concerning usage of the band 17.3–17.8 GHz by the fixed-satellite service for the purpose of providing feeder links to the broadcasting-satellite service, systems may be authorized for this purpose subject to the condition that adjustments in certain systems design or technical parameters may become necessary during the system lifetime. The necessity for such adjustments, and their extent, will be dependent upon the Final Acts of the 1983 Regional Administrative Radio Conference and subsequent Commission decisions.

NG141—The frequencies 42.40 MHz and 44.10 MHz are authorized on a primary basis in the State of Alaska for meteor burst communications by fixed stations in the Rural Radio Service operating under the provisions of Part 22 of this chapter. The frequencies 44.20 MHz and 45.90 MHz are authorized on a primary basis in Alaska for meteor burst communications by fixed private radio stations operating under the provisions of Part 90 of the chapter. The private radio station frequencies may be used by Common Carrier stations on a secondary, noninterference basis and the Common Carrier frequencies may be used by private radio stations for meteor burst communications on a secondary, noninterference basis. Users shall cooperate to the extent practical to minimize potential interference. Stations utilizing meteor burst communications shall not cause harmful interference to stations of other radio services operating in accordance with the Table of Frequency Allocations.

NG142—TV broadcast stations authorized to operate in the bands 54–72, 76–88, 174–216, 470–512, and 512–806 MHz may use a portion of the television vertical blanking interval for the transmission of telecommunications signals, on the conditions that harmful interference will not be caused to the reception of primary services and that such telecommunications services must accept any interference caused by primary services operating in these bands.

NG143—In the band 11.7–12.2 GHz protection from harmful interference shall be afforded to transmissions from space stations not in conformance with International Footnote 839 only if the operations of such space stations impose no unacceptable constraints on operations or orbit locations of space stations in conformance with 839.

NG144—Stations authorized as of September 9, 1983 to use frequencies in the band 17.7–19.7 GHz may, upon proper application, continue to be authorized for such operation.

NG145—In the band 11.7–12.2 GHz, transponders on space stations in the fixed-satellite service may be used addi-

tionally for transmissions in the broadcasting-satellite service, provided that such transmissions do not have a maximum eirp greater than 53 dBW per television channel and do not cause greater interference or require more protection from interference than the coordinated fixed-satellite service frequency assignments. With respect to the space services, this band shall be used principally for the fixed-satellite service.

NG147—Stations in the broadcast auxiliary service and private radio services licensed as of July 25, 1985, or on a subsequent date following as a result of submitting an application for license on or before July 25. 1985, may continue to operate on a primary basis with the mobile-satellite service and the radio-determination satellite service.

NG148—The frequencies 154.585 MHz, 159.480 MHz, 160.725 MHz, 160.785 MHz, 454.000 MHz, and 459.000 MHz may be authorized to maritime mobile stations for offshore radiolocation and associated telecommand operations.

NG149—The frequency bands 54–72 MHz, 76–88 MHz, 174–216 MHz, 470–512 MHz, 512–608 MHz, and 614–746 MHz are also allocated to the fixed service to permit subscription television operations in accordance with Part 73 of the rules.

NG151—In the frequency bands 824–849 MHz and 869–894 MHz, cellular land mobile licensees are permitted to offer auxiliary services on a secondary basis subject to the provisions of Part 22.

NG152—The band 219–220 MHz is also allocated to the amateur service on a secondary basis for stations participating, as forwarding stations, in point-to-point fixed digital message forwarding systems, including intercity packet backbone networks.

NG153—The 2145–2150 MHz and 2160–2165 MHz bands are reserved for future emerging technologies on a coprimary basis with the fixed and mobile services. Allocations to specific services will be made in future proceedings.

NG154—The 157.1875–157.45 MHz and 161.775–162.0125 MHz bands are also allocated to the land mobile service for assignment to stations as described in 47 CFR Part 90.

NG155—The bands 159.500–159.675 MHz and 161.375–161.550 MHz are allocated to the maritime service as described in Part 80 of this chapter. Additionally, the frequencies 159.550, 159.575, and 159.600 MHz are available for low-power intership communications.

NG158—The frequency bands 764–776 MHz and 794–806 MHz are available for assignment exclusively to the public safety services, to be defined in Docket No. WT 96–86.

NG159—Full-power analog television stations licensed pursuant to applications filed before January 2, 2001, and new digital television (DTV) broadcasting operations in the 746–806 MHz band, will be entitled to protection from harmful interference until the end of the DTV transition period. After the end of the DTV transition period, the Commission may assign licenses in the 746–806 MHz band without regard to existing television and DTV operations.

Low-power television and television translators in the 746–806 MHz band must cease operations in the band at the end of the DTV transition period.

Frequency Allotments

Allotment of 27 575 and 27 585 kHz for Short-Distance Low-Power Service

These allotments are to provide for intermittent miscellaneous US Government short-distance low-power radiocommunications, radio signaling, and the control of remote objects or devices by means of radio (where the radiated power exceeds the limit established under Part 7.9).

The designated frequencies are allotted for use by US Government agencies and may be authorized for use by agencies as required upon application. All stations operating on these frequencies shall meet the conditions and standards established for this service.

The designated frequencies are available on a shared basis only and will not be authorized for exclusive use of any one agency. No protection from interference can be assured to any station operating in this service. Services involving safety of life and property should not employ these frequencies in view of their unprotected status. All transmissions are to be restricted to official US Government business that requires the use of radio.

Stations in this service shall utilize FCC type-accepted or type-approved Citizens Radio Band equipment or the equivalent. The maximum transmitter output power shall be 5 W.

Stations shall be identified in accordance with the regulations of each agency.

The only class of station authorized is Mobile (including portable-type operation).

Frequencies 27 575 and 27 585 kHz with 6KA2A, 6KA2D, and 6KA3E emission are designated for the US Government short-distance low-power radio service.

All applications for the use of these frequencies must bear the note S159, which reads, "US Government short-distance low-power service."

Allotments in the Band 1 710–1 850 MHz for Fixed Security Surveillance Systems

The frequencies 1 720, 1 740, 1 760, 1 780, and 1 800 MHz are allotted for use in fixed security surveillance systems, on a secondary basis to other stations operating in accordance with the Government Table of Frequency allocations.

Allotment of 163.100, 418.050, and 418.575 MHz for Wide Area Use

(*Assignments made under these procedures shall no longer be authorized after December 31, 2004.*)

1. The frequencies 163.100, 418.050, and 418.575 MHz are allotted for use by all US Government agencies and are to satisfy intermittent wide area requirements of a transient nature. Coordination in accordance with Section 8.3.18 is not required.
2. All operations shall be authorized in accordance with Chapter 9 of the Manual. The frequencies are available on a shared nonpriority basis only

and will not be authorized nor are they intended for the exclusive use of any one agency. No protection from interference will be provided to any station operating on these frequencies from other stations operating on the same frequency. The use of equipment with coded squelch is strongly encouraged to reduce nuisance interference from other users.

3. The intent of these allotments is for use by Government stations in the Land or Maritime Mobile Services, which are unlikely to cause harmful interference to other stations operating in these Services (Table of Services, Station Classes, and Stations, Section 6.1.4), and the following restrictions apply:
   (a) The minimum ERP (Effective Radiated Power) necessary to support the intended use shall be employed.
   (b) The maximum base or mobile station transmitter output power shall not exceed 30 W.
   (c) The gain of the base station antenna shall not exceed 6 dBi.
   (d) The height of the base station antenna shall not exceed 6 m above the height of the structure supporting the antenna.
   (e) Station classes are limited to FB, FC, ML, MLP, MS, MSP. However, these station classes may be suffixed with the letter "R" as applicable and restricted by 3.(e)(1) below.
      (1) Mobile and/or transportable repeater transmitting stations (as defined in Section 6.1.2, Paragraph 3 and Section 9.8.2, Paragraph 15c) may be authorized only on 163.1 or 418.05 MHz but are restricted to a maximum placement period of 45 days and a maximum transmitter output power of 30 W. (For transportable repeater stations, Note S362 applies.) The repeater receive frequencies are 168.35 or 408.4 MHz.
   (f) Stations in the Fixed Service (FX station class) may be authorized but are restricted to transportable stations (Note S362 applies).
   (g) All equipment shall conform to Part 5.6 of the Manual.
4. All applications utilizing these allotted frequencies must be affixed with Record Note S352 "This assignment is for intermittent wide area requirements of transient, itinerant nature pursuant to Section 4.2.3 of the Manual."

Allotment of 168.350, 408.400, and 418.075 MHz for Common Use Frequencies

(*Assignments made under these procedures shall no longer be authorized after December 31, 2004.*)

1. The frequencies 168.350, 408.400, and 418.075 MHz are allotted for use by all US Government agencies and are to provide for radiocommunications that do not justify the assigning of a radio frequency exclusively to that use, i.e., the frequency can be shared with other users. Coordination in accordance with Section 8.3.18 is not required.
2. All operations shall be authorized in accordance with Chapter 9 of the Manual. The frequencies are available on a shared nonpriority basis only and will not be authorized nor are they intended for the exclusive use of any one agency. No protection from interference will be provided to any station operating on these frequencies from other stations operating on the same frequency. The use of equipment with coded squelch is strongly encouraged to reduce nuisance interference from other users.
3. The intent of these allotments is for use by Government stations in the Land or Maritime Mobile Services, which are unlikely to cause harmful interference to other stations operating in these Services (Table of Services, Station Classes, and Stations, Section 6.1.4), and the following restrictions apply:
   (a) The minimum ERP necessary to support the intended use shall be employed.
   (b) The maximum base or mobile station transmitter output power shall not exceed 30 W.
   (c) The gain of the base station antenna shall not exceed 6 dBi.

TIME SCALES

The world operates on a single international time system, Coordinated Universal Time (UTC), an average of the best clocks in the world. The time scales of the Department of Commerce National Institute of Standards and Technology (NIST) and the US Naval Observatory (USNO) are synchronized to the international time scale maintained by the Bureau International des Poids et Mesures (BIPM) in Sèvres, France. NIST and USNO also maintain atomic clocks that contribute to the UTC average.*

There is an international agreement that UTC scales within a given country are to be kept (if possible) to within one microsecond of this international scale. In the United States, there are two principal timing centers: UTC(NIST) operated by NIST in Boulder, CO, and UTC(USNO) operated by the USNO Time Services Division in Washington, DC. UTC(NIST) serves the civilian sector, and the UTC(USNO) has direct responsibilities for Department of Defense activities. The official United States time is maintained and distributed by both NIST and USNO.

Since both UTC(NIST) and UTC(USNO) are synchronized to UTC, they are also synchronized to each

* Bodson, D., Adair, R. T., and Meister, M. D. "Time and Frequency Information in Telecommunications Systems Standardized by Federal Standard 1002A." *Proceedings of the IEEE*, Vol. 79, No. 7, July 1991, pp. 1077–1078.

other, typically within 50 ns. Greater accuracies with respect to these sources can be achieved by obtaining the necessary corrections from the respective agency.

A new United States standard for time reference, Federal Standard 1002A, was developed in 1991 by the Federal Government in cooperation with the telecommunications industry.

International Definition of the Second

The second is one of seven base units in the International System of Units (SI). The base units are used to derive other units of physical quantities. Use of the SI means that physical quantities such as the second and hertz are defined and measured in the same way throughout the world.

There have been several definitions of the SI second. Until 1956, the definition was based on the *mean solar day*, or one revolution of the earth on its axis. The *mean solar second* was defined as 1/86 400 of the mean solar day and provided the basis for several astronomical time scales known as Universal Time (UT):

- UT0—The original mean solar time scale, based on the rotation of the earth on its axis. UT0 was first kept with pendulum clocks. When quartz clocks became available, astronomers noticed errors in UT0 caused by polar motion and developed the UT1 time scale.
- UT1—The most widely used astronomical time scale, UT1 improves upon UT0 by correcting for longitudinal shifts of the observing station caused by polar motion. Because the earth's rotational rate is not uniform the uncertainty of UT1 is about 2 to 3 ms per day.
- UT2—Mostly of historical interest, UT2 is a smoothed version of UT1 that corrects for deviations in the period of the earth's rotation caused by angular momenta of the earth's core, mantle, oceans, and atmosphere.

The *ephemeris second* served as the SI second from 1956 to 1967. The ephemeris second was a fraction of the tropical year, or the interval between the annual vernal equinoxes, which occur on or about March 21. The tropical year was defined as 31 556 925.9747 ephemeris seconds. Determining the precise instant of the equinox is difficult, and this limited the uncertainty of Ephemeris Time (ET) to ±50 ms over a 9-year interval. ET was used mainly by astronomers and was replaced by *Terrestrial Time* (TT) in 1984, equal to International Atomic Time (TAI) + 32.184 s. The uncertainty of TT is ±10 μs.

The era of atomic time keeping formally began in 1967, when the SI second was redefined based on the resonance frequency of the cesium atom:

> The duration of 9,192,631,770 periods of the radiation corresponding to the transition between two hyperfine levels of the ground state of the cesium-133 atom.

Owing to the atomic second, time interval and frequency can now be measured with less uncertainty and more resolution than any other physical quantity. Today, the best time and frequency standards can realize the SI second with uncertainties of $\cong 1 \times 10^{-15}$. Physical realizations of the other base SI units have much larger uncertainties (Table 4).

International Atomic Time (TAI) is an atomic time scale that attempts to realize the SI second as closely as possible. TAI is maintained by the Bureau International des Poids et Mesures in Sèvres, France. The BIPM averages data collected from more than 200 atomic time and frequency standards located at more than 40 laboratories, including the National Institute of Standards and Technology.

Coordinated Universal Time (UTC) runs at the same rate as TAI. However, it differs from TAI by an integral number of seconds. This difference increases when *leap seconds* occur. When necessary, leap seconds are added to UTC on either June 30 or December 31. The purpose of adding leap seconds is to keep atomic time (UTC) within ±0.9 s of astronomical time (UT1). Some time codes contain a UT1 correction that can be applied to UTC to obtain UT1.

Leap seconds have been added to UTC at a rate of slightly less than once per year, beginning in 1972. UT1 is currently losing about 700 to 800 ms per year with respect to UTC. This means that atomic seconds are shorter than astronomical seconds and that UTC runs faster than UT1. There are two reasons for this. The first reason involves the definition of the atomic second, which made it slightly shorter than the astronomical second to begin with. The second reason is that the earth's rotational rate is gradually slowing down and the astronomical second is gradually getting longer. When a positive leap second is added to UTC, the sequence of events is:

23 h 59 m 59 s
23 h 59 m 60 s
0 h 0 m 0 s

TABLE 4. UNCERTAINTIES OF PHYSICAL REALIZATIONS OF THE BASE SI UNITS

SI Base Unit	Physical Quantity	Uncertainty
candela	luminous intensity	10^{-3}
mole	amount of substance	10^{-6}
kelvin	thermodynamic temperature	10^{-6}
ampere	electric current	10^{-7}
kilogram	mass	10^{-8}
meter	length	10^{-11}
second	time interval	10^{-15}

The insertion of the leap second creates a minute that is 61 s long. This "stops" UTC for 1 s, so that UT1 can catch up.

Time Zones

The world is divided into 24 time zones, each 15° of longitude, or 1 hour angle, apart. The meridian of Greenwich, England, is the center of the zero zone, which extends to 7.5° east and west. Proceeding eastward from Greenwich, the zones are numbered 1 to 12 with the prefix "plus" to indicate the hour angle to be added to Universal Time to obtain local "standard time". Proceeding westward, the zones are numbered 1 to 12 with the prefix "minus" to indicate the hour angle to be subtracted from Universal Time to obtain local "standard time." For example, Washington, DC, at longitude 77° West, is in time zone –5.

The actual boundaries of time zones are defined by law or custom in the various countries and generally do not coincide with the theoretical zone, even in some places at sea. In many areas, local legal "standard time" differs by 60 or 30 minutes from theoretical standard time. Fig. 3 in this chapter is a map showing the standard time zones of the world; Chart 1 in Chapter 49 relates the times in several major cities of the world.

TIME AND FREQUENCY STANDARDS

The stability of time and frequency standards is closely related to their quality factor, or Q. The Q of an oscillator is its resonance frequency divided by its resonance width. The resonance frequency is the natural frequency of the oscillator. The resonance width is the range of possible values where the oscillator will run. A high-Q resonator will not oscillate at all unless it is near its resonance frequency. Obviously a high resonance frequency and a narrow resonance width are both advantages when seeking a high Q. Generally speaking, the higher the Q, the more stable the oscillator, since a high Q means that an oscillator will stay close to its natural resonance frequency.

Quartz oscillators achieve the highest Q of any mechanical-type device. Oscillators based on the atomic resonance of rubidium, hydrogen, and cesium achieve much higher Q factors. Each oscillator type is briefly described below and Table 5 provides a summary.

Quartz Oscillators

Quartz crystal oscillators are by far the most common time and frequency standard. An estimated two billion (2×10^9) quartz oscillators are manufactured annually. Most are small devices built for wristwatches, clocks, and electronic circuits. However, they are also found inside test and measurement equipment, such as counters, signal generators, and oscilloscopes, and interestingly enough, inside every atomic oscillator.

A typical Q for a quartz oscillator ranges from 10^4 to 10^6. The maximum Q for a high-stability quartz oscillator can be estimated as Q = 16 million/f, where f is the resonance frequency in MHz.

Environmental changes such as temperature, humidity, pressure, and vibration can change the resonance frequency of a quartz crystal, and there are several designs that reduce the environmental problems. The *oven-controlled crystal oscillator* (OCXO) encloses the crystal in a temperature-controlled chamber called an oven. An alternate solution to the temperature problem is the *temperature-compensated crystal oscillator* (TCXO). In a TCXO, the signal from a temperature sensor generates a correction voltage that is applied to a voltage-variable reactance, or varactor. The varactor then produces a frequency change equal and opposite to the frequency change produced by temperature. TCXOs are used when high stability over a wide temperature range is not required.

Quartz oscillators have excellent short-term stability. An OCXO might be stable ($\sigma_y\tau$, at τ = 1 s) to 1×10^{-12}. The limitations in short-term stability are mainly due to noise from electronic components in the oscillator circuits. Long term stability is limited by *aging*, or a change in frequency with time caused by internal changes in the oscillator. Aging is usually a nearly linear change in the resonance frequency that can be either positive or negative, and occasionally, a reversal in aging direction occurs. Aging has many possible causes including a buildup of foreign material on the crystal, changes in the oscillator circuitry, or changes in the quartz material or crystal structure. A high-quality OCXO might age at a rate of $< 5 \times 10^{-9}$ per year, while a TCXO might age 100 times faster.

Because of aging and environmental factors such as temperature and vibration, it is hard to keep even the best quartz oscillators within 1×10^{-10} of their nominal frequency without constant adjustment. For this reason, atomic oscillators are used for applications that require higher long-term accuracy and stability.

Rubidium Oscillators

Rubidium oscillators are the lowest priced members of the atomic oscillator family. They operate at 6 834 682 608 Hz, the resonance frequency of the rubidium atom (^{87}Rb), and use the rubidium frequency to control the frequency of a quartz oscillator. A microwave signal derived from the crystal oscillator is applied to the ^{87}Rb vapor within a cell, forcing the atoms into a particular energy state. An optical beam is then pumped into the cell and is absorbed by the atoms as it forces them into a separate energy state. A photocell detector measures how much of the beam is absorbed and tunes a quartz oscillator to a frequency that maximizes the amount of light absorption. The quartz oscillator is then locked to the resonance frequency of rubidium,

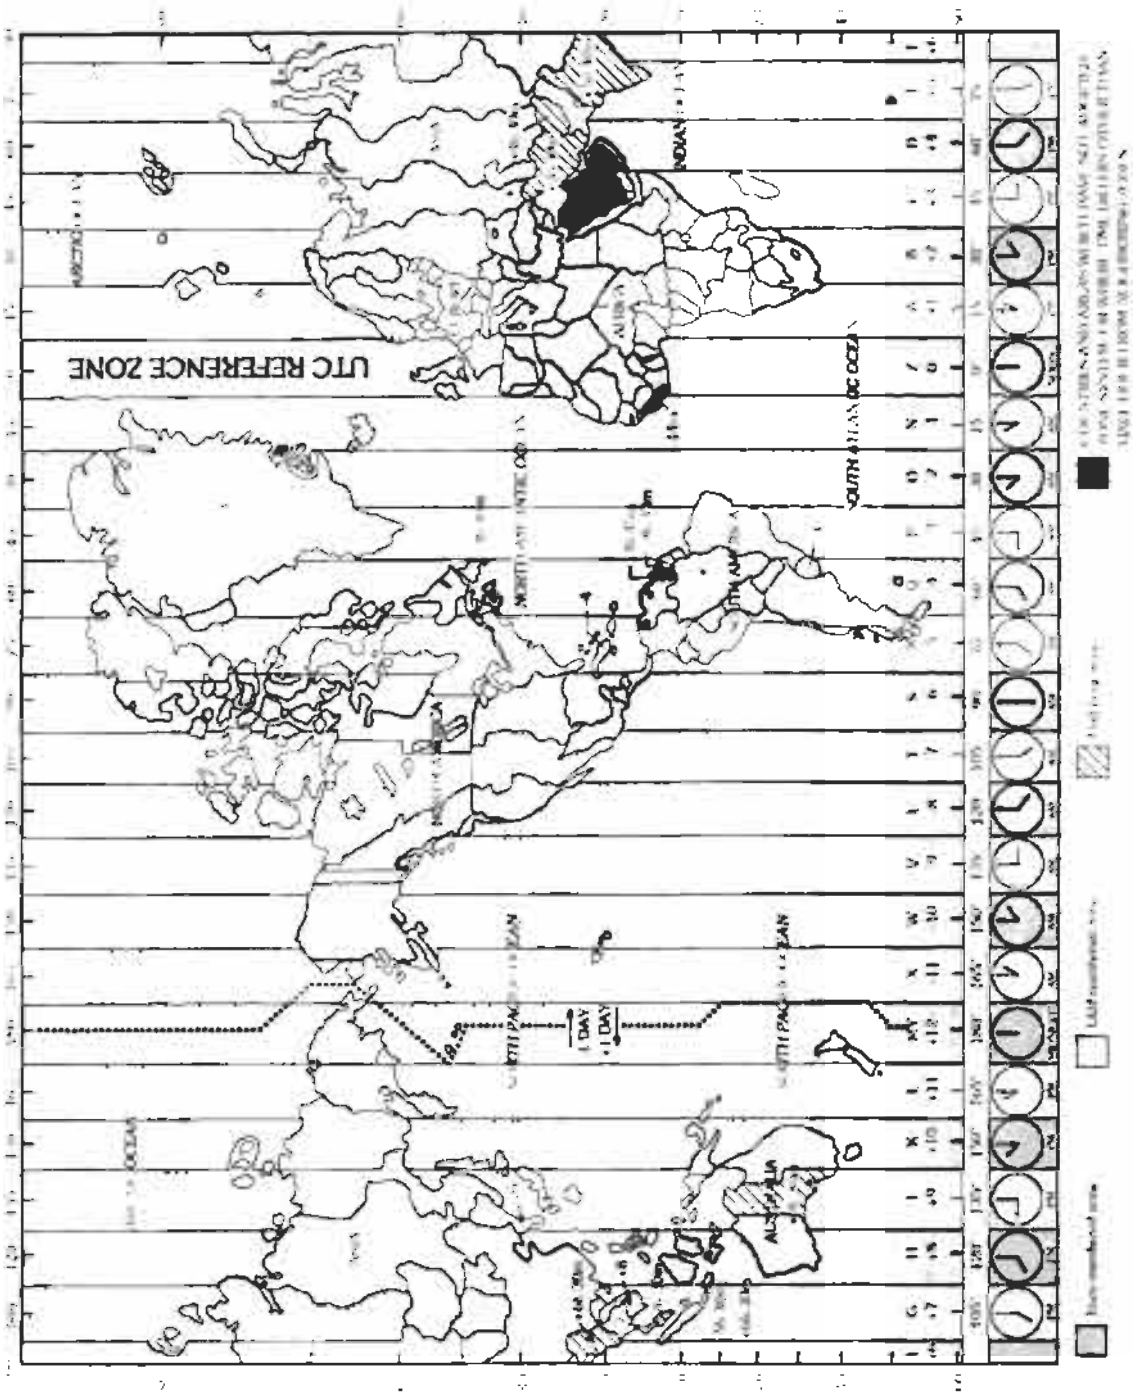

Fig. 3. Standard time zones of the world and their relationship to UTC.

TABLE 5. SUMMARY OF OSCILLATOR TYPES

Oscillator Type	Quartz (TCXO)	Quartz (OCXO)	Rubidium	Commercial Cesium Beam	Hydrogen Maser
Q	10^4 to 10^6	3.2×10^6 (5 MHz)	10^7	10^8	10^9
Resonance frequency	Various	Various	6.834 682 608 GHz	9.192 631 770 GHz	1.420 405 752 GHz
Leading cause of failure	None	None	Rubidium lamp (15 years plus)	Cesium beam tube (3 to 25 years)	Hydrogen depletion (7 years plus)
Stability, $\sigma_y(\tau)$, $\tau = 1$ s	1×10^{-8} to 1×10^{-9}	1×10^{-12}	5×10^{-11} to 5×10^{-12}	5×10^{-11} to 5×10^{-12}	1×10^{-12}
Noise floor, $\sigma_y(\tau)$	1×10^{-9} ($\tau = 1$ to 10^2 s)	1×10^{-12} ($\tau = 1$ to 10^2 s)	1×10^{-12} ($\tau = 10^3$ to 10^5 s)	1×10^{-14} ($\tau = 10^5$ to 10^7 s)	1×10^{-15} ($\tau = 10^3$ to 10^5 s)
Aging/year	5×10^{-7}	5×10^{-9}	1×10^{-10}	None	$\cong 1 \times 10^{-13}$
Frequency offset after warm-up	1×10^{-6}	1×10^{-8} to 1×10^{-10}	5×10^{-10} to 5×10^{-12}	5×10^{-12} to 1×10^{-14}	1×10^{-12} to 1×10^{-13}
Warm-up period	< 10 s to 1×10^{-6}	< 5 min to 1×10^{-8}	< 5 min to 5×10^{-10}	30 min to 5×10^{-12}	24 h to 1×10^{-12}

and standard frequencies are derived and provided as outputs.

Rubidium oscillators continue to get smaller and less expensive, and they offer perhaps the best price/performance ratio of any oscillator. Their long-term stability is much better than that of a quartz oscillator and they are also smaller, more reliable, and less expensive than cesium oscillators.

The Q of a rubidium oscillator is about 10^7. The shifts in the resonance frequency are mainly caused by collisions of the rubidium atoms with other gas molecules. These shifts limit the long-term stability. Stability ($\sigma_y\tau$, at τ = 1 s) is typically 1×10^{-11}, and about 1×10^{-12} at one day. The frequency offset of a rubidium oscillator ranges from 5×10^{-10} to 5×10^{-12} after a warm-up period of a few minutes, and so they meet the accuracy requirements of most applications without adjustment.

Cesium Oscillators

Cesium oscillators are *primary frequency standards* since the SI second is defined using the resonance frequency of the cesium atom (^{133}Cs), which is 9 192 631 770 Hz. A properly working cesium oscillator should be close to its nominal frequency without adjustment, and there should be no change in frequency due to aging.

Commercially available oscillators use *cesium beam* technology. Inside a cesium oscillator, ^{133}Cs atoms are heated to a gas in an oven. Atoms from the gas leave the oven in a high-velocity beam that travels through a vacuum tube toward a pair of magnets. The magnets serve as a gate that allows only atoms of a particular magnetic energy state to pass into a microwave cavity, where they are exposed to a microwave frequency derived from a quartz oscillator. If the microwave fre-

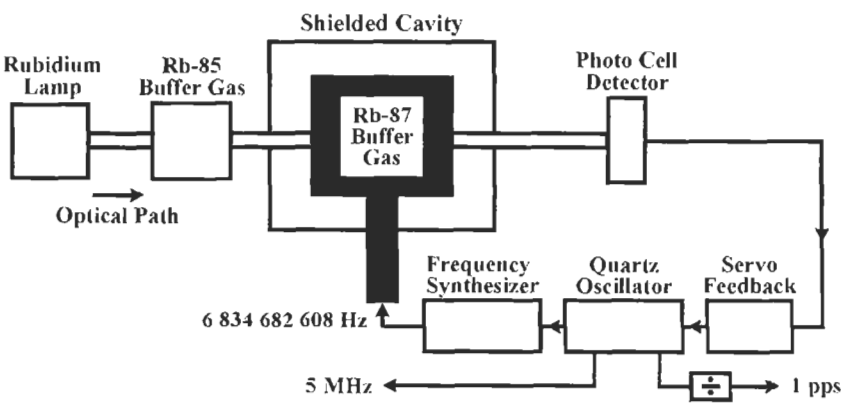

Fig. 4. Rubidium oscillator.

quency matches the resonance frequency of cesium, the cesium atoms will change their magnetic energy state.

The atomic beam then passes through another magnetic gate near the end of the tube. Those atoms that changed their energy state while passing through the microwave cavity are allowed to proceed to a detector at the end of the tube. Atoms that did not change state are deflected away from the detector. The detector produces a feedback signal that continually tunes the quartz oscillator in a way that maximizes the number of state changes so that the greatest number of atoms reaches the detector. Standard output frequencies are derived from the locked quartz oscillator (Fig. 5).

The Q of a commercial cesium standard is a few parts in 10^8. The beam tube is typically < 0.5 m in length, and the atoms travel at velocities of > 100 ms inside the tube. This limits the observation time to a few milliseconds, and the resonance width to a few hundred hertz. Stability ($\sigma_y\tau$, at τ = 1 s) is typically 5×10^{-12} and reaches a noise floor near 1×10^{-14} at about one day, extending out to weeks or months. The frequency offset is typically near 1×10^{-12} after a warm-up period of 30 minutes.

The current state-of-the-art in cesium technology is the *cesium fountain* oscillator, named after its fountain-like movement of cesium atoms. A cesium fountain named NIST-F1 serves as the primary standard of time and frequency for the United States.

A cesium fountain works by releasing a gas of cesium atoms into a vacuum chamber. Six infrared laser beams are directed at right angles to each other at the center of the chamber. The lasers gently push the cesium atoms together into a ball. In the process of creating this ball, the lasers slow down the movement of the atoms and cool them to temperatures a few thousandths of a degree above absolute zero. This reduces their thermal velocity to a few centimeters per second.

Two vertical lasers gently toss the ball upward and then all of the lasers are turned off. This little push is just enough to loft the ball about a meter high through a microwave-filled cavity. Under the influence of gravity, the ball then falls back down through the microwave cavity. The round trip up and down through the microwave cavity lasts for about 1 s and is limited only by the force of gravity pulling the atoms to the ground. During the trip, the atomic states of the atoms might or might not be altered as they interact with the microwave signal. When their trip is finished, another laser is pointed at the atoms. Those atoms whose states were altered by the microwave signal emit photons (a state known as *fluorescence*) that are counted by a detector. This process is repeated many times while the microwave signal in the cavity is tuned to different frequencies. Eventually, a microwave frequency is found that alters the states of most of the cesium atoms and maximizes their fluorescence. This frequency is the cesium resonance (Fig. 6).

The Q of a cesium fountain is about 10^{10}, or about 100 times higher than a traditional cesium beam. Although the resonance frequency is the same, the resonance width is much narrower (< 1 Hz), owing to the longer observation times made possible by the combination of laser cooling and the fountain design. The combined frequency uncertainty of NIST-F1 is estimated at $< 2 \times 10^{-15}$.

Hydrogen Masers

The *hydrogen maser* is the most elaborate and expensive commercially available frequency standard. The word *maser* is an acronym that stands for microwave amplification by stimulated emission of radiation. Masers operate at the resonance frequency of the hydrogen atom, which is 1 420 405 752 Hz.

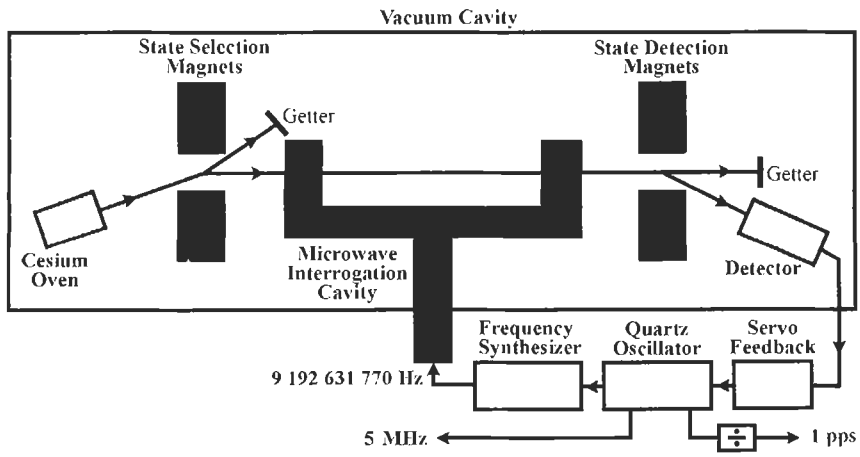

Fig. 5. Cesium beam oscillator.

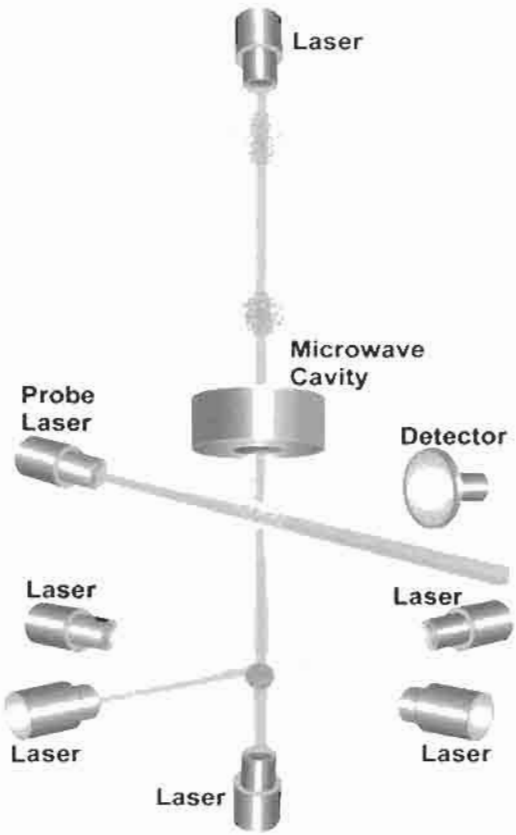

Fig. 6. Cesium fountain oscillator.

A hydrogen maser works by sending hydrogen gas through a magnetic gate that only allows atoms in certain energy states to pass through. The atoms that make it through the gate enter a storage bulb surrounded by a tuned, resonant cavity. Once inside the bulb, some atoms drop to a lower energy level, releasing photons of microwave frequency. These photons stimulate other atoms to drop their energy level, and they in turn release additional photons. In this manner, a self-sustaining microwave field builds up in the bulb. The tuned cavity around the bulb helps to redirect photons back into the system to keep the oscillation going. The result is a microwave signal that is locked to the resonance frequency of the hydrogen atom and that is continually emitted as long as new atoms are fed into the system. This signal keeps a quartz crystal oscillator in step with the resonance frequency of hydrogen (Fig. 7).

The resonance frequency of hydrogen is much lower than that of cesium, but the resonance width of a hydrogen maser is usually just a few hertz. Therefore, the Q is about 10^9, or at least one order of magnitude better than a commercial cesium standard. As a result, the short-term stability is better than a cesium standard for periods out to a few days—typically $< 1 \times 10^{-12}$ ($\sigma_y\tau$, at $\tau = 1$ s) and reaching a noise floor of $\cong 1 \times 10^{-15}$ after about 1 hour. However, when measured for more than a few days or weeks, a hydrogen maser might fall below a cesium oscillator's performance. The stability decreases because of changes in the cavity's resonance frequency over time.

TIME AND FREQUENCY BROADCASTS

Short-Wave Services—WWV and WWVH

The Department of Commerce National Institute of Standards and Technology operates two high-frequency (short-wave) radio stations, WWV at Fort Collins,

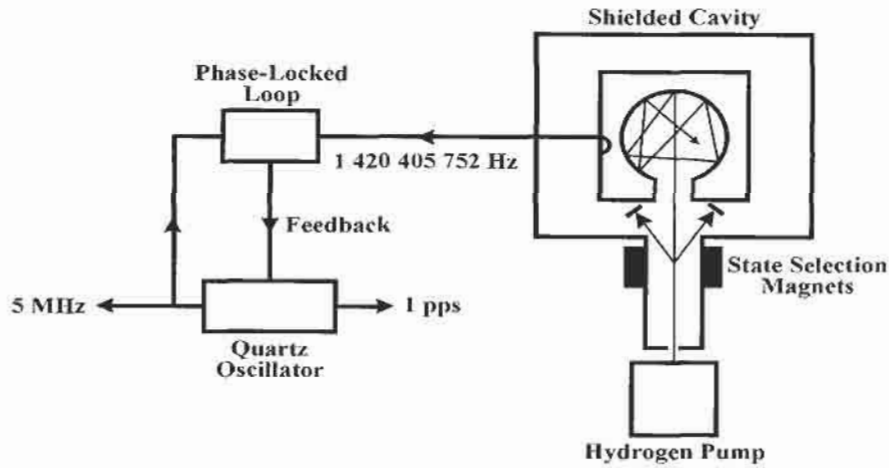

Fig. 7. Hydrogen maser oscillator.

Colorado, and WWVH at Kauai, Hawaii. Both stations broadcast continuous time and frequency signals on 2.5, 5, 10, and 15 MHz. WWV also broadcasts on 20 MHz. All frequencies provide the same information. Although radio reception conditions in the high-frequency band vary greatly with factors such as location, time of year, time of day, the particular frequency being used, atmospheric and ionospheric propagation conditions, and the type of receiving equipment used, at least one frequency should be usable at all times. As a general rule, frequencies above 10 MHz work best in the daytime, and the lower frequencies work best at night.

Services provided by WWV and WWVH include:

- Time announcements
- Standard time intervals
- Standard frequencies
- UT1 time corrections
- BCD time code
- Geophysical alerts
- Marine storm warnings
- Global Positioning System (GPS) status reports

Figs. 8 and 9 show the hourly broadcast schedules of these services.

The station addresses and telephone numbers are:

NIST Radio Station WWV
2000 East County Rd. 58
Fort Collins, CO 80524
(303) 497-3914

NIST Radio Station WWVH
P.O. Box 417
Kekaha, Kauai, HI 96752
(808) 335-4361

Accuracy and Stability—WWV and WWVH are both referenced to the primary NIST frequency standard and atomic time scales located in Boulder, Colorado. The transmitted frequency is accurate to within a few parts in 10^{11} and stable to 1×10^{-12} per day. However, the *received* accuracy is far less due to various propagation effects. The usable *received* accuracy is a few parts in 10^{8} for frequency and about 1 millisecond for timing.

Facilities and Services—The facilities and services of the NIST radio stations are summarized in Table 6.

The WWV antennas are half-wave vertical antennas that radiate omnidirectional patterns. There are actually five antennas at the station site, one for each frequency.

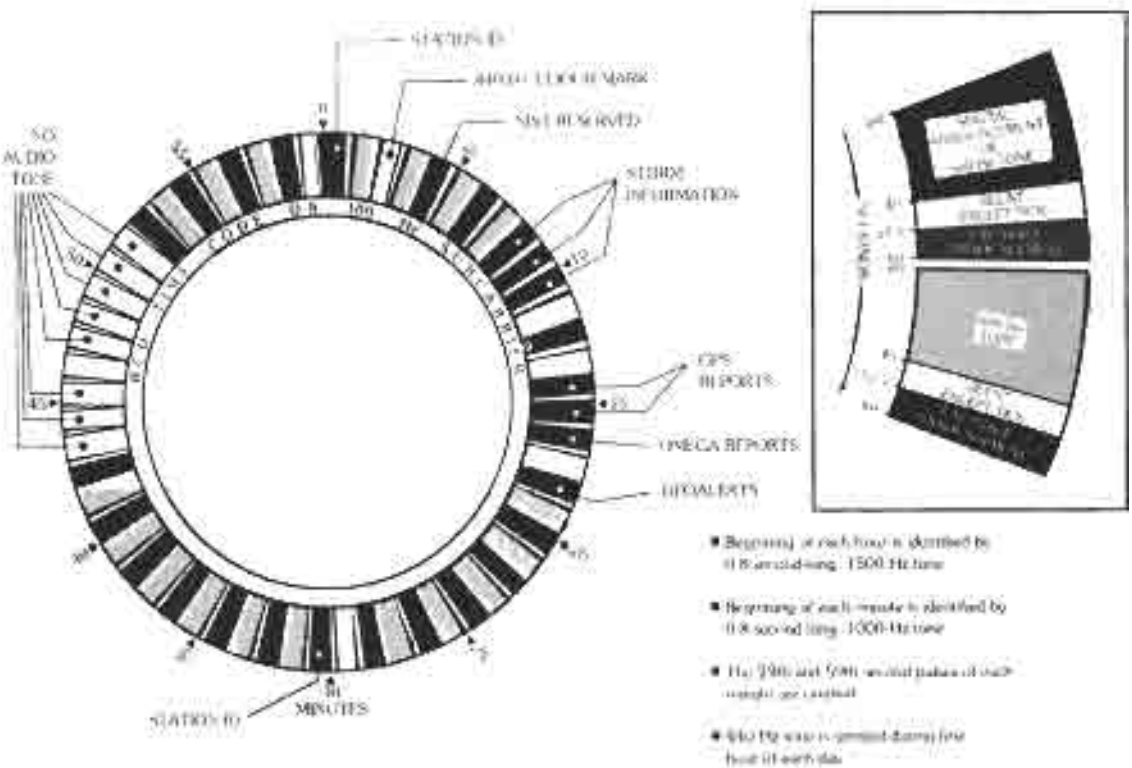

Fig. 8. The hourly broadcast schedules of WWV.

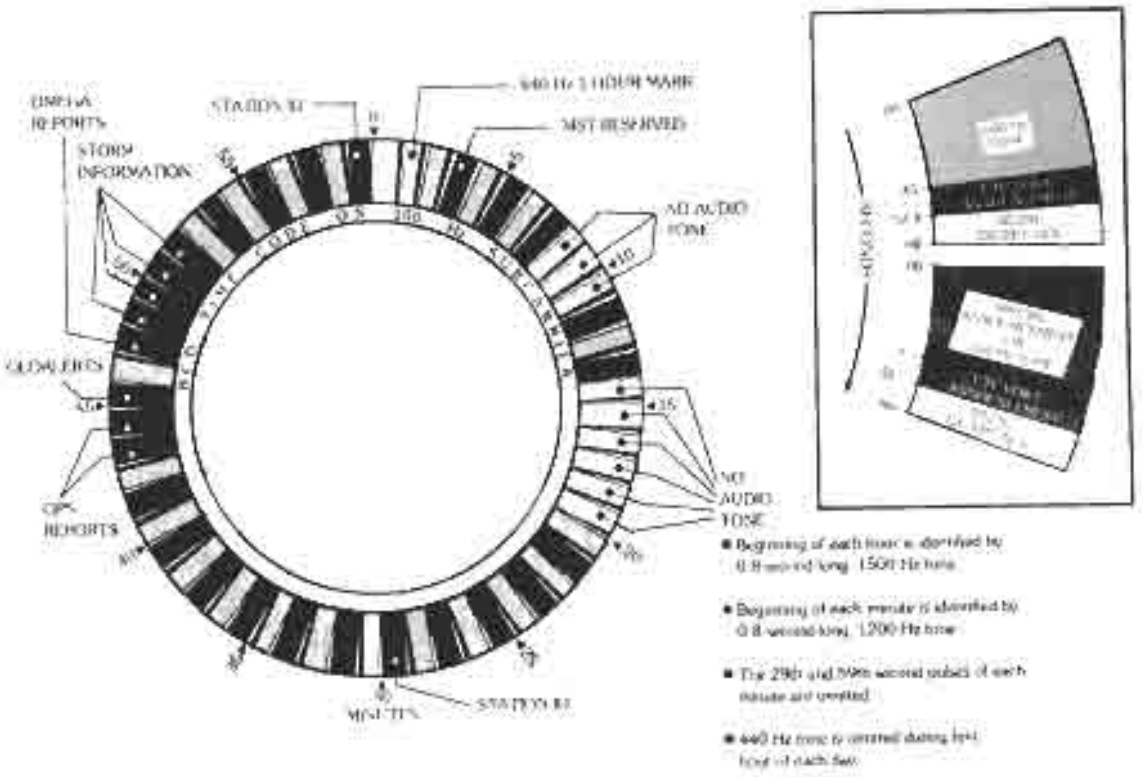

Fig. 9. The hourly broadcast schedules of WWVH

TABLE 6. SUMMARY OF NIST RADIO BROADCAST SERVICES

Characteristics and Services	WWV		WWVH		WWVB
Date Service Began	March 1923		November 1948		July 1956
Average Geographical Coordinates	40° 40' 49.0" N 105° 02' 27.0" W		21° 59' 26.0" N 159° 46' 00.0" W		40° 40' 28.3" N 105° 02' 39.5" W
Standard Carrier Frequencies	2.5 & 20 MHz	5, 10, & 15 MHz	2.5 MHz	5, 10, & 15 MHz	60 kHz
Power	2500 W	10 000 W	5000 W	10 000 W	50 000 W
Standard Audio Frequencies	440 (A above middle C), 500, & 600 Hz				—
Time Intervals	1 pulse/s, minute mark, hour mark				s, min.
Time Signals: Voice	Once per minute				—
Time Signals: Code	BCD code on 100-Hz subcarrier, 1 pulse/s				BCD code
UT1 Corrections	UT1 corrections are broadcast with an accuracy of ±0.1 s				
Special Announcements	Geoalerts, Marine Storm Warnings, Global Positioning System Status Reports				—

Each antenna is connected to a single transmitter using a rigid coaxial line, and the site is designed so that no two coaxial lines cross. Each antenna is mounted on a tower that is approximately one-half-wavelength tall. The tallest tower, for 2.5 MHz, is about 60 m tall. The shortest tower, for 20 MHz, is about 7.5-m tall. The

top half of each antenna is a quarter-wavelength radiating element. The bottom half of each antenna consists of nine quarter-wavelength wires that connect to the center of the tower and slope downward to the ground at a 45° angle. This sloping skirt functions as the lower half of the radiating system and also guys the antenna. The WWV antenna coordinates are listed in Table 7.

The 2.5-MHz antenna at WWVH is nearly identical to its WWV counterpart. However, the 5-, 10-, and 15-MHz antennas are phased-array vertical dipoles. They consist of two half-wave vertical dipoles that are separated by a quarter-wavelength and driven 90° out of phase. These antennas radiate a cardioid pattern with the maximum gain pointed toward the west. The WWVH antenna coordinates are listed in Table 8.

Both stations use double sideband amplitude modulation. The modulation level is 50 percent for the steady tones, 25 percent for the BCD time code, 100 percent for the seconds pulses and the minute and hour markers, and 75 percent for the voice announcements.

Time Announcements—Voice announcements are made from WWV and WWVH once every minute. Since both stations can be heard in some locations, a man's voice is used on WWV and a woman's voice is used on WWVH to reduce confusion. The WWVH announcement occurs first, at about 15 s before the minute. The WWV announcement follows at about 7.5 s before the minute. Though the announcements occur at different times, the tone markers are transmitted at the exact same time from both stations. However, they may not be *received* at exactly the same instant owing to differences in the propagation delays from the two station sites.

The announced time is *Coordinated Universal Time* (UTC). UTC was established by international agreement in 1972, and is governed by the International Bureau of Weights and Measures (BIPM) in Sèvres, France. Coordination with the international UTC time scale keeps NIST time signals in close agreement with signals from other time and frequency stations throughout the world.

UTC differs from local time at a given location by a specific number of hours. The number of hours depends on the number of time zones between the location in question and the zero meridian (which passes through Greenwich, England). When local time changes from Daylight Saving to Standard Time, or vice versa, UTC does not change. However, the difference between UTC and local time does change—by 1 hour. Fig. 3 may be used to find how many hours to add to or subtract from UTC to obtain local standard time. If DST is in effect, subtract 1 hour less in the United States than shown in Fig. 3. Thus, Eastern Daylight Time (EDT) is only 4 hours behind UTC, not 5 as shown in Fig. 5 for EST.

UTC is a 24-hour clock system. The hours are numbered beginning with 00 hours at midnight through 12 hours at noon to 23 hours and 59 minutes just before the next midnight.

Standard Time Intervals—On WWV and WWVH, the seconds pulses are heard every second except on the 29th and 59th seconds of each minute. The first pulse of each hour is an 800-ms pulse of 1 500 Hz. The first pulse of each minute is an 800-ms pulse of 1 000 Hz at WWV and 1 200 Hz at WWVH. The remaining seconds pulses are short audio bursts (5-ms pulses of 1 000 Hz at WWV and 1 200 Hz at WWVH) that sound like the ticking of a clock.

Each seconds pulse is preceded by 10 ms of silence and followed by 25 ms of silence. The silence makes it easier to pick out the pulse. The total 40-ms protected zone around each seconds pulse is shown in Fig. 10.

Standard Audio Frequencies—In alternate minutes during most of each hour, 500-Hz or 600-Hz audio tones are broadcast. A 440-Hz tone (the musical note A above middle C) is broadcast once each hour. In addition to being a musical standard, the 440-Hz tone

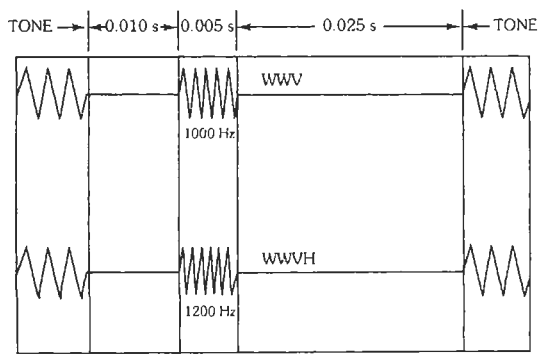

Fig. 10. Format of WWV and WWVH seconds pulses.

provides an hourly marker for chart recorders and other automated devices. The 440-Hz tone is omitted, however, during the first hour of each UTC day. (See Figs. 8 and 9 for further details.)

Silent Periods—The silent periods are without tone modulation. However, the carrier frequency, seconds pulses, time announcements, and the 100-Hz BCD time code continue during the silent periods. In general, one station will not broadcast an audio tone while the other station is broadcasting a voice message.

On WWV, the silent period extends from 43 to 46 and from 47 to 52 minutes after the hour. WWVH has two silent periods: from 8 to 11 minutes after the hour, and from 14 to 20 minutes after the hour. Minutes 29 and 59 on WWV and minutes 00 and 30 on WWVH are also silent.

BCD Time Code—WWV and WWVH continuously broadcast a binary coded decimal (BCD) time code on a 100-Hz subcarrier. The information carried by the time code includes the current minute, hour, and day of year. The time code also contains the 100-Hz frequency from the subcarrier. The 100-Hz frequency may be used as a standard with the same accuracy as the audio frequencies.

The WWV/WWVH time code is a modified version of the IRIG-H code. The code is transmitted on a 100-Hz subcarrier at a rate of 1 pulse per second. The code is in binary coded decimal format. Groups of binary digits (bits) are used to represent decimal numbers. The binary-to-decimal weighting scheme is 1–2–4–8. The least significant bit is always sent first. Table 9 shows the BCD groups and the equivalent decimal numbers.

The decimal number is obtained by multiplying each bit in the binary group by the weight of its respective column and then adding the four products together. For example, the table shows that the binary group 1010 is equal to 5. This is derived by:

TABLE 9. 1–2–4–8 BCD-DECIMAL EQUIVALENTS

Binary Group	Decimal Equivalent
Weight: 1 2 4 8	
0 0 0 0	0
1 0 0 0	1
0 1 0 0	2
1 1 0 0	3
0 0 1 0	4
1 0 1 0	5
0 1 1 0	6
1 1 1 0	7
0 0 0 1	8
1 0 0 1	9

$$(1 \times 1) + (0 \times 2) + (1 \times 4) + (0 \times 8) = 1 + 0 + 4 + 0 = 5$$

In the standard IRIG-H code, a "0" bit consists of exactly 20 cycles of 100-Hz amplitude modulation (200-ms duration), and a "1" bit consists of 50 cycles of 100-Hz (500-ms duration). The WWV/WWVH code differs from IRIG-H because all tones are suppressed briefly while the seconds pulses are transmitted (see "Standard Time Intervals," above).

Tone suppression also deletes the first 30 ms of each binary pulse in the time code. This makes the WWV/WWVH bits 30 ms shorter than the IRIG-H bits. Therefore, 170-ms pulses are recognized as "0" bits, and 470-ms pulses are recognized as "1" bits. The leading edge of each pulse coincides with the positive-going crossing of the 100-Hz subcarrier, but due to the tone suppression, it occurs 30 ms after the start of the second.

Refer to Fig. 11. Within 1 minute, enough bits are sent to express the minute, hour, and day of year, two digits of the current year; a leap-second warning indicator; the UT1 correction; and a Daylight Saving Time (DST) indicator. The coded time information refers to the time at the start of the one-minute frame. Seconds are determined by counting pulses within the frame. Two BCD groups each are needed to express the hour (00 to 23), minute (00 to 59), and year (00–99); and three groups are needed to express the day of year (001 to 366). Some bits in the BCD groups are unused, but may provide additional information in the future. To represent units, tens, or hundreds, the basic 1–2–4–8 weights are multiplied by 1, 10, or 100 as appropriate.

Each frame begins with a unique spacing of pulses that mark the start of a new minute. During the first second of the minute, no pulse is transmitted. This creates a 1-s (1000-ms) hole. Since the pulses are already delayed 30 ms by the tone suppression, the UTC minute actually begins 1030 ms (1.03 s) earlier than the first pulse in the frame.

For synchronization purposes, a position identifier pulse is transmitted every 10 s. The position identifier pulse lasts for 770 ms (77 cycles of 100 Hz).

UT1 corrections are sent during the final 10 s of each frame. These corrections are to the nearest 0.1 s. The UT1 correction is expressed with bits called control functions. Control function 1 occurs at 50 s, and tells whether the UT1 correction is negative or positive. If a "0" bit is sent the correction is negative, and if a "1" bit is sent the correction is positive. Control functions 7, 8, and 9 tell the amount of the UT1 correction. They occur at 56, 57, and 58 s, respectively. Since the UT1 corrections are in tenths of seconds, the binary-to-decimal weights, are multiplied by 0.1.

During the first half of 1991, an improved procedure for alerting users of impending DST changes was implemented. Two bits, number 2 and number 55, are used to indicate whether "Standard Time" or "Daylight Saving Time" is in effect at any particular time. Bit number 55 is changed from "0" to "1" at 0000 UTC of the day the time is to be changed from "Standard" time

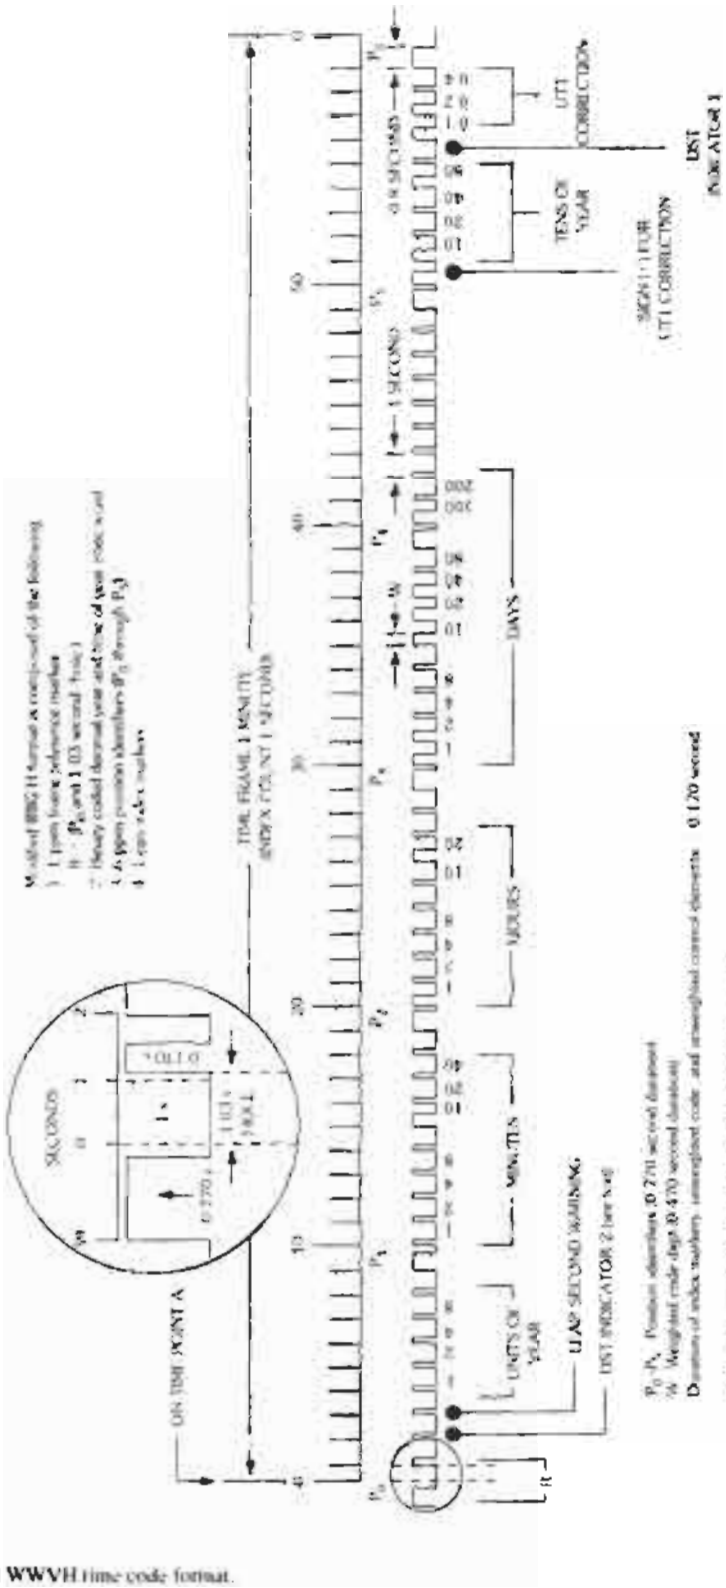

Fig. 11. WWV and WWVH time code format.

to DST and from "1" to "0" for the change back to "Standard" time in the fall. The second DST bit, number 2, is changed in the same way as bit 55 but 24 hours later, at 0000 UTC on the day *following* the time change. The use of two separate bits in this manner allows timing receivers that are powered on during the day of a time change to be able to determine whether it is a day of change and, if so, how to adjust their current time correctly.

Also beginning during 1991, the last two digits of the current year (for example, "90" for 1990) are encoded using bits 4 through 7 (for units of year) in a 1–2–4–8 weighting sequence and bits 51 through 54 (for tens of year) in a 10–20–40–80 weighting sequence.

Bit 3 is used to indicate that a leap second is to be inserted at the end of the current month. A "1" is transmitted beginning early in the month at the end of which a leap second is to be inserted. Bit 3 is returned to "0" at 0000 UTC of the first day of the following month.

Fig. 11 shows one frame of the time code. The six position identifiers are labeled P_1, P_2, P_3, P_4, P_5, and P_0. The minutes, hours, days, year, and UT1 sets are marked, with the weighting factors printed below the bits. Wide pulses represent "1" bits and narrow pulses represent "0" bits. Unused bits are set to 0.

In Fig. 11, the decoded UTC at the start of the frame is 1990, 173 days, 21 hours, and 10 minutes. Since the UT1 correction is +0.3 s, the decoded UT1 is 1990, 173 days, 21 hours, 10 minutes, and 0.3 s.

UT1 Time Corrections—The UTC time scale broadcast by WWV and WWVH meets the needs of most users. UTC runs at an almost perfectly constant rate, since its rate is based on cesium atomic frequency standards. Somewhat surprisingly, some users need time *less* stable than UTC but related to the rotation of the Earth. Applications such as celestial navigation, satellite observations of the Earth, and some types of surveying require time referenced to the rotational position of the Earth. These users rely on the UT1 time scale. UT1 is derived by astronomers who monitor the speed of the Earth's rotation.

UT1 time can be obtained by applying a correction to the UTC time signals broadcast from WWV and WWVH. UT1 time corrections are included in the WWV and WWVH broadcasts at two levels of accuracy. First, for those users only needing UT1 to within 1 s, occasional corrections of exactly 1 s are inserted into the UTC time scale. These corrections, called leap seconds, keep UTC within ±0.9 s of UT1. Leap seconds are coordinated under international agreement by the International Earth Rotation Service in Paris, France. Leap seconds can be either positive or negative, but so far, only positive leap seconds have been needed. A positive leap second is normally added every 1 or 2 years, usually on June 30 or December 31. More information about leap seconds is given below under "Dating of Events in the Vicinity of Leap Seconds."

The second level of correction is for the small number of users needing UT1 accurate to within 0.1 s. These corrections are encoded into the broadcasts by using doubled ticks during the first 16 s of each minute. The amount of correction (in tenths of 1 s) is determined by counting the number of successive doubled ticks heard each minute. The sign of the correction depends on whether the doubled ticks are in the first 8 s of the minute or in the second 8 s. If the doubled ticks are in the first 8 s (1–8) the sign is positive, and if they are in the second 8 s (9–16) the sign is negative. For example, if ticks 1, 2, and 3 are doubled, the correction is "plus" 0.3 s. This means that UT1 equals UTC + 0.3 s. If UTC is 8:45:17, then UT1 is 8:45:17.3. If ticks 9, 10, 11, and 12 are doubled, the correction is "minus" 0.4 s. If UTC is 8:45:17, then UT1 is 8:45:16.6. An absence of doubled ticks indicates that the current correction is 0.

Dating of Events in the Vicinity of Leap Seconds—Leap seconds are sometimes needed to keep UTC within ±0.9 s of UT1. The addition or deletion of a leap second always occurs at the end of a month. By international agreement, first preference is given to December 31 or June 30. Second preference is given to March 31 or September 30, and third preference is given to any other month.

When UT1 is slow relative to UTC, a positive leap second is needed. The second is inserted beginning at $23^h\ 59^m\ 60^s$ of the last day of the month and ending at $0^h\ 0^m\ 0^s$ of the first day of the following month. The minute containing the leap second is 61-s long. Fig. 12 shows how to assign dates to events occurring near the leap second.

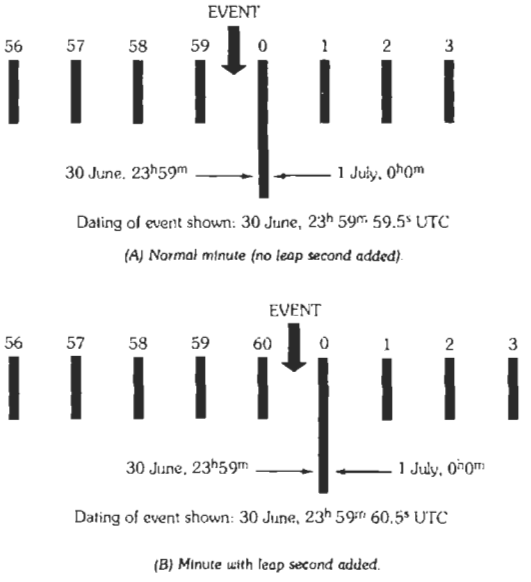

Fig. 12. Dating of events near a leap second.

Official Announcements—Announcement segments 45-s long are available to other Federal agencies by subscription (see Figs. 8 and 9). These segments are used for public service messages. The accuracy and content of these messages is the responsibility of the originating agency.

Geophysical Alerts: The National Oceanic and Atmospheric Administration (NOAA) uses WWV and WWVH to broadcast geophysical alert messages that provide information about solar–terrestrial conditions. Geophysical alerts are broadcast from WWV at 18 minutes after the hour and from WWVH at 45 minutes after the hour. The messages are less than 45 s in length and are updated every 3 hours (typically at 0000, 0300, 0600, 0900, 1200, 1500, 1800, and 2100 UTC). More frequent updates are made when necessary.

The geophysical alerts provide information about the current conditions for long-distance HF radio communications. The alerts use a standardized format and terminology that requires some explanation. Before looking at a sample message, let us define some of the terminology:

Solar flux is a measurement of the intensity of solar radio emissions with a wavelength of 10.7 cm (a frequency of about 2800 MHz). The daily solar flux measurement is recorded at 2000 UTC by the Dominion Radio Astrophysical Observatory of the Canadian National Research Council located at Penticton, British Columbia, Canada. The value broadcast is in solar flux units that range from a theoretical minimum of about 50 to numbers larger than 300. During the early part of the 11-year *sunspot cycle*, the flux numbers are low; but they rise and fall as the cycle proceeds. The numbers will remain high for extended periods around sunspot maximum.

The A and K indices are a measurement of the behavior of the *magnetic field* in and around the earth. The *K index* uses a scale from 0 to 9 to measure the change in the horizontal component of the geomagnetic field. A new K index is determined and added to the broadcast every 3 hours based on magnetometer measurements made at the Table Mountain Observatory, north of Boulder, Colorado, or an alternate middle latitude observatory. The *A index* is a daily value on a scale from 0 to 400 to express the range of disturbance of the geomagnetic field. It is obtained by converting and averaging the eight 3-hour K index values. An estimate of the A index is first announced at 2100 UTC, based on seven measurements and one estimated value. At 0000 UTC, the announced A index consists entirely of known measurements, and the word "estimated" is dropped from the announcement.

Space weather describes the conditions in space that affect earth and its technological systems. Space weather is a consequence of the behavior of the sun, the nature of earth's magnetic field and atmosphere, and our location in the solar system.

Space weather storms observed and expected are characterized using the NOAA Space Weather Scales.

TABLE 10. NOAA SPACE WEATHER SCALES

Geomagnetic Storms	Solar Radiation Storms	Radio Blackouts	Descriptor
G5	S5	R5	Extreme
G4	S4	R4	Severe
G3	S3	R3	Strong
G2	S2	R2	Moderate
G1	S1	R1	Minor

The abbreviated Table 10 shows the levels of activity that are included in the announcements and the associated terminology. The descriptor used to identify observed or expected conditions is the maximum level reached or predicted. The NOAA Space Weather Scales are further described at http://www.sec.noaa.gov on the Space Environment Center's Website.

Geomagnetic storm levels are determined by the estimated 3-hour planetary K indices derived in real time from a network of Western Hemisphere ground-based magnetometers (see Table 11).

Solar radiation storms levels are determined by the proton flux measurements made by NOAA's primary *Geostationary Operational Environmental Satellite (GOES)* (see Table 12).

Radio blackouts are determined by the x-ray level measured by the primary *GOES* satellite (see Table 13).

Every geophysical alert consists of three parts as shown in Tables 14 and 15. Table 14 describes the

TABLE 11. GEOMAGNETIC STORM LEVELS

Planetary K Index	Geomagnetic Storm Level
K = 5	G1
K = 6	G2
K = 7	G3
K = 8	G4
K = 9	G5

TABLE 14. INFORMATION IN GEOPHYSICAL ALERT VOICE MESSAGE

Section	Information in Voice Message
1	The solar–terrestrial indices for the day: specifically the solar flux, the A index, and the K index.
2	Space weather storms observed during the previous 24 hours. Includes all observed geomagnetic storms, solar radiation storms (proton events), and radio blackouts (class M1 and greater flares).
3	Space weather expected during the following 24 hours.

TABLE 15. EXAMPLE TEXT FROM ACTUAL GEOPHYSICAL ALERT MESSAGE

Section	Example of Actual Geophysical Alert Message
1	Solar–terrestrial indices for 08 November follow.
	Solar flux 173 and midlatitude A index 14
	The midlatitude K index at 1500 UTC on 08 November was 3.
2	Space weather for the past 24 hours has been severe.
	Solar radiation storm(s) reaching the S4 level is in progress.
	Radio blackouts(s) reaching the R2 level occurred.
Alternate Section 2	No space weather storms have been observed during the past 24 hours.
3	Space weather for the next 24 hours is expected to be severe.
	Solar radiation storms reaching the S4 level are expected to continue. Radio blackouts reaching the R2 level are expected.
Alternate Section 3	No space weather storms are expected during the next 24 hours.

information contained in the geophysical alert. Table 15 provides example text from an actual message.

The announcements include the descriptor of the largest space weather event observed (2) or expected (3) in the first line of each section. The remaining lines give the type of events and the level observed for each one. In the example above, no geomagnetic storm information is included because no geomagnetic storms were observed or were expected during the period. In the case where none of the three types of events are observed or expected, the announcement would contain Section 1, plus alternate Section 2 and alternate Section 3.

To hear the current geophysical alert message by telephone, dial (303) 497-3235. Inquiries regarding these messages should be addressed to: Space Weather Operations, NOAA R/SEC, 325 Broadway, Boulder, CO 80305-3328 (E-mail: swo@sec.noaa.gov; Voice: (303) 497-3171).

Marine Storm Warnings: Marine storm warnings are broadcast for the marine areas that the United States has warning responsibility for under international agreement. The storm warning information is provided by the National Weather Service. Storm warnings for the Atlantic and eastern North Pacific are broadcast by voice on WWV at 8, 9, and 10 minutes after the hour. Storm warnings for the western, eastern, southern, and north Pacific are broadcast by WWVH at 48, 49, 50, and 51 minutes after the hour. An additional segment (at 11 minutes after the hour on WWV and at 52 minutes after the hour on WWVH) is used occasionally if there are unusually widespread storm conditions. The brief voice messages warn mariners of storm threats present in their areas.

The storm warnings are based on the most recent forecasts. Updated forecasts are issued by the National Weather Service at 0500, 1100, 1700, and 2300 UTC for WWV; and at 0000, 0600, 1200, and 1800 UTC for WWVH.

A typical storm warning announcement text is as follows:

> North Atlantic weather West of 35 West at 1700 UTC; Hurricane Donna, intensifying, 24 North, 60 West, moving northwest, 20 knots, winds 75 knots: storm, 65 North, 35 West, moving east, 10 knots; winds 50 knots, seas 15 feet.

For more information about marine storm warnings, write to: National Weather Service, NOAA, 1325 East West Highway, Silver Spring, MD 20910. Or see the National Weather Service Website at http://www.nws.noaa.gov.

Global Positioning System (GPS) Status Announcements: The United States Coast Guard sponsors two voice announcements per hour on WWV and WWVH, giving current status information about the GPS satellites and related operations. The 40-s announcements begin at 10 minutes after each hour on WWV and at 40

minutes after each hour on WWVH. For further information, contact the US Coast Guard Navigation Center, 7323 Telegraph Road, Alexandria, VA 22310, or call (703) 313–5900.

WWV and WWVH Audio Signals by Telephone—The audio portions of the WWV and WWVH broadcasts can also be heard by telephone. The accuracy of the telephone time signals is normally 30 ms or better in the continental United States. In rare instances when the telephone connection is made by satellite, there is an additional delay of 0.25 to 0.5 s.

To hear these broadcasts, dial (303) 499–7111 for WWV and (808) 335–4363 for WWVH. Callers are disconnected after 3 minutes. *These are not toll-free numbers*; callers outside the local calling area are charged for the call at regular long-distance rates.

Low-Frequency Services—WWVB

NIST radio station WWVB is located on the same site as WWV near Fort Collins, Colorado. WWVB continuously broadcasts time and frequency signals at 60 kHz, in the part of the radio spectrum known as low frequency (LF). The WWVB signal includes a time code that is used to automatically synchronize millions of radio clocks every day in the continental United States and the surrounding areas. These radio clocks include wristwatches, desk clocks, alarm clocks, wall clocks, and clocks integrated into other devices such as televisions and radios. In addition, calibration and testing laboratories use the 60-kHz carrier frequency from WWVB to calibrate electronic equipment and frequency standards.

Accuracy and Stability—WWVB is referenced to the primary NIST frequency standard and atomic time scales located in Boulder, Colorado. The transmitted frequency is accurate to within a few parts in 10^{13} and stable to 1×10^{-13} per day. Propagation effects are minor compared to those of WWV and WWVH. If it is possible to receive the groundwave signal, and proper averaging techniques are used, the received accuracy should be nearly as good as the transmitted accuracy.

Station Identification—WWVB identifies itself by advancing its carrier phase 45° at 10 minutes after the hour and returning to normal phase at 15 minutes after the hour. WWVB is also identified by its unique time code.

Radiated Power, Antenna, and Coverage—The effective radiated power from WWVB is 50 000 watts. WWVB uses two identical antennas spaced 860 m apart. Each antenna is a top-loaded dipole consisting of four 122-m towers arranged in a diamond shape. A system of cables, called a capacitance hat or top hat, is suspended between the four towers. This top hat is electrically isolated from the towers and is electrically connected to a downlead suspended from the center of the top hat. The downlead serves as the radiating element.

The WWVB signal provides coverage of the continental United States 24 hours per day. During the nighttime hours, the coverage area extends to cover nearly all of North America and parts of South America.

WWVB Time Code—The WWVB time code is synchronized with the 60–kHz carrier and is broadcast continuously at a rate of 1 pulse per second using pulse-width modulation. Each pulse is generated by reducing the carrier power 10 dB at the start of the second, so that the leading edge of every negative-going pulse is on time. Full power is restored 0.2, 0.5, or 0.8 s later as described below.

The WWVB code contains information on the current year, day of year, hour, minute, second, status of Daylight Saving Time, leap year, and a leap-second warning.

The WWVB time code is also sent in BCD format, but the weighting is different from the WWV/WWVH weighting. Bits are sent by shifting the power of the 60–kHz carrier. The carrier power is reduced 10 dB at the start of each second. If full power is restored 200 ms later, it represents a "0" bit. If full power is restored 500 ms later, it represents a "1" bit. Reference markers and position identifiers are sent by restoring full power 800 ms later.

The binary-to-decimal weighting scheme is 8-4-2-1. The *most significant bit* is sent first. This is the reverse of the WWV/WWVH time code. The BCD groups and the equivalent decimal numbers are shown in Table 16.

The decimal number is obtained by multiplying each bit in the binary group by the weight of its respective column and then adding the four products

TABLE 16. 8–4–2–1 BCD–DECIMAL EQUIVALENTS

Binary group	Decimal Equivalent
Weight: 8 4 2 1	
0 0 0 0	0
0 0 0 1	1
0 0 1 0	2
0 0 1 1	3
0 1 0 0	4
0 1 0 1	5
0 1 1 0	6
0 1 1 1	7
1 0 0 0	8
1 0 0 1	9

together. For example, the table shows that the binary group 0101 is equal to 5. This is derived by

$$(0 \times 8) + (1 \times 4) + (0 \times 2) + (1 \times 1) = 0 + 4 + 0 + 1 = 5$$

Every minute, the WWVB time code contains the current minute, hour, day of year, two digits of the current year, a UT1 correction, a leap-second warning bit, and Daylight Saving Time (DST) and leap year indicators. Two BCD groups each are needed to express the hour (00 to 23), minute (00 to 59), and year (00–99); and three groups are needed to express the day of year (001 to 366). Some bits in the BCD groups are unused but may provide additional information in the future. To represent units, tens, or hundreds, the basic 8–4–2–1 weights are simply multiplied by 1, 10, or 100 as appropriate. The coded information refers to the time at the start of the one-minute frame. Seconds are determined by counting pulses within the frame.

Each minute begins with a frame reference pulse lasting for 0.8 s (Fig. 13). A position identifier pulse lasting for 0.8 s is transmitted every 10 s.

UT1 corrections are broadcast at seconds 36 through 43 of each frame. These corrections are to the nearest 0.1 s. The bits transmitted at seconds 36, 37, and 38 show if UT1 is positive or negative with respect to UTC. If "1" bits are sent at seconds 36 and 38, the UT1 correction is positive. If a "1" bit is sent at second 37, the UT1 correction is negative. The amount of the UT1 correction is sent in a four-bit BCD group at seconds 40, 41, 42, and 43. The binary-to-decimal weights are multiplied by 0.1, because the UT1 corrections are expressed in tenths of seconds.

The WWVB time code also contains information about leap years, DST, and leap seconds. The leap year bit is transmitted at second 55. If it is set to "1," the current year is a leap year. The bit is set to "1" during each leap year sometime after January 1 but before February 29. It is set back to "0" shortly after January 1 of the year following the leap year. Receivers that read this bit can automatically adjust themselves during leap years.

The two DST bits are sent at 57 and 58 s after each minute. If standard time is in effect, both bits (57 and 58) are set to "0." If DST is in effect, both bits are set to 1. On the day of change from standard to DST, bit 57 is changed from "0" to "1" at 0000 UTC. Exactly 24 hours later, bit 58 also changes from "0" to "1" at 0000 UTC. On the day of change from DST back to standard time, bit 57 goes from "1" to "0" at 0000 UTC, followed 24 hours later by bit 58. Receivers displaying local time can read the DST bits and make the one-hour adjustment automatically when time changes occur locally.

Bit 56 is used to warn users that a leap second will be inserted into the UTC(NIST) time scale at the end of the current month. The bit is set to "1" near the beginning of the month in which a leap second is added. It is reset to "0" immediately following the leap second insertion.

Fig. 13 shows one frame of the time code. The six position identifiers are labeled as P_1, P_2, P_3, P_4, P_5, and P_0. The minutes, hours, days, year, and UT1 sets are marked, with the weighting factors printed below the bits. Wide pulses represent "1" bits, and narrow pulses represent "0" bits. Unused bits are set to "0."

In Fig. 13, the decoded UTC at the start of the frame is 1990, 258 days, 18 hours, and 42 minutes. Since the UT1 correction is 0.7 s, the decoded UT1 is 1990, 258 days, 18 hours, 41 minutes, 59.3 s.

Internet Time Signals—One common time and frequency application is to synchronize a computer clock to the correct date and time-of-day. This is usually done with a time code received through an Internet or telephone connection.

Internet time servers use standard timing protocols defined in a series of RFC (Request for Comments) documents. The three most common protocols are the Time Protocol, the Daytime Protocol, and the Network Time Protocol (NTP). An Internet time server waits for timing requests sent using any of these protocols, and when a request is received it sends a time code in the correct format.

Client software is available for all major operating systems, and most client software is compatible with either the Daytime Protocol or NTP. Client software that uses the Simple Network Time Protocol (SNTP) makes the same timing request as an NTP client but does less processing and provides less accuracy. Table 17 summarizes the various protocols and their port assignments, or the port where the server "listens" for a client request. NIST operates an Internet time service using multiple servers distributed around the United States. A list of IP addresses for the NIST servers and sample client software can be obtained from the NIST Time and Frequency Division Website:

http://www.boulder.nist.gov/timefreq

The uncertainty of Internet time signals is usually < 100 ms, but results vary with different computers, operating systems, and client software.

Telephone Time Signals—Telephone time services allow computers with analog modems to synchronize their clocks using ordinary telephone lines. These services are useful for synchronizing computers that are not on the Internet, or that reside behind an Internet firewall. One example of a telephone service is NIST's Automated Computer Time Service (ACTS). The telephone number is (303) 494–4774.

ACTS requires a computer, a modem, and client software. When a computer connects to ACTS it receives a time code containing the month, day, year, hour, minute, second, leap second and daylight savings time indicators, and a UT1 correction. The last character in the ACTS time code is the on-time marker (OTM). To compensate for the path delay between NIST and the user, the server sends the OTM 45 ms early. If the client returns the OTM, the server can cal-

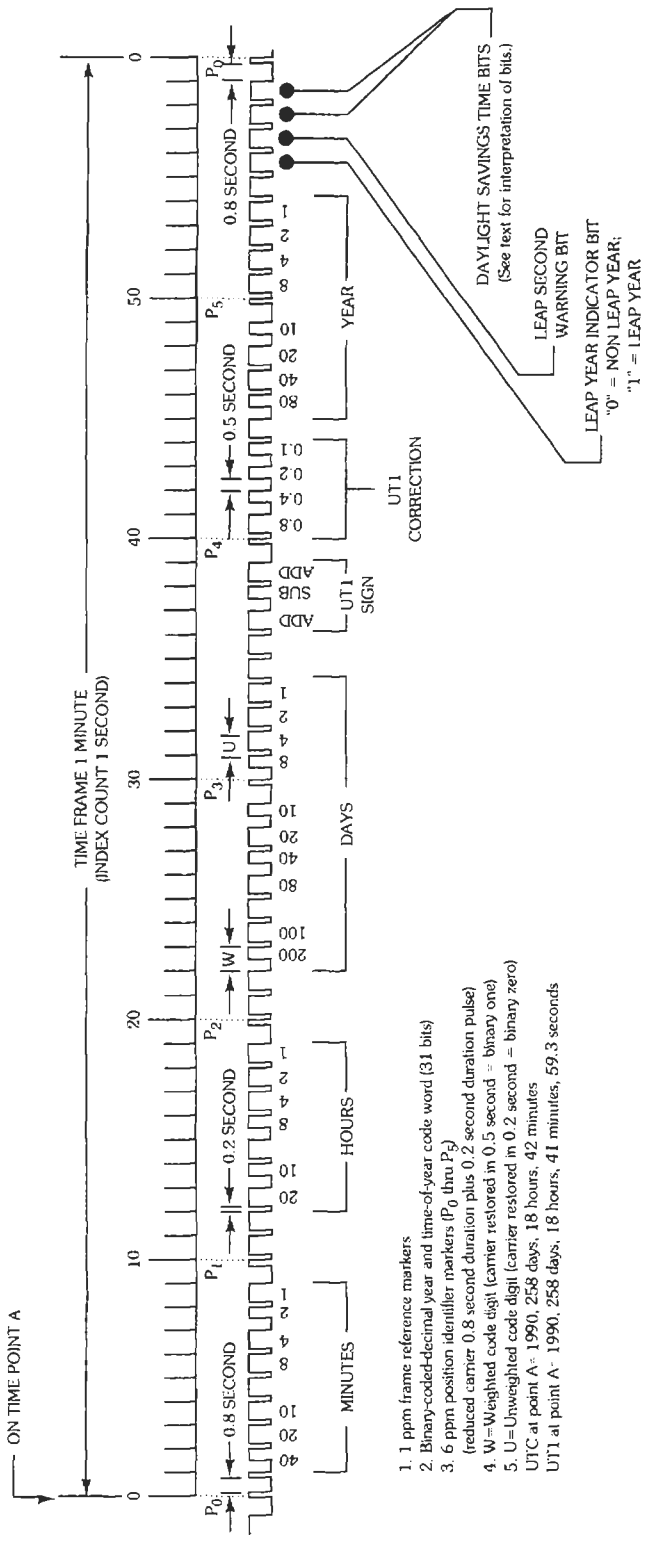

Fig. 13. WWVB time code format.

TABLE 17. INTERNET TIME PROTOCOLS

Protocol Name	Document	Format	Port Assignments
Time Protocol	RFC-868	Unformatted 32-bit binary number contains time in UTC seconds since January 1, 1900.	Port 37 tcp/ip, udp/ip
Daytime Protocol	RFC-867	Exact format not specified in standard. Only requirement is that the time code is sent as ASCII characters.	Port 13 tcp/ip, udp/ip
Network Time Protocol (NTP)	RFC-1305	The server provides a data packet with a 64-bit timestamp containing the time in UTC seconds since January 1, 1900 with a resolution of 200 ps. NTP provides accuracy of 1 to 50 ms. The client software runs continuously and gets periodic updates from the server.	Port 123 udp/ip
Simple Network Time Protocol (SNTP)	RFC-1769	The data packet sent by the server is the same as NTP, but the client software does less processing and provides less accuracy.	Port 123 udp/ip

ibrate the path using the *loop-back* method. Each time the OTM is returned, the server measures the round-trip path delay and divides this quantity by 2 to estimate the one-way path delay. This path calibration reduces the uncertainty to < 15 ms.

Global Positioning System (GPS)—GPS, well known as a versatile, global tool for positioning, has also become a primary system for distributing time and frequency. GPS receivers are fixtures in telecommunication networks and in calibration and testing laboratories. They make it possible to synchronize clocks and calibrate and control oscillators in any facility that can place an antenna outdoors for line-of-sight reception of the GPS satellites.

The GPS satellites are controlled and operated by the United States Department of Defense (USDOD). The constellation includes at least 24 satellites that orbit the earth at a height of 20 200 km in six fixed planes inclined 55° from the equator. The orbital period is 11 h 58 m, which means that a satellite will orbit the earth twice per day. By processing signals received from the satellites, a GPS receiver can determine its position with an uncertainty of < 10 m.

The GPS satellites broadcast on two carrier frequencies: L1 at 1 575.42 MHz and L2 at 1 227.6 MHz. Each satellite broadcasts a spread-spectrum waveform, called a pseudo-random noise (PRN) code on L1 and L2, and each satellite is identified by the PRN code it transmits. There are two types of PRN codes. The first type is a coarse acquisition (C/A) code with a chip rate of 1 023 chips per millisecond. The second type is a precision (P) code with a chip rate of 10 230 chips per millisecond. The C/A code is broadcast on L1, and the P code is broadcast on both L1 and L2. GPS reception is line-of-sight, which means that the antenna must have a clear view of the sky. If a clear sky view is available, the signals can be received nearly anywhere on earth.

Each satellite carries either rubidium or cesium oscillators, or a combination of both. The on-board oscillators provide the reference for both the carrier and code broadcasts. They are steered from USDOD ground stations and are referenced to Coordinated Universal Time (UTC) maintained by the United States Naval Observatory (USNO). By mutual agreement UTC(USNO) and UTC(NIST) are maintained within 100 ns of each other, and the frequency difference between the two time scales is $< 1 \times 10^{-13}$.

GPS Measurement Techniques: GPS measurements can be divided into two categories: one-way and common-view. Most GPS measurements are one-way measurements, based on direct reception of the GPS signals. Common-view measurements require more effort, including a data exchange between two receivers and postprocessing of the measurement data. For this reason, they are usually reserved for international comparisons between metrology laboratories when the measurement uncertainties must be as small as possible. Table 18 compares the GPS measurement techniques.

One-Way GPS: The one-way GPS technique uses the signals obtained from a GPS receiver as a time and frequency reference. The GPS signals are used in real time, and no postprocessing of the measurement results is required. The signal is normally used either

TABLE 18. TYPICAL UNCERTAINTY OF GPS MEASUREMENT TECHNIQUES

Technique	Timing Uncertainty, 24 h, 2σ	Frequency Uncertainty, 24 h, 2σ
One-Way	< 20 ns	$< 2 \times 10^{-13}$
Single-Channel Common-View	≅10 ns	$\cong 1 \times 10^{-13}$
Multichannel Common-View	< 5 ns	$< 5 \times 10^{-14}$

to synchronize an on-time pulse or to calibrate a frequency source.

Since the GPS satellites transmit signals that are steered to agree with UTC, the long-term accuracy of a GPS receiver has always been excellent. The performance of C/A code receivers became even better on May 2, 2000 (MJD 51666) when the USDOD set selective availability (SA) to zero. SA is a USDOD directive that can be used to intentionally introduce noise on the GPS signal to reduce its positioning and timing accuracy. Fig. 14 is a phase plot showing data from a typical GPS receiver, recorded in the days immediately before and after SA was set to zero.

The data points shown in Fig. 14 are 10-minute averages of the received signal obtained by comparing the 1 pps output from a typical GPS timing receiver to UTC(NIST) using a time interval counter. The phase plot shows that the GPS broadcasts are tightly controlled. The peak-to-peak variation in the received signal is < 30 ns at one day after SA was set to 0. This leads to excellent long-term accuracy and stability. The Allan deviation, $\sigma_y(\tau)$, plot in Fig. 15 shows that the stability of the receiver is near 1×10^{-13} at 1 day.

Common-View GPS Measurements: The common-view method is a simple but elegant way to compare two clocks or oscillators located in different places. Unlike one-way measurements that compare a clock or oscillator to GPS, a common-view measurement compares two clocks or oscillators to each other.

Fig. 16 shows how the common-view technique works. A GPS satellite (S) serves as a single reference transmitter. The two clocks or oscillators being compared (A and B) are measured against two GPS receivers. The satellite is in common view of both receivers, and its signals are simultaneously received by both.

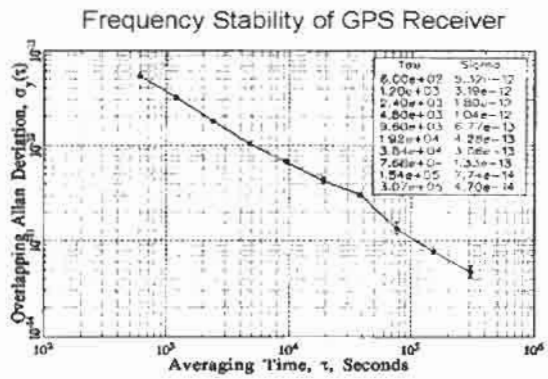

Fig. 15. Frequency stability (Allan deviation) of GPS receiver after SA was set to 0.

Each receiver compares the received signal to its local clock and records the data. Receiver A receives the signal over the path τ_{SA} and compares the reference to the local clock (S–Clock A). Receiver B receives the signal over the path τ_{SB} and records (S–Clock B). The two receivers then exchange and difference the data.

Common-view directly compares two time and frequency standards. Errors from the two paths (τ_{SA} and τ_{SB}) that are common to the reference cancel out, including the performance of the satellite clock. The final measurement result is (Clock A–Clock B)–(τ_{SA}–τ_{SB}).

The common-view technique has long been used for international comparisons of time and frequency standards. The international time scales—International Atomic Time (TAI) and Coordinated Universal Time (UTC)—are created by averaging data collected from

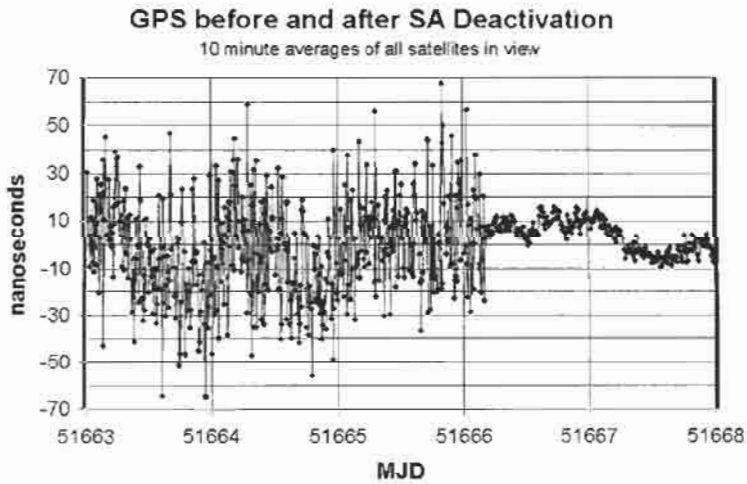

Fig. 14. Phase plot showing GPS performance before and after SA was set to 0.

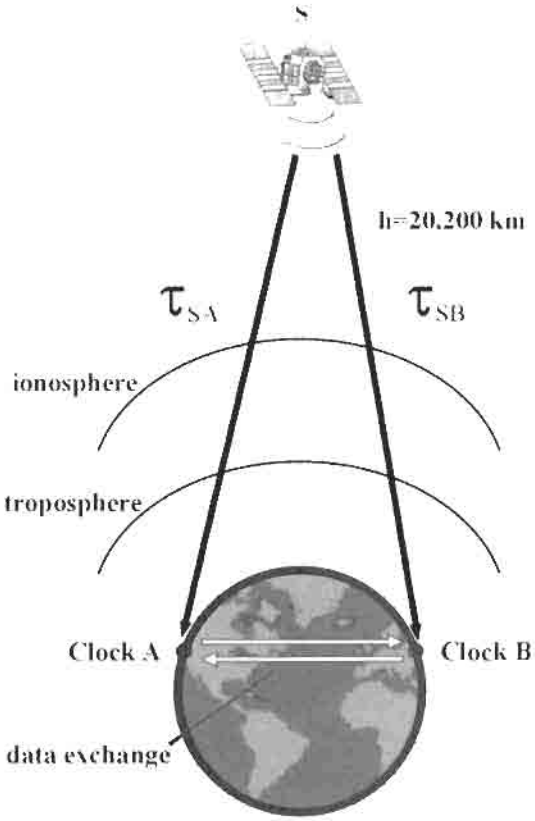

Fig. 16. The common-view measurement technique.

more than 200 atomic clocks located in more than 40 laboratories. Most of these data are collected using common-view GPS measurements. Once the data are sent to the BIPM, the TAI and UTC time scales are computed using a weighted average of all the oscillators. The stability of TAI and UTC is currently about 1 part in 10^{15} over a period of a few weeks.

Common-view measurements can be single channel or multichannel. The BIPM has conventions for recording the data used in both types of measurements. However, it is not necessary to use the BIPM format to make common-view measurements. Any data format can be used if all participants in a common-view comparison record and process their data in the same way.

Information from the Internet

Radio frequency spectrum management information is available on the Internet. The telecommunications regulatory administrations of many countries have active websites that should be consulted when dealing with spectrum issues involving those nations. Three extensively used sites are:

1. National Telecommunications and Information Administration at www.ntia.doc.gov
2. Federal Communications Commission at www.fcc.gov
3. International Telecommunication Union at www.itu.int

Spectrum Management Training

Radio frequency spectrum management training is available from two sources:

1. George Washington University, Center for Professional Development, Washington, DC. www.cpd.gwu.edu
2. For students from developing nations: United States Telecommunications Training Institute, Washington, DC. www.ustti.org

Time and Frequency

Blair, B. E., Ed. "Time and Frequency: Theory and Fundamentals." NBS Monograph 140. Boulder, CO: National Bureau of Standards, Dept. of Commerce, 1974.

Technical standards published as reports and recommendations of the International Radio Consultative Committee (CCIR), International Telecommunication Union (ITU), Geneva, Switzerland. Reports and recommendations are revised periodically, and it is best to refer to the latest version. In particular:

"Performance of Standard-Frequency Generators," Report 346–6 or later version, Reports of the CCIR, 1990 or later, Annex to Volume VII, Standard Frequencies and Time Signals.

"Standard-Frequency and Time-Signal Emissions," Recommendation 460–4 or later version, Recommendations of the CCIR, 1990 or later, Volume VII, Standard Frequencies and Time Signals.

2 International Telephony Recommendations

Revised by
Douglass D. Crombie and Dorothy M. Cerni

INTERNATIONAL STANDARDS

Administrations and operating companies throughout the world carry on studies of technical and other problems related to the interworking of their respective national telecommunication systems to provide a worldwide telecommunications network. Two international committees exist for this purpose: The International Telegraph and Telephone Consultative Committee (CCITT), and the International Radio Consultative Committee (CCIR). They operate under the auspices of the International Telecommunication Union (ITU). They promulgate their decisions in the form of Recommendations, which are published by the ITU. Generally, these Recommendations cover features of international circuits, but where essential, they deal with relevant characteristics of the national systems which may form part of international connections. This compendium collects, in condensed form, major Recommendations dealing with telephone, telegraph, and data-transmission circuits and equipment.

Recommendations of the CCITT

The CCITT develops new Recommendations, and updates existing ones, through the activities of Study Groups, whose reports are acted on at Plenary Assemblies, which meet at intervals of three or four years. The resulting Recommendations of the Second Plenary Assembly, New Delhi, 1960, were published by the ITU in a number of volumes, called collectively the Red Book. The subsequent study periods culminated in the Third Plenary Assembly, Geneva, 1964 (Blue Book); the Fourth Plenary Assembly, Mar del Plata, 1968 (White Book); the fifth Plenary Assembly, Geneva, 1972 (Green Book); the Sixth Plenary Assembly, Geneva, 1976 (Orange Book); and the Seventh Plenary Assembly, Geneva, 1980 (Yellow Book). This compendium refers to Yellow Book Recommendations, designated thus: (G.101), (H.31), (V.2), etc.

Recommendations of the CCIR

The CCIR also functions with Study Groups and Plenary Assemblies. The Eleventh Plenary Assembly was held at Oslo in 1966, the Twelfth Plenary Assembly at New Delhi in 1970, the Thirteenth Plenary Assembly at Geneva in 1974, the Fourteenth Plenary Assembly at Kyoto in 1978, and the Fifteenth Plenary Assembly at Geneva in 1982. After each Plenary Assembly, the ITU publishes volumes which contain the currently accepted Recommendations, including such Recommendations of the Plenary Assemblies at London (1953), Warsaw (1956), Los Angeles (1959), and Geneva (1963) which are still in effect. No color coding is used. This compendium deals with those Recommendations which treat point-to-point radio relay systems. A purpose of those Recommendations is to make the performance of such systems compatible with metallic line systems which follow the CCITT Recommendations. References to the CCIR Recommendations are made thus: (CCIR,391).

NOTE: This chapter is primarily concerned with telephony, but additional material is included in chapter 38, Common Carrier Transmission. For more information on data communications, the reader is referred to chapter 26, Computer Communications Networks.

ZERO-RELATIVE-LEVEL POINTS AND RELATIVE LEVELS

Many CCITT and CCIR Recommendations specify signal or noise levels at "a point of zero relative level," or in dBm0 or pWp0, etc., where "0" (zero) stands for "measured at or referred to a point of zero relative level."

(A) In two-wire switching systems, the sending-end terminals of a long-distance circuit have long been considered to be at a point of zero relative level. The relative levels of all other points are calculated from this reference point, as the algebraic sum of all transmission losses and gains from it to the point in question. Any point in a circuit with the same relative level as the sending terminals is a point of zero relative level, which may be written 0 dBr (*dB* relative level). The American term for *relative level* is *transmission level*. Thus: "Zero-transmission-level point" (0TLP).

For convenience in comparing circuit noise performance, it is customary to convert absolute noise measurements made at the receiving ends of circuits having various relative levels, to absolute power levels at a zero-relative-level point. For example, −50 dBmp of noise at a −7-dBr point would be reported as −43 dBm0p. Signaling-tone levels are similarly expressed. For example, a tone introduced at a −3.5-dBr point with an absolute power level of −18.5 dBm may be referred to as a −15-dBm0 signal. The latter designation would apply to such a tone no matter where it appeared; the "0" denotes that its level is referred to a point of zero relative level. (Refer to Table 1.)

Statistics of speech power, requirements for linearity and limiting, system loading factors, cross talk, and noise have become well known in terms of their values at points of zero relative level. The proper performance of voice repeaters, carrier terminal and line equipment, radio relay systems, etc., depends on adherence to the relative levels for which they were designed. Many relative levels associated with such equipment have been standardized.

(B) In four-wire switching systems, it is often considered desirable to handle speech and signaling at lower values of absolute power through the switching

TABLE 1. RELATIVE LEVELS, PLUS LEVELS OF ABSOLUTE AND REFERRED POWER, FOR A 2-WIRE CIRCUIT

	Sending Point	Circuit Loss: 5 dB Direction→	Receiving Point
		2-Wire Circuit	
Relative levels, or transmission levels	0 dBr	−5 dBr	
"Milliwatt" test tone	0 dBm	−5 dBm absolute power	
At any point	0 dBm0	0 dBm0 referred power	
Signaling tone	−10 dBm	−15 dBm absolute power	
At any point	−10 dBm0	−10 dBm0 referred power	
Circuit noise, picked up along circuit	—	−65 dBmp absolute power	
Circuit noise, referred to 0-dBr point	—	−60 dBm0p referred power	

equipment than is customary in two-wire systems. In 1964, the CCITT adopted a relative level of −3.5 dBr for the sending end of a four-wire circuit, at the "virtual" switching points. These are theoretical points; their exact location depends on national practice, and the CCITT considers it unnecessary to define them. (In the American commercial system, −2 dBr is widely used.) (G.101, Section B)

Therefore, to ensure that carrier and other transmission equipment will be subjected to the same absolute speech and signaling power levels as in two-wire systems, determination of relative levels in four-wire circuits must take into account the relative level of the virtual switching points. In a four-wire circuit, there may be no actual point of zero relative level. Nevertheless, standards will continue to refer many requirements to a zero relative point. (Refer to Table 2.)

Currently, many transmission measurements are made with a standard 800- or 1000-hertz test tone, with an absolute power of 1 milliwatt at a zero-relative-level point: a power of 0 dBm0. The actual level applied is adjusted to the relative level of the sending point. The test-tone level in dBm will be numerically equal to the relative level in dBr at any point in the circuit, but it is not proper to express *relative* levels in dBm, since dBm represents absolute power levels. If the standard-test-tone power is ever changed to another value, such as −10 dBm0, as has been tentatively proposed, the distinction between relative levels and test-tone levels will be more apparent.

PSOPHOMETRIC NOISE AND POWER

The CCITT calls a noise measuring set a "psophometer." A psophometer includes a device for measuring power through a weighting network. For measurements on commercial telephone circuits, a weighting characteristic is used which results in the objective instrument

TABLE 2. RELATIVE LEVELS, PLUS LEVELS OF ABSOLUTE AND REFERRED POWER, FOR ONE DIRECTION OF A 4-WIRE CIRCUIT

	Sending Point	Circuit Loss: 5 dB Direction→	Receiving Point
		One side of 4-Wire Circuit	
Relative levels, or transmission levels	− 3.5 dBr	− 8.5 dBr	
"Milliwatt" test tone	− 3.5 dBm	− 8.5 dBm absolute power	
At any point	0 dBm0	0 dBm0 referred power	
Signaling tone	−13.5 dBm	−18.5 dBm absolute power	
At any point	−10 dBm0	−10 dBm0 referred power	
Circuit noise, picked up along circuit	—	−68.5 dBmp absolute power	
Circuit noise, referred to 0-dBr point	—	−60 dBm0p referred power	

measurements approximately paralleling the results of subjective tests with human observers using modern telephone sets. The CCITT weighting characteristic for commercial circuits is nominally identical with the American F1A line weighting. Psophometric noise power may be expressed in dBm0 "psophometrically weighted," or dBm0p. The conventional conversion equation used between dBm0p and dBa0 (F1A) is

$$\text{dBm0p} = \text{dBa0} - 84$$

Psophometric Weighting for Commercial Telephone Circuits

Frequency (hertz)	Level (dB)	Frequency (hertz)	Level (dB)
100	−41.0	1350	−0.65
150	−29.0	1500	−1.30
200	−21.0	1750	−2.22
250	−15.0	2000	−3.00
300	−10.6	2250	−3.60
400	−6.3	2500	−4.20
500	−3.6	2750	−4.87
600	−2.0	3000	−5.60
700	−0.9	3500	−8.5
800	0.0	4000	−15.0
900	+0.6	4200	−18.7
1000	+1.0	4500	−25.0
1100	+0.6	4700	−29.4
1200	0.0	5000	−36.0

(Extracted from G.223, which gives weighting for 84 frequencies.)

Psophometric Weighting Factor

If uniform-spectrum random noise is measured in a 3.1-kilohertz band with a flat attenuation/frequency characteristic, the noise level must be reduced by 2.5 decibels to obtain the psophometric power level. For another bandwidth B, the weighting factor will be equal to

$$2.5 + 10 \log_{10}(B/3.1) \text{ decibels}$$

When B = 4 kilohertz, for example, this gives a weighting factor of 3.6 decibels. (G.223)

Psophometric Power

Where power addition of noise can be assumed, it has been found convenient for calculations and design of international circuits to use the concept of "psophometric power."

psophometric power

= (psophometric voltage)^2/600

= (psophometric emf)^2/(4 × 600)

A convenient unit is the picowatt (pW) = 10^{-12} watt, so that

psophometric power in pW

= (psophometric emf in mV)^2/0.0024 (G.212)

CONVENTIONAL TELEPHONE SIGNAL

For the calculation or measurement of cross-talk noise between adjacent channels, of the balance return loss for echo, and generally speaking, when it is desired to simulate the speech currents transmitted by a telephone channel, the CCITT recommends the use of a conventional telephone signal. This signal may be produced by passing the output of a generator of a uniform-spectrum random noise signal ("white noise") through a weighting network with a characteristic as shown in Fig. 1. The amount of this signal that appears in another circuit because of cross talk, etc., is measured with a psophometer or weighted-noise measuring set, with standard psophometric weighting for commercial telephone circuits. (G.227)

TELEPHONE CIRCUIT LOADING

Nominal Mean Power During Busy Hour

To simplify calculations when designing carrier systems on cables or radio links, the CCITT has adopted a *conventional* value to represent the *mean absolute power level*, at a point of zero relative level, of the speech-plus-signaling currents, etc., transmitted over a telephone channel in one direction of transmission during the busy hour, which is −15 dBm (−1.73 nepers) (mean power = 31.6 microwatts); this is the mean with time and the mean for a large batch of circuits. This total mean power of about 32 microwatts is conventionally distributed as follows (nominal mean power): 10 microwatts, all signaling and tones; 22 microwatts, to include speech currents (including echoes), carrier leak, and telegraph signals, based on a speech activity factor of 0.25 for one direction of a telephone channel. No account is taken of pilot signals, which are assumed to be an integral part of the carrier system, not affecting telephone channel power. (G.223, Section 1)

Conventional Load

It will be assumed for the calculation of intermodulation noise below the overload point that the multiplex signal during the busy hour can be represented by a

uniform-spectrum random noise signal, the mean absolute power level of which, at a zero-relative-level point, $n(\bar{P})$, is given by

$$n(\bar{P}) = -15 + 10 \log_{10} N \text{ dB}$$

for $N = 240$ or more

and

$$n(\bar{P}) = -1 + 4 \log_{10} N \text{ dB}$$

for values of N between 12 and 240

where N is the total number of telephone channels in the system.

Typical values so calculated are as follows

N	$n(\bar{P})$, dB
12	3.3
24	4.5
36	5.2
48	5.7
60	6.1
120	7.3
⋮	⋮
240	8.8
300	9.8
600	12.8
960	14.8
1800	17.0
2700	19.3

Assumed: No pre-emphasis, and use of independent amplifiers for each direction. (G.223, Section 2)

POWER LEVELS

Maximum Power Level for Signaling Pulses

For cross-talk reasons, each component of a short-duration signal should not exceed the following absolute power levels, at a zero-relative-level point.

Signaling Frequency (hertz)	Absolute Power Level at Zero-Relative-Level Point (dBm0)
800	−1
1200	−3
1600	−4
2000	−5
2400	−6
2800, 3200	−8

(G.224)

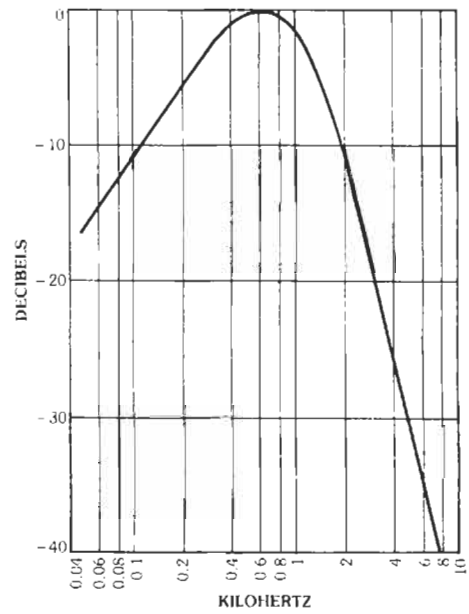

Fig. 1. Relative response curve for the weighting network of the conventional telephone signal generator (G.227).

Private Telegraph Transmission on a Rented International Circuit, With Alternative Private Telephone Service

The frequency of 1500 hertz is recommended for private telegraph transmission between subscribers permanently connected via a rented international circuit. The permissible power for a continuously transmitted telegraph marking signal is 0.3 milliwatt at a zero-relative-level point (−5 dBm0). (H.31)

Simultaneous Communication by Telephony and Telegraphy on a Telephone Circuit

A continuously transmitted telegraph signal should not exceed a level of −13 dBm0. There should not be more than three telephone circuits of this type per group, nor more than the number of supergroups in a wideband system. (H.32)

Phototelegraphy Transmissions Over Telephone Circuits That Are Entirely 4-Wire Between Phototelegraph Stations

The sent voltage for the phototelegraph signal corresponding to maximum amplitude should be so adjusted

that the absolute power level of the signal, at a zero-relative-level point, is 0 dBm0 for amplitude-modulation facsimile, and −10 dBm0 for frequency-modulation facsimile. In the former, the "black" level is about 30 decibels lower than the "white" level. (H.41)

Power Levels for Data Transmission Over Telephone Circuits

Private Wires on Carrier Systems—

(A) Maximum power output of subscriber's apparatus into line: 1 milliwatt.

(B) Continuous-tone systems (for example, frequency modulation): Maximum power level at zero-relative-level point: −10 dBm0, to be reduced to or below −20 dBm0 when data transmission is discontinued for any appreciable time.

(C) Noncontinuous-tone systems (for example, amplitude modulation): Maximum power level at zero-relative-level point: −6 dBm0, provided that busy-hour mean power in both directions of transmission added does not exceed 64 microwatts (−15 dBm0 mean level in each direction simultaneously). Also, the level of tones above 2400 hertz should conform to recommendations for signaling tones in G.224. (H.51)

Switched Telephone Network—

(A) Maximum power output of subscriber's apparatus into line: 1 milliwatt.

(B) Continuous-tone systems (for example frequency- or phase-modulation systems): The power level at the subscriber's equipment should be adjusted not to exceed −10 dBm0 (simplex operation) or −13 dBm0 (duplex operation).

(C) Noncontinuous-tone systems (for example amplitude-modulation or multifrequency systems): Higher levels may be used, if mean power at international-circuit input is limited to 64 microwatts in any hour (both directions), i.e., −15 dBm0 in each direction simultaneously. (H.51)

HYPOTHETICAL REFERENCE CIRCUITS

General Definitions (G.212)

Hypothetical Reference Circuit—A hypothetical circuit of defined length and with a specified number of terminal and intermediate equipments, this number being sufficient but not excessive. It forms the basis for the study of certain characteristics of long-distance circuits, for example, noise.

Hypothetical Reference Circuit for Telephony—This is a complete telephone circuit, between audio-frequency terminals, established on a hypothetical international telephone carrier system and having a specified length and a specified number of modulations and demodulations of the groups, supergroups, and mastergroups, these numbers being reasonably great but not having their maximum possible values.

Various hypothetical reference circuits for telephony have been defined by the CCITT and CCIR to allow the coordination of the different specifications concerning the constituent parts of the multichannel carrier telephone systems, so that the complete telephone circuits set up on these systems can meet CCITT standards.

Homogeneous Section—A section without diversion or modulation of any one of the mastergroups, supergroups, groups, or channels established on the system being considered, except for those modulations or demodulations defined at the ends of the section. All the hypothetical reference circuits defined below consist of homogeneous sections of equal length (six or nine sections). It is assumed that at the end of each homogeneous section, the channels, groups, supergroups, and mastergroups, as appropriate, are connected through at random.

Important Hypothetical Reference Circuits Defined by CCITT and CCIR

Hypothetical Reference Circuit on Symmetric Cable Pairs—This circuit is 2500 kilometers long and is set up on a symmetric-cable-pair carrier system. For each direction of transmission, it has a total of three pairs of channel modulators and demodulators, six pairs of group modulators and demodulators, and six pairs of supergroup modulators and demodulators.

Fig. 2A shows that there are 15 modulations and 15 demodulations for each direction of transmission, assuming that single-stage translations are used. There are six homogeneous sections of equal length. (G.322)

Hypothetical Reference Circuit for 4-Megahertz Systems on Coaxial Cable—This circuit is 2500 kilometers long and is set up on a 4-megahertz carrier system on 0.104/0.375-inch coaxial cable pairs. For each direction of transmission, it has a total of three pairs of channel modulators and demodulators, six pairs of group modulators and demodulators, and nine pairs of supergroup modulators and demodulators.

Fig. 2B shows that there are 18 modulations and 18 demodulations for each direction of transmission, assuming that single-stage translations are used. There are nine homogeneous sections of equal length. (G.338, Orange Book)

Hypothetical Reference Circuit for 12-Megahertz Systems on Coaxial Cable—This circuit is 2500 kilometers long and is set up on a 12-megahertz carrier system on 0.104/0.375-inch coaxial cable pairs. For each direction of transmission, it has a total of three pairs of channel modulators and demodulators, three

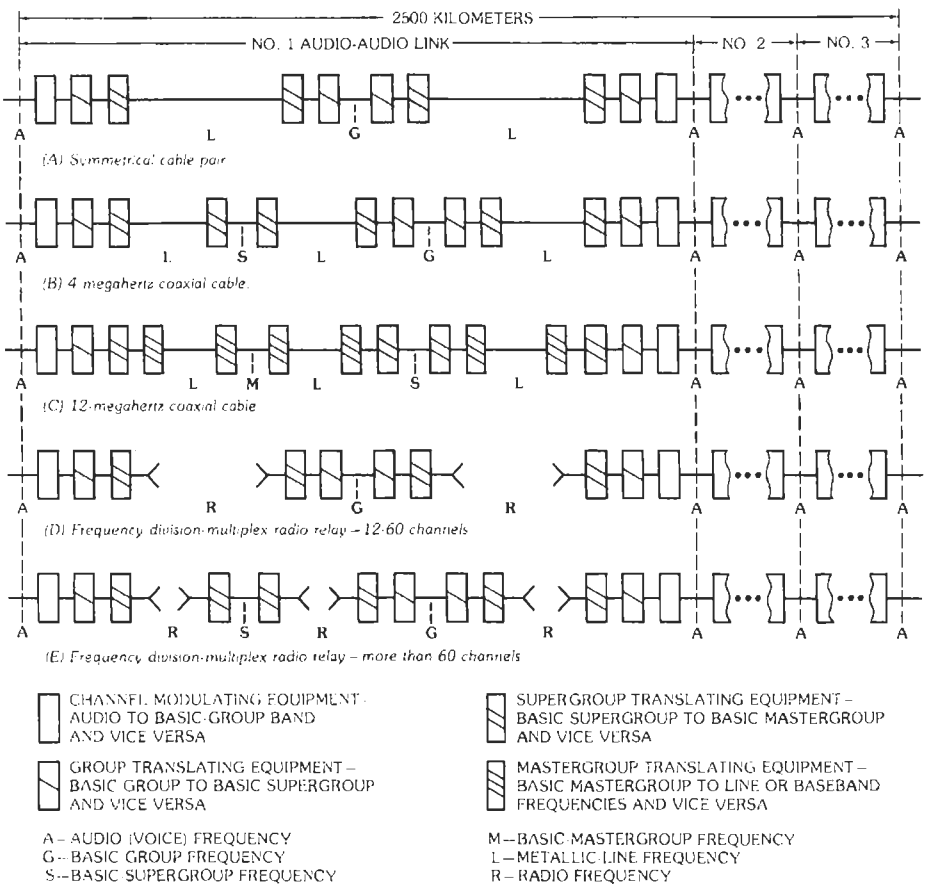

Fig. 2. Typical hypothetical reference circuits for systems using frequency-division multiplex.

pairs of group modulators and demodulators, six pairs of supergroup modulators and demodulators, and nine pairs of mastergroup modulators and demodulators.

Fig. 2C shows that there are 21 modulations and 21 demodulations for each direction of transmission, assuming that single-stage translations are used. There are nine homogeneous sections of equal length. (G.332)

Hypothetical Reference Circuit Over Radio Relay Systems With Frequency-Division Multiplex, Providing 12 to 60 Channels—This circuit is 2500 kilometers long and is set up on a carrier system providing 12 to 60 channels per radio channel over line-of-sight and near-line-of-sight radio relay systems. For each direction of transmission, it has a total of three sets of channel modulators and demodulators, six sets of group modulators and demodulators, six sets of supergroup modulators and demodulators, and six sets of radio modulators and demodulators. The circuit is divided into six homogeneous sections of equal length. (See Fig. 2D.) (CCIR, 391)

Hypothetical Reference Circuit Over Radio Relay Systems With Frequency-Division Multiplex, Providing More than 60 Channels—This circuit is 2500 kilometers long and is set up on a carrier system providing more than 60 channels per radio channel over line-of-sight or near-line-of-sight radio relay systems. For each direction of transmission, it has a total of three sets of channel modulators and demodulators, six sets of group modulators and demodulators, nine sets of supergroup modulators and demodulators, and nine sets of radio modulators and demodulators. The circuit is divided into nine homogeneous sections of equal length. (See Fig. 2E.) (CCIR, 392)

Hypothetical Reference Circuit Over Transhorizon Radio Relay Systems—This circuit is 2500 kilometers long and is set up over a transhorizon radio relay system for telephony using frequency-division multiplex. For each direction of transmission it has a total of three sets of channel modulators and demodulators, six sets of group modulators and demodulators, and nine sets of supergroup modulators and demodulators.

It is recommended that the hypothetical reference circuit not be divided into homogeneous sections of

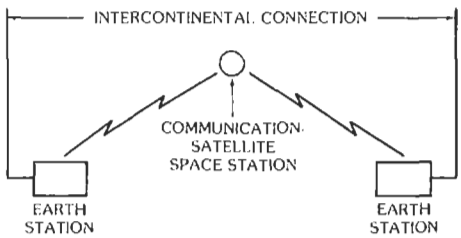

Fig. 3. Basic hypothetical reference circuit, active intercontinental communication-satellite system (CCIR, 352-3).

fixed length, because these systems, as distinct from line-of-sight systems, are usually composed of long radio sections, the lengths of which depend on local conditions and may vary considerably (between 100 and 400 kilometers). If a radio section under study is L kilometers long, the hypothetical reference circuit should be composed of $(2500/L)$ sections of this type in tandem, the value $(2500/L)$ being taken to the nearest whole number. (CCIR, 396-1)

Hypothetical Reference Circuit Over Active Intercontinental Communication-Satellite Systems—This circuit has no fixed length. For intercontinental connections, satellite links should be capable of spanning 7500 kilometers. For great-circle distances up to 25 000 kilometers, it will be necessary to connect two or three satellite links in tandem. The basic hypothetical reference circuit shall consist of one earth-satellite-earth link, as shown in Fig. 3. It shall contain one pair of modulation and demodulation equipments for translation from the baseband to the radio-frequency carrier and back. (CCIR, 352-3)

TELEPHONE CIRCUIT CHARACTERISTICS

Impedance of International and National Trunks

All circuits (whether international circuits or national two-wire or four-wire trunk circuits) terminating at the same trunk exchange should have the same nominal value of impedance as seen from the switchboard or selectors. The preferred value is 600 ohms. (G.232, Section M)

One-Way Propagation Time

The one-way propagation time of connections when echo sources exist and echo suppressors are used is considered to be: acceptable without reservation, 0–150 milliseconds; provisionally acceptable, 150–400 milliseconds; and provisionally unacceptable, 400 milliseconds or higher (should not be used except under extraordinary circumstances).

On National Extension Circuits—Probable propagation time, most distant subscriber to international center: 12 plus (0.0064 × distance in statute miles) milliseconds or 12 plus (0.004 × distance in kilometers) milliseconds.

International Circuits, Terrestrial (Including Submarine Cable)—100 statute miles (160 kilometers) per millisecond, including effects of terminal or intermediate multiplex equipment.

International Circuits, Communication-Satellite Systems—Moving satellite, altitude 8700 miles (14 000 kilometers): 110 milliseconds. Geostationary satellite, altitude 22 500 miles (36 000 kilometers): 260 milliseconds. (G.114)

Group Delay Distortion

The permissible differences, for a worldwide chain of 12 circuits, between the minimum group delay throughout the frequency band transmitted and the group delay at the upper and lower limits of this band in milliseconds are as follows:

Facility	At the Limits of the Frequency Band: Lower Limit	At the Limits of the Frequency Band: Upper Limit
International chain	30	15
Each of the national 4-wire extensions	15	7.5
Entire 4-wire chain	60	30

(G.113, P.13)

The CCITT does not recommend limiting values for the group delay at different frequencies, but offers information on typical values reported by four Administrations. Values are in milliseconds measured on a pair of equipments.

Administration	Frequency (hertz): 300	400	2000	3000	3400
Belgium (b)	4.0	2.7	1.0	1.3	2.6
France (b)	4.2	2.9	1.0	1.4	2.8
Federal Republic of Germany (b)	3.9	2.7	1.2	1.6	3.0
United Kingdom (a)	2.6	2.2	1	1.4	2.6
(b)	4.2	2.7	1.2	1.8	3.4
For 12 pairs (c)	50	35	14	22	41

(a) With in-band signaling
(b) With out-band signaling
(c) Typical maximum values in milliseconds for 12 pairs of equipments.

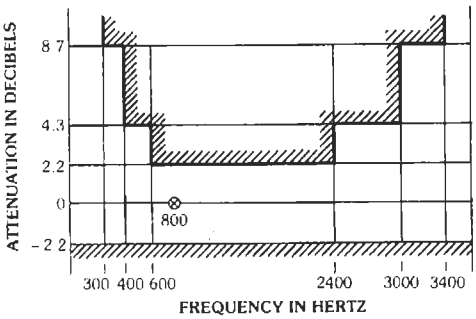

Fig. 4. Attenuation vs. frequency objective for worldwide chain of 12 circuits in terminal service (G.132).

Attenuation Distortion in Worldwide Chain

The objectives for the variation with frequency of transmission loss in the terminal condition of a worldwide chain of 12 circuits (international plus national extensions), each one routed over a single group link, are shown in Fig. 4, which assumes that no use is made of high-frequency radio circuits or 3-kilohertz channel equipment. (G.132)

Variation of Transmission Loss With Time

(A) The standard deviation for the variation in transmission loss of a circuit should not exceed 1 decibel. This can be met for circuits on single-group links with automatic regulation, and it should be met on any national circuit whether regulated or not. For other international circuits, the standard deviation should not exceed 1.5 decibels. Standard deviation is sometimes called "distribution grade."

(B) The difference between the mean value of the transmission loss and the nominal value (that is, the bias) should not exceed 0.5 dB. (G.151, Section C)

Linear Cross Talk

(A) Between circuits, the near-end or far-end cross-talk ratio (intelligible only), measured at audio frequency at a national or international center between two complete circuits in terminal service, should not be less than 58 decibels for 90 percent of all two-circuit combinations, and 52 decibels for all combinations. The planning objective for modern systems for all combinations is 58 dB.

(B) Between the go and return channels of a four-wire circuit, the near-end cross-talk ratio must be at least 43 decibels.

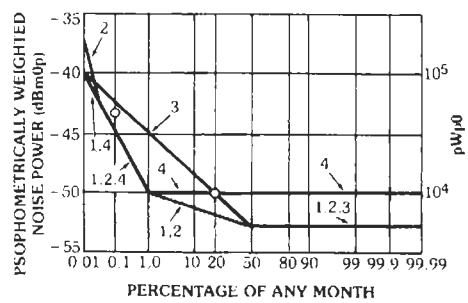
Note: The above refers to telephone circuits that are not equipped with (or used in conjunction with) modern echo suppressors designed for long propagation times. Circuits that can form part of switched connections with a long propagation time and lie between terminal half-echo suppressors of modern design should conform to high standards. (G.151, Section D)

Frequency Accuracy of Virtual Carrier Frequencies on an International Circuit

As the channel of any international telephone circuit should be suitable for voice-frequency telegraphy, the accuracy of the virtual carrier frequencies should be such that the difference between an audio frequency applied to one end of the circuit and the frequency received at the other end should not exceed 2 hertz, even when there are intermediate modulating and demodulating processes.

Considering either the hypothetical reference circuit proper to each system or the worldwide hypothetical reference connection, the accuracy of restitution of frequency that is recommended above should be assured if the channel and group carrier frequencies of the various stages have the following accuracies. (G.223)

Virtual channel carrier frequencies in a group	$\pm 10^{-6}$
Group and supergroup carrier frequencies	$\pm 10^{-7}$
Mastergroup and supermastergroup carrier frequencies	
for 12-MHz system	$\pm 5 \times 10^{-8}$
for 60-MHz system	$\pm 10^{-8}$
(G.225, Section a)	
For 12-channel open wire carrier systems, channel carriers	$\pm 5 \times 10^{-6}$
(G.311)	



The noise figures include 2500 pW for terminal equipment
O – design objectives, including terminal noise.
The numbers 1 to 4 are used to distinguish the curves

Fig. 5. Examples of distribution curves for the psophometrically weighted 1-minute mean noise power at the end of the hypothetical reference circuit (CCIR, 393-1).

CIRCUIT NOISE OBJECTIVES

Noise Characteristics for 2500-Kilometer Hypothetical Reference Circuits

The following design objectives should apply to any telephone channel provided by multichannel carrier systems on cable and radio relay links, having the same composition as the appropriate hypothetical reference circuit of 2500 kilometers. The noise is to be measured at or referred to a point of zero relative level. The objectives are intended to ensure adequate speech and signaling performance. They include an allowance of 2500 pWp0 due to frequency-division-multiplex equipment. (See Fig. 5.)

(A) The mean psophometric power during any hour shall not exceed 10 000 pWp0.

(B) The mean noise power over 1 minute shall not exceed 10 000 pWp0 for more than 20 percent of any month.

(C) The mean noise power over 1 minute shall not exceed 50 000 pWp0 for more than 0.1 percent of any month.

(D) The unweighted noise power, measured or calculated with an integrating time of 5 milliseconds, shall not exceed 1 000 000 pW0 (10^6 pW0) for more than 0.01 percent (10^{-4}) of any month. However, this is reduced to 0.001 percent (10^{-5}) of any month, or 0.1 percent of any hour, if the telephone channel is to be used for 50-baud amplitude-modulated voice-frequency telegraph, if recommended quality of telegraph operation is to be obtained. This stiffer requirement need not apply to frequency-modulated noise-frequency telegraph systems operating at 50 bauds.

In part of a hypothetical reference circuit consisting of one or more homogeneous sections, the values of noise power in **(A)** and **(B)** above, and the small percentage of time in **(C)** and **(D)** above, shall be considered to be proportional to the number of homogeneous sections involved.

These are design objectives, "and it is not intended that they be quoted in specifications for equipment or used for acceptance tests." (G.222, and CCIR, 393-3)

Noise Characteristics for Long Circuits Not More Than 2500 Kilometers in Length

Circuits on Land, in Submarine-Cable Systems, or on Radio Relay Systems—The mean psophometric power during any hour should be of the order of 4 pWp0 per kilometer, including noise due to frequency-division-multiplex equipment, except for very short circuits or those with a very complicated composition. (G.153, Section A)

Circuits on Transhorizon Relay Systems—The CCIR divides transhorizon systems into two classes, from the viewpoint of performance.

Transhorizon systems of the first class are those intended to operate between two points that might, without excessive difficulty, be connected by line-of-sight radio relay or cable systems. The hypothetical reference circuit described for transhorizon systems applies to this class. The noise power at the end of this circuit will be calculated by statistical combination of the noise power in each of its radio sections. The statistical noise distribution curve should meet requirements **(A)** through **(D)** above.

Transhorizon systems of the second class are those used between points for which other transmission systems cannot be used without excessive difficulty. If the design objectives given above cannot be met without excessive difficulty, the calculated noise-power distribution should meet the following objectives: The mean psophometric power during 1 minute must not exceed 25 000 pWp0 for more than 20 percent of any month, nor exceed 63 000 pWp0 for more than 0.5 percent of any month. Also, the unweighted noise power (integrated over 5 milliseconds) stated in **(D)** above should not be exceeded for more than 0.05 percent of the most unfavorable month. (CCIR, 397-3)

Noise Characteristics for International Circuits More Than 2500 Kilometers in Length

Circuits in Cable or Radio Relay Systems, With No Long Submarine-Cable Section—Such circuits, between 2500 and 25 000 kilometers in length, are generally carried in land cable or radio relay systems designed to 2500-kilometer objectives, and the number of channel demodulations seldom exceeds that in the corresponding part of the worldwide hypothetical reference chain. Automatic regulation should be used on each group link. The noise objectives are:

(A) The mean psophometric noise power during any hour, due to the line, should not exceed 3 pWp0 per kilometer; preferably, it should be 2 pWp0 per kilometer or even less. It is noted that in some countries, long overland systems (5000 kilometers or more) have the same objectives as the submarine-cable system (1 pWp0/km).

(B) For systems up to about 7500 kilometers long, the 1-minute mean power should not exceed 50 000 pWp0 for more than 0.3 percent of any month.

(C) For systems up to about 7500 kilometers long, the unweighted noise power, measured or calculated with an integrating time of 5 milliseconds, should not exceed 1 000 000 pW0 for more than 0.03 percent of any month.

Note: **(B)** and **(C)** are prorated from 2500-kilometer objectives, and proportional values should be used for

lengths between 2500 and 7500 kilometers. The CCITT does not yet recommend short-term objectives for systems longer than 7500 kilometers. (G.153, Section A)

Circuits With a Long Submarine-Cable Section—The circuit noise attributable to the submarine section, without compandors, should not exceed a mean psophometric noise value of 3 pWp0 per kilometer in the worst hour on the worst channel. The mean noise power for each direction of transmission, over all channels used for the longest circuits, should not exceed 1 pWp0 per kilometer. No objectives are given for circuits equipped with compandors. The other parts of the circuit should conform to normal 2500-kilometer objectives. (G.153, Section B)

Circuits on Communication-Satellite Systems—The psophometrically weighted noise power at a point of zero relative level in any telephone circuit in the basic hypothetical reference circuit (as defined in Recommendation 352) should not exceed the provisional values of 10 000 pWp0 mean in any hour, 10 000 pWp0 one-minute mean for more than 20 percent of any month, 50 000 pWp0 one-minute mean for more than 0.3 percent of any month, and 1 000 000 pW0 (5-millisecond integrating time) for more than 0.01 percent of any year. The multiplex noise is not included in these figures. (CCIR, 353-3)

Circuits on Open Wire Carrier Systems—In systems of about 10 000 kilometers in length, with lines of strict regularity of construction, accurately operating automatic line regulators, adjustment of line levels to take account of special climatic conditions, and carefully chosen repeater spacings, the following objectives may apply: The mean psophometric power, during any hour, at the end of a circuit of about 10 000 kilometers, taking into account all noise that exists, with the exception of noise due to radio transmitters, should not exceed 50 000 pWp0. This is for a reasonable distribution of wet weather in the territory crossed by the circuit. (G.153, Section D, Orange Book)

Noise in Actual Circuits

Radio Relay Circuits, 280 to 2500 Kilometers in Length—In a telephone channel of an actual radio relay system using frequency-division multiplex, whose composition does not differ appreciably from the hypothetical reference circuit and whose length L is between 280 and 2500 kilometers, the psophometrically weighted noise power, excluding multiplex noise, should not exceed (A) $3L$ pWp0 mean power in any hour, (B) $3L$ pWp0 one-minute mean power for more than 20 percent of any month, and (C) 47 500 pWp0 one-minute mean power for more than $(L/2500) \times 0.1$ percent of any month, as a planning objective. (CCIR, 359-4)

Radio Relay Circuits, Over Real Links, 50 to 2500 Kilometers in Length—If, for planning reasons, the composition of a real link differs substantially from the hypothetical reference circuit, the noise power of a circuit of length L, carried in one or more baseband sections of frequency-division-multiplex radio links, should not exceed the values in Table 3.

National Circuits on Carrier Systems Over Very Short Distances—Assuming that circuits in an international connection, making use of frequency-division-multiplex carrier systems over very short distances, can be limited in number to four, the mean psophometric power should not exceed 2000 pWp0 per circuit during any hour, including cross talk.

For CCITT Recommendations for pulse-code-modulation systems see G.123.

Design Objectives for Noise Produced by Modulating Equipments

The mean psophometric power, which corresponds to the noise produced by all modulating equipment mentioned in the definition of the hypothetical reference circuit in question, should not exceed 2500 pWp0. This value includes noise due to various causes, such as thermal noise, intermodulation, cross talk, power supplies, etc. Its allocation between the various equipments can be left somewhat to the discretion of designers, but the following maximum values are recommended for the modulating equipments

TABLE 3. MAXIMUM NOISE POWER

Length of System, (km)	Mean Power in Any Hour	1-Minute Mean Power for More Than 20% of Any Month	1-Minute Mean Power of 47 500 pWp0, for More Than Stated % of Any Month
50–280	$3L$ pWp0 + 200 pWp0	$3L$ pWp0 + 200 pWp0	(280/2500) × 0.1%
280–840	$3L$ pWp0 + 200 pWp0	$3L$ pWp0 + 200 pWp0	(L/2500) × 0.1%
840–1670	$3L$ pWp0 + 400 pWp0	$3L$ pWp0 + 400 pWp0	(L/2500) × 0.1%
1670–2500	$3L$ pWp0 + 600 pWp0	$3L$ pWp0 + 600 pWp0	(L/2500) × 0.1%

Note 1: Frequency-division-multiplex noise is not included.

Note 2: The hourly mean-noise-power objective and its subdivision are under study.

	pWp0
One pair of channel modulators	200–400
One pair of group modulators	60–100
One pair of supergroup modulators	60–100
One pair of mastergroup modulators	40–60

(G.222, Section d)

CCITT AND TELEGRAPHY

The CCITT Yellow Book contains the CCITT Recommendations, including those adopted by the Seventh Plenary Assembly held in Geneva in 1980. The recommendations on Telegraph Technique are included in Volume VII. Those on Data Transmission are included in Volume VIII, and the Recommendations on Telegraph Operations and Tariffs are contained in Volume II.

Numbering

There is a worldwide system of Destination Indicators for the telegraph-message retransmission network. These indicators consist of two letters signifying the country and its telegraph network (if more than one) followed by two letters signifying the town on that network. Examples: Vienna AUWI, Panama City (Tropical Radio) PAPA, Balboa (ITTCACR) PZBA, Stockholm SWSM, San Francisco (ITT Worldcom) UISF.

The CCITT has approved a worldwide numbering system for telex services. The telex destination code consists of two or three numerical digits signifying the country or network within the country. The destination code is followed by the telex subscriber's national number, also consisting of numerical digits.

The telex system provides also for *designation* codes, for identifying the country and network of the originator of a communication. The designation code consists of two letters, the same two letters that compose the first half of the message-retransmission-system *destination* indicator.

Examples of destination codes are:

North and Central America: 200 Cuba, 205 Puerto Rico (RCA), 206 Puerto Rico (ITTWC), 207 Puerto Rico (C & W), 21 Canada (except TWX), 22 Mexico, 25 USA (TWX), 271 Guatemala, 290 Bermuda, 292 Virgin Islands.

South America: 304 Surinam, 305 Paraguay, 31 Venezuela, 36 Peru, 381 Brazil (Radio Brazil), 383 Brazil (PTT), 387 Argentina (ITTCM), 390 Netherlands Antilles, 391 Trinidad.

Europe: 400 Canary Islands, 403 Spain, 409 Algeria, 41 Germany, 46 Belgium, 492 Syria, 496 Kuwait, 501 Iceland, 51 United Kingdom, 57 Finland.

Eastern Europe: 601 Greece, 606 Israel, 61 Hungary, 65 Romania.

Pacific: 702 Guam, 704 Hawaii (RCA), 705 Hawaii (ITTWC), 71 Australia, 72 Japan, 75 Philippines.

Asia: 801 Korea, 802 Hong Kong, 81 India, 85 China, 88 Iran.

Africa: 901 Libya, 94 Ghana, 95 South Africa, 975 Niger, 991 Angola, 992 Mozambique.

CCITT AND TELEPHONY

International Country Codes

The addressing signals of worldwide automatic telephony consist of the national telephone number, as used for long-distance dialing within a country, prefixed by a country code. Country codes are grouped by continental regions; for example, the country codes of all South American countries begin with "5." Where the national numbering system includes more than one country, the country code may also include the countries included in the national system. Thus the country code for the United States—"1"—includes Canada and some other countries. The following are examples of some country codes, grouped by world numbering regions or zones, as assigned by the Third Plenary Assembly of the CCITT in Geneva in 1964.

Zone 1—Code 1: USA, Canada, Mexico and Central America, Bahamas, Bermuda, Jamaica, French Antilles, Netherlands Antilles.
Zone 2—Africa: 51 countries, 48 country codes (Algeria, Morocco, Tunisia, Libya in one group—the Maghreb—code 21). United Arab Republic 20, South Africa 27, 45 three-digit codes.
Zones 3 and 4—Europe, Iceland, Malta, Cyprus: 17 two-digit and 13 three-digit country codes. Examples: France 33, Spain 34, Italy 39, United Kingdom 44, Germany 49, Iceland 354, Finland 401, Hungary 402.
Zone 5—South America and Cuba: 6 two-digit and 8 three-digit country codes. Examples: Cuba 53, Argentina 54, Brazil 55, Chile 56, Columbia 57, Venezuela 58, Peru 596.
Zone 6—Southwestern Pacific: 6 two-digit and 14 three-digit country codes. Examples: Malaysia 60, Australia 61, Indonesia 62, Philippines 63, New Zealand 64, Thailand 66, Guam 682.
Zone 7—Country code 7: Soviet Union
Zone 8—Northwestern Pacific: 4 two-digit and 6 three-digit country codes. Examples: Japan 81, Korea 82, Vietnam 84, China (Formosa) 85, Hong Kong 852, Mongolia 854, Laos 856.
Zone 9—East: 5 two-digit and 15 three-digit country codes. Examples: India 91, Burma 95, Iran 98, Lebanon 961, Saudi Arabia 966, Israel 972.

TELEPHONE SIGNALING

CCITT signaling systems have been standardized for international use. General descriptions are given in

TABLE 4. CCITT SIGNALING SYSTEMS

No.	Systems
1	500/20-hertz system used in the international manual service (ringdown). Used until 1980.
2	600/750-hertz two-frequency system. Never used in international service.
	International Automatic and Semiautomatic Systems
3	For unidirectional operation of circuits. Uses one inband frequency (2280 hertz) for the transmission of both line and interregister signals; used for terminal traffic; in general not to be used for new installations. Used until late 1970s.
4	For undirectional operation of circuits (circuits seized from one end only). Uses two in-band frequencies (2040 and 2400 hertz) for the end-to-end transmission of both line and register signals; used for international intracontinental traffic; suitable for terminal and transit traffic; in the latter case two or three circuits equipped with System No. 4 may be switched in tandem. Suitable for submarine- or land-cable circuits and microwave radio circuits; not applicable to TASI-equipped systems. Capable of interworking with System No. 5
5	For both-way operation of circuits. Uses two in-band signaling frequencies (2400 and 2600 hertz) for the link-by-link transmission of line signals, and six in-band frequencies (700, 900, 1100, 1300, 1500, and 1700 hertz) in a two-out-of-six code (numerical information transmitted *en bloc*) for the link-by-link transmission of register signals; used for intercontinental traffic. Suitable for submarine- or land-cable circuits and microwave links, whether or not TASI is used; suitable for terminal or transit traffic—in the latter case, two or more circuits equipped with System No. 5 may be switched in tandem but are subject to possible undesirable delays if all are TASI-equipped. Capable of interworking with System No. 4
6	Based on principles of common channel signaling techniques in which the signaling is removed from the voice path; for both analog and digital transmission facilities; signaling link carries information by serial mode of synchronous data transmission; link-by-link operation; can be associated, quasi-associated, or non-associated mode; capable of interworking with No. 4, No. 5, and No. 5 bis. (Yellow Book, V1.3)
7	A common channel system specified in 1980; conceived for the digital environment; preferred system for integrated digital networks (IDN) for both telephony and circuit switched data; designed for interexchange signaling in integrated services digital network (ISDN); optimized for operation over 64 kb/s digital channels; employs packet-type information transfer. Flexible enough to evolve with future enhanced service requirements. (Yellow Book, VI.6)

Table 4, and some of the signaling characteristics are given in Table 5.

Signals in communications are used for passing information, for identifying the called subscriber or addressee (with resulting internal system signals concerned with the establishment of a connection), and for supervising and controlling the connection once it has been established.

Information signals may be analog (voice, telemetry, or facsimile) or digital (teleprinter or data).

Addressing signals may be dial pulse, multifrequency, or binary. They are not needed once a communication has been established.

(A) *Dial pulse* signals consist of a series of from one to ten pulses representing the corresponding numerical digits 1 to 9 and 0. The pulses are breaks in a continuous direct current on the line, usually lasting from 58 to 67 percent of the time interval between the starts of successive pulses. These breaks in direct current may have to be converted into pulses in a tone, or to frequency shifts between tones, in order to pass through some media or multiplexing systems. Dial pulse speeds are usually 10 pulses per second, although high-speed dials of nearly twice that speed are sometimes used.

(B) *Multifrequency* signals represent numerical digits by one pulse (or sometimes four pulses) of a specific frequency combination. The two-out-of-six and four-by-four multifrequency codes are shown in Tables 6 and 7. Inherent in both is the constant-ratio error-control principle (the simultaneous receipt of three or more, or one only, frequencies indicates an error). Table 8 shows the US Army two-out-of-five numerical code. The CCITT two-voice-frequency code, consisting of two frequencies sent one at a time in four pulses, is given in Table 9.

(C) *Binary* signals for addressing are usually in a numeric or alphanumeric code used also for information signals, such as in telegraph addresses or headings. Multifrequency signals are sometimes directly converted to binary signals by changing the two-frequencies-out-of-six code to a corresponding two-time-slots-out-of-six synchronous six-element binary code. Another example of a binary code used only for addressing is the CCITT one-voice-frequency code, and four-element start-stop code given in Table 10. (The CCITT two-voice-frequency code is not truly binary since it uses a third condition—no tone—in addition to the two tones.)

Supervisory or Line Signals

Supervisory or line signals cannot be generated exclusively by registers because they are required during the entire use of the connection, after the registers that established the connection have been disconnected. Supervisory signals are an extension of the original basic signals of ringing and of closing a line loop to allow direct current to flow. Supervisory signals may be classified as spurt (discontinuous) and continuous.

ST	1500 + 1700	7 + 11 end of pulsing

Continuous signals are based on conditions of on-hook and off-hook, representing the condition of locked or flowing direct current on the subscriber's line, and their extension to trunk signaling is given in Table 11. Either condition is continuous and may be detected at any time. On the other hand, discontinuous signals must be recorded, and the condition represented is presumed to continue until a new signal is sent. Supervisory signaling in a backward direction (toward the calling end) is also needed in automatic working and is also described as on-hook or off-hook, although on two-wire metallic circuits the signaling condition is usually a reversal of flow of the direct current rather than an interruption.

Continuous supervisory signaling over longer distances is effected by use of signaling paths distinct from the voice path. These signaling paths may be telegraph legs of a composite telegraph system, simplexing of the voice pair, or special tones inside or outside of the voice

8	1900 + 2300
9	2100 + 2700
0	1900 + 2500

channel. Whatever the paths, they are extensions of separate direct-current leads from the trunk circuits, known as *E* and *M* leads. The relation between the conditions of these leads and the on-hook or off-hook signaling conditions they represent is shown in Fig. 6. The usual method of extending the *E* and *M* leads over tone channels is shown in Fig. 7. The frequency of the tone used is preferably higher than 2000 hertz and is usually 2600 hertz on four-wire circuits. A 3825-hertz signaling system is known as "out-of-band" and must be built into the carrier system using it.

Spurt signaling avoids the necessity of using distinct signaling paths. For manual operation, ringdown signaling is usually satisfactory. For semiautomatic or automatic operation, however, more elaborate systems are required. Voice-frequency signals are used, and they are distinguished from voice transmissions by filters and timing. Single-frequency systems use one or two long or short pulses of the specific signaling frequency, with the pulses carefully timed to within minimum and maximum limits. Two-frequency systems use a gate-opening prefix pulse of the two frequencies together, followed, without a silent period, by a long or short pulse of either of the two frequencies. The submarine-cable signaling system (CCITT No. 5) uses two frequencies in the "compel" mode, wherein the signal frequencies are sent until acknowledged, and the acknowledging signal is sent until the original signal is stopped. No gate-opening prefix is used.

Ringdown Signals

Ringdown signals are spurts of ringing current (16 to 25 hertz) applied usually through the ringing key of an operator and intended to operate a bell, ringer, or drop at the called end. The current may be generated by a manually operated magneto or by a ringing machine with or without automatically inserted silent periods. Ringing to telephone subscribers in automatic central offices is stopped or "tripped" automatically by relay action resulting from the subscriber's off-hook condition. Ringing signals may be converted to 500 or 1000 hertz, usually interrupted at a 20-hertz rate, to pass through voice channels of carrier equipment. A ringing signal to a manual switchboard usually lights a switchboard lamp, which can be darkened again only by local action and not by stopping or repeating the ringing signal. This characteristic makes ringdown operation unsuitable for fully automatic operation. Ringdown signaling over carrier circuits has the advantages of simplicity and of not requiring the distinct signaling channels of *E* and *M* systems.

Tones

A special case of signaling is that of information in the form of tones to the subscriber of a telephone

TABLE 9. NUMERICAL CODE, TWO-VOICE-FREQUENCY SIGNALING SYSTEM, CCITT NO. 4

	Successive Elements			
Digit	1	2	3	4
1	*y*	*y*	*y*	*x*
2	*y*	*y*	*x*	*y*
3	*y*	*y*	*x*	*x*
4	*y*	*x*	*y*	*y*
5	*y*	*x*	*y*	*x*
6	*y*	*x*	*x*	*y*
7	*y*	*x*	*x*	*x*
8	*x*	*y*	*y*	*y*
9	*x*	*y*	*y*	*x*
0	*x*	*y*	*x*	*y*

Note: The two frequencies are sent one at a time, with a silent space between pulses. The duration of both frequency and silent periods is 35±7 milliseconds. Frequencies: x = 2040±6 hertz; y = 2400±6 hertz. Power level: −9 decibels.

TABLE 10. NUMERICAL CODE, ONE-VOICE-FREQUENCY SIGNALING SYSTEM, CCITT NO. 3.

	Time Elements					
Digit	Start	1	2	3	4	Stop
1	1				1	
2	1			1

8	1	1				
9	1	1			1	
0	1	1		1		

Note: "1" signifies frequency present. Length of each time element is 50 milliseconds±1 percent. Frequency: 2280±6 hertz. Power level: −6 decibels.

TABLE 11. ON-HOOK AND OFF-HOOK SIGNALS

Direct Current Telephone Line	Trunk
On-hook signifies loop is open to direct current supplied from other end.	If idle, signals on-hook to other end. Seizure at calling end signals off-hook to called end. While calling end awaits answer, called end signals on-hook to calling end.
Off-hook signifies loop is closed, allowing relay at other end to operate. Signaling in reverse direction is ring-down.	Answer results in signaling off-hook from called end.
	If called end is not ready to receive address signals when seized, it signals off-hook to calling end until ready.

system. The basic tones are dial tone, busy tone, and ring-back tone (representing the ringing of the called subscriber's line). The dial tone is generated at the subscriber's local switching center, but the busy tone and ring-back tone, plus special tones such as no-such-number and line-out-of-order, are generated at the called subscriber's switching center and should be standardized for universal intelligibility. A proposal by the American Telephone and Telegraph Company for standard tones is described in Table 12. On some international calls, the busy and ring-back tones are generated locally in accordance with spurt supervisory signals from the called end.

Alternative Routing

Switching systems in which the complete called number is recorded in the first center to which the subscriber is connected permit a translation of digits from those identifying the called subscriber to those most conveniently used by the switching mechanism to

TABLE 12. TABLE OF PROPOSED STANDARD OF AUDIBLE TONES IN NORTH AMERICA (FROM CCITT DOCUMENT AP III-84)

	Frequencies§ (hertz)				Power per Frequency at Exchange Where Tone is Applied	
Use	350	440	480	620	(dBm0)	Cadence
Dial tone	x	x			−13	Continuous
Busy tone			x	x	−24	0.5 second on 0.5 second off
Reorder tone*			x	x	−24	0.2 second on 0.3 second off or 0.3 second on 0.2 second off
Audible ringing tone		x	x		−16	2 seconds on 4 seconds off
High tone†			x		−16	Varies according to use
Preemption tone‡		x		x	−18	Single 200/500-ms pulse
Call-waiting tone		x			−13	Single 500-ms pulse

Notes:

* A possible alternative is the use of a call-failure tone, which would identify the office and type of condition that prevented the successful completion of the call.

† High tone is used in many ways. For example:

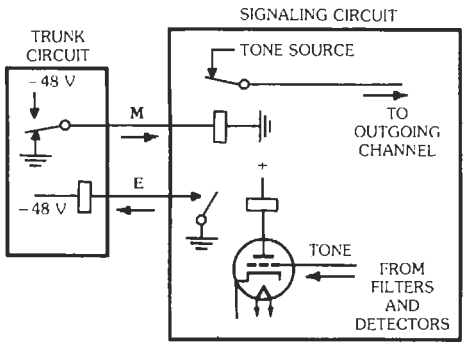
(A) Spurts of tone to indicate specific orders to operators in the manual service (order tones).

(B) To inform operators of lines that are temporarily out of service (permanent signal tone).

(C) To alert customers that their services are in a permanent off-hook condition.

‡ Preemption tones are used in certain private switched networks which may interconnect with the national networks.

§ Frequency limits are ±0.5 percent of nominal.



SIGNAL	TONE	OPERATION	LEAD	CONDITION
ON-HOOK	ON	SENDING	M	GROUND
		RECEIVING	E	OPEN
OFF-HOOK	OFF	SENDING	M	BATTERY
		RECEIVING	E	GROUND

establish the desired connection. This translation of digits permits the controlling mechanism to use a variety of routes in such a way that if the first-choice route is occupied or disabled a second-choice route may be tried, etc. Safeguards are required to prevent doubling back of routes and dead-end choices. In the near future, many sophisticated plans may be expected that depend on rapid analysis of network possibilities by data-transmission means. The signals used for this purpose are interregister signals and are classed with addressing signals in that they are used in establishing a connection to the desired addressee, not being needed after a connection has been established.

3 Units, Constants, and Conversion Factors

Revised by
Eugene A. Mechtly

SI UNITS*

There are two classes of units in the *International System of Units* (SI): *base units* and *derived units*. The units of these two classes form a *coherent* set of units. This coherent set of units is designated by the name "SI Units."

SI Base Units

The SI is founded on seven *base units*, respectively, for seven *base quantities*. The base quantities are assumed to be mutually independent. These base units and base quantities are given in Table 1.

TABLE 1. SI BASE UNITS

Base Quantity	SI Base Unit	
	Name	Symbol
Length	meter	m
Mass	kilogram	kg
Time	second	s
Electric current	ampere	A
Thermodynamic temperature	kelvin	K
Amount of substance	mole	mol
Luminous intensity	candela	cd

SI Derived Units

Other quantities, called *derived quantities*, are defined in terms of the seven base quantities through a system of quantity equations. *Derived units* for these derived quantities are obtained from the system of equations and the seven base units in a *coherent* manner. Here, the term *coherent* is used to mean a system of units where all derived units are obtained from the base units by the rules of multiplication and division, with no numerical factor other than one (1) ever occurring in the expressions for the derived units in terms of the base units.

Table 2 lists, in alphabetical order, SI derived units and reiterates the seven SI base units.

SI Prefixes

Table 3 gives the twenty SI prefixes used to form decimal multiples and submultiples of SI units.

* The information on the SI in this chapter is based on *Metric System of Measurement: The International System of Units for the United States*, published in the U.S. Federal Register, Vol. 63, No. 144, 1998, pp. 40334–40340. This Federal Register Notice can be viewed and downloaded over the World Wide Web from the website of the US Government Printing Office. Go to www.gpo.gov. Click on "Federal Register," select "1998," select "Notices," and enter "SI" as the search term.

TABLE 2. SI BASE AND DERIVED UNITS

Name	Symbol	Quantity
ampere (an SI base unit)	A	electric current
ampere per meter	A/m	magnetic field strength
ampere per square meter	A/m^2	current density
becquerel	Bq s^{-1}	activity (of a radionuclide)
candela (an SI base unit)	cd	luminous intensity
candela per square meter	cd/m^2	luminance
coulomb	C s·A	electric charge, quantity of electricity
coulomb per cubic meter	C/m^3	electric charge density
coulomb per kilogram	C/kg	exposure (x and gamma rays)
coulomb per square meter	C/m^2	electric flux density
cubic meter	m^3	volume
cubic meter per kilogram	m^3/kg	specific volume
degree Celsius*	°C	Celsius temperature
farad	F C/V	capacitance
farad per meter	F/m	permittivity
gray	Gy	absorbed dose, specific energy imparted, kerma, absorbed dose index
gray per second	Gy/s	absorbed dose rate
henry	H Wb/A	inductance
henry per meter	H/m	permeability
hertz	Hz s^{-1}	frequency
joule	J N·m	energy, work, quantity of heat
joule per cubic meter	J/m^3	energy density
joule per kelvin	J/K	heat capacity, entropy
joule per kilogram	J/kg	specific energy
joule per kilogram kelvin	J/(kg·K)	specific heat capacity, specific entropy
joule per mole	J/mol	molar energy
joule per mole kelvin	J/(mol·K)	molar entropy, molar heat capacity

* The kelvin (symbol K) is the SI unit of thermodynamic temperature, T. The degree Celsius (symbol °C) is the commonly used unit of Celsius temperature, t. Celsius temperature is defined by the equation $t = T - T_o$, where $T_o = 273.15$ kelvins.

TABLE 2 (CONT). BASE AND DERIVED UNITS

Name	Symbol	Quantity
kelvin (an SI base unit)	K	thermodynamic temperature
kilogram (an SI base unit)	kg	mass
kilogram per cubic meter	kg/m^3	density, mass density
kilogram per kilogram	kg/kg = 1	mass fraction
lumen	lm	luminous flux
lux	lx lm/m^2	illuminance
meter (an SI base unit)	m	length
meter per second	m/s	speed, velocity
meter per second squared	m/s^2	acceleration
mole (an SI base unit)	mol	amount of substance
mole per cubic meter	mol/m^3	concentration (of amount of substance)
newton	N	force
newton meter	N·m	moment of force
newton per meter	N/m	surface tension
number per meter	m^{-1}	wave number
ohm	Ω V/A	electric resistance
pascal	Pa N/m^2	pressure, stress
pascal second	Pa·s	dynamic viscosity
radian	rad	plane angle
radian per second	rad/s	angular velocity
radian per second squared	rad/s^2	angular acceleration
reciprocal meter	m^{-1}	wave number
second (an SI base unit)	s	time
siemans	S A/V	electric conductance
sievert	Sv	dose equivalent, equivalent dose
square meter	m^2	area
steradian	sr	solid angle
tesla	T Wb/m^2	magnetic flux density
volt	V W/A	electric potential, potential difference, electromotive force
volt per meter	V/m	electric field strength
watt	W J/s	power, radiant flux
watt per meter kelvin	W/(m·K)	thermal conductivity
watt per square meter	W/m^2	heat flux density, irradiance, power density
watt per square meter steradian	$W·m^{-2}·sr^{-1}$	radiance
watt per steradian	W/sr	radiant intensity
weber	Wb V·s	magnetic flux

TABLE 3. SI PREFIXES

Factor	Name	Symbol
10^{24}	yotta	Y
10^{21}	zetta	Z
10^{18}	exa	E
10^{15}	peta	P
10^{12}	tera	T
10^{9}	giga	G
10^{6}	mega	M
10^{3}	kilo	k
10^{2}	hecto	h
10	deka	da
10^{-1}	deci	d
10^{-2}	centi	c
10^{-3}	milli	m
10^{-6}	micro	μ
10^{-9}	nano	n
10^{-12}	pico	p
10^{-15}	femto	f
10^{-18}	atto	a
10^{-21}	zepto	z
10^{-24}	yocto	y

Example: In the expression I = 150 mA, I is the symbol for a physical quantity (current), A is the symbol for the unit of current (ampere), and m is the symbol for the prefix milli. Together, m and A form the symbol for a submultiple unit of current, the milliampere.

Note that the kilogram, for historical reasons, is the only SI unit with a prefix (kilo) as part of its name (kilogram) and as part of its symbol (kg). In the special case of the kilogram, the prefix names are used with the name "gram" and the prefix symbols are used with the symbol "g" for gram. For example, "mg" is the symbol for milligram. With this exception, any SI prefix may be used with any SI unit.

ADDITIONAL INFORMATION ON THE SI

Additional information on the SI may be found in the NIST Special Publication 811, *Guide for the Use of the International System of Units (SI)*, by Barry N. Taylor. SP 811 is for sale by the Government Printing

Office and is also available at the NIST website: www.physics.nist.gov/cuu.

Units outside the SI

Certain units are not part of the International System of Units, that is, they are outside the SI but are important and widely used. The units in this category that are approved for use in the United States, with the SI, are given in Tables 4 and 5.

Rules and Style Conventions*

Rules and style conventions ensure that communication is not hindered by ambiguity. Some well-established rules are:

1. Symbols for units and prefixes are printed in Roman (upright) type regardless of the type used in the surrounding text.
2. Uppercase and lowercase symbols must be used for units and prefixes as defined in Tables 1 through 5 of this chapter. Failure to distinguish between upper and lower cases of the same letter is not acceptable. For example, mW (milliwatt) and MW (megawatt) must not be confused.
3. When the name of a unit is spelled out, it is always written with a lowercase initial letter unless it begins a sentence.
4. Unit symbols are unaltered in the plural.
5. Unit symbols are not followed by a period unless at the end of a sentence.
6. Symbols for units formed from other units by multiplication are indicated by means of a half-high (that is, centered) dot or space. Example: N·m or N m.
7. Symbols for units formed from other units by division are indicated by the means of a solidus (oblique stroke, /), a horizontal line, or negative exponents. For example,

$$\text{m/s}, \frac{\text{m}}{\text{s}}, \text{or m} \cdot \text{s}^{-1}$$

* Most of these rules and style conventions are copied from the Federal Register Notice of 1998.

TABLE 4. UNITS OUTSIDE THE SI THAT ARE ACCEPTED FOR USE WITH THE SI

Name		Symbol	Value in SI Units
minute	time	min	1 min = 60 s
hour	time	h	1 h = 60 min = 3600 s
day	time	d	1 d = 24 h = 86 400 s
degree	plane angle	°	$1° = (\pi/180)$ rad
minute	plane angle	′	$1′ = (1/60)° = (\pi/10\,800)$ rad
second	plane angle	″	$1″ = (1/60)′ = (\pi/648\,000)$ rad
liter*		L	$1\ \text{L} = 1\ \text{dm}^3 = 10^{-3}\ \text{m}^3$
metric ton†		t	$1\ \text{t} = 10^3$ kg
neper‡		Np	1 Np = 1
bel		B	1 B = (1/2) ln 10 Np

* The liter and its symbol, l, are approved for use internationally. The alternative symbol for the liter, L, was approved internationally in 1979 to avoid the risk of confusion between the letter l and the number 1. The preferred symbol for use in the United States is L. Neither a lowercase script letter l nor an uppercase script letter L are approved symbols for the liter.

† The name "metric ton" is preferred for use in the United States for the unit with symbol t and is defined as $1\ \text{t} = 10^3$ kg. The "metric ton" is also used in some other English-speaking countries. The name "tonne" is used in many other countries.

‡ Although the neper is coherent with SI units and is accepted by the CIPM, it has not been adopted by the CGPM and is thus not an SI unit.

TABLE 5. UNITS OUTSIDE THE SI THAT ARE ACCEPTED FOR USE WITH THE SI, BUT WHOSE VALUES IN SI UNITS ARE OBTAINED EXPERIMENTALLY

Name	Symbol	Value in SI Units*
electron volt†	eV	$1\ \text{eV} = 1.602\ 177\ 33(49) \times 10^{-19}$ J
unified atomic mass unit‡	u	$1\ \text{u} = 1.660\ 540\ 2(10) \times 10^{-27}$ kg
astronomical unit§	ua	$1\ \text{ua} = 1.495\ 978\ 70(30) \times 10''$m

* The combined standard uncertainty (that is, estimated standard derivation) of the last two figures is shown in parentheses.

† The electronvolt is the kinetic energy acquired by an electron in passing through a potential difference of 1 V in vacuum.

‡ The unified atomic mass unit is equal to 1/12 of the mass of an unbound atom of the nuclide ^{12}C at rest and in its ground state.

§ The astronomical unit is a unit of length approximately equal to the mean Earth–Sun distance. Its value is such that, when used to describe the motion of bodies in the Solar System, the heliocentric gravitation constant is $(0.017\ 202\ 098\ 95)^2\ \text{ua}^3 \cdot \text{d}^{-2}$.

However, to avoid ambiguity, the solidus must not be repeated on the same line unless parentheses are used. Examples are

m/s^2 or $m \cdot s^{-2}$ *but not:* m/s/s
$m \cdot kg/(s^3 \cdot A)$ or $m \cdot kg \cdot s^{-3} \cdot A^{-1}$ *but not:* $m \cdot kg/s^3/A$

Negative exponents should be used in complicated cases.

8. Prefixes symbols are printed in Roman (upright) type regardless of the type used in the surrounding text and are attached to unit symbols without a space between the prefix symbol and the unit symbol. This last rule also applies to prefix names attached to unit names. Examples include

   1 ml (one milliliter)
   1 pm (one picometer)
   1 GΩ (one gigaohm)
   1 THz (one terahertz)

9. The grouping formed by a prefix symbol attached to a unit symbol constitutes a new inseparable symbol (forming a multiple or submultiple of the unit concerned), which can be raised to a positive or negative power and which can be combined with other unit symbols to form compound unit symbols. Some examples are

$$2.3\ cm^3 = 2.3\ (cm)^3 = 2.3\ (10^{-2}m)^3 = 2.3 \times 10^{-6} m^3$$

$$1\ cm^{-1} = 1\ (cm)^{-1} = 1\ (10^{-2}m)^{-1} = 10^2\ m^{-1}$$

$$5000\ \mu s^{-1} = 5000\ (\mu s)^{-1} = 5000\ (10^{-6}s)^{-1} = 5000 \times 10^6 s^{-1} = 5 \times 10^9\ s^{-1}$$

   Prefix names are also inseparable from the unit names to which they are attached. Thus, for example, millimeter, micropascal, and meganewton are single words.

10. Compound prefix symbols, that is, prefix symbols formed by the juxtaposition of two or more prefix symbols, are not permitted. This rule also applies to compound prefix names. For example,

    1 nm (one nanometer) *but not:* 1 mμm (one millimicrometer)

11. An SI prefix symbol (and name) cannot stand alone but must be attached to a unit symbol (or name). For example,

$$5 \times 10^6/m^3 \textit{ but not: } 5\ M/m^3$$

12. In the expression for the value of a quantity, the unit symbol is placed after the numerical value and a space is left between the numerical value and the unit symbol. The only exceptions to the rule are for the unit symbols for degree, minute, and second for plane angle: °, ′, and ″, respectively (see Table 4), in which case no space is left between the numerical value and the unit symbol. For example,

$$\alpha = 30°22'8''$$

This rule means that:

(a) The symbol °C for the degree Celsius is preceded by a space when one expresses the values of Celsius temperatures. Thus

$t = 30.2$ °C *but not:* $t = 30.2$°C or $t = 30.2°$ C

(b) Even when the value of a quantity is used in an adjectival sense, a space is left between the numerical value and the unit symbol. (This rule recognizes that unit symbols are not like ordinary words or abbreviations but are mathematical entities and that the value of a quantity should be expressed in a way that is as independent of language as possible.) Some examples are

a 1 m end gauge *but not:* a 1-m end gauge

a 10 kΩ resistance *but not:* a 10-kΩ resistance

However, if there is any ambiguity, the words should be rearranged accordingly. For example, the statement "the samples were placed in 22 mL vials" should be replaced with the statement "the samples were placed in vials of volume 22 mL" or "the samples were placed in 22 vials of volume 1 mL," whichever was meant.

NOTE: When unit names are spelled out as is often the case in nontechnical writing, the normal rules of English apply. Thus, for example, "a roll of 35-millimeter film" is acceptable.

When there is a risk of confusion in using the standard symbol (e.g., "s" or "T") the name of the unit should be spelled out (e.g., second or tesla).

When a rarely used multiple or submultiple of an SI unit is first used in text, the full name should be stated. Subsequently, the corresponding symbols may be used alone. For example: The solar energy incident each year at the top of the Earth's atmosphere is about 5.6 yottajoules (5.6 YJ). The total energy of a solar flare is about 10 YJ.

Dimensionless Quantities (Quantities of Dimension 1)

Ratios of two quantities of the same dimension are called *dimensionless quantities* or *quantities of dimension 1*. They are expressed as pure numbers. The SI unit of all dimensionless quantities is the number 1. The two quantities may be of the same kind or they may be of a different kind.

Examples of dimensionless ratios of quantities of the same kind are: relative permittivity, relative permeability, refractive index, mass fraction, and characteristic numbers (e.g., Mach number and Reynolds number).

Examples of dimensionless ratios of quantities of different kinds are the radian, with unit symbol rad for plane angle (arc length divided by radius), and the steradian, with unit symbol sr, for solid angle (area divided by radius squared). The special names, radian

and steradian, are given to the number 1 in these two cases to aid understanding, e.g., to indicate that a particular plane angle is expressed on the basis of arc length divided by radius rather than on the basis of a full circle divided into 360 degrees.

Decibels and Nepers

The decibel, symbol dB, represents the ratio of two values of power. The number n of decibels is 10 times the logarithm to the base 10 of the power ratio:

$$n(\text{dB}) = 10 \log_{10} (P_2/P_1)$$

Where the power ratio is less than unity, it is usual to invert the fraction and express the answer as a loss in decibels.

In the electrical case of voltage V, current I, and impedance Z (when Z is a pure resistance):

$$P_2/P_1 = (V_2/V_1)^2(Z_1/Z_2) = (I_2/I_1)^2(Z_2/Z_1)$$

Thus,

$$n_V(\text{dB}) = 20 \log_{10} (V_2/V_1) + 10 \log_{10} (Z_1/Z_2)$$

and

$$n_I(\text{dB}) = 20 \log_{10} (I_2/I_1) + 10 \log_{10} (Z_2/Z_1)$$

Only in the special case of matched impedances ($Z_2 = Z_1$) does

$$n = n_{\text{Z-matched}} = 20 \log_{10} (V_2/V_1) + 20 \log_{10} (I_2/I_1)$$

The neper, symbol Np, is a dimensionless unit for expressing the ratio of two values of amplitude. The number n of neper is the natural logarithm of the amplitude ratio:

$$n(\text{Np}) = \ln (A_2/A_1)$$

To convert decibels to nepers, multiply by 0.1151.

Numerical Values

To facilitate the reading of numbers, the digits may be separated into groups of three, counting from the decimal sign toward the left and the right. The groups should be separated by a small space, but not by a comma or a point. In numbers of four digits, the space is usually not necessary. For example:

2.141 596 73 772 7372 0.133 47

$\pi = 3.141\ 592\ 653\ 589$

$e = 2.718\ 281\ 828\ 459$

American-English documents use a period for the decimal sign. British-English documents use a raised dot (·). For all other languages, the recommended decimal sign is a comma.

If the magnitude of a number is less than unity, the decimal sign should be preceded by a zero.

The sign of multiplication of numbers is a cross (×) or a raised dot (·).

Greek Alphabet

Name	Capital	Small	Commonly Used to Designate
Alpha	A	α	angles, coefficients, attenuation constant, absorption factor, area
Beta	B	β	angles, coefficients, phase constant
Gamma	Γ	γ	complex propagation constant (cap), relative density, angles, electrical conductivity, propagation constant
Delta	Δ	δ	increment or decrement (cap or small), determinant (cap), density, angles
Epsilon	E	ϵ	permittivity, electric intensity
Zeta	Z	ζ	coordinates, coefficients
Eta	H	η	intrinsic impedance, efficiency, surface charge density, hysteresis, coordinates
Theta	Θ	ϑ, θ	angular phase displacement, time constant, reluctance, angles
Iota	I	ι	unit vector
Kappa	K	κ	susceptibility, coupling coefficient, thermal conductivity
Lambda	Λ	λ	permeance (cap), wavelength, attenuation constant
Mu	M	$\propto$	permeability, amplification factor, prefix micro
Nu	N	ν	reluctivity, frequency
Xi	Ξ	ξ	coordinates
Omicron	O	o	
Pi	Π	π	3.1416 (see more precise value in text)
Rho	P	ρ	resistivity, volume charge density, coordinates
Sigma	Σ	σ	summation (cap), surface charge density, complex propagation constant, electrical conductivity, leakage coefficient, deviation
Tau	T	τ	time constant, volume resistivity, time-phase displacement, transmission factor, density
Upsilon	Υ	υ	
Phi	Φ	ϕ, φ	scalar potential (cap), magnetic flux, angles
Chi	X	χ	electrical susceptibility, angles
Psi	Ψ	ψ	dielectric flux, phase difference, coordinates, angles
Omega	Ω	ω	resistance in ohms (cap), solid angle (cap), angular velocity

Note: Small letter is used except where capital (cap) is indicated.

FUNDAMENTAL PHYSICAL CONSTANTS

The following values of the fundamental physical constants are recommended by the international *Committee on Data for Science and Technology* (CODATA). They are called "1998 CODATA Recommended Values." They are available on the World Wide Web at the URL: http://www.physics.nist.gov/cuu/Constants/index.html.

The 1998 values replace the 1986 set. A detailed description of the data and their analysis that led to the 1998 values is published in the *Journal of Physical and Chemical Reference Data*, Vol. 28, No. 6, 1999 and in the *Reviews of Modern Physics*, Vol. 72, No. 2, 2000. That paper was prepared under the auspices of the CODATA Task Group on Fundamental Constants.

Wien displacement law constant				
$b = \lambda_{max} T = c_2/4.965\,114\,231...$	b	2.897 7686(51) × 10^{-3}	m K	1.7 × 10^{-6}

[a] See the "Adopted values" table for the conventional value adopted internationally for realizing representations of the volt using the Josephson effect.

[b] See the "Adopted values" table for the conventional value adopted internationally for realizing representations of the ohm using the quantum Hall effect.

[c] Value recommended by the Particle Data Group, Caso et al., Eur. Phys. J. C 3(1-4), 1-794 (1998).

[d] Based on the ratio of the masses of the W and Z bosons m_W/m_Z recommended by the Particle Data Group (Caso et al., 1998). The value for $\sin^2\theta_W$ they recommend, which is based on a particular variant of the modified minimal subtraction ($\overline{MS}$) scheme, is $\sin^2\hat{\theta}_W(M_Z)$ = 0.231 24(24).

[e] The helion, symbol h, is the nucleus of the ^{3}He atom.

[f] This and all other values involving m_τ are based on the value of $m_\tau c^2$ in MeV recommended by the Particle Data Group, Caso et al., Eur. Phys. J. C 3(1-4), 1-794 (1998), but with a standard uncertainty of 0.29 MeV rather than the quoted uncertainty of −0.26 MeV, +0.29 MeV.

[g] The numerical value of F to be used in coulometric chemical measurements is 96 485.3432(76) [7.9 × 10^{-8}] when the relevant current is measured in terms of representations of the volt and ohm based on the Josephson and quantum Hall effects and the internationally adopted conventional values of the Josephson and von Klitzing constants K_{J-90} and R_{K-90} given in the "Adopted values" table.

[h] The entropy of an ideal monoatomic gas of relative atomic mass A_r is given by $S = S_0 + \frac{3}{2}R \ln A_r - R \ln(p/p_0) + \frac{5}{2}R \ln(T/K)$.

CONVERSION FACTORS*

Exact numerical values (based on definitions) are followed by *** ....
The symbol E marks a power-of-ten multiplier in the usual way for the entry of data into calculators and computers.

meter (based on constant c)†		

† On October 20, 1983, the 17th CGPM adopted the following definition: "The meter is the length of the path traveled by light in vacuum during a time interval of 1/299 792 458 of a second." This new definition has the effect of giving a fixed value to the speed of light in vacuum of c = 299 792 458 m/s exactly. (Metrologia, *Vol. 19, p. 163, 1984.*)

4 Properties of Materials

Revised by
Eugene A. Mechtly

GENERAL PROPERTIES OF THE ELEMENTS

Some properties of the elements are listed in Table 1.* Some of the listed quantities are defined as follows.

Atomic number Z represents the number of protons per atom.

Mass number $Z + N$ is equal to the number of protons Z plus the number of neutrons N present in the nuclei. Mass numbers of the most abundant isotopes are given in order of decreasing abundance. For example, Cadmium Cd-48 mass numbers 114–112 means that cadmium atoms of greater abundance (28.86%) have a mass number of 114; that is, the nucleus of Cd^{114} has $114 - 48 = 66$ neutrons while isotope Cd^{112} of lower abundance (24.07%) has $112 - 48 = 64$ neutrons.

Atomic radius values listed provide a comparison of sizes (deduced from interatomic spacing of bound atoms).

Gram atomic volume in cubic centimeters gives the volume occupied in the solid state by an atom at its melting point. The gram atomic volume contains the Avogadro number of atoms.†

Electronegativity represents the relative tendency of an atom to attract shared electron pairs. The highest electronegativity is assigned to fluorine with the value 3.90.

First ionization potential is the work in electron volts required to pull 1 electron off an isolated neutral atom.

$$1 \text{ electron volt} = 1.602 \times 10^{-19} \text{ joule}\dagger$$

Electron work function, expressed in electronvolts, represents the energy that must be supplied to an electron to cross over the surface barrier of a metal. That energy may be supplied by heat (thermionic work function), by light (photoelectric work function), or by contact with a dissimilar metal (contact potential).

Electrochemical equivalents are expressed in joules per gram (J/g) liberated at the electrode.

PERIODIC CLASSIFICATION OF THE ELEMENTS

Fig. 1 is a periodic table of the elements.

Oxidation number is defined as the charge that an atom appears to have in a compound when electrons are counted according to certain rules:

(A) In the free elements each atom has an oxidation number of 0.
(B) Electrons shared between two unlike atoms are counted with the more electronegative atom.
(C) Electrons shared between the two like atoms are divided equally between sharing atoms.

PHYSICAL PROPERTIES OF THE ELEMENTS

Some of the physical properties of the elements are listed in Table 2.

GALVANIC SERIES IN SEA WATER

In sea water, two dissimilar metals connected by a conductor form a galvanic cell. If the two metals are in different groups of Chart 1 (separated by spaces), the metal coming first in the series—starting from corroded end to protected end—will be anodic (i.e., corroded by the metal contained in the group farther from the corroded end). If the two metals are in the same group, no appreciable corrosive action will take place.

TEMPERATURE–EMF CHARACTERISTICS OF THERMOCOUPLES‡

Fig. 2 shows temperature–emf characteristics of thermocouples.

Electromotive Force and Other Properties

Electromotive force and other properties of thermocouples are listed in Tables 3 and 4.

CONDUCTING MATERIALS

Conducting materials (Tables 5–7) can be classified as follows:

Conductors: Resistivities from 10^{-6} to 10^{-4} Ω·cm (1 to 100 $\mu\Omega$·cm). Conductivities from 10^{4} to 10^{6} S·cm^{-1}.

Semiconductors: Resistivities from 10^{-4} to 10^{9} Ω·cm. Conductivities from 10^{-9} to 10^{4} S·cm^{-1}.

Insulators: Resistivities from 10^{9} to 10^{25} Ω·cm. Conductivities from 10^{-25} to 10^{-9} S·cm^{-1}.

SEMICONDUCTING MATERIALS

Some properties of semiconductor materials are listed in Table 8.

---

* Tables 1 and 2, Chart 1, and Fig. 1 of this chapter are partly based on data from the following sources: *Handbook of Chemistry and Physics,* 55th ed., CRC Press, Inc., 1974; *Fundamentals of Chemistry,* John Wiley & Sons; *The Encyclopedia of Electrochemistry,* Reinhold Publishing Corp., 1964; *American Institute of Physics Handbook,* 3rd ed., McGraw-Hill Book Co., 1972; *Lange's Handbook of Chemistry,* 11th ed., McGraw-Hill Book Co., 1973.

† See Chapter 3 for precise valve.

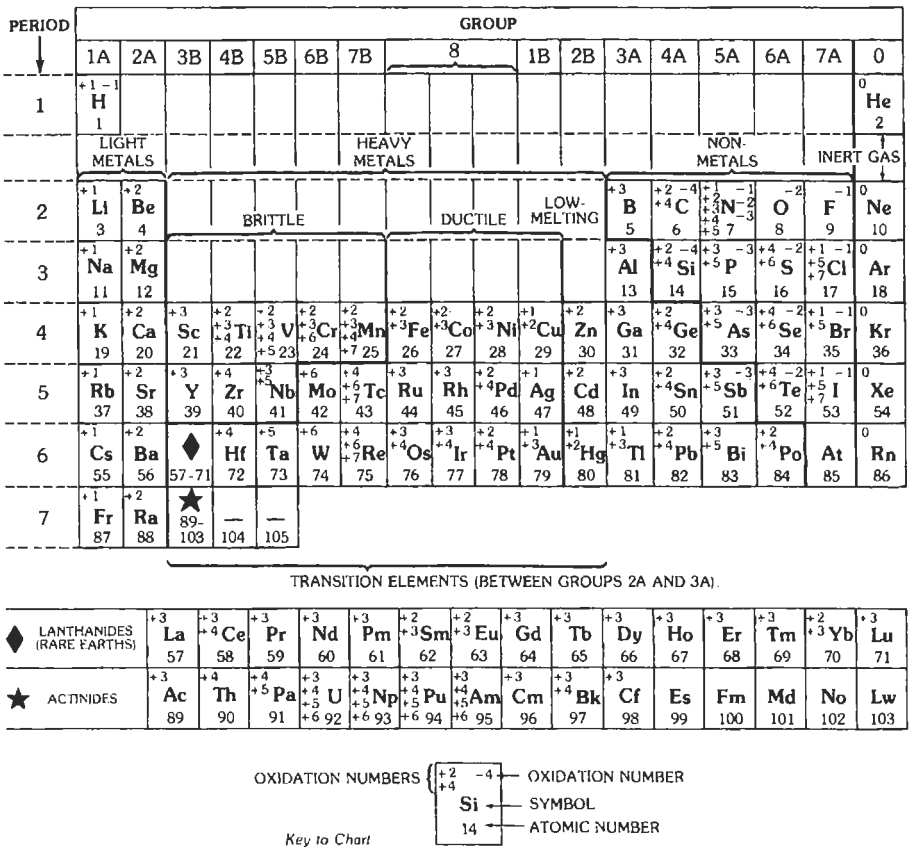

Fig. 1. Periodic classification of the elements.

INSULATING MATERIALS

The permittivity, ϵ, of an insulating material is defined by

$$\epsilon = \epsilon_0 + (P/E)$$

where,

ϵ_0 = permittivity of free space,
P = flux density from dipoles within the dielectric medium,
E = electric-field intensity,
P/E = electric susceptibility.

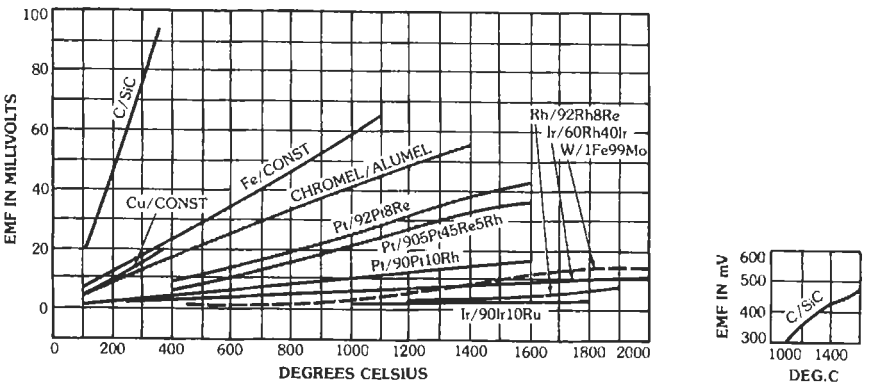

Fig. 2. Temperature–emf characteristics of thermocouples.

CHART 1. GALVANIC SERIES IN SEA WATER

Corroded end (anodic)	Lead
	Tin
Magnesium	
Magnesium alloys	Muntz metal
	Manganese bronze
Zinc	Naval brass
Galvanized steel	
Galvanized wrought iron	Nickel (active)

Aluminum:	
52SH, 4S, 3S, 2S, 53ST	
Aluminum clad	Yellow brass
	Admiralty brass
	Aluminum bronze
Cadmium	Red brass
	Copper
Aluminum:	Silicon bronze
A17ST, 17ST, 24ST	Ambrac
	70–30 copper–nickel
Mild steel	Comp. G, bronze
Wrought iron	Comp. M, bronze
Cast iron	
Ni-resist	Nickel (passive)
	Inconel (passive)
13% chromium stainless steel (type 410—active)	Monel
50–50 lead-tin solder	18–8 stainless steel type 304 (passive)
18–8 stainless steel type 304 (active)	18–8–3 stainless steel type 316 (passive)
18–8–3 stainless steel type 316 (active)	Protected end (cathodic or most noble)

It is often convenient to use the relative permittivity, ϵ_r, defined by

$$\epsilon_r = \epsilon/\epsilon_0$$

The relative permittivity, ϵ_r, is a function of temperature and frequency. From Table 9, which gives the values of ϵ_r as a function of frequencies at room temperature, it is easy to get values of ϵ from

$$\epsilon = \epsilon_r/\epsilon_0$$

In the international system of units, the permittivity of vacuum is equal to

$$\epsilon_0 = 8.854 \times 10^{-12} \text{ F/m}$$

and we have

Coulomb's Law

$$F = (1/4\pi\epsilon_0\epsilon_r)(q_1q_2/R^2)$$

Gauss's Law

$$\Phi = (\epsilon_0\epsilon_r)^{-1}\Sigma q_i$$

The dissipation factor of an insulating material (Table 9) is defined as the ratio of the energy dissipated to the energy stored in the dielectric per hertz, or as the tangent of the loss angle. For dissipation factors less than 0.1, the dissipation factor may be considered equal to the power factor of the dielectric, which is the cosine of the phase angle by which the current leads the voltage.

Many of the materials listed are characterized by a peak dissipation factor that occurs somewhere in the frequency range, this peak being accompanied by a rapid change in the permittivity. These effects are the result of a resonance phenomenon occurring in polar materials. The position of the dissipation-factor peak in the frequency spectrum is very sensitive to temperature. An increase in the temperature increases the frequency at which the peak occurs, as illustrated qualitatively in Fig. 3. Nonpolar materials have very low losses without a noticeable peak; the permittivity remains essentially unchanged over the frequency range.

Another effect that contributes to dielectric losses is that of ionic or electronic conduction. This loss, if present, is important usually at the lower end of the frequency range only and is distinguished by the fact that the dissipation factor varies inversely with frequency.

Influence of temperature and gas atmosphere	Subject to oxidation and alteration above 400 °C due to Cu. above 600° due to constantan wire. Ni-plating of Cu tube gives protection in acid-containing gas. Contamination of Cu affects calibration greatly. Resistance to oxide. aun. good. Resistance to reducing atm. good. Requires protection from acid fumes.	Oxidizing and reducing atmosphere have little effect on accuracy. Best used in dry atmosphere. Resistance to oxidation good to 400 °C. Resistance to reducing atmosphere good. Protect from oxygen, moisture, sulphur.	Chromel attacked by sulphurous atmosphere. Resistance to oxidation good. Resistance to reducing atmosphere poor.	Resistance to oxidizing atmosphere very good. Resistance to reducing atmosphere poor. Affected by sulphur, reducing or sulphurous gas, SO_2 and H_2S.	Resistance to oxidizing atmosphere very good. Resistance to reducing atmosphere poor. Susceptible to chemical alteration by As, Si, P vapor in reducing gas (CO_2, H_2, H_2S, SO_2). Pt corrodes easily above 1000 °C. Used in gas-tight protecting tube.		Used as tube element. Carbon sheath chemically inert.
Particular applications	Low temperature, industrial. Internal-combustion engine. Used as a tube element for measurements in steam line.	Low temperature, industrial. Steel annealing, boiler flues, tube stills. Used in reducing or neutral atmosphere.		Used in oxidizing atmosphere. Industrial. Ceramic kilns, tube stills, electric furnaces.	International Standard 630 to 1065 °C.	Similar to Pt/PtRh (10) but has higher emf.	Steel furnace and ladle temperatures. Laboratory measurements.

* For prolonged use; can he used at higher temperature for short periods.

* From *Smithsonian Physical Tables*, 9th revised ed., Vol. 120 (Washington, DC: Smithsonian Institution, 1969).

Increase in temperature increases the loss due to ionic conduction because of increased ionic mobility.

The data given on dielectric strength are accompanied by the thickness of the specimen tested because the dielectric strength, expressed in volts/mil, varies inversely with the square root of thickness, approximately.

The direct-current volume resistivity of many materials is influenced by changes in temperature or humidity. The values given in the table may be reduced several decades by raising the temperature toward the higher end of the working range of the material, or by raising the relative humidity of the air surrounding the material to above 90 percent.

MAGNETIC MATERIALS*

All materials that are magnetized by a magnetic field are called magnetic materials. Depending on the magnetic response, various kinds of magnetism are classified. Most magnetic materials of commercial importance today are ferromagnets or ferrimagnets. Iron, nickel, cobalt, and their alloys are examples of ferromagnets; spinel ferrites and garnets are examples of ferrimagnets. These exhibit spontaneous magnetism and develop a flux density B upon application of a magnetic field of strength H in accordance with

$$B = \mu_0 H + J$$

In this equation, $\mu_0 = 1.257 \times 10^{-6}$ H/m is the permeability of free space, and J is the magnetic polarization. The units of B and J are teslas (T) or webers

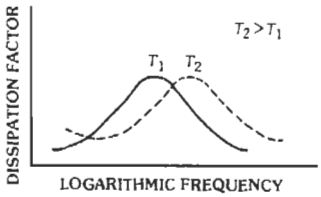

Fig. 3. Variation of dissipation factor with frequency.

per square meter (Wb/m^2), and H is in amperes per meter (A/m).

The permeability of a magnetic material is

$$\mu = B/H = \mu 0 + J/H$$

It is, however, customary to use the relative permeability, μ_r, defined by

$$\mu_r = \mu/\mu_0 = 1 + J/\mu_0 H$$

The permeability of a ferromagnet (or ferrimagnet) is a function of applied field, temperature, and frequency. For electronic transformer and inductor applications where a small field is impressed, the initial relative permeability, μ_i (often measured at $B = 4$ mT), is the most useful quantity. For power transformer applications, values at higher fields are more useful. Sometimes the value of the maximum relative permeability, μ_m, is quoted. This is a useful quantity for materials exhibiting a square hysteresis loop ideal for amplifier-type applications. Magnetic materials are classified as soft or hard (permanent) depending on the value of coercivity H_c, which is the field strength required to reduce the flux density to zero after the material has been magnetized. Soft magnets have values of H_c less than about 1 kA/m, and hard magnets have H_c greater than about 10 kA/m. Some applications such as reed contacts make use of semihard magnets with 1 kA/m < H_c < 10 kA/m.

Soft Magnetic Metals

Table 10 lists some typical commercial soft magnetic metals generally used in low-frequency transformers and inductors. They are often available as laminations, cut cores, and tape-wound cores. The nickel–iron alloys known as permalloys exhibit the highest initial relative permeability and lowest coercivity. The most commonly used materials in this category are the 48-percent nickel alloy with μ_i about 11 000 and the 80-percent nickel–5-percent molybdenum alloy with μ_i about 80 000, the latter being more expensive. The nickel–iron alloys can also be processed to exhibit a square hysteresis loop, useful for amplifier-type applications, or a skewed loop, useful for unipolar pulse transformer designs. For common 50 Hz or 60 Hz transformers used in the electrical utility industry, silicon steel is the most common material. Low-carbon steels are very inexpensive and widely used in small motors and generators. The cobalt–iron alloys, usually known as permendur, have the highest values of saturation polarization and Curie temperature and tend to be used in high-performance, lightweight applications such as airborne motors. Appearing on the market recently is a new class of soft magnetic alloys called amorphous magnets or metallic glasses. These materials are rapidly solidified from the melt into thin tapes such that the usual crystalline structure is absent. Some amorphous magnets have been prepared to have properties similar to the silicon steels but with substantially lower core losses, while others have been prepared with properties similar to the best grades of the permalloys.

Permanent-Magnet Materials

Table 11 lists some typical permanent-magnet materials. The alnicos are brittle and hence can be used only in cast or sintered form. The hexagonal ferrites are oxides having the general formula $MO \cdot 6Fe_2O_3$, where M is barium or strontium. The magnets are prepared by ceramic techniques and are often called ceramic magnets. Large numbers of low-cost ferrite magnets are bonded in plastics and widely used in door catches, wall magnets, refrigerator door gaskets, and toys.

In recent years, a new class of high-performance permanent magnets made of cobalt rare earths, particularly those containing samarium, have been developed commercially. These magnets have the highest combination of coercivity and maximum energy product available on the market, with applications ranging from tiny wristwatch and earphone magnets to horsepower-size industrial dc and synchronous motors and generators. Some are available in plastic bonded form.

An emerging class of permanent-magnet alloys is the iron chromes, containing iron, chromium, and cobalt. These have magnetic properties similar to the alnicos, but they are sufficiently ductile that they can be cold-rolled to thin strips, drawn into fine wires, or machined or punched into intricate shapes. They also contain less cobalt than the alnicos.

Ferrites

"Ferrite" is the common term applied to a wide range of different ceramic ferromagnetic materials. Specifically, the term applies to those materials with the spinel crystal structures having the general formula XFe_2O_4, where X is any divalent metallic ion having the proper ionic radius to fit in the spinel structure. Several ceramic ferromagnetic materials have been prepared that deviate stoichiometrically from the basic formula XFe_2O_4, but common usage has included them in the family of ferrite materials.

The behavior of the conductivity and permittivity of ferrites can be understood by considering them as grains (crystals) of fairly low-resistance material separated by thin layers of a relatively poor conductor. Therefore, the permittivity and conductivity show a

* Mostly taken from *Tables of Dielectric Materials*, Vols. I–IV, prepared by the Laboratory for Insulation Research of the Massachusetts Institute of Technology, Cambridge, Massachusetts, January 1953; from *Dielectric Materials and Applications*, A. R. von Hippel, ed., John Wiley & Sons, New York, NY, 1954; and from *Modern Plastics Encyclopedia*, Joel Frados, ed., 1301 Avenue of the Americas, New York, NY, 1962. Materials listed are typical of a class. Further data should be sought for a particular material of interest.

relaxation as a function of frequency with the relaxation frequency varying from 1 000 to several million hertz. Most ferrites have relatively high resistivities (~ 10^6 Ω·cm) if they are prepared carefully so as to avoid the presence of any divalent iron ion in the material. However, if the ferrite is prepared with an appreciable amount of divalent iron, then both the conductivity and permittivity are very high. Relative permittivities as high as 100 000 and resistivities less than 1 Ω·cm have been measured in several ferrites having a small amount of divalent iron in their composition.

Since the electrical resistivity of ferrites is typically 10^6 times that of metals, ferrite components have much lower eddy-current losses and hence are used at frequencies above about 10 kHz. Table 12 lists some of the pertinent information with respect to typical commercial ferrites used in transformers and inductors. As a general rule, manganese zinc (MnZn) ferrites are used at frequencies up to about 1 MHz, beyond which nickel zinc (NiZn) ferrites become more efficient as a result of greater electrical resistivity. Relative initial permeabilities can be as high as 20 000 in commercial MnZn ferrites for transformer applications, while the relative loss factor, tan δ/μ, can be as low as 10^{-6} (at 100 kHz) for some low-loss-inductor MnZn ferrites. For filter applications, a low-temperature coefficient of permeability and a low disaccommodation factor are often critical. Table 12 also contains data for some MnZn ferrites used in the design of switched-mode power supplies where a high saturation flux density is desirable.

For microwave applications, devices make use of the nonreciprocal propagation characteristics of ferrites close to or at a gyromagnetic resonance frequency between about 1 and 100 GHz. The most important of such devices are isolators and circulators. Table 13 lists the pertinent design values of several current commercial microwave ferrites, including saturation polarization J_s, resonance line width ΔH, relative permeability ϵ_r, loss tangent tan δ, and Curie temperature T_c. Materials having a range of J_s are needed, depending on the operating frequency, ω, of the device, since for resonance, $J_s < \omega/\delta$, where δ is the gyromagnetic ratio. In the low-frequency range (1–5 GHz), a

class of ferrites called garnets (general formula $R_3Fe_5O_{12}$ with R being yttrium or other rare earth element) is used, whereas in the high-frequency range, the spinel ferrites are used.

MAGNETOSTRICTION

The static strain $\Delta l/l$ produced by a direct-current polarizing flux density B_0 is given by

$$\Delta l/l = cB_0^2$$

where c is a material constant expressed in m^4/Wb^2.

If a small alternating-current driving field is superimposed on a large constant polarizing field B_0, we have

$$d(\Delta l/l) = 2cB_0B = \beta B$$

The magnetostriction stress constant Λ in newtons/weber is

$$\Lambda = \beta Y_0 = 2cB_0Y_0$$

where Y_0 is the Young's modulus for a free bar.

Nickel contracts with increasing B, so Λ is a negative. Permalloy and Alfer expand, and their Λ is positive (Fig. 4).

Table 14 gives values for the three important transducer materials in SI units: annealed nickel, 45 Permalloy (45-percent nickel, 55-percent iron), and Alfer (an alloy of 13-percent aluminum and 87-percent

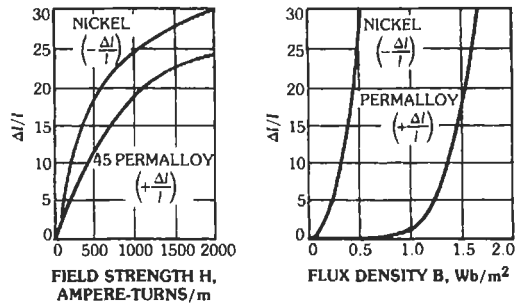

Fig. 4. Strain versus field strength (left) and versus flux density (right). From T. F. Hueter and R. H. Bolt, Eds., *Sonics* (New York: John Wiley & Sons, Inc., 1955; p. 173).

iron). For nickel the values for two different polarizing conditions are given: 160 ampere-turns per meter and 1 200 ampere-turns per meter, the latter appearing in parentheses. Table 15 compares properties of six magnetostriction materials.

PIEZOELECTRICITY

Table 16 lists piezoelectric strain coefficients d_{ij}, which are ratios of piezoelectric polarization components to components of applied stress at constant electric field (direct piezoelectric effect) and also ratios of piezoelectric strain components to applied electric field components at constant mechanical stress (con-

* From T. F. Hueter and R. H. Bolt, eds., *Sonics* (New York: John Wiley & Sons, Inc., 1955; p. 175).

† The number of external ampere-turns per meter required to produce H_0 depends on the shape of the core. For closed magnetic loops H_{ext} is equal to H_0. For rod-shaped cores external fields larger than H_0 are necessary to compensate for the demagnetizing effect of the poles at the free ends.

** The values for two different polarizing conditions are given: 160 and 1200 ampere-turns/meter, the latter in parentheses.

TABLE 15. OTHER CONSTANTS FOR SOME MAGNETOSTRICTION MATERIALS

Composition	$\Delta l/l$ at Saturation of B	Λ (N/Wb)	μ_i (H/m)	Young's modulus (N/m^2)	k_c (%)	Curie Temperature (°C)

(E) Polarized Polycrystalline Substance	d_{15}	d_{31}	d_{33}
Barium titanate ceramic $\epsilon_r = 1700$	750	–235	+570

Note: If the sign of a coefficient is not given, it is unknown (not necessarily positive).

* From *Smithsonian Physical Tables*, 9th revised ed., Vol. 120 (Washington, DC: Smithsonian Institution, 1969; p. 432).

† The coefficient d_{14} of Rochelle salt is extremely dependent on temperature and amplitude. The ratio of d_{14} to dielectric constant ϵ_r is, however, nearly constant.

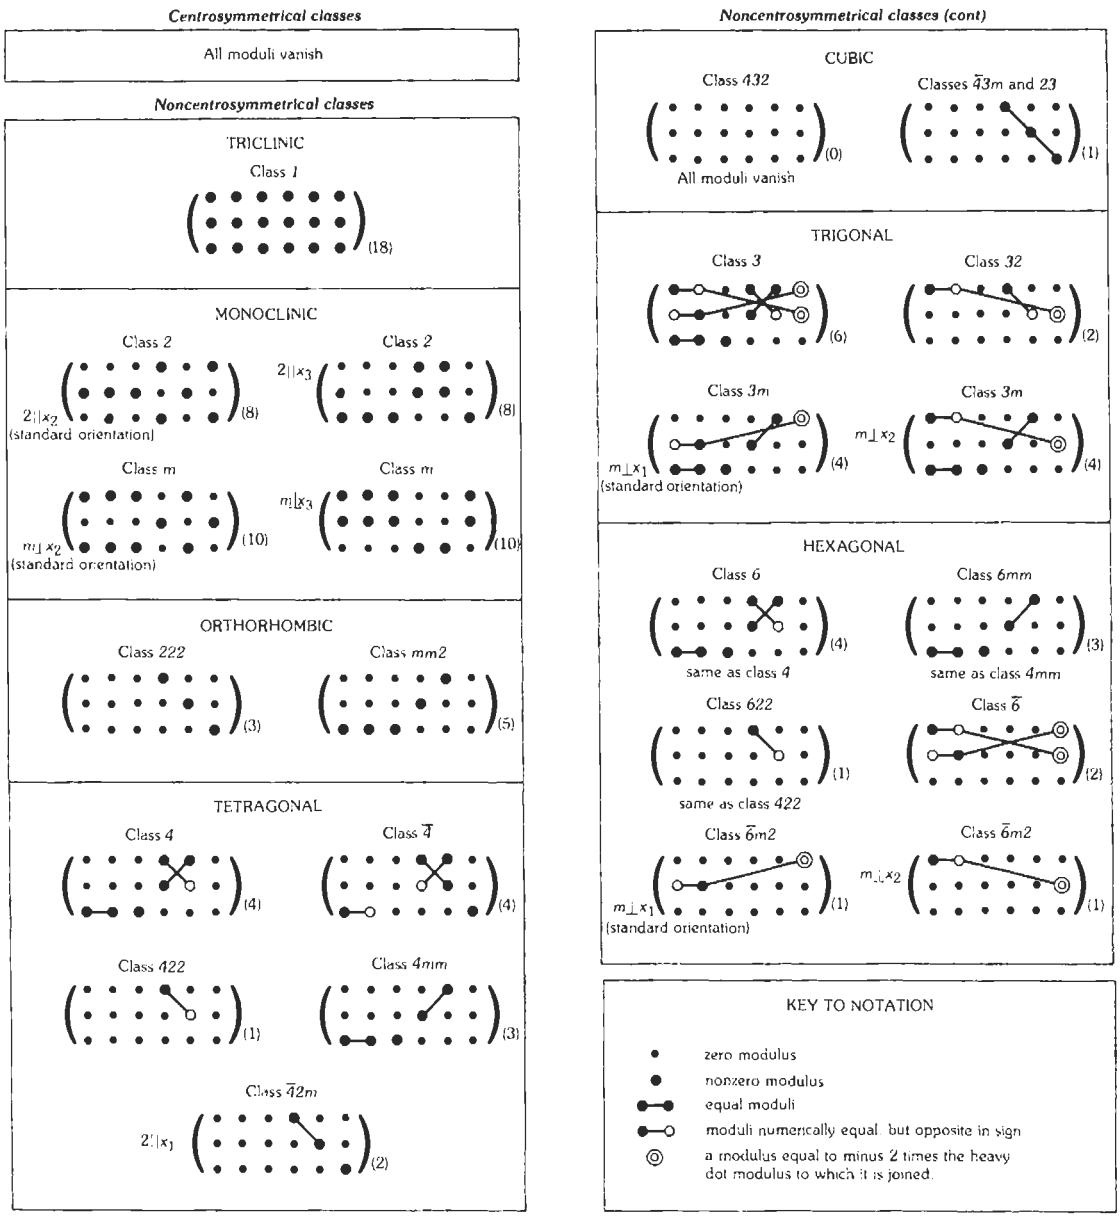

Fig. 5. Form of the (d_{ij}) matrix. From Nye, J. F., *Physical Properties of Crystals* (Oxford: Oxford University Press, 1986; pp. 123–124).

In the monoclinic system, indices 2 and 5 refer to the symmetry (b) axis, in distinction from the older convention relating indices 3 and 6 to the symmetry axis. Crystal classes are designated by international (Hermann–Mauguin) symbols. A dash in place of a coefficient indicates that it is equal by symmetry from another listed coefficient; a blank space indicates that the coefficient is zero by symmetry. If the sign of a coefficient is not given, it is unknown, not necessarily positive.

$$\text{Unit for } d_{ij} = 1/3 \times 10^{-12} \text{ C/N}$$

$$= 1/3 \times 10^{-12} \text{ m/V}$$

Coupling factor k is defined practically by

k^2 = (mechanical energy converted into electric energy)/(mechanical energy put into the crystal)

The converse effect is also true. The same type of relationship holds, and the coupling coefficient is numerically identical to what it was before, namely

k^2 = (electrical energy converted into mechanical energy)/(electrical energy put into the crystal)

d is the measure of the deflection caused by an applied voltage or the amount of charge produced by a given force (units = meters per volt or coulombs per newton)

g denotes a field produced in a piezoelectric crystal by an applied stress unit:

$$\frac{\text{V/m}}{\text{N/m}^2}$$

Equations that relate g, d, and k are:

$$g = d/\epsilon_r\epsilon_0$$

and

$$k^2 = gdE$$

where

ϵ_r = relative permittivity of the dielectric,
ϵ_0 = permittivity of free space = 8.854×10^{-12} F/m,
E = Young's modulus.

Constants of some piezoelectric materials are listed in Table 17.

ACOUSTIC PROPERTIES OF SOME MATERIALS

Information regarding the acoustic properties of some materials is contained in Tables 18 and 19.

TABLE 17. CONSTANTS OF SOME PIEZOELECTRIC MATERIALS*†

Physical Property	Quartz O° X-cut	Lithium Sulfate O° Y-cut	Barium Titanate Type B	Lead Zirconate-/ Titanate PZT-4	Lead Zirconate-/ Titanate PZT-5	Lead Meta-/ Niobate	Units

5 Components or Parts

Revised by
John J. Bohrer, Robert Blaszczyk,
Pierre J. Gerondeau, Jack Isken, Edward Mette,
Rick Price, Joseph A. Toro, and Theodore E. VanKampen

GENERAL STANDARDS

Standardization of electronic components or parts is handled by several cooperating agencies.

In the US, the Electronic Industries Association (EIA)* and the American National Standards Institute (ANSI)† are active in the commercial field. Electron-tube and semiconductor-device standards are handled by the Joint Electron Device Engineering Council (JEDEC), a cooperative effort of EIA and the National Electrical Manufacturers Association (NEMA)‡. Military (MIL) standards are issued by the US Department of Defense or one of its agencies such as the Defense Electronics Supply Center (DESC).

International standardization in the electronics field is carried out by the various Technical Committees of the International Electrotechnical Commission (IEC)§. A list of the available IEC Recommendations is included in the ANSI Index (outside the US, consult the national standardization agency or the IEC). Documents from the IEC may be used directly, or their recommendations may be incorporated in whole or in part in national standards issued by the EIA or ANSI. A few broad areas may be covered by standards issued by the International Standards Organization (ISO).

These organizations establish standards for electronic components or parts (and in some cases, for equipments) to provide interchangeability among different products regarding size, performance, and identification; minimum number of sizes and designs; and uniform testing of products for acceptance. This chapter presents a brief outline of the requirements, characteristics, and designations for the major types of component parts used in electronic equipment. Such standardization offers economic advantages to both the parts user and the parts manufacturer, but is not intended to prevent the manufacture and use of other parts under special conditions.

Color Coding

The color code of Table 1 is used for marking electronic parts.

Tolerance

The maximum deviation allowed from the specified nominal value is known as the tolerance. It is usually given as a percentage of the nominal value, though for very small capacitors the tolerance may be specified in picofarads (pF). For critical applications it is important to specify the permissible tolerance; where no tolerance is specified, components are likely to vary by ±20 percent from the nominal value.

Do not assume that a given lot of components will have values distributed throughout the acceptable range of values. A lot ordered with a ±20% tolerance may include *no* parts having values within 5% of the desired nominal value; these may have been sorted out before shipment. The manufacturing process for a given lot may produce parts in a narrow range of values only, not necessarily centered in the acceptable tolerance range.

Preferred Values

To maintain an orderly progression of sizes, preferred numbers are frequently used for the nominal values. A further advantage is that all parts manufactured are salable as one or another of the preferred values. Each preferred value differs from its predecessor by a constant multiplier, and the final result is conveniently rounded to two significant figures.

ANSI Standard Z17.1-1973 covers a series of preferred numbers based on $(10)^{1/5}$ and $(10)^{1/10}$ as listed in Table 2. This series has been widely used for fixed wirewound power-type resistors and for time-delay fuses.

Because of the established practice of using ±20-, ±10-, and ±5-percent tolerances, a series of values based on $(10)^{1/6}$, $(10)^{1/12}$, and $(10)^{1/24}$ has been adopted by the EIA, and is now an ANSI Standard (C83.2-1971) (EIA RS-385). It is widely used for such small electronic components as fixed composition resistors and fixed ceramic, mica, and molded paper capacitors. These values are listed in Table 2. (For series with smaller steps, consult the ANSI or EIA Standard.)

Voltage Rating

Distinction must be made between the breakdown-voltage rating (test volts) and the working-voltage rating. The maximum voltage that may be applied (usually continuously) over a long period of time without causing the part to fail determines the working-voltage rating. Application of the test voltage for more than a very few minutes, or even repeated applications of short duration, may result in permanent damage or failure of the part.

Characteristic

The term "characteristic" is frequently used to include various qualities of a part such as temperature coefficient of capacitance or resistance, Q value, maximum permissible operating temperature, stability when subjected to repeated cycles of high and low temperature, and deterioration when it is subjected to moisture either as humidity or water immersion. One or two letters are assigned in EIA or MIL type designations, and the characteristic may be indicated by color coding

---

* EIA Engineering Dept., Washington, D.C. Index of standards is available. EIA was formerly Radio-Electronics-Television Manufacturers' Association (RETMA).

† ANSI, New York, New York. Index of standards is available. ANSI was formerly the USA Standards Institute (USASI).

‡ NEMA, New York, New York. Index of standards is available.

§ IEC, Central Office; Geneva, Switzerland. The US National Committee for the IEC operates within the ANSI.

TABLE 1. STANDARD COLOR CODE OF ELECTRONICS INDUSTRY

Color	Significant Figure	Decimal Multiplier	Tolerance in Percent*	Voltage Rating	Characteristic
Black	0	1	±20 (M)	—	A
Brown	1	10	±1 (F)	100	B
Red	2	100	±2 (G)	200	C
Orange	3	1 000	±3	300	D
Yellow	4	10 000	GMV‡	400	E
Green	5	100 000	±5(J)†, (0.50(D))§	500	F
Blue	6	1 000 000	±6(0.25(C))§	600	G
Violet	7	10 000 000	±12.5, (0.10(B))§	700	—
Gray	8	0.01†	±30, (0.05(N))§	800	I
White	9	0.1†	±10†	900	J
Gold	—	0.1	±5 (J), (0.50(E))‖	1 000	—
Silver	—	0.01	±10 (K)	2 000	—
No Color	—	—	±20	500	—

* Tolerance letter symbol as used in type designations has tolerance meaning as shown. ±3, ±6, ±12.5, and ±30 percent are tolerances for USA Std 40-, 20-, 10-, and 5-step series, respectively.
† Optional coding where metallic pigments are undesirable.
‡ GMV is −0 to +100-percent tolerance or Guaranteed Minimum Value.
§ For some film and other resistors only.
‖ For some capacitors only.

on the part. An explanation of the characteristics applicable to a component or part will be found in the following sections covering that part.

ENVIRONMENTAL TEST METHODS

Since many component parts and equipments have the same environmental exposure, environmental test methods are becoming standardized. The principal standards follow.

EIA Standard RS-186-E (ANSI C83.58-1978): Standard Test Methods for Passive Electronic Component Parts.

IEC Publication 68: Basic Environmental Testing Procedures for Electronic Components and Electronic Equipment (published in multiple).

MIL-STD-202F: Military Standard Test Methods for Electronic and Electrical Component Parts.

MIL-STD-750B: Test Method for Semiconductor Device.

MIL-STD-810C: Military Standard Environmental Test Methods.

MIL-STD-883B: Test Methods and Procedures for Microelectronics.

MIL-STD-1344A: Test Methods for Electrical Connectors.

ASTM Standard Test Methods*—Primarily applicable to the materials used in electronic component parts.

* ASTM = American Society for Testing and Materials; Philadelphia, Pa. Index of standards is available.

Wherever the test methods in these standards are reasonably applicable, they should be specified in preference to other methods. This simplifies testing of a wide variety of parts, testing in widely separated locations, and comparison of data.

When selecting destructive environmental tests to determine the probable life of a part, distinguish between the environment prevailing during normal equipment operation and the environment used to accelerate deterioration. During exposure to the latter environment, the item may be out of tolerance with respect to its parameters in its normal operating-environment range. Accelerated tests are most meaningful if some relation between the degree of acceleration and component life is known. Such acceleration factors are known for many insulation systems.

STANDARD AMBIENT CONDITIONS FOR MEASUREMENT

Standard ambient conditions for measurement are listed in Table 3.

OTHER STANDARD ENVIRONMENTAL TEST CONDITIONS

Ambient Temperature

Dry heat, °C: +30, +40, (+49), +55, (+68), +70, (+71), +85, +100, +125, +155, +200 (values in parentheses not universally used).

Cold, °C: −10, −25, −40, −55, −65.

TABLE 2. PREFERRED VALUES*

	USA Standard Z17.1-1973†		USA Standard C83.2-1971 (R 1977)‡		
Name of Series	"5"	"10"	±20% (E6)	±10% (E12)	±5% (E24)
Percent step size	60	25	≈40	20	10

	—	—	—	27	27
	—	31.5	—	—	30
	—	(32)	—	—	—
	—	—	33	33	33
	—	—	—	—	36
	—	—	—	39	39
	40	40	—	—	—
	—	—	—	—	43
	—	—	47	47	47
	—	50	—	—	—
	—	—	—	—	51
	—	—	—	56	56
	—	—	—	—	62
	63	63	—	—	—
	—	—	68	68	68
	—	—	—	—	75
	—	80	—	—	—
	—	—	—	82	82
	—	—	—	—	91
	100	100	100	100	100

* ANSI Standard C83.2-1971 applies to most electronics components. It is the same as EIA Standard RS-385 (formerly GEN-102) and agrees with IEC Publication 63. ANSI Standard Z17.1-1973 covers preferred numbers and agrees with ISO 3 and ISO 497.

† "20" series with 12-percent steps ($(10)^{1/20}=1.122$ multiplier) and a "40" series with 6-percent steps ($(10)^{1/40}=1.059$ multiplier) are also standard.

‡ Associate the tolerance ±20%, ±10%, or ±5% only with the values listed in the corresponding column. Thus, 1200 ohms may be either ±10 or ±5, but not ±20 percent; 750 ohms may be ±5, but neither ±20 nor ±10 percent.

Constant-Humidity Tests

40 °C, 90 to 95% RH; 4, 10, 21, or 56 days.

66 °C, ≈ 100% RH: 48, 96, or 240 hours (primarily for small items).

Cycling Humidity Tests

Fig. 1 shows a number of cycling humidity tests. (See applicable chart in standard for full details.) Preconditioning is customary before starting cycle series. RH = relative humidity.

High-Altitude Tests

Information regarding high-altitude tests is given in Table 4.

Vibration Tests

The purposes of vibration tests are:

(A) Search for resonance.

(B) Determination of endurance (life) at resonance (or at specific frequencies).

(C) Determination of deterioration resulting from

TABLE 3. STANDARD AMBIENT CONDITIONS FOR MEASUREMENT

	Standard	Temperature (°C)	Relative Humidity (%)	Barometric Pressure	
				mm Hg	mbar
Normal range	RS-186-D	15–35	47–75	650–800	860–1060
	IEC-68	15–35	45–75	(645–795)	860–1060
	MIL-STD-202E	15–35	45–75	650–800	(866–1066)
	MIL-STD-810C	13–33	20–80	650–775	(866–1033)
Closely controlled range	IEC-68	20±1	65±2	(645–795)	860–1060
	IEC-68	23±1	50±2	(645–795)	860–1060
	MIL-STD-202E	23±1	50±2	650–800	(866–1066)
	MIL-STD-810C	23±1.4	50±5	650–775	(866–1033)
	IEC-68	27±1	65±2	(645–795)	860–1060
	RS-186-D	25±2	50±2	650–800	860–1060

Notes:
1. Use the closely controlled range only if the properties are sensitive to temperature or humidity variations, or for referee conditions in case of a dispute. The three temperatures 20°, 23°, and 27 °C correspond to normal laboratory conditions in various parts of the world.
2. Rounded derived values are shown in parentheses ().
3. 25±2 °C, 20 to 50% relative humidity (RH) has been widely used as a closely controlled ambient for testing electronics components.

long exposure to swept frequency (or random vibration).

Recommended Frequency Ranges for Tests—Hertz: 1 to 10, 5 to 35, 10 to 55, 10 to 150, 10 to 500, 10 to 2000, 10 to 5000.

Recommended Combinations of Amplitude and Frequency—IEC Publication 68 recommends testing at constant amplitude below and constant acceleration above the crossover frequency (57 to 62 hertz). MIL-STD-202 and MIL-STD-810 also follow this principle but use different crossover points and low-frequency severities. The choice of frequency range and vibration amplitude or acceleration should bear some relation to the actual service environment. Successful completion of 10^7 vibration cycles indicates a high probability of no failures in a similar service environment. Resonances may make the equipment output unusable, although the mechanical life may be adequate.

TABLE 4. HIGH-ALTITUDE TESTS

Pressure			Approximate Corresponding Altitude		
mbar	mm Hg	in. Hg	feet	meters	Standard
700	*525*	*20.67*	*7 218*	2 200	IEC
600	*450*	*17.72*	*11 483*	3 500	IEC
533	*400*	*15.74*	*14 108*	4 300	IEC

20	*17.2*	*0.677*	*85 300*	26 000	IEC
10.6	8.00	0.315	100 000	30 480	MIL-202
1.28	1.09	0.043	150 000	45 720	MIL-202
3.18×10^{-6}	2.40×10^{-6}	9.44×10^{-8}	656 000	200 000	MIL-202

Notes:
1. The inconsistency in the pressure–altitude relation arises from the use of different model atmospheres. For testing purposes always specify the desired pressure rather than an elevation in feet or meters.
2. Values in italics are derived from the values specified in the associated standard.

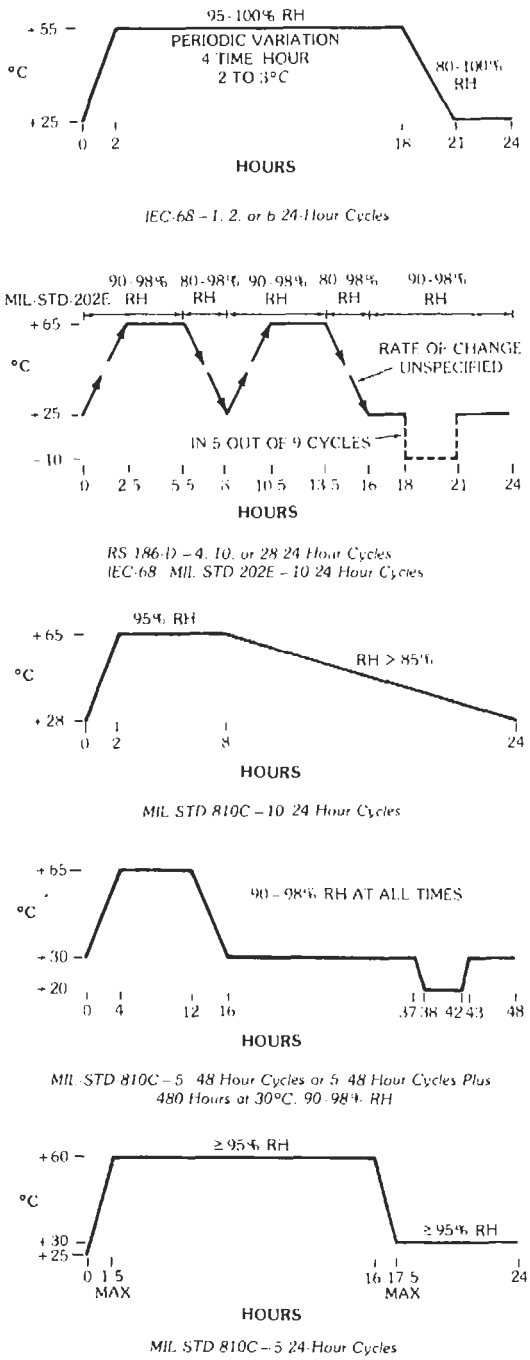

Fig. 1. Cycling humidity tests. Relative humidity for RS-186-D is 90–95% but may be uncontrolled during temperature changes.

COMPONENT VALUE CODING

Axial-lead and some other components are often color coded by circumferential bands to indicate the resistance, capacitance, or inductance value and its tolerance. Usually the value may be decoded as indicated in Fig. 2 and Table 1.

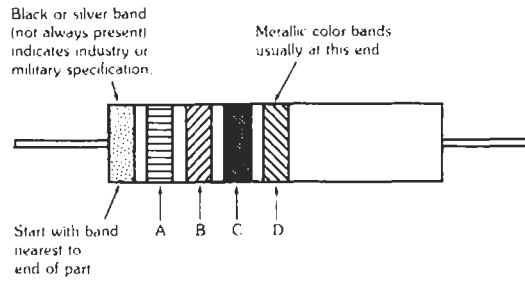

Fig. 2. Component value coding. The code of Table 1 determines values. Band A color = First significant figure of value in ohms, picofarads, or microhenries. Band B color = Second significant figure of value. Band C color = Decimal multiplier for significant figures. Band D color = Tolerance in % (if omitted, the broadest tolerance series of the part applies).

Sometimes, instead of circumferential bands, colored dots are used as shown in Fig. 3 and Table 5.

Semiconductor-Diode Type-Number Coding

The sequential number portion (following the "1N" of the assigned industry type number) may be indicated by color bands* as shown in Fig. 4. Colors have the numerical significance given in Table 1.

Bands J, K, L, M represent the digits in the sequential number (for two-digit numbers, band J is black). Band N is used to designate the suffix letter as shown in Table 6. Band N may be omitted in two- or three-digit number coding if not required, but it will always be present in 4-digit number coding (black if no suffix letter is required). See Table 7 for examples.

A single band indicates the cathode end of a diode or rectifier.

TABLE 5. COLOR-CODE EXAMPLES

Component Value	Band or Dot Color			
	A	B	C	D
3300±20%	Orange	Orange	Red	Black or omitted
5.1±10%	Green	Brown	Gold or white	Silver
1.8 megohms ±5% (as applied to a resistor)	Brown	Gray	Green	Gold

* EIA Standard RS-236-B.

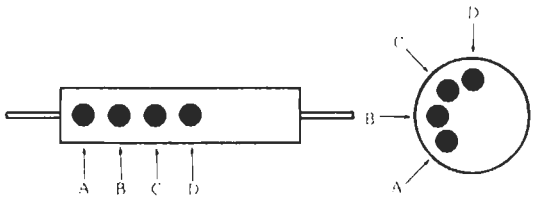

Fig. 3. Alternative methods of component value coding.

RESISTORS—DEFINITIONS

Wattage Rating: The maximum power that the resistor can dissipate, assuming (A) a specific life, (B) a standard ambient temperature, and (C) a stated long-term drift from its no-load value. Increasing the ambient temperature or reducing the allowable deviation from the initial value (more-stable resistance value) requires derating the allowable dissipation. With few exceptions, resistors are derated linearly from full wattage at rated temperature to zero wattage at the maximum temperature.

Temperature Coefficient (Resistance-Temperature Characteristic): The magnitude of change in resistance due to temperature, usually expressed in percent per degree Celsius or parts per million per degree Celsius (ppm/°C). If the changes are linear over the operating temperature range, the parameter is known as "temperature coefficient"; if nonlinear, the parameter is known as "resistance-temperature characteristic." A large temperature coefficient and a high hot-spot temperature cause a large deviation from the nominal condition; e.g., 500 ppm/°C and 275 °C result in a resistance change of over 12 percent.

Maximum Working Voltage: The maximum voltage that may be applied across the resistor (maximum working voltage) is a function of (A) the materials used, (B) the allowable resistance deviation from the low-voltage value, and (C) the physical configuration of the resistor. Carbon composition resistors are more voltage-sensitive than other types.

Noise: An unwanted voltage fluctuation generated within the resistor. Total noise of a resistor always includes Johnson noise, which depends only on resistance value and the temperature of the resistance element. Depending on type of element and construction, total noise may also include noise caused by current and noise caused by cracked bodies and loose end caps or leads. For adjustable resistors, noise may also be caused by jumping of the contact over turns of wire and by imperfect electrical path between contact and resistance element.

N	—	Red	Black
	1N254	1N254B	1N3672

Hot-Spot Temperature: The maximum temperature measured on the resistor due to both internal heating and the ambient operating temperature. The allowable maximum hot-spot temperature is predicated on thermal limits of the materials and the design. Since the maximum hot-spot temperature may not be exceeded under normal operating conditions, the wattage rating of the resistor must be lowered if it is operated at an ambient temperature higher than that at which the wattage rating was established. At zero dissipation, the maximum ambient around the resistor may be at its maximum hot-spot temperature. The ambient temperature for a resistor is affected by surrounding heat-

producing devices; resistors stacked together do not experience the ambient surrounding the stack except under forced cooling.

Critical Resistance Value: A resistor of specified power and voltage ratings has a critical resistance value above which the allowable voltage limits the permissible power dissipation. Below the critical resistance value, the maximum permitted voltage across the resistor is never reached at rated power.

Inductance and Other Frequency Effects: For other than wirewound resistors, the best high-frequency performance is secured if (A) the ratio of resistor length to cross section is a maximum, and (B) dielectric losses are kept low in the base material and a minimum of dielectric binder is used in composition types.

Carbon composition types exhibit little change in effective dc resistance up to frequencies of about 100 kHz. Resistance values above 0.3 megohm start to decrease in resistance at approximately 100 kHz. Above 1 MHz, all resistance values decrease.

Wirewound types have inductive and capacitive effects and are unsuited for use above 50 kHz, even when specially wound to reduce the inductance and capacitance. Wirewound resistors usually exhibit an increase in resistance at high frequencies because of "skin" effect.

Film types have the best high-frequency performance. The effective dc resistance for most resistance values remains fairly constant up to 100 MHz and decreases at higher frequencies. In general, the higher the resistance value the greater the effect of frequency.

Established-Reliability Resistors: Some resistor styles can be purchased with maximum-failure-rate guarantees. Standard-failure-rate levels are:

%/1000 hours—1.0; 0.1; 0.01; 0.001.

Resistance Value and Tolerance Choice: A calculated circuit-resistance nominal value should be checked to determine the allowable deviation in that value under the most unfavorable circuit, ambient, and life conditions. A resistor type, resistance value, and tolerance should be selected considering (A) standard resistance values (specials are uneconomical in most cases), (B) purchase tolerance, (C) resistance value changes caused by temperature, humidity, voltage, etc., and (D) long-term drift.

RESISTORS—FIXED COMPOSITION

Color Code

EIA-standard and MIL-specification requirements for color coding of fixed composition resistors are identical (see Fig. 2). The exterior body color of insulated axial-lead composition resistors is usually tan, but other colors (except black) are permitted. Noninsulated axial-lead composition resistors have a black body color.

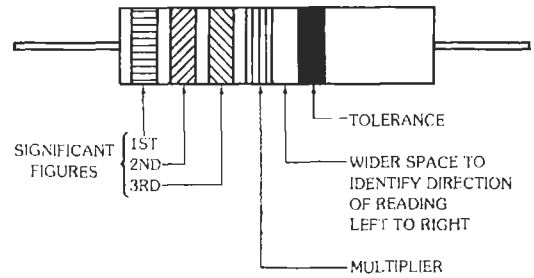

Fig. 5. Resistor value color code for three significant figures. Colors of Table 1 determine values.

If three significant figures are required, Fig. 5 shows the resistor markings (EIA Std RS-279).

Another form of resistor color coding (MIL-STD-1285A) is shown in Fig. 6. Colors have the significance shown in Table 8 for the fifth band.

Tolerance

Standard resistors are furnished in ±20-, or ±10-, and ±5-percent tolerances, and in the preferred-value series of Table 2. "Even" values, such as 50 000 ohms, may be found in old equipment, but they are seldom used in new designs.

Packaging Styles

In addition to the familiar axial-lead configuration, resistors are also available in SIP (single in-line package), DIP (dual in-line package), flat-pack, and leadless chip configurations.

The SIP and DIP types are designed for thru-hole or socket mounting on printed circuit boards. Flat-pack and chip configurations are surface mounted.

Flat-packs, SIPs, and DIPs contain multiple resistors, which may be internally connected to form networks or to have a common terminal pin.

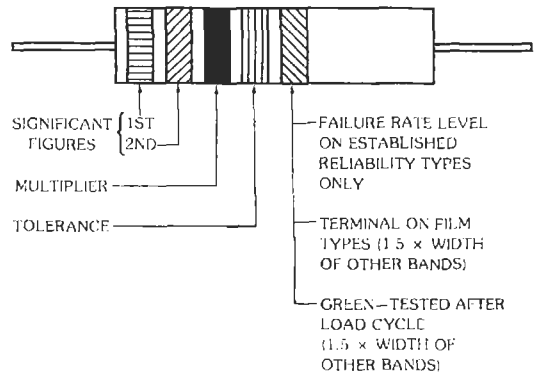

Fig. 6. Resistor color code per MIL-STD-1285A.

TABLE 8. COLOR CODE FOR FIFTH BAND (FIG. 6)

	Brown	Red	Orange	Yellow	Green	White
Failure Rate Level:						
Letter	M	P	R	S	—	—
Rate (%/1000 hrs)	1.0	0.1	0.01	0.001	—	—
Terminal	—	—	—	—	—	Weldable
Special	—	—	—	—	Fig. 6	—

The chip configuration allows increased component density and is autoinsertable. Since there are no leads, basic circuit reliability and high-frequency performance are improved.

Temperature and Voltage Coefficients

Resistors are rated for maximum wattage at an ambient temperature of 70 °C; above these temperatures up to the maximum allowable hot-spot temperature of 130 or 150 °C, it is necessary to operate at reduced wattage ratings. Resistance values are a function of voltage as well as temperature; present specifications allow a maximum voltage coefficient of resistance as given in Table 9 and permit a resistance-temperature characteristic as in Table 10.

A 1000-hour rated-load life test should not cause a change in resistance greater than 12% for ⅛-watt resistors and 10% for all other ratings. A severe cycling humidity test may cause resistance changes of 10% average and 15% maximum; 250 hours at 40 °C and 95% relative humidity may cause up to 10% change. Five temperature-change cycles, −55 °C to +85 °C, should not change the resistance value by more than 4% from the 25 °C value. Soldering the resistor in place may cause a resistance change of 3%. Always allow ¼-inch minimum lead length; use heat-dissipating clamps when soldering confined assemblies. The preceding summary indicates that close tolerances cannot be maintained over a wide range of load and ambient conditions.

Noise

Composition resistors above 1 megohm have high Johnson noise levels, precluding their use in critical applications.

RF Effects

The end-to-end shunted capacitance effect may be noticeable because of the short resistor bodies and small internal distance between the ends. Operation at VHF or higher frequencies reduces the effective resistance because of dielectric losses (Boella effect).

Good Design Practice

Operate at one-half the allowable wattage dissipation for the expected ambient temperature. Provide an adequate heat sink. Mount no other heat-dissipating parts within one diameter. Use only in applications where a 15% change from the installed value is permissible or where the environment is controlled to reduce the resistance-value change.

RESISTORS—FIXED WIREWOUND

Fixed wirewound resistors are available as low-power insulated types, precision types, and power types.

EIA Low-Power Insulated Resistors*

These resistors are furnished with power ratings from 1 watt through 15 watts, in tolerances of ±5 and ±10 percent, and in resistance values from 0.1 ohm to 30 000 ohms in the preferred-value series of Table 2. They may be color coded as described in Fig. 2, but band A will be twice the width of the other bands. They may also be typographically marked in accordance with the EIA Standard.

The stability of these resistors is somewhat better than that of composition resistors, and they may be preferred except where a noninductive resistor is required.

EIA Precision Resistors†

These resistors are furnished in ±1.0-, ±0.5-, ±0.25-, ±0.1-, and ±0.05-percent tolerances and in any value from 1.0 ohm to 1.0 megohm in the preferred-value series of Table 2. Power ratings range from 0.1 watt to 0.5 watt. The maximum ambient temperature for full wattage rating is 125 °C. If the resistor is mounted in a confined area or may be required to operate in higher ambient temperatures (145 °C maximum), the allowable dissipation must be reduced in accordance with the EIA Standard.

* EIA Standard RS-344.
† EIA Standard RS-229-A.

TABLE 9. STANDARD RATINGS FOR COMPOSITION RESISTORS

Watts	Working Volts (Maximum)	Hot-Spot Temperature (°C)(Maximum)	Critical Resistance (Megohms)	Voltage Coefficient* (%/Volt) (Maximum)
⅛	150	150	0.22	0.05
¼	250	130	0.25	0.035
½	350	130	0.25	0.035
1	500	130	0.25	0.02
2	500	130	0.12	0.02

* Applicable only to resistors of 1000 ohms and over.

These resistors have an inherently low noise level, approaching the thermal agitation level, and their stability is excellent—the typical change in resistance for the lifetime of the resistor will not exceed 50 percent of the initial resistance tolerance when used within the specified design limits of the EIA Standard.

The temperature coefficient of resistance over the range −55 °C to +145 °C, referred to 25 °C, may have maximums as follows:

Value	EIA Standard
Above 10 ohms	±0.002%/°C
5 ohms to 10 ohms	±0.006%/°C
Below 5 ohms	±0.010%/°C

Where required, temperature coefficients of less than ±20 ppm/°C can be obtained by special selection of the resistance wire. Temperature coefficients of ±10 ppm/°C may be obtained by limiting the range of temperatures for testing from −40 °C to +105 °C. The application of temperature coefficient to resistors should be limited, where possible, to the actual temperatures at which the equipment will operate.

EIA Power Resistors*

These resistors are furnished in 3 styles (strip; tubular, open end; and axial lead) and 24 power ratings ranging from 1 watt to 210 watts in tolerances of ±1.0 percent and ±5 percent. Resistance values range from 1.0 ohm to 182 kilohms in the preferred-value series of Table 2.

Axial-lead types are available in two general inductance classifications—inductive winding and noninductive winding. The noninductive styles have a maximum resistance value of ½ the maximum resistance of inductive styles because of the special manner in which they are wound. The inductance of noninductive styles must not exceed 0.5 microhenry when measured at a test frequency of 1.0 megahertz ±5%. However, these resistors should not be used in very-high-frequency circuits where the inductance may affect circuit operation.

The maximum ambient temperature for full wattage rating for these resistors is 25 °C. When the resistors are operated at ambient temperatures above 25 °C, the wattage dissipation must be reduced in accordance with the EIA Standard.

* EIA Standard RS-155-B.

RESISTORS—FIXED FILM

Film-type resistors use a thin layer of resistive material deposited on an insulating core. The low-power types are more stable than the usual composition resistors. Except for very high-precision requirements, film-type resistors are a good alternative to accurate wirewound resistors, being both smaller and less expensive and having excellent noise characteristics.

The power types are similar in size and performance to conventional wirewound power resistors. While their 200 °C maximum operating temperature limits the

TABLE 10. TEMPERATURE COEFFICIENT OF RESISTANCE FOR COMPOSITION RESISTORS

	Characteristic*	Percent Maximum Allowable Change from Resistance at 25 Degrees Celsius†

* Resistance-temperature.

† Up to 1 megohm, data also apply to MIL Established Reliability characteristic *G* (= former *GF*).

power rating, the maximum resistance value available for a given physical size is much higher than that of the corresponding wirewound resistor.

Construction

For low resistance values, a continuous film is applied to the core, a range of values being obtained by varying the film thickness. Higher resistances are achieved by the use of a spiral pattern, a coarse spiral for intermediate values and a fine spiral for high resistance. Thus, the inductance is greater in high values, but it is likely to be far less than in wirewound resistors. Special high-frequency units having greatly reduced inductance are available.

Resistive Films

Resistive-material films presently used are microcrystalline carbon, boron-carbon, and various metallic oxides or precious metals.

Deposited-carbon resistors have a negative temperature coefficient of 0.01 to 0.05 percent/°C for low resistance values and somewhat larger for higher values. Cumulative permanent resistance changes of 1 to 5 percent may result from soldering, overload, low-temperature exposure, and aging. Additional changes up to 5 percent are possible from moisture penetration and temperature cycling.

The introduction of a small percentage of boron into the deposited-carbon film results in a more stable unit. A negative temperature coefficient of 0.005 to 0.02 percent/°C is typical. Similarly, a metallic dispersion in the carbon film provides a negative coefficient of 0.015 to 0.03 percent/°C. In other respects, these materials are similar to standard deposited carbon. Carbon and boron-carbon resistive elements have the highest random noise of the film-type resistors.

Metallic-oxide and precious-metal-alloy films permit higher operating temperatures. Their noise characteristics are excellent. Temperature coeficients are predominantly positive, varying from 0.03 to as little as 0.0025 percent/°C.

Applications

Power ratings of film resistors are based on continuous direct-current operation or on root-mean-square operation. Power derating is necessary for operation at ambient temperatures above the rated temperature. In pulse applications, the power dissipated during each pulse and the pulse duration are more significant than average power conditions. Short high-power pulses may cause instantaneous local heating sufficient to alter or destroy the film. Excessive peak voltages may result in flashover between turns of the film element. Derating under these conditions must be determined experimentally.

Film resistors are fairly stable up to about 10 megahertz. Because of the extremely thin resistive film, skin effect is small. At frequencies above 10 megahertz, it is advisable to use only unspiraled units if inductive effects are to be minimized (these are available in low resistance values only).

Under extreme exposure, deposited-carbon resistors deteriorate rapidly unless the element is protected. Encapsulated or hermetically sealed units are preferred for such applications. Open-circuiting in storage as the result of corrosion under the end caps has been reported in all types of film resistors. Silver-plated caps and core ends effectively overcome this problem.

Technical Characteristics

Some technical characteristics of film resistors are given in Tables 11, 12, and 13.

The MIL "RN" series of film resistors is more stable than the "RL" series and is available in a wider range of ratings. Commercial equivalents are also offered. Where stability and reliability are desired, the "RN" series is economically very competitive with the "RC" or "RL" series.

RESISTORS—ADJUSTABLE

Adjustable resistors may be divided into three separate and distinct categories, potentiometers, trimmers, and rheostats.

Potentiometers are control devices that are used where the frequency of adjustment is high. They may be operated manually by human effort or mechanically served by machine. Potentiometers are designed with a long mechanical life in view, generally from 10 000 to 100 000 cycles, with certain types having life capabilities in the millions of cycles. A cycle, or excursion, consists of wiper traverse from one limit of travel to the other limit and back.

Trimmers differ from potentiometers in that they are designed to be adjusted infrequently, sometimes only once, and normally exhibit greater setting stability once

TABLE 11. STABLE EQUIVALENTS FOR COMPOSITION RESISTORS; AXIAL LEADS; DATA FOR MIL "RL" SERIES

Watts	¼	½	1	2
Voltage rating	250	350	500	500

Resistance Values: E96 series (E48 preferred): 1% tolerance;
E192 series (E96 preferred): 0.5%, 0.25%, 0.1% tolerances.

*Uninsulated commercial versions have lower temperature limits and greater resistance change. Color coding is the same as previously indicated for composition resistors.

set. Their employment eliminates the use of expensive precision related components and provides an easily retunable vehicle to compensate for drift or aging in related parts. Normal life designs are rated at approximately 200 excursions. Some typical trimmer characteristics are listed in Table 14.

Unlike potentiometers and trimmers, whose primary function is to control voltage, the rheostat is basically a current-controlling device. Rheostats are made in much the same manner as potentiometers and trimmers, but with more attention paid to wiper current-carrying ability and generally higher power ratings. Some rheostats are wirewound tubular ceramic power resistors with a track of exposed wire to allow for the adjustable feature. The wiper is in the form of a dimpled clamp band that is screw-tightened at the desired setting. Due to the heat generated by these units, care should be exercised in the circuit location.

Wattage ratings of adjustable resistors apply only when all the resistance is in the circuit. To avoid

overloading any section, never exceed the maximum rated current based on total resistance.

Types of Adjustable Resistors

Wirewound Resistors—Wirewound resistor elements are made by winding a very fine resistance wire precisely around a mandrel. Most resistance wire is made from a nickel-chrome alloy with other elemental additives to enhance its electrical characteristics.

Wirewound adjustable resistors exhibit superior independent linearity characteristics, and it is for this reason that they are frequently specified for direct motion controls. Precision wirewounds are available with independent linearity ratings as low as 0.1%. They are very stable over a wide range of operating temperatures. Panel controls and precision potentiometers are recommended for normal operating temperature ranges from −65° to + 125 °C, and most trimmers will perform satisfactorily from −55° to + 150 °C. Temperature coefficients of resistance as low as ±20 ppm/°C are available.

Wirewound elements, with rare exceptions, change value in steps as the wiper traverses each individual winding. Resolution may be improved by using multiturn adjustable resistors. This type of construction increases the winding length and decreases incremental resistance steps from one winding to the next.

Wirewound resistive elements are usually not suitable for frequency-sensitive RF circuits because of inductive and capacitive effects. They are impractical above a resistance value determined by the winding space available and the smallest resistance wire that can be space-wound. If infinite resolution is required, then a cermet or composition element must be substituted.

Cermet-Element Resistors—Cermets are a mixture of fine metal-oxide or precious-metal particles and glass in a viscous organic vehicle. This paste is screened onto a ceramic substrate and fired at vitrifying temperatures.

Cermet adjustable resistors are designed for low to moderate adjustment life. They feature infinite resolution and are generally available having temperature coefficients of resistance of ±100 ppm/°C. Sheet resistivities* are available from one ohm per square (1 Ω/□) to one megohm per square (1 MΩ/□). Ultimate resistance values are limited by substrate geometry.**

Carbon Composition Resistors—A mixture of carbon powders and a binder is molded under heat and pressure into a solid mass. In some constructions, the carbon composition is molded at the same time as the plastic substrate. This process is called comolding.

Carbon composition adjustable resistors are the least expensive and most common type of potentiometer for general electronics use. Their low noise makes them ideal for use in live audio controls.

In addition to a linear rotation-vs-resistance characteristic, composition elements can have a wide range of nonlinear output curves. Standard logarithmic curves (tapers) are used as volume controls for radio, TV, etc.

Temporary resistance changes up to ±10% can be expected when these devices are operated near the extreme limits of a temperature range of −55 °C to +120 °C. Their use is not recommended for precision controls or in varying hostile environments.

Conductive Plastic—Conductive plastic is an ink formulated from carbon, other proprietary materials, a resin, and solvent. It is applied to a substrate by screening, dipping, or comolding. The low curing temperature (150 to 300 °C) of the ink allows it to be applied to a wide variety of substrates.

Conductive-plastic potentiometers are most notable for their high rotational life, and they are used most frequently as machine-operated servo-controls. Another desirable feature is their low noise or output smoothness.

Resistance ranges in sheet resistivities of up to 50 000 Ω/□ are available with temperature coefficients of ±500 ppm/°C. As with cermets, ultimate resistance values are limited by substrate geometry.

---

* Sheet resistivity (Ω/□) is the resistance of a square sheet of material. It is independent of the units of length used because the resistance increases with length but decreases with width.

** For material of given volume resistivity ρ (ohm-meter), sheet resistivity given by ρ/d will increase as depth d is decreased.

Terminal Identification

Industry standards have been developed for identification of potentiometer terminals. Most potentiometer terminals are either numbered or color coded as follows:

1	Yellow	Always the counterclockwise element limit.
2	Red	Wiper (or collector).
3	Green	Always the clockwise element limit.

For rotary potentiometers, clockwise is always defined by viewing from the specified mounting end of the potentiometer.

Mounting Characteristics

Potentiometers usually must be accessible from the outside of a product, and they are often mounted on a panel by means of a threaded bushing. Most precision potentiometers are manufactured with both bushing and servo-mount options. Servo-mount units are secured by servo clamps to assure precise shaft alignment.

Trimmers are usually not accessible from outside the instrument. Most are circuit-board mounted by their terminals and are small in size to conserve space.

CAPACITORS—DEFINITIONS

Dielectric: A dielectric is a medium that can withstand high electric stress without appreciable conduction. When such stress is applied, energy in the form of an electric charge is held by the dielectric. Most of this stored energy is recovered when the stress is removed. The only perfect dielectric in which no conduction occurs and from which the whole of the stored energy may be recovered is a perfect vacuum.

Relative Capacitivity: The relative capacitivity or relative permittivity or dielectric constant is the ratio by which the capacitance is increased when another dielectric replaces a vacuum between two electrodes.

Dielectric Absorption: Dielectric absorption is the absorption of charge by a dielectric when subjected to an electric field by other than normal polarization. This charge is not recovered instantaneously when the capacitor is short-circuited, and a decay current will continue for many minutes. If the capacitor is short-circuited momentarily, a new voltage will build up across the terminals afterward. This is the source of some danger with high-voltage dc capacitors or with ac capacitors not fitted with a discharge resistor. The phenomenon may be used as a measure of dielectric absorption.

Tangent of Loss Angle: This is a measure of the energy loss in the capacitor. It is expressed as $\tan\delta$ and is the power loss of the capacitor divided by its reactive power at a sinusoidal voltage of specified frequency. (This term also includes power factor, loss factor, and dielectric loss. The true power factor is $\cos(90 - \delta)$.)

Insulation Resistance: This is a measure of the conduction in the dielectric. Because this conduction takes a very long time to reach a stable value, it is usually measured after 2 minutes of electrification for nonelectrolytic types and 3 minutes for electrolytics. It is measured preferably at the rated working voltage or at a standardized voltage.

The insulation resistance is usually multiplied by the capacitance to give the ohm-farad value, which is the apparent discharge time constant (seconds). This is a figure of merit for the dielectric, although for small capacitances a maximum value of insulation resistance is usually also specified.

In electrolytics, the conduction is expressed as leakage current at rated working voltage. It is calculated as $\mu A/\mu FV$, which is the reciprocal of the ohm-farad value. In this case, a maximum value of leakage current is specified for small capacitances.

Leakage Current: The current flowing between two or more electrodes by any path other than the interelectrode space is termed the leakage current, and the ratio of this to the test voltage is the insulation resistance.

Impedance: Impedance is the ratio of voltage to current at a specified frequency. At high frequencies, the inductance of leads becomes a limiting factor, in which case a transfer impedance method may be employed. This then measures the impedance of the shunt path only.

DC or AC Capacitor: A dc capacitor is designed to operate on direct current only. It is normally not suitable for use above 200 volts ac because of the occurrence of discharges in internal gas bubbles (corona). An ac capacitor is designed to have freedom from internal discharges and low tangent of loss angle to minimize internal heating.

Rated Voltage and Temperature: The rated voltage is the direct operating voltage that may be applied continuously to a capacitor at the rated temperature.

Category Voltage and Temperature: The category voltage is the voltage that may be applied to the capacitor at the maximum category temperature. It differs from the rated voltage by a derating factor.

Ripple Voltage: If alternating voltages are present in addition to direct voltage, the working voltage of the capacitor is taken as the sum of the direct voltage and the peak alternating voltages. This sum must not exceed the value of the rated voltage.

In electrolytics, the permissible ripple may be expressed as a rated ripple current.

Surge Voltage: This is a voltage above the rated voltage which the capacitor will withstand for a short time.

Voltage Proof Test (Dielectric Strength): This is the highest possible voltage that may be applied without breakdown to a capacitor during qualification approval

testing to prove the dielectric. The repeated application of this voltage may cause failure.

Forming Voltage (Electrolytics): The voltage at which the anodic oxide has been formed. The thickness of the oxide layer is proportional to this voltage.

Burnout Voltage (Metallized Types): The voltage at which metallized types burn out during manufacture.

Self-Healing (Metallized Types): A momentary partial discharge of a capacitor resulting from a localized failure of the dielectric. Burning away the metallized electrodes isolates the fault and effectively restores the properties of the capacitor. The self-healing action is also called "clearing."

Equivalent Series Resistance (ESR): Equivalent series resistance (ESR) is a single resistive value that represents the sum of the ac losses (due to the leads, electrode plates, and junction terminations), the resistive losses due to leakage currents, and the resistive losses due to the inherent molecular polarization dielectric absorption factors of the base dielectric material.

Volt-Ampere Rating (VA): This is the reactive power in a capacitor when an ac voltage is applied. VA $\cos\theta$ gives the amount of heat generated in the capacitor. Since the amount of heat that can be dissipated is limited, the VA must also be limited and in some cases a VA rating is quoted. (Note that $\cos\theta = \cos(90 - \delta) \approx \tan\delta$, when δ is small.)

Scintillation: Minute and rapid fluctuations of capacitance formerly exhibited by silvered mica or silvered ceramic types but overcome by modern manufacturing techniques.

Corona Discharge: Partial discharge of a capacitor due to ionization of the gas in a bubble in the dielectric. On ac or pulse operation, this may occur in dielectric stressed above 200 volts and is a major cause of failure. On dc, such discharges are very infrequent and normally are not a cause of failure.

CLASSES OF CAPACITORS

Modern electronic circuits require the smallest possible capacitors, which are usually made with the thinnest possible dielectric material since they are for operation at low voltages. There are three broad classes of capacitors.

(A) Low-loss capacitors with good capacitance stability. These are usually of mica, glass, ceramic, or a low-loss plastic such as polypropylene or polystyrene.

(B) Capacitors of medium loss and medium stability, usually required to operate over a fairly wide range of ac and dc voltages. This need is met by paper, plastic film, or high-K ceramic types. The first two of these may have electrodes of metal foil or electrodes of evaporated metal which have a self-healing characteristic.

(C) Capacitors of the highest possible capacitance per unit volume. These are the electrolytics, which are normally made either of aluminum or tantalum. Both of these metals form extremely thin anodic oxide layers of high dielectric constant and good electrical characteristics. Contact with this oxide layer is normally by means of a liquid electrolyte that has a marked influence on the characteristics of the capacitor. In solid tantalum, the function of the electrolyte is performed by a manganese-dioxide semiconductor.

PLASTIC FILM CAPACITORS

Advances in organic chemistry have made it possible to produce materials of high molecular weight. These are formed by joining together a number of basic elements (monomers) to produce a polymer. Some of these have excellent dielectric characteristics.

Physically, they can be classified as thermoplastic or thermosetting. In the former case, the molecule consists of long chains with little or no branching, whereas in the latter the molecules are crosslinked. Thermosetting materials have no clearly defined melting point and are usually hard and brittle, making them unsuitable for the manufacture of plastic films. A cast film is usually amorphous, but by extrusion, stretching, and heat treatment, oriented crystalline films are produced with good flexibility and dielectric characteristics.

The electrical properties of the plastics depend on the structure of the molecule. If the molecule is not symmetrical, it will have a dipole moment giving increased dielectric constant. On the other hand, the dielectric constant and $\tan\delta$ are then dependent on frequency. Generally speaking, nonpolar materials have electrical characteristics that are independent of frequency, while polar materials exhibit a decrease in capacitance with increasing frequency, and $\tan\delta$ may pass through a maximum in the frequency range.

Figs. 7, 8, and 9 show some characteristics of several types of capacitors. At the present time, two classes of plastic film capacitors are recognized.

(A) *Polystyrene and Polypropylene Capacitors.* Polystyrene and polypropylene are nonpolar plastics that have excellent electrical characteristics which are independent of frequency.

(B) *Polyester Films.* Strictly speaking, these are the polyethylene terephthalates (Mylar, Melinex, Hostaphan), but the polycarbonates are now included in this group because they have similar electrical characteristics.

Plastic films for capacitor manufacture are usually of the oriented crystalline type because of their good combinations of characteristics. One important feature of some of these films is that they tend to shrink back to their original shape after being heated. This fact is sometimes exploited in manufacturing the capacitor.

Moisture usually has little effect on the dielectric properties of plastic films, and capacitors made from them require less protection than paper or mica types.

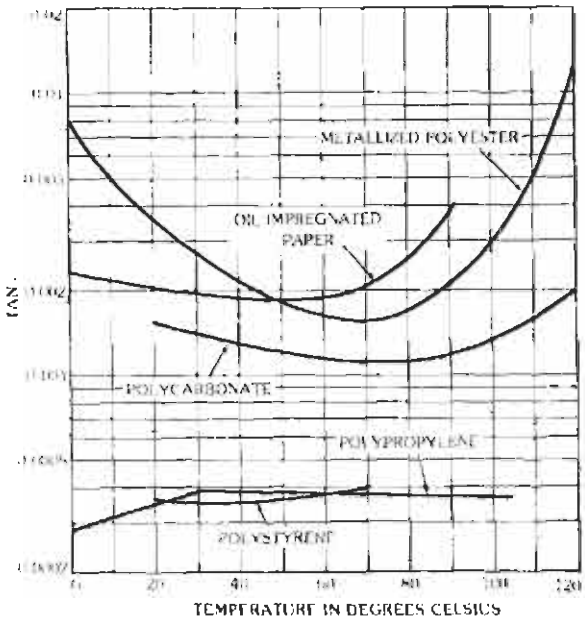

Fig. 7. Variation of tanδ with temperature for various plastic films compared with oil-impregnated paper.

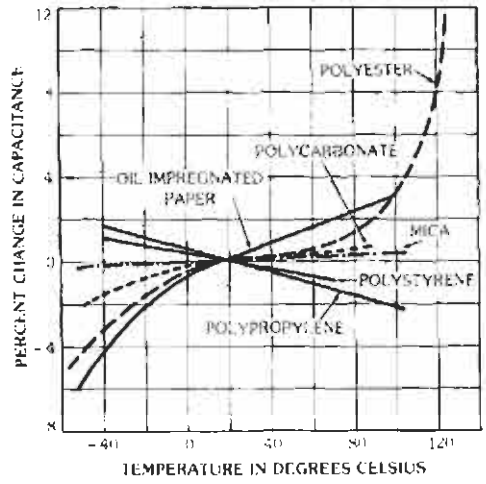

Fig. 8. Typical capacitance characteristics of various capacitors as a function of temperature. Measured on 0.1-microfarad capacitors at 1000 hertz.

This, together with simple processing, has permitted them to be mass-produced at relatively low cost.

The electrical characteristics of capacitors made with these materials depend on the construction employed. The resistance of metallized electrodes and the shape and method of connection to the unit are particularly important.

Many plastic materials are being used in the manufacture of capacitors for which there are no internationally agreed specifications. In this case, it is necessary to obtain the relevant data from the manufacturer. There is no doubt that in the future the range of plastic film capacitors will be considerably extended.

Polystyrene Film Capacitors With Foil Electrodes

Polystyrene has excellent electrical characteristics. The film employed is of the oriented crystalline type, which makes it flexible and suitable for forming into thin films. On heat treatment, the film shrinks considerably, and this is used in the manufacturing process to obtain capacitance stability. The film is affected by greases and solvents, and care must be taken both in manufacture and in use to ensure that capacitors do not come into contact with these materials.

The power factor of polystyrene is low over the whole frequency range, but the resistance of the electrodes may result in an increase of power factor at high frequencies in the larger values, as shown in Table 15.

Polyester Film Capacitors With Foil Electrodes

The generic title "polyester" is usually used to apply to polyethylene terephthalate. It is a slightly polar plastic film suitable for operation up to temperatures of 125 °C. Capacitors are available with foil electrodes.

Plastic Film Capacitors With Metallized Electrodes

Plastic film capacitors with metallized electrodes have superseded metallized paper capacitors in dc applications because of superior electrical characteristics, less tendency for self-healing to occur during service, higher and more stable insulation resistance, and approximately the same space factors. Three types of film are generally used, polyethylene terephthalate, polycarbonate, and polypropylene. For some purposes these are comparable, but polypropylene has a lower loss angle, and polycarbonate has a smaller change of capacitance with temperature. Polyester and polycarbonate are also available in thinner films, giving an advantage of space factor.

ELECTROLYTIC CAPACITORS

Electrolytic capacitors (Fig. 10) employ for at least one of their electrodes a "valve metal." This metal, when operated in an electrolytic cell as the anode, forms a layer of dielectric oxide. The most commonly used metals are aluminum and tantalum. The valve-metal behavior of these metals was known about 1850. Tantalum electrolytic capacitors were introduced in the

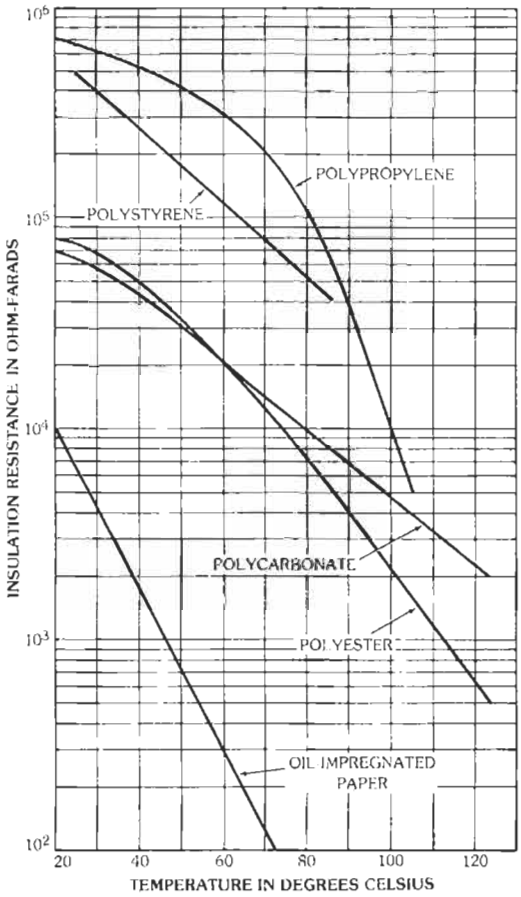

Fig. 9. Variation of insulation resistance with temperature for various plastic films compared with the resistance variation for oil-impregnated paper.

1950s because of the need for highly reliable miniature capacitors in transistor circuits over a wide temperature range. These capacitors were made possible by improved refining and powder metallurgy techniques.

The term "electrolytic capacitor" is applied to any capacitor in which the dielectric layer is formed by an electrolytic method. The capacitor does not necessarily contain an electrolyte.

The oxide layer is formed by placing the metal in a bath containing a suitable forming electrolyte, and applying voltage between the metal as anode and another electrode as cathode. The oxide grows at a rate determined by the current, but this rate of growth decreases until the oxide has reached a limiting thickness determined by the voltage. For most practical purposes, it may be assumed that the thickness of the oxide is proportional to the forming voltage.

Properties of aluminum and tantalum and their oxides are shown in Table 16.

The structure of these oxide layers plays an important part in determining their performance. Ideally they are

TABLE 15. POWER FACTOR OF POLYSTYRENE AT VARIOUS FREQUENCIES

	Nominal Capacitance (pF)			
Frequency (hertz)	Up to 1 000	1 000 to 10 000	10 000 to 100 000	Above 100 000
800	0.0003	0.0003	0.0003	0.0003
10 000	0.0003	0.0003	0.0003	0.001
100 000	0.0003	0.0005	0.001–0.003	—
1 000 000	0.001	0.002	0.005–0.02	—

amorphous, but aluminum tends to form two distinct layers, the outer one being porous. Tantalum normally forms an amorphous oxide which, under conditions of a high field strength of the oxide layer, may become crystalline. Depending on the forming electrolyte and the surface condition of the metal, there is an upper limit of voltage beyond which the oxide breaks down. The working voltage is between 25 and 90 percent (according to type) of the forming voltage at which stable operation of the oxide layer can be obtained.

To produce a capacitor, it is necessary to make contact to the oxide layer on the anode, and there are two distinct methods of doing this. The first is to use a working electrolyte that has sufficient conductivity over the temperature range to give a good power factor. There are many considerations in choosing the working electrolyte, and the choice is usually a compromise between high- and low-temperature performance. The working electrolyte also provides a rehealing feature in

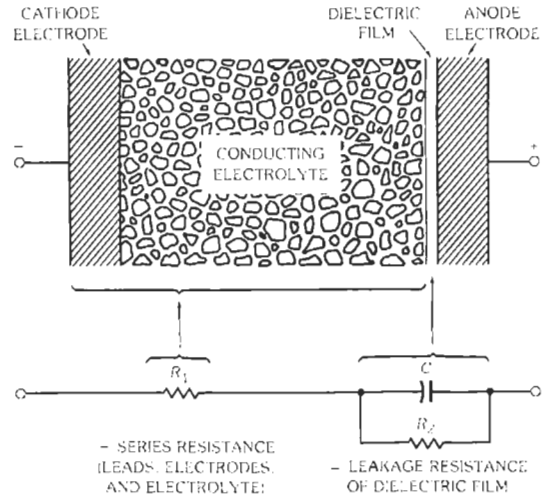

Fig. 10. Basic cell and simplified equivalent circuit for polar electrolytic capacitor.

TABLE 16. ALUMINUM AND TANTALUM PROPERTIES

Metal	Density	Principal Oxide	Dielectric Constant	Thickness (Å/V)
Aluminum	2.7	Al_2O_3	8	13.5
Tantalum	16.6	Ta_2O_5	27.6	17

that any faults in the oxide layer will be repaired by further anodization.

In aluminum electrolytic capacitors, the working electrolyte must be restricted to those materials in which aluminum and its oxide are inert. Corrosion can be minimized by using the highest possible purity of aluminum. This also reduces the tendency of the oxide layer to dissolve in the electrolyte, giving a better shelf life.

Tantalum, on the other hand, is very inert and therefore allows a wider choice of electrolyte. Since there is no gas evolution, better methods of sealing can be employed. The characteristics of aluminum and tantalum electrolytic capacitors are shown in Figs. 11 and 12.

A major problem with all electrolytic capacitors is to ensure that the electrolyte is retained within the case under all operating conditions. In the aluminum capacitor, allowance must be made for gas evolution on reforming. Even the tantalum capacitor usually must employ only organic materials for sealing, and these do not provide completely hermetic sealing. All organic materials have finite moisture transmission properties, and, therefore, at the maximum category temperature the high vapor pressure of the electrolyte results in some diffusion.

An elegant solution to this problem, using a semiconductor instead of an electrolyte, was found by Bell Telephone Laboratories. The semiconductor is manganese dioxide in a polycrystalline form and has a higher conductivity than conventional electrolyte systems. This material also provides a limited self-healing feature at a fault, resulting in oxidation of the tantalum and reduction of the manganese dioxide to a nonconducting form.

Electrolytic capacitors take many forms, and the anode may be of foil, wire, or a porous sintered body. The foil may be either plain or etched. The porous body may be made with fine or with coarse particles, and the body itself may be short and fat or long and thin. The aluminum-foil capacitor has a space factor about six times better than that of the equivalent paper capacitor, whereas tantalum capacitors are even smaller and enjoy a space factor up to 20 times better.

When electrolytic capacitors are operated in series-parallel, stabilizing resistors should be used to equalize the voltage distribution. It should also be noted that, even when the case is not connected to one terminal, a low resistance path exists between it and the electrodes. The case must be insulated from the chassis, particularly if the chassis and the negative terminal are not at the same potential.

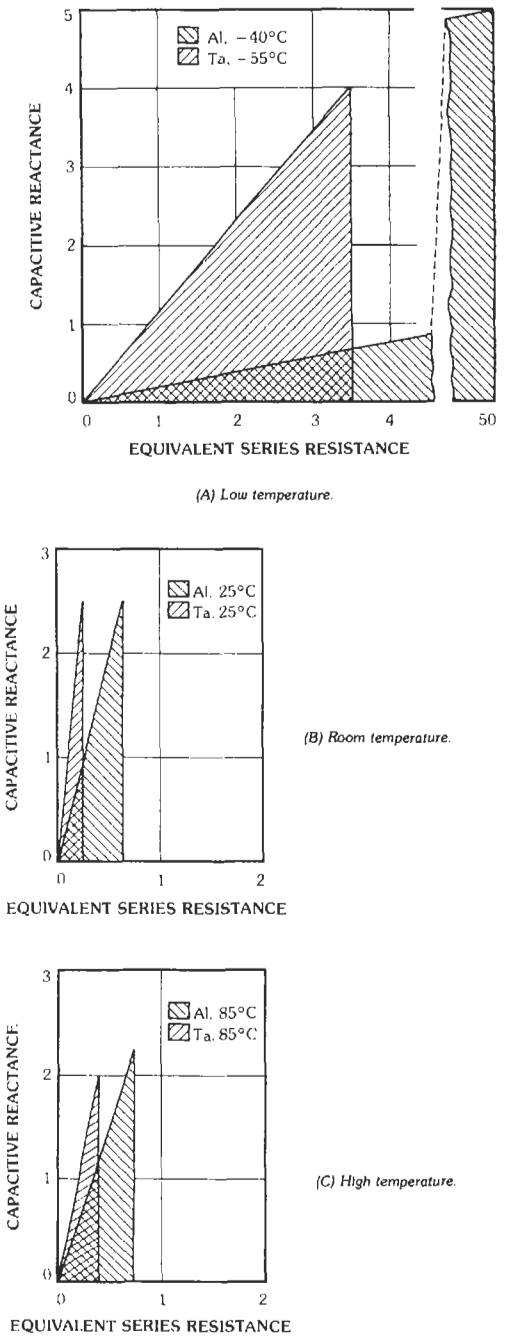

Fig. 11. Typical 120-hertz impedance diagrams for aluminum (Al) and tantalum (Ta) plain-foil polar electrolytic capacitors of 150-volt rating.

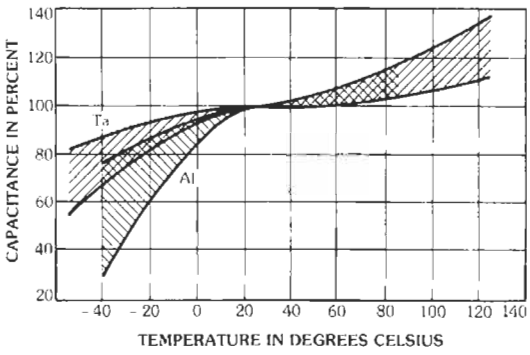
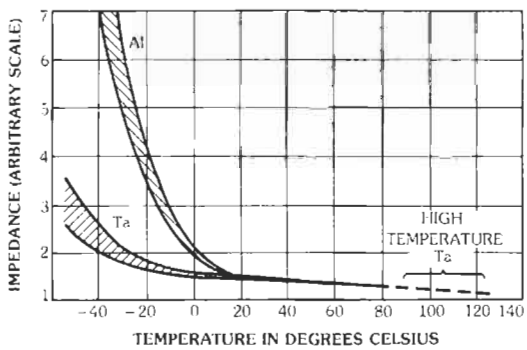
Aluminum Electrolytics

The aluminum type is the most widely known electrolytic capacitor and is used extensively in radio and television equipment. It has a space factor about six times better than the equivalent paper capacitor. Types



(A) Capacitance.



(B) Impedance.

Fig. 12. Capacitance and 120-hertz impedance as a function of temperature for aluminum (Al) and tantalum (Ta) electrolytic capacitors.

of improved reliability are now available using high-purity (better than 99.99%) aluminum.

Conventional aluminum electrolytic capacitors which have gone six months or more without voltage applied may need to be reformed. Rated voltage is applied from a dc source with an internal resistance of 1500 ohms for capacitors with a rated voltage exceeding 100 volts, or 150 ohms for capacitors with a rated voltage equal to or less than 100 volts. The voltage must be applied for one hour after reaching rated value with a tolerance of ±3 percent. The capacitor is then discharged through a resistor of 1 ohm/volt.

Tantalum-Foil Electrolytics

The tantalum-foil type of capacitor was introduced around 1950 to provide a more reliable type of electrolytic capacitor without shelf-life limitation. It was made possible by the availability of thin, high-purity annealed tantalum foils and wires. Plain-foil types were introduced first, followed by etched types. The purity, and particularly the surface purity, of these materials plays a major part in determining the leakage current and their ability to operate at the higher working voltages.

These capacitors are smaller than their aluminum counterparts and will operate at temperatures up to about 125 °C (Figs. 13–15). The plain-foil types usually exhibit less variation of capacitance with temperature or frequency.

Tantalum Electrolytics With Porous Anode and Liquid Electrolyte

The tantalum electrolytic with porous anode and liquid electrolyte was the first type of tantalum electrolytic capacitor to be introduced and still has the best space factor. Types using sulphuric-acid electrolyte have excellent electrical characteristics up to about 70 working volts. Other types contain neutral electrolytes.

Basically, this type of capacitor consists of a sintered porous anode of tantalum powder housed in a silver or silver-plated container. The porous anode is made by pressing a high-purity tantalum power into a cylindrical body and sintering in vacuum at about 2000 °C.

Tantalum Electrolytics With Porous Anode and Solid Electrolyte

The so-called "solid" tantalum capacitor originally developed by Bell Telephone Laboratories developed from the porous-anode type with liquid electrolyte by replacing the liquid with a semiconductor. This overcame the problem of sealing common to all other types of electrolytic capacitors. Since there is no liquid electrolyte, it is possible to use a conventional hermetic seal.

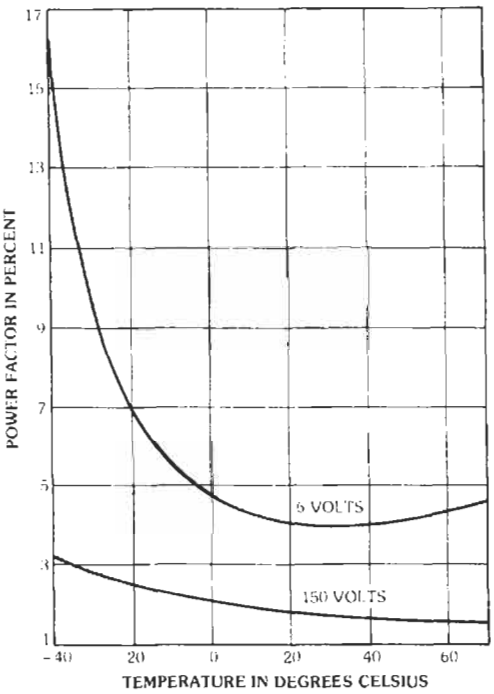

Fig. 14. Variation of power factor with temperature for plain tantalum-foil electrolytic capacitors.

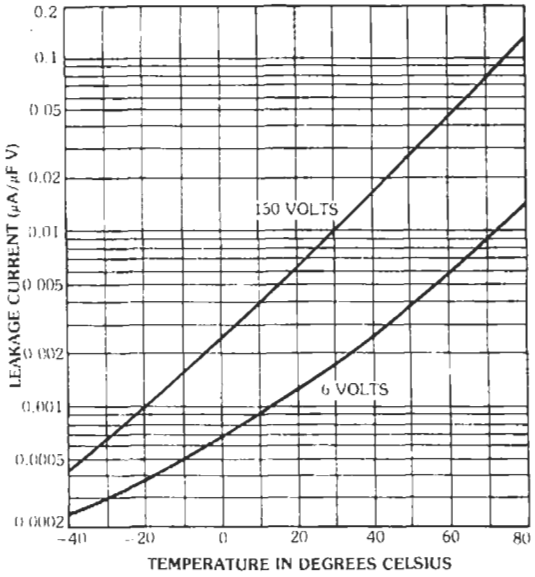

Fig. 15. Variation of leakage current with temperature for plain tantalum-foil electrolytic capacitors.

CERAMIC CAPACITORS

Ceramic capacitors are defined in classes based on their distinct and inherent electrical properties.

Class I

Class I capacitors are stable temperature-compensating capacitors that have essentially linear characteristics with properties independent of frequency over the normal range. Materials are usually magnesium titanate for positive temperature coefficient of capacitance and calcium titanate for negative temperature coefficient of capacitance. Combinations of these and other materials produce a dielectric constant of 5 to 150 and temperature coefficient of capacitance of +150 to −4700 ppm/°C with tolerances of ±15 ppm/°C.

Low-K ceramics are suitable for resonant-circuit or filter applications, particularly where temperature compensation is a requirement. Disc and tubular types are the best forms for this purpose. Stability of capacitance is good, being next to that of mica and polystyrene capacitors.

Class II

Class II includes ceramic dielectrics suitable for fixed capacitors used for bypass, coupling, and decoupling. This class is usually divided into two subgroups for which the temperature characteristics define the characteristics.

(A) Embody stable K values of 250 to 2400 over a temperature range of −55 °C to +125 °C with maximum capacitance change 15% from a 25 °C ambient.

(B) Embody combinations of materials, including titanates, with K values of 3000 to 12 000 made by keeping the Curie point near room ambient.

The high-K materials are the ferroelectrics. Because of their crystal structure, they sometimes have very high values of internal polarization, giving very high effective dielectric constants. In this way, these materials are comparable with ferromagnetic materials. Above the Curie temperature, a change of domain structure occurs that results in a change of electrical characteristics. This region is known as the paraelectric region. In common with the ferromagnetic materials, a hysteresis effect is apparent, and this makes the capacitance voltage-dependent.

The ferroelectrics are based on barium titanate, which has a peak dielectric constant of 6000 at the Curie point of 120 °C. Additions of barium stanate, barium zirconate, or magnesium titanate reduce this dielectric constant but make it more uniform over the temperature range. Thus a family of materials can be obtained with a Curie point at about room temperature and with the dielectric constant falling off on either side. The magnitude of this change increases with increasing dielectric constant. These materials exhibit a decrease of capacitance with time and, as a result of the hysteresis effect, with increasing voltage.

Inductance in the leads and element causes parallel resonance in the megahertz region. Care is necessary in

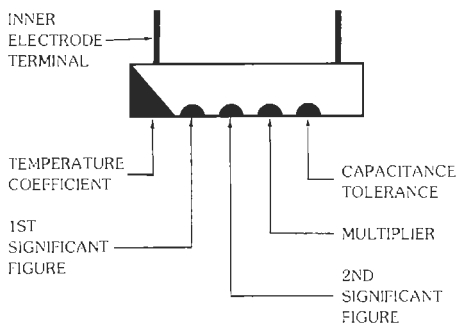
their application above about 50 megahertz for tubular styles and about 500 megahertz for disc types.

Class III

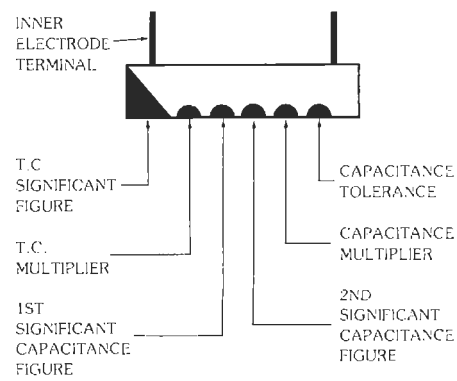
Class III includes reduced barium titanate in which a reoxidized layer or diffusion zone is the effective dielectric. Also included are internal grain boundary layer strontium titanate capacitors in which an internal insulating layer surrounds each grain. These capacitors are suitable for use in low-voltage circuits for coupling and bypass where low insulation resistance and voltage coefficient can be tolerated.

Color Code

The significance of the various colored dots for EIA Standard RS-198-B (ANSI C83.4-1972) fixed ceramic dielectric capacitors is explained by Figs. 16 and 17 and may be interpreted from Table 17.



(A) Five-dot system.



(B) Six-dot system.

Fig. 16. Color coding of EIA Class-I ceramic dielectric capacitors. See Table 17 for color code. Tubular style shown to illustrate identification of inner electrode. For disc or plate styles, color code will read from left to right as observed with lead wires downward.

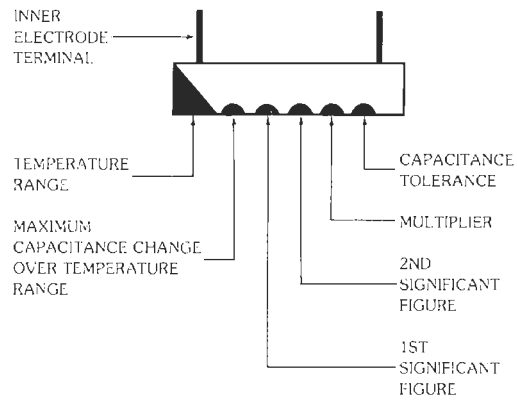


Fig. 17. Color coding of EIA Class-II ceramic dielectric capacitors. See Table 17 for color code. Tubular style shown to illustrate identification of inner electrode. For disc or plate styles, color code will read from left to right as observed with lead wires downward.

Temperature Coefficient

Standard temperature coefficients of capacitance expressed in parts per million per degree Celsius are: +150, +100, +33, 0, −33, −75, −150, −220, −330, −470, −750, −1500, −2200, −3300, and −4700.

PAPER FOIL-TYPE CAPACITORS

In general, paper capacitors have been largely replaced by plastic film capacitors in both foil and metallized constructions and in most dc electronic circuits. Impregnated paper capacitors for ac power applications are also being replaced with plastic film capacitors with both impregnated and dry constructions.

Construction usually consists of multiple layers of paper as the dielectric interleaved with aluminum or tin alloy foil electrodes. Termination is either tabs inserted during winding or leads welded to extended foils.

Paper capacitors are impregnated with stabilized waxes or oils. Most chlorinated materials, such as chlorinated diphenyls, have been banned by the EPA as impregnants. The impregnant usually has a dielectric constant of about 6 and is used for size reduction and improvement in corona start and to reduce internal discharge in ac power applications.

Included among dc applications are coupling, decoupling, bypass, smoothing filters, power-separating filters, energy-storage capacitors, etc. Included among ac applications are motor start, fluorescent lighting, interference suppression, power-factor correction, power-line coupling, distribution capacitors for high-voltage switching gear, capacitor voltage dividers for ac measurement, etc.

TABLE 17. COLOR CODE FOR CERAMIC DIELECTRIC CAPACITORS, CLASSES I AND II*

			Class I					Class II		
			Capacitance Tolerance		Temperature Coefficient ppm/°C (5-Dot System)	Temperature Coefficient Significant Figure (6-Dot System)	Temperature Coefficient Multiplier (6-Dot System)	Capacitance Tolerance (%)	Temperature Range (°C)	Maximum Capacitance Change Over Temperature Range (%)

* EIA Standard RS-198-B (ANSI C83.4-1972). This standard classifies ceramic dielectric, fixed capacitors as follows:

Class I —Temperature compensating ceramics suited for resonant circuit or other applications where high Q and stability of capacitance characteristics are required.

Class II —Ceramics suited for bypass and coupling applications, or for frequency discriminating circuits where high Q and stability of capacitance characteristics are not of major importance.

Class III—Low-voltage ceramics specifically suited for transistorized or other electronic circuits for bypass, coupling, or frequency determination where dielectric losses, high insulation resistance, and capacitance stability are not of major importance.

Note: Where size permits, EIA Class-III ceramics are typographically marked as follows:

(1) Capacitance value in microfarads. (2) Rated voltage. (3) Manufacturer's mark or EIA source code.

(4) Capacitance value tolerance or appropriate code letter; either ±20% (Code M) or +80, −20% (Code Z).

(5) Temperature stability code (see the EIA or ANSI Standard).

MICA CAPACITORS

Mica capacitors fall within the classification of low loss and good capacitance stability. Mica is one of the earliest dielectric materials used and has an unrivaled combination of physical and electrical characteristics. It is of mineral origin and, because of its monoclinic structure, can be readily split into thin plates. It has a dielectric constant of about 6 (largely independent of frequency) together with a very low loss.

Construction

Mica capacitor constructions of the eyelet, molded, bonded, and button styles have been largely replaced by precision polystyrene, polypropylene, and polyester plastic film capacitors and by ceramic capacitors. The main surviving style is the dipped epoxy-coated radial-leaded capacitor using a clamp-type silvered mica stack with tin electrodes.

Applications

Their low temperature coefficient of capacitance and good stability with temperature and frequency make mica capacitors a good choice for critical precision circuitry such as filter applications.

Type Designation

A comprehensive numbering system, the type designation, is used to identify mica capacitors. Type designations are of the form shown in Fig. 18. MIL specifications now require type designation marking. Color coding is now used only for EIA standard capacitors.

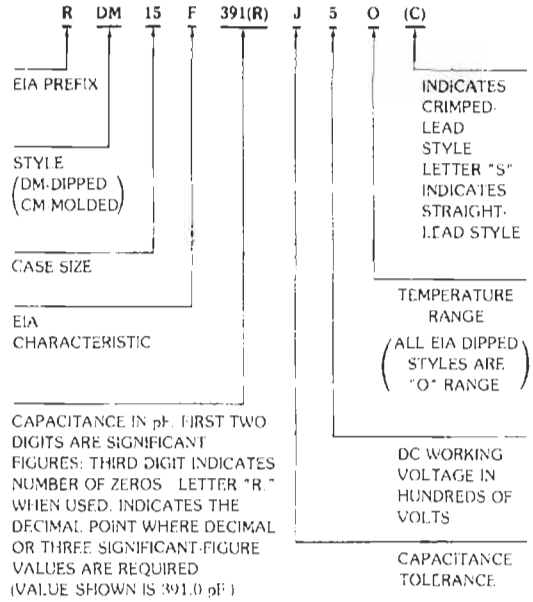
Component Designation—Fixed mica-dielectric capacitors are identified by the symbol CM. For EIA, a prefix letter R is always included, and dipped types are identified by the symbol DM.

Case Designation—The case designation is a two-digit symbol that identifies a particular case size and shape.

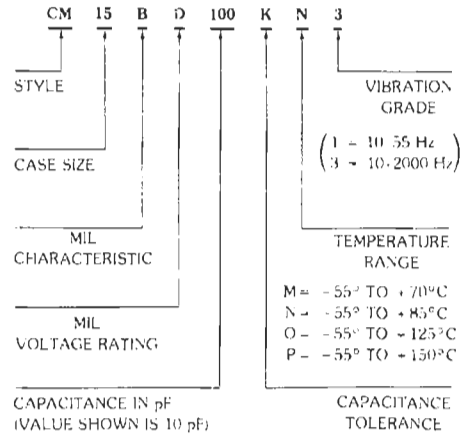
Characteristic—The EIA or MIL characteristic is indicated by a single letter in accordance with Table 18.

Capacitance Value—The nominal capacitance value in picofarads is indicated by a three-digit number. The first two digits are the first two digits of the capacitance value in picofarads. The final digit specifies the number of zeros that follow the first two digits. For EIA, if more than two significant figures are required, an additional digit is used, and the letter "R" is inserted to designate the decimal position.

Capacitance Tolerance—The symmetrical capacitance tolerance in percent is designated by a letter as shown in Table 1.



(A) EIA.



(B) MIL.

Fig. 18. Type designation for mica-dielectric capacitors.

Voltage Rating—MIL voltage ratings are designated by a single letter as follows. A = 100, B = 250, C = 300, D = 500, E = 600, F = 1000, G = 1200, H = 1500, J = 2000, K = 2500, L = 3000, M = 4000, N = 5000, P = 6000, Q = 8000, R = 10 000, S = 12 000, T = 15 000, U = 20 000, V = 25 000, W = 30 000, and X = 35 000 volts. EIA dc working voltage is a number designating hundreds of volts.

Temperature Range—MIL specifications provide for four temperature ranges, all of which have a lower limit of −55 °C; the upper limits are M = +70, N = +85, O = +125, and P = +150 °C. The EIA uses only N and O, which are identical to the MIL standard.

TABLE 18. FIXED-MICA-CAPACITOR REQUIREMENTS BY EIA AND MIL CHARACTERISTIC

EIA or MIL Characteristic	Maximum Capacitance Drift	Maximum Range of Temperature Coefficient (ppm/°C)
B	Not Specified	Not Specified
C	±(0.5% + 0.1 pF)	±200
D	±(0.3% + 0.1 pF)	±100
E	±(0.1% + 0.1 pF)	−20 to +100
F	±(0.05% + 0.1 pF)	0 to +70

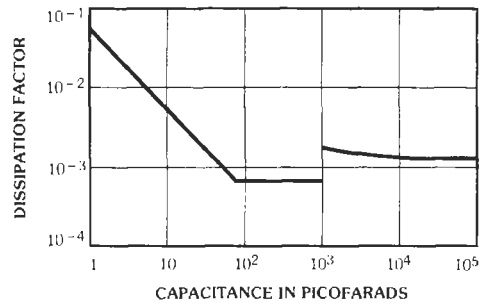


Fig. 19. EIA and MIL maximum dissipation factor at 1 megahertz for capacitance of 1000 picofarads or less and at 1 kilohertz for capacitance greater than 1000 picofarads.

Vibration Grade—The MIL vibration grade is a number, 1 corresponding to vibration from 10 to 55 hertz at 10g for 4.5 hours and 3 corresponding to 10 to 2000 hertz at 20 g for 12 hours.

Capacitance

Capacitance is measured at 1 megahertz for capacitors of 1000 picofarads or smaller. Larger capacitors are measured at 1 kilohertz.

Temperature Coefficient

Measurements to determine the temperature coefficient of capacitance and the capacitance drift are based on one cycle over the following temperature values (all in degrees Celsius): +25, −55, −40, −10, +25, +45, +65, +70, +85, +125, +150, +25. Measurements at +85, +125, and +150 are not made if these values are not within the applicable temperature range of the capacitor.

Dissipation Factor

The EIA and MIL specifications require that for molded and dipped capacitors the dissipation factor not exceed the values shown in Fig. 19. For potted and cast epoxy capacitors, the dissipation factor shall not exceed 0.35 percent from 1 to 1000 picofarads and 0.15 percent above 1000 picofarads.

High-Potential or Withstanding-Voltage Test

Molded or dipped mica capacitors are subjected to a test potential of twice their direct-current voltage rating.

Humidity and Thermal-Shock Tests

EIA Standard RS-153-B capacitors must withstand 5 cycles of −55, +25, +85, or +125 (as applicable), and +25 degrees Celsius thermal shock followed by a humidity test of 10 cycles (each of 24 hours) given for EIA Standard RS-186-D in Fig. 1. Units must pass a withstanding-voltage test. Capacitance may not change by more than 1.0 percent or 1.0 picofarad, whichever is greater. Insulation resistance must meet or exceed 30 percent of the initial requirements at 25 °C (50 000 megohms for capacitances of 20 000 picofarads or less; 1000 ohm-farads for larger capacitances).

MIL Specification MIL-C-5D capacitors must withstand 5 cycles of −55; +25; +85, +125, or +150 (as applicable); and +25 degrees Celsius thermal shock followed by a humidity test of 10 cycles (each of 24 hours) given for MIL-STD-202E in Fig. 1. Units must pass a withstanding-voltage test. Capacitance may not change by more than ±(0.2 percent +0.5 picofarad). Insulation resistance must meet or exceed 30 percent of the initial requirements at 25 °C (100 000 megohms for 10 000 picofarads or less; 1000 megohm-microfarads for larger capacitances).

Life

Capacitors are given accelerated life tests at 85 degrees Celsius with 150 percent of rated voltage applied for 2000 hours for MIL specification or 250 hours for EIA standard. If capacitors are rated above +85 °C, the test will be at their maximum rated temperature.

PRINTED CIRCUITS

A printed circuit is a conductive circuit pattern on one or both sides of an insulating substrate. Multilayer boards with tens of levels of circuitry are manufactured with conducting thru-holes to interconnect the circuitry levels. The conductive pattern can be formed by any of several techniques after which component lead holes are drilled or punched in the substrate and components are installed and soldered in place. Printed-circuit construction is ideal for assembly of circuits that employ miniature solid-state components. Its advantages over conventional chassis and point-to-point wiring include:

(A) Considerable space savings over conventional construction methods is usually a result.

(B) A complex circuit may be modularized by using several small printed circuits instead of a single larger one. Modularization simplifies troubleshooting, circuit modification, and mechanical assembly in an enclosure.

(C) Soldering of component leads may be accomplished in an orderly sequence by hand or by dip or wave soldering.

(D) A more uniform product is produced because wiring errors are eliminated and because distributed capacitances are constant from one production unit to another.

(E) The printed-circuit method of construction lends itself to automatic assembly and testing.

(F) Using appropriate base metals, flexible cables or flexible circuits can be built.

(G) By using several layers of circuits (in proper registry) in a sandwich construction, with the conductors separated by insulating layers, relatively complex wiring can be provide.

Printed-Circuit Base Materials

Rigid printed-circuit base materials are available in thicknesses varying from 1/64 to ½ inch. The important properties of the usual materials are given in Table 19. For special applications, other rigid or flexible materials are available as follows:

(A) Glass-cloth Teflon (polytetrafluoroethylene, PTFE) laminate.

(B) Kel-F (polymonochlorotrifluoroethylene) laminate

(C) Silicone rubber (flexible)

(D) Glass-mat-polyester-resin laminate.

(E) Teflon film.

(F) Ceramic.

The most widely used base material is NEMA-XXXP paper-base phenolic.

Conductor Materials

Copper is used almost exclusively as the conductor material, although silver, brass, and aluminum also have been used. The common thicknesses of foil are 0.0014 inch (1 oz/ft^2) and 0.0028 inch (2 oz/ft^2). The current-carrying capacity of a copper conductor may be determined from Fig. 20.

Manufacturing Processes

The most widely used production methods are:

(A) Etching process, wherein the desired circuit is printed on the metal-clad laminate by photographic, silk-screen, photo-offset, or other means, using an ink or lacquer resistant to the etching bath. The board is then placed in an etching bath that removes all of the unprotected metal (ferric chloride is a commonly used mordant for copper-clad laminates). After the etching is completed, the ink or lacquer is removed to leave the conducting pattern exposed.

(B) Plating process, wherein the designed circuit pattern is printed on the unclad base material using an electrically conductive ink, and, by electroplating, the conductor is built up to the desired thickness. This method lends itself to plating through punched holes in the board for making connections from one side to the other.

(C) Other processes, including metal spraying and die stamping.

Circuit-Board Finishes

Conductor protective finishes are required on the circuit pattern to improve shelf-storage life of the circuit boards and to facilitate soldering. Some of the most widely used finishes are:

(A) Hot-solder coating (done by dip-soldering in a solder bath) is a low-cost method and gives good results where coating thickness is not critical.

(B) Silver plating used as a soldering aid but is subject to tarnishing and has a limited shelf life.

(C) Hot-rolled or plated solder coat gives good solderability and uniform coating thickness.

(D) Other finishes for special purposes are gold plate, for corrosion resistance and solderability, and electroplated rhodium over nickel, for wear resistance. Insulating coatings such as acrylic, polystyrene, epoxy, or silicone resin are sometimes applied to circuit boards to improve circuit performance under high humidity or to improve the anchorage of parts to the board. Conformal coatings are relatively thick and tend to smooth the irregular contour of the mounted items; they add less mass than encapsulation. A protective organic coating (unless excessively thick) will not improve the electrical properties of an insulating base material during long exposure to high humidity. On two-sided circuit boards, where the possibility of components shorting out the circuit patterns exists, a thin sheet of insulating material is sometimes laminated over the circuit before the parts are inserted.

Design Considerations

Before a printed-circuit layout is made, the circuit must be breadboarded and tested under the anticipated final operating conditions. This procedure will permit operating deficiencies and quirks to be detected and corrected before the time-consuming process of producing the circuit board is begun. It is important to note that certain circuits may operate differently on a printed-circuit board than on a breadboard, and appropriate corrective steps may be necessary. For example, inductive coupling between foil patterns may cause

TABLE 19. PROPERTIES OF TYPICAL PRINTED-CIRCUIT DIELECTRIC BASE MATERIALS

unwanted oscillation in high-frequency or amplifier circuits.

All features (terminal areas, contacts, board boundaries, holes, etc.) should be arranged to be centered at the intersections of a 0.100-, 0.050-, or 0.025-inch rectangular grid, with preference in the order stated. Many components are available with leads spaced to match the standard grids. Devices with circular lead configurations and a few other multilead devices are exceptions that require special attention and dimensioning. Following this grid-layout principle simplifies drafting and subsequent machine operations in board manufacture and assembly.

Drilled holes must be employed if the stated requirements for punched holes cannot be met, or if the material is not of a punching grade. Drilling is less detrimental to the laminate surrounding the hole; punching may cause crazing or separation of the laminate layers.

The diameter of punched holes in circuit boards should not be less than ⅔ the thickness of the base material.

The distance between punched holes or between holes and the edge of the material should not be less than the material thickness.

Punched-hole tolerance should not be less than ±0.005 inch on the diameters.

Hole sizes should not exceed by more than 0.020 inch the diameter of the wire to be inserted in the hole. With smaller holes, hand insertion of the wire is

difficult. Machine insertion requires the larger allowance. Clinching of the lead is desirable if the clearance is larger.

Tolerances with respect to the true-grid location for terminal area centers and for locating edges of boards or other locating features (datums) should not exceed on the board: 0.014 inch diameter for conductor widths and spacings above 0.031 inch; 0.010 inch diameter for conductor widths and spacings 0.010 to 0.031 inch, inclusive. Tolerances on other dimensions (except conductor widths and spacings) may be larger. Closer tolerances may be needed if machine insertion is required.

Terminal area diameters should be at least (A) 0.020 inch larger than the diameter of the flange or projection of the flange on eyelets or standoff terminals, or the diameter of a plated-through hole, and (B) 0.040 inch larger than the diameter of an unsupported hole. Since the terminal area should be unbroken around the finished hole, the diameter should be further increased over the above minimum to allow for the permitted hole-position tolerance.

Conductor widths should be adequate for the current carried. See Fig. 20. For a given conductor-width and copper-thickness intersection, proceed vertically to the allowable temperature-rise line and then horizontally to the left to determine the permissible current. An additional 15% derating is recommended for board thicknesses of 1/32 inch or less, or for conductors thicker than 0.004 inch (3 oz). The normal ambient temperature surrounding the board plus the allowable temperature rise should not exceed the maximum safe operating temperature of the laminate. For ordinary work, copper conductor widths of 0.060 inch are convenient; with high-grade technique (extra cost), conductor widths as small as 0.010 inch can be readily produced.

Conductor spacing requirements are governed by the applied voltage, the maximum altitude, the conductor protective coating used, and the power-source size. The guide in Table 20 is suggested.

Preparation of Artwork

In preparing the master artwork for printed circuits, careful workmanship and accuracy are important. When circuits are reproduced by photographic means, much retouching time is saved if care is taken with the original artwork.

Artwork should be prepared on a dimensionally stable material. Tracing paper and bristol board are now outmoded, and specially treated (toothed) polyethylene terephthalate (Mylar, Cronar) base drafting films are used for most printed-circuit layouts. The layout pattern may be produced by one of the following methods:

1. Hand application of opaque, permanent black ink
2. Pressure-sensitive tape
3. Hand-cut stencil made from self-adhesive opaque film
4. Preformed self-adhesive layout patterns

Artwork should be prepared to a scale that is two to five times oversize. Photographic reduction to final negative size should be possible, however, in one step.

Avoid the use of sharp corners when laying out the circuit. See Fig. 21.

The centers of holes to be manually drilled or punched in the circuit board should be indicated by a circle of 1/32-inch diameter (final size after reduction). See Fig. 22. This feature is not needed on each board if templates or numerically controlled machine tools are

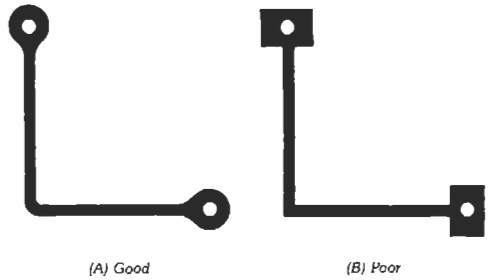

Fig. 21. Design of bends for printed-circuit conductors.

used for hole preparation; however, it is still a convenience for checking drawings, master artwork, and photographic negatives.

When drawing the second side of a printed-circuit board, corresponding centers should be taken directly from the back of the drawing of the first side.

In addition to the illustration of the circuit pattern, the trim line, registration marks, and two scale dimensions at right angles should be shown. Nomenclature, reference designations, operating instructions, and other information may also be added.

Assembly

All components should be inserted on one side of the board if practicable. In the case of boards with the circuit on one side only, the parts should be inserted on the side opposite the circuit. This allows all connections to be soldered simultaneously by dip-soldering.

Dip-soldering consists of applying a flux, usually a rosin-alcohol mixture, to the circuit pattern and then placing the board in contact with molten solder. Slight agitation of the board will ensure good fillets around the wire leads. In good present technique, the circuit board with its components assembled (on one side only) has its conductor pattern passed through the crest of a "wave" of molten solder; all junctions are soldered as

Fig. 22. Indication for hole.

the board progresses through the wave. The flux, board temperature, solder temperature, and immersion time are interrelated and must be adjusted for best results. Long exposure to hot solder is detrimental to the insulating material and to the adhesive that joins the copper foil to the insulation. For hand dipping, a 5-second dip in a 60/40 tin-lead solder bath maintained at a temperature of 450 degrees Fahrenheit will give satisfactory results.

After solder-dipping, the residual flux should be removed by a suitable solvent. Be sure the solvent is compatible with the materials used in the component parts mounted on the board; solvents frequently dissolve cements or plastics and marking inks, or cause severe stress cracking of plastics.

To secure the advantages of machine assembly:

(A) Components should be of similar size and shape, or separate inserting heads will be required for each different shape of item.

(B) Components of the same size and shape must be mounted using the same terminal lead spacing at all points.

(C) Different values of a part, or even different parts of similar shape and sizes (if axial-lead style) may be specially sequenced in a lead-taped package for insertion by one programmed insertion head.

(D) A few oddly sized or shaped components may be economically inserted by hand after the machine insertion work is completed.

6 Fundamentals of Networks

INDUCTANCE OF SINGLE-LAYER SOLENOIDS

The approximate value of the low-frequency inductance of a single-layer solenoid is*

$$L = Fn^2d$$

where,

L = inductance in microhenrys,
F = form factor, a function of the ratio d/l (value of F may be read from Fig. 1),
n = number of turns,
d = diameter of coil (inches) between centers of conductors,
l = length of coil (inches) = n times the distance between centers of adjacent turns.

The equation is based on the assumption of a uniform current sheet, but the correction due to the use of spaced round wires is usually negligible for practical purposes. For higher frequencies, skin effect alters the inductance slightly. This effect is not readily calculated, but is often negligibly small. However, it must be borne in mind that the equation gives approximately the true value of inductance. In contrast, the apparent value is affected by the shunting effect of the distributed capacitance of the coil.

Example: Required, a coil of 100 microhenrys inductance, wound on a form 2 inches in diameter by 2 inches winding length. The $d/l = 1.00$, and $F = 0.0173$ in Fig. 1.

$$n = (L/Fd)^{1/2}$$

$$= [100/(0.0173 \times 2)]^{1/2}$$

$$= 54 \text{ turns}$$

Reference to Table 1 will assist in choosing a desirable size of wire, allowing for a suitable spacing between turns according to the application of the coil. A slight correction may then be made for the increased diameter (diameter of form, plus two times radius of wire), if this small correction seems justified.

Approximate Equation

For single-layer solenoids of the proportions normally used in radio work, the inductance in microhenrys is given to an accuracy of about 1 percent by the formula

$$L = n^2[r^2/(9r + 10l)]$$

where $r = d/2$ and the other quantities are as defined for the previous inductance formula.

* Equations and Fig. 1 are derived from equations and tables in Bureau of Standards Circular No. C74.

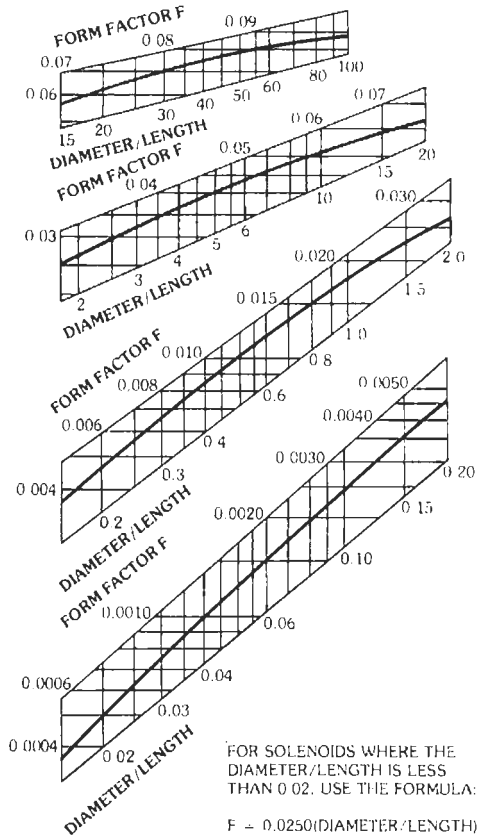

Fig. 1. Chart showing inductance of a single-layer solenoid, form factor = F.

General Remarks

In the use of various charts, tables, and calculators for designing inductors, the following relationships are useful in extending the range of the devices. They apply to coils of any type or design.

(A) If all dimensions are held constant, inductance is proportional to n^2.

(B) If the proportions of the coil remain unchanged, then for a given number of turns the inductance is proportional to the dimensions of the coil. A coil with all dimensions m times those of a given coil (having the same number of turns) has m times the inductance of the given coil. That is, inductance has the dimensions of length.

Decrease of Solenoid Inductance by Shielding*

When a solenoid is enclosed in a cylindrical shield, the inductance is reduced by a factor given in Fig. 2. This effect has been evaluated by considering the shield

* Nominal bare diameter plus maximum additions.
For additional data on copper wire, see Chapters 4 and 13.

to be a short-circuited single-turn secondary. The curves in Fig. 2 are reasonably accurate provided the clearance between each end of the coil winding and the corresponding end of the shield is at least equal to the radius of the coil. For square shield cans, take the equivalent shield diameter (for Fig. 2) as being 1.2 times the width of one side of the square.

Example: Let the coil winding length be 1.5 inches and its diameter 0.75 inch, while the shield diameter is 1.25 inches. What is the reduction of inductance due to the shield? The proportions are

$$\text{(winding length)/(winding diameter)} = 2.0$$

$$\text{(winding diameter)/(shield diameter)} = 0.6$$

Referring to Fig. 2, the actual inductance in the shield is 72 percent of the inductance of the coil in free space.

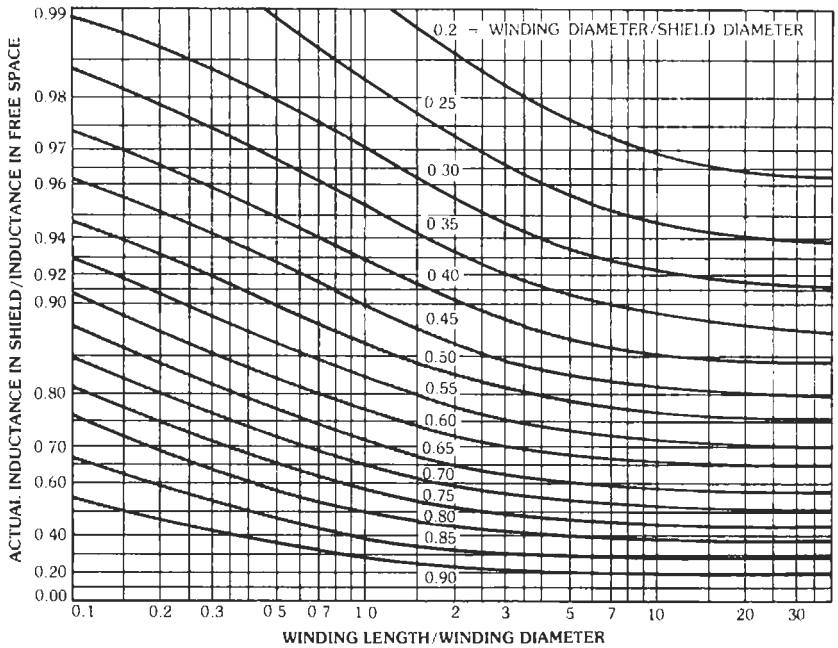

Fig. 2. Inductance decrease when a solenoid is shielded. *By permission of RCA, copyright proprietor.*

Q of Unshielded Solenoid

Fig. 3 can be used to obtain the unloaded Q of an unshielded solenoid.

REACTANCE CHARTS

Figs. 4, 5, and 6 give the relationships of capacitance, inductance, reactance, and frequency. Any one value may be determined in terms of two others by use of a straightedge laid across the correct chart for the frequency under consideration.

Example: Given a capacitance of 0.001 microfarad, find the reactance at 50 kilohertz and inductance required to resonate. Place a straightedge through these values and read the intersections on the other scales, giving approximately 3200 ohms and 11 millihenrys. See Fig. 5.

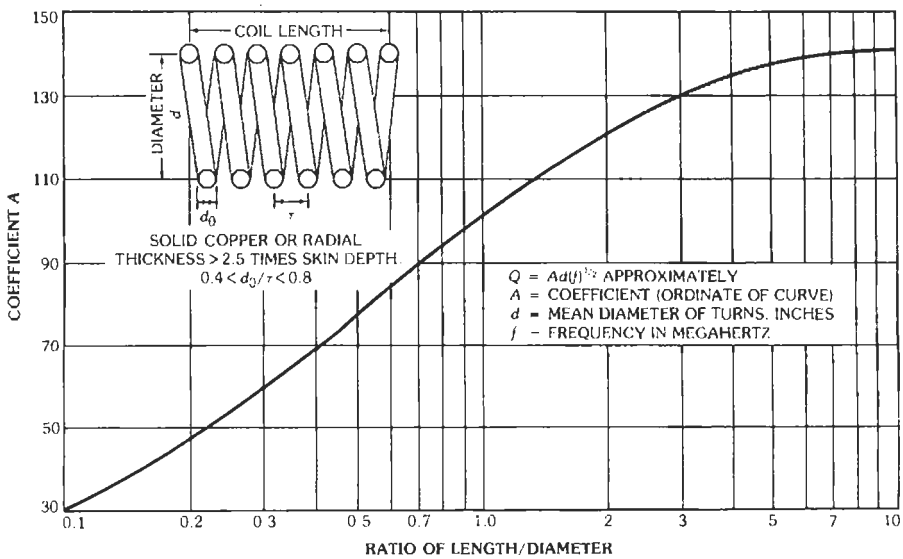

Fig. 3. Q of unshielded coil.

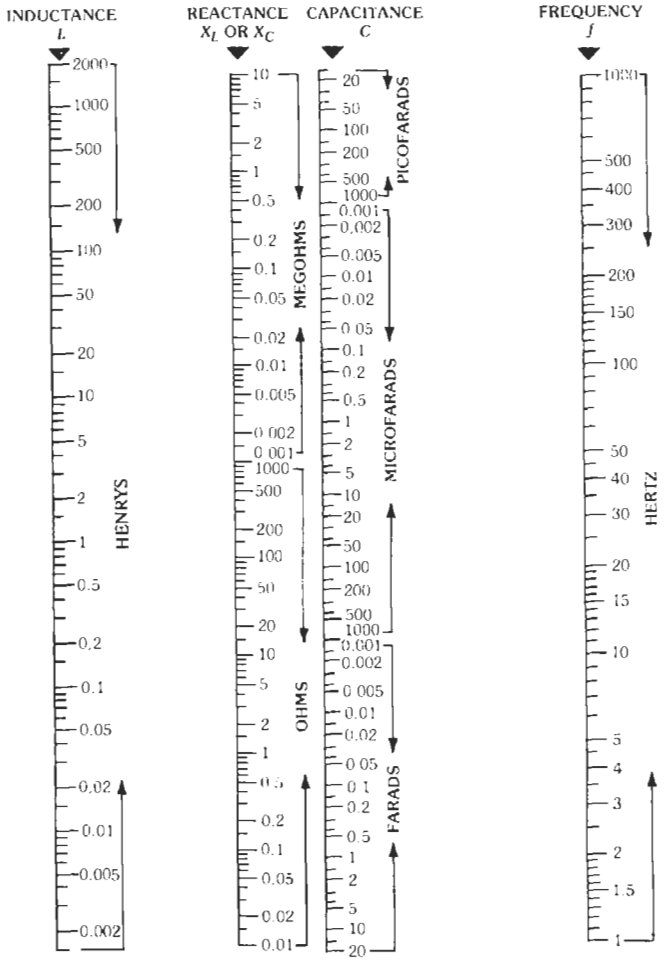

Fig. 4. Chart covering 1 hertz to 1000 hertz.

IMPEDANCE FORMULAS

Impedance and admittance formulas for various combinations of L, C, and R are given in Tables 2 and 3.

SKIN EFFECT

Symbols

A = correction coefficient
D = diameter of conductor in inches
f = frequency in hertz
R_{ac} = resistance at frequency f
R_{dc} = direct-current resistance
R_{sq} = resistance per square
T = thickness of tubular conductor in inches
T_1 = depth of penetration of current
δ = skin depth
λ = free-space wavelength in meters
μ_r = relative permeability of conductor material (μ_r = 1 for copper and other nonmagnetic materials)
ρ = resistivity of conductor material at any temperature
ρ_c = resistivity of copper at 20 °C = 1.724 microhms-centimeter

Skin Depth

The skin depth is that distance below the surface of a conductor where the current density has diminished to $1/e$ of its value at the surface. The thickness of the conductor is assumed to be several (perhaps at least three) times the skin depth. Imagine the conductor replaced by a cylindrical shell of the same surface shape but of thickness equal to the skin depth, with uniform current density equal to that which exists at the surface of the actual conductor. Then the total current in the shell and its resistance are equal to the corresponding values in the actual conductor.

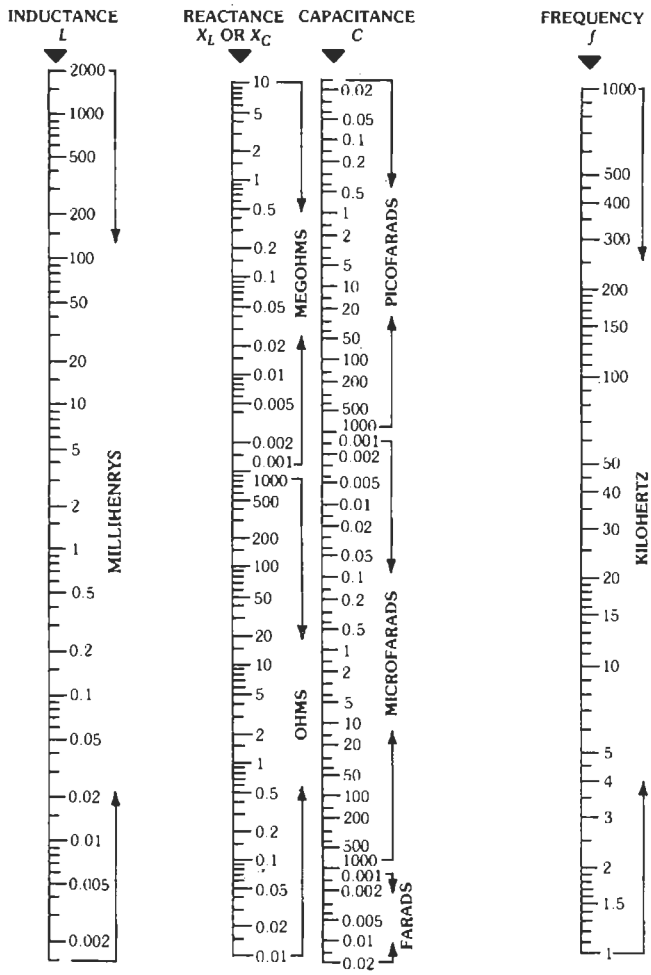

Fig. 5. Chart covering 1 kilohertz to 1000 kilohertz.

The skin depth and the resistance per square (of any size), in meter-kilogram-second (rationalized) units, are

$$\delta = (\lambda/\pi\sigma\mu c)^{1/2}$$

$$R_{sq} = 1/\delta\sigma$$

where,

δ = skin depth in meters,
R_{sq} = resistance per square in ohms,
c = velocity of light *in vacuo*
$= 2.998 \times 10^8$ meter/second,
$\mu = 4\pi \times 10^{-7}\ \mu_r$ henry/meter,
$1/\sigma = 1.724 \times 10^{-8}\ \rho/\rho_c$ ohm-meter.

For numerical computations

$$\delta = (3.82 \times 10^{-4}\ \lambda^{1/2})k_1$$
$$= (6.61/f^{1/2})k_1 \text{ centimeter}$$
$$\delta = (1.50 \times 10^{-4}\lambda^{1/2})k_1$$
$$= (2.60/f^{1/2})k_1 \text{ inch}$$
$$\delta_m = (2.60/f_{mc}^{1/2})k_1 \text{ mil}$$
$$R_{sq} = (4.52 \times 10^{-3}/\lambda^{1/2})k_2$$
$$= (2.61 \times 10^{-7}f^{1/2})k_2 \text{ ohm}$$
$$k_1 = [(1/\mu_r)\rho/\rho_c]^{1/2}$$
$$k_2 = (\mu_r\rho/\rho_c)^{1/2}$$
$$k_1, k_2 = \text{unity for copper}$$

Example: What is the resistance/foot of a cylindrical copper conductor of diameter D inches?

$$R = (12/\pi D)R_{sq}$$

$$= (12/\pi D) \times 2.61 \times 10^{-7}(f^{1/2})$$

$$= 0.996 \times 10^{-6}(f^{1/2})/D \text{ ohm/foot}$$

If $D = 1.00$ inch and $f = 100 \times 10^6$ hertz, then $R = 0.996 \times 10^{-6} \times 10^4 \approx 1 \times 10^{-2}$ ohm/foot.

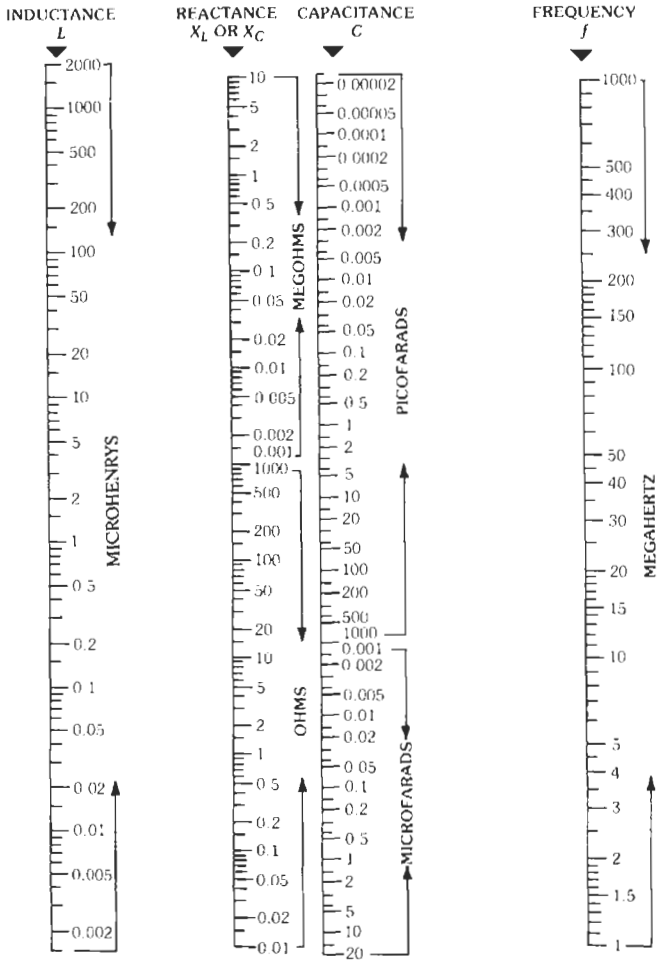

Fig. 6. Chart covering 1 megahertz to 1000 megahertz.

General Considerations

Fig. 7 shows the relationship of R_{ac}/R_{dc} versus $D(f^{1/2})$ for copper, or versus $D(f^{1/2})(\mu_r\rho_c/\rho)^{1/2}$ for any conductor material, for an isolated straight solid conductor of circular cross section. Negligible error in the equations for R_{ac} results when the conductor is spaced at least $10D$ from adjacent conductors. When the spacing between axes of parallel conductors carrying the same current is $4D$, the resistance R_{ac} is increased about 3 percent, when the depth of penetration is small. The equations are accurate for concentric lines due to their circular symmetry.

For values of $D(f^{1/2})(\mu_r\rho_c/\rho)^{1/2}$ greater than 40

$$R_{ac}/R_{dc} = 0.0960\, D(f^{1/2})(\mu_r\rho_c/\rho)^{1/2} + 0.26 \quad \text{(Eq. 1)}$$

The high-frequency resistance in ohms/foot of an isolated straight conductor (either solid or tubular for $T < D/8$ or $T_1 < D/8$) is given in Eq. (2). If the current is along the inside surface of a tubular conductor, D is the inside diameter.

$$R_{ac} = A[(f^{1/2})/D][\mu_r(\rho/\rho_c)]^{1/2} \times 10^{-6} \quad \text{(Eq. 2)}$$

The values of the correction coefficient A for solid conductors and for tubular conductors are given in Table 4.

The value of $T(f^{1/2})(\mu_r\rho_c/\rho)^{1/2}$ that just makes $A = 1$ indicates the penetration of the currents below the surface of the conductor. Thus, approximately

$$T_1 = [3.5/(f^{1/2})](\rho/\mu_r\rho_c)^{1/2} \quad \text{(Eq. 3)}$$

where T_1 is in inches.

When $T_1 < D/8$, the value of R_{ac} as given by Eq. (2) (but not the value of R_{ac}/R_{dc} in Table 4, "Tubular Conductors") is correct for any value $T \geq T_1$.

Under the limitation that the radius of curvature of all parts of the cross section is appreciably greater than T_1,

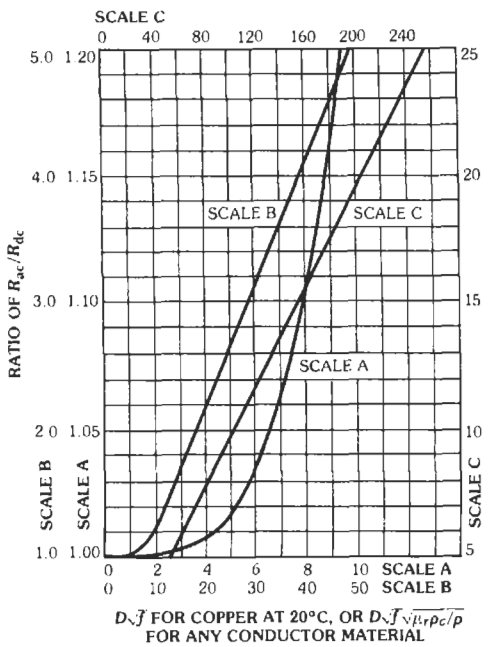

Fig. 7. Resistance ratio for isolated straight solid conductors of circular cross section.

Eqs. (2) and (3) hold for isolated straight conductors of any shape. In this case the term D = (perimeter of cross section)/π.

Examples:

(A) At 100 megahertz, a copper conductor has a depth of penetration $T_1 = 0.00035$ inch.

(B) A steel shield with 0.005-inch copper plate, which is practically equivalent in R_{ac} to an isolated copper conductor 0.005-inch thick, has a value of $A = 1.23$ at 200 kilohertz. This 23-percent increase in resistance over that of a thick copper sheet is satisfactorily low as regards its effect on the losses of the components within the shile.d By comparison, a thick aluminum sheet has a resistance $(\rho/\rho_c)^{1/2} = 1.28$ times that of copper.

EQUATIONS FOR SIMPLE R, L, AND C NETWORKS*

Self-Inductance of Circular Ring of Round Wire at Radio Frequencies, for Nonmagnetic Materials

$$L = (a/100) \times [7.353 \log_{10}(16a/d) - 6.386]$$

* Many equations for computing capacitance, inductance, and mutual inductance will be found in Bureau of Standards Circular No. C74, obtainable from the Superintendent of Documents, Government Printing Office, Washington, D.C. 20402.

TABLE 4. SKIN-EFFECT CORRECTION COEFFICIENT A FOR SOLID AND TUBULAR CONDUCTORS

Solid Conductors	
$D(f^{1/2})[\mu_r(\rho_c/\rho)]^{1/2}$	A
> 370	1.000
220	1.005
160	1.010
98	1.02
48	1.05
26	1.10
13	1.20
9.6	1.30
5.3	2.00
< 3.0	$R_{ac} \approx R_{dc}$

$R_{dc} = (10.37/D^2)(\rho/\rho_c) \times 10^{-6}$ ohm/foot

Tubular Conductors		
$T(f^{1/2})[\mu_r(\rho_c/\rho)]^{1/2}$	A	R_{ac}/R_{dc}
$= B$ where $B > 3.5$	1.00	$0.384B$
3.5	1.00	1.35
3.15	1.01	1.23
2.85	1.05	1.15
2.60	1.10	1.10
2.29	1.20	1.06
2.08	1.30	1.04
1.77	1.50	1.02
1.31	2.00	1.00
$= B$ where $B < 1.3$	$2.60/B$	1.00

where,

L = self-inductance in microhenrys,
a = mean radius of ring in inches,
d = diameter of wire in inches,
$a/d > 2.5$.

Capacitance

For Parallel-Plate Capacitor:

$$C = 0.0885\epsilon_r[(N - 1)A]/t$$

$$= 0.225\epsilon_r[(N - 1)A''/t'']$$

where,

C = capacitance in picofarads,
A = area of one side of one plate in square centimeters,
A'' = area in square inches,
N = number of plates,
t = thickness of dielectric in centimeters,
t'' = thickness in inches,
ϵ_r = dielectric constant relative to air.

This equation neglects "fringing" at the edges of the plates.

For Coaxial Cylindrical Capacitor (Fig. 8):

$$C = 2\pi\epsilon_r\epsilon_v/[\log_e(b/a)]$$

$$= \{(5 \times 10^6\epsilon_r)/[c^2\log_e(b/a)]\}$$

where,

C = capacitance per unit axial length in farads/meter,
c = velocity of light in vacuo, meters per second $= 2.998 \times 10^8$,
ϵ_r = dielectric constant relative to air,
ϵ_v = permittivity of free space in farads/meter $= 8.85 \times 10^{-12}$

Alternative forms of the equation are:

$C = 0.2416\epsilon_r/[\log_{10}(b/a)]$ picofarads/centimeter
$= 0.614\epsilon_r/[\log_{10}(b/a)]$ picofarads/inch
$= 7.36\epsilon_r/[\log_{10}(b/a)]$ picofarads/foot

When $1.0 < (b/a) < 1.4$, then with accuracy of 1 percent or better, the capacitance in picofarads/foot is:

$$C = 8.50\epsilon_r \frac{(b/a) + 1}{(b/a) - 1}$$

T-π or Y-Δ Transformation

The two networks (Fig. 9) are equivalent, as far as conditions at the terminals are concerned, provided the listed equations are satisfied (either the impedance equations or the admittance equations may be used)

$$Y_1 = 1/Z_1 \qquad Y_c = 1/Z_c, \quad \text{etc.}$$

TRANSIENTS—ELEMENTARY CASES

The complete transient in a linear network is, by the principle of superposition, the sum of the individual transients due to the store of energy in each inductor and capacitor and to each external source of energy connected to the network. To this is added the steady-state condition due to each external source of energy. The transient may be computed as starting from any arbitrary time $t = 0$ when the initial conditions of the energy of the network are known.

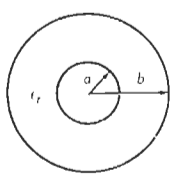

Fig. 8. Coaxial cylindrical capacitor.

Time Constant

The time constant (designated T) of the discharge of a capacitor through a resistor is the time $t_2 - t_1$ required for the voltage or current to decay to $1/\epsilon$ of its value at time t_1. For the charge of a capacitor, the same definition applies, the voltage "decaying" toward its steady-state value. The time constant of discharge or charge of the current in an inductor through a resistor follows an analogous definition.

Stored energy, in joules (watt-seconds), is:

$$\text{Energy stored in a capacitor} = CE^2/2$$

$$\text{Energy stored in an inductor} = LI^2/2$$

In the equations in this section, T and t are in seconds, R is in ohms, L is in henrys, C is in farads, E is in volts, and I is in amperes. Values of the numerical constants are:

$$\epsilon = 2.718 \qquad 1/\epsilon = 0.3679 \qquad \log_{10}\epsilon = 0.4343$$

Capacitor Charge and Discharge

Closing of switch (Fig. 10) occurs at time $t = 0$.
Initial conditions (at $t = 0$): Battery $= E_b$; $e_c = E_0$.
Steady state (at $t = \infty$): $i = 0$; $e_c = E_b$.
Transient:

$$i = [(E_b - E_0)/R]\exp(-t/RC)$$

$$= I_0 \exp(-t/RC)$$

$$\log_{10}(i/I_0) = -(0.4343/RC)t$$

$$e_c = E_0 + C^{-1}\int_0^t i\,dt$$

$$= E_0 \exp(-t/RC) + E_b[1 - \exp(-t/RC)]$$

Time constant:

$$T = RC$$

Fig. 11 shows current:

$$i/I_0 = \exp(-t/T)$$

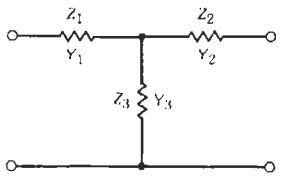
Fig. 11 shows discharge (for $E_b = 0$):

$$e_c/E_0 = \exp(-t/T)$$

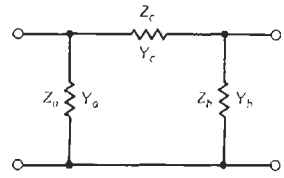
Fig. 12 shows charge (for $E_0 = 0$):

$$e_c/E_b = 1 - \exp(-t/T)$$

These curves are plotted for a wider range in Fig. 13.



(A) T or Y.



(B) π or Δ.

Impedance Equations:

$$Z_c = (Z_1Z_2 + Z_1Z_3 + Z_2Z_3)/Z_3$$
$$Z_a = (Z_1Z_2 + Z_1Z_3 + Z_2Z_3)/Z_2$$
$$Z_b = (Z_1Z_2 + Z_1Z_3 + Z_2Z_3)/Z_1$$

$$Z_1 = Z_aZ_c/(Z_a + Z_b + Z_c)$$
$$Z_2 = Z_bZ_c/(Z_a + Z_b + Z_c)$$
$$Z_3 = Z_aZ_b/(Z_a + Z_b + Z_c)$$

Admittance Equations:

$$Y_c = Y_1Y_2/(Y_1 + Y_2 + Y_3)$$
$$Y_a = Y_1Y_3/(Y_1 + Y_2 + Y_3)$$
$$Y_b = Y_2Y_3/(Y_1 + Y_2 + Y_3)$$

$$Y_1 = (Y_aY_b + Y_aY_c + Y_bY_c)/Y_b$$
$$Y_2 = (Y_aY_b + Y_aY_c + Y_bY_c)/Y_a$$
$$Y_3 = (Y_aY_b + Y_aY_c + Y_bY_c)/Y_c$$

(C) Equations.

Fig. 9. T or Y network and π or Δ network.

Two Capacitors

Closing of switch (Fig. 14) occurs at time $t = 0$. Initial conditions (at $t = 0$):

$$e_1 = E_1; \qquad e_2 = E_2$$

Steady state (at $t=\infty$):

$$e_1 = E_f; \quad e_2 = -E_f; \quad i = 0$$

$$E_f = (E_1C_1 - E_2C_2)/(C_1 + C_2)$$

$$C' = C_1C_2/(C_1 + C_2)$$

Transient:

$$i = [(E_1 + E_2)/R] \exp(-t/RC')$$

$$e_1 = E_f + (E_1 - E_f) \exp(-t/RC')$$

$$= E_1 - (E_1 + E_2)(C'/C_1)$$

$$\times [1 - \exp(-t/RC')]$$

$$e_2 = -E_f + (E_2 + E_f) \exp(-t/RC')$$

$$= E_2 - (E_1 + E_2)(C'/C_2)$$

$$\times [1 - \exp(-t/RC')]$$

Original energy (joules) $= (C_1E_1^2 + C_2E_2^2)/2$

Final energy (joules) $= (C_1 + C_2)E_f^2/2$

Loss of energy (joules) $= \int_0^\infty i^2R\,dt$

$$= C'(E_1 + E_2)^2/2$$

(Loss is independent of the value of R.)

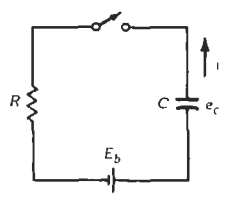


Fig. 10. Circuit for capacitor charge and discharge.

Inductor Charge and Discharge

Initial conditions (at $t = 0$) in Fig. 15:

$$\text{Battery} = E_b; \qquad i = I_0$$

Steady state (at $t = \infty$):

$$i = I_f = E_b/R$$

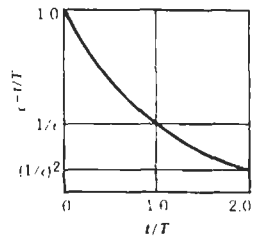

Fig. 11. Capacitor discharge.

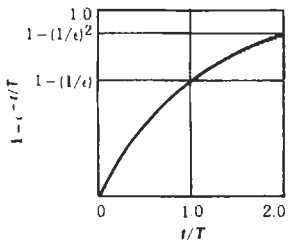

Fig. 12. Capacitor charge.

Transient plus steady state:

$$i = I_f[1 - \exp(-Rt/L)] + I_0 \exp(-Rt/L)$$

$$e_L = -L\, di/dt$$

$$= -(E_b - RI_0) \exp(-Rt/L)$$

Time constant:

$$T = L/R$$

Fig. 11 shows discharge (for $E_b = 0$):

$$i/I_0 = \exp(-t/T)$$

Fig. 12 shows charge (for $I_0 = 0$)

$$i/I_f = [1 - \exp(-t/T)]$$

These curves are plotted for a wider range in Fig. 13.

Charge and Discharge of Series R-L-C Circuit

Initial conditions (at $t = 0$) in Fig. 16:

$$\text{Battery} = E_b; \qquad e_c = E_0; \qquad i = I_0$$

Steady state (at $t = \infty$):

$$i = 0; \qquad e_c = E_b$$

Differential equation:

$$E_b - E_0 - C^{-1} \int_0^t i\, dt - Ri - L(di/dt) = 0$$

when

$$L(d^2i/dt^2) + R(di/dt) + (i/C) = 0$$

Solution of equation:

$$i = \exp(-Rt/2L) \left[\frac{2(E_b - E_0) - RI_0}{R(D^{1/2})} \sinh (Rt/2L) \right.$$

$$\left. \times (D^{1/2}) + I_0 \cosh (Rt/2L)(D^{1/2}) \right]$$

where $D = 1 - (4L/R^2C)$.

Case 1: When L/R^2C is small

$$i = (1 - 2A - 2A^2)^{-1} \left\{ \left[\frac{E_b - E_0}{R} - I_0(A + A^2) \right] \right.$$

$$\times \exp\left(-\frac{t}{RC} (1 + A + 2A^2) \right)$$

$$+ \left[I_0(1 - A - A^2) - \frac{E_b - E_0}{R} \right]$$

$$\left. \times \exp\left(-\frac{Rt}{L} (1 - A - A^2) \right) \right\}$$

where $A = L/R^2C$.

For practical purposes, the terms A^2 can be neglected when $A < 0.1$. The terms A may be neglected when $A < 0.01$.

Use exponential $\exp(-t/T)$ for charge or discharge of capacitor or discharge of inductor:

(current at time t)/(initial current)

Discharge of capacitor:

(voltage at time t)/(initial voltage)

Use exponential $1 - \exp(-t/T)$ for charge of capacitor:

(voltage at time t)/(battery or final voltage)

Charge of inductor:

(current at time t)/(final current)

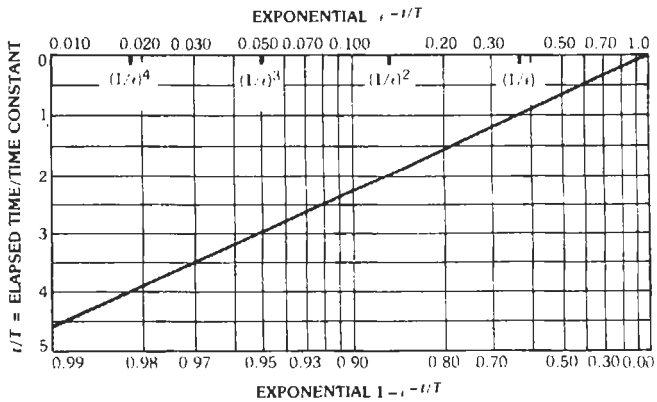

Fig. 13. Exponential functions $\exp(-t/T)$ and $1 - \exp(-t/T)$ applied to transients in R-C and L-R circuits.

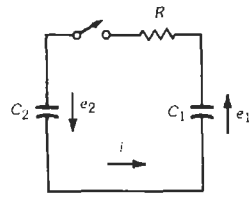

Fig. 14. Circuit for two capacitors.

Case 2: When $4L/R^2C < 1$ for which $D^{1/2}$ is real

$$i = \frac{\exp(-Rt/2L)}{D^{1/2}} \left\{ \left[\frac{E_b - E_0}{R} - \frac{1}{2} I_0 \left(1 - D^{1/2}\right) \right] \times \exp\left(\frac{Rt}{2L} D^{1/2}\right) + \left[\frac{1}{2} I_0 \left(1 + D^{1/2}\right) - \frac{E_b - E_0}{R} \right] \exp\left(-\frac{Rt}{2L} D^{1/2}\right) \right\}$$

Case 3: When D is a small positive or negative quantity

$$i = \exp(-Rt/2L) \left\{ \frac{2(E_b - E_0)}{R} \left[\frac{Rt}{2L} + \frac{1}{6}\left(\frac{Rt}{2L}\right)^3 D \right] + I_0 \left[1 - \frac{Rt}{2L} + \frac{1}{2}\left(\frac{Rt}{2L}\right)^2 D - \frac{1}{6}\left(\frac{Rt}{2L}\right)^3 D \right] \right\}$$

This equation may be used for values of D up to ± 0.25, at which values the error in the computed current i is approximately 1 percent of I_0 or of $(E_b - E_0)/R$.

Case 3A: When $4L/R^2C = 1$ for which $D = 0$, the equation reduces to

$$i = \exp(-Rt/2L) \left[\frac{E_b - E_0}{R} \frac{Rt}{L} + I_0 \left(1 - \frac{Rt}{2L}\right) \right]$$

or $i = i_1 + i_2$, plotted in Fig. 17. For practical purposes, this equation may be used when $4L/R^2C = 1 \pm 0.05$ with errors of 1 percent or less.

Case 4: When $4L/R^2C > 1$ for which $D^{1/2}$ is imaginary

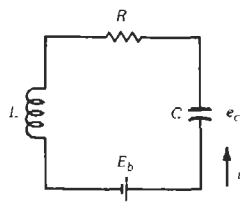

Fig. 16. Series R-L-C circuit.

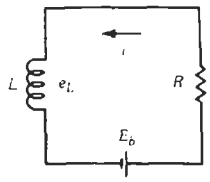

Fig. 15. Circuit for inductor charge and discharge.

$$i = \exp(-Rt/2L) \left[\left(\frac{E_b - E_0}{\omega_0 L} - \frac{RI_0}{2\omega_0 L} \right) \times \sin\omega_0 t + I_0 \cos\omega_0 t \right]$$

$$= I_m \exp(-Rt/2L) \sin(\omega_0 t + \Psi)$$

where,

$$\omega_0 = [(LC)^{-1} - (R^2/4L^2)]^{1/2}$$
$$I_m = (\omega_0 L)^{-1} \{[E_b - E_0 - (RI_0)/2]^2 + \omega_0^2 L^2 I_0^2\}^{1/2}$$
$$\Psi = \tan^{-1}\{\omega_0 L I_0/[E_b - E_0 - RI_0)/2]\}$$

The envelope of the voltage wave across the inductor is

$$\pm \exp(-Rt/2L)[\omega_0 (LC)^{1/2}]^{-1} \times \{[E_b - E_0 - (RI_0)/2]^2 + \omega_0^2 L^2 I_0^2\}^{1/2}$$

Example: Relay with transient-suppressing capacitor (Fig. 18). The switch is closed until time $t = 0$, then opened.

Let $L = 0.10$ henry, $R_1 = 100$ ohms, and $E = 10$ volts.

Suppose we choose $C = 10^{-6}$ farad and $R_2 = 100$ ohms.

Then $R = 200$ ohms, $I_0 = 0.10$ ampere, $E_0 = 10$ volts, $\omega_0 = 3 \times 10^3$, and $f_0 = 480$ hertz.

Maximum peak voltage across L (envelope at $t = 0$) is approximately 30 volts. Time constant of decay of envelope is 0.001 second.

Nonoscillating Condition: It is preferable that the circuit be just nonoscillating (Case 3A) and that it present a pure resistance at the switch terminals for any frequency.

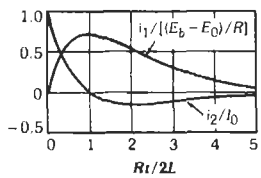

Fig. 17. Transients for $4L/R^2C = 1$.

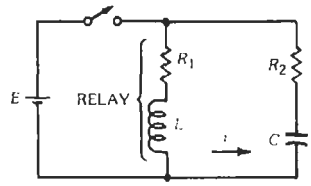

Fig. 18. Equivalent circuit of relay with transient-suppressing capacitor.

$$R_2 = R_1 = R/2 = 100 \text{ ohms}$$

$$4L/R^2C = 1$$

$$C = 10^{-5} \text{ farad} = 10 \text{ microfarads}$$

At the instant of opening the switch, the voltage across the parallel circuit is $E_0 - R_2 I_0 = 0$.

Series R-L-C Circuit With Sinusoidal Applied Voltage

By the principle of superposition, the transient and steady-state conditions are the same for the actual circuit and the equivalent circuit shown in Fig. 19, the closing of the switch occurring at time $t = 0$. In the equivalent circuit, the steady state is due to the source e acting continuously from time $t = -\infty$, while the transient is due to short-circuiting the source $-e$ at time $t = 0$.

Source:

$$e = E \sin(\omega t + \alpha)$$

Steady state:

$$i = (E/Z) \sin(\omega t + \alpha - \phi)$$

where,

$$Z = \{R^2 + [\omega L - (1/\omega C)]^2\}^{1/2}$$

$$\tan\phi = (\omega^2 LC - 1)/\omega CR$$

The transient is found by determining current $i = I_0$ and capacitor voltage $e_c = E_0$ at time $t = 0$, due to the source $-e$. These values of I_0 and E_0 are then substituted in the equations of Case 1, 2, 3, or 4, above, according to the values of R, L, and C.

At time $t = 0$, due to the source $-e$:

$$i = I_0 = -(E/Z) \sin(\alpha - \phi)$$

$$e_c = E_0 = (E/\omega CZ) \cos(\alpha - \phi)$$

This form of analysis may be used for any periodic applied voltage e. The steady-state current and the capacitor voltage for an applied voltage $-e$ are determined, the periodic voltage being resolved into its harmonic components for this purpose, if necessary. Then the instantaneous values $i = I_0$ and $e_c = E_0$ at the time of closing the switch are easily found, from which the transient is determined. It is evident, from this method of analysis, that the waveform of the transient need bear no relationship to that of the applied voltage, depending only on the constants of the circuit and the hypothetical initial conditions I_0 and E_0.

TRANSIENTS—OPERATIONAL CALCULUS AND LAPLACE TRANSFORMS

Among the various methods of operational calculus used to solve transient problems, one of the most efficient makes use of the Laplace transform.

If we have a function $v = f(t)$, then by definition the Laplace transform is $\mathcal{L}[f(t)] = F(p)$, where

$$F(p) = \int_0^\infty \exp(-pt) f(t)\, dt \qquad \text{(Eq. 4)}$$

The inverse transform of $F(p)$ is $f(t)$. Most of the mathematical functions encountered in practical work fall in the class for which Laplace transforms exist. Transforms of several functions are given in Chapter 46.

In the following, an abbreviated symbol such as $\mathcal{L}[i]$ is used instead of $\mathcal{L}[i(t)]$ to indicate the Laplace transform of the function $i(t)$.

The electrical (or other) system for which a solution of the differential equation is required is considered

only in the time domain $t \geq 0$. Any currents or voltages existing at $t = 0$, before the driving force is applied, constitute initial conditions. Driving force is assumed to be 0 when $t < 0$.

Example

Take the circuit of Fig. 20, in which the switch is closed at time $t = 0$. Before the closing of the switch, suppose the capacitor is charged; then at $t = 0$, we have $v = V_0$. It is required to find the voltage v across capacitor C as a function of time.

Since $i = dq/dt = C(dv/dt)$, the differential equation of the circuit in terms of voltage is:

$$e(t) = v + Ri = v + RC(dv/dt) \qquad \text{(Eq. 5)}$$

where $e(t) = E_b$.

Referring to the table of transforms, the applied voltage is E_b multiplied by unit step, or $E_b S_{-1}(t)$; the transform for this is E_b/p. The transform of v is $\mathcal{L}[v]$. That of $RC(dv/dt)$ is $RC[p\,\mathcal{L}[v] - v(0)]$, where $v(0) = V_0$ = value of v at $t = 0$. Then the transform of Eq. (5) is:

$$E_b/p = \mathcal{L}[v] + RC[p\,\mathcal{L}[v] - V_0]$$

Rearranging and resolving into partial fractions:

$$\mathcal{L}[v] = \frac{E_b}{p(1 + RCp)} + \frac{RCV_0}{1 + RCp}$$

$$= E_b[p^{-1} - (p + 1/RC)^{-1}] + \frac{V_0}{p + 1/RC} \qquad \text{(Eq. 6)}$$

Now we must determine the equation that would transform into Eq. (6). The inverse transform of $\mathcal{L}[v]$ is v, and those of the terms on the right-hand side are found in the table of transforms. Then, in the time domain $t \geq 0$

$$v = E_b[1 - \exp(-t/RC)] + V_0 \exp(-t/RC) \qquad \text{(Eq. 7)}$$

This solution is also well known by classical methods. However, the advantages of the Laplace transform method become more and more apparent in reducing the labor of solution as the equations become more involved.

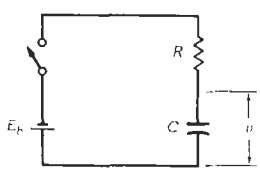

Fig. 20. Series R-C circuit.

Circuit Response Related to Unit Impulse

Unit impulse (see Laplace transforms) has the dimensions of time^{-1}. For example, suppose a capacitor of 1 microfarad is suddenly connected to a battery of 100 volts, with the circuit inductance and resistance negligibly small. Then the current is 10^{-4} coulomb multiplied by unit impulse.

The general transformed equation of a circuit or system may be written

$$\mathcal{L}[i] = \psi(p)\,\mathcal{L}[e] + \psi(p) \qquad \text{(Eq. 8)}$$

Here $\mathcal{L}[i]$ is the transform of the required current (or other quantity) and $\mathcal{L}[e]$ is the transform of the applied voltage or driving force $e(t)$. The transform of the initial conditions, at $t = 0$, is included in $\psi(p)$.

First considering the case when the system is initially at rest, $\psi(p) = 0$. Writing i_a for the current in this case

$$\mathcal{L}[i_a] = \phi(p)\,\mathcal{L}[e] \qquad \text{(Eq. 9)}$$

Now apply unit impulse $S_0(t)$ (multiplied by 1 volt-second), and designate the circuit current in this case by $B(t)$ and its transform by $\mathcal{L}[B]$. The Laplace transform of $S_0(t)$ is 1, so

$$\mathcal{L}[B] = \phi(p) \qquad \text{(Eq. 10)}$$

Equation (9) becomes, for any driving force

$$\mathcal{L}[i_a] = \mathcal{L}[B]\,\mathcal{L}[e] \qquad \text{(Eq. 11)}$$

Applying the convolution function (Laplace transform)

$$i_a = \int_0^t B(t - \lambda)\, e(\lambda)\, d\lambda$$

$$= \int_0^t B(\lambda)\, e(t - \lambda)\, d\lambda \qquad \text{(Eq. 12)}$$

To this there must be added the current i_0 due to any initial conditions that exist. From (8)

$$\mathcal{L}[i_0] = \psi(p) \qquad \text{(Eq. 13)}$$

Then i_0 is the inverse transform of $\psi(p)$.

Circuit Response Related to Unit Step

Unit step is defined and designated $S_{-1}(t) = 0$ for $t < 0$ and equals unity for $t > 0$. It has no dimensions. Its Laplace transform is $1/p$. Let the circuit current be designated $A(t)$ when the applied voltage is $e = S_{-1}(t) \times$ (1 volt). Then, the current i_a for the case when the

system is initially at rest, and for any applied voltage $e(t)$, is given by any of

$$i_a = A(t)\, e\,(0) + \int_0^t A(t-\lambda)\, e'\,(\lambda)\, d\lambda$$

$$= A(t)\, e\,(0) + \int_0^t A(\lambda)\, e'\,(t-\lambda)\, d\lambda$$

$$= A(0)\, e\,(t) + \int_0^t A'(t-\lambda)\, e\,(\lambda)\, d\lambda$$

$$= A(0)\, e\,(t) + \int_0^t A'\,(\lambda)\, e\,(t-\lambda)\, d\lambda \quad \text{(Eq. 14)}$$

where A' is the first derivative of A and similarly for e' of e.

As an example, consider the problem of Fig. 20 and Eqs. (5) to (7) above. Suppose $V_0 = 0$, and that the battery is replaced by a linear source

$$e(t) = Et/T_1$$

where T_1 is the duration of the voltage rise in seconds. By Eq. (7), setting $E_b = 1$

$$A(t) = 1 - \exp(-t/RC)$$

Then using the first equation in (14) and noting that $e(0) = 0$, and $e'(t) = E/T_1$ when $0 \le t \le T_1$, the solution is

$$v = (Et/T_1) - (ERC/T_1)[1 - \exp(-t/RC)]$$

This result can, of course, be found readily by direct application of the Laplace transform to Eq. (5) with $e(t) = Et/T_1$.

Heaviside Expansion Theorem

When the system is initially at rest, the transformed equation is given by Eq. (9) and may be written

$$\mathcal{L}\,[i_a] = [M(p)/G(p)]\,\mathcal{L}\,[e] \quad \text{(Eq. 15)}$$

$M(p)$ and $G(p)$ are rational functions of p. In the following, $M(p)$ must be of lower degree than $G(p)$, as is usually the case. The roots of $G(p) = 0$ are p_r, where $r = 1, 2, \cdots, n$, and there must be no repeated roots. The response may be found by application of the Heaviside expansion theorem.

For a force $e = E_{max} \exp(j\omega t)$ applied at time $t = 0$

$$\frac{i_a(t)}{E_{max}} = \frac{M(j\omega)}{G(j\omega)} \exp\,(j\omega t) + \sum_{r=1}^{n} \frac{M\,(p_r)\,\exp(p_r t)}{(p_r - j\omega)G'(p_r)} \quad \text{(Eq. 16a)}$$

$$= \frac{\exp(j\omega t)}{Z(j\omega)} + \sum_{r=1}^{n} \frac{\exp(p_r t)}{(p_r - j\omega)Z'(p_r)} \quad \text{(Eq. 16b)}$$

The first term on the right-hand side of either form of (16) gives the steady-state response, and the second term gives the transient. When $e = E_{max} \cos\omega t$, take the real part of (16), and similarly for $\sin\omega t$ take the imaginary part. $Z(p)$ is defined in Eq. (19). If the applied force is the unit step, set $\omega = 0$ in Eq. (16).

Application to Linear Networks

The equation for a single mesh is of the form

$$A_n(d^n i/dt^n) + \cdots + A_1(di/dt) + A_0 i + B \int i\, dt = e(t) \quad \text{(Eq. 17)}$$

System Initially at Rest—Then, Eq. (17) transforms into

$$(A_n p^n + \cdots + A_1 p + A_0 + B_p{}^{-1})\,[i] = [e] \quad \text{(Eq. 18)}$$

where the expression in parentheses is the operational impedance, equal to the alternating-current impedance when we set $p = j\omega$.

If there are m meshes in the system, we get m simultaneous equations like (17) with m unknowns i_1, i_2, $\cdots$, i_m. The m algebraic equations like (18) are solved for $\mathcal{L}\,[i_1]$, etc., by means of determinants, yielding an equation of the form of (15) for each unknown, with a term on the right-hand side for each mesh in which there is a driving force. Each such driving force may of course be treated separately and the responses added.

If any two meshes are designated by the letters h and k, the driving force $e(t)$ being in either mesh and the mesh current $i(t)$ in the other, then the fraction $M(p)/G(p)$ in (15) becomes

$$M_{hk}(p)/G(p) = 1/Z_{hk}(p) = Y_{hk}\,(p) \quad \text{(Eq. 19)}$$

where $Y_{hk}(p)$ is the operational transfer admittance between the two meshes. The determinant of the system is $G(p)$, and $M_{hk}(p)$ is the cofactor of the row and column that represent $e(t)$ and $i(t)$.

System Not Initially at Rest—The transient due to the initial conditions is solved separately and added to the above solution. The driving force is set equal to zero in Eq. (17), $e(t) = 0$, and each term is transformed according to

$$\mathcal{L}\,[d^n i/dt^n] = p^n \mathcal{L}[i] - \sum_{r=1}^{n} p^{n-r}[d^{r-1} i/dt^{r-1}]_{t=0} \quad \text{(Eq. 20a)}$$

$$\mathcal{L}\left[\int_0^t i\, dt\right] = p^{-1}\,\mathcal{L}[i] + p^{-1}\left[\int i\, dt\right]_{t=0} \quad \text{(Eq. 20b)}$$

where the last term in each equation represents the initial conditions. For example, in Eq. (20b) the last term would represent, in an electrical circuit, the quantity of electricity existing on a capacitor at time $t = 0$, the instant when the driving force $e(t)$ begins to act.

Resolution into Partial Fractions—The solution of the operational form of the equations of a system involves rational fractions that must be simplified before the inverse transform is found. Let the fraction be $h(p)/g(p)$ where $h(p)$ is of lower degree than $g(p)$, for example $(3p + 2)/(p^2 + 5p + 8)$. If $h(p)$ is of equal or higher degree than $g(p)$, it can be reduced by division.

The reduced fraction can be expanded into partial fractions. Let the factors of the denominator be $(p - p_r)$ for the n nonrepeated roots p_r of the equation $g(p) = 0$, and $(p - p_a)$ for a root p_a repeated m times.

$$\frac{h(p)}{g(p)} = \sum_{r=1}^{n} \frac{A_r}{p - p_r} + \sum_{r=1}^{m} \frac{B_r}{(p - p_a)^{m-r+1}} \qquad \text{(Eq. 21a)}$$

There is a summation term for each root that is repeated. The constant coefficients A_r and B_r can be evaluated by reforming the fraction with a common denominator. Then the coefficients of each power of p in $h(p)$ and the reformed numerator are equated and the resulting equations solved for the constants. More formally, they may be evaluated by

$$A_r = \frac{h(p_r)}{g'(p_r)} = \left[\frac{h(p)}{g(p)/(p - p_r)}\right]_{p=pr} \qquad \text{(Eq. 21b)}$$

$$B_r = [1/(r - 1)!]f^{(r-1)}(p_a) \qquad \text{(Eq. 21c)}$$

where

$$f(p) = (p - p_a)^m[h(p)/g(p)]$$

and $f^{(r-1)}(p_a)$ indicates that the $(r - 1)$th derivative of $f(p)$ is to be found, after which we set $p = p_a$.

Fractions of the form $(A_1p + A_2)/(p^2 + \omega^2)$ or, more generally

$$\frac{A_1p + A_2}{p^2 + 2ap + b} = \frac{A(p + a) + B\omega}{(p + a)^2 + \omega^2} \qquad \text{(Eq. 22a)}$$

where $b > a^2$ and $\omega^2 = b - a^2$ need not be reduced further. From the Laplace transforms the inverse transform of (22a) is

$$\exp(-at)(A \cos\omega t + B \sin\omega t) \qquad \text{(Eq. 22b)}$$

where

$$A = \frac{h(-a + j\omega)}{g'(-a + j\omega)} + \frac{h(-a - j\omega)}{g'(-a - j\omega)} \qquad \text{(Eq. 22c)}$$

$$B = j\left[\frac{h(-a + j\omega)}{g'(-a + j\omega)} - \frac{h(-a - j\omega)}{g'(-a - j\omega)}\right] \qquad \text{(Eq. 22d)}$$

Similarly, the inverse transform of the fraction

$$[A(p + a) + B\alpha]/[(p + a)^2 - \alpha^2]$$

is $\exp(-at)(A \cosh\alpha t + B \sinh\alpha t)$, where A and B are found by (22c) and (22d), except that $j\omega$ is replaced by α and the coefficient j is omitted in the expression for B.

7 Fourier Waveform Analysis

Revised by
David C. Munson, Jr.

FOURIER TRANSFORM OF A FUNCTION

The Fourier transform, F, of function f is defined by the integral (where x and y are real variables)

$$F(y) = \int_{-\infty}^{\infty} f(x) \exp(-j2\pi xy)\, dx$$

provided this integral exists.

A sufficient, but not necessary, existence condition is that f be absolutely integrable; that is

$$\int_{-\infty}^{\infty} |f(x)|\, dx < \infty$$

An important example of a function that has a Fourier transform even though it is not absolutely integrable is $(\sin x)/x$.

In general, F and f may be complex. Letting $f(x) = f_r(x) + jf_i(x)$, where f_r and f_i are real-valued, one has

$$F(y) = \int_{-\infty}^{\infty} [f_r(x) \cos 2\pi yx + f_i(x) \sin 2\pi yx]dx$$

$$- j \int_{-\infty}^{\infty} [f_r(x) \sin 2\pi yx - f_i(x) \cos 2\pi yx]dx$$

Conversely, the function f, whose Fourier transform is a given function F, is given by the integral (inverse Fourier transform)

$$f(x) = \int_{-\infty}^{\infty} F(y) \exp(j2\pi xy)\, dy$$

where it is assumed that, at points of discontinuity of the integral (if any), the function $f(x)$ is given the value

$$f(x) = [f(x^+) + f(x^-)]/2$$

The functions $f(x^+)$ and $f(x^-)$ are the limits of $f(x + t)$ as t approaches 0 through positive and negative values, respectively.

Letting $F(y) = F_r(y) + jF_i(y)$, one has

$$f(x) = \int_{-\infty}^{\infty} [F_r(y) \cos 2\pi yx - F_i(y) \sin 2\pi yx]dy$$

$$+ j \int_{-\infty}^{\infty} [F_r(y) \sin 2\pi yx + F_i(y) \cos 2\pi yx]dy$$

In many engineering applications it is customary to denote the variable y as "frequency"; in most cases x represents time or space.

If the radian frequency $\omega = 2\pi y$ is introduced as a variable, the definitions of the Fourier transform and of its inverse are written as

$$F(\omega/2\pi) = F_1(\omega)$$

$$= \int_{-\infty}^{\infty} f(x) \exp(-j\omega x)dx$$

$$f(x) = (2\pi)^{-1} \int_{-\infty}^{\infty} F_1(\omega) \exp(j\omega x)d\omega$$

Properties of the Fourier transform are listed in Table 1. Table 2 contains normalized graphs of the Fourier transform (or its magnitude) for a number of common pulse shapes.

FOURIER SERIES

Real Form of Fourier Series

A periodic function with period T, defined by its values in the intervals $-T/2$ to $+T/2$ or 0 to T can be written in a Fourier series expansion as

$$f(x) = (1/2)A_0 + \sum_{n=1}^{\infty} [A_n \cos(n\omega_0 x) + B_n \sin(n\omega_0 x)$$

where $\omega_0 = 2\pi/T$, and the coefficients are given by

$$A_n = (2/T) \int_{-T/2}^{T/2} f(x) \cos(n\omega_0 x)dx$$

$$= (2/T) \int_0^T f(x) \cos(n\omega_0 x)dx$$

$$B_n = (2/T) \int_{-T/2}^{T/2} f(x) \sin(n\omega_0 x)dx$$

$$= (2/T) \int_0^T f(x) \sin(n\omega_0 x)dx$$

for $n = 0, 1, 2, \cdots$.

An alternative form of the above expansion is

$$f(x) = (1/2)C_0 + \sum_{n=1}^{\infty} C_n \cos(n\omega_0 x + \phi_n)$$

where

$$C_0 = A_0$$
$$C_n = (A_n^2 + B_n^2)^{1/2}$$
$$\cos\phi_n = A_n/C_n$$
$$\sin\phi_n = -B_n/C_n$$

Complex Form of Fourier Series

The Fourier series can be written more concisely as

$$f(x) = \sum_{n=1}^{\infty} D_n \exp(jn\omega_0 x)$$

Van Nostrand Co., Inc., 1948. See also Erdélyi, A., ed. *Tables of Integral Transforms*, Vol. 1, Bateman Manuscript Project. New York: McGraw-Hill Book Co., 1954.

where

$$D_n = T^{-1}\int_0^T f(x)\exp(-jn\,\omega_0 x)dx$$

and

$$D_0 = (1/2)A_0 = (1/2)C_0$$
$$D_n = (1/2)(A_n - jB_n)$$
$$D_{-n} = (1/2)(A_n + jB_n)$$

$n = 1, 2, \cdots$.

Average Power

The average power of the periodic waveform $f(x)$ is given by

$$T^{-1}\int_0^T |f(x)|^2 dx = \sum_{n=-\infty}^{+\infty} |D_n|^2$$
$$= (1/4)C_0^2 + (1/2)\sum_{n=1}^{\infty} C_n^2$$
$$= (1/4)A_0^2 + (1/2)\sum_{n=1}^{\infty}(A_n^2 + B_n^2)$$

Odd and Even Functions

If $f(x)$ is an odd function, i.e.,

$$f(x) = -f(-x)$$

then all the coefficients of the cosine terms (A_n) vanish, and the Fourier series consists of sine terms alone.

If $f(x)$ is an even function, i.e.,

$$f(x) = f(-x)$$

then all the coefficients of the sine terms (B_n) vanish, and the Fourier series consists of cosine terms alone, and a possible constant.

The Fourier expansions of functions in general include both cosine and sine terms. Every function capable of Fourier expansion consists of the sum of an even and an odd part.

$$f(x) = \underbrace{(1/2)A_0 + \sum_{n=1}^{\infty} A_n \cos n\omega_0 x}_{\text{even}} + \underbrace{\sum_{n=1}^{\infty} B_n \sin n\omega_0 x}_{\text{odd}}$$

To separate a general function $f(x)$ into its odd and even parts, use

$$f(x) \equiv \underbrace{(1/2)\,[f(x)+f(-x)]}_{\text{even}} + \underbrace{(1/2)\,[f(x) - f(-x)]}_{\text{odd}}$$

In some cases by suitable selection of the origin, the function may be made either odd or even, thus simplifying the expansion.

Odd or Even Harmonics

An odd or even function may contain odd or even harmonics. A condition that causes a function $f(x)$ of

period T to have only odd harmonics in its Fourier expansion is

$$f(x) = -f(x + T/2)$$

A condition that causes a function $f(x)$ of period T to have only even harmonics in the Fourier expansion is

$$f(x) = f(x + T/2)$$

To separate a general function $f(x)$ into its odd and even harmonics, use

$$f(x) \equiv \underbrace{(1/2)[f(x) + f(x + T/2)]}_{\text{even harmonics}} + \underbrace{(1/2)[f(x) - f(x + T/2)]}_{\text{odd harmonics}}$$

A periodic function may sometimes be changed from odd to even (and vice versa) by a shift of the origin, but the presence of particular odd or even harmonics is unchanged by such a shift.

PULSE-TRAIN ANALYSIS

If the pulse defined by the function $g(t)$ is repeated every interval T, a periodic waveform

$$y(t) = \sum_{n=-\infty}^{+\infty} g(t - nT)$$

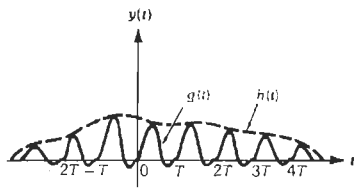
results with period T and repetition frequency $F = 1/T$ (see A and B in Table 3).

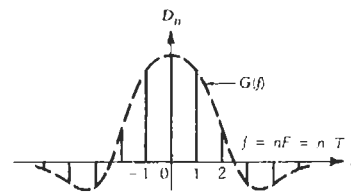
This pulse train may be expressed as a convolution product

$$y(t) = [\sum_{n=-\infty}^{+\infty} \delta(t - nT)] * g(t)$$

and, from application of properties 8 and 10 (Table 1), its Fourier transform is

TABLE 3. THE SPECTRUM FOR PULSE TRAIN*

Waveform	Spectrum
A. Single pulse	
	B. Infinite periodic pulse train	
	C. Limited pulse train	
	




* Spectra are in general complex functions. They are represented here by real curves only to simplify the illustration.

$$Y(f) = (1/T)\left[\sum_{n=-\infty}^{+\infty} \delta(f - nF)\right] G(f)$$

The function $y(t)$ is represented by the Fourier series

$$y(t) = \sum_{n=-\infty}^{+\infty} D_n \exp(jn\omega_0 t)$$

where

$$D_n = (1/T)G(nF)$$

The coefficients D_n are obtained by sampling the pulse spectrum at frequencies that are multiples of the repetition frequency.

The amplitude C_n of the nth harmonic in the real representation (see subsection headed "Real Form of Fourier Series" earlier in this chapter) is

$$C_n = 2|D_n| = (2/T)\,|G(nF)|$$

The constant term of the series

$$D_0 = A_0/2 = C_0/2$$

is the average amplitude

$$A_{av} = \mathcal{A}\,T = G(0)/T$$

where

$$\mathcal{A} = \int_0^T g(t)dt$$

is the area under one pulse.

If the pulses do not overlap (i.e., if function $g(t)$ is zero outside of some period a to $a + T$), the energy in a pulse is

$$E = \int_a^{a+T} g^2(t)dt = \int_{-\infty}^{+\infty} |G(f)|^2\, df$$

The root-mean-square amplitude is

$$A_{rms} = (E/T)^{1/2}$$

The average power of the pulse train is

$$E/T = A_{rms}^2 = \sum_{n=-\infty}^{+\infty} |D_n|^2$$

$$= (1/4)\,C_0^2 + (1/2)\sum_{n=1}^{+\infty} C_n^2$$

A pulse train of finite extent, where all pulses have the same shape and are spaced periodically, may be represented as a product

$$y(t) = h(t)\sum_{n=-\infty}^{+\infty} g(t - nT)$$

The function $h(t)$ defines the envelope of the pulse train.

The Fourier transform

$$Y(f) = (1/T)\sum_{n=-\infty}^{+\infty} G(nF)H(f - nF)$$

is given by a weighted sum of shifted Fourier transforms of $h(t)$. If $h(t) = 1$, then $H(f)$ is the δ function and the pulse train is a periodic waveform having a line spectrum as in B of Table 3. However, if $h(t)$ does not have infinite support, then this line spectrum is broadened. If $h(t)$ has support over a large number of periods T, so that $H(f)$ is narrow compared to F, then $Y(f)$ is approximately as shown in C of Table 3 where the envelope is $G(f)$ and each pulse is a scaled, shifted version of $H(f)$.

The Fourier series coefficients for a number of commonly encountered pulse trains are given in Table 4.

SPECTRAL ANALYSIS

If $g(t)$ is band-limited and also nearly time-limited, then approximate samples of its Fourier transform $G(f)$ can be computed from samples of $g(t)$ by using the discrete Fourier transform (DFT). The DFT of the sampled sequence $\{g(nT_s)\}_{n=0}^{N-1}$ is defined by

$$G_m = \sum_{n=0}^{N-1} g(nT_s)\exp[-j(2\pi/N)nm]$$

$$m = 0, \ldots, N-1$$

If the sampling frequency $1/T_s$ is greater than twice the highest frequency contained in $g(t)$, and if $g(t)$ is nearly zero outside the interval $[0, (N-1)T_s]$, then it can be shown that

$$G_m \approx \begin{cases} (1/T_s)\,G\left(\dfrac{m}{NT_s}\right) & 0 \le m < N/2 \\ (1/T_s)\,G\left(\dfrac{m-N}{NT_s}\right) & N/2 \le m \le N-1 \end{cases}$$

where the argument of the Fourier transform G is in hertz. Ordinarily $g(t)$ is not time-limited, and only a finite-length section of $g(t)$ can be sampled and processed. This places a limit on achievable spectral resolution.

For additional discussion, including implementation of the DFT using the fast Fourier transform (FFT) algorithm, see Chapter 28.

TABLE 4. PERIODIC WAVEFORMS AND FOURIER SERIES

Waveform	Coefficient of Fourier Series
A. Rectangular wave	$C_n=2D_n=2A_{Av}\left\lvert\frac{\sin(n\pi t_0/T)}{n\pi t_0/T}\right\rvert$
	Can be read off curve of $(\sin x)/x$, A in Table 2, by sampling at $n\pi t_0/T$
	Example: If $T=2t_0$
	$y(t)=2A_{Av}[\frac{1}{2}+(2/\pi)\cos\theta-(2/3\pi)\cos3\theta+\cdots]$
	where $\theta=2\pi t/T$
Derived from rectangular pulse, A in Table 2	
$A_{Av}=A(t_0/T)$ $A_{rms}=A(t_0/T)^{1/2}$	
B. Isosceles-triangle wave	$C_n=2A_{Av}\left(\frac{\sin(n\pi t_1/T)}{n\pi t_1/T}\right)^2$
	Example: If $T=2t_1$
	$y(t)=2A_{Av}[\frac{1}{2}+(2/\pi)^2\cos\theta+(2/3\pi)^2\cos3\theta+\cdots]$
	where $\theta=2\pi t/T$
Derived from triangular pulse, B in Table 2	
$A_{AV}=A(t_1/T)$ $A_{rms}=A(2t_1/3T)^{1/2}$	
C. Sawtooth wave	$C_n=2A_{Av}(1/\pi n)$
	$y(t)=2A_{Av}[\frac{1}{2}-(1/\pi)\sin\theta-(1/2\pi)\sin2\theta-\cdots]$
Derived from triangular pulse, C in Table 2	
$A_{Av}=A/2$ $A_{rms}=A(3^{-1/2})$	
D. Clipped sawtooth wave	$C_n=2A_{Av}(1/\alpha^2)[\sin^2\alpha+\alpha(\alpha-\sin2\alpha)]^{1/2}$
	where $\alpha=n\pi t_0/T$
Derived from triangular pulse, C in Table 2	
$A_{Av}=A(t_0/2T)$ $A_{rms}=A(t_0/3T)^{1/2}$	

Continued on next page.

TABLE 4 (CONT). PERIODIC WAVEFORMS AND FOURIER SERIES

Waveform	Coefficient of Fourier Series
E. Sawtooth wave  Derived from the sum of two triangular pulses, C in Table 2 $A_{Av} = A/2 \quad A_{rms} = A(3^{-1/2})$	$C_n = 2A_{Av}(T^2/\pi^2 n^2 t_1 t_2)\lvert\sin(n\pi t_1/T)\rvert$ where $t_1+t_2=T$
F. Symmetrical trapezoidal wave  Derived as in D in Table 2 $A_{Av} = A[(t_0+t_1)/T]$ $A_{rms} = A[(3t_0+2t_1)/3T]^{1/2}$	$D_n = A_{Av}\dfrac{\sin(\pi nt_1/T)}{\pi nt_1/T}\dfrac{\sin[\pi n(t_1+t_0)/T]}{\pi n(t_1+t_0)/T}$ $C_n = 2\lvert D_n\rvert$
G. Train of cosine pulses  Derived from cosine pulse, E in Table 2 $A_{Av} = (2/\pi)A(t_0/T) \quad A_{rms} = A(t_0/2T)^{1/2}$	$C_n = 2A_{Av}\left\lvert\dfrac{\cos(n\pi t_0/T)}{1-(2nt_0/T)^2}\right\rvert$ For $nt_0T=1/2$, this becomes $\pi A_{Av}/2$
H. Full-wave-rectified sine wave  Derived from cosine pulse, E in Table 2 (same as G in Table 4 with $t_0 = T$) $A_{AV} = (2/\pi)A \quad A_{rms} = A/(2^{1/2})$	$C_0 = 2A_{Av}$ $C_n = 2A_{Av}(4n^2-1)^{-1}$, for $n\neq 0$ $y(t) = 2A_{Av}[1/2+(1/3)\cos\theta-(1/15)\cos2\theta+(1/35)\cos3\theta\cdots$ $-(-1)^n(4n^2-1)^{-1}\cos n\theta\cdots]$ where $\theta = 2\pi t/T$

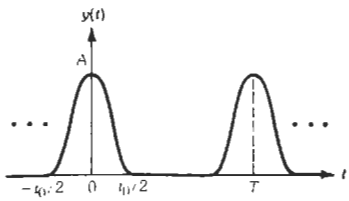
$C_{2n}=2A_{Av}(4n^2-1)^{-1}$, for $n\neq 0$

$y(t)=2A_{Av}[1/2+(\pi/4)\cos\theta+(1/3)\cos 2\theta-(1/15)\cos 4\theta+\cdots$
$-(-1)^n(4n^2-1)^{-1}\cos 2n\theta\cdots]$

Derived from cosine pulse, E in Table 2 (same as G in Table 4 with $t_0=T/2$)

$A_{Av}=(1/\pi)A \qquad A_{rms}=A/2$

J. Train of cosine-squared pulses

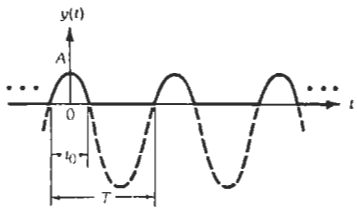


$$C_n = 2A_{Av}\left|\frac{\sin(n\pi t_0/T)}{(n\pi t_0/T)[1-(nt_0/T)^2]}\right|$$

Derived from cosine-squared pulse, F in Table 2

$A_{Av} = (1/2)A(t_0/T) \qquad A_{rms} = (1/2)4(3t_0/2T)^{1/2}$

K. Fractional sine wave



$$C_n = 2A_{Av}\left|\frac{\sin n\alpha\cos\alpha - n\sin\alpha\cos n\alpha}{n(n^2-1)(\sin\alpha-\alpha\cos\alpha)}\right|$$

$$A_{Av} = \frac{A}{\pi}\frac{\sin\alpha-\alpha\cos\alpha}{1-\cos\alpha}$$

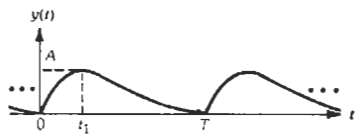
when $n = 1$,

$$C_1 = A_{Av}\left|\frac{\alpha-\cos\alpha\sin\alpha}{\sin\alpha-\alpha\cos\alpha}\right|$$

$$A_{rms} = \frac{A}{(2\pi)^{1/2}}\frac{[2\alpha+\alpha\cos 2\alpha-(3/2)\sin 2\alpha]^{1/2}}{1-\cos\alpha}$$

where $\alpha = \pi t_0/T$

L. Critically damped exponential wave



$$C_n = 2A_{Av}[1+(2\pi nt_1/T)^2]^{-1}$$
$$= 2A_{Av}\cos^2\theta_n$$

where $\tan\theta_n = 2\pi nt_1/T$

Derived from exponential pulse, H in Table 2 (period $T >>$ period t_1 to make overlap negligible)

$A_{Av} = Ae(t_1/T) \qquad A_{rms} = (Ae/2)(t_1/T)^{1/2}$

$e=2.71828\cdots$

8 Filters, Simple Bandpass Design

COEFFICIENT OF COUPLING

Several types of coupled circuits are shown in Table 1 (pages 8-4 and 8-5) and Figs. 1 and 2, together with equations for the coefficient of coupling. Also shown is the dependence of bandwidth on resonance frequency. This dependence is only a rough approximation to show the trend and may be altered radically if L_m, M, or C_m is adjusted in tuning to various frequencies.

K_{12} = coefficient of coupling between resonant circuits
X_{10} = reactance of inductor (or capacitor) of first circuit at f_0
X_{20} = reactance of similar element of second circuit at f_0
$(\text{bw})_C$ = bandwidth with capacitive tuning
$(\text{bw})_L$ = bandwidth with inductive tuning

GAIN AT RESONANCE

Single Circuit

In Table 1A

$$E_0/E_g = -g_m|X_{10}|Q$$

where,

E_0 = output volts at resonance frequency f_0,
E_g = input volts to active device,
g_m = transconductance of active device.

Pair of Coupled Circuits

Pairs of coupled circuits are illustrated in Figs. 3 and 4.

In B through F in Table 1

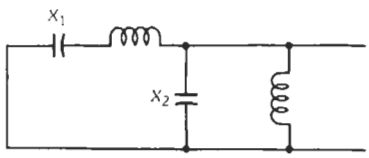
$$E_0/E_g = jg_m(X_{10}X_{20})^{1/2}Q[K_{12}Q/(1 + K_{12}^2Q^2)]$$

This is maximum at critical coupling, where $K_{12}Q = 1$.

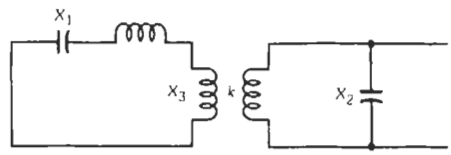
$Q = (Q_1Q_2)^{1/2}$ = geometric-mean Q for the two circuits, as loaded with active device input and output impedances

For circuits with critical coupling and overcoupling, the approximate gain is

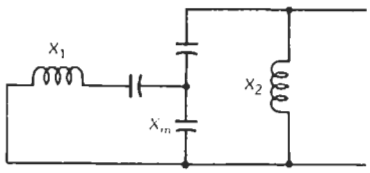
$$|E_0/E_g| \approx 0.1g_m/(C_1C_2)^{1/2}(\text{bw})$$



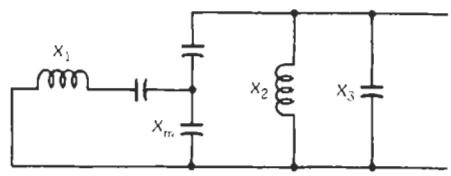
$K_{12} = (X_2/X_1)^{1/2} = (L_2/L_1)^{1/2} = (C_1/C_2)^{1/2}$



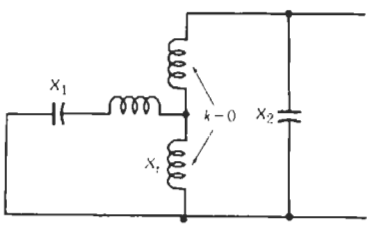
$K_{12} = k(X_3/X_1)^{1/2}$



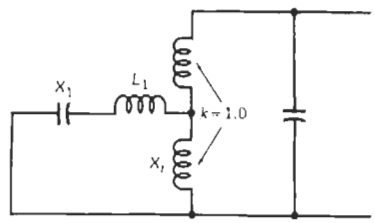
$K_{12} = X_m/(X_1X_2)^{1/2}$



$K_{12} = (X_m/(X_1X_2)^{1/2})(1 - X_2/X_3)$



$K_{12} = X_t/(X_1X_2)^{1/2}$



$K_{12} = (X_t/X_1)^{1/2} = (L_t/L_1)^{1/2}$

Fig. 1. Additional coefficient-of-coupling configurations (the node resonator is tuned to the desired midfrequency with the mesh resonator open-circuited, or the mesh resonator is tuned to this midfrequency with the node resonator short-circuited).

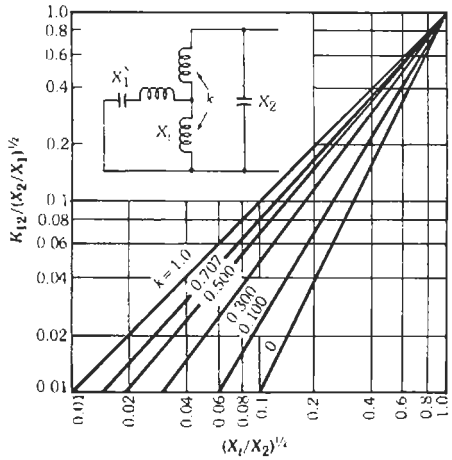


Fig. 2. Coefficient of coupling for configuration shown.

where,

(bw) is the useful passband in megahertz,
g_m is in micromhos,
C is in picofarads.

SELECTIVITY FAR FROM RESONANCE

The selectivity curves of Fig. 5 are based on the presence of only a single type of coupling between the circuits. The curves are useful beyond the peak region treated in the section on selectivity near resonance.

In the equations for selectivity in Table 1

E = output volts at signal frequency f for same value of E_g as that producing E_0

For Inductive Coupling

$$A = \frac{Q^2}{1 + K_{12}^2 Q^2}\left[\left(\frac{f}{f_0} - \frac{f_0}{f}\right)^2 - K_{12}^2\left(\frac{f}{f_0}\right)^2\right]$$

$$\approx \frac{Q^2}{1 + K_{12}^2 Q^2}\left(\frac{f}{f_0} - \frac{f_0}{f}\right)^2$$

For Capacitive Coupling

A similar equation for A applies, except that the neglected term is $-K_{12}^2(f_0/f)^2$. The 180-degree phase shift far from resonance is indicated by the minus sign in the expression for E_0/E.

Example. The use of the curves in Figs. 5, 6, and 7 is indicated by the following example. Given the circuit of Table 1C with input to PB across capacitor C_1. Let $Q = 50$, $K_{12}Q = 1.50$, and $f_0 = 16.0$ megahertz. Required is the response at $f = 8.0$ megahertz.

Here, $f/f_0 = 0.50$ and curve C, Fig. 5, gives -75 decibels. Then applying the corrections from Figs. 6 and 7 for Q and $K_{12}Q$, we find

Response $= -75 + 12 + 4 = -59$ decibels

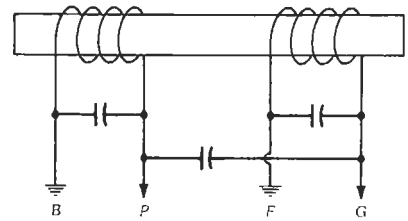

Fig. 3. Connection wherein k_m opposes k_c (k_c may be due to stray capacitance). Peak of attenuation is at $f = f_0(-k_m/k_c)^{1/2}$. Reversing connections or winding direction of one coil causes k_m to aid k_c.

SELECTIVITY OF SINGLE- AND DOUBLE-TUNED CIRCUITS NEAR RESONANCE

Equations and curves are presented for the selectivity and phase shift of n single-tuned circuits and of m pairs of coupled tuned circuits. The conditions assumed are

(A) All circuits are tuned to the same frequency, f_0.
(B) All circuits have the same Q, or each pair of circuits includes one circuit having Q_1 and the other having Q_2.
(C) Otherwise the circuits need not be identical.
(D) Each successive circuit or pair of circuits is isolated from the preceding and following ones by active devices, with no regeneration around the system.

Certain approximations have been made to simplify the equations. In most actual applications of the types of circuits treated, the error involved is negligible from a practical standpoint. Over the narrow frequency band in question, it is assumed that

(A) The reactance around each circuit is equal to $2X_0\Delta f/f_0$.
(B) The resistance of each circuit is constant and equal to X_0/Q.
(C) The coupling between two circuits of a pair is reactive and constant. (When an untuned link is used to couple the two circuits, this condition frequently is far from satisfied, resulting in a lopsided selectivity curve.)
(D) The equivalent input voltage, taken as being in series with the tuned circuit (or the first of a

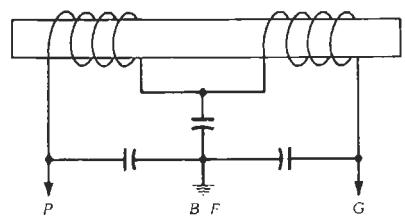

Fig. 4. Connection wherein k_m aids k_c. If mutual-inductance coupling is reversed, k_m will oppose k_c and there will be a transfer minimum at $f = f_0(-k_m/k_c)^{1/2}$.

pair), is assumed to bear a constant proportionality to the input voltage of the active device or other driving source, at all frequencies in the band.

(E) Likewise, the output voltage across the circuit (or the final circuit of a pair) is assumed to be proportional only to the current in the circuit.

The following symbols are used in the equations in addition to those defined previously:

$\Delta f/f_0 = (f - f_0)/f_0$ = (deviation from resonance frequency)/(resonance frequency)

(bw) = bandwidth $= 2\Delta f$

X_0 = reactance at f_0 of inductor in tuned circuit

n = number of single-tuned circuits

m = number of pairs of coupled circuits

ϕ = phase shift of signal at f relative to shift at f_0 as signal passes through cascade of circuits

$p = K_{12}^2Q^2$ or $p = K_{12}^2Q_1Q_2$, a parameter determining the form of the selectivity curve of coupled circuits

$B = p - (1/2)[(Q_1/Q_2) + (Q_2/Q_1)]$

Selectivity and Phase Shift of Single-Tuned Circuits

The configuration of a single-tuned circuit is shown in Fig. 8.

$$E/E_0 = \{[1 + (2Q\Delta f/f_0)^2]^{-1/2}\}^n$$

$$\Delta f/f_0 = \pm(2Q)^{-1}[(E_0/E)^{2/n} - 1]^{1/2}$$

Decibel response $= 20 \log_{10}(E/E_0)$

(dB response of n circuits) $= n \times$ (dB response of single circuit)

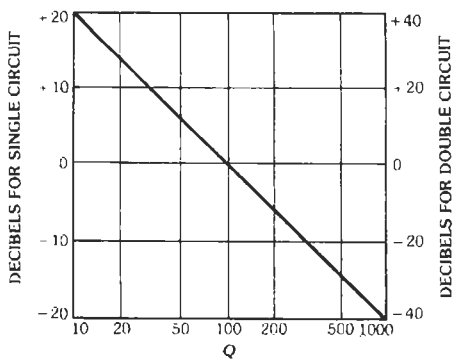

Fig. 6. Correction for $Q \neq 100$.

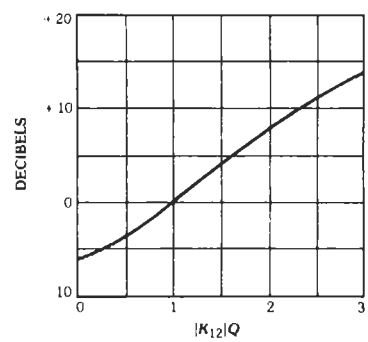

Fig. 7. Correction for $|K_{12}|\ Q \neq 1.0$.

Fig. 8. Single-tuned circuit.

$$\phi = n \tan^{-1} (-2Q\Delta f/f_0)$$

These equations are plotted in Figs. 9 and 10.

Example of the use of Figs. 9 and 10: Suppose there are three single-tuned circuits ($n = 3$). Each circuit has a Q of 200 and is tuned to 1000 kilohertz. The results are shown in Table 2.

Q Determination by 3-Decibel Points

For a single-tuned circuit, when

$E/E_0 = 0.707$ (3 decibels down)

$$Q = f_0/2\Delta f$$

$$= (\text{resonance frequency})/(\text{bandwidth})_{3dB}$$

Selectivity and Phase Shift of Pairs of Coupled Tuned Circuits

An example of a pair of coupled tuned circuits is shown in Fig. 11.

CASE 1: When $Q_1 = Q_2 = Q$:

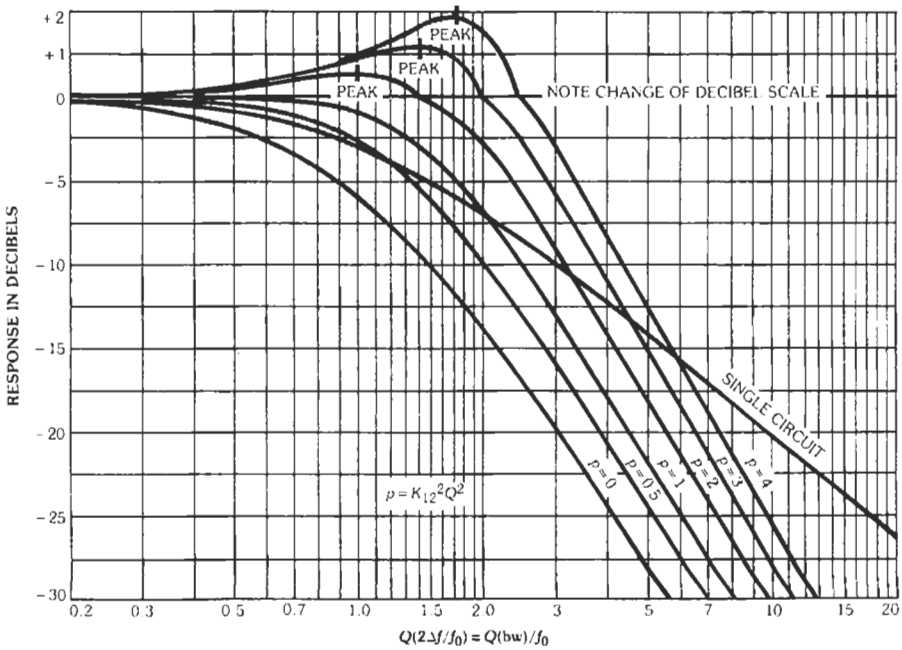
These equations can be used with reasonable accuracy when Q_1 and Q_2 differ by ratios up to 1.5 or even 2 to 1. In such cases, use the value $Q = (Q_1 Q_2)^{1/2}$.

$$E/E_0 = \left[\frac{p+1}{\{[(2Q\Delta f/f_0)^2 - (p-1)]^2 + 4p\}^{1/2}}\right]^m$$

$$\Delta f/f_0 = \pm(2Q)^{-1} \times \{(p-1) \pm [(p+1)^2(E_0/E)^{2/m} - 4p]^{1/2}\}^{1/2}$$

For very small values of E/E_0,

$$E/E_0 = [(p+1)/(2Q\Delta f/f_0)^2]^m$$



The selectivity curves are symmetrical about the axis $Q\Delta f/f_0 = 0$ for practical purposes. Extrapolation beyond lower limits of chart:

Δ Response for Doubling Δf	Circuit	Useful Limit at (bw)/f_0	Error becomes
- 6 dB	— single —	0.6	1 to 2 dB
- 12 dB	- pair —	0.4	3 to 4 dB

Fig. 9. Selectivity curves showing response of a single circuit, $n = 1$, and a pair of coupled circuits, $m = 1$.

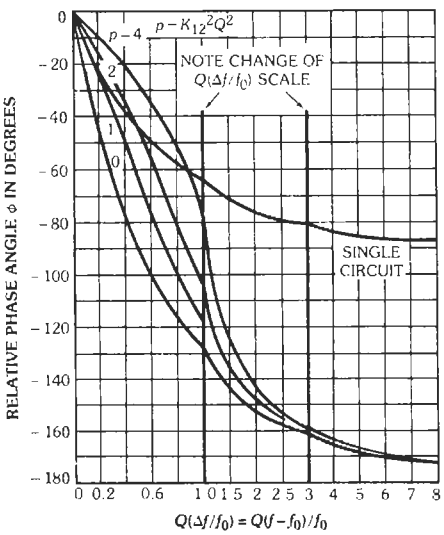


Fig. 10. Phase-shift curves for a single circuit, $n = 1$, and a pair of coupled circuits, $m = 1$. For $f > f_0$, ϕ is negative, while for $f < f_0$, ϕ is positive. The numerical value is identical in either case for the same $|f - f_0|$.

Decibel response $= 20 \log_{10}(E/E_0)$

(dB response of m pairs of circuits) $= m \times$ (dB response of one pair)

$$\phi = m \tan^{-1}\left[\frac{-4Q\Delta f/f_0}{(p+1) - (2Q\Delta f/f_0)^2}\right]$$

As p approaches zero, the selectivity and phase shift approach the values for n single circuits, where $n = 2m$ (gain also approaches zero).

The above equations are plotted in Figs. 9 and 10.

For Overcoupled Circuits ($p > 1$):
Location of peaks:

$$(f_{peak} - f_0)/f_0 = \pm(2Q)^{-1}(p-1)^{1/2}$$

Amplitude of peaks:

$$E_{peak}/E_0 = [(p+1)/2(p^{1/2})]^m$$

Phase shift at peaks:

$$\phi_{peak} = m \tan^{-1}[\mp(p-1)^{1/2}]$$

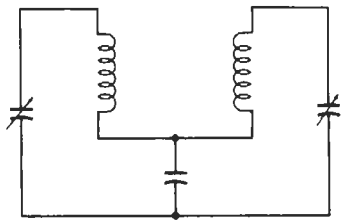

Fig. 11. One of several types of coupling.

Approximate passband (where $E/E_0 = 1$) is

$$(f_{unity} - f_0)/f_0 = \sqrt{2}\,[(f_{peak} - f_0)/f_0]$$
$$= \pm Q^{-1}[(1/2)(p-1)]^{1/2}$$

CASE 2: General equation for any Q_1 and Q_2:

$$E/E_0 = \left[\frac{p+1}{\{[(2Q\Delta f_0/f_0)^2 - B]^2 + (p+1)^2 - B^2\}^{1/2}}\right]^m$$

$$B = p - (1/2)|(Q_1/Q_2) + (Q_2/Q_1)|$$

$$\Delta f/f_0 = \pm(2Q)^{-1}$$
$$\times \{B \pm [(p+1)^2(E_0/E)^{2/m} - (p+1)^2 + B^2]^{1/2}\}^{1/2}$$

$$\phi = m \tan^{-1}$$
$$\times \left(-\frac{2Q\,\Delta f/f_0|(Q_1/Q_2)^{1/2} + (Q_2/Q_1)^{1/2}|}{(p+1) - (2Q\,\Delta f/f_0)^2}\right)$$

For Overcoupled Circuits:
Location of peaks:

$$(f_{peak} - f_0)/f_0 = \pm B^{1/2}/2Q$$
$$= \pm(1/2)|K_{12}^2 - (1/2)(1/Q_1^2 + 1/Q_2^2)]^{1/2}$$

Amplitude of peaks:

$$E_{peak}/E_0 = \{(p+1)/[(p+1)^2 - B^2]^{1/2}\}^m$$

CASE 3: Peaks just converged to a single peak:

Here $B = 0$ or $K_{12}^2 = (1/2)(1/Q_1^2 + 1/Q_2^2)$

$$E/E_0 = \{(2/[(2Q'\Delta f/f_0)^4 + 4]^{1/2}\}^m$$

TABLE 2. EXAMPLE OF USE OF FIGS. 9 AND 10

Abscissa $Q(\text{bw})/f_0$	Bandwidth (kilohertz)	Ordinate dB Response for $n=1$	Decibels Response for $n=3$	ϕ^* for $n=1$	ϕ for $n=3$
1.0	5.0	−3.0	−9	∓45°	∓135°
3.0	15	−10.0	−30	∓71½°	∓215°
10.0	50	−20.2	−61	∓84°	∓252°

* ϕ is negative for $f > f_0$, and vice versa.

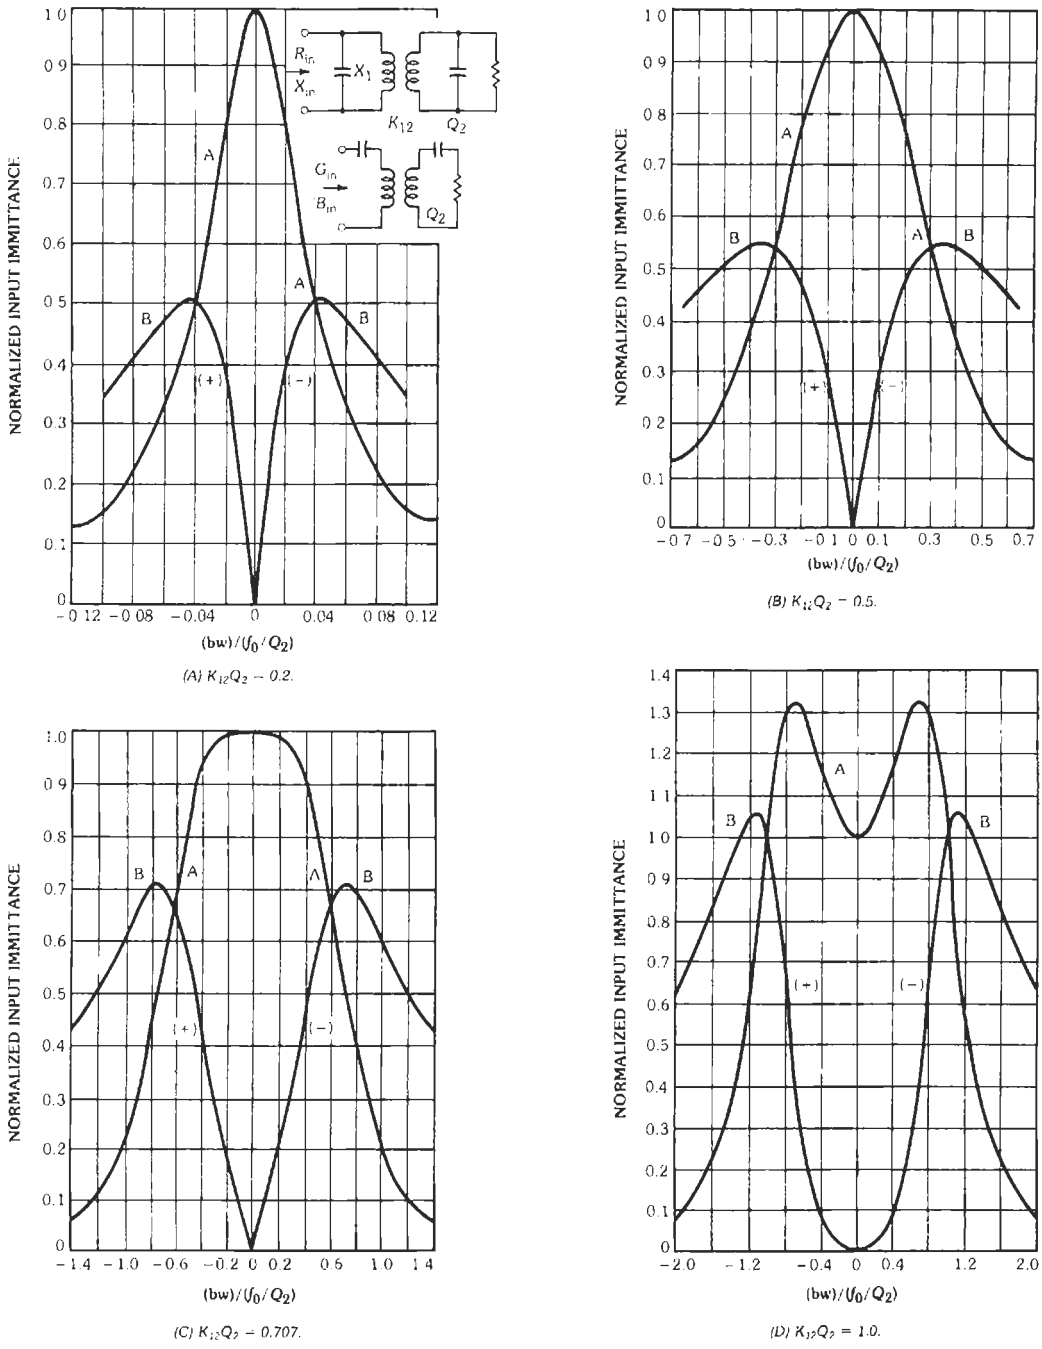

Fig. 12. Normalized input immittance versus normalized frequency of double-tuned circuits. $A = R_{in}/(X_1/K_{12}^2Q_2)$ or $G_{in}/(B_1/K_{12}^2Q_2)$. $B = X_{in}/(X_1/K_{12}^2Q_2)$ or $B_{in}/(B_1/K_{12}^2Q_2)$.

where,

$$Q' = 2Q_1Q_2/(Q_1 + Q_2)$$

$$\Delta f/f_0 = \pm(\sqrt{2}/4)(1/Q_1 + 1/Q_2)[(E_0/E)^{2/m} - 1]^{1/4}$$

$$\phi = m \tan^{-1}\left[-\frac{4Q'\,\Delta f/f_0}{2 - (2Q'\,\Delta f/f_0)^2}\right]$$

The curves of Figs. 9 and 10 may be applied to this case, using the value $p = 1$ and substituting Q' for Q.

NODE INPUT IMPEDANCE OR MESH INPUT ADMITTANCE OF A DOUBLE-TUNED CIRCUIT

Fig. 12 gives the normalized input immittance versus the normalized frequency of double-tuned circuits.

9 Filters, Modern-Network-Theory Design

Ford Shepherd

In contrast to filter design by image-parameter methods, the design of filters by the use of modern network theory is a domain for specialists with digital computers because of the complex calculations required. There are sufficient advantages of filter circuits computed by this method, however, to warrant making some application of them easy and straightforward. This chapter focuses on a very limited subset of the limitless possibilities for low-pass networks and simple transform methods to allow calculation of high-pass, bandpass, and band-stop circuits.

The design information is drawn from experience in the application of modern network theory to the design of electric wave filters. As stated above, only limited design results are supplied, and a concentrated study of the cited references is essential to gain a working knowledge of the synthesis process through which these results were computed. References 1, 4, and 6 provide details of the design theory. Reference 5 provides a concise summary of the theory with graphs and tables to enable an engineer to compute filter circuits with the help of a computer program.

Reference 2 provides a much larger tabulation of Cauer-parameter and Chebyshev filter networks up to degree 9, and Saal has also produced another volume that extends to degree 15. Reference 3 presents many practical ideas (drawn from a 25-year career in Europe and the USA) on designing, testing, and manufacturing filters and mentions two of the computer programs that are available. Many books and articles written on this subject since the work of Cauer and Darlington in the late 1930s are more than worthy of mention here. However, the scope of this chapter and the space available do not necessitate nor permit a detailed discussion. Reference 7 is an example of some of the work done toward practical implementation of these filter networks with standard-value capacitors.

No attempt has been made to present details of the theory and formulation involved, of the approximation of transfer polynomials to performance requirements, or the very useful but less frequently required topics such as zero and infinite terminations, phase and delay performance, and the effects of and compensation for the losses in real coils and capacitors.

INTRODUCTION

Filter networks continue to be of great importance in the design of electrical equipment, especially in communication engineering. Unlike previous methodologies to design spectrum-shaping networks, modern network theory enables the engineer to design filter networks that are based on the actual requirements for signal transmission. While image-parameter design is rather simplistic, only a very limited approximation of the specific requirements can be achieved. Today's methods are not so straightforward and are generally considered beyond the scope of nonspecialists, since the mathematical design process does not directly parallel physical conceptions and the calculations are complex and extensive. The development of digital computers has led to the capture of much of the knowledge of the specialist and the complex calculation algorithms into programs that allow many engineers to design some of their own networks. Still, the sophisticated requirements necessitate the special expert.

Many of the less complex requirements can be satisfied by designs that can be done with the procedures described here and without access to the computer programs. To accomplish this task, the requirements for all the filter types considered here (low-pass, high-pass, bandpass and band-stop) are transformed to a set of reference low-pass requirements. From the reference low-pass requirements, the network complexity is determined, and a normalized reference low-pass is selected. Then the suitable transformation is applied to this low-pass to arrive at the network to satisfy the initial requirements.

Fig. 1 shows a "reasonably typical" requirement for a filter network. To satisfy this requirement with the minimum network, it is necessary to use one of the available computer programs. However, it is possible to satisfy the modified requirements, as shown in Fig. 2, by the simple computations of this chapter. The requirements depicted by the tolerance plot of Fig. 2 can be transformed to the basic reference low-pass tolerance plot shown by Fig. 3 with $A_p = A_1$ and $A_s = A_6$. The algorithm for this transform is covered in the section headed "The Reference Low-Pass."

NORMALIZATION

To simplify the calculations, frequencies are normalized with respect to some reference frequency, f_{ref}, and the impedances are normalized with respect to a refer-

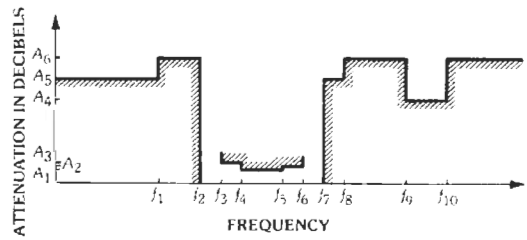

Fig. 1. Requirement for a filter network.

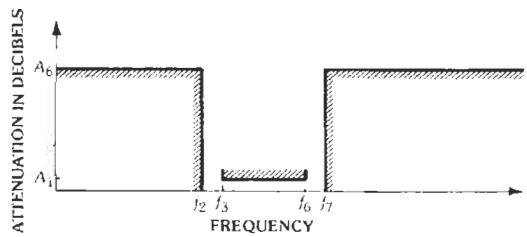

Fig. 2. Modified requirements for filter network.

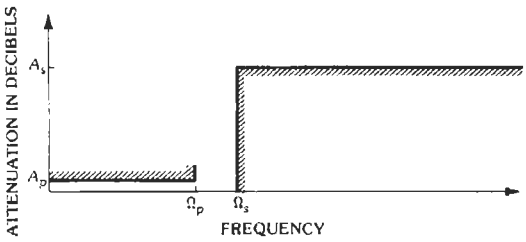

Fig. 3. Basic reference low-pass tolerance plot.

ence resistance, R_{ref}. Hence, normalized frequencies are defined by $\Omega_i = f_i/f_{ref}$, and the normalized resistances are defined by $r_i = R_i/R_{ref}$.

In the case of low-pass filters, it is appropriate to use the upper edge of the passband (or cutoff frequency), f_p, as the reference frequency (hence, $\Omega_p = 1.0$) and use the input resistance, R_1, as the reference resistance ($r_1 = 1.0$).

Conversely, all normalized data of a circuit can be converted to any frequency range and any impedance level by selection of f_{ref} and R_{ref}. By defining

$$L_{ref} = R_{ref}/2\pi f_{ref}$$

and

$$C_{ref} = 1/2\pi f_{ref} R_{ref}$$

the entire circuit can be computed for the appropriate range of frequency and impedance.

$$R_i = r_i \cdot R_{ref} \text{ (ohms)}$$

$$f_i = \Omega_i \cdot F_{ref} \text{ (hertz)}$$

$$L_i = l_i \cdot L_{ref} \text{ (henrys)}$$

$$C_i = c_i \cdot C_{ref} \text{ (farads)}$$

THE REFERENCE LOW-PASS

Fig. 4 shows a normal tolerance plot of the requirements for a low-pass filter. Also shown are the associated formulas to calculate the quantities for the reference low-pass of Fig. 3. With $f_{ref} = f_p$ ($\Omega_p = 1.0$), three

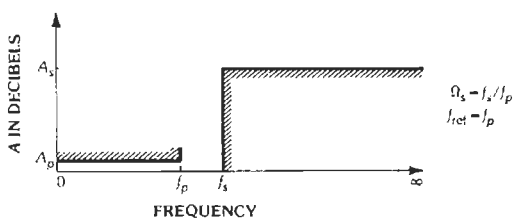

Fig. 4. Requirements for a low-pass filter.

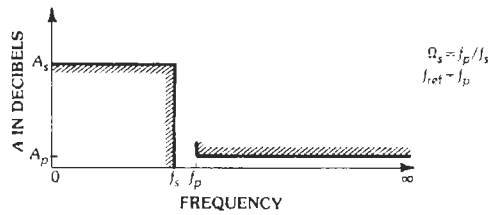

Fig. 5. Requirements for a high-pass filter.

parameters are required: (1) $\Omega_s = f_s/f_{ref}$; (2) A_p (decibels), the maximum acceptable ripple in the passband; and (3) A_s (decibels), the minimum attenuation in the stopband.

Fig. 5 shows a tolerance plot of requirements for a high-pass filter. Also shown are the equations to determine the reference low-pass parameters.

Fig. 6 shows a tolerance plot of requirements for a bandpass filter, together with the equations to resolve the parameters for the reference low-pass. Note that geometric symmetry is required for both stopband and passband limits. Generally, an "over-design" will result for one or more of the frequencies.

Fig. 7 shows the tolerance plot of the requirements for a band-stop network, together with the associated equations to calculate the reference low-pass parameters. Again, symmetry is required as for the bandpass case.

In both the bandpass and band-stop equations, a transformation factor, a, is defined and is needed for transforming the reference low-pass into the desired circuit.

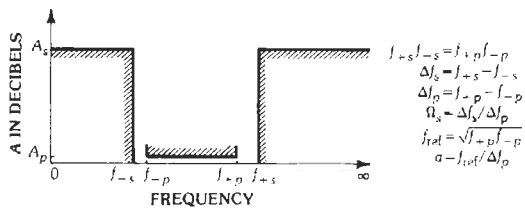

Fig. 6. Requirements for a bandpass filter.

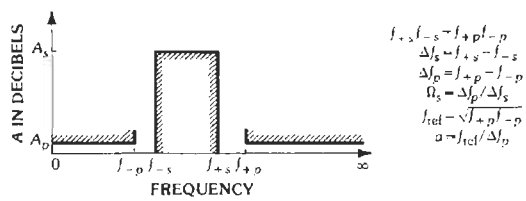

Fig. 7. Requirements for a band-stop network.

CAUER-PARAMETER LOW-PASS FILTERS

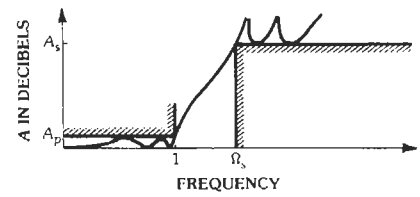
Probably the most important type of low-pass filter is the elliptic-function, or Cauer-parameter, network, which provides equal attenuation maxima in the passband region and equal attenuation minima in the stopband. Fig. 8 shows the attenuation versus frequency performance and the two possible circuit configurations for this type of filter when the degree is odd.

While the attenuation maximum (A_p) in the passband region is one of the parameters necessary to determine the reference low-pass, practical experience is that filter networks are terminated with other transmission networks within a system rather than pure resistances. The transmission quality through these networks connected to filters is adversely affected by excessive variations in the impedance of the filter network. The maximum variation of the input impedance, and consequently the related reflection coefficient (ρ), in the passband of a filter designed with elliptic functions is directly related to the variation in attenuation (A_p) by

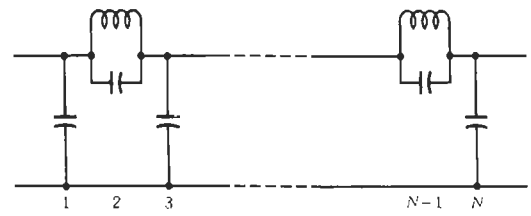
$$A_p = -\ln \sqrt{1 - \rho^2}$$

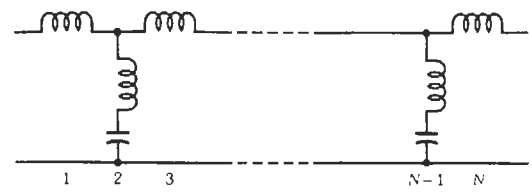
Normally, the attenuation maximum related to the allowable reflection coefficient is so small that it cannot be measured by practical means and is, in fact, masked by the component losses. Table 1 shows the relationships among A_p, ρ, and return loss in networks with equal passband variations of attenuation.

Tables 2 through 8 include normalized Cauer-parameter low-pass filters of degree 3 through 9 with reflection coefficients of 2, 5, 10, and 25 percent. For each reflection coefficient, ten different cutoff rates, and



(A) Performance.





(B) Configurations.

hence ten different stopband minima, are tabulated. In fact, any finer graduation of cutoff sharpness can be computed, and in several publications (Reference 2) the fine graduation is by integer degree of the modular angle, θ ($0° \leq \theta \leq 90°$). For odd degree, $\theta = \arcsin(1/\Omega_s)$.

To determine the degree of the reference low-pass for a Cauer-parameter filter, Fig. 9 (and for sharp cutoff rates, Fig. 10) is used. On the grid of A_p and A_s, an intersection point is found where the two lines meet. From that point, a horizontal line is drawn to the left until the value of Ω_s is reached, and the next curve

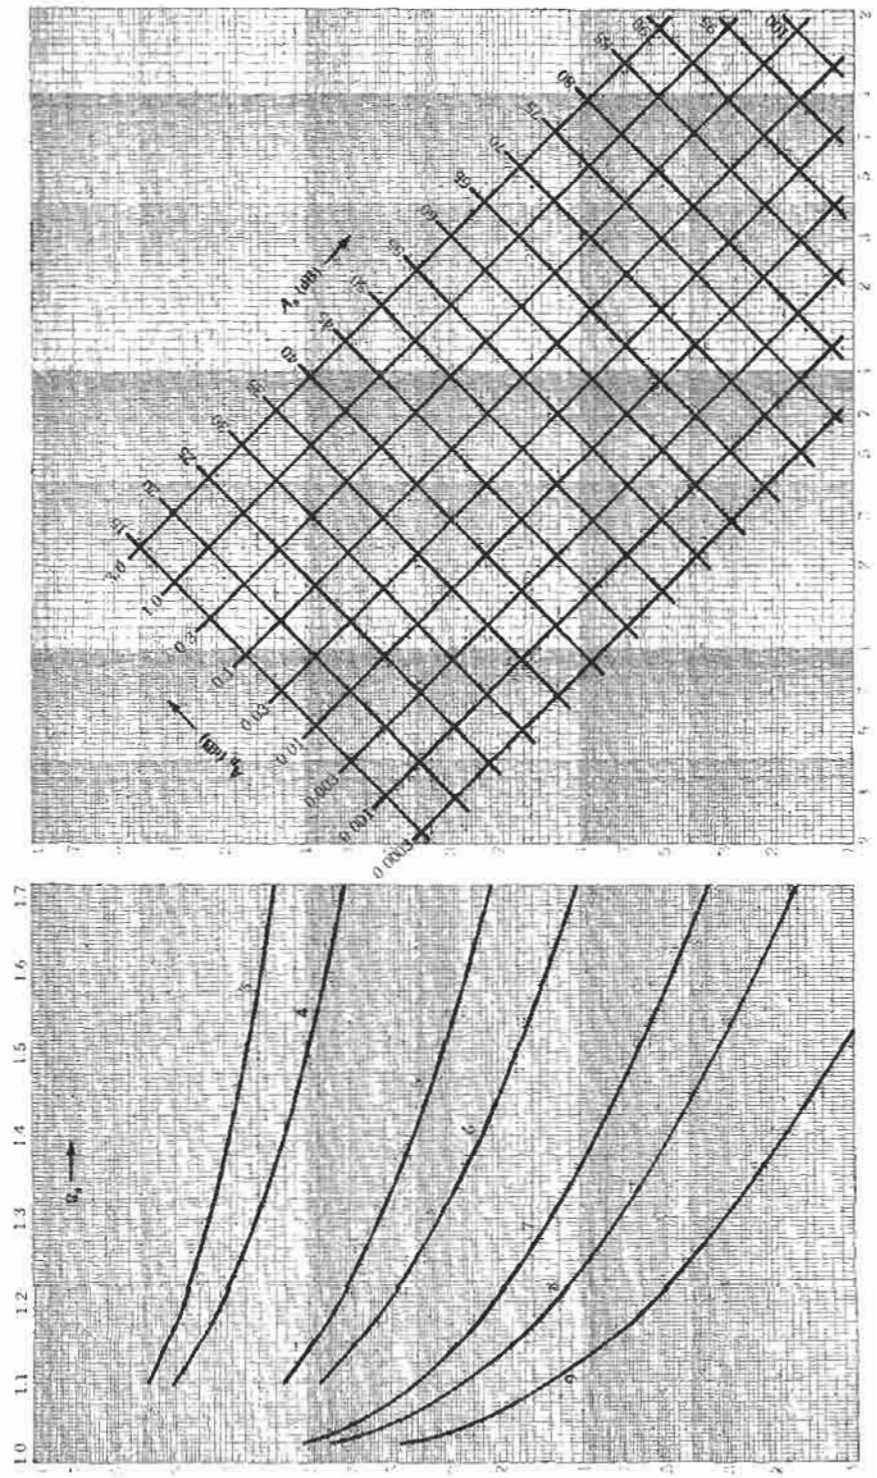

Fig. 10. Selecting the degree for a Cauer-parameter low-pass—expanded.

beyond that intersection specifies the necessary degree. Example 1 in the section headed "Numerical Examples" demonstrates this application.

CHEBYSHEV LOW-PASS FILTERS

If the passband requirement is for a variation of attenuation between zero and a maximum and the stop requirement is only to increase monotonically to infinity, a Chebyshev (sometimes spelled "Tchebyscheff") filter can be used. Fig. 11 shows this performance characteristic and the circuit configurations for both odd- and even-degree filters.

The discussion of impedance variation in the preceding section also applies for this network type.

Table 9 contains data for a number of normalized Chebyshev low-pass filters for degree 2 through 9. For each degree, one network is tabulated for reflection coefficients of 2, 5, 10, and 25 percent. Since stopband attenuation increases monotonically, there is only one circuit for a given A_p.

Figs. 12 and 13 are used in the same way as described for Cauer-parameter filters to ascertain the order of low-pass required.

BUTTERWORTH LOW-PASS FILTERS

Whenever a filter performance is desired with monotonically increasing attenuation from frequency equal to zero to infinity, Butterworth filters may be applicable. Fig. 14 shows the performance characteristic and circuit configurations for Butterworth low-pass filters of odd and even degree.

Table 10 contains data for a number of normalized Butterworth low-pass filters of degree 2 through 9. For each degree, circuit elements are tabulated for attenuation maxima at f_{ref} of 0.011, 0.044, 0.28, and 3.0 dB.

Figs. 15 and 16 are used in the same way as described for Cauer-parameter filters to determine the degree of the low-pass to satisfy the requirements.

LOW-PASS TO HIGH-PASS TRANSFORMATION

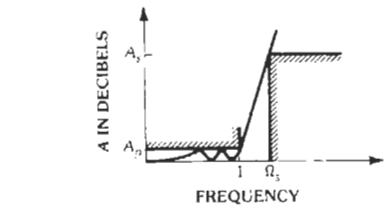
The frequency performance of a low-pass filter can be transformed into high-pass performance by the frequency transformation

$$\Omega_{HP} = 1/\Omega_{LP}$$

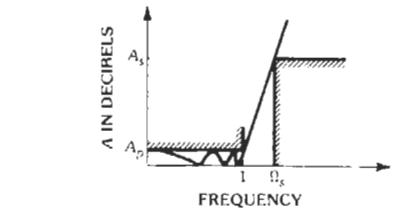
The transformation of normalized circuit-element values is shown in Fig. 17.

LOW-PASS TO BANDPASS TRANSFORMATION

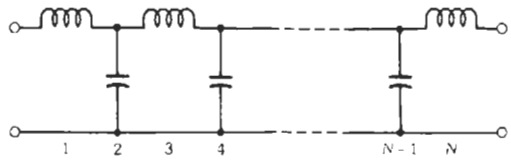
By the transformation



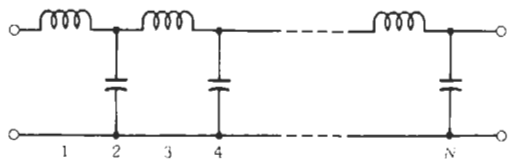
(A) Odd-degree performance.



(B) Even-degree performance.



(C) Odd-degree configuration.



(D) Even-degree configuration.

Fig. 11. Chebyshev low-pass filters.

$$\Omega = a(\eta - 1/\eta)$$

the frequency characteristic of a low-pass filter is converted into that of a bandpass filter. Two normalized bandpass frequencies, $\eta_p = f_{+p}/f_{ref}$ and $\eta_{-p} = 1/\eta_p = f_{-p}/f_{ref}$, correspond to the normalized low-pass Ω_p. Similarly, the geometrically symmetrical stopband limits, $\eta_s = f_s/f_{ref}$ and $\eta_{-s} = f_{-s}/f_{ref}$ are defined as shown in Fig. 6, and:

$$\Omega_p = a(\eta_{-p} + \eta_{+p}) = 1$$

$$\Omega_s = a(\eta_{-s} + \eta_s)$$

The relation between stopband limits and passband limits is

$$\Omega_s = (\eta_s - \eta_{-s})/(\eta_p - \eta_{-p})$$

The transformation of normalized circuit-element values is shown in Fig. 18.

LOW-PASS TO BAND-STOP TRANSFORMATION

The transformation of a low-pass filter into a band-stop filter is similar to the bandpass transform.

$$\Omega = 1/a(\eta - 1/\eta)$$

The resulting transformation of circuit-element values is shown in Fig. 19.

NUMERICAL EXAMPLES

Example 1

A low-pass filter with input impedance of 600 ohms and output impedance less than or equal to 600 ohms is needed to pass frequencies up to 3.4 kHz with less than 0.05 dB attenuation and to attenuate frequencies at 8.0 kHz and above by at least 45 dB (Fig. 20). Design both a Cauer-parameter and a Chebyshev low-pass to meet the requirement.

The value of Ω_s for the reference low-pass is calculated

$$\Omega_s = 8000/3400 = 2.353$$

Cauer-Parameter Design—To determine the Cauer-parameter low-pass, use Fig. 9 and proceed as follows.

Find the 45-dB (A_s) line on the grid (1), and move to the crossing with the $A_p = 0.05$ line (2). From this intersection (3), move to the left to intersect with the curves of degree versus cutoff rate. Note that for degree 3, Ω_s is $\cong 5.0$; for degree 4, $\Omega_s \cong 2.9$. Not until the curve for degree 5 is reached is an $\Omega_s < 2.353$ attained ($\Omega_s \cong 1.65$).

So a fifth-order low-pass with $A_s = 45$ dB, $A_p = 0.05$ dB and $\Omega_s = 1.65$ can be designed to meet the specified requirements. The tables included here are limited, however, so they must be checked to see what is available. From Table 4 (for filters of degree 5), $\theta = 37°$ with 10% reflection (0.044 dB) and $\Omega_s = 1.66164$ meets the requirements. The normalized low-pass is shown in Fig. 21.

Since only an $\Omega_s \leq 2.353$ is required, some overdesign can be accomplished. Generally, the losses erode the passband performance more rapidly than the stopband performance. As a result, the reference frequency (f_{ref}) can be chosen such that $f_s = 8000$ Hz.

$$f_{ref} = 4.6245 \text{ kHz}$$

and since $R_{ref} = 600$ ohms,

$$L_{ref} = 20.6492 \text{ mH}$$

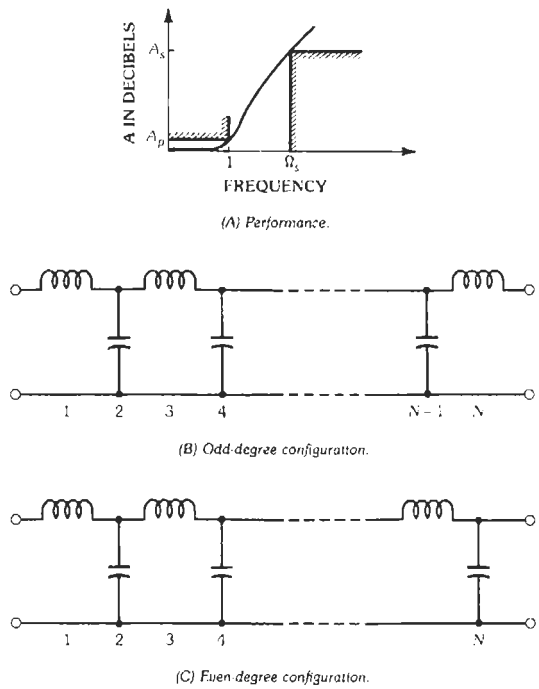

Fig. 14. Butterworth low-pass.

$$C_{ref} = 57.3588 \text{ nF}$$

The actual low-pass circuit (Fig. 21) then is:

$$C_1 = 50.665 \text{ nF}$$

$$C_2 = 6.625 \text{ nF} \quad L_2 = 25.75 \text{ mH}$$

$$C_3 = 89.021 \text{ nF} \quad L_4 = 20.67 \text{ mH}$$

$$C_4 = 19.141 \text{ nF} \quad f_2 = 12.188 \text{ kHz}$$

$$C_5 = 40.954 \text{ nF} \quad f_4 = 8.000 \text{ kHz}$$

Chebyshev Design—To determine the Chebyshev low-pass, use Fig. 12 and proceed as for the Cauer-parameter design. Here $N = 5$ results in $\Omega_s \cong 2.7$, and $N = 6$ provides $\Omega_s \cong 2.1$. Thus a sixth-order filter is required. From Table 9 for sixth degree and 10% reflection coefficient the normalized low-pass is as shown in Fig. 22.

With

$$f_{ref} = 3.8 \text{ kHz}$$

$$L_{ref} = 25.1297 \text{ mH}$$

$$C_{ref} = 69.8048 \text{ nF}$$

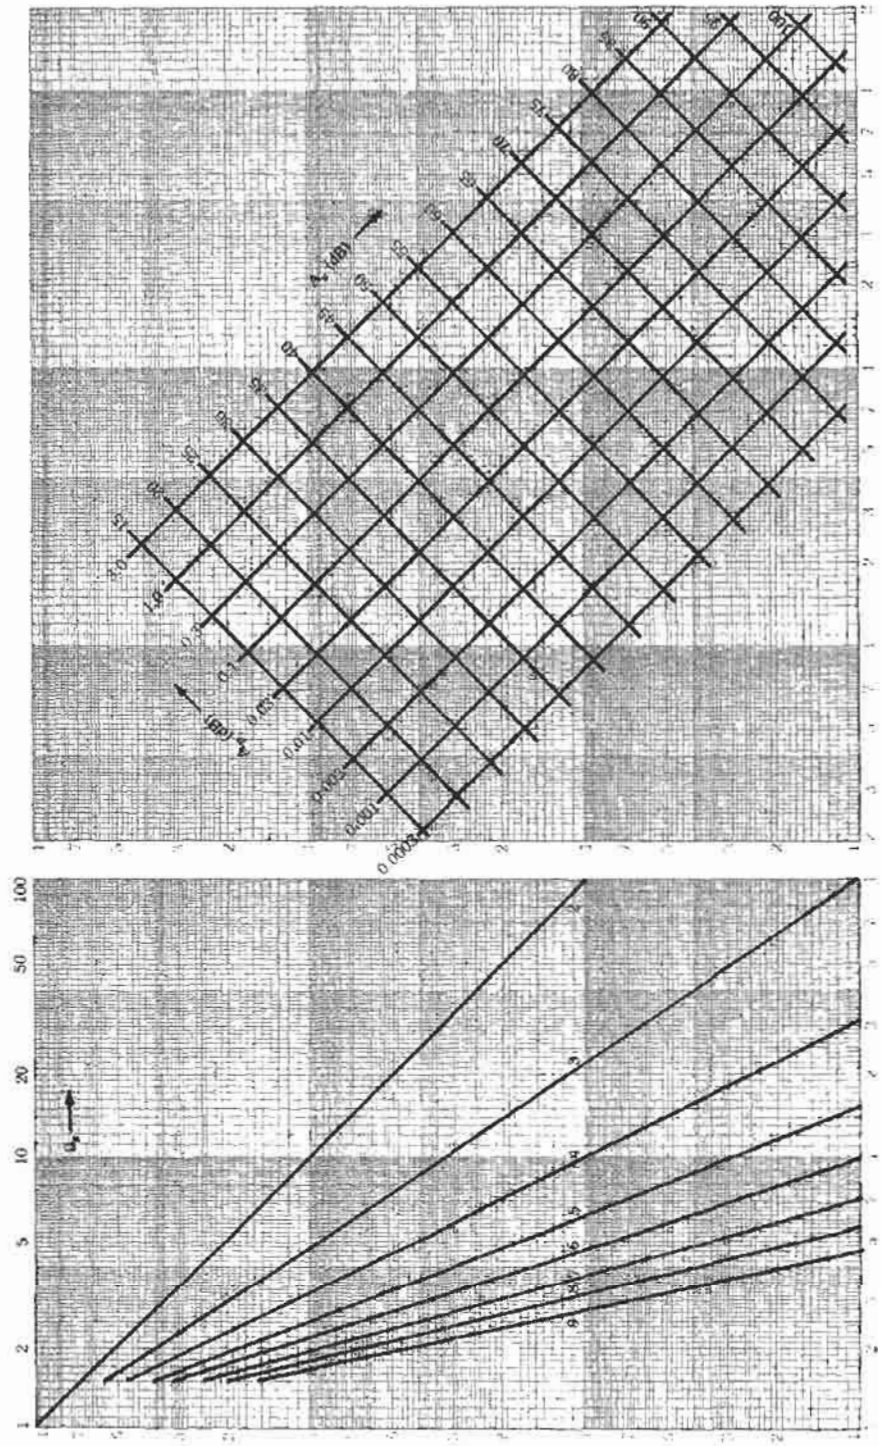

Fig. 15. Selecting the degree for a Butterworth low-pass.

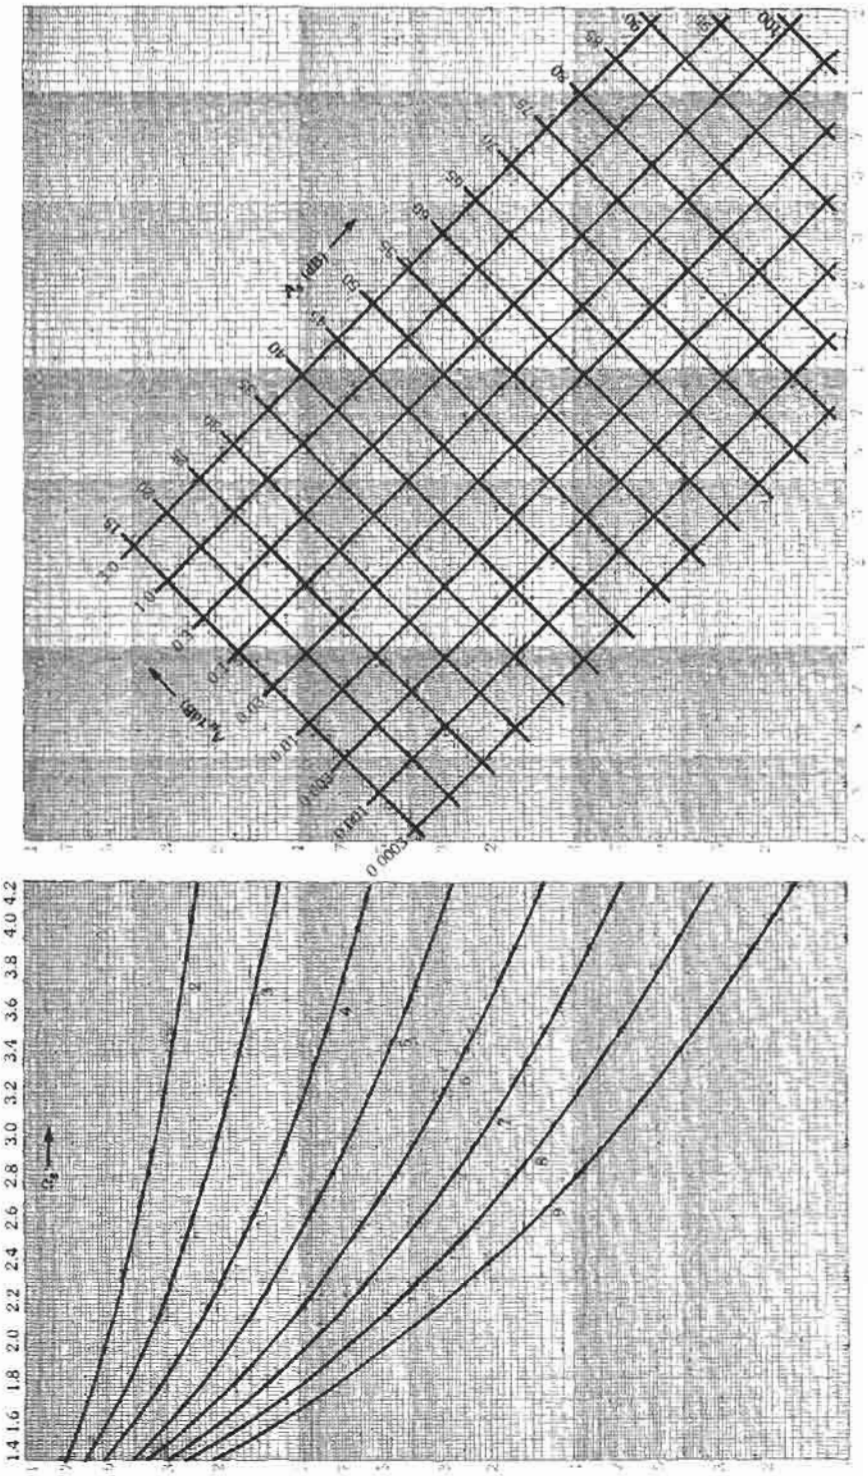

Fig. 16. Selecting the degree for a Butterworth low-pass —expanded.

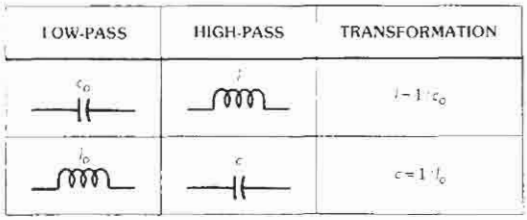

Fig. 17. Low-pass to high-pass transform.

the actual circuit elements are:

$C_1 = 69.512$ nF $\quad L_2 = 35.508$ mH

$C_3 = 132.28$ nF $\quad L_4 = 38.951$ mH

$C_5 = 120.55$ nF $\quad L_6 = 20.473$ mH

$R_t = 490.9$ ohms

Example 2

A high-pass filter is needed to pass frequencies of 64 kHz and greater and to attenuate frequencies below 16 kHz by 40.0 dB with input and output impedances of 600 ohms. A Butterworth filter is preferred with less than 0.4-dB passband variation. (See Fig. 23.) From Fig. 5, $\Omega_s = 64/16 = 4.0$.

To determine the reference low-pass, use Fig. 15, which shows that for degree 5 an Ω_s of 3.2 is attainable. In Table 10, however, the choice is more limited, and with $N = 5$ and $A_p = 0.28$, an Ω_s of 3.3 is found (return to Fig. 15 with $A_p = 0.28$ dB).

The normalized reference low-pass is shown in Fig. 24. From the transform of Fig. 17, the normalized high-pass shown in Fig. 25 is obtained. With $f_{ref} = 64.000$ kHz and R_{ref} 600 ohms,

$L_{ref} = 1.4921$ mH

$C_{ref} = 4.1447$ nF

and the actual circuit becomes

$L_2 = 1.209$ mH $\quad C_1 = 8.791$ nF

$L_4 = 1.209$ mH $\quad C_3 = 2.716$ nF

$C_5 = 8.791$ nF

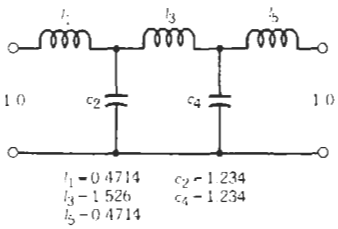

Fig. 24. Normalized reference low-pass for Example 2.

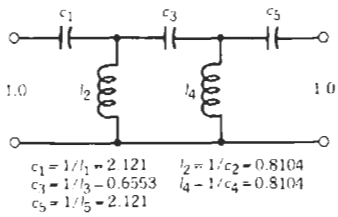

Fig. 25. Normalized high-pass for Example 2.

Example 3

A bandpass as shown by the tolerance plot of Fig. 26 with input and output impedances of 300 ohms is needed with stopband attenuation of 58 dB and a reflection coefficient of 5%. From Fig. 6 we might compute a reference low-pass $\Omega_s = (104 - 72)/(96 - 80) = 2.0$. However, geometric symmetry is required for both passband and stopband, so more calculation is necessary. From Fig. 6, it can be found that:

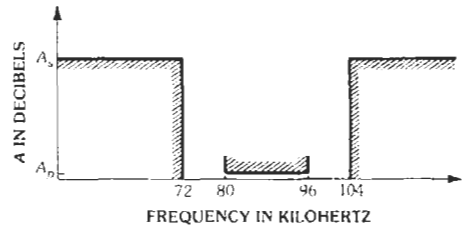
$$f_{ref}^2 = f_{+s}f_{-s} = f_{+p}f_{-p}$$

There are, then, two choices for the reference low-pass:

(A) Calculate a new f_{-p}

$$f_{-p} = f_{-s}f_{+s}/f_{+p} = 78.0 \text{ kHz}$$

from which



$A_p = 0.01087$ dB $f_{-p} = 80$ kHz
$A_s = 58$ dB $f_{+p} = 96$ kHz
$f_{-s} = 72$ kHz
$f_{+s} = 104$ kHz

Fig. 26. Tolerance plot for Example 3.

$$\Omega_s = (104 - 72)/(96 - 78) = 1.778$$

(B) Calculate a new f_{-s}

$$f_{-s} = f_{+p}f_{-p}/f_{+s} = 73.846 \text{ kHz}$$

from which

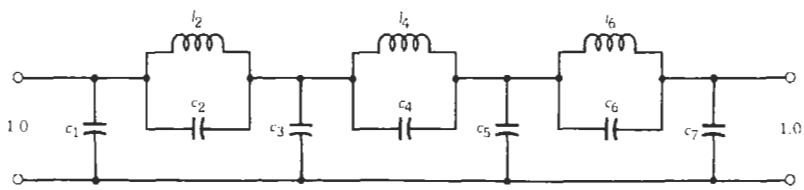
$$\Omega_s = (104 - 73.846)/(96 - 80) = 1.885$$

Fig. 9 shows that a seventh-order filter is required to achieve an Ω_s as sharp as 1.885, and, in fact, $\Omega_s \cong 1.475$ can be achieved. From Table 6 with 5% reflection coefficient, $\theta = 43°$ yields $\Omega_s = 1.46628$ and $A_s = 60.6$ dB. (For filters of this complexity, only Cauer-parameter networks are generally considered.) The normalized reference low-pass is shown in Fig. 27.

Since this low-pass has a sharper cutoff rate than was required by either choice A or B, the bandpass transformation can be made with some overdesign throughout the tolerance plot. For instance, choose

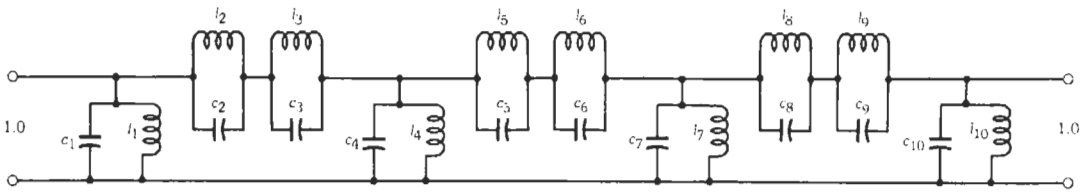
$$f_{+p} = 97 \text{ kHz}$$

with $f_{ref} = \sqrt{104 \times 72} = 86.5332$ kHz



$c_1 = 0.7387$ $l_2 = 1.296$
$c_2 = 0.0859$ $l_4 = 1.136$
$c_3 = 1.435$ $l_6 = 1.031$
$c_4 = 0.3945$
$c_5 = 1.332$ $\Omega_2 = 2.9970$
$c_6 = 0.3081$ $\Omega_4 = 1.4936$
$c_7 = 0.5612$ $\Omega_6 = 1.7741$

Fig. 27. Normalized reference low-pass for Example 3.



$c_1 = 3.2272$	$c_6 = 4.1460$	$l_1 = 0.3098$	$l_6 = 0.3389$	$\Omega_1 = 1.0$	$\Omega_6 = 0.8436$
$c_2 = 0.5668$	$c_7 = 5.7764$	$l_2 = 0.9000$	$l_7 = 0.1731$	$\Omega_2 = 1.4001$	$\Omega_7 = 1.0$
$c_3 = 1.1111$	$c_8 = 2.2457$	$l_3 = 1.7643$	$l_8 = 0.2975$	$\Omega_3 = 0.7142$	$\Omega_8 = 1.2234$
$c_4 = 6.2702$	$c_9 = 3.3612$	$l_4 = 0.1595$	$l_9 = 0.4453$	$\Omega_4 = 1.0$	$\Omega_9 = 0.8174$
$c_5 = 2.9504$	$c_{10} = 2.4521$	$l_5 = 0.2412$	$l_{10} = 0.4078$	$\Omega_5 = 1.1854$	$\Omega_{10} = 1.0$

Fig. 28. Normalized bandpass circuit for Example 3.

$f_{-p} = f_{ref}^2/f_{+p} = 77.196$ kHz

$\Delta f_p = 19.804$ kHz

$\Delta f_s = \Omega_s \cdot \Delta f_p = 29.032$ kHz

Solving $f_{+s}f_{-s} = f_{ref}^2$ with $f_{+s} - f_{-s} = 29.032$

$f_{+s} = 102.259$ kHz

$f_{-s} = 73.226$ kHz

and

$a = 4.369$

With the transformations of Fig. 18, the normalized bandpass circuit becomes as shown in Fig. 28. (In Fig. 28, $\Omega_i = 1/\sqrt{c_i l_i}$.) Since $R_{ref} = 300$ ohms and $f_{ref} = 86.5332$ kHz,

L_{ref}=551.77 μH

C_{ref}=6.131 nF

Then the actual circuit elements are:

$C_1 = 19.788$ nF $L_1 = 170.95\ \mu$H $f_1 = 86.533$ kHz

$C_2 = 3.475$ nF $L_2 = 496.59\ \mu$H $f_2 = 121.157$ kHz

$C_3 = 6.812$ nF $L_3 = 973.48\ \mu$H $f_3 = 61.804$ kHz

$C_4 = 38.441$ nF $L_4 = 88.00\ \mu$H $f_4 = 86.533$ kHz

$C_5 = 18.088$ nF $L_5 = 133.09\ \mu$H $f_5 = 102.578$ kHz

$C_6 = 25.418$ nF $L_6 = 187.01\ \mu$H $f_6 = 72.998$ kHz

$C_7 = 35.414$ nF $L_7 = 95.52\ \mu$H $f_7 = 86.533$ kHz

$C_8 = 13.768$ nF $L_8 = 164.16\ \mu$H $f_8 = 105.866$ kHz

$C_9 = 20.607$ nF $L_9 = 245.70\ \mu$H $f_9 = 70.731$ kHz

$C_{10} = 15.034$ nF $L_{10} = 225.02\ \mu$H $f_{10} = 86.533$ kHz

Example 4

Design a band-stop filter to operate between resistances of 75 ohms with 5% reflection coefficient and $A_s = 40$ dB, per Fig. 29.

Two options exist for computing the reference low-pass (see Fig. 7) with geometric symmetry:

(A) Calculate a new f_{-p}:

$f_{-p} = (200 \times 248)/272 = 182.35$ kHz

from which

$\Omega_s = (272 - 182.35)/(248 - 200) = 1.867$

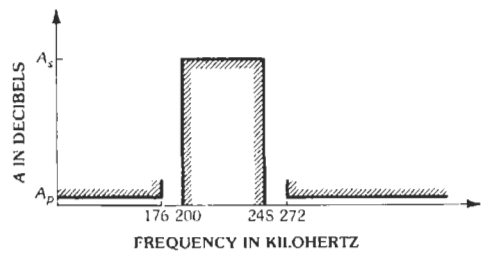
(B) Calculate a new f_{-s}:

$f_{-s} = (272 - 176)/248 = 193.03$ kHz

from which

$\Omega_s = (272 - 176)/(248 - 193.03) = 1.7465$

Fig. 9 indicates that a fifth-order filter is sufficient to meet the requirements. In fact, $\Omega_s \cong 1.70$ is achievable. From Table 4, for a reflection coefficient of 5%,



$A_s = 40$ dB
$A_p = 0.01087$ dB
$f_{-s} = 200$ kHz
$f_{+s} = 248$ kHz
$f_{-p} = 176$ kHz
$f_{+p} = 272$ kHz

Fig. 29. Tolerance plot for Example 4.

$\theta = 36°$ produces $\Omega_s = 1.7013$ and $A_s = 40.8$ dB. The normalized reference low-pass is shown in Fig. 30. Selecting $f_{ref} = \sqrt{200 \times 248} = 222.711$ kHz and $f_s = 249.000$ kHz gives:

$$f_{-s} = f_{ref}^2/f_s = 199.197 \text{ and } \Delta f_s = 49.803 \text{ kHz}$$

$$\Delta f_p = \Delta f_s \cdot \Omega_s = 84.730 \text{ kHz}$$

and solving $f_{-p}f_{+p} = f_{ref}^2$ with $\Delta f_p = f_{+p} - f_{-p}$ gives:

$$f_{-p} = 184.339 \text{ kHz}$$

$$f_{+p} = 269.069 \text{ kHz}$$

$$a = 2.6285$$

After application of the transformation of Fig. 19, the normalized bandstop circuit is as shown in Fig. 31. With $R_{ref} = 75$ ohms and $f_{ref} = 222.711$ kHz

$$L_{ref} = 53.597 \ \mu\text{H}$$

$$C_{ref} = 9.5284 \text{ nF}$$

and the actual circuit elements are:

$L_1 = 207.26\ \mu$H $C_1 = 2.464$ nF $f_1 = 222.711$ kHz

$L_2 = 11.254\ \mu$H $C_2 = 39.437$ nF $f_2 = 238.898$ kHz

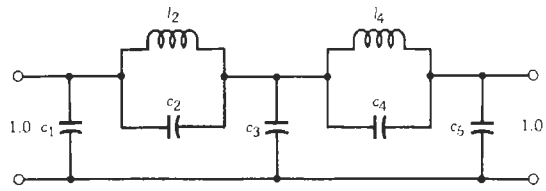
$L_3 = 12.950\ \mu$H $C_3 = 45.378$ nF $f_3 = 207.620$ kHz

$L_4 = 102.58\ \mu$H $C_4 = 4.978$ nF $f_4 = 222.711$ kHz

$L_5 = 8.391\ \mu$H $C_5 = 49.121$ nF $f_5 = 247.897$ kHz

$L_6 = 10.397\ \mu$H $C_6 = 60.859$ nF $f_6 = 200.083$ kHz

$L_7 = 277.85\ \mu$H $C_7 = 1.838$ nF $f_7 = 222.711$ kHz



$c_1 = 0.6798$ $l_2 = 1.187$
$c_2 = 0.1148$ $l_4 = 0.9214$
$c_3 = 1.373$
$c_4 = 0.3456$ $\Omega_2 = 2.7089$
$c_5 = 0.5070$ $\Omega_4 = 1.7721$

Fig. 30. Normalized reference low-pass for Example 4.

10 Active Filter Design

Rolf Schaumann

The information in this chapter enables the engineer to design a wide variety of practical active filters for operation in the audio-frequency range, and higher if fast operational amplifiers (op amps) are available. If operational transconductance amplifiers (OTAs) are used, filters even into the range of hundreds of megahertz can be designed. The equations presented permit the user to complete the design and arrive at a fairly comprehensive evaluation of the performance to be expected from the filter, without requiring complicated mathematics. Out of the countless different filters proposed in the technical literature, only those few circuits that have been proven to be practical, state-of-the-art designs are discussed in this chapter. Given the limited space available in a reference volume such as this, sufficient information can be provided only for the design of filters of relatively simple specifications. If system requirements are very stringent, the reader should consult the many excellent books* or papers referred to in the text.

INTRODUCTION

The technology of hybrid and monolithic integrated circuits has profoundly influenced the design and implementation of filters in the audio-frequency range and beyond. Frequency limitations are always set by the bandwidth of the available op amps. Integration has allowed the realization of filters that are small in size, inexpensive, and mass-producible. During the past 25 years, active *RC* networks, typically comprising resistors, capacitors, and operational amplifiers, have been the primary means of hybrid-integrated audio-filter implementation. Active *RC* filters have eliminated the need for the bulky, expensive inductors required in passive implementations, and tuning is simplified and usually involves the adjustment of only resistors. Furthermore, tuning can be automated in manufacture, using commercial laser trimming systems. In addition, active *RC* filters have provided opportunities for standardization and modularity that significantly simplify design and fabrication.

Switched-capacitor (SC) networks† have allowed audio-frequency active filters to be realized with the metal-oxide-semiconductor (MOS) large-scale-integration (LSI) technologies associated with digital networks. Switched-capacitor filters typically contain capacitors, MOSFET switches, and operational amplifiers. The switches are operated by clock signals that are digitally derived from a stable frequency source such as a crystal-controlled oscillator. The characteristics of the filter are then determined by capacitor ratios and the clock frequency, both inherently precise and stable parameters. Hence, SC filters rarely require trimming. The most important attribute of SC filters is that their implementation in silicon is compatible with digital-circuit integration, enabling digital and analog circuitry to coexist on the same LSI chip.

For applications at much higher frequencies, such as in the read/write channels of magnetic disk recording systems or high-frequency communication systems, active *RC* filters based on operational amplifiers prove insufficient because of the op amps' bandwidth limitations. In these cases, when signals in the tens to hundreds of megahertz, or even gigahertz, must be processed, the designer uses operational transconductance amplifiers (OTAs) as active devices. OTAs are voltage-to-current converters described by their transconductance parameter g_m. It is quite possible to design OTAs with much higher bandwidth than op amps (up to several hundred megahertz and even gigahertz) so that analog active filters in the radio-frequency (RF) range become possible. Because discrete OTAs are not readily available, this latter technology is used mainly for integrated filters, where the use of only OTAs and capacitors enables the designer to implement high-frequency analog g_m-C filters compatible with digital CMOS technology. The filter performance depends unavoidably on OTA parameters, which must somehow be tuned. Techniques for handling these problems are becoming available on ICs.‡

At gigahertz frequencies, also passive *LC* filters can be implemented in integrated form because inductors of very small values (typically, nH) can be realized on an IC as single-layer or multiple-layer metal spirals. These inductors are very lossy, with quality factors of the order of only 10, so that active loss compensation techniques are usually employed; also, the spirals consume a relatively large silicon area, but the filters can be shown to have a lower noise and superior dynamic range than those using g_m-C techniques. For an overview of this design approach, the reader may consult Reference 28.

Integrated analog filters, especially for high-frequency applications, must be designed in fully differential, balanced form. Normally these filters will share an IC chip with digital circuitry where ground and power-supply lines (ac ground) are noisy, due, for example, to digital switching transients. Referring a signal to ac ground will, therefore, likely result in a severely restricted dynamic range (low signal-to-noise ratio). This problem is greatly reduced by referring two differential signal lines with equal and opposite signal voltages $\pm v_s/2$ to each other: $v_o = v_s/2-(-v_s/2) = v_s$. Noise voltages on power-supply and ground lines appear as common-mode signals and are rejected in the differential circuit. Because OTA-based filters are intended mainly for IC implementation and for high frequencies, the corresponding examples below will be shown in differential form. Conversions from single-ended to differential form are straightforward.§

§ Reference 6.

Although the design of high-frequency integrated OTA-*C* filters is, in principle, quite simple, in practice numerous constraints must be considered and these are beyond this introductory discussion. The presentation in this book should make the reader aware of the possibilities, but details are left to References 6, 7, and 10–14.

Active filters are used extensively in instrumentation and communication systems. To design these circuits, whether in active *RC* (based on op amps or OTAs), g_m-*C*, or SC techniques, one must first understand what an active filter is and how its performance requirements are specified. An electric filter is a network that transforms an input signal in some specified way into a desired output signal. Although many applications exist where filter requirements are set in terms of time-domain specifications, the majority of filters are designed to satisfy certain frequency-domain criteria. Thus, as shown in Fig. 1, a filter is a two-port network with input voltage V_1 and output voltage V_2; the circuit response is described by a transfer function $H(s)$ defined by

$$H(s) = V_2/V_1 = N(s)/D(s) \qquad \text{(Eq. 1)}$$

where, in steady-state,

$s = j\omega$ is the frequency parameter,
$\omega = 2\pi f$ is the radian frequency (rad/s),
f is the frequency in Hertz (Hz).

As indicated, $H(s)$ is a ratio of two polynomials $N(s)$ and $D(s)$. The roots of $N(s)$ are the transmission zeros of the filter, i.e., points of infinite attenuation; the roots of $D(s)$ are its poles. The transfer function is a complex quantity that may be expressed as

$$H(j\omega) = |H(j\omega)| \exp[\phi(\omega)] \qquad \text{(Eq. 2)}$$

where $|H(j\omega)|$ is the magnitude and $\phi(\omega)$ is the phase. Thus, to specify a transfer function completely, both magnitude and phase must be given at a sufficient number of frequency points. In many cases, the magnitude response is the dominant specification with the phase response either loosely specified or unspecified. In this case, a minimum-phase filter (having all zeros in the right half-plane) is designed to meet the magnitude specification, and whatever phase the design provides is accepted. When both magnitude and phase are specified, a widely accepted design procedure is first to design a minimum-phase filter to meet the magnitude response, as previously mentioned. Then, an all-pass filter is designed, which, when cascaded with the minimum-phase filter, meets the desired phase specification. This all-pass network is often referred to as a phase or delay equalizer. Filtering implies that certain frequency components of the input signal, those in the passband or passbands, are transmitted or passed to the output, whereas those in the stopband(s) are not transmitted. The most frequently used method of identifying the location of passbands and stopbands on the frequency axis is by specifying, versus frequency, the magnitude characteristic via the loss curve in decibels (dB), defined as

$$\alpha(\omega) = -20 \log |H(j\omega)| = -20 \log |V_2/V_1| \qquad \text{(Eq. 3)}$$

In the stopbands, where $|V_2| << |V_1|$, $|H(j\omega)|$ is small and the loss α is large, for example $|H(j\omega)| < 0.01$ or $\alpha > 40$ dB. In the passbands, $|V_2| \approx |V_1|$ or even $|V_2| \geq |V_1|$, so that $|H(j\omega)| \approx 1 (\alpha = 0$ dB) or $|H(j\omega)| > 1$ ($\alpha < 0$ dB), i.e., the circuit provides gain, something an active filter can do, whereas a passive filter always provides a loss.

If the phase response is of prime importance, then $\phi(\omega)$ is specified directly in degrees or radians; alternatively, and perhaps more frequently, one prescribes the delay $T(\omega)$ in seconds, defined as

$$T(\omega) = -d\phi(\omega)/d\omega \qquad \text{(Eq. 4)}$$

For best, distortion-free transmission, the delay should be constant, $T(\omega) = T_0$, i.e., the phase should be linear, $\phi(\omega) = -\omega T_0$, over the frequency range of interest. This is especially important when filtering pulse signals, such as in read/write channels of magnetic disk drives.

Some additional criteria of practical interest in active-filter design are sensitivity, dynamic range, noise, power dissipation, number and range of components, method of fabrication, and cost. All of these specifications place limitations and constraints on an acceptable design. In more cases than one would like, the specifications conflict so that engineering tradeoffs have to be made to resolve the conflict.

In the following sections, the components used for active filters, some important design criteria, and several state-of-the-art practical active filters will be discussed.

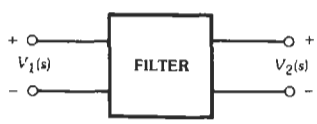

Fig. 1. A general filter representation.

CIRCUIT ELEMENTS

Active filters are constructed from resistors, capacitors, and, usually, operational amplifiers for low-frequency applications or operational transconductance amplifiers for applications at high frequencies. A few comments will be made about these components, especially about the op amp because of its serious effect on filter performance. A suitably simple model for the OTA will also be presented. Spiral inductors of a few nanohenries (nH) in size are occasionally employed at the highest (GHz) frequencies in ICs.

Resistors*

Resistors used in active-filter design are carbon composition, metal or carbon film, thin or thick film,

* References 3 and 9.

wirewound, and diffused. The selection depends on cost, on the technology used to implement the filter, and on filter requirements. Carbon composition resistors are the least expensive, but they have large tolerances and temperature coefficients. Further, tracking is not very good so that composition resistors should be used only for noncritical applications. Metal-film and wirewound resistors, although more expensive, are better than composition types in all respects and are the most frequently used resistors in active-filter design today. Wirewound resistors have somewhat larger parasitics (L and C) than metal-film resistors and should not be used for high-frequency applications.

Capacitors*

Of the numerous different types of capacitors available, those commonly used in active filters are ceramic disc, Mylar, polystyrene, Teflon, and thin-film capacitors. Again, the selection depends on factors such as cost, available range, tolerances, temperature coefficients, and dissipation factor (loss). Ceramic and Mylar capacitors are the least expensive types and have the highest loss; they should be used only for noncritical applications. Teflon, thin-film, and especially polystyrene (or for small values, mica) capacitors are more expensive but have much lower dissipation factors and are therefore better suited for critical filter designs. Of course, in integrated implementations, on-chip metal-oxide-semiconductor (MOS) capacitors are being used.

In setting filter parameters, apart from tolerances and temperature coefficient, the dissipation factor (DF) or quality factor (Q_c) is of some importance. If loss is modeled by means of a resistor R_c in parallel with the capacitor C, Q_c and DF are defined as

$$Q_c = 1/\mathrm{DF} = \omega C R_c \qquad \text{(Eq. 5)}$$

where ω is some critical frequency of interest, usually chosen at the passband edge. It should also be remembered that Q_c is a strong function of temperature. Typical values of Q_c range from less than 100 (ceramic) up to several thousand (polystyrene).

Operational Amplifiers

Although, as was mentioned, IC filters preferably use OTAs, the active element used in the vast majority of all discrete active *RC* filters and integrated SC filters is the operational amplifier. The "op amp" is an integrated circuit with five or more terminals, three of which are used for handling the signal (Fig. 2): the inverting (V^-) and noninverting (V^+) input terminals, at which the input voltages are applied, and the output terminal (V_o). The remaining terminals are for power supply and, in some models, for offset compensation and frequency compensation. The function of the op amp is described by

$$V_o = A(s)\left(V^+ - V^-\right) = A(s)V_i \qquad \text{(Eq. 6)}$$

Thus, the output voltage is obtained by multiplying the differential input voltage, V_i, by $A(s)$, the op amp's open-loop gain.

In the ideal op amp, A is assumed to be infinite (i.e., $A \to \infty$) and, furthermore, all input impedances are infinite and the output impedance is zero. Thus, the ideal op amp is an ideal voltage-controlled voltage source with infinite gain; the input currents into the inverting and noninverting input terminals are zero. Further, since $A \to \infty$ and V_o must remain finite in practice, it follows that the input voltage $V_i = V^+ - V^-$ is zero; the operation is defined such that $V_o = 0$ when $V_i = 0$. Note that $V_i = 0$ implies that $V^- = 0$ when $V^+ = 0$. In that case, the V^- terminal is referred to *virtual ground*—the voltage is zero, but also the current is zero because of the op amp's infinite input impedance.

To get a feel for their operation, op-amp circuits often are first analyzed or designed under the assumption of ideal amplifiers ($A \to \infty$). It should, however, be strongly emphasized at this point that, except for uncritical applications at *very* low frequencies ($f < 1$ kHz), the operation of an active filter will rarely be satisfactory in practice if its design is based on ideal op amps. The main reason is that the op-amp gain $A(s)$ is a strong function of frequency. Specifically, for most inexpensive op amps used in active-filter design, the gain decreases from a high value of about 100 dB below 10 Hz throughout the useful frequency range by 20 dB/decade to 0 dB at about 1 MHz. This frequency response is required for stability reasons and is achieved by use of internal or external compensation capacitors.

Thus, the most widely used and quite realistic op-amp model is

$$A(s) = A_0\,\sigma/(s+\sigma) = \omega_t/(s+\sigma) \qquad \text{(Eq. 7)}$$

where

$s = j\omega$ (as defined previously),
σ is the open-loop –3-dB frequency (usually $\leq 2\pi \times 10$ Hz),
A_0 is the dc gain (usually > 100 dB),
$\omega_t = A_0\sigma$ is the gain-bandwidth product ($\approx 2\pi \times 1$ MHz).

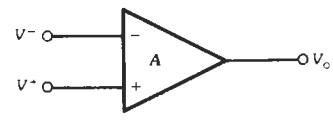

Fig. 2. Op-amp symbol.

* References 3 and 9.

In most practical applications, $|s| >> \sigma$, so that, instead of Eq. 7, a commonly used model is

$$A(s) \approx \omega_t / s \qquad \text{(Eq. 8)}$$

Analyzing an active filter with op amps represented by Eqs. 7 or 8 rather than by a simple constant-gain model increases the degree of the describing network function (Eq. 1) by one for each amplifier used. Thus, the filter acquires parasitic poles and zeros in addition to suffering shifts of the nominal pole-zero locations. Stated differently, the two polynomials $N(s)$ and $D(s)$ in Eq. 1 change from their prescribed ideal form. It is for this reason that filters designed with the assumption of ideal amplifiers ($\omega_t \to \infty$) do not normally have a satisfactory frequency response but show a potentially large deviation from their nominal performance because of finite ω_t.

Occasionally, a filter will behave unpredictably, possibly even oscillate, in spite of a design based on the op-amp model of Eqs. 7 or 8. The reason may often be found in the fact that, whereas the representation of Eq. 7 describes the op-amp *gain* very well, the phase shift is larger than indicated by Eq. 7. An adequate remedy is to multiply Eq. 7 by an "excess phase factor," $\exp(-j\omega/\omega_2)$, where ω_2 is a normalizing frequency of value $\omega_2 \approx 3\omega_t$, and to use this augmented model in the analysis. Because for all practical purposes ω_2 is much larger than the operating frequency ω, we can set $\exp(-s/\omega_2) \approx 1 - s/\omega_2$ to keep the algebra manageable; i.e., a very accurate op-amp model for use in highly selective filters at fairly high frequencies is

$$A(s) \approx (\omega_t / s)(1 - s/\omega_2) \qquad \text{(Eq. 9)}$$

In most applications, however, the use of Eq. 8 leads to entirely satisfactory results.

Further op-amp characteristics of concern to filter designers are slew rate and dc offset voltage. Slew rate (SR), given in volts per microsecond, refers to the maximum rate of change of a signal voltage that the amplifier can maintain at its output. Violating slew-rate limitations results in gross signal and/or transfer-function distortion and should be avoided. Thus, if $v_o(t) = V_0 \sin \omega t$ is the amplifier output voltage, one needs to observe $V_0 < \mathrm{SR}/\omega$. For example, if SR = 0.7 V/μs (a typical value for inexpensive op amps) and the signal frequency is 15 kHz, the signal amplitude must satisfy $V_0 \le 7.3$ V to avoid slew-rate limitations.

There are two main reasons* for offset voltage. One is the need for dc input bias currents into the input stage of bipolar op amps. (There is no input bias current in MOS op amps.) The second arises from imbalances in the input stage. To be able to provide the input bias, dc paths must exist from the inverting and noninverting input terminals to ground. To minimize offset, the resistances seen from these two terminals back into the network ought to be equal. Then the voltage drops caused by the two bias currents at the op-amp inputs are equal and the direct differential input voltage is zero, resulting in zero contribution to offset. In practice, things are not quite so simple because imbalances in the op-amp input stage cause the bias currents not to be exactly equal, resulting in a finite differential direct input voltage. This voltage is multiplied by the dc closed-loop gain (see below), leading to an output offset voltage that, however, frequently can be reduced to zero by means of a potentiometer connected to the offset-adjust terminals of the op amp.

All amplifier parameters, especially the important terms A_0 and ω_t, are strong functions of bias voltages and temperature, and in general are not well determined or even predictable from unit to unit. Therefore, one strives to minimize filter dependence on these parameters and always uses op amps in *closed-loop feedback* configurations (Fig. 3) where the gain dependence on device parameters is reduced. Using straightforward analysis, and remembering that op-amp input currents are zero and that $V^- = -V_2/A$, yields for Fig. 3A the inverting gain

$$V_2/V_1 = -(Z_2/Z_1)/[1 + (1 + Z_2/Z_1)/A] \qquad \text{(Eq. 10)}$$

and for Fig. 3B the noninverting gain

$$V_2/V_1 = +(1 + Z_2/Z_1)/[1 + (1 + Z_2/Z_1)/A] \qquad \text{(Eq. 11)}$$

In both circuits, R is chosen to equal $1/[Y_1(0) + Y_2(0)]$ in line with the above discussion about offset minimization so that both op-amp inputs see the same dc impedance back into the circuit. Note, though, that resistor R does not affect the signal gain because no signal cur-

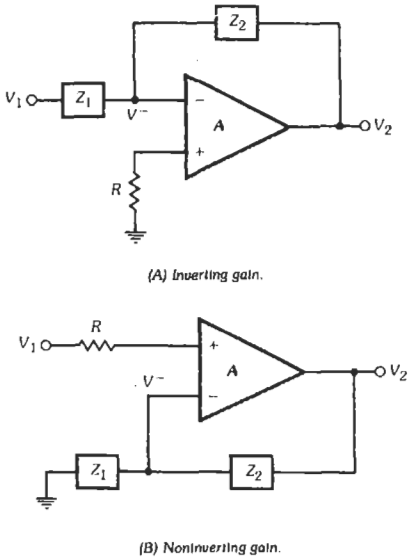

Fig. 3. Closed-loop feedback configurations.

* References 3, 7, and 9.

rent flows through it. Thus, for simplicity, in the remaining discussion in this chapter, R will be neglected; i.e., $R = 0$ is assumed.

For ideal amplifiers, or, in practice, in the frequency range where $|A(j\omega)| >> |1 + Z_2(j\omega)/Z_1(j\omega)|$, Eqs. 10 and 11 reduce to

$$V_2/V_1 = -Z_2(s)/Z_1(s) \qquad \text{(Eq. 12)}$$

and

$$V_2/V_1 = 1 + Z_2(s)/Z_1(s) \qquad \text{(Eq. 13)}$$

respectively. As desired, the closed-loop gain functions are then independent of amplifier parameters and are determined only by presumably accurately adjustable and stable external impedances. The quantities $Z_1(s)$ and $Z_2(s)$ are finally chosen to yield the desired frequency dependence of the gain. For example, setting $Z_1 = R_1$ and $Z_2 = KR_1$ results, of course, in the well-known amplifiers of inverting gain $-K$ (Fig. 3A) and noninverting gain $1 + K$ (Fig. 3B). More will be said later about these important building blocks.

Operational Transconductance Amplifiers

As mentioned previously, an operational transconductance amplifier (OTA) is a voltage-to-current converter described by the conversion parameter g_m, the transconductance. Its circuit symbol is shown in Fig. 4A, and its function is given by

$$I_o = g_m(V^+ - V^-) \qquad \text{(Eq. 14)}$$

Naturally, at very high frequencies the gain, g_m, of a transconductance decreases because of parasitic poles. Just as in op amps, this decrease can be modeled by

$$g_m(s) = g_{m0}/(s + \sigma) \qquad \text{(Eq. 15)}$$

but in an OTA, the pole σ is at far higher frequencies (several tens to a few hundred megahertz) so that the effect may be neglected for most applications. Equation 14 indicates that an OTA generates an output current I_o proportional to the differential input voltage $V^+ - V^-$. Ideally, the input and output impedances and the bandwidth of an OTA are infinite. In practice, for well-designed circuits, the input resistor is greater than 10^8 Ω and the output resistor is greater than 10^5 Ω, but there are parasitic input and output capacitors of some small fraction of a picofarad (pF) in size. These capacitors *must* be accounted for in accurate designs at very high frequencies. The OTA's bandwidth is several hundred megahertz or, depending on technology and design, reaches the gigahertz range. From these few numbers it can be seen that, in contrast to op amps, OTAs can be treated as almost ideal components for most active-filter design tasks. Only at the highest frequencies must OTA nonidealities, in particular the parasitic capacitors and the parasitic pole σ, be taken into account. Fig. 4B shows an OTA with differential output terminals, and Fig. 4C shows an OTA with multiple differential inputs (here two) and differential outputs realizing

$$I_o^+ = I_o^- = g_m\left[\left(V_1^+ - V_1^-\right) + \left(V_2^+ - V_2^-\right)\right] \qquad \text{(Eq. 16)}$$

FUNDAMENTALS AND TECHNIQUES OF ACTIVE-FILTER DESIGN

The Transfer Function

In Eq. 1 the transfer characteristic of a filter was introduced as a ratio of polynomials, i.e.,

$$H(s) = \frac{N(s)}{D(s)} = \frac{n_m s^m + n_{m-1} s^{m-1} + \cdots + n_1 s + n_0}{s^r + d_{r-1} s^{r-1} + \cdots + d_1 s + d_0} \qquad \text{(Eq. 17)}$$

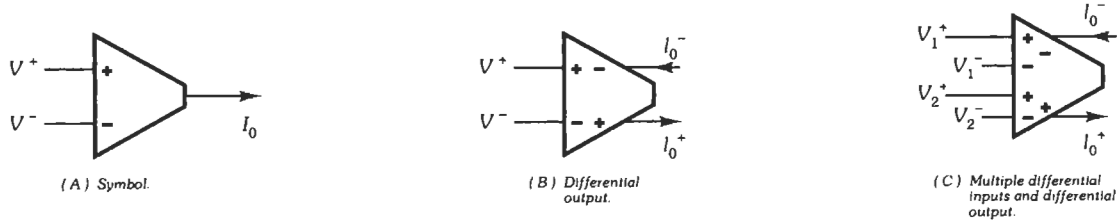
where

$m \le r$,
r is the order of $H(s)$,
n_i and d_i are real coefficients, with $d_i > 0$.

It is customary to scale the frequency parameter by some convenient normalizing frequency ω_n; i.e., s in Eq. 17 is a normalized frequency

$$s = j\omega/\omega_n \qquad \text{(Eq. 18)}$$

Similarly, because a voltage transfer function is independent of the impedance level, all components (R and C) in the filter are scaled by a suitable normalizing resistor R_n so that the circuit is composed of dimensionless normalized resistors R/R_n and capacitors $\omega_n C R_n$. The advantages of this step are that all parameters in Eq. 17



(A) Symbol. (B) Differential output. (C) Multiple differential inputs and differential output.

Fig. 4. Operational transconductance amplifiers.

are dimensionless and, more importantly, that the element values of the filter are dimensionless quantities, scaled for easier numerical computation.

In the following, it shall be assumed that $H(s)$ is given and our concern will be how to design an active filter to realize this prescribed transfer function. Space limitations do not permit us to discuss how to obtain $H(s)$ so that it approximates some desired magnitude or phase frequency response. This topic is treated in great detail in many excellent textbooks.*

General Realization Methods

If a high-order function such as Eq. 17 with $r \geq 4$ is prescribed, the engineer has to decide how to find a network structure and element values such that the measured voltage ratio V_2/V_1 is indeed as prescribed in $H(s)$. Numerous different techniques have been developed for this purpose, but they fall essentially into two different groups. One method attempts to break Eq. 17 into simpler functions of lower order, usually first-order

$$T_1(s) = (as+b)/(s+c) \qquad c>0 \qquad \text{(Eq. 19)}$$

and second-order sections

$$T_2(s) = \frac{as^2+bs+c}{s^2+s\omega_0/Q+\omega_0^2} \qquad Q>0,\ \omega_0>0 \qquad \text{(Eq. 20)}$$

which are then interconnected in a configuration suitable to implement Eq. 17. To keep with standard nomenclature, the denominator coefficients in Eq. 20 have been expressed in terms of the pole frequency ω_0 and the pole quality factor Q.

The second method draws on the vast experience in the many references and the numerous available tables for passive *LC* ladder filters, and their known excellent performance. In this case, either the structure or the equations describing the *LC* ladder are simulated via active *RC* filters; the inconvenient inductors are thereby avoided, but the positive properties of *LC* ladders are retained.

The details of high-order-function design are discussed in a later section of this chapter. Various popular and practically proven techniques are presented so that well-performing filters of reasonable complexity can be designed. In preparation for this step, realization methods for a number of elementary building blocks, such as first- and second-order sections, summers, integrators, and simulated inductors, are first discussed in the next two sections. Besides being useful in their own right, these components form the essential building blocks of high-order filters.

To decide which of the high-order design methods or which of the numerous available second-order filter sections might be best for a given application, it is necessary to establish practically useful performance criteria that permit the designer to make an informed selection. In addition to obvious points, such as ease of design effort, number of active and passive components needed, spread and size of element values, and required power consumption, all of which reflect themselves in the final price of the filter, the generally accepted most important criterion for a good filter is that of low sensitivity.

Sensitivity

The response or performance parameters of networks depend in general on some or all of the components in the circuit. For example, the gain of the closed-loop amplifier in Fig. 3A, Eq. 10, depends on the impedances Z_1 and Z_2 and on the op-amp gain $A(s)$. In practice, the components cannot be expected to have or even maintain their ideal, calculated, nominal values. Rather, owing to factors such as fabrication tolerances, aging, and temperature drifts, the element values will vary, and, consequently, so will the circuit response.

Clearly, it is of great interest to the filter designer to get an estimate of the expected magnitude of the response deviation caused by element variations. Preferably, this information should be available before the circuit is ever fabricated so that judgments can be made about the likelihood of the initial and continued operation of the circuit within specifications. The theory of sensitivity addresses this question.

Assume that a circuit response depends on the N elements or parameters k_i, $i = 1, \ldots, N$, i.e., $H(j\omega) = H(j\omega, k_1, k_2, \ldots, k_N)$. When the elements change from k_i to $k_i + \Delta k_i$ with Δk_i a small change, the total variation of H is obtained from

$$\Delta H \approx \frac{\partial H}{\partial k_1}\Delta k_1 + \frac{\partial H}{\partial k_2}\Delta k_2 + \cdots + \frac{\partial H}{\partial k_N}\Delta k_N \qquad \text{(Eq. 21)}$$

where higher order terms are neglected (Δk_i is assumed small!) and $\partial H/\partial k_i$ is the partial derivative of H with respect to k_i, evaluated at the nominal point. Upon normalizing, Eq. 21 can be rewritten as

$$\Delta H/H = \sum_{i=1}^{N} S_{k_i}^{H}\left(\Delta k_i/k_i\right) \qquad \text{(Eq. 22)}$$

where

$$S_{k_i}^{H} = \frac{k_i}{H}\frac{\partial H}{\partial k_i} = \frac{\partial H/H}{\partial k_i/k_i} = \frac{d\ln H}{d\ln k_i} \qquad \text{(Eq. 23)}$$

is the classical definition of the *single-parameter small-change sensitivity*; i.e., $S_{k_i}^{H}$ is a measure that indicates the percentage deviation dH/H caused by the percentage variation dk_i/k_i of the element k_i. Thus, with $S_{k_i}^{H}$ and the component tolerance known, for a change in a single parameter the expected response deviation is, from Eqs. 22 and 23,

$$\Delta H/H \approx S_{k_i}^{H}\left(\Delta k_i/k_i\right) \qquad \text{(Eq. 24)}$$

* References 1–8.

Equation 22, of course, gives an indication of the total change in H due to variations in all N parameters k_i. As an example, consider the op-amp stage with positive gain G in Fig. 3B, assuming for now $Z_i(s) = R_i$. From Eq. 11,

$$G = V_2/V_1 = \left(1 + R_2/R_1\right) \Big/ \left[1 + \left(1 + R_2/R_1\right)/A\right]$$

Using Eq. 23, it is easy to show that

$$S_{R_2}^G = -S_{R_1}^G = \frac{R_2/R_1}{\left(1 + R_2/R_1\right)\left[1 + \left(1 + R_2/R_1\right)/A\right]}$$

and

$$S_A^G = \frac{1 + R_2/R_1}{1 + \left(1 + R_2/R_1\right)/A} \cdot \frac{1}{A}$$

Thus, if the desired value of G is, say, 50 and if in the frequency range of interest $|A(j\omega)| >> 50$ can be assumed, then $R_2/R_1 = 49$ and

$$S_{R_2}^G = -S_{R_1}^G \approx 49/50 \approx 1 \qquad \text{(Eq. 25a)}$$

$$S_A^G \approx 50/A << 1 \qquad \text{(Eq. 25b)}$$

Using Eqs. 22, 24, and 25,

$$\frac{\Delta G}{G} \approx -\frac{\Delta R_1}{R_1} + \frac{\Delta R_2}{R_2} + \frac{50}{A}\frac{\Delta A}{A} \qquad \text{(Eq. 26)}$$

These numbers indicate that, as long as $|A(j\omega)| >> G$, changes in A have a negligible effect on ΔG, but that the percentage deviation of gain equals that of R_2 for constant R_1 and equals the negative of that of R_1 for constant R_2. Note also that if R_1 and R_2 track, i.e., if they increase or decrease by the same amount, say, due to temperature changes in a thin-film hybrid circuit, then $\Delta G/G \simeq 0$, because the ratio R_2/R_1 stays constant.

Several further observations can be made at this point. First note that since $A(j\omega)$ is a function of frequency, as for example in Eq. 8, G and all sensitivities also are functions of frequency and the sensitivity to $A(s)$ will increase with increasing ω because $|A(j\omega)| \simeq \omega_t/\omega$ decreases. Second, note that the frequency limitation imposed on the validity of Eq. 26, the requirement $|A| >> G = 50$, implies $\omega << \omega_t/50$ (e.g., $f << 20$ kHz for a 741-type op amp). This reemphasizes the point made earlier that active-network designs based on assumptions of ideal op amps can be expected to give reasonable results only at very low frequencies. Finally, remember that the op-amp gain is a very unreliable parameter: A_0 and ω_t often vary by more than 50% from unit to unit. Thus, this simple example indicates already that the circuit response, here the gain G, is very sensitive (Eq. 26) to A variations unless strong feedback is applied, i.e., $G << |A|$.

A number of interesting relationships that simplify sensitivity calculations can be derived.* Two of the more useful ones will be discussed. First, if a network response function depends on a parameter k_1 that in turn depends on a second variable k_2,

$$H = H(k_1)$$

where

$$k_1 = k_1(k_2)$$

then it is easy to show from Eq. 23 that

$$S_{k_2}^H = S_{k_1}^H \cdot S_{k_2}^{k_1} \qquad \text{(Eq. 27)}$$

For example, if k_1 is a resistor R and k_2 the temperature T (i.e., $R = R(T)$), Eq. 27 permits an easy evaluation of S_T^H.

The second relationship makes use of Eq. 2; if Eq. 2 is inserted in Eq. 23, it should be clear that S_k^H is a complex number equal to

$$S_k^{H(j\omega)} = S_k^{|H(j\omega)|} + j\frac{\partial \phi(\omega)}{\partial k/k} \qquad \text{(Eq. 28)}$$

Thus, the real part of the sensitivity of the transfer function $H(j\omega)$ to a parameter k equals the sensitivity of the magnitude (gain) of $H(j\omega)$, and its imaginary part specifies the absolute variation of phase resulting from the relative error in k. Thus, gain and phase deviations can easily be estimated.

Equation 24 describes the change to be expected in $H(s)$ when only one circuit parameter k_i varies. To minimize this change, $\Delta k_i/k_i$ has to be minimized (implying components of tight tolerances and therefore high cost) and/or a design has to be found that minimizes $S_{k_i}^H$. Thus, the importance of low-sensitivity filter circuits should be clear.

Although useful, the insight provided by single-parameter sensitivities is somewhat limited in many cases because the effect of the remaining element variations is not taken into account. Therefore, for a more realistic picture, the deterministic multiparameter sensitivity measure, Eq. 22, ought to be consulted and a performance criterion, such as

$$\sqrt{\sum_{i=1}^{N} \left|S_{k_i}^H\right|^2} \rightarrow \text{Min} \qquad \text{(Eq. 29)}$$

should be evaluated for a given selection of circuits to arrive at a best choice. Since $\Delta k_i/k_i$ and $S_{k_i}^H$ in general can be of either sign, some cancellations can be expected when $\Delta H/H$ is calculated from Eq. 22. Thus, Eq. 29 gives a somewhat pessimistic worst-case picture of circuit performance. Further, this measure does not take into account that in many modern filter technologies, such as in hybrid or monolithic integrated circuits, the element variations are statistically related and frequently highly correlated. For example, all resistors may track and increase and all capacitors track and decrease with changes in temperature or during fabrication. Treatment of this case is beyond the scope of this chapter; the interested reader is referred to Reference 6.

* Reference 6.

Although the above sensitivity discussion has been concentrated solely on deviations of the transfer function $H(s)$ caused by component changes, it should be understood that sensitivity calculations apply to any network parameter whose value depends on variable circuit components. For example, the center frequency and the selectivity of a bandpass function, or the cutoff frequency of a low-pass filter, depend in general on several resistors and capacitors and possibly on op-amp or OTA gain. Any shift in these parameters resulting from component variations can be estimated by calculating the corresponding sensitivities. Similarly, the precise location of transmission zeros or filter poles depends, of course, on the correct element values. Any variations or tolerances in the latter cause shifts in these critical frequencies and therefore transfer-function errors that can readily be evaluated by sensitivity calculations. All second- and higher-order filters discussed in the remaining four sections of this chapter have been evaluated extensively as to their sensitivity performance and are recognized as the best designs available. If a different active *RC* filter out of the numerous topologies presented in the literature is to be used, the sensitivities of the contemplated circuit should be carefully investigated to make sure that the design will work satisfactorily in practice. It is noted again that simple postdesign tuning to eliminate fabrication tolerances will in general not suffice because circuit components cannot be expected to retain their values under environmental stresses, such as aging or temperature fluctuations, Thus, low sensitivity is a necessary requirement for any circuit. When evaluating a filter, the reader ought to keep in mind that the sensitivity results presented are valid for *small changes* in element values because of the linearization involved in the analysis: Note from Eq. 21 that the function $H(j\omega, k)$ has been replaced by its slope in the nominal point $k = k_0$ to estimate changes caused by varying k from k_0 to $k_0 + \Delta k$. In particular, this means that a circuit with the desirable property $S_k^H = 0$ may not be entirely independent of the parameter k; it only says that at the nominal value $k = k_0$ the slope dH/dk is zero, usually implying a quadratic dependence on k. Large variations Δk can still cause unacceptable performance errors!

It is also emphasized that sensitivity expressions are usually functions of frequency so that the results ought to be evaluated in the frequency range of interest (normally in the passband or at the passband edges) when different possible designs are compared.

Finally, a last point is worth noting: Sensitivity is only an intermediate result and by itself can still create a misleading picture of circuit performance. In the ultimate analysis, what is important is the deviation or variability $\Delta H/H$, i.e., by Eqs. 21 or 24, the sensitivity multiplied by the expected component tolerances. Hence, relatively large sensitivities are acceptable when the relevant "component" (e.g., a resistor ratio in a thin-film hybrid realization) can be expected to be very accurate and stable. However, when a component varies strongly (e.g., op-amp gain–bandwidth product), very low sensitivities must be insisted upon.

FREQUENTLY USED BUILDING BLOCKS

Active filters are generally constructed by interconnecting a number of well-understood elementary building blocks. Understanding the performance of those blocks enables the designer to assemble a filter that works better and more reliably. Thus, in this section, the most important functional blocks are being introduced: the summer, the integrator, the general impedance converter (GIC), the gyrator (which is a circuit that is used to simulate an inductor via a capacitor), the frequency-dependent negative resistor (FDNR), and a circuit for realizing a first-order voltage transfer function. A separate section is devoted to the realization of second-order biquadratic transfer functions because of their special importance.

Summers

As the name implies, a summer is used to add different signals in a filter to form a desired sum signal. The circuit is essentially an extension of Fig. 3A in which various input signals V_i, $i = 1, \ldots, n$, are fed through weighting resistors to the virtual ground node V^- of the op amp (Fig. 5). Simple analysis yields

$$V_o = -\left(\sum_{i=1}^{n} a_i V_i\right) \Bigg/ \left[1 + \frac{1}{A}\left(1 + \sum_{i=1}^{n} a_i\right)\right]\Bigg|_{A\to\infty} = -\sum_{i=1}^{n} a_i V_i \qquad \text{(Eq. 30)}$$

Thus, for ideal amplifiers ($A \to \infty$), the output voltage is simply the negative sum of the input voltages, weighted by resistor ratios a_i. If the op-amp gain is finite and frequency-dependent, e.g., via Eq. 8, the summing coefficients exhibit frequency-dependent errors (specifically low-pass behavior) as is evident from Eq. 30. Whether or not this effect causes unacceptable deviations in a given filter depends on several factors and must be carefully investigated from case to case; no general rule can be given.

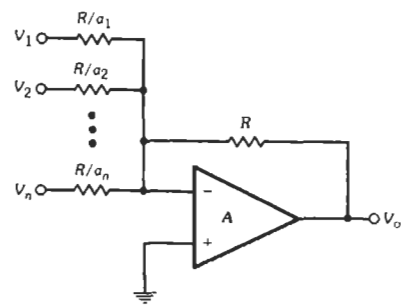


Fig. 5. Resistive op-amp summer.

In an OTA design, voltages are converted at each stage into currents as indicated by Eq. 14. *Current summing* is performed *automatically* at any circuit node via Kirchhoff's current law and so does not cost any elements. The designer is advised, therefore, to construct the circuit such that required summing functions are performed with currents rather than voltages. However, if voltages must be summed, it can be done as shown in differential form in Fig. 6. The circuits realize

$$g_{m1}(V_1^+ - V_1^-) + g_{m2}(V_2^+ - V_2^-) - g_{m3}(V_o^+ - V_o^-) = 0 \qquad \text{(Eq. 31)}$$

or

$$(V_o^+ - V_o^-) = (g_{m1}/g_{m3})(V_1^+ - V_1^-) + (g_{m2}/g_{m3})(V_2^+ - V_2^-) \qquad \text{(Eq. 32)}$$

Obviously, if the transconductances are identical, as is assumed in Figs. 6B and 6C, the scaling factors are unity. In Fig. 6B, the two OTAs g_{m1} and g_{m3} are merged into a two-input device; in Fig. 6C, all three devices are merged into one. This merging technique can be used whenever OTAs share a common output node and will generally result in significant savings of electronic components and power. Observe also that the transconductance g_{m3} with output fed back to the input realizes a grounded resistor of value $R = 1/g_{m3}$.

Integrators

One of the most basic functions in analog signal processing is that of integration; i.e., an output signal is obtained by integrating an input signal over time. In the frequency domain, this results in the transfer function

$$V_2/V_1 = \pm 1/(s\tau) \qquad \text{(Eq. 33)}$$

where τ is the integrator time constant. Equation 33 can be implemented by use of Fig. 3A with $Z_1 = R$ and $Z_2 = 1/(sC)$; i.e., assuming ideal op amps, the simple inverting integrator realizes

$$V_2/V_1 = -1/(sCR) \qquad \text{(Eq. 34)}$$

so that $\tau = RC$. Constructing filters by use of these very elementary, so-called Miller integrators results invariably in large errors, even at frequencies as low as 1 kHz, because of the overly ideal assumptions made about the op-amp gain. The problem can be appreciated by substituting the more realistic model of Eq. 8 into Eq. 10 with the result, for $\tau >> 1/\omega_t$

$$V_2/V_1 = -1/(s\tau + s^2\tau/\omega_t) \qquad \text{(Eq. 35)}$$

Thus, compared with the ideal case of Eq. 34, the integrator transfer function is no longer purely imaginary (it has acquired a parasitic pole), and its phase is not $\pi/2$ as an ideal integrator would demand. In analogy to the quality (Q) factor of capacitors and inductors, the ratio of imaginary to real part of the denominator of Eq. 35 is defined as the integrator Q-factor

$$Q_I = -\omega_t/\omega \approx -|A(j\omega)| \qquad \text{(Eq. 36)}$$

That is, the Q-factor of the Miller integrator is the negative of the op-amp gain at the frequency of interest.

It is apparent from Eq. 35 that the op amp introduces an excess phase lag into the integrator transfer function when compared to the ideal. Since filter behavior is usually particularly sensitive to such phase errors, procedures for their elimination have been devised; they can be classified as passive and active compensation methods, respectively. Fig. 7A shows a Miller integrator with passive phase compensation. Adding a compensation resistor of value $R_c = 1/(\omega_t C)$ into the feedback loop approximately cancels the phase lag introduced by the op amp at some nominal operating condition. The difficulty is that ω_t is not well determined and is variable (e.g., with temperature), and so compensation is difficult to maintain. A better, though more expensive, approach is active compensation (Fig. 7B), which attempts to cancel the errors by use of a second op amp. For well-matched amplifiers, routine analysis shows that the integrator of Fig. 7B has the large Q-factor of value $Q \approx -(\omega_t/\omega)^3 = -|A(j\omega)|^3$, a significant improvement. Two further integrators are shown in Figs. 7C and 7D. They are noninverting (plus sign in Eq. 33) and are very useful in their own right and especially because in filter circuits normally inverting and noninverting integrators are paired. The circuit

Fig. 7. Different phase-compensated integrator circuits.

in Fig. 7C again has a Q-factor of value $Q \approx -|A(j\omega)|$, whereas Fig. 7D can be shown to have $Q \approx +|A(j\omega)|$. It is noted here especially that the Q-factor of Fig. 7D is positive; i.e., the integrator has a leading phase error. This fact is significant because active-filter structures often consist of two-integrator loops where the total phase error can be virtually eliminated by pairing the circuit in Fig. 7D together with the regular Miller integrator in Fig. 7A (with $R_c = 0$). The result is much improved filter performance in spite of the relatively large phase error in each individual integrator.

In principle, building an integrator with OTAs requires only two elements: the OTA and a capacitor. The differential circuit in Fig. 8A shows how a *voltage* is integrated. The OTA converts the input voltage to be integrated into a current, which is then sent through a capacitor to produce a voltage that is the integral of the input:

$$V_o/V_i = g_m/(sC) \qquad \text{(Eq. 37)}$$

The positions of capacitor and OTA can also be interchanged (Fig. 8B) so that an input *current* first charges the capacitor whose voltage is sensed by the OTA and converted into an output current. The resulting *current* transfer function is identical to that in Eq. 37, $I_o/I_i = g_m/(sC)$. Filters based on this type of integration are called *current-mode filters*, which have a few desirable properties but behave essentially the same as voltage mode circuits. In the following, only voltage-mode circuits will be discussed.

As a practical matter, observe that the OTA output resistor $r_o = 1/g_o$ in Fig. 8A is in parallel with the capacitor C, so that the realized integration is lossy as described by

$$V_o/V_i = g_m/(sC + g_o) \qquad \text{(Eq. 38)}$$

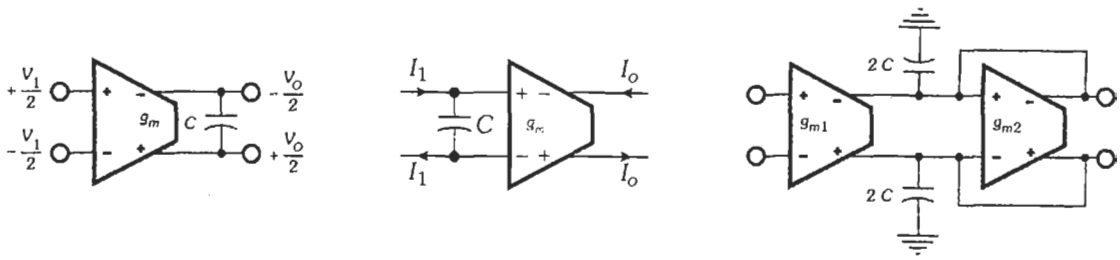
As mentioned earlier, for well-designed OTAs g_o can often be neglected, but the engineer should be aware of this effect and of the need of very small values of g_o (large values of r_o). Fig. 8C illustrates two concepts: (1) the integration can be made lossy on purpose as required for many filter blocks by including a resistor $1/g_{m2}$, and (2) the capacitors can be realized by grounded elements, which are often advantageous for reduced parasitics in IC implementation; the circuit realizes

$$V_o/V_i = g_{m1}/(sC + g_{m2}) \qquad \text{(Eq. 39)}$$

Because the two OTAs in Fig. 8C share common output terminals, they can be merged into one for potential savings in components and power. The process was illustrated in Fig. 6.

The General Impedance Converter (GIC)

One of the motivations for *active* filters is the elimination of inductors. Thus, finding methods for inductance simulation is an important topic in active-filter design. The best op-amp-based circuit for inductance simulation is the general impedance converter (GIC) shown in Fig. 9. Figure 9A shows the circuit and Fig. 9B shows a symbol that will be



(A) Circuit for Eq. 37. (B) Alternative circuit for Eq. 37 (C) Circuit for Eq. 39.

Fig. 8. OTA-*C* integrators.

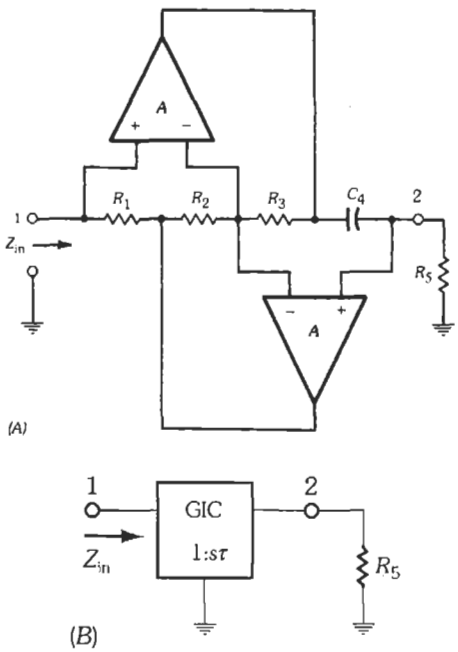


Fig. 9. GIC circuit to simulate a grounded inductor: (A) op-amp circuit, (B) GIC circuit symbol.

used later in the discussion of ladder networks. The circuit realizes between terminals 1 and ground the input impedance

$$Z_{in}(s) = s\left(C_4 R_1 R_3 / R_2\right) R_5 = s\tau R_5 \qquad \text{(Eq. 40)}$$

The definition of the time constant τ is apparent. Evidently, the circuit simulates a grounded inductor of value $L_0 = \left(C_4 R_1 R_3 / R_2\right) R_5 = \tau R_5$. To minimize the dependence of L_0 on op-amp performance (finite ω_t), the circuit is carefully optimized by setting $R_2 = R_3$ and $C_4 = 1/(\omega_c R_5)$. Here ω_c is some critical frequency value chosen in the passband or at the passband edge of the filter that uses the inductor. For these conditions, $L_0 = R_1/\omega_c$. R_1 is chosen to set the inductor value, and the inductor error and the inductor quality factor can be shown to be

$$\Delta L_0 / L_0\big|_{\omega=\omega_c} \approx 4 \Big/ \left|A(j\omega_c)\right| \qquad \text{(Eq. 41)}$$

$$Q \approx \left|A(j\omega_c)\right| \Big/ (2\varepsilon_r) \qquad \text{(Eq. 42)}$$

where $\varepsilon_r = \left|R_2 - R_3\right| / R_2$ represents the fractional mismatch between R_2 and R_3. Note that $Q = \infty$ can be obtained by tuning the circuit such that $R_2 = R_3$, i.e., $\varepsilon_r = 0$.

Fig. 9 simulates a grounded inductor. Although several procedures exist for simulating floating inductors with operational amplifiers, none has ever been found satisfactory in practice. Thus, alternative procedures had to be invented for those (e.g., low-pass) filters whose passive equivalent requires floating inductors. One such method was proposed by Gorski-Popiel.* It uses the fact that a GIC converts a load resistor, R_5 in Fig. 9, into an equivalent inductor of value τR_5 (Eq. 40) at its input terminals. As will be explained below, connecting two GICs back-to-back provides us with a floating inductor. Alternatively, impedance transformations may be used, which lead to the so-called frequency-dependent negative resistor (FDNR). This method will also be discussed below.

The Gyrator

A gyrator† is a two-port device whose input impedance is inversely proportional to the load impedance, i.e.,

$$Z_{in}(s) = r^2 / Z_{Load}(s) \qquad \text{(Eq. 43)}$$

where r is the *gyration resistance*, a parameter set by the implementation of the gyrator circuit. Evidently, if the load is a capacitor, $Z_{Load} = 1/(sC)$, the input impedance becomes that of an inductor, $Z_{in}(s) = sr^2C$, i.e., $L = r^2C$, and the circuit is readily realized in IC form. A gyrator is, in principle, a combination of an inverting and a noninverting voltage-controlled current source; it is quite difficult to build a good gyrator via op amps, but it is almost trivial to achieve such a component with transconductors. The circuit in Fig. 10A shows a

† References 2, 6, or 7.

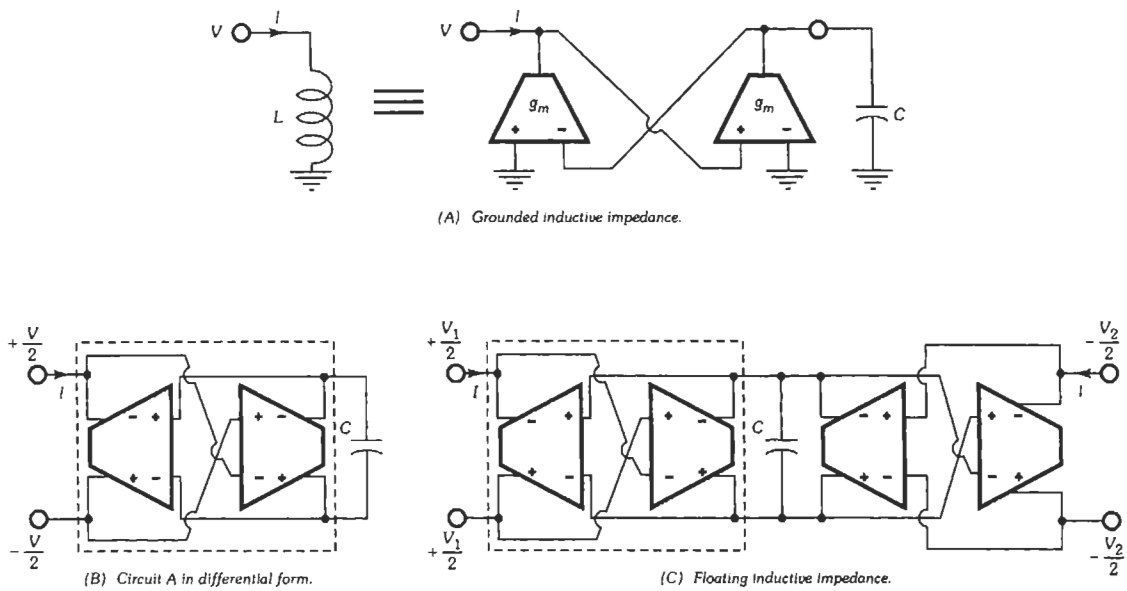

Fig. 10. Grounded and floating inductor simulation with OTA-based gyrators.

gyrator loaded by a capacitor C to realize the grounded inductive impedance

$$V/I = sL = sC/g_m^2 \qquad \text{(Eq. 44)}$$

For this circuit, the gyration resistance equals $1/g_m$. A floating inductor, as required for example in low-pass filters, can be built with two cascaded gyrators. The dashed box in Fig. 10B shows the circuit of Fig. 10A in differential form, and as an illustration, Fig. 10C contains an implementation of a floating inductor $Z_L = sL = (V_1 - V_2)/I$ in fully differential form. If all g_m values are the same, the inductor value realized is always given by Eq. 44.

The FDNR Element

The use of and motivation for FDNR elements in designing active filters based on passive LC prototypes will be discussed in a later section. Here, only the building block is introduced. The input impedance between terminal n and ground in the circuit of Fig. 11 is

$$Z_{in}(s) = \left[R_3/(C_1R_2R_4C_5)\right]/s^2 = 1/(D_0s^2) \qquad \text{(Eq. 45)}$$

For $s = j\omega$, Z_{in} is a frequency-dependent negative resistor of value $-1/(\omega^2 D_0)$ with $D_0 = C^2R_2R_4/R_3$ where $C_1 = C_5 = C$ was assumed. Again, to minimize the dependence of D_0 on op-amp parameters (finite ω_t), the circuit is carefully optimized by choosing $R_2 = R_3$ and $R_4 = 1/(\omega_c C)$, where ω_c is a critical frequency value chosen in the passband of the filter or at the band edge. The fractional deviation of D_0 is then

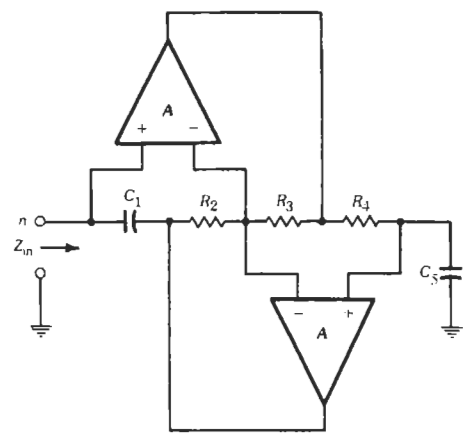

Fig. 11. FDNR element.

$$\Delta D_0/D_0 = 4/|A(j\omega_c)| \qquad \text{(Eq. 46)}$$

and its quality factor, defined as the ratio of real to imaginary part of $Z_{in}(j\omega)$, is

$$Q \approx |A(j\omega_c)|/(2\varepsilon_r) \qquad \text{(Eq. 47)}$$

where ε_r is the fractional mismatch between R_2 and R_3.

First-Order Transfer Functions

It was stated earlier that one technique for realizing a high-order transfer function involves breaking the func-

tion into first- and/or second-order subfunctions. These are then realized by suitable networks that are interconnected in an appropriate fashion. The realization of first-order voltage transfer functions is relatively simple and will be treated in the following. Second-order functions are discussed in the next section.

Fig. 12 shows different realizations of a function of the form of Eq. 19, repeated here as Eq. 48:

$$T(s) = V_2/V_1 = (as+b)/(s+c) \quad c>0 \qquad \text{(Eq. 48)}$$

Fig. 12A is an appropriate realization if $0 \le a \le 1$ and $0 \le b \le c$. Note that in this case $T(s)$ is realized by a passive RC network. The amplifier is a special case of Fig. 3B for $Z_2 = 0$ and $Z_1 = \infty$; it is a buffer amplifier with unity gain and very high input and zero output impedance. The buffer has been included for the case in which the RC network may have a significant load; otherwise it can be omitted. Fig. 12B, a special case of Fig. 3A, realizes $-T(s)$; the minus sign, a 180° phase shift, is immaterial in many applications. Fig. 12C realizes $T(s)$ for the case in which $a \ge 1$ and $0 \le c \le b$. Finally, Fig. 12D takes care of the case when $a = 1$ and $b < 0$, i.e., $T(s) = (s-|b|)/(s+c)$, a regime important for all-pass functions (see below).

It is noted here that the circuits in Figs. 12B, 12C, and 12D realize Eq. 48 under the assumption of ideal amplifiers. As discussed earlier, if the op amp is described by Eq. 8, discrepancies from the ideal frequency response must be expected. Fortunately, however, the majority of all cases require only the realization of Eq. 48 with either $a = 0$ or $b = 0$. Fig. 12A can then always be used, possibly after factoring out a multiplying (gain) constant that can be taken care of in the remaining parts of the circuit. The unity-gain buffer amplifier requires for perfect operation only $|A(j\omega)| >> 1$, as can readily be seen from Eq. 11.

With OTAs, a general and versatile first-order function can be implemented as shown in Fig. 13. The fully differential circuit realizes

$$V_o/V_i = -(sC_1 + g_{m1})/(sC_2 + g_{m2}) \qquad \text{(Eq. 49)}$$

Note that depending on the polarity of the transconductances and their connections, the values of g_{m1} and g_{m2} may be positive or negative so that zeros anywhere in the s-plane and both inverting and noninverting transfer functions can be realized.

SECOND-ORDER TRANSFER FUNCTIONS—THE BIQUADS

Probably the most important basic building block used in the design of active filters is the biquad, a second-order circuit that realizes the transfer function of Eq. 20, which is repeated here as Eq. 50:

$$T(s) = \frac{N(s)}{D_2(s)} = \frac{as^2+bs+c}{s^2+s\omega_0/Q+\omega_0^2} \qquad \text{(Eq. 50)}$$

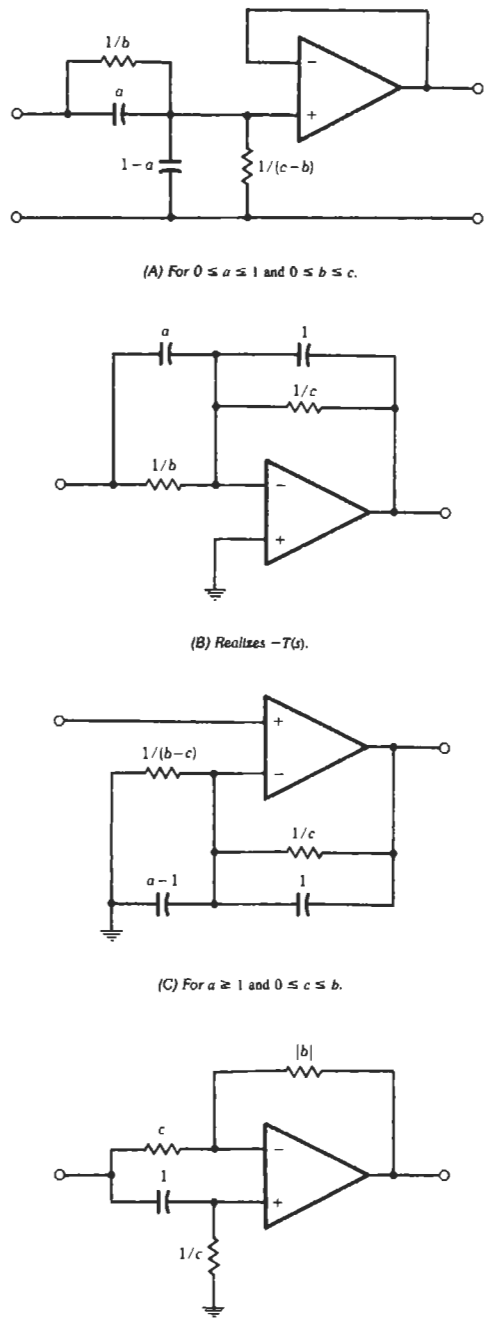

Fig. 12. Different realizations of $T(s)$ in Eq. 48. The element values are normalized resistors and capacitors.

where $\omega_0 > 0$ and $Q > 0$. It is standard practice to identify the coefficients of the second-order denominator polynomial $D_2(s)$ via the pole frequency ω_o and the

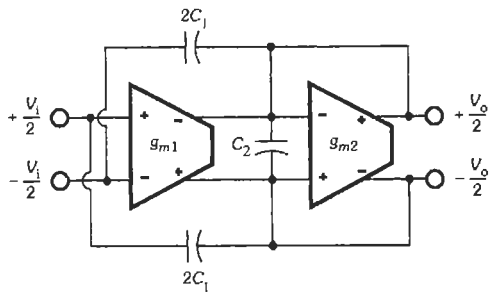

Fig. 13. First-order OTA-*C* filter section.

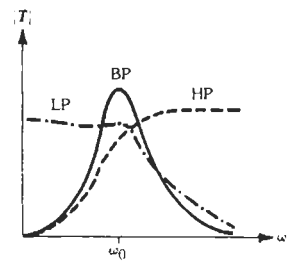
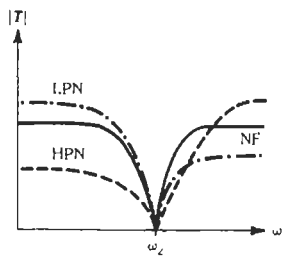
pole quality factor Q. The coefficients a, b, and c of the numerator polynomial $N(s)$ specify the type of transfer function realized (Fig. 14): If $N(s) = c$, i.e., $a = b = 0$, $T(s)$ is a low-pass (LP) function; if $N(s) = as^2$, i.e., $b = c = 0$, $T(s)$ is a high-pass (HP) function; if $N(s) = bs$, i.e., $a = c = 0$, $T(s)$ reduces to a bandpass (BP) function. A finite transmission zero at $\omega = \omega_z$ is obtained by setting $b = 0$; i.e., $N(s) = as^2 + c = a(s^2 + \omega_z^2)$ where $\omega_z^2 = c/a$. Such a circuit is called a "notch" filter (NF) and is distinguished further between a high-pass notch (HPN) if $\omega_z \le \omega_0$ and a low-pass notch (LPN) if $\omega_z \ge \omega_0$. Finally, if $N(s)$ can be brought into the form $N(s) = a(s^2 + sb/a + c/a) = a\left(s^2 - s\omega_0/Q + \omega_0^2\right)$, i.e., $a \ne 0$, $c > 0$, $b < 0$, then $|N(j\omega)| = |D_2(j\omega)|$, so that $|T(j\omega)| = 1$.



(A) Pass characteristics.



(B) Notch characteristics.

Fig. 14. Typical plots of the basic second-order transfer functions.

Such an "all-pass" (AP) filter passes signals of all frequencies without attenuation but imposes a frequency-dependent phase shift of value

$$\phi = -2\arctan\left[\left(\omega\omega_0/Q\right)/\left(\omega_0^2 - \omega^2\right)\right] \qquad \text{(Eq. 51)}$$

To realize the function of Eq. 50 or any of the mentioned special cases, the technical literature contains literally hundreds of different circuits. Fortunately, the choice is simplified for the engineer because closer examination reveals that the vast majority of all circuits have some drawback or another, usually excessive sensitivities, so that only two or three structures are used for practical active filters. These will be discussed in the following.

Single-Amplifier Filters

Fig. 15 contains three state-of-the-art single-amplifier active filters that can be used to realize the function in Eq. 50 with any of its special cases. The circuits are related to each other by complementary and by *RC*:*CR* transformations. The transfer-function pole sensitivities, i.e., the ω_0 and Q sensitivities, can be shown to be the same for all three circuits. Specifically, the sensitivities of ω_0 to the passive elements are at their theoretical minima, $S_{k_i}^{\omega_0} = -0.5$, where k_i stands for any of the resistors and capacitors, and the passive sensitivities of Q satisfy

$$\left|S_{k_i}^{Q}\right| \approx Q/q - 0.5 \qquad \text{(Eq. 52)}$$

where q is a free design parameter, defined as a resistor ratio in Fig. 15. Further, it can be shown that ω_0 and Q deviations caused by the finite op-amp gain–bandwidth product ω_t are

$$\Delta\omega_0/\omega_0 \approx -q\,\omega_0/\omega_t \qquad \text{(Eq. 53)}$$

$$\Delta Q/Q \approx q\left(\omega_0/\omega_t\right)\left(1 - 2QK\,\omega_0/\omega_t\right) \qquad \text{(Eq. 54)}$$

where K is defined in Fig. 15. The value of free parameter q is arrived at through a compromise dictated by the technology chosen to implement the filter: It is apparent from Eqs. 52, 53, and 54 that increasing q will reduce the passive Q sensitivities but will increase the ω_0 and Q deviations caused by the active element via finite ω_t. Taking into consideration that in the design, Eq. 60b below, the value of K depends on the choice of q, we can show that for sensitivity and realizability reasons (see Eq. 59) the value of q must be restricted by

$$\sqrt{6}/2 \le q \le Q \qquad \text{(Eq. 55)}$$

In practice, q in the range of 3 to 5 is a reasonable tradeoff between active and passive sensitivities.

The initial error caused by finite ω_t can be eliminated by predistortion, i.e., by applying the negative of the deviations, Eqs. 53 and 54, to the nominal values

(C) High-pass biquad.

Fig. 15. Single-amplifier biquads.

of ω_0 and Q and by basing the design on the predistorted values

$$\omega_{0p} = \omega_0 + \Delta\omega_0 = \omega_0\left(1 + q\,\omega_0/\omega_t\right) \qquad \text{(Eq. 56)}$$

$$Q_p = Q + \Delta Q = Q\left[1 - q\left(\omega_0/\omega_t\right)\left(1 - 2QK\,\omega_0/\omega_t\right)\right] \qquad \text{(Eq. 57)}$$

The transfer functions of the three circuits in Fig. 15A, B, and C can be shown to be

$$T_i(s) = N_i(s)/D(s) \quad i = A, B, C$$

where the denominator equals

$$D(s) = s^2 + s\,\omega_0/Q + \omega_0^2 \qquad \text{(Eq. 58)}$$

with $\omega_0 = 2qG/C$ and $Q = q/\left[1 - 2q^2(K-1)\right]$, and the numerators are

$$N_A(s) = -s4Kmq^2\,G/C \qquad \text{(Eq. 59a)}$$

$$N_B(s) = K\left\{s^2(n-p) + s\frac{2G}{C}\left[n - p\left(2q^2+1\right)\right] + \omega_0^2(m-p)\right\} \qquad \text{(Eq. 59b)}$$

$$N_C(s) = K\left\{s^2(m-p) + s\frac{2G}{C}\left[n - p\left(2q^2+1\right)\right] + \omega_0^2(n-p)\right\} \qquad \text{(Eq. 59c)}$$

where the parameter $p = k(K-1)/K$. To realize a transfer function of the form of Eq. 50 with given pole quality factor Q and pole frequency ω_0, by Eq. 58 the elements C and $G = 1/R$ and the resistor ratio K in all three circuits in Fig. 15 are determined from

$$RC = 2q/\omega_{0p} \qquad \text{(Eq. 60a)}$$

$$K = 1 + \left(1 - q/Q_p\right)/\left(2q^2\right) \qquad \text{(Eq. 60b)}$$

where q should satisfy Eq. 55 and ω_{0p} and Q_p are replaced by ω_0 and Q if predistortion is not used. The resistor $R_0 = 1/G_0$ is arbitrary, because only the ratio $K - 1$ enters the transfer function. Further, either C or $R = 1/G$ can be chosen for convenience because only the RC product is determined by Eq. 60. As a rule, C is chosen because of the more limited number of available standard values.

The values of the circuit parameters m, n, and k (all less than or equal to unity) determine the type of transfer function. They are defined in Fig. 15 and as indicated in Eq. 59 determine the coefficients a, b, and c in Eq. 50. Equation 59 shows that the two circuits in Figs. 15B and 15C can realize a complete biquadratic transfer function as in Eq. 50; however, the transmission zero (ω_z) sensitivities and the notch depth of the circuit in Fig. 15C increase with increasing ratio ω_z/ω_0. The opposite is true for the circuit in Fig. 15B. Thus, Fig. 15B gives the preferred circuit for a low-pass-notch, $\omega_z \geq \omega_0$ (see Fig. 14), and low-pass applications, whereas Fig. 15C shows the preferred circuit for high-pass-notch ($\omega_z \leq \omega_0$) and high-pass applications. Further, an all-pass filter can be designed using either of the biquads in Figs. 15B and 15C, and a bandpass filter is best built using the circuit in Fig. 15A.

With the help of Eqs. 58 through 60, arbitrary second-order functions can be designed. Specific design

information for the six basic biquads (those in Fig. 14 plus the all-pass filter) is given in Table 1 and Eqs. 50, 51, and 55 through 60. The design of a general biquadratic transfer function can be derived with Eqs. 59. The reader is also referred to References 7 and 15 on which the information in this subsection is based.

A couple of examples will illustrate the use of the information presented. First, assume the bandpass function

$$T(s) = -2s_n / \left(s_n^2 + 0.1s_n + 1\right) \qquad \text{(Eq. 61)}$$

has to be realized, where the frequency parameter s_n is normalized with respect to $\omega_0 = 2\pi \times 3$ kHz, i.e., $s_n = s/\omega_0$. Equation 61 is a special case of Eq. 50 with $a = c = 0$, $b = -2\omega_0$; $\omega_0 = 2\pi \times 3$ kHz, and $Q = 10$. Note that at $\omega = \omega_0$, i.e., $|s_n| = 1$), $T(s_n) = -20$; the midband gain of the filter is inverting with a magnitude of 20, or 26 dB. From Eq. 55, q should satisfy $1.2 \le q \le 10$; a good choice, as stated earlier, is $q = 4$. Assuming the circuit will be built using a 741-type op amp with $\omega_t = 2\pi \times$ 900 kHz, the expected sensitivities and deviations are, from Eqs. 52 through 54, $\left|S_k^Q\right| \le 2$, $\Delta\omega_0/\omega_0 \approx -0.013$, and $\Delta Q/Q \approx 0.013(1 - 0.07K)$, where, from Eq. 60b with $Q_p = Q$, $K = 1.01875$. Thus $\Delta Q \approx 0.12$, giving a 1.2% error. To reduce this error, predistortion may be used, i.e., from Eqs. 56 and 57 the circuit is designed for $Q = Q_p = 9.88$, resulting in $K - 1 = 0.0186$. Further, from Eq. 56, $\omega_{0p} = 2\pi \times 3.04$ kHz so that, from Eq. 60a, $RC = 418.83$ μs. Choosing $C = 10$ nF gives $R = 41.9$ kΩ. Finally, the bandpass design is completed by calculating, from Eq. 59a, $m = |b| / \left(2Kq\omega_{0p}\right) = 1/(Kq) = 0.2454$ (note that in this example $b < 0$). Choosing arbitrarily $R_0 = 1$ kΩ, gives the resulting bandpass filter shown in Fig. 16.

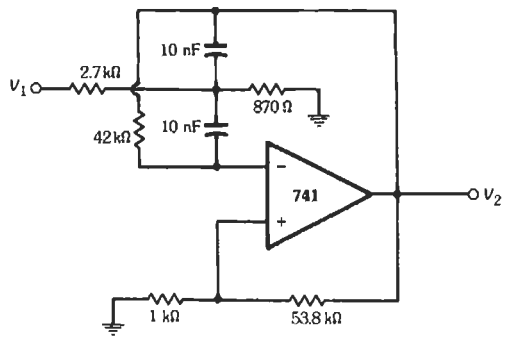

Fig. 16. Bandpass circuit of Fig. 15A realizing the example of Eq. 61.

As the next example, design a low-pass notch filter realizing, with the maximum possible high-frequency gain H,

$$T(s) = H\left(s_n^2 + 2.3\right) / \left(s_n^2 + 0.12s_n + 1\right) \qquad \text{(Eq. 62)}$$

where s_n is normalized with respect to $\omega_0 = 2\pi \times 2.4$ kHz. Comparing Eq. 62 with Eq. 50 results in $\omega_0 = 2\pi \times 2.4$ kHz, $Q = 1/0.12 = 8.333$, $a = H$, $b = 0$, and $c = 2.3\omega_0^2 H$, i.e., $\omega_z = 1.5166\,\omega_0$. Choosing $q = 3.5$ and assuming $\omega_t = 2\pi \times 900$ kHz gives $\left|S_k^Q\right| \le 1.881$, $\Delta\omega_0/\omega_0 \approx -0.009$, $\Delta Q/Q \approx 0.009$, and $K \approx 1.0237$, where Eqs. 52 through 54 and 60b were used. The deviations are quite small, so predistortion appears unnecessary; thus, selecting $C = 10$ nF, from Eq. 60a, we get $R = 2q/\left(\omega_0 C\right) = 46.24$ kΩ. The function will be realized via the circuit in Fig. 15B; thus from Table 1: $k = 1.724H$, $m = 2.289H$, and $n = 1.0167H$. Since k, m, and n must be less than or equal to 1, $H_{max} = 0.4369$; then $k = 0.7532$, $m = 1$, and $n = 0.4442$. Finally, R_0 is chosen equal to 1 kΩ, and the final low-pass notch circuit is as shown in Fig. 17.

Two-Amplifier Filters

The literature contains several multiamplifier second-order filters whose main advantage over single-amplifier circuits is that the sensitivities both to the passive components and to the op amps' finite gain–bandwidth product, ω_t, are reduced. Based on a sensitivity comparison, only a few of these circuits have been shown to result in practical designs. Among

TABLE 1. DESIGN DATA FOR CIRCUITS IN FIG. 15

these, the biquad based on inductance simulation using an alternative version of the general impedance converter (GIC) of Fig. 9 has emerged as one of the best biquads owing to the reduced dependence of filter parameters on ω_t.

The circuit capable of realizing a general biquadratic transfer function (except low-pass) is shown in Fig. 18. Simple analysis yields, for $\omega_t \to \infty$,

$$T(s) = \frac{V_2}{V_1} = \frac{N(s)}{D(s)} = \frac{a_2 s^2 + a_1 s\omega_0 + a_0\omega_0^2}{s^2 + s\omega_0\left(1/Q + R/R_c\right) + \omega_0^2} \qquad \text{(Eq. 63)}$$

with

$$\omega_0 = 1/(RC) \qquad \text{(Eq. 64a)}$$

and

$$a_0 = b \qquad \text{(Eq. 64b)}$$

$$a_1 = \left[aH - b(H-1)\right]\left(1/Q + R/R_c\right) - aH\,R/R_c \qquad \text{(Eq. 64c)}$$

$$a_2 = cH - b(H-1) \qquad \text{(Eq. 64d)}$$

The resistor R_c is a compensation resistor used only for the case when $H \neq 2$ (see Eq. 68). $R_c = \infty$ for $H = 2$.

Different types of transfer functions are realized by an appropriate choice of the parameters a, b, and c that are defined in Fig. 18. Table 2 gives details. Of course, a, b, and c must be less than or equal to 1, and $H > 1$. The circuit of Fig. 18 cannot realize a good low-pass function because the finite value of ω_t degrades the performance. Thus, a low-pass filter is built with a slightly modified circuit as shown in Fig. 19; it realizes, with $\omega_0 = 1/(CR)$,

$$T(s) = V_2/V_1 = 2\omega_0^2/\left(s^2 + s\omega_0/Q + \omega_0^2\right) \qquad \text{(Eq. 65)}$$

A few observations are in order about the performance of GIC-based filters: As was the case with the GIC in Fig. 9, the circuit is optimally insensitive to ω_t if all GIC-internal resistors are equal. In Fig. 18, this clearly requires $H = 2$, which according to Table 2 implies that the midband gain of the bandpass filter and the high-frequency gain of the high-pass filter are fixed at $H = 2$. However, in many applications, especially in high-order filters based on second-order building blocks (see next section), the gain must be adjustable to maximize dynamic range.

If the required gain is less than 2, the lead-in element (QR for the bandpass filter, C for the high-pass filter), can simply be split into a voltage divider of an appropriate ratio. This step does not upset the desirable value $H = 2$. However, $H > 2$ can be achieved only by setting the two resistors $(H - 1)R$ in Fig. 18 to the appropriate value (or using an additional amplifier to raise the signal). The effect of $H > 2$ can be shown to result in a very significant enhancement of Q in addition to a decrease of ω_0 with increasing values of ω_0/ω_t. The ω_0 error

$$\Delta\omega_0/\omega_0 = \left(\omega_a - \omega_0\right)/\omega_0 \approx -0.5\left[H^2/(H-1)\right]\omega_0/\omega_t \qquad \text{(Eq. 66)}$$

* Not realizable well with this circuit (see Fig. 19).

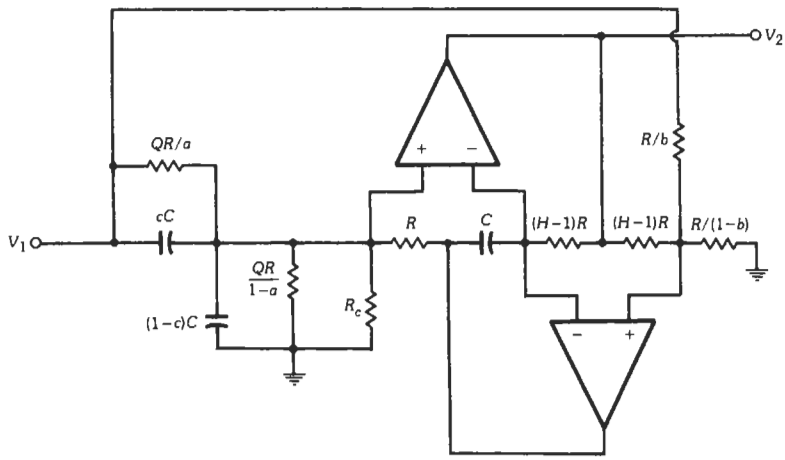

Fig. 18. A GIC-based biquad.

(where ω_a is the actually realized pole frequency) has its minimum at $-2\omega_0/\omega_t$ for $H = 2$. It can be corrected only by predistortion. The Q deviation, expressed as

$$Q_a = Q\Big/\Big\{1+\big[1-2Q(2-H)/H\big]\Delta\omega_0/\omega_0 + 2\big(3-4/H\big)Q\big(\Delta\omega_0/\omega_0\big)^2\Big\} \qquad \text{(Eq. 67)}$$

(where Q_a is the actually realized pole quality factor) also is minimized for $H = 2$ and can be shown to be reduced approximately to zero, i.e., $Q_a \approx Q$, by connecting a compensation resistor

$$R_c \approx R(1+m)^2\big/\big[m(H-2-m)\big] \qquad \text{(Eq. 68)}$$

in shunt with the GIC input, as indicated in Fig. 18. In Eq. 68,

$$m = \big[H/(H-1)\big]\omega_0/\omega_t \qquad \text{(Eq. 68a)}$$

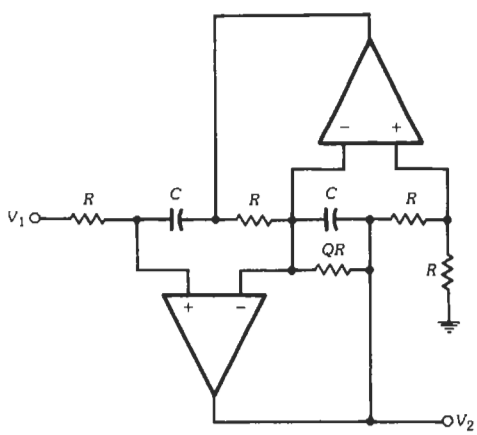

Fig. 19. GIC low-pass filter.

Equation 68 is valid for pole frequencies satisfying (approximately)

$$\omega_0 \le 0.3\,\omega_t/H \qquad \text{(Eq. 69)}$$

For larger values of ω_0, Eq. 68 becomes increasingly inaccurate, but Q compensation can still be achieved by functional tuning of R_c. A note of caution must be made: The value of R_c is seen to depend on ω_t, which is process-, temperature-, and bias-dependent, is very inaccurate, and changes from op amp to op amp. Compensating this parameter with a passive resistor can, at best, be only approximate.

The function of R_c is only to eliminate ω_t-caused Q enhancement for $H > 2$; otherwise, it has no effect on the realized transfer function apart from the slight dependence of a_1 on R_c shown by Eq. 64c. Since by Eq. 69a m is small, as is seen from Eq. 68, R_c is eliminated, i.e., $R_c \to \infty$ for $H = 2$.

In the all-pass and notch circuits, nothing significant is gained by choosing $H \neq 2$, and no usable compensation exists for $H \neq 2$ in the low-pass filter of Fig. 19. Thus, all GIC-internal resistors are set equal in these circuits.

Finally, it should be mentioned that Q is quite sensitive to capacitor losses. Labeling the capacitor loss resistor R_L and using Eqs. 5 and 64a, we obtain $Q_c = \omega_0 CR = R_L/R$. The actual quality factor, Q_a, can be shown to be

$$Q_a = Q\big/\big(1+2Q/Q_c\big) \qquad \text{(Eq. 70)}$$

where by Q we labeled the ideal quality factor, independent of such effects as finite ω_t and $H \neq 2$. Thus, high-quality capacitors should be used to build these filters. Further details about GIC-filter performance can be found in References 2, 6, and 7, on which most of this discussion is based.

As a design example, assume that the bandpass function

$$T(s) = 0.8 s_n / \left(s_n^2 + 0.1 s_n + 1\right) \qquad \text{(Eq. 71)}$$

with $s_n = s/\omega_0$ and $\omega_0 = 2\pi \times 6$ kHz has to be realized. Assume further that op amps with $\omega_t = 2\pi \times 900$ kHz are available. From Eq. 71, pole frequency, quality factor, and midband gain are, respectively, $f_0 = 6$ kHz, $Q = 10$, and $H = 8$. From Table 2 for a bandpass filter: $a = 1$ and $b = c = 0$. From Eq. 69 it follows that $f_0 = 6$ kHz < 33.7 kHz so that Eq. 68 applies. Thus, $R_c = 22.24R$ will compensate for ω_t-caused Q enhancement that by Eq. 67 would be 79%; i.e., without R_c, $Q_a = 1.79Q = 17.9$. Remember though that this compensation depends on the specific value of ω_t assumed in the design. Further, from Eq. 66, $\Delta f_0 \approx -183$ Hz, a –3.0% error. To eliminate this nominal deviation, the filter is designed with predistortion to realize $f_0 = 6.189$ kHz so that a –3% error gives $f_a = 6$ kHz. Thus, from Eq. 64a with $C = 10$ nF, $R = 2572\ \Omega$; therefore, $QR = 25.7$ kΩ and $(H - 1)R = 18.0$ kΩ. The circuit is shown in Fig. 20.

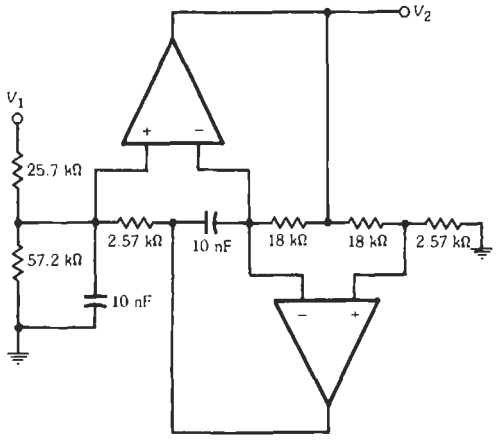

Fig. 20. GIC filter realizing Eq. 71.

Three-Amplifier Filters*

As demonstrated in the previous discussion, using additional amplifiers may lead to design and performance advantages for active filters. Thus, let us briefly present a three-amplifier section, the so-called Åckerberg–Mossberg (AM) biquad depicted in the top part of Fig. 21. The circuit consists of an inverting integrator (amplifier A_1, C, R, QR, R/k) and a noninverting integrator (A_3, C, and the inverter, A_2 and R_a) connected in a feedback loop. At the outputs V_L and V_B, respectively, the circuit realizes the inverting low-pass and bandpass transfer functions

$$T_L(s) = -k\omega_0^2 / D(s), \quad T_B(s) = -k\left(s\omega_0/Q\right)/D(s) \qquad \text{(Eq. 72)}$$

where

$$D(s) = s^2 + s\,\omega_0/Q + \omega_0^2, \quad \text{with } \omega_0 = 1/(RC) \qquad \text{(Eq. 73)}$$

R, C, k, and Q are identified in the figure. If a fourth op amp is available, e.g., in a "quad" (four op amps on an IC chip), a general biquadratic transfer function can readily be obtained by adding the three outputs (V_L, $-V_L$, V_B) available in the AM circuit to its input. This is illustrated in Fig. 21 by the additional summer (built with A_4 and five resistors). The final circuit realizes the function

$$T(s) = \frac{N_2(s)}{D(s)} = \frac{\alpha s^2 + s\left[\alpha - \beta k Q\right]\omega_0/Q + \left[\alpha - (\gamma - \delta)k\right]\omega_0^2}{s^2 + s\,\omega_0/Q + \omega_0^2} \qquad \text{(Eq. 74)}$$

Evidently, any kind of second-order transfer function, as called for in Eq. 50, can be implemented with this circuit by choosing of the values (G_0, αG_0, βG_0, γG_0, δG_0) of the summing resistors appropriately. Table 3 gives the design details. Of course, low-pass and bandpass functions can be obtained directly from the basic AM circuit (Eq. 72) without any need for a summer.

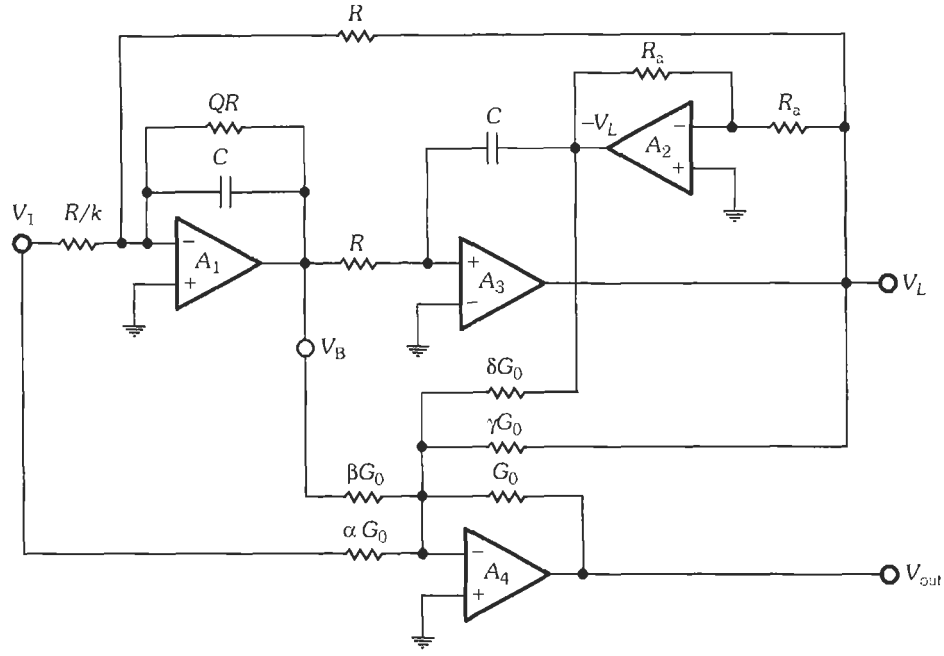

Fig. 21. The Åckerberg–Mossberg biquad with summer.

Transconductance-*C* (g_m-*C*) Filters

For applications at high frequencies, especially in integrated form, it is usually necessary to resort to g_m-C implementations of biquads because of the restrictions imposed by op-amp realizations. For these situations, a suitable biquad is shown in Fig. 22. (For ease of understanding, a single-ended version is shown; see Reference 6 for a simple and systematic method of converting a single-ended circuit into fully differential form.) The circuit realizes

$$V_o = \frac{(bV_3)s^2 + [bV_3 - aQ^2V_2](\omega_0/Q)s + (g_{m1}/g_m)\omega_0^2 V_1}{s^2 + s\,\omega_0/Q + \omega_0^2} \qquad \text{(Eq. 75)}$$

where the capacitors were selected as

$$C_1 = (g_m/\omega_0)Q, \quad C_2 = (g_m/\omega_0)/Q \qquad \text{(Eq. 76)}$$

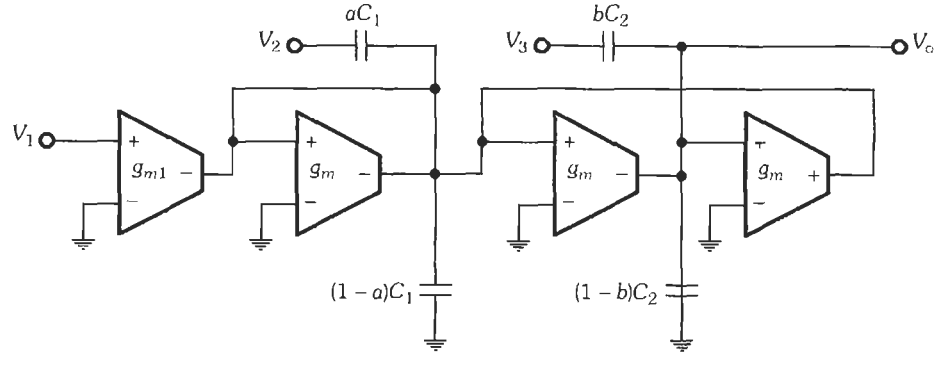

Fig. 22. Second-order g_m-C biquad.

and, therefore,

$$\omega_0 = g_m/\sqrt{C_1C_2} \quad \text{and} \quad Q = \sqrt{C_1/C_2} \qquad \text{(Eq. 77)}$$

Depending on whether the input V_{in} is applied to the terminal V_1, V_2, and/or V_3, the circuit in Fig. 22 can realize any type of second-order function. In particular, a fully biquadratic function can be obtained by setting $V_1 = V_2 = V_3 = V_{in}$.

As an example, a practical differential low-pass circuit is shown in Fig. 23; it is obtained from the circuit in Fig. 22 setting $a = b = 0$ and converting the result to fully differential form. This circuit realizes

$$V_o/V_{in} = (g_{m1}/g_m)\omega_0^2/(s^2 + s\omega_0/Q + \omega_0^2) \qquad \text{(Eq. 78)}$$

Very similar low-pass sections have been used to implement fully integrated seventh-order constant-delay low-pass filters in the frequency range of 10–80 MHz for the read/write channels of magnetic disk storage systems.* Observe that all transconductors with common output terminals can be merged into one transconductor, a step that may save considerable power and electronic components on the integrated circuit.

HIGH-ORDER TRANSFER FUNCTIONS

As indicated earlier, high-order transfer functions are realized by one of three methods: (1) by cascading first- and/or second-order sections, (2) by connecting second-order sections in a suitable feedback topology, and (3) by simulating the elements of a lossless *LC* ladder or their operation. The primary advantage of Methods 2 and 3 is that they lead to designs with lower sensitivity to component variations than the cascade approach. The price paid for this benefit is a more complicated design and more difficult tuning, but a major benefit of Method 3 is the possibility of using numerous design tables† and other filter information.

In the following, the cascade method, "follow-the-leader feedback" (FLF) designs, and the ladder simulation approach are discussed in sufficient detail to permit construction of reliable high-order filters. Derivations, proofs, and further details about these and several other approaches are contained in many excellent textbooks and papers.‡

Cascade Realization

The easiest and most popular method for realizing a high-order function $H(s)$ is via a cascade connection of second-order filter sections as shown in Fig. 24. For many applications cascade circuits are entirely adequate. Assuming no interaction between the sections T_i, $i = 1, ..., l$, i.e., each filter block $T_i(s)$ has a low output and/or high input impedance, the overall voltage gain of the circuit in Fig. 24 is

$$H(s) = \frac{V_o}{V_i} = \frac{V_1}{V_i}\frac{V_2}{V_1}\cdots\frac{V_{l-1}}{V_{l-2}}\frac{V_o}{V_{l-1}} = T_1T_2\cdots T_l \qquad \text{(Eq. 79)}$$

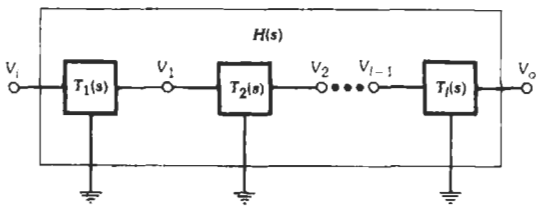

Fig. 24. Cascade connection of blocks $T_i(s)$.

† References 17 and 18.

‡ References 1–3, 6, and 7.

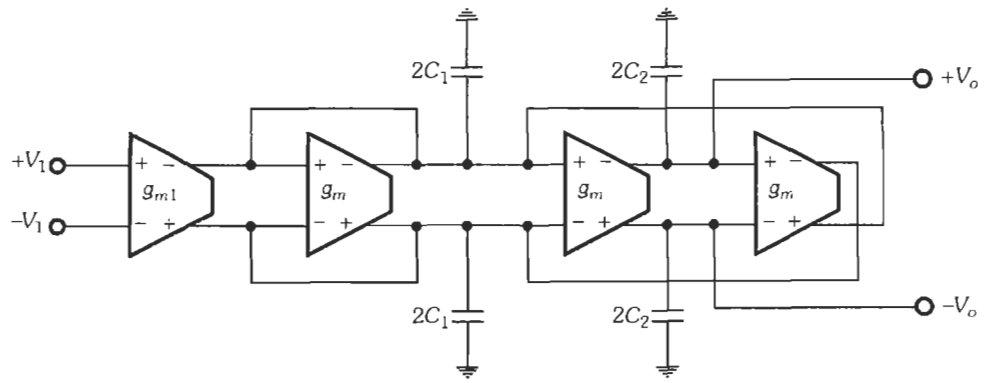

Fig. 23. Fully differential g_m-C second-order low-pass filter.

To this end, Eq. 17 is factored into the product of l second-order transfer functions $T_i(s) = N_i(s)/D_i(s)$ of the form of Eq. 50, such that

$$N(s) = \prod_{i=1}^{l} N_i(s), \quad D(s) = \prod_{i=1}^{l} D_i(s) \qquad \text{(Eq. 80)}$$

This step is accomplished simply by finding the (in general) complex roots of $N(s)$ and $D(s)$ and keeping conjugate complex terms together so that all coefficients in $T_i(s)$ are real.

The notation in Eqs. 17, 79, and 80 has tacitly assumed that $H(s)$ is of even order, i.e., that r is even. Of course, if r is odd, one of the transfer functions $T_i(s)$ in Eq. 79 must be of first order; that is, it must be of the form of Eq. 48, whose realizations are given in Figs. 12 and 13. Such a first-order function can always be cascaded with the remainder of the network. If in Eq. 17 $m < r$, some of the terms $N_i(s)$ in Eq. 80 are frequency independent constants so that the corresponding biquads are low-pass functions. Thus, it should be clear that the discussion can concentrate on the synthesis of even-order functions only; i.e., the question is how to realize Eq. 17 as expressed in Eq. 79 with Eq. 80. This, in turn, implies that practical methods have to be found to realize biquadratic transfer functions of the form of Eq. 50, a topic discussed in the previous section of this chapter.

As a simple example for the steps discussed, assume the function

$$H(s) = \frac{K(s^2 + 4\pi^2 \times 3.3551)}{s^4 + 2.7555s^3 + 3.7964s^2 + 3.099s + 1.4246} \qquad \text{(Eq. 81)}$$

a low-pass function with the frequency response sketched in Fig. 25, has to be realized. In Eq. 81, s is normalized with respect to the low-pass cutoff frequency $f_{3\,dB} = 4.55$ kHz; i.e., the filter passband is in $0 \le f \le f_{3\,dB}$, and $s = j\omega/(2\pi \times f_{3\,dB})$. Realizing Eq. 81 as a cascade of two second-order sections requires factoring the denominator and writing $H(s)$ as a product of two functions, T_1 and T_2. Simple algebra (root finding) results in

$$H(s) = \frac{K_1}{s^2 + 2.0905s + 1.3544} \cdot \frac{K_2(s^2 + 132.45)}{s^2 + 0.6650s + 1.0518}$$
$$= T_1(s)T_2(s) \qquad \text{(Eq. 82)}$$

where $K_1K_2 = K$. The low-pass and low-pass-notch functions $T_1(s)$ and $T_2(s)$ can then be realized as described in the previous section, e.g., by the circuit in Fig. 15B.

In Eq. 82, with equal justification, the numerator factor $s^2 + 132.45$ could have been assigned to $T_1(s)$, the order of T_1 and T_2 could have been interchanged, or any combination of the above could have been performed. Thus, since only the product of the functions $T_i(s)$ is prescribed, it is clear that considerable freedom exists, especially in functions of high order. Pole-zero pairing, assignments of the gain constants K_i, and ordering of the functions T_i in the cascade are not unique. The final choice of these factors determines such important practical characteristics as sensitivity and, most importantly, dynamic range.

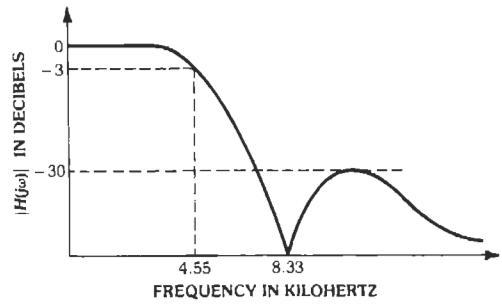

Fig. 25. Frequency-response plot, Eq. 81.

The dynamic range of a filter is a number, usually given in decibels (e.g., 75 dB) that specifies the range of signal voltages the circuit can process without being corrupted by electrical noise at the low end and without causing nonlinear distortion at the high end because of clipping or slew-rate limiting in the amplifier. Clearly, dynamic range ought to be maximized as far as possible and a judicious choice of pole-zero pairing, gain-factor assignment, and section ordering can go a long way toward this goal. Arriving at the optimal choice is fairly complicated and so a computer algorithm is usually needed. If a suitable computer program is not available, a good suboptimal choice can frequently be obtained by

1. assigning the poles with the highest Q factor to the closest transmission zero,
2. choosing a low-pass or bandpass section as the first block and a high-pass or bandpass section as the last block in the cascade (this choice helps to keep high-frequency signals out of the filter, and prevents low-frequency noise from reaching the output),
3. ordering the remaining sections in the order of increasing values of Q, i.e., $Q_i < Q_{i+1}$, so that the voltages at the intermediate section outputs in the passband are as "flat" (that is, independent of frequency) as possible, and, finally,
4. assigning the gain constants K_i such that the voltage maxima at all section outputs are equal.

For critical filter specifications, requiring a transfer function of order 6 to 8 or higher, cascade realizations have been found to be too sensitive to element variations in some cases. That is, the filter response cannot be tuned correctly or maintained within specifications because of fabrication tolerances or later component

changes, such as those caused by aging or temperature drifts. Such sensitivity problems are particularly severe in filters with high-Q (narrow bandwidth or steep roll-off from passband to stopbands). For these cases, frequently, multiple-feedback topologies give useful solutions. For very critical and stringent filter specifications, active simulations of passive LC ladder filters show the best sensitivity performance and are preferred as alternative realizations.

Multiple-Feedback Topologies

Fig. 26 shows one of the many multiple-feedback topologies that have been proposed in the literature. It is recognized as essentially a cascade connection of l (second-order) sections $T(s)$, embedded into a resistive feedback network that ties all section outputs to an input summer. Because in this structure all l second-order sections are identical, it has been labeled the primary-resonator-block (PRB) topology.

The transfer function of the circuit in Fig. 26 can be shown, for an ideal summing amplifier, to be equal to

$$H(s) = \frac{V_l}{V_{in}} = -\frac{F_0 T^l(s)}{1 + \sum_{i=2}^{l} F_i T^i(s)} \qquad \text{(Eq. 83)}$$

where

$$F_i = R_i/R_{in},\ i = 0, 2, ..., l.$$

Such multiple-feedback structures are most convenient for the realization of even-order symmetrical all-pole bandpass transfer functions, $H_{BP}(s)$ (Butterworth and Chebyshev filters; see Chapter 9). Such filters are most easily designed by transforming $H_{BP}(s)$, into a *prototype low-pass* transfer function, $H_{LP}(p)$, via the frequency transformation $p = \hat{Q}(s^2+1)/s$. Here p is the frequency parameter of the low-pass filter, normalized to the corner frequency of the low-pass filter's passband and $s = j\omega/\omega_0$ is the normalized frequency parameter of the bandpass function. ω_0 is the center frequency of the bandpass and $\hat{Q} = \omega_0/\Delta\omega$, where $\Delta\omega$ is the desired bandwidth. The function

$$H_{LP}(p) = -\frac{K_0}{p^l + d_{l-1}p^{l-1} + \cdots d_1 p + d_0} \qquad \text{(Eq. 84)}$$

then corresponds to the to-be-designed bandpass function

$$H_{BP}(s) = -\frac{Ks^{r/2}}{s^r + D_{r-1}s + \cdots + D_1 s + 1} \quad (r = 2l = \text{even}) \qquad \text{(Eq. 85)}$$

In Eq. 84, K_0 is the prescribed *mid*band gain of the bandpass filter. In Eqs. 85 and 84, $r = 2l$ is the degree of desired bandpass and l is the degree of prototype low-pass filter. For this situation, the blocks T in the low-pass equivalent of the circuit in Fig. 26 are

$$T(p) = Mk/(p+k) \qquad \text{(Eq. 86)}$$

To design the circuit, one substitutes Eq. 86 into Eq. 83, brings the resulting equation into the form of Eq. 84, and compares coefficients with the prescribed function. If the definition

$$f_i = F_i M^i \qquad (i = 2, \ldots, l) \qquad \text{(Eq. 87)}$$

is used, this process yields the following solution:

$$k = d_{l-1}/l \qquad \text{(Eq. 88a)}$$

$$f_2 = d_{l-2}/k^2 - l(l-1)/2! \qquad \text{(Eq. 88b)}$$

$$f_i = \frac{d_{l-i}}{k^i} - \frac{1}{(l-i)!}\left[\frac{l!}{i!} - \sum_{j=2}^{i-1} f_i \frac{(l-j)!}{(i-j)!}\right] \quad (i = 3, \cdots, l) \qquad \text{(Eq. 88c)}$$

Applying now the frequency transformation $p = Q(s^2+1)/s$ to Eq. 86 results in $T(s)$, the blocks in Fig. 26, being second-order bandpass functions

$$T(s) = (M/Q)s/(s + s/Q + 1) \qquad \text{(Eq. 89)}$$

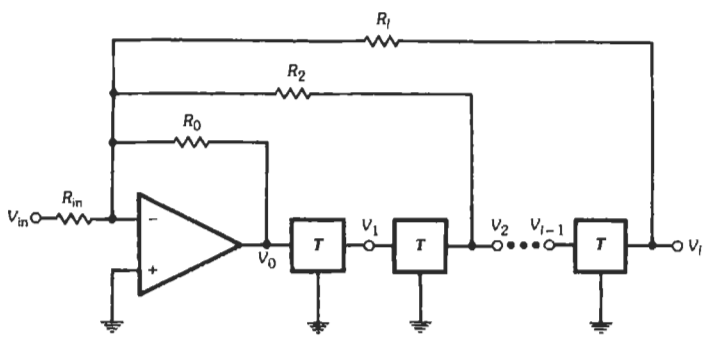

Fig. 26. The FLF topology for the special case of all identical sections $T(s)$.

where $Q = \hat{Q}l/d_{l-1}$ is the quality factor of $T(s)$, i.e., ω_0 divided by the 3-dB bandwidth of T. Note that all blocks $T(s)$ are tuned to the same ω_0 because $s = j\omega/\omega_0$. The gain constant M of $T(s)$ should be selected for best dynamic range, such that all filter-internal signal maxima are equal. In general, this requires a computer routine and results in different M factors for each section; a good suboptimal choice, however, which at the same time retains all identical sections, is simply

$$M = \sqrt{1 + \left(Q/\hat{Q}\right)^2} \qquad \text{(Eq. 90)}$$

With M and f_i, $i = 2, \ldots, l$, known from Eqs. 88 and 90, the actual feedback factors $F_i = R_i/R_{in}$ can then be determined from Eq. 87. Finally, the PRB bandpass design is completed by setting

$$F_0 = R_0/R_{in} = (K_0/M^l)(Q/\hat{Q})^l \qquad \text{(Eq. 91)}$$

so that the prescribed gain constant K_0 is realized correctly.

An example will illustrate the process: To be designed is a sixth-order bandpass filter with a Butterworth magnitude characteristic, center frequency f_0 = 4.8 kHz, center-frequency gain $K_0 = 5$ (14 dB), and 3-dB bandwidth Δf = 600 Hz. For this case, the prototype third-order Butterworth low-pass transfer function, corresponding to Eq. 84, is

$$H_{LP}(p) = -5/\left(p^3 + 2p^2 + 2p + 1\right) \qquad \text{(Eq. 92)}$$

and the low-pass-to-bandpass transformation, with $\hat{Q} = 4.8\ \text{kHz}/0.6\ \text{kHz} = 8$, is

$$p = 8(s^2 + 1)/s \qquad \text{(Eq. 93)}$$

where $s = j\omega/(2\pi \times 4.8\ \text{kHz})$. Then, from Eqs. 87 and 92, $k = 2/3$, $f_2 = 1.5$, and $f_3 = 0.875$. From Eqs. 89 and 90, the second-order sections have a pole quality factor $Q = 8 \times 3/2 = 12$ and a gain constant $M = [1 + (3/2)^2]^{1/2} = 1.8028$; that is, the functions to be realized are

$$T(s) = 0.1502s/\left(s^2 + s/12 + 1\right) \qquad \text{(Eq. 94)}$$

Finally, the feedback resistor ratios F_i are, from Eq. 87, $F_2 = f_2/M^2 = 0.4615$ and $F_3 = f_3/M^3 = 0.1493$ and from Eq. 91, $F_0 = 2.880$.

The single-amplifier bandpass filter of Fig. 15A will be used to realize the function of Eq. 94. The design is completed as follows: From Eqs. 59, 56, and 57 with a choice of $q = 5$, one obtains $K = 1.01149$ and the predistorted values, if $f_t = 1$ MHz, $f_{0p} = 4.915$ kHz, and $Q_p = 11.75$. If $C = 12$ nF is chosen, Eq. 58 yields $R = 27.0$ kΩ. Finally, from Table 1, with $|b| = 0.1502\omega_{0p}$, $m = 0.0149 = 1/67.3$. The complete circuit realizing the prescribed bandpass filter is shown in Fig. 27. Note that an inverter is needed in the outer feedback loop because the bandpass sections have an inverting gain and the total loop gain must be negative to assure stability.

For other multiple-loop feedback topologies or for multiple-feedback structures for realizing bandpass fil-

ters with finite transmission zeros, the reader is referred to the literature.*

Ladder Simulation

Doubly terminated passive *LC* ladder filters are known to be optimally insensitive to element variations. Thus, in recent years, many methods have been proposed that simulate the operation, the topology, and/or the elements of *LC* ladders by active networks. The goal is to eliminate inductors and, at the same time, to retain the ladder's superior sensitivity performance. A few simple but powerful procedures are described in the following; for more details and for the design of very demanding filter circuits, the reader is referred to the literature.†

Operational Simulation—The process of simulating the operation of an *LC* ladder is best explained by an example from which the general design procedure should become clear.

Consider the simple *LC* low-pass filter in Fig. 28. Analysis yields the equations

$$V_o = I_3/(sC_4 + G_L) \qquad \text{(Eq. 95a)}$$

$$I_3 = (V_C - V_o)/sL_3 \qquad \text{(Eq. 95b)}$$

$$V_C = (I_1 - I_3)/sC_2 \qquad \text{(Eq. 95c)}$$

$$I_1 = (V_i - V_C)/(sL_1 + R_S) \qquad \text{(Eq. 95d)}$$

where the currents and voltages are interpreted as signals to be represented in a signal-flow graph. Since all signals ought to be voltages, Eqs. 95 are then normalized by an arbitrary resistor R, and the notation $R_S/R = r_S$; $R_L/R = r_L$; $I_m R = V_m$; $L_m/R = l_m$, $m = 1, 3$; $C_k R = c_k$, $k = 2, 4$, is introduced. For example,

$$V_o = I_3 R/(sC_4 R + G_L R)$$

becomes

$$V_o = V_3/(sc_4 + g_L)$$

Using this notation, and using judicious minus signs so that all capacitors become inverting integrators and inductors noninverting integrators, and allowing only summing, we can rewrite Eqs. 95 as follows:

$$V_o = -V_3[-1/(sc_4 + g_L)] \qquad \text{(Eq. 96a)}$$

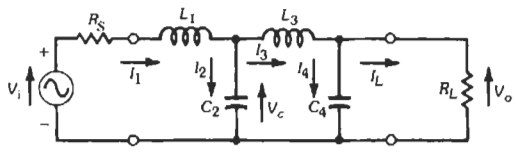

Fig. 28. *LC* low-pass ladder.

$$-V_3 = [(-V_C) + V_o]/(sl_3) \qquad \text{(Eq. 96b)}$$

$$-V_C = [V_1 + (-V_3)]/(-sc_2) \qquad \text{(Eq. 96c)}$$

$$V_1 = [V_i + (-V_C)]/(sl_3 + r_S) \qquad \text{(Eq. 96d)}$$

These equations are represented in the flow graph of Fig. 29, which demonstrates that the operation of the ladder in Fig. 28 is simulated by use of summers and inverting and noninverting integrators. These two functions are easy to realize with active circuits, as was shown earlier in this chapter. Note that all internal integrators are ideal, i.e., lossless, reflecting that the *LC* prototype ladder is lossless, but that the two end sections are realized via lossy integrators, thereby taking care of the resistive source and load terminations. Note further that each loop contains one inverting and one noninverting integrator (see Fig. 7), thereby assuring inverting loop gains for stability reasons. Stability will always be assured if all inductors are simulated by noninverting and all capacitors by inverting integrators. Lossy integrators are implemented by connecting a resistor in parallel with the integrator capacitor, and the summing operation indicated in Fig. 29 is realized by combining the summer of Fig. 5 and an integrator of Fig. 7 into one circuit. These operations are implemented in Fig. 30 and described by

$$V_o = -\frac{V_1}{sCR_1 + R_1/R_3} - \frac{V_2}{sCR_2 + R_2/R_3} \qquad \text{(Eq. 97)}$$

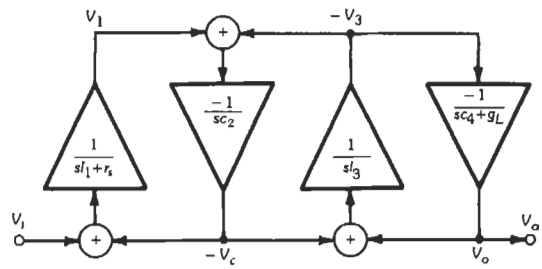

Fig. 29. Signal-flow diagram representing the *LC* filter shown in Fig. 28.

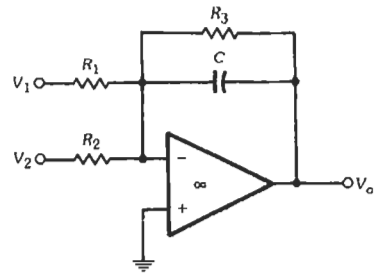

Fig. 30. A summing lossy integrator.

* References 1 and 6.

† References 2, 6, and 7.

Clearly, if $R_3 = \infty$ the summing integrator is lossless. Of course, to obtain a noninverting summing integrator operation, one of the circuits of Fig. 7C or 7D is used instead of a simple Miller integrator.

The actual circuit implementing the *LC* ladder of Fig. 28 is shown in Fig. 31; the similarity of this diagram to the flow diagram in Fig. 29 should be apparent. To minimize phase errors caused by the finite gain–bandwidth product ω_t of the op amps, each loop consists of a Miller integrator with $Q_l < 0$ (see Eq. 36) and a phase-lead integrator with $Q_l > 0$ (Fig. 7D). This is the preferred choice of integrator pairing. For convenience, all capacitors are selected to be equal. To determine resistors R_2 and R_9 in Fig. 31, the time constants of the corresponding integrators are set equal to the time constants of the input and output branches of the *LC* prototype in Fig. 28. Thus

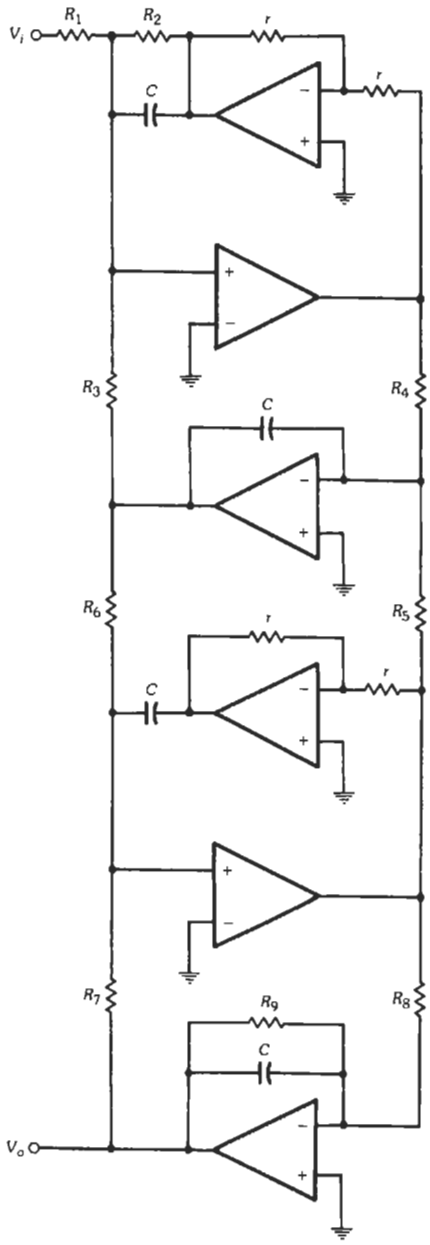

Fig. 31. Active simulation of the *LC* ladder of Fig. 28.

$$CR_2 = L_1/R_S \qquad \text{(Eq. 98a)}$$

$$C_4R_L = CR_9 \qquad \text{(Eq. 98b)}$$

or, for some suitable choice of C,

$$R_2 = L_1/(CR_S) \qquad \text{(Eq. 99a)}$$

$$R_9 = (C_4/C)R_L \qquad \text{(Eq. 99b)}$$

The "internal" resistors R_i, $i = 3, \ldots, 8$, for Fig. 31 are obtained by equating the loop gains in the active circuit, i.e., the product of any two adjacent integrator time constants, to the product of the two corresponding reactances in the *LC* prototype. Thus

$$L_1C_2 = CR_3 \times CR_4 \qquad \text{(Eq. 100a)}$$

$$C_2L_3 = CR_5 \times CR_6 \qquad \text{(Eq. 100b)}$$

$$L_3C_4 = CR_7 \times CR_8 \qquad \text{(Eq. 100c)}$$

So, with the reactances of the *LC* ladder known and some suitable choice of C, as for Eqs. 99, one has, for example,

$$R_3 = R_4 = \sqrt{L_1C_2}/C \qquad \text{(Eq. 101a)}$$

$$R_5 = R_6 = \sqrt{L_3C_2}/C \qquad \text{(Eq. 101b)}$$

$$R_7 = R_8 = \sqrt{L_3C_4}/C \qquad \text{(Eq. 101c)}$$

Finally, resistor R_1 determines the desired dc gain of the filter. In the active network, this can be chosen freely, whereas in the passive prototype it is fixed at $R_L/(R_S + R_L)$. Let the dc gain be called K; then it can be shown that

$$R_1 = (R_S/R)(R_D/K) \qquad \text{(Eq. 102a)}$$

if the *LC* low-pass ladder starts with a series inductor (as in Fig. 28) and

$$R_1 = (R/R_S)(R_D/K) \qquad \text{(Eq. 102b)}$$

if the *LC* ladder starts with a shunt capacitor. In Eqs. 102, R_D is the damping resistor of the first integrator (R_2 in Fig. 31), and R is the value of the normalizing resistor that was chosen in connection with Eqs. 96.

In a similar fashion, any type of *LC* filter can be simulated as an active *RC* filter by going through a signal-flow graph. For a detailed discussion see References 2, 6, and 7. If the desired filter function is an all-pole bandpass function obtained via the low-pass-to bandpass transformation from a prototype low-pass

function, as illustrated in connection with the transformation from Eq. 84 to Eq. 85, the design is particularly simple. One only needs to simulate the low-pass filter by a signal-flow graph, as shown in Fig. 29 for a fourth-order case, and then use the low-pass-to-bandpass transformation to transform each integrator of the form $T_i(p) = a/(bp + c)$ into a second-order bandpass section

$$T_i(s) = \left[sa/\left(b\hat{Q}\right)\right] \Big/ \left[s + sc/\left(b\hat{Q}\right) + 1\right] \qquad \text{(Eq. 103)}$$

similar to the transformation from Eq. 86 to Eq. 89 above. For ideal integrators, the coefficient $c = 0$, implying a bandpass of infinite Q^* for all internal sections of the simulated ladder (compare Fig. 29). After a suitable realization for the second-order sections is obtained as discussed earlier, these are then interconnected in a "leapfrog" topology as shown in Fig. 32, where the resistors of the feedback network are adjusted for the correct loop gains. The "leapfrog" method owes its name to the resulting circuit structure. For details of the design of these very well behaved active ladder simulations, References 1, 3, 6, or 7 should be consulted.

Ladders Using Inductor Simulation—It was pointed out earlier that high-quality grounded inductors can be simulated by the use of general impedance converters implemented with two op amps. Fig. 9 shows the op amp circuit realizing, for $R_2 = R_3$ and $R_5 = 1/(\omega_c C_4)$, an inductor of value $L = R_1/\omega_c$, where ω_c is a frequency in or at the edge of the filter passband (Eq. 40). It stands to reason, therefore, that an LC ladder can be simulated simply by replacing all inductors by the circuit in Fig. 9, *provided* the inductors are *grounded*. An illustration of this rather straightforward procedure for grounded inductors is given in Fig. 33. Fig. 33A shows an LC ladder, which may have been obtained from tables and/or filter design handbooks. The filter has only grounded inductors and a finite transmission zero at the frequency $\omega_z = \sqrt{L_2 C_2}$ where C_2 and L_2 resonate.

If *floating* inductors need to be simulated, as is true for all low-pass and most bandpass filters, a different approach must be used. The strategy, suggested by Gorski-Popiel† is obtained by a different interpretation of the general impedance converter in Fig. 9: If R_5 is considered the load of the GIC (Fig. 9B), then the GIC with the conversion time constant τ converts a load resistor R_5 into the inductor $L = \tau R_5$ (Eq. 40). Generalizing this idea, we can prove the following fact:

> If GICs with the conversion constant τ are inserted between the outside world and all terminals (except ground) of a purely resistive network containing the resistors R_i, (the resistive circuit forms the load of the GICs) then the resulting circuit will appear as an inductive network of the same topology containing the inductors $L_i = \tau R_i$. Conversely, an inductor network with components L_i is replaced by a resistive network with components L_i/τ embedded between GICs with time constant τ.

Fig. 34 shows this method, of which Fig. 9 is the simplest special case. Evidently, in Fig. 34A a floating inductor is simulated and in Fig. 34B an inductive T.

The design proceeds as follows: In the first step the inductive subnetwork(s) are cut from the filter and the cuts replaced by properly connected GICs with conversion constant τ. If then all inductors L_i are replaced by resistors $R_i = L_i/\tau$, the resulting filter behaves like the original LC circuit, bearing in mind, of course, the frequency limitations (not much beyond upper audio range) imposed by the op amps used in the design. Fig. 35 shows Gorski-Popiel's method on a simple low-pass filter.

In the active realization of ladders, often a network transformation can be used to eliminate all floating inductors that would use many op amps for their simulation. A procedure that works particularly well for low-pass filters makes use of frequency-dependent negative resistors (FDNRs).

Ladders Using FDNR Circuits—If the normalized impedances of a circuit are scaled (multiplied) by an impedance scaling factor $1/s$, the result is as follows: A resistor of value R_i Ω becomes a capacitor of value $(1/R_i)$ F, an inductor of L_i H becomes a resistor of L_i Ω, and a capacitor of C_i F is converted into a frequency-dependent negative resistor of value $D_i = C_i$. This was introduced in the section "The FDNR Element." Thus, an impedance $Z = R + sL + 1/(sC)$ is transformed into

$$Z_t = \frac{Z}{s} = \frac{R}{s} + L + \frac{1}{s^2 C} \Rightarrow \frac{1}{sC_i} + R_i + \frac{1}{s^2 D_i} \qquad \text{(Eq. 104)}$$

* In practice, a very large but finite Q is sufficient.

† See References 2, 6, or 7.

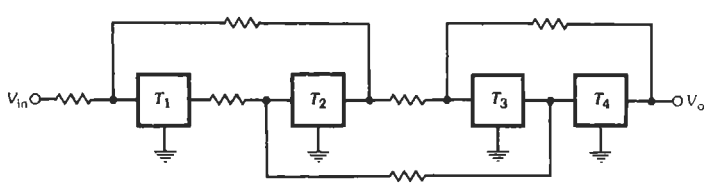

Fig. 32. Leapfrog bandpass filter.

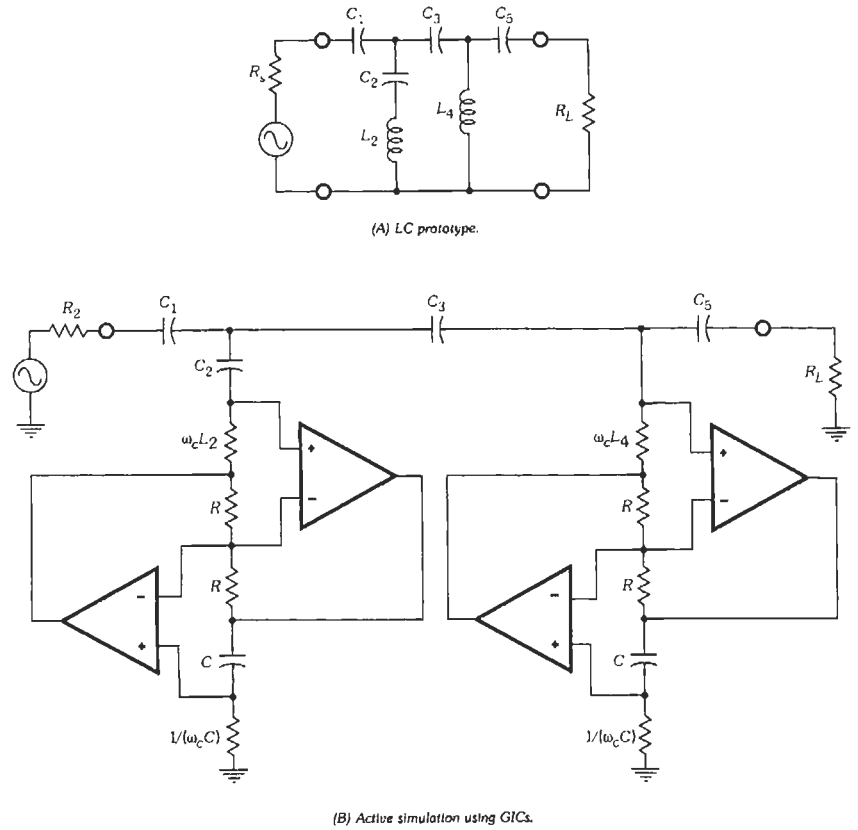

Fig. 33. Simulation of an *LC* ladder.

The voltage transfer function, being a dimensionless quantity, is of course unaffected by impedance scaling so that the transformed circuit has the same response as the original filter. Hence, according to Eq. 104, inductors are eliminated, and FDNR elements are introduced that can readily be realized as discussed earlier in connection with Fig. 11 (Eq. 45). One limitation is that a good floating FDNR is very difficult to realize. Thus, this approach is most useful for passive *LC* prototype filters that have no floating capacitors. In this sense, the FDNR and inductor simulation methods are complementary.

A brief example will illustrate the procedure: Fig. 36A shows an *LC* low-pass filter with finite transmission zeros at $\omega_1 = (L_2C_2)^{-1/2}$ and $\omega_4 = (L_4C_4)^{-1/2}$. Impedance scaling by a factor $1/s$ transforms the circuit into that of Fig. 36B, which shows also the commonly used symbol for FDNR elements. For further design details concerning problems with biasing, buffering input and output, and the selection of element values, the reader is referred to the literature.*

Ladders Using OTAs—It was mentioned before that for active filters at higher frequencies—say above a few hundred kilohertz—op-amp circuits are generally not useful because of the limited bandwidth of op amps. In contrast, the bandwidth of transconductors extends, depending on the technology, to several hundred megahertz or even gigahertz.† In addition, as will become apparent shortly, the design of ladder simulations with OTAs is fairly simple and systematic and lends itself particularly well to high-frequency integrated filters. As discussed earlier in this section, ladders can be implemented by simulating the inductors in the structure. This can be done for grounded as well as floating inductors via g_m-based gyrators (Eq. 44, Fig. 10). Alternatively, the operation of each branch or mesh of the ladder can be simulated by the signal-flow graph method, using g_m-based integrators (Eq. 37, Fig. 8). Both methods will be illustrated in the following. For further details, the reader is referred to References 6, 7, 11–14, or 20.

Inductor Simulation: The process is illustrated best with a simple example. Consider the third-order elliptic (see Chapter 9) low-pass filter in Fig. 37A. To

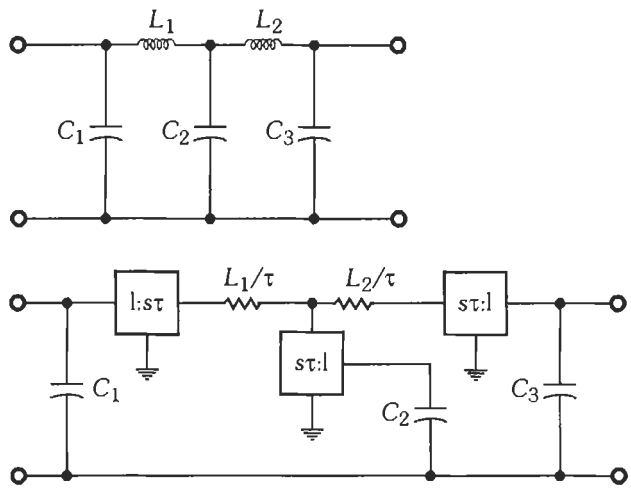

Fig. 35. Simulation of an *LC* ladder filter.

implement this circuit as an active fully differential integrated filter, the floating inductor must be simulated by the circuit in Fig. 10C. The result is shown in Fig. 37B. OTA 1 converts the input voltage into a current (source transformation); OTAs 2 and 7 simulate the source and load resistors; and OTAs 3 through 6 with the capacitor $C_L/2$ form the floating inductor. Also shown in Fig. 37C is a version that merges OTAs for savings in power and components as was discussed in connection with Figs. 6B and 6C. OTAs 2 and 3 are merged into OTA *b*, OTAs 4 and 5 into OTA *c*, and OTAs 6 and 7 into OTA *d*. To be able to use identical OTAs, OTA *a* has its inputs connected as shown, thereby doubling the transconductance value to $2g_m$. This, in turn, eliminates the inherent 6-dB loss of the *LC* prototype in Fig. 37A. (Note that at dc,

the gain of the *LC* filter is 0.5 because of the resistive voltage divider.) Extensions of this technique to ladders of higher order, such as the one in Fig. 38A, are obvious.

Signal-Flow Graph (SFG) Simulation: In deriving the active circuit to perform an operational or SFG simulation of the passive ladder, the node and mesh equations are written such that each capacitor and

inductor is recognized as performing a signal integration, $1/(sC_j)$ or $1/(sL_j)$. As was done before, a source transformation is first performed on the ladder input so that the source resistor R is in parallel with C_1, and both the first and the last branch form lossy integrators. Referring to Fig. 38A and denoting $1/R$ by G, one obtains the equations for the five state variables, analogous to Eqs. 95 above:

$$V_1 = \frac{1}{sC_1 + G}\left[\left(V_i G - I_{L2}\right) - sC_2\left(V_1 - V_3\right)\right] \quad \text{(Eq. 105a)}$$

$$I_{L2} = [1/(sL_2)](V_1 - V_3) \quad \text{(Eq. 105b)}$$

$$V_3 = \frac{1}{sC_3}\left[\left(I_{L2} - I_{L4}\right) + sC_2\left(V_1 - V_3\right) - sC_4\left(V_3 - V_5\right)\right] \quad \text{(Eq. 105c)}$$

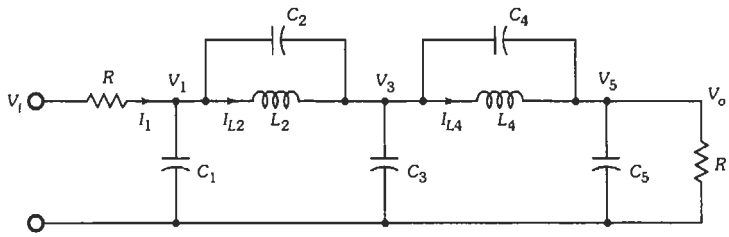
$$I_{L4} = [1/(sL_4)](V_3 - V_5) \quad \text{(Eq. 105d)}$$

$$V_5 = \frac{1}{sC_5 + G}\left[I_{L4} + sC_4\left(V_3 - V_5\right)\right] \quad \text{(Eq. 105e)}$$

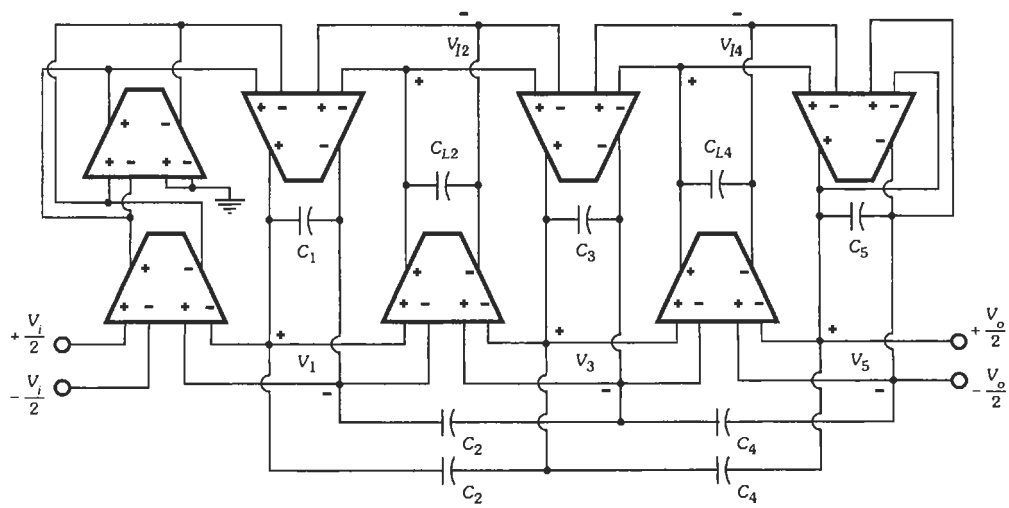
The equations are then scaled by a dimensionless factor to assure that all signal maxima are of equal magnitude. As discussed in detail in, for example, References 2, 6, 21, and 22, this step results in a realization with maximum dynamic range. Finally, as explained earlier, a suitable normalization, here illustrated for Eq. 105b,

$$V_{I2} = \frac{I_{L2}}{g_m} = \frac{1}{sL_2 g_m^2} g_m\left(V_1 - V_3\right) \quad \text{(Eq. 106)}$$

leaves the currents as voltage signal variables ($I/g_m = V$) and converts the inductors to capacitors ($Lg_m^2 = C_L$); all integrators can then be implemented via transconductors as indicated in Fig. 8. Note that the floating capacitors C_2 and C_4 are not realized via integrators because the currents through these two elements (see Eqs. 105a, 105c, and 105e) can be obtained by connecting C_2 and C_4 directly to the nodes V_1, V_3, and V_3, V_5, respectively. At the cost of floating capacitors and the resulting parasitic substrate capacitances, this process saves several transconductors, silicon area, and



(A) LC prototype.



(B) Fully differential g_m-C ladder simulation.

Fig. 38. Fifth-order elliptic low-pass filter using signal-flow graph simulation.

power and reduces noise. Making use of multiple-input transconductors to achieve a fully differential circuit, the five equations (Eqs. 105) are implemented step by step, and interconnected as indicated in Fig. 38B. The normalized signal voltages, representing the state variables V_{12}, V_{14}, V_1, V_3, and V_5, are marked in Fig. 38B for easy reference.

Observe that the ladder simulation technique leads to a very efficient and systematic active realization of the passive prototype. The fifth-order active ladder requires five two-input summing transconductors, plus two for simulating the source and load resistors, and five capacitors, plus two for each floating C in the passive prototype. All transconductors are identical. Again, it should be apparent how the method is extended to filters of higher order.

SWITCHED-CAPACITOR FILTERS

Metal-oxide-semiconductor (MOS) integrated circuit (IC) technology is used widely in industry because of its superior logic density and lower power consumption compared to that achievable with other IC technologies. With very large scale integration (VLSI), hundreds of thousands to millions of MOS transistors can be placed on a single chip. The ubiquitous presence of CMOS chips in appliances, entertainment electronics, and personal computers indicates the economic and social impact of MOS VLSI on modern society.

Switched-capacitor (SC) techniques, in addition to the g_m-C circuits discussed earlier, provide analog signal processing capability that is needed in MOS technology for "mixed-mode" analog/digital signal processing requirements. The marriage of analog SC functions and high-density digital logic on the same piece of silicon extends to mixed-mode systems the same cost and space savings associated with memories and microcomputers. One advantage of properly designed SC filters over g_m-C implementations is that the realized characteristics usually require no trimming and are inherently stable over process and environmental variations. However, because of their sampled-data nature, at the time of this writing, SC filters are commercially useful only at relatively moderate frequencies (from the audio range up to possibly a few hundred kilohertz), whereas continuous-time (c-t) g_m-C circuits can be made to operate commercially at several tens and even hundreds of megahertz. Consequently, these two integrated analog filter design techniques rarely compete in the same applications.

SC filters* consisting of MOS capacitors, switches, and op amps realize infinite impulse response (IIR) analog sampled-data filters, similar topologically to the active RC filters described in previous sections. Narrow and flat passbands can be realized efficiently. Unlike their c-t active RC and g_m-C counterparts, SC filters are sampled-data systems. This complicates their use and design, but SC filters do indeed take full advantage of the inherent precision achieved by MOS technology. As shown later, the transfer functions are completely determined by precise crystal-controlled clocks and capacitor ratios. Capacitor ratios can be held to an accuracy of about 0.3 percent or less and, with appropriate parasitics insensitive circuit techniques,† capacitors as small as 0.2 pF can be used. Furthermore, MOS capacitors are nearly ideal, with very low dissipation factors and good temperature stability. These properties can be achieved with either NMOS or CMOS processing, but CMOS, with its added flexibility for realizing high-gain, low-noise op amps and low power dissipation, is recognized as the technology of choice.

Sampled-Data Filter Systems

Consider a sampled-data filter system that is suitable for use in a c-t analog (i.e., analog input/analog output) environment. This represents, from a hardware point of view, the most demanding environment for any sampled-data filter, and specifically for a SC filter. The system given in Fig. 39 shows the analog signal being passed through a c-t antialiasing low-pass filter; an input sample-and-hold circuit, $(S/H)_i$, which samples the band-limited analog input at intervals of $1/f_{s1}$; the SC filter; an output sample-and-hold circuit, $(S/H)_o$, which resamples the output of the SC filter at intervals $1/f_{sn}$; and a final c-t low-pass reconstruction filter, which smoothes the sharp transitions in the sampled-data output waveform. The SC filter is shown, in general, to be controlled by clocks of multiple frequencies (f_{s2} through $f_{s,n-1}$). Because the capacitor ratios (hence the silicon area) required to realize a given transfer function scale in proportion to the ratio of the clock frequency to the pole and zero frequencies (see Eq. 115), silicon area can be minimized by employing multiple clocks.‡ However, for simplicity and to minimize aliasing of out-of-band signals (including system noise and power-supply feedthrough), SC filter systems are often operated with a single clock ($f_{s1} = f_{s2} = \ldots = f_{sn} = f_s$). f_s is typically in the range of 100 to 256 kHz, much higher than the highest signal frequency. Sampling rates (input and output) in this range serve to reduce the complexity of the c-t antialiasing and reconstruction filters. It should be noted that in many SC filters, particularly low-pass filters, the sample-and-hold operations shown in Fig. 39 are inherent to the SC filter. In these cases, the SC filter includes the three blocks enclosed by the dashed box in Fig. 39. Typical frequency responses for the various blocks (shown for a low-pass SC filter) in Fig. 39 are depicted below each system block, assuming the typical case

* References 1, 6, 7, 10, 24, and 25.

† References 1, 6, 7, 10, and 25.

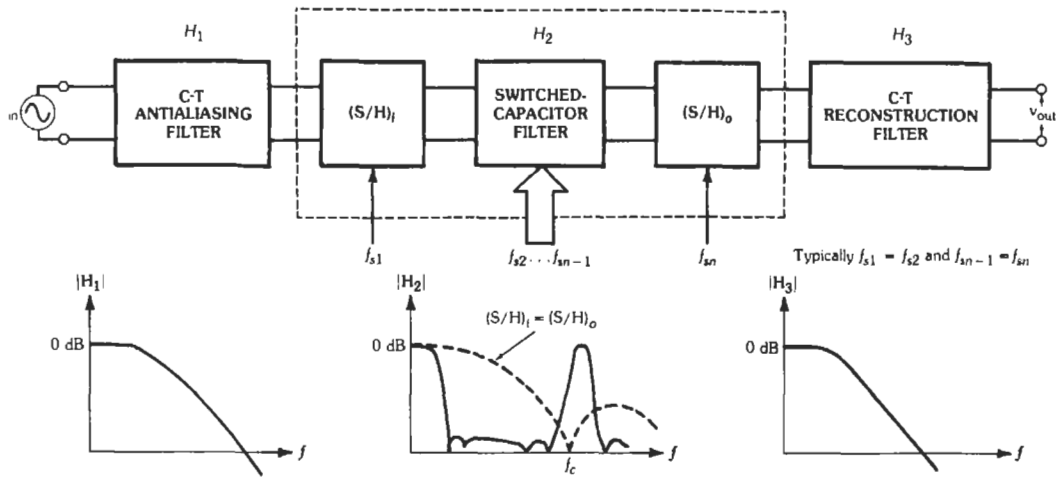

Fig. 39. Sampled-data filter system for continuous-time analog input and smooth analog output.

that all clock frequencies are the same $f_{si} = f_s$, $i = 1, \ldots, n$.

It is noted that when an input or output is interfaced with digital or sampled-data circuitry, such as D/A and A/D converters, some of this circuitry is no longer needed. For example, when the output is to be interfaced to another sampled-data function, the reconstruction filter is not required, and a sample-and-hold circuit is typically included at the input of this function. Although the need for c-t filtering is reduced, interfacing to digital and sampled-data circuits requires careful synchronization between the clocks that control the SC filter and those that control the external sampling operations. This is accomplished by passing synchronization pulses between the SC network and the external samplers. One reason for synchronization is to ensure that the SC network output is sampled after all transients have settled and the output is steady.

Another consequence of the sampled-data character of SC networks is the mathematical convenience of the z transform in analyzing or specifying SC filters. The z transform, where $z = \exp(s\tau)$ and τ is the clock period, is covered in Chapter 28 (or refer to References 1, 6–8, or 10) as a mathematical tool for digital filters and discrete-time systems. The sampling instants, the instants at which switches open, are the times at which capacitor charges are updated. These discrete instants of time are the most important times in the operation of the filter. In fact, one can completely describe the behavior of the filter by considering operation at only these discrete instants. This aspect of SC filter behavior is analogous to the operation of digital filters; hence, the mathematical analysis follows in a similar manner.

It has been mentioned that the input and output of an analog sampled-data system are analog signals. Note that the antialiasing filter serves to band-limit the input spectrum to $f_c < f_s/2$ so that the signal can be reconstructed without error. Here, f_c refers to the highest component allowed in the input spectrum, and $f_s = 1/\tau$ is the sampling frequency. The antialiasing filter will also serve to band-limit high-frequency input noise, which would otherwise be aliased back into the baseband. Inherent in all analog sampled-data systems is the means to provide some sort of analog reconstruction. With $\tau = 1/f_s$, the simplest form of reconstruction is the zero-order hold or sample-and-hold (S/H) circuit. The impulse response of the zero-order hold is described by

$$h_0(t) = \begin{cases} 1/\tau & \text{for } 0 \le t \le \tau \\ 0 & \text{elsewhere} \end{cases} \qquad \text{(Eq. 107)}$$

The sample-and-hold impulse response is sketched in Fig. 40, and an S/H reconstructed signal $x_r(t)$ is shown in Fig. 41. The transfer function for this sample-and-hold is

$$H_0(s) = (1 - e^{-s\tau})/(s\tau) \qquad \text{(Eq. 108)}$$

and its frequency response is

$$H_0(j\omega) = \frac{1 - e^{j\omega\tau}}{j\omega\tau} = e^{-j\omega\tau/2}\,\frac{\sin \omega\tau/2}{\omega\tau/2} \qquad \text{(Eq. 109)}$$

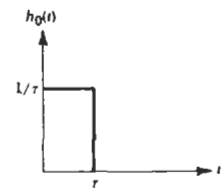

Fig. 40. Impulse response for sample-and-hold.

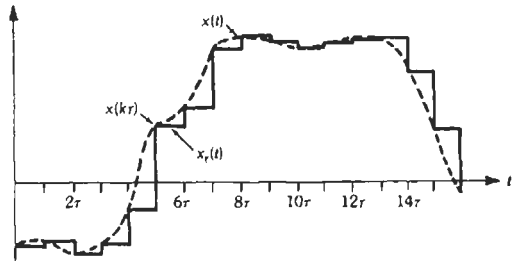

Fig. 41. Reconstruction with sample-and-hold.

It can be seen that $H_0(j\omega)$ has the $(\sin x)/x$ magnitude response shown in Fig. 42A and the phase characteristic shown in Fig. 42B.

Examine the effect on the spectrum of a sampled signal $X^{\#}(j\omega)$, as predicted by z-transform analysis, when the sampled signal is reconstructed with a sample-and-hold. The spectrum of the reconstructed signal $X_r(j\omega)$ is simply the product of the sampled signal spectrum $X^{\#}(j\omega)$ and the sample-and-hold spectrum $H_0(j\omega)$ as shown in Fig. 43. Note that the high-frequency content of the sampled signal outside the baseband has been substantially reduced and the baseband spectrum is slightly altered near the band edge. When $f_s/f_c >> 1$, as is usually the case in SC filters, this baseband distortion is negligible and

$$X_r(j\omega) = X^{\#}(j\omega) \text{ for } \omega < \omega_s/2 = \pi f_s \qquad \text{(Eq. 110)}$$

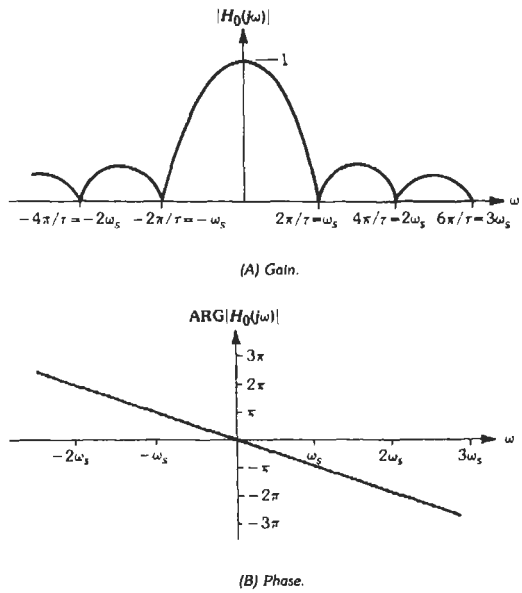

Fig. 42. Sample-and-hold responses.

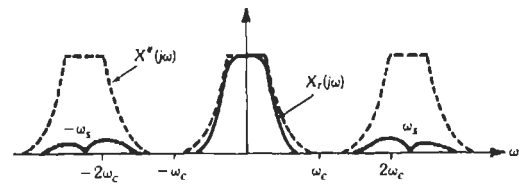

Fig. 43. Spectrum of reconstructed sampled signal.

For lower sampling rates, the sampled-data filter that operates on the signal X is designed with a peak to compensate for the S/H-related band-edge droop. To further smooth $X_r(j\omega)$ (i.e., further attenuate the high-frequency components of X_r) the analog sampled-data system can be followed by a c-t low-pass filter as shown in Fig. 39.

Now that the concept of analog sampled-data systems has been discussed in general terms and the necessary hardware to support the sampled system in a non-band-limited analog environment has been identified, attention will now be focused on the SC-filter portion of this system.

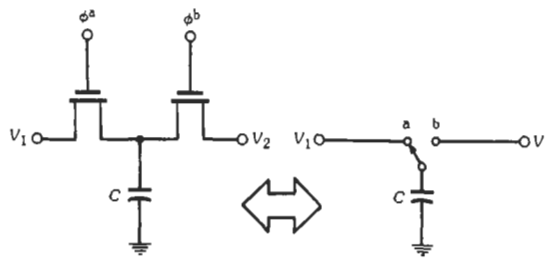
The Operation of Ideal SC Filters

Consider the operation of an ideal SC filter, made up of ideal capacitors, ideal switches, and ideal op amps (infinite gain and infinite bandwidth). It is noted that MOS op amps that settle to within 0.1 percent of final value in less than 2 μs and achieve dc gains of greater than 60 dB have been designed.* One subtle difference between SC filters and their active *RC* counterparts is the effect of op-amp dynamics on filter behavior. Although related, op-amp settling time, rather than op-amp frequency response, is the important op-amp characteristic for SC filters. In fact, it is op-amp settling time that establishes the upper limit for the sampling rate. It has been demonstrated that settling errors can be minimized by carefully orchestrating the timing among the various samples within the filter.† Hence, for sampling rates f_s of no more than 256 kHz and careful timing, a practical MOS op amp usually can be modeled as a voltage-controlled voltage source with gain equal to the dc gain of the op amp.

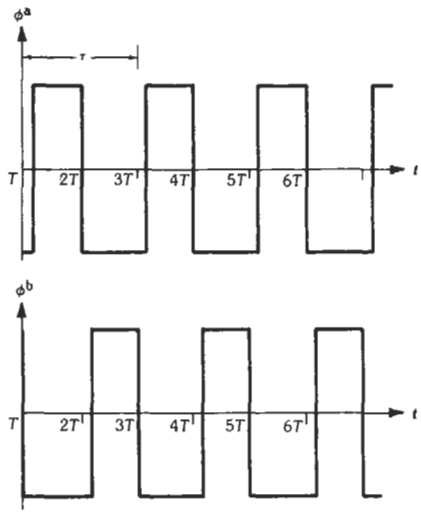
Consider for the moment the simple SC circuit in Fig. 44A. It consists of a single capacitor with bottom plate grounded and top plate connected between two switches controlled by the clocks ϕ^a and ϕ^b. As shown in Fig. 44B, the clocks ϕ^a and ϕ^b are two-phase, *nonoverlapping* clocks of frequency $f_s = 1/(2T) = 1/\tau$. The clock's duty cycles must be less than 50 percent for the clock pulses to be nonoverlapping. However, to allow maximum time for op-amp settling, duty cycles of

* Reference 24.

† Reference 25.



(A) Circuit.



(B) Biphase nonoverlapping clocks.

Fig. 44. Simple SC circuit.

greater than 35 percent are typically used. Most SC filters are insensitive to duty cycle, but nonoverlap is essential for the circuit to operate correctly. The fact that op-amp settling typically establishes the upper limit for f_s has already been mentioned. It was also mentioned in the previous section that high f_s results in large capacitor ratios and low f_s results in complex antialiasing/reconstruction filters. Other factors that impact the selection of a sampling rate are noise and capacitor leakage. Evidently the choice of sampling rate involves a compromise among several conflicting factors and no general rule can be stated. One can find in the literature* SC filters with sampling frequencies that range from many megahertz to as low as 8 kHz.

The circuit in Fig. 44A, although simple, provides a rather interesting and important function. Consider the following simple analysis of this circuit and assume initially that the capacitor C is uncharged. When switch ϕ^a closes and switch ϕ^b opens, at $t = 0$, capacitor C charges to the voltage V_1. When $t = T = \tau/2$, switch ϕ^a opens and switch ϕ^b closes, and capacitor C discharges to the voltage V_2. The amount of charge that flows into (or out of) V_2 during the time τ is given by

$$\Delta Q = C(V_2 - V_1) \qquad \text{(Eq. 111)}$$

If the process repeats at $t = \tau, 2\tau, \ldots$, etc., the equivalent average current I is

$$I = \frac{\Delta Q}{\tau} = \frac{C}{\tau}(V_2 - V_1) = Cf_s(V_2 - V_1) \qquad \text{(Eq. 112)}$$

Equation 112 is recognized to be the instantaneous voltage–current relation for a series resistor of value

$$R = 1/(Cf_s) \qquad \text{(Eq. 113)}$$

Equations 111–113 establish the well-known switched-capacitor–resistor equivalence. An oversimplified application of Eq. 113 is to derive SC filters from active RC prototypes by replacing each resistor with an equivalent switched capacitor (with $C = 1/(Rf_s)$). However, a careful analysis of Fig. 44A reveals that Eq. 113 is an approximation in that the charge transfer described in Eq. 111 involves a delay of T seconds. The approximation improves as T becomes small (f_s becomes large). Hence, the SC filter synthesis method of replacing resistors in an active RC prototype with switched capacitors is not a recommended procedure. In fact, if one were to replace the resistor in the feedback loop of a high-Q active RC biquad with the SC circuit in Fig. 44A, the added delay would no doubt result in instability. This result can be proven rigorously.† Fortunately, all these pitfalls can be avoided by working directly in the z-domain. Such an analysis renders an exact characterization of the ideal SC filter at the sampling instants.

By loading the SC circuit in Fig. 44A with a grounded capacitor, a simple one-pole low-pass filter can be constructed. This circuit is shown in Fig. 45. If we resort again for the purpose of demonstration to the resistor equivalence in Eq. 113, the pole frequency of the equivalent RC filter becomes

$$\omega_p = 1/(R_1C_2) \qquad \text{(Eq. 114)}$$

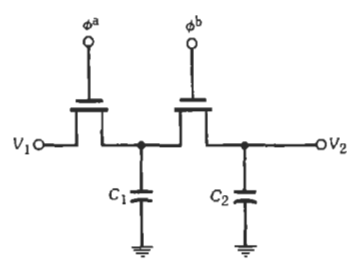


Fig. 45. One-pole low-pass SC filter.

* References 1 and 24.

† Reference 1.

Substituting the SC equivalent for resistor R_1 in Eq. 114 yields the pole frequency for the SC filter, i.e.,

$$\omega_p \approx f_s(C_1/C_2) \text{ for } f_s >> 2\pi f_p \quad \text{(Eq. 115)}$$

Equation 115 provides much of the motivation for SC filters. From Eq. 115, the inherent accuracy of the SC implementation is seen immediately: ω_p no longer depends on the *product* of the components R and C, but on the clock, f_s, and the *ratio* of two Cs. It was mentioned previously that MOS capacitor ratios can be held to tight tolerances and f_s is derived from a very precise crystal-controlled master clock. In addition, note that the capacitor ratio C_2/C_1 equals f_s/ω_p. That is, for constant ω_p, C_2/C_1 scales in direct proportion to f_s. As a consequence, the silicon area required to realize the SC filter in Fig. 44 (for a fixed ω_p and minimum capacitance C_1) scales with f_s. For IC realizations, minimum capacitors on the order of 1 pF are typically used.

SC Integrators

Most practical SC filters are realized with one op amp per pole (and zero), and they use SC integrators as basic building blocks. Moreover, SC filters implemented in this manner can be made insensitive to the unavoidable parasitic capacitances that occur in an IC realization and can, therefore, be implemented with minimum-size capacitors.

Let us first consider the inverting SC integrator in Fig. 46. Also shown are the parasitic capacitances associated with each node of the circuit. Capacitors (C_1 and C_2 in Fig. 46) are typically implemented as a thin SiO_2 dielectric sandwiched between two polysilicon plates. The interconnecting lines are typically polysilicon and metal that lie on top of a thick layer of SiO_2 (referred to as field oxide). The switches are usually either polysilicon-gate CMOS or enhancement NMOS devices. In the process of constructing these features in an integrated circuit, parasitic capacitors to the reverse-biased substrate (= signal ground) are unavoidably created. The parasitic capacitances are not controllable, do not track the intended capacitors, and sometimes are nonlinear. Hence, it is important to significantly reduce or eliminate the effect of parasitic capacitances on the transfer characteristic of the SC filter.

Returning to the integrator in Fig. 46, consider the effect of each of the parasitic capacitances, C_{p1} through C_{p4}. First, the parasitics C_{p1} and C_{p4} shunt low-impedance voltage sources (the output of an op amp and the input voltage possibly derived from another op amp as indicated in the figure). C_{p3} shunts the "virtual ground" of a high-gain op amp and is never charged. These parasitics have no effect on circuit performance. Parasitic C_{p2}, in contrast, parallels C_1 and adds directly to its value. In the absence of parasitics, the z-domain transfer function for the inverting SC integrator in Fig. 45 can be shown to be*

$$H(z) = -(C_1/C_2)z^{-1/2}/(1-z^{-1}) \quad \text{(Eq. 116)}$$

If C_{p2} is included, the transfer function becomes

$$H(z) = -\frac{C_1}{C_2}\left(1+\frac{C_{p2}}{C_1}\right)\frac{z^{-1/2}}{1-z^{-1}} \quad \text{(Eq. 117)}$$

From Eq. 117, the parasitic capacitance is seen to cause a gain error factor of $1 + C_{p2}/C_1$.

For the intended use of a minimum-size C_1 this error is large and an alternative circuit configuration is necessary. Consider the SC inverting integrator shown in Fig. 47, which also shows the two important parasitic capacitances. All other parasitic capacitances (shunting either a voltage source or the op-amp virtual ground) have been shown to have no effect. To determine the effect of C_{p1} and C_{p2}, examine the circuit as switches ϕ^a and ϕ^b turn on and off. With ϕ^a on and ϕ^b off, parasitics C_{p1} and C_{p2} shunt a voltage source and the op-amp virtual ground, respectively. When ϕ^a turns off and ϕ^b turns on, both C_{p1} and C_{p2} are shorted harmlessly to ground and do not contribute any charges to the circuit operation. Hence, this SC inverting integrator operates without error. The realization in Fig. 47 is said to be *parasitic insensitive*. The transfer function for this integrator is†

$$V_{out}/V_{in} = -(C_1/C_2)z^{-1/2}/(1-z^{-1}) \quad \text{(Eq. 118)}$$

* References 1, 6–8, and 10.

† References 1, 6, 7, and 10.

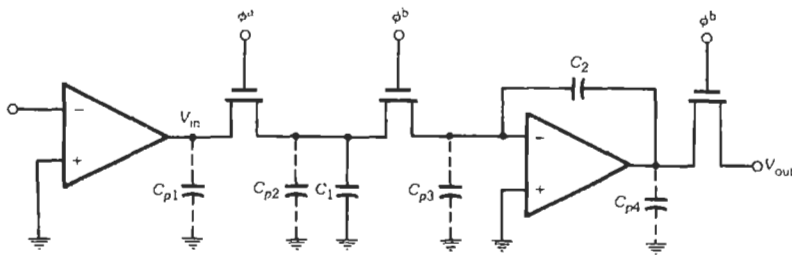

Fig. 46. Parasitic-sensitive SC inverting integrator with associated parasitic capacitors.

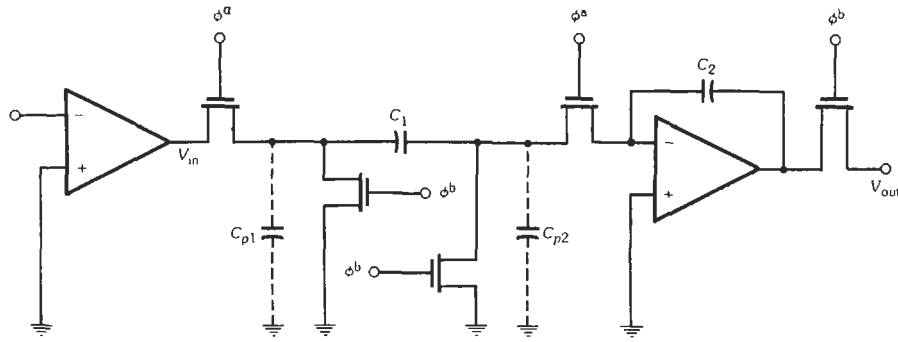

Fig. 47. Parasitic-insensitive SC inverting integrator with associated parasitic capacitances.

Note the presence of the $z^{-1/2}$ (one-half clock period delay) term in Eqs. 116–118. In the digital and SC filter literature, integrators of the form $Kz^{-1/2}/(1-z^{-1})$ are known as lossless discrete integrators (LDI).

Noninverting integrators can be implemented very efficiently with SC techniques. As shown in Fig. 48, an SC noninverting integrator can be realized with a single op amp. As seen in Figs. 7C and 7D, in the active *RC* world noninverting integrators require two op amps. With the switching arrangement shown for switched capacitor C_1, the additional inversion is elegantly performed by C_1 with a simple change of switch phasing. It can be verified that this circuit, like that in Fig. 47, is parasitic insensitive. The transfer function for the noninverting integrator in Fig. 48 is

$$H(z) = (C_1/C_2)\, z^{-1/2}/(1-z^{-1}) \qquad \text{(Eq. 119)}$$

With the inverting and noninverting integrators in Figs. 47 and 48, parasitic-insensitive SC filters of all transfer-function types can be realized. Parasitic insensitivity is not achieved at the expense of design generality. In fact, there is no reason to implement SC filters in any other way.

SC *z*-Domain Biquadratic Transfer Functions

To design an SC filter, one must first derive a *z*-domain transfer function from the filter requirements. This can be done by first obtaining the *s*-domain transfer function according to classic methods. The desired *z*-domain transfer function can then be obtained from the *s*-domain function by using the well-known bilinear transform

$$s = (2/\tau)(1-z^{-1})/(1+z^{-1}) \qquad \text{(Eq. 120)}$$

where τ represents one clock period. The bilinear transform is treated in Chapter 28 of this handbook and will not be discussed further here. Alternatively, *z*-domain transfer functions can be obtained directly from specified filter requirements by using any one of several computational techniques (see Chapter 28).

It was noted in previous sections that active *RC* biquads play a dominant role in the realization of high-order active *RC* filters. Although SC filters provide the opportunity to implement filters of much higher order on a single chip, the same substantial advantages are

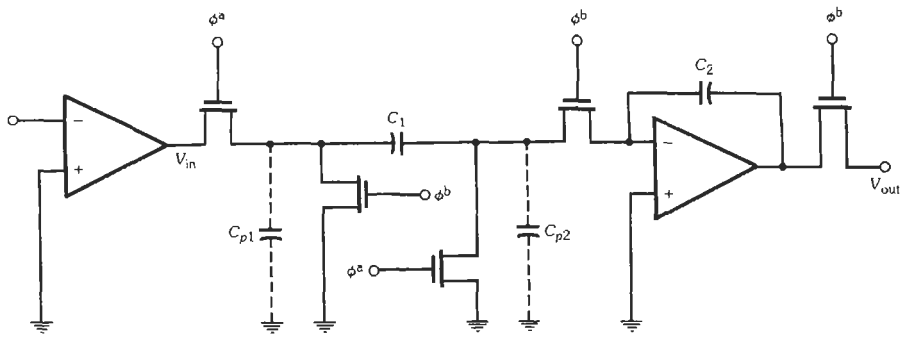

Fig. 48. Parasitic-insensitive SC noninverting integrator with associated parasitic capacitances.

obtained from biquads as in the *RC* case. Using biquads lends regularity to the design process and can reduce considerably the chip layout effort.

As active *RC* biquads realize biquadratic transfer functions in the *s*-domain, SC biquads realize biquadratic *z*-domain transfer functions. Thus, the transfer functions to be realized are of the form

$$H(z) = \frac{N(z)}{D(z)} = \frac{\gamma + \varepsilon z^{-1} + \delta z^{-2}}{1 + \alpha z^{-1} + \beta z^{-2}} \quad \text{(Eq. 121)}$$

The well-known special cases of Eq. 121, namely low-pass (LP), high-pass (HP), bandpass (BP), low-pass notch (LPN), high-pass notch (HPN), and all-pass (AP), can be derived by applying the bilinear transform to the corresponding second-order *s*-domain transfer functions.

One important property of the bilinear transfer function to be considered at this point is that the *z*-plane zeros at the one-half sampling frequency (i.e., $z = -1$) are mapped by Eq. 120 into *s*-plane zeros at infinity. Such zeros appear in low-pass (LP) and bandpass (BP) functions. Although use of the bilinear transform provides desirable steep cutoff to BP and LP filters in the vicinity of the half-sampling frequency (at $s \to \infty$), it may not result in the most economical SC realization. The additional attenuation provided at the half-sampling frequency is of little importance and diminishes in importance for relatively small pole, ω_p, and zero, ω_z, frequencies of the biquad (as $\omega_p\tau$ and $\omega_z\tau$ become small for the typical high sampling frequencies). When this relation is taken into account, several alternative LP and BP biquadratic transfer functions can be derived by replacing the zeros factors $1 + z^{-1}$ (i.e., for zeros at $z = -1$) with either 2 or $2z^{-1}$.

In Table 4, the numerators $N(z)$ are listed for the various elementary *z*-domain second-order forms. The LP and BP forms are referred to in this table as LP*ij* and BP*ij*, where *i* and *j* may have the value 0, 1, or 2. The suffix *i* denotes the number of $1 + z^{-1}$ factors and *j* the number of z^{-1} factors.

The recommended design procedure is first to obtain $D(z)$ and $N(z)$ via the bilinear transform. This will ensure the proper placement of the poles and zeros (other than those at $z = -1$). One or more of the zeros at $z = -1$ can then be replaced by either 2 or $2z^{-1}$. To place the gain level accurately, the gain constant K may then require slight alteration.

Parasitic-Insensitive SC Biquads

A general SC biquad that realizes Eq. 121 and its special cases in Table 4 was introduced by Fleischer and Laker, and by others.* This parasitic-insensitive biquad is shown in Fig. 49, in which capital letters *A* through *L*, of course, identify capacitors. This circuit is widely used throughout the industry. Because of space limitations, only the salient properties of this circuit will be highlighted. The interested reader is referred to the references for detailed derivations and demonstrations of individual features.

It simplifies the general analysis of this biquad to assume the input, V_{in}, is sampled and held for the full clock period. Although not necessary in every special-case implementation of Fig. 49, the condition is readily arranged. Furthermore, if the input to a cascade of such SC biquads is presented with a full-clock-period sampled-and-held signal, the switch timing in the biquads will propagate this condition through the entire filter. This condition is provided inherently by LP02 and BP01 biquads for any properly band-limited input signal.

Since, depending on the application, the desired output may be either at V or V', both the corresponding transfer functions are of interest. They are derived as

$$H = V/V_{in} = -N/D \quad \text{and} \quad H' = V'/V_{in} = N'/D \quad \text{(Eq. 122a)}$$

* References 1 and 26.

where

$$D(z) = D(F+B) + (AC + AE - DF - 2BD)z^{-1} + (DB - AE)z^{-2} \qquad \text{(Eq. 122b)}$$

is, of course, the same for both transfer functions, and

$$N(z) = D(I+K) + (AG + AL - DI - DJ - 2DK)z^{-1} + (DJ + DK - AH - AL)z^{-2} \qquad \text{(Eq. 122c)}$$

$$N'(z) = (IC + IE + KC + KE - GF - GB - LF - LB) + (FII + BH + BG + FL + 2BL - JC - JE - IE - KC - 2KE)z^{-1} + (EJ + EK - BH - BL)z^{-2} \qquad \text{(Eq. 122d)}$$

From Fig. 49 and Eqs. 122, it will be recognized that the transfer-function poles are determined by the feedback loop, consisting of capacitors A, B, C, D, E, and F. Further, the transfer-function zeros are determined by the two feed-forward paths, consisting, respectively, of capacitors G, H, L and I, J, K. As expected, both H and H' share the same denominator; however, the numerators are quite different.

The properties of this general biquad circuit are much more easily discerned if certain simplifications are introduced. Thus, it may be readily observed that the general circuit of Fig. 49 is not minimal, with redundancy occurring in both the feedback and feed-forward paths. In the feedback paths, capacitor E and switched capacitor F provide two means for damping the transfer function poles. Thus, in practice either E or F is used, but not both. Accordingly, it is useful to define an "E-circuit" in which $E \neq 0$ and $F = 0$ and an "F-circuit" in which $E = 0$ and $F \neq 0$.

Also, as noted before, the two zero-forming feed-forward paths consist of six elements. At most, four of these, that is, two elements for each path, are required to realize arbitrary zero locations. Consequently, during the initial design of a biquad, it is convenient to assign $K = I = 0$. This degree of freedom is readily restored to the design by using the element equivalencies shown in Fig. 50. That is, after an initial design is completed, these equivalencies are employed to modify the circuit until an acceptable design is obtained. The z-domain validity of the equivalencies relies on terminals 1 and 2 being connected to a voltage source (independent voltage source or op-amp output) and virtual ground, respectively.*

Because the transfer function of switched-capacitor filters depends only on capacitor ratios, one capacitor

* References 1 and 26.

in each stage may be arbitrarily chosen. It is convenient to exercise these degrees of freedom by setting $B = D = 1$. In addition, it may be shown that one can initially set $A = 1$. The effect of this choice is to relinquish temporarily control of the gain constant associated with the transfer function to the "secondary" output. Once the initial design is completed, the stages may be properly rescaled to restore full generality to the biquad.

In view of the above, it is convenient to set $K = L = 0$ and $A = B = D = 1$ in Eqs. 122 and further to consider the E-circuit and the F-circuit separately. This results in the following equations:

$$H_E(z) = -\frac{I + (G - I - J)z^{-1} + (J - H)z^{-2}}{1 + (C + E - 2)z^{-1} + (1 - E)z^{-2}} \quad \text{(Eq. 123a)}$$

$$H'_E(z) = \frac{(IC + IE - G) + (H + G - JC - JE - IE)z^{-1} + (EJ - H)z^{-2}}{1 + (C + E - 2)z^{-1} + (1 - E)z^{-2}} \quad \text{(Eq. 123b)}$$

$$H_F(z) = -\frac{\hat{I} + (\hat{G} - \hat{I} - \hat{J})z^{-1} + (\hat{J} - \hat{H})z^{-2}}{(\hat{F} + 1) + (\hat{C} - \hat{F} - 2)z^{-1} + z^{-2}} \quad \text{(Eq. 124a)}$$

$$H'_F(z) = -\frac{(\hat{G}\hat{F} + \hat{G} - \hat{I}\hat{C}) + (\hat{J}\hat{C} - \hat{F}\hat{H} - \hat{H} - \hat{G})z^{-1} + \hat{H}z^{-2}}{(\hat{F} + 1) + (\hat{C} - \hat{F} - 2)z^{-1} + z^{-2}} \quad \text{(Eq. 124b)}$$

The "hats" are placed on the F-circuit elements to distinguish them from the E-circuit elements.

The synthesis equations for the biquad can be readily derived from Eqs. 121, 123, and 124. To avoid repetition, design equations will be given only for the more frequently used H_E and H_F functions. A complete set of design equations can be found in Reference 26.

For pole placement, the synthesis equations for E, C and $\hat{F}$, $\hat{C}$ in terms of the z-domain transfer-function coefficients α and β can be stated as follows:

For the "E-circuit"

$$E = 1 - \beta \quad \text{(Eq. 125a)}$$

$$C = 1 + \alpha + \beta \quad \text{(Eq. 125b)}$$

For the "F-circuit"

$$\hat{F} = (1 - \beta)/\beta \quad \text{(Eq. 126a)}$$

$$\hat{C} = (1 + \alpha + \beta)/\beta \quad \text{(Eq. 126b)}$$

The synthesis equations for placing the zeros can be derived in terms of the z-domain transfer-function coefficients γ, ε, and δ by comparing Eqs. 123 and 124 with the numerator forms in Table 4. Since in Eqs. 123 and 124 those numerator coefficients are determined by four capacitors, the solution is not unique. Hence, in Table 5 a complete set of design equations is given

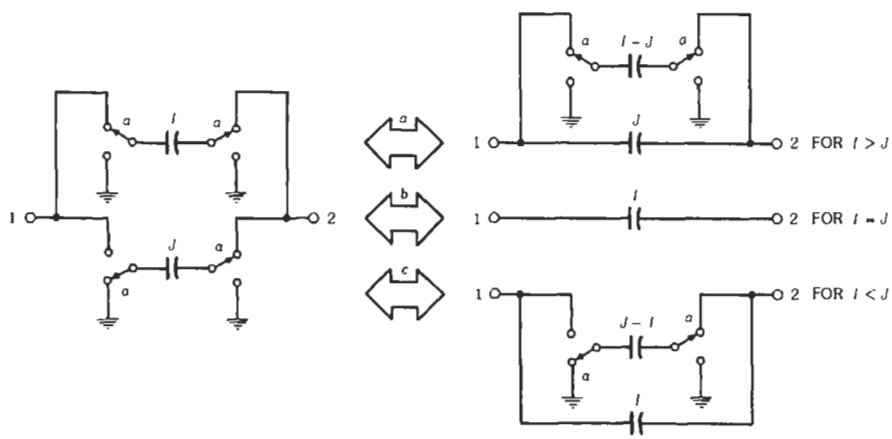

Fig. 50. SC element equivalencies.

TABLE 5. ZERO PLACEMENT FORMULAS FOR H_E AND H_F

Filter Type	Design Equations	Simple Solution
LP 20	$I = \|K\|$ $G - I - J = 2\|K\|$ $J - H = \|K\|$	$I = J = \|K\|$ $G = 4\|K\|, H = 0$
LP 11	$I = 0$ $G - I - J = \pm\|K\|$ $J - H = \pm\|K\|$	$I = 0, J = \|K\|$ $G = 2\|K\|, H = 0$
LP 10	$I = \|K\|$ $G - I - J = \|K\|$ $J - H = 0$	$I = \|K\|, J = 0$ $G = 2\|K\|, H = 0$
LP 02	$I = 0$ $G - I - J = 0$ $J - H = \pm\|K\|$	$I = J = 0$ $G = 0, H = \|K\|$
LP 01	$I = 0$ $G - I - J = \pm\|K\|$ $J - H = 0$	$I = J = 0$ $G = \|K\|, H = 0$
LP 00	$I = \|K\|$ $G - I - J = 0$ $J - H = 0$	$I = \|K\|, J = 0$ $G = \|K\|, H = 0$
BP 10	$I = \|K\|$ $G - I - J = 0$ $J - H = -\|K\|$	$I = \|K\|, J = 0$ $G = H = \|K\|$
BP 01	$I = 0$ $G - I - J = \pm\|K\|$ $J - H = \pm\|K\|$	$I = 0, J = \|K\|$ $G = H = 0$
BP 00	$I = \|K\|$ $G - I - J = -\|K\|$ $J - H = 0$	$I = \|K\|, J = 0$ $G = H = 0$
HP	$I = \|K\|$ $G - I - J = -2\|K\|$ $J - H = \|K\|$	$I = J = \|K\|$ $G = H = 0$
HPN and LPN	$I = \|K\|$ $G - I - J = \|K\|\varepsilon$ $J - H = \|K\|$	$I = J = \|K\|$ $G = \|K\|\{2 + \varepsilon\}, H = 0$
AP ($\beta > 0$)	$I = \|K\|\beta$ $G - I - J = \|K\|\alpha$ $J - H = \|K\|$	$I = \|K\|\beta, J = \|K\|$ $G = \|K\|(1 + \beta + \alpha) = \|K\|C$ $H = 0$
General ($\gamma > 0$)	$I = \gamma$ $G - I - J = \varepsilon$ $J - H = \delta$	$I = \gamma$ $J = \delta + x$ $G = \gamma + \delta + \varepsilon + x$ $H = x \geq 0$

Note: $\hat{G} = G(1 + \hat{F})$, $\hat{H} = H(1 + \hat{F})$, $\hat{I} = I(1 + \hat{F})$, and $\hat{J} = \hat{J}(1 + \hat{F})$.

for each case. For each of the cases, a "simple" solution is also offered.

The synthesis equations given in the previous paragraphs result in unscaled capacitor values. To complete the synthesis in practice, some scaling is required. The first order of business is to adjust the voltage level at the "secondary" output. If this voltage is too high, amplifier overloads may result; if it is too low, unnecessary noise penalties may be taken.

Although the voltage levels and necessary scaling factors may be obtained by using analysis techniques,* the simplest procedure is to simulate the unscaled circuit on an analysis program. This method serves also as a confirmation of the correctness of the design.

To adjust the voltage level V', i.e., the flat gain of H', without affecting H, only capacitors A and D need to be scaled. More precisely, if it is desired to modify the gain constant associated with V' according to

$$H' \rightarrow \mu H' \qquad \text{(Eq. 127)}$$

* Reference 1.

then it is only necessary to scale A and D as

$$(A, D) \rightarrow (1/\mu)A, (1/\mu)D \qquad \text{(Eq. 128)}$$

The gain constant associated with H remains invariant under this scaling. The correctness of this procedure follows directly from signal-flow graph concepts.

In a similar fashion, it can be shown that if the flat gain associated with V is to be modified, i.e.,

$$H \rightarrow \nu H \qquad \text{(Eq. 129)}$$

the following capacitors must be scaled:

$$(B, C, E, F) \rightarrow (1/\nu)B, (1/\nu)C, (1/\nu)E, (1/\nu)F \qquad \text{(Eq. 130)}$$

Once satisfactory gain levels have been obtained at both outputs, it is convenient to scale the admittances associated with each stage so that the minimum capacitor value in the circuit becomes unity. This makes it easier to observe the maximum capacitor ratios required to realize a given circuit and also serves to "standardize" different designs so that the total capacitance required can be readily observed. The two groups of capacitors that are to be scaled together are listed below:

Group 1: (C, D, E, G, H, L)
Group 2: (A, B, F, I, J, K)

Note that capacitors in each group are distinguished by the fact that they are all incident on the same input node of one of the operational amplifiers.

This completes the design process for synthesizing practical SC-biquad networks. In the next section, a detailed example is given to demonstrate each step of the design.

Low-Pass Notch Example

The transfer function to be realized will be based on the s-domain low-pass notch function

$$H(s) = \frac{0.891975s^2 + \omega_p^2}{s^2 + s\omega_p/30 + \omega_p^2} \qquad \text{(Eq. 131)}$$

where

$$\omega_p = 2\pi f_p \text{ with } f_p = 1700 \text{ Hz}.$$

This transfer function provides a notch frequency of f_z = 1800 Hz, a peak corresponding to a quality factor Q_p = 30, and 0-dB dc gain. The assigned sampling frequency is 128 kHz; i.e., $\tau = 7.8125\ \mu s$.

The z-domain transfer function is conveniently obtained via the bilinear transformation shown in Eq. 120. Because the band-edge frequency of 1700 Hz is much less than the sampling rate, it is not necessary to prewarp (see Chapter 28) $H(s)$. Applying the bilinear transformation to Eq. 131 yields, after some algebraic manipulations,

$$H(z) = 0.89093\frac{1 - 1.99220z^{-1} + z^{-2}}{1 - 1.99029z^{-1} + 0.99723z^{-2}} \qquad \text{(Eq. 132)}$$

Note that in obtaining this transfer function a high degree of numerical precision is required. However, this does not result in high sensitivities, since the capacitor ratios define only the departures from –2 and +1 in the above terms.

Only the H_E and H_F realizations of the above circuit will be given here, because they are more economical in the number of capacitors required. The synthesis itself is straightforward. Capacitors C, E or $\hat{C}$, $\hat{F}$ are determined from Eqs. 125 or 126, respectively, and capacitors G, H, I, J or $\hat{G}$, $\hat{H}$, $\hat{I}$, $\hat{J}$ are obtained from the "simple" solution entry in Table 5. Finally, of course, A, B, D or $\hat{A}$, $\hat{B}$, $\hat{D}$ are set equal to unity. The resulting unscaled capacitor values are given in the appropriate columns of Table 6. Note that in this table the "hats" are omitted from the F-circuit capacitors for notational convenience. Also note that since $I = J$ these two switched capacitors are replaced by the unswitched capacitor K ($K = I = J$) in accordance with Fig. 50.

As the next step, it is appropriate to simulate the unscaled E- and F-circuits to verify the design. The results of the simulation will confirm the correctness of H_E and H_F, in particular, that the maximum gain in both these realizations is approximately 10.56 dB. However, the maximum gains for H'_E and H'_F are very low. To make the first stage no more susceptible to overloads than the second stage, it is recommended that these gains also be increased to a maximum of 10.56 dB. Specifically, it was found that

$$H'_{E,max} \approx -11.05 \text{ dB}, H'_{F,max} \approx -10.96 \text{ dB}$$

Therefore, in accordance with Eq. 127,

$$\mu = 12.0365, \hat{\mu} = 11.9124$$

Using these factors to rescale A, D and $\hat{A}$, $\hat{D}$, respectively, as given in Eq. 128, yields the "dynamic range adjusted" capacitor values also shown in Table 6. Finally, the capacitors associated with each operational-amplifier stage are separately rescaled so that the minimum capacitor value becomes 1 pF. Table 6 shows the "final" values.

In comparing the "final" realizations, we note that the F-circuit requires roughly 12 times the total capacitance of the E-circuit, in spite of the fact that the initial values were almost identical. Thus, alternative designs must be carried to completion before they can be meaningfully compared. It should be noted that other practical examples exist in which the F-circuit designs are dramatically more efficient than the corresponding E-circuit designs. The sensitivities for both designs are found to be equivalent.

Other Topologies and Comments

SC filters, as any other type of analog active filter, consist of active inverting and noninverting integrators (see Figs. 46 and 47). It stands to reason, therefore,

TABLE 6. LOW-PASS NOTCH REALIZATION

that other filter structures, such as ladders, discussed in the earlier parts of this chapter can also be implemented in the SC technique. Because of space limitations and the fact that SC filters are built only in fully integrated form, requiring a considerable design effort and expertise, the reader is referred to the literature* for a discussion of design details. Suffice it here to make the reader aware that analog active SC filters of very high quality and of high and low order have found commercial acceptance for a wide variety of signal-processing and control applications at moderate frequencies. Attention must be paid only to the fact that SC filters are sampled-data circuits, which calls for some care in the system design. Finally, we emphasize again that integrated SC filters, just as g_m-C circuits, should be built in fully differential form for reasons outlined earlier: better dynamic range, power-supply rejection, and clock feedthrough.†

11 Attenuators

Revised by
Bruno O. Weinschel

DEFINITIONS

An attenuator is a network that reduces the input power by a predetermined ratio. The ratio of input power to output power is expressed in logarithmic terms such as decibels (dB).

$$\text{Attenuation in dB} = 10 \log_{10} P_{in}/P_{out} \equiv 20 \log_{10} E_{in}/E_{out}$$

NOTE: $Z_{source} = Z_{load} = Z_{attenuator}$
All resistive, matched

Examples:

1) $P_{in}/P_{out} = 13.18 = 10 \times 1.318$
$10 \log_{10} P_{in}/P_{out}$ dB $= 10 (\log_{10} 10 + \log_{10} 1.318)$ dB
$= 10(1 + 0.1199)$ dB $\simeq 11.2$ dB
2) $E_{in}/E_{out} = 3.630$
$20 \log_{10} E_{in}/E_{out}$ dB $= 20 \log_{10} 3.630$ dB
$= 20 \times 0.560$ dB $= 11.2$ dB

To convert attenuation in decibels into power or voltage ratio:

$$P_{in}/P_{out} = \log_{10}{}^{-1} \text{ dB}/10 = 10^{\text{dB}/10}$$
$$E_{in}/E_{out} = \log_{10}{}^{-1} \text{ dB}/20 = 10^{\text{dB}/20}$$

Examples:

3) 11.2 dB $P_{in}/P_{out} = 10^{11.2/10} = 10^{1.12} = 13.18$
4) 11.2 dB $E_{in}/E_{out} = 10^{11.2/20} = 10^{0.56} = 3.630$

Table 1 lists a few decibel values together with the corresponding power and voltage ratios.

The power ratio used in the *characteristic insertion loss* relation (page 82, IEEE Standard 100—1972) is shown in Fig. 1. The ratio specified is equal to the characteristic insertion loss since source and load are reflectionless. Usually, one is interested in resistive attenuators of nominally equal impedance as the source and load impedance. Resistive devices are most common. Attenuators include absorptive and reflective devices having at least two ports.

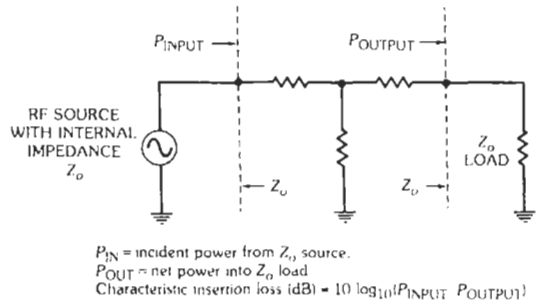

Fig. 1. Definition of characteristic insertion loss.

There are fixed attenuators, continuously variable attenuators, and step attenuators. This chapter treats principally Z_o *matched, two-port* attenuators, for use in a Z_o *system*. They are reversible except for a high-power attenuator designed for unilateral power flow. Minimum-loss L-pads for matching between two different impedances are also treated.

TYPICAL DESIGNS OF RESISTIVE ATTENUATORS

Simple wirewound resistors are used to upper audio frequencies. Nonreactive wirewound resistors (mica card, Ayrton-Perry winding, woven resistors) can be used to higher frequencies for low characteristic impedance values of, for example, 50 ohms. Preferred US impedance values are 600 ohms for audio and 50 or 75 ohms for coaxial video, RF, and microwave transmissions. For coaxial applications to over 26.5 GHz, thin-film resistors on low-loss insulators are used as attenuating elements. Up to a few gigahertz, lumped rod and disc resistors can be used as series and shunt elements in coaxial lines. The rods should be shorter than $\lambda/8$ at the maximum frequency (Figs. 2 and 3). For

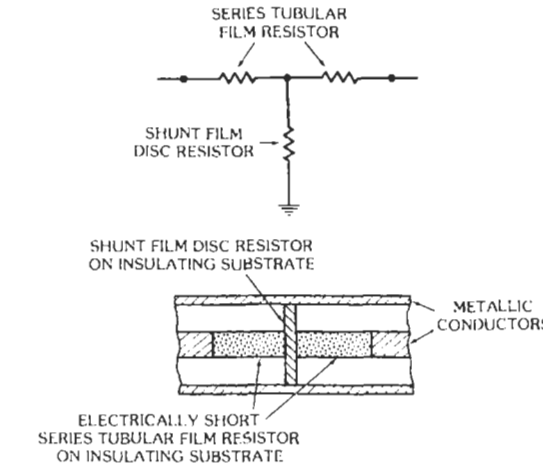

Fig. 2. Coaxial tee section.

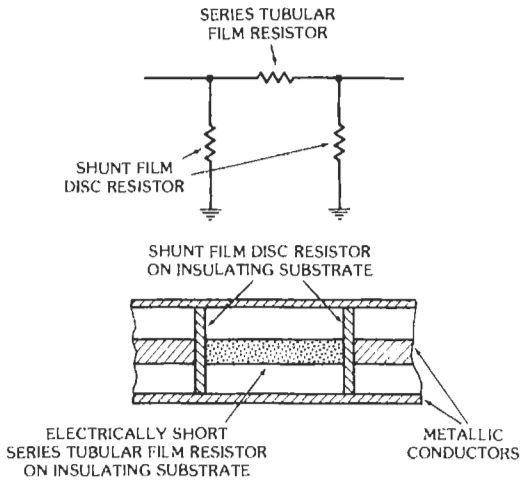

Fig. 3. Coaxial pi section.

higher frequencies, distributed resistive films on suspended substrates are used (Fig. 4).

Resistance Networks for Attenuators

Four types of symmetrical pads are shown in Fig. 5. The formulas for the resistance values in ohms for these pads when R_o = 1 ohm are given below. If R_o has a value other than 1 ohm, multiply each of the resistance values (a, b, c, $1/a$, $1/b$, and $1/c$) by R_o.

$$a = (10^{dB/20} - 1)/(10^{dB/20} + 1)$$
$$b = 2.10^{dB/20}/(10^{dB/10} - 1)$$
$$c = 10^{dB/20} - 1$$

An unsymmetrical matching pad is shown in Fig. 6. The formulas for this pad are:

$$j = R_1 - kR_2/(k + R_2)$$
$$k = [R_1R_2^2/(R_1 - R_2)]^{1/2}, \text{ where } R_1 > R_2$$

$$\text{Minimum loss in dB} = 20 \log_{10}\{[(R_1 - R_2)/R_2]^{1/2} + (R_1/R_2)^{1/2}\}$$

Typical values for the pads in Fig. 5 are listed in Table 2. Typical values for the pad in Fig. 6 are listed in Table 3.

Balanced pads are used in balanced transmission lines. For voice, Z_o is typically 600 ohms; for VHF TV, Z_o is typically 300 ohms. Bridged tee pads are common in low-frequency step attenuators. Lumped-element pi pads are short and easily matched up to about 1.5 GHz, with 75- or 50-ohm impedance. Coaxial tee pads of 50-ohm impedance can work above 10 GHz if the series elements are short in comparison with the wavelength. For low frequency sensitivity, thin resistive films (Ni-

* These values have been multiplied by 10^5.

NOTES:

1. If $R_o \neq 1$ ohm, multiply all values by R_o.
2. For other decibel values, use formulas in text.

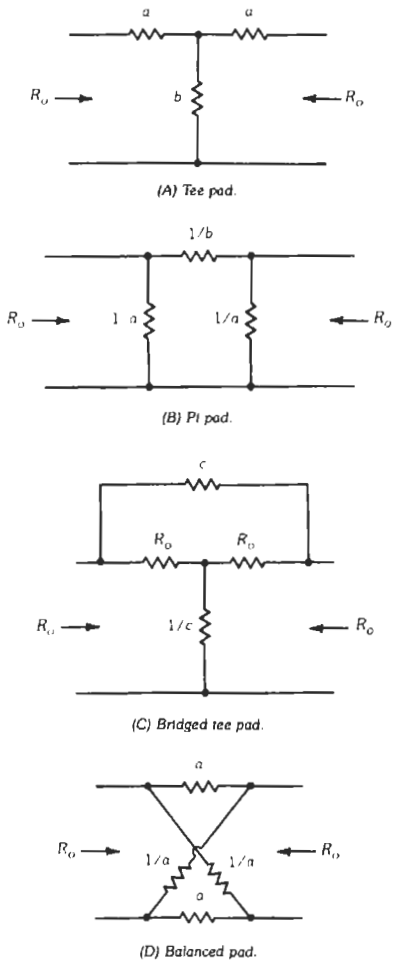

Fig. 5. Symmetrical pads for use between equal characteristic impedances.

chrome, cracked carbon, tantalum nitride) on an insulating substrate (mica, ceramic, quartz) are used. Figs. 2, 3, and 4 illustrate coaxial cross sections.

For a broadband match between impedances R_1 and R_2, use the minimum-loss L pad (Fig. 6).

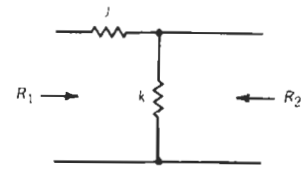

Fig. 6. Unsymmetrical matching pad between R_1 and R_2.

Power Dissipation Within a Tee Pad

Table 4 lists values of power dissipation within a tee pad. The values in the table are for an input of 1 watt; for other input powers, multiply the values in the table by the input power.

CONNECTORS

Each connector of an attenuator must mate nondestructively with connectors that comply with the governing standard, typically Mil-C-39012, IEEE Std. 287-1968, or Mil-F-3922, as shown in Table 5.

MEASUREMENT OF ATTENUATION

The methods covered are fixed-frequency, broadband, and swept or stepped in frequency. All accuracies exclude the effects of mismatch uncertainty and connector nonrepeatability. In Fig. 7, the most commonly used attenuation-measurement systems are compared as to dynamic range and typical accuracy.

Fixed-Frequency

Measurement of Small Attenuation (< 5 dB)

Dual-channel audio substitution (Fig. 8)

Accuracy: 0.01 dB

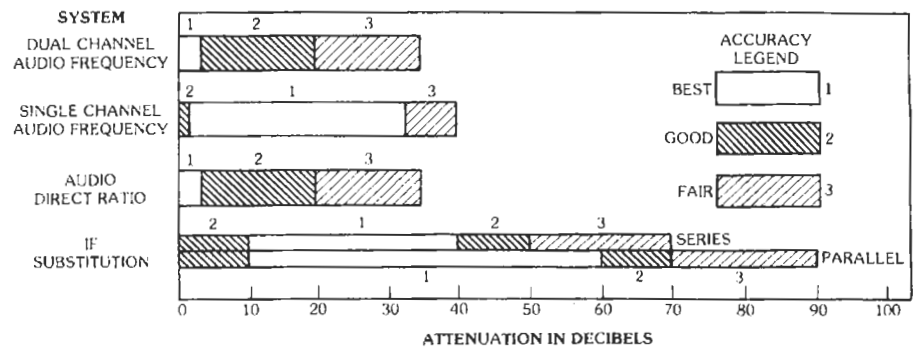

Fig. 7. Comparison of most commonly used attenuation measurement systems.

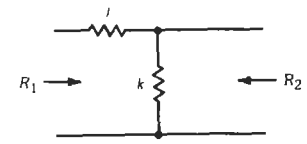
TABLE 3. RESISTANCE VALUES AND ATTENUATION FOR MINIMUM-LOSS L PAD*



R_1/R_2	j	k	dB
20.0	19.49	1.026	18.92
16.0	15.49	1.033	17.92
12.0	11.49	1.044	16.63
10.0	9.486	1.054	15.79
8.0	7.484	1.069	14.77
6.0	5.478	1.095	13.42
5.0	4.472	1.118	12.54
4.0	3.469	1.155	11.44
3.0	2.449	1.225	9.96
2.4	1.833	1.310	8.73
2.0	1.414	1.414	7.66
1.6	0.9798	1.633	6.19
1.2	0.4898	2.449	3.77
1.0	0	∞	0

* For $R_2 = 1$ ohm and $R_1 > R_2$. If $R_2 \neq 1$ ohm, multiply values by R_2. For ratios not in the table, use the formulas in the text.

Examples of use of table:

If $R_1 = 50$ ohms and $R_2 = 25$ ohms, then $R_1/R_2 = 2.0$, and $j = k = 1.414 \times 25$ ohms $= 35.35$ ohms.

If $R_1/R_2 = 1.0$, minimum loss $= 0$ dB.

For $R_1/R_2 = 2.0$, the insertion loss with the use of j and k for matching is 7.66 dB above that for $R_1/R_2 = 1.0$.

Advantage: Single radio-frequency source

Attenuation standards: Audio attenuator (resistive)
Ratio transformer (inductive)

Measurement of Moderate Attenuation (1 to 30 dB)

Audio substitution

(A) Single channel (Fig. 9)
Accuracy: 0.1 dB

(B) Dual channel (Fig. 8)
Accuracy: 0.05 dB

The major advantage of systems (A) and (B) is simplicity.

Measurement of High Attenuation (30 to > 100 dB)

Intermediate-frequency substitution

(A) Series substitution (Fig. 10)

Accuracy: 0.1 to 1 or 2 dB

Disadvantage: Minimum loss of standard attenuator (typically 30 dB for a waveguide-below-cutoff attenuator) in series with the mixer reduces dynamic range.

(B) Parallel substitution (Fig. 11)

Accuracy: 0.1 to 1 or 2 dB

Advantage: Minimum loss of standard intermediate-frequency attenuator does not affect system sensitivity; gain stability of intermediate-frequency amplifier does not influence accuracy.

Disadvantage: More complex

All intermediate-frequency systems have an inherent limitation due to the range of power conversion linearity of the mixer. Beyond 90 dB, corrections may have to be made for linearity deviation. Partial radio-frequency substitution is often used to extend range, but mismatch and leakage errors are prevalent.

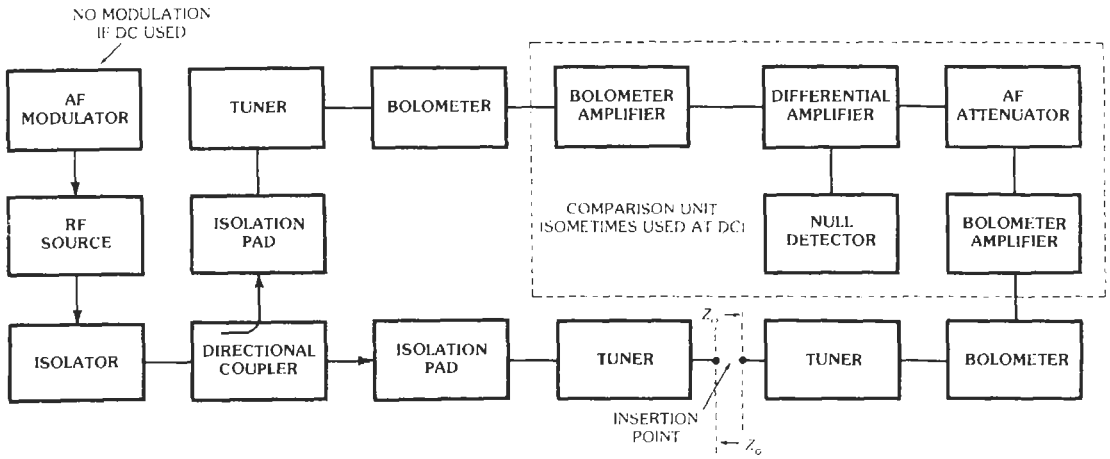


Fig. 8. Dual-channel audio substitution system (Reference 1).

References—Mil-C-39012 on Coaxial Connectors; Mil-F-3922 on Waveguide Flanges, General Purpose; IEEE Std. 287-1968 on Precision Coaxial Connectors

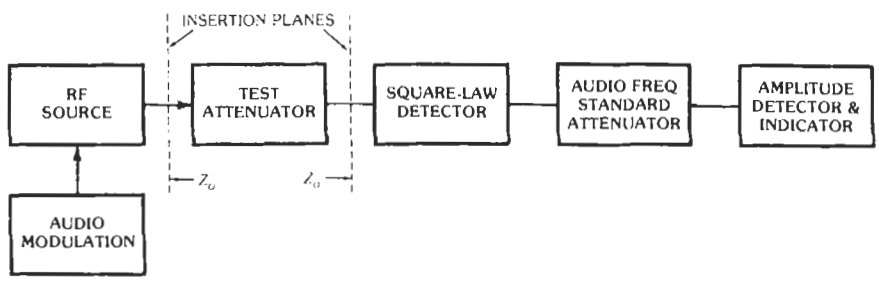

Fig. 9. Single-channel audio substitution system (Reference 1).

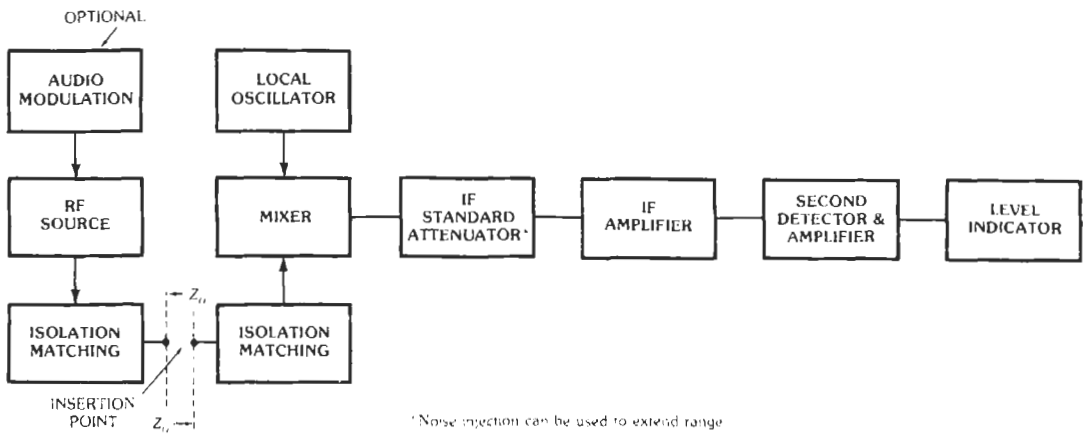

Fig. 10. Series type intermediate-frequency substitution system (References 3 and 4).

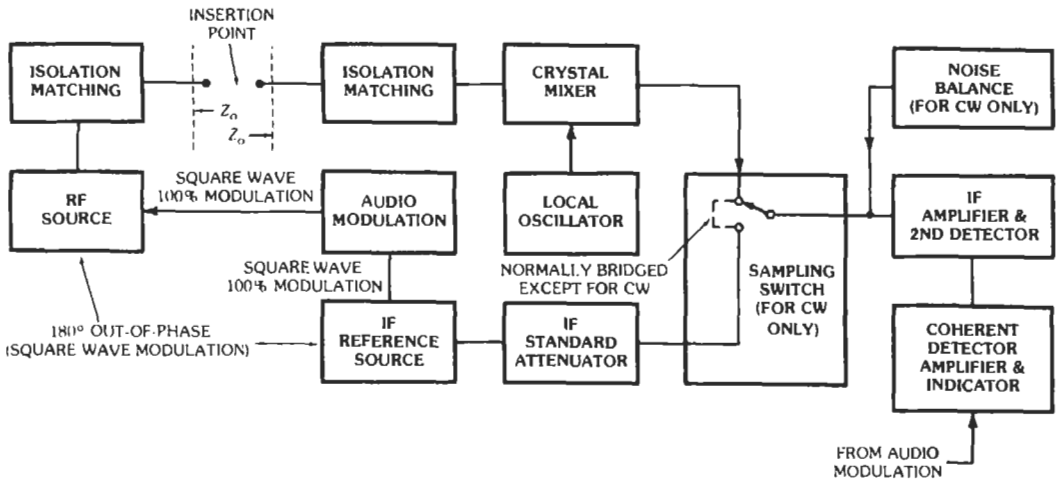

Fig. 11. Parallel IF substitution system with noise injection and coherent detection (References 5 and 6).

Disadvantage: Limited dynamic range (about 30 dB) without partial radio-frequency substitution

The major difficulty in broadband techniques is maintaining a Z_o-matched source and terminating impedance. The increased mismatch uncertainty due to impedance variations of source and load with frequency may degrade the above accuracy figures by an order of magnitude. A technique producing an equivalent Z_o-matched source impedance is discussed in Reference 9.

Swept or Stepped in Frequency

Measurement of Attenuation Less than 30 dB

(1) Audio-substitution dual channel (Fig. 8 with addition of level-stabilized swept radio-frequency source)

Accuracy: 0.05 to 0.1 dB

Advantage: Potentially most accurate system

Disadvantage: Impedance variation

(2) Audio ratio technique (Fig. 12)

Accuracy: 0.1 to 0.3 dB

Advantage: Rapid measurement, simplicity

Disadvantage: Curvilinear reference lines which can be straightened through the use of memory circuits

(3) Sampling (Fig. 13)

Accuracy: 0.1 to 0.5 dB dependent on uncertainty of system precalibration

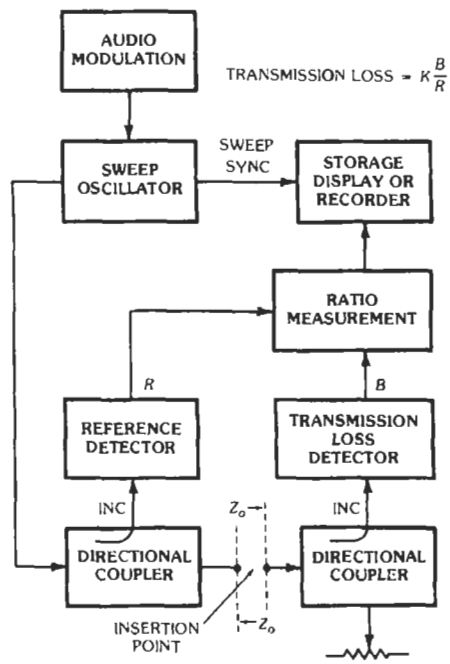

Fig. 12. Diagram of broadband direct-ratio system (References 2 and 9).

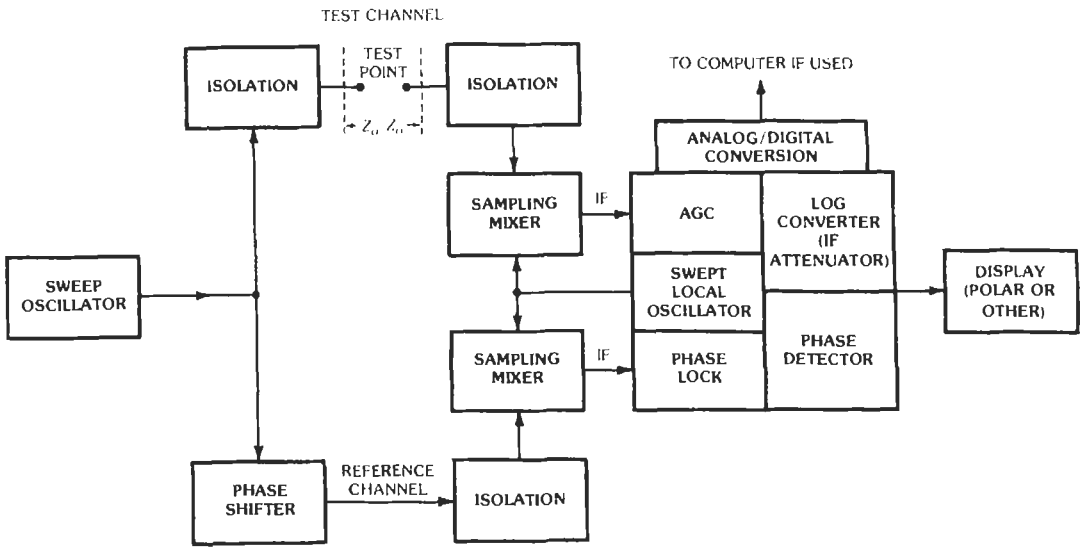

Fig. 13. Sampling conversion method of attenuation measurement (Reference 8).

Advantages: (A) Digital technique permits use of logic circuitry for automatic correction of measurement errors

(B) Extremely rapid measurement technique

Disadvantage: Very complex

Measurement of Attenuation Greater than 30 dB

Sampling (Fig. 13)

Accuracy: 0.5–2 dB to 50 or 60 dB dependent on uncertainty of system precalibration

Advantages: (A) Digital technique permits use of logic circuitry for automatic correction of measurement errors

(B) Extremely rapid measurement technique

Disadvantage: Very complex

The aforementioned measurement techniques are not intended to be all-inclusive. These are representative of current practices only. No mention has been made of specialized power ratio, modulated subcarrier, radio-frequency substitution, homodyne, impedance, or self-calibrating methods, or range extension by using a supervised change of incident power level.

12 Measurements and Analysis

Arthur Fong, Robert Coackley, John J. Dupre, Stephen J. Greer, Siegfried Linkwitz, John R. Page, Ronald E. Pratt, Douglas K. Rytting, and Gary D. Sasaki

The aim of this chapter is to provide a condensed description of methods of electronic measurements. Science and technology would indeed be vague without the ability to measure. Lord Kelvin cautioned that "Knowledge not expressible in numbers is of a meager and unsatisfactory kind"; he was identifying an essential aspect of scientific knowledge.

In the past, measurements of voltage, frequency, impedance, or power were made by using bridges or substitution methods with prototype standards derived from primary standards. Now, using digital techniques, one can create signals with precise voltage, frequency, and phase and can measure signals with the same precision. Many measurements are now made by stimulating the network or system with a precise signal, measuring the response, and using a microprocessor to compute the impedance, gain, phase, or other required results.

Another method for determination of measured quantities uses the technique of ratio measurements. For example, the complex ratio of E/I can be determined very precisely for a given frequency; then a microprocessor instantaneously calculates the impedance or response. In addition, the sequential steps of measurements, computation, and final display can also be controlled by the same microprocessor. Touch and read instruments were created by these technologies.

These measurements topics will be covered:

Impedance
Networks
Signals
Time and Frequency
Power
Microwave Links
IEEE 488 Data Bus
EMI/EMC/EMS

It is assumed that the reader is already familiar with such fundamental topics as voltage, current, gain, phase, distortion, etc. Specialized measurements for linear systems, digital signals, time domains, fields, magnetics, etc., are left for specialized publications. (Some chapters in this book covering specialized topics do contain information on the associated measurements.)

IMPEDANCE BRIDGES

In the diagrams of bridges in this section, the source (generator) and the detector (headphones) may be interchanged as dictated by the location of grounds. For all but the lowest frequencies, a shielded transformer is required at either the input or output (but not usually both) terminals of the bridge. The detector is chosen according to the frequency of the source. When insensitivity of the ear makes direct use of headphones impractical, a simple radio receiver or its equivalent is essential. Some selectivity is desirable to discriminate against harmonics, for the bridge is often frequency sensitive. The source may be modulated to obtain an audible signal, but greater sensitivity and discrimination against interference are obtained by the use of a continuous-wave source and a heterodyne detector. An oscilloscope is sometimes preferred for observing nulls. In this case, it is convenient to have an audible output signal available for the preliminary setup and for locating trouble, since much can be deduced from the quality of the audible signal that would not be apparent from observation of amplitude only.

Fundamental Alternating-Current or Wheatstone Bridge

Refer to Fig. 1. The balance condition is $Z_x = Z_s Z_a / Z_b$. Maximum sensitivity exists when Z_d is the conjugate of the bridge output impedance and Z_g is the conjugate of its input impedance. Greatest sensitivity exists when the bridge arms are equal; for example, for resistive arms

$$Z_d = Z_a = Z_b = Z_x = Z_s = Z_g$$

Wagner Ground Connection

None of the bridge elements (Fig. 2) is grounded directly. First balance the bridge with the switch to B. Throw the switch to G, and rebalance by means of R and C. Recheck the bridge balance and repeat as required. The capacitor balance C is necessary only when the frequency is above the audio range. The transformer may have only a single shield as shown, with the capacitance of the secondary to the shield kept to a minimum.

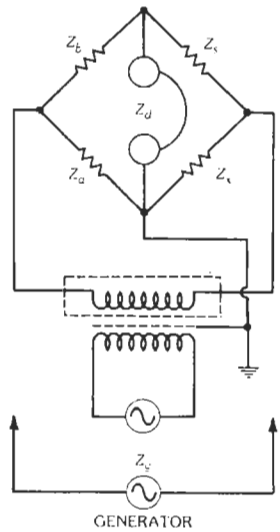

Fig. 1. Fundamental ac bridge.

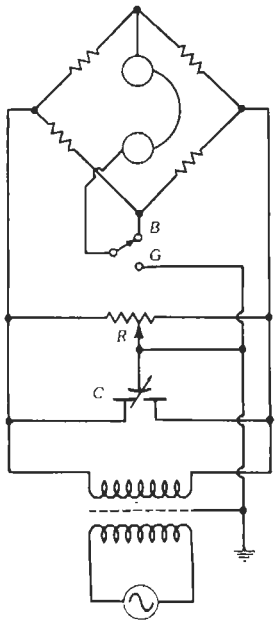

Fig. 2. Wagner ground connection.

Capacitor Balance

A capacitor balance is useful when one point of the bridge must be grounded directly and only a simple shielded transformer is used (Fig. 3). Balance the bridge, then open the two arms at P and Q. Rebalance by auxiliary capacitor C. Close P and Q and check the balance.

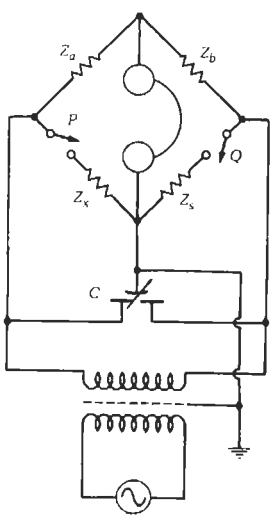

Fig. 3. Capacitor balance.

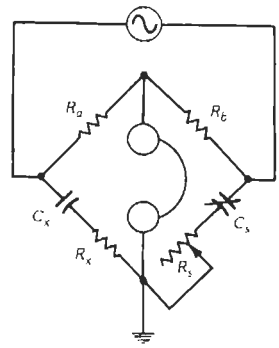

Fig. 4. Series-resistance-capacitance bridge.

Series-Resistance-Capacitance Bridge

In the bridge of Fig. 4:

$$C_x = C_s R_b / R_a$$

$$R_x = R_s R_a / R_b$$

Wien Bridge

In the bridge of Fig. 5:

$$C_x C_s = (R_b / R_a) - (R_s / R_x)$$

$$C_s / C_x = 1 / \omega^2 R_s R_x$$

For measurement of frequency, or in a frequency-selective application, if we make $C_x = C_s$, $R_x = R_s$, and $R_b = 2R_a$, then

$$f = (2\pi C_s R_s)^{-1}$$

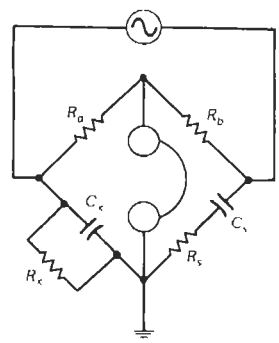

Fig. 5. Wien bridge.

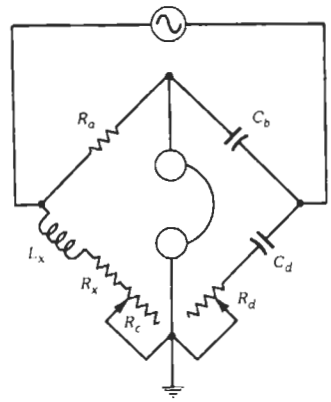

Fig. 6. Owen bridge.

Owen Bridge

In the bridge of Fig. 6:

$$L_x = C_b R_a R_d$$

$$R_x = (C_b R_a / C_d) - R_c$$

Resonance Bridge

In the bridge of Fig. 7:

$$\omega^2 LC = 1$$

$$R_x = R_s R_a / R_b$$

Maxwell Bridge

In the bridge of Fig. 8:

$$L_x = R_a R_b C_s$$

$$R_x = R_a R_b / R_s$$

$$Q_x = \omega(L_x/R_x) = \omega C_s R_s$$

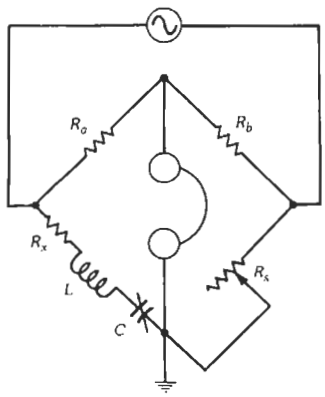

Fig. 7. Resonance bridge.

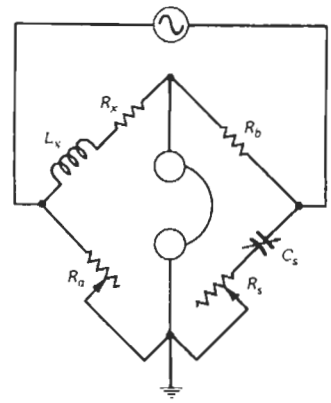

Fig. 8. Maxwell bridge.

Hay Bridge

The bridge of Fig. 9 is for the measurement of large inductance.

$$L_x = R_a R_b C_s / (1 + \omega^2 C_s^2 R_s^2)$$

$$Q_x = \omega L_x / R_x = (\omega C_s R_s)^{-1}$$

Schering Bridge

In the bridge of Fig. 10:

$$C_x = C_s R_b / R_a$$

$$1/Q_x = \omega C_x R_x = \omega C_b R_b$$

Substitution Method for High Impedances

Refer to Fig. 11.
Initial balance (unknown terminals $x - x$ open):

$$C_s' \text{ and } R_s'$$

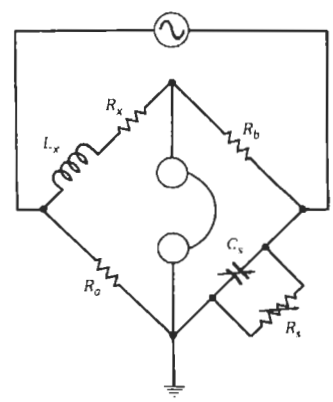

Fig. 9. Hay bridge.

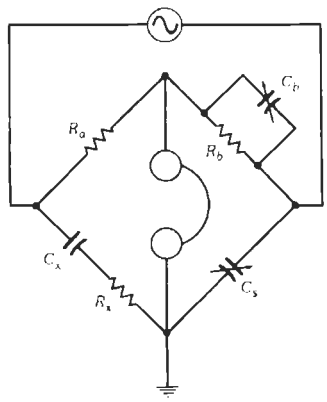

Fig. 10. Schering bridge.

Final balance (unknown connected to $x - x$):

$$C_s'' \text{ and } R_s''$$

Then when $R_x > 10/\omega C_s'$, there results, with error < 1 percent

$$C_x = C_s' - C_s''$$

The parallel resistance is

$$R_x = [\omega^2 C_s'^2 (R_s' - R_s'')]^{-1}$$

If unknown is an inductor

$$L_x = -(\omega^2 C_x)^{-1} = [\omega^2 (C_s'' - C_s')]^{-1}$$

Measurement With Capacitor in Series With Unknown

Refer to Fig. 12.

Initial balance (unknown terminals $x - x$ short-circuited):

$$C_s' \text{ and } R_s'$$

Final balance ($x - x$ unshorted):

$$C_s'' \text{ and } R_s''$$

Then

$$R_x = (R_s'' - R_s')R_a/R_b$$

$$C_x = \frac{R_b C_s' C_s''}{R_a (C_s' - C_s'')}$$

$$= \frac{R_b}{R_a} C_s' \left(\frac{C_s'}{C_s' - C_s''} - 1 \right)$$

When $C_s'' > C_s'$

$$L_x = \frac{1}{\omega^2} \frac{R_a}{R_b C_s'} \left(1 - \frac{C_s'}{C_s''} \right)$$

Measurement of Direct Capacitance

Refer to Fig. 13.

Connection of N to N' places C_{nq} across the detector and C_{np} across R_b, which requires only a small readjustment of R_s.

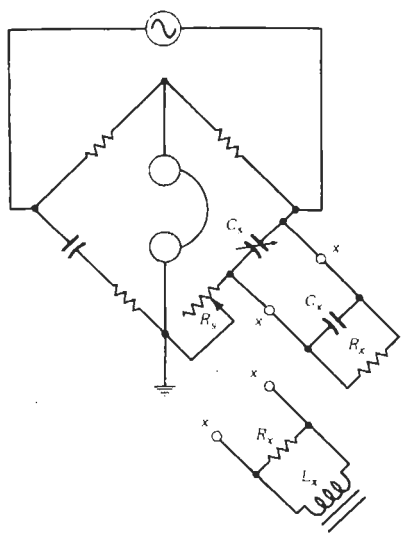

Fig. 11. Substitution method.

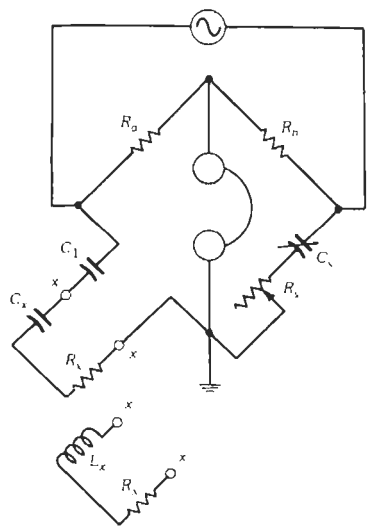

Fig. 12. Measurement with capacitor in series with unknown.

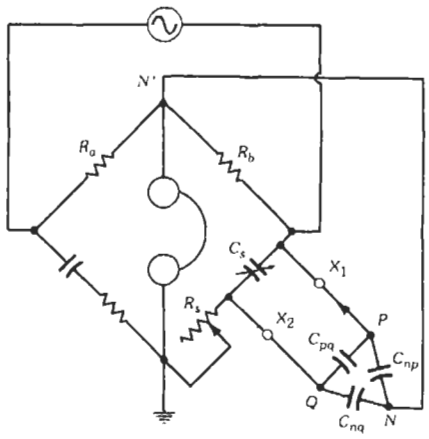

Fig. 13. Measurement of direct capacitance.

Initial balance: Lead from P disconnected from X_1 but lying as close to the connected position as practical.

Final balance: Lead connected to X_1.

By the substitution method above

$$C_{pq} = C_s' - C_s''$$

Felici Mutual-Inductance Balance

At the null (Fig. 14):

$$M_x = -M_s$$

This is useful at lower frequencies where capacitive reactances associated with windings are negligibly small.

Mutual-Inductance Capacitance Balance

With a low-loss capacitor (Fig. 15), at the null:

$$M_x = 1/\omega^2 C_s$$

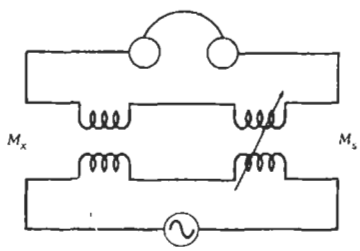

Fig. 14. Felici mutual-inductance balance.

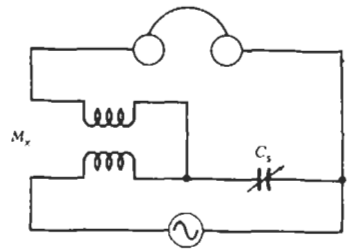

Fig. 15. Mutual-inductance capacitance balance.

Hybrid-Coil Method

At the null (Fig. 16):

$$Z_1 = Z_2$$

The transformer secondaries must be accurately matched and balanced to ground. This is useful at audio and carrier frequencies.

Q of Resonant Circuit by Bandwidth

The method of Fig. 17 may be used to evaluate Q by finding the 3-dB, or half-power, points. The source should be loosely coupled to the circuit. Adjust the frequency to each side of resonance, noting the bandwidth between the points where $V = 0.71 \times (V$ at resonance). Then

$$Q = \text{(resonance frequency)/(bandwidth)}$$

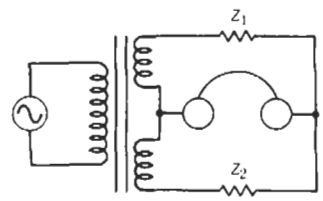

Fig. 16. Hybrid-coil method.

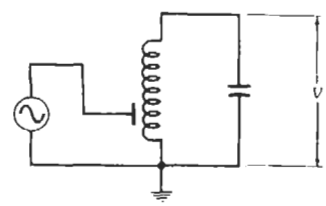

Fig. 17. Measurement of Q by bandwidth.

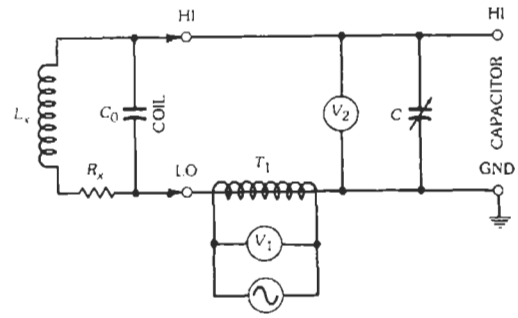

Fig. 18. Q meter.

Q Meter (Hewlett-Packard 4342A)

Refer to Fig. 18. In this circuit, T_1 is a wideband transformer with n turns in the primary and one turn in the secondary. The secondary impedance is 0.001 ohm. The combination $L_xR_xC_0$ represents an unknown coil plugged into the COIL terminals for measurement; V_2 is a very high impedance voltmeter. With this arrangement,

$$Q = nV_2/V_1$$

Correction of Q Reading—The value of Q corrected for distributed capacitance C_0 of the coil is given by

$$Q_{true} = Q[(C + C_0)/C]$$

where,

Q = reading of Q-meter (corrected for internal resistors R_1 and R_2 if necessary),
C = capacitance reading of Q-meter.

Measurement of C_0 and True L_x—The plot of $1/f^2$ against C is a straight line (Fig. 19).

L_x = true inductance

$$= \frac{1/f_2^2 - 1/f_1^2}{4\pi^2(C_2 - C_1)}$$

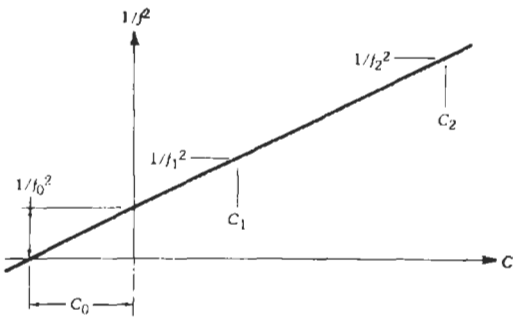

Fig. 19. Plot of C and $1/f^2$.

C_0 = negative intercept

f_0 = natural frequency of coil

When only two readings are taken and $f_1/f_2 = 2.00$

$$C_0 = (C_2 - 4C_1)/3$$

With values in microhenrys, megahertz, and picofarads

$$L_x = 19\,000/f_2^2(C_2 - C_1)$$

Measurement of Admittance—An initial reading, $C'Q'$, is taken as in Fig. 20A (LR_p is any suitable coil). For the final reading, $C''Q''$ (Fig. 20B):

$$1/Z = Y = G + jB = 1/R_p + j\omega C$$

Then

$$C = C' - C''$$

$$1/Q = G/\omega C$$

$$= C'/C(1000/Q'' - 1000/Q') \times 10^{-3}$$

If Z is inductive

$$C'' > C'$$

Measurement of Impedances Lower Than Those Directly Measurable—For the initial reading, $C'Q'$, the CAPACITOR terminals are open (Fig. 21A).

On the second reading, $C''Q''$, a capacitive divider, C_aC_b (Fig. 21B), is connected to the CAPACITOR terminals.

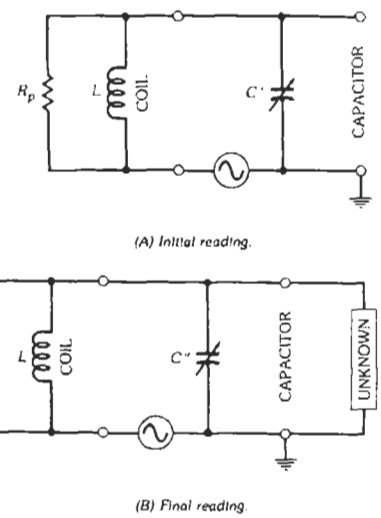

Fig. 20. Measurement of admittance.

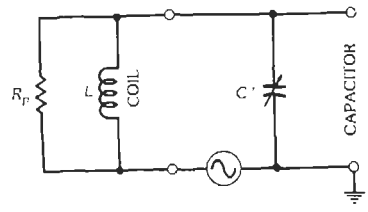
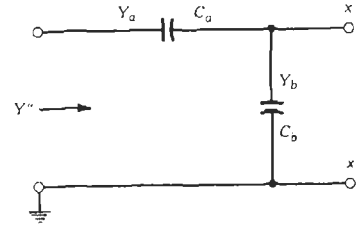
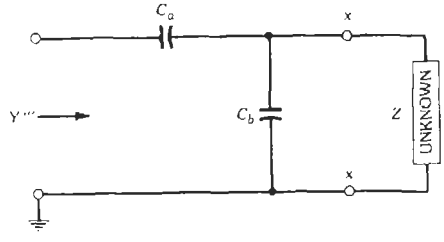


(A) Initial reading.



(B) Capacitive divider.



(C) Connection of unknown.

Fig. 21. Measurement of low impedances.

For the final reading, $C'''Q'''$, the unknown is connected to $x - x$ (Fig. 21C). Admittances Y_a and Y_b are

$$Y_a = G_a + j\omega C_a \qquad Y_b = G_b + j\omega C_b$$

with G_a and G_b not shown in the diagrams.

Then the unknown impedance is

$$Z = [Y_a/(Y_a + Y_b)]^2(Y''' - Y'')^{-1} - (Y_a + Y_b)^{-1} \text{ ohms}$$

where, with capacitance in picofarads and $\omega = 2\pi \times$ frequency in megahertz

$$(Y''' - Y'')^{-1} = \frac{10^6/\omega}{C'(1000/Q''' - 1000/Q'') \times 10^{-3} + j(C'' - C''')}$$

Usually G_a and G_b may be neglected; then there results

$$Z = \left(\frac{1}{1 + C_b/C_a}\right)^2 (Y''' - Y'')^{-1} + j\frac{10^6}{\omega(C_a + C_b)} \text{ ohms}$$

For many measurements, C_a may be 100 picofarads. Capacitance $C_b = 0$ for very low values of Z and for highly reactive values of Z. For unknowns that are principally resistive and of low or medium value, C_b may take sizes up to 300 to 500 picofarads. When $C_b = 0$

$$Z = (Y''' - Y'')^{-1} + j(10^6/\omega C_a) \text{ ohms}$$

and the "second" reading above becomes the "initial," with $C' = C''$ in the equations.

Measurement of Coupling Coefficient of Loosely Coupled Coils—The coefficient of coupling

$$k = M/(L_1L_2)^{1/2}$$

between two high-Q coils can be obtained by measuring the inductance L with S_1 closed and again with S_1 open (Fig. 22). From these two measurements

$$k = (1 - L_{\text{closed}}/L_{\text{open}})^{1/2}$$

When the coil self-inductances are known, a measurement of L_a and L_b (Fig. 23) yields

$$k = (L_a - L_b)/4(L_1L_2)^{1/2}$$

If $L_1 = L_2$

$$k = (L_a - L_b)/(L_a + L_b)$$

Neither of the above methods provides adequate precision when two high-Q coils are only about critically coupled. In that case, the Q of each coil is measured with the other coil open-circuited. Then the coupled coils (L_1R_1 and L_2R_2) and a low-loss adjustable capacitor (C_2) are connected to the Q-meter as shown in Fig. 24, C_2 is disconnected, and C is adjusted to maximize

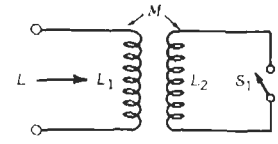


Fig. 22. Method of determining coefficient of coupling between two coils.

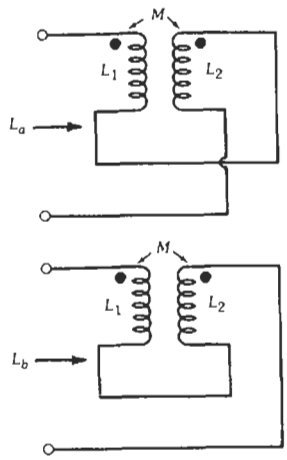

Fig. 23. Method of determining coefficient of coupling when self-inductances are known.

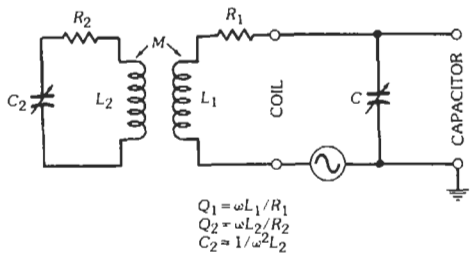

Fig. 24. Method of determining coefficient of coupling when coils are only about critically coupled.

the Q-meter reading; C_2 is then connected and adjusted to minimize the reading. If the final reading is Q_0

$$K = [1/Q_2(1/Q_0 - 1/Q_1)]^{1/2}$$

If the final reading is too small to be read accurately, Q_2 may be reduced by inserting a small resistance in series with L_2R_2.

Twin-T Admittance-Measuring Circuit (General Radio Type 821-A)

The circuit in Fig. 25 may be used for measuring admittances in a range somewhat exceeding 400 kilohertz to 40 megahertz. It is applicable to the special measuring techniques described above for the Q-meter.

Conditions for a null in the output are

$$G + G_l = R\omega^2 C_1 C_2 (1 + C_g/C_3)$$

$$C + C_b = 1/\omega^2 L - C_1 C_2 (1/C_1 + 1/C_2 + 1/C_3)$$

With the unknown disconnected, call the initial balance C_b' and C_g'. With the unknown connected, the final balance is C_b'' and C_g''. Then the components of the unknown, $Y = G + j\omega C$, are

$$C = C_b' - C_b''$$

$$G = (R\omega^2 C_1 C_2/C_3)(C_g'' - C_g')$$

Ratio-Arm Bridges (Wayne Kerr)*

Transformer ratio-arm bridges can be designed to operate at radio frequencies up to about 250 MHz. Beyond that point, other forms of bridges based on transmission lines become practicable.

Fig. 26 illustrates a practical circuit for a bridge

* From Calvert, R. *The Transformer Ratio-Arm Bridge*. Bognor Regis, Sussex, England: Wayne Kerr Co. Ltd.

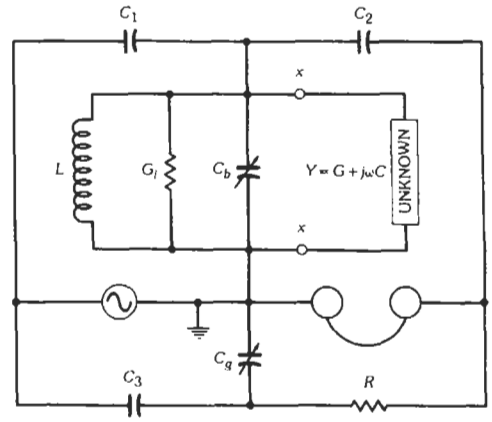

Fig. 25. Twin-T admittance-measuring circuit.

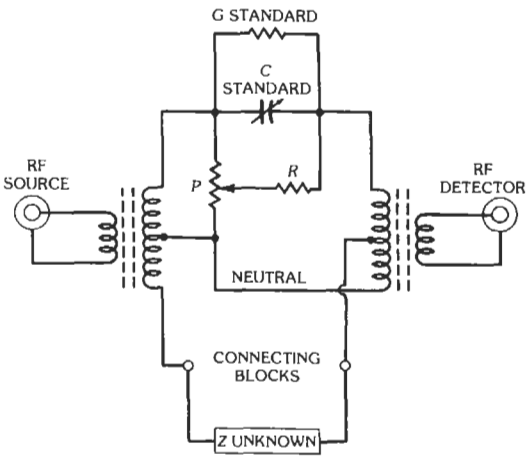

Fig. 26. Ratio-arm bridge.

capable of operating at frequencies up to 100 MHz. The transformers are formed by winding thin silver tapes onto ferrite or ferrous-dust ring cores, which are mounted inside individual screening cans. Drums of low-inductance resistors forming fixed conductance standards are arranged to engage with spring contacts. A variable conductance for interpolation is formed by means of resistor R, which is fed with a voltage derived from a resistive potential divider, P.

Radio-frequency bridge measurements require that considerable care should be taken in setting up the apparatus. Any leakage of power from the source to the detector that bypasses the bridge network will give errors.

Automatic Impedance Meters

The availability of digital voltmeter technology has created a generation of touch-and-read impedance meters. One basic technique is to impress a known current or voltage upon an impedance and measure the magnitude and phase of the voltage or current resulting from it (Fig. 27). In its simplest form, the ratio of the complex voltage to the complex current is the value of the impedance:

$$Z\angle\theta = E\angle\theta_1 / I\angle\theta_2$$

Automation can also be achieved by using feedback to balance a bridge with an unknown impedance and a known standard impedance. The complex voltage required for balance is a measure of the unknown impedance.

At frequencies above 10 MHz, it is convenient to compare an impedance to a precise 50-ohm coaxial transmission line and measure the reflection coefficient. The impedance is calculated using microprocessor techniques.

An example of each technique is shown below.

Four-Terminal-Pair Bridge, 5 Hz–13 MHz—Refer to Fig. 28. A four-terminal-pair configuration is used to avoid errors caused by mutual coupling between leads. The bridge provides a complex voltage, V_x, across the device under test (DUT) and another complex voltage V_r proportional to the current through the DUT at bridge balance. The bridge is balanced by a heterodyne method through the frequency range of 5 Hz to 13 MHz.*

A vector ratio detector is used to measure V_x/V_r. Since

$$V_x/Z_x = i_x = i_r = -V_r/R_r$$

therefore,

$$Z_x = -R_r(V_x/V_r)$$

Automatic LCR Meters, 1 MHz—Refer to Fig. 29. A reference voltage, e_r, is applied to the unknown, and the feedback voltage, e_v, feeds the standard resistor for C-G measurements. The voltages are reversed for L-R measurements. If the bridge is not balanced, an unbalanced current, i_d, flows into the current detector, which produces an error voltage, e_d. This voltage is amplified, phase-detected, and rectified to produce dc voltages E_1 proportional to the real part of e_d and E_2 proportional to the imaginary part of e_d.†

Voltages E_1 and E_2 are integrated and used to modulate reference voltage e_r and je_r, thus creating e_1 and e_2, which correspond to the real and imaginary parts of voltage e_d. At balance, the vector sum e_v reduces i_d to zero.

At balance

$$G_x + j\omega C_x = -e_v/e_r R_s$$

or

$$R_x + j\omega L_x = -(e_v/e_r)R_s$$

A digital voltmeter is used to measure the vector ratio of e_v and e_r.

Vector Impedance Analyzer, to 1000 MHz—Refer to Fig. 30. Outputs from a directional RF bridge channel and a compensated reference channel go to a receiver for synchronous detection and processing by a dual-slope integrator, thus providing a vector ratio that is a measure of the reflection coefficient, Γ. With a microprocessor, the impedance, admittance, inductance, capacitance, or Q of the device under test can be calculated.

The key component of the RF bridge is the balun transformer. It is wound with fine semirigid coaxial cable on a ferrite core. The construction must maintain

Capacitance

$$C = B/2\pi f$$

Quality factor

$$Q = |X|/R$$

NETWORK ANALYSIS

A network analyzer consists of the five basic blocks shown in Fig. 31. At low frequencies, voltage and current can be measured by probes to determine the Z, Y, or h parameters (Fig. 32). Typically, a network analyzer is used to characterize small signal parameters. For higher frequencies (up through microwave frequencies), network analyzers primarily characterize the magnitude and phase of reflection coefficients, transmission coefficients, and S parameters of networks (Fig. 33). (See Chapter 31 for a definition of S parameters.)

At microwave frequencies, it is difficult to build perfect structures that have no frequency-response, directivity, or port-match errors. It is widely accepted practice to reduce these errors with a mathematical error-correction procedure implemented with a computer.

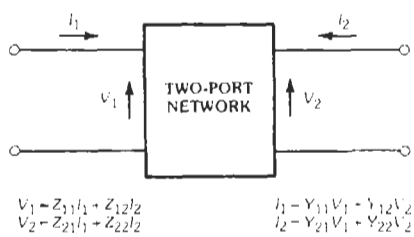

Fig. 32. Z and Y parameters typically used at low frequency.

* Ichino, T., et al. "Vector Impedance Analysis at 1000 MHz." *H-P Journal*, Jan. 1980.

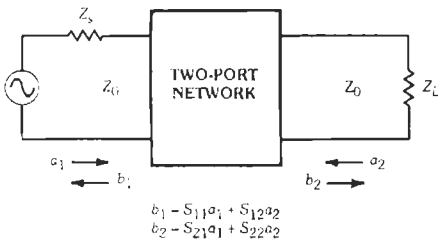

Fig. 33. Parameters used at higher frequencies.

Sources

The most common source used for network analysis is a sweep oscillator. This provides a real-time frequency response of the network characteristics. When greater frequency accuracy is required, synthesizers are used. However, the switching times can be long (10 ms to 50 ms). These synthesizers provide the best phase accuracy and repeatability, but at the expense of fast real-time measurements.

Receivers

There are three common receiver techniques, the diode detector, homodyne or self-mixing, and the heterodyne approach (both fundamental and harmonic), usually with multiple inputs.

Test Sets

The test-set portion provides connection of the source and receiver to the network under test. At low frequencies, voltage and current probes are sufficient, but at microwave frequencies, couplers, directional bridges, power splitters, and slotted lines are required.

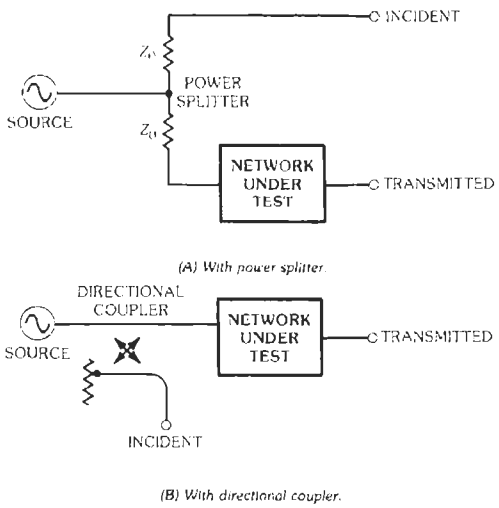

Fig. 34. Transmission measurements.

Test configurations are shown as follows: for transmission measurements, Fig. 34; for reflection measurements, Fig. 35; for S parameters, Fig. 36; and for transmission and reflection measurements, Fig. 37.

Displays and Output

The most useful display is the digital storage CRT system (Fig. 38). Data can be written into the digital display at any speed from real time to very slow (digital sweep for example) and then read out at a flicker-free rate. The display can also store traces, and trace math can be calculated to remove frequency-response errors, etc. Almost all commercial network analyzers have a digital I/O port to an external controller to provide for data transfer and operational commands.

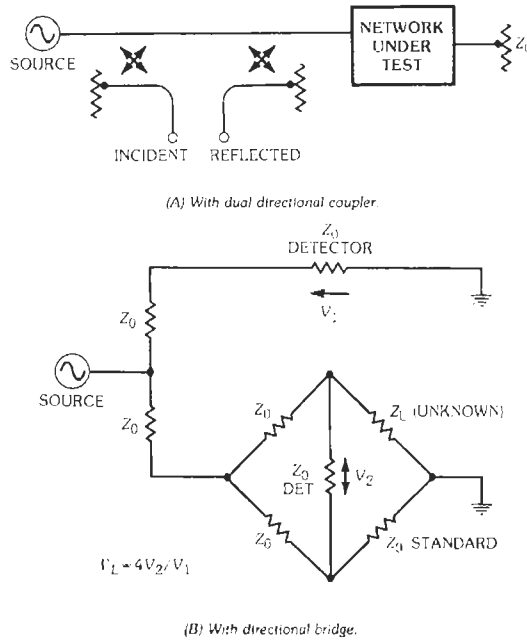

Fig. 35. Reflection measurements.

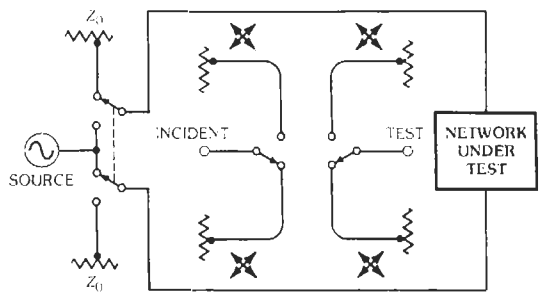

Fig. 36. Measurement of S parameters, using directional couplers with switching.

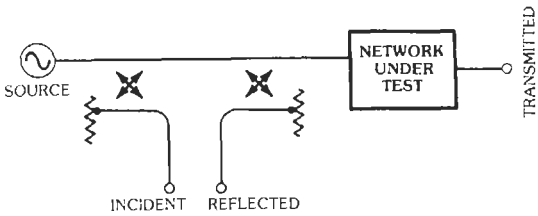

Fig. 37. Transmission and reflection measurements.

Six-Port Network

A six-port structure can be used to make magnitude and phase measurements using magnitude-only detectors such as the diode, thermistor, or bolometer. The general solution is shown below (refer to Fig. 39).

$$\rho_i = |b_i|^2 = |A_i a + B_i b|^2 \qquad i = 3 \text{ to } 6$$

where A_i and B_i are functions of the S parameters of the six-port network, which can be determined by calibration. Rearranging yields

$$\rho_i = |B_i|^2\ |b|^2 |(A_i/B_i)\Gamma + 1|^2 \qquad i = 3 \text{ to } 6$$

The above four equations can be solved for Γ, the reflection coefficient of the device under test:

$$\Gamma = \frac{\Sigma C_i \rho_i + j\Sigma S_i \rho_i}{\Sigma \beta_i \rho_i} \qquad i = 3 \text{ to } 6$$

where C_i, S_i, and β_i are functions of A_i and B_i. Note that Γ consists of a sum of noncomplex terms.

A dual six-port structure can be used to measure the S parameters of a two-port network provided that the restriction $S_{12} = S_{21}$ is applied (Fig. 40). The mathematical approach of calibrating and measuring with the six-port structure is divided into two steps. Step one is the calibration of the six-port structure to determine phase from the magnitude-only measurements. Step two is the same as the error-correction procedure for the four-port network analyzers. There has been some excellent work done on six-port networks by Glen Engen and Cletus Hoer of the National Bureau of Standards.

The approach can be realized in all frequency bands from audio to greater than 100 GHz. Great stability of the measurement system is required to achieve accurate results. There are also limitations in measuring active devices where power setting flexibility is needed and when S_{21} does not equal S_{12}. Typically, data gathering time is slow but accuracy is very good.

Error Correction

There are error-correction procedures by which the linear time invariant errors of the network analyzer can be characterized and then, by an inverse mathematical procedure, be removed from the measured data. See references 1 through 9 (listed at the end of this chapter) for descriptions of these error-correction procedures.

Frequency and Time-Domain Relationships

With the advent of the modern computer, measuring data in the frequency domain and then converting to the time domain by means of the inverse-Fourier transform has become practical. This ability to observe measurements in the time domain adds additional insight to microwave measurements. Many times in microwave measurements, circuit discontinuities are separated by lengths of transmission lines. Taking the Fourier transform of such a circuit allows us to isolate the various impulse responses to the circuit discontinuities (see Fig. 41C).

Also, by mathematically generating a step stimulus, a traditional time-domain reflectometer (TDR) display with high resolution and stability is achieved (see Fig.

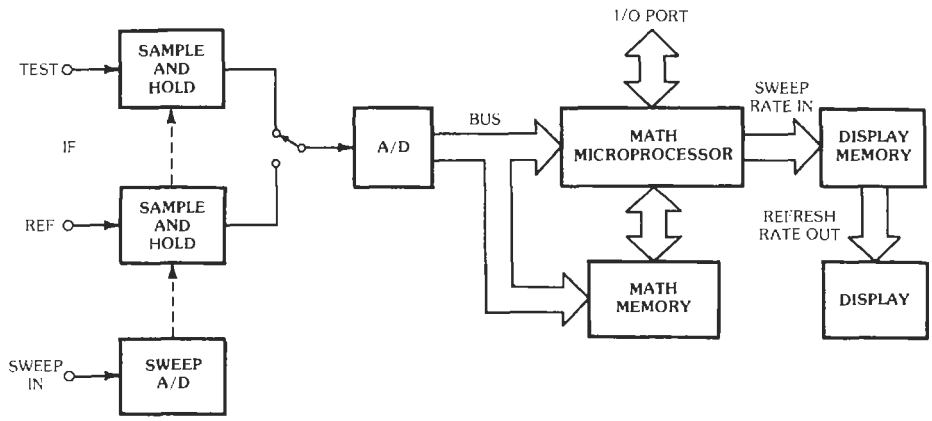

Fig. 38. Digital storage CRT system.

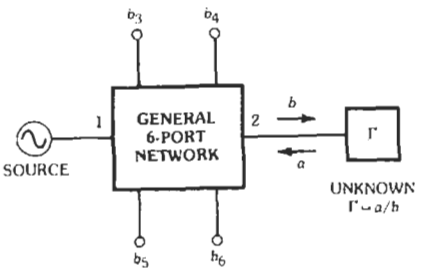

Fig. 39. Measurements with six-port system.

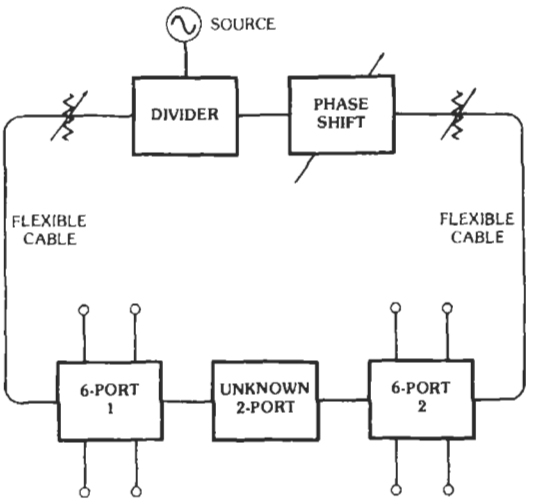

Fig. 40. A dual six-port structure used to measure a two-port network.

41D). With the time data isolated, it is possible to filter out unwanted time-domain responses and then transform back to the frequency domain. By means of this technique, connector discontinuities, launches, and other unwanted responses can be filtered (or deconvolved) from the original data (Fig. 42). This technique can greatly enhance measurement accuracy.

Large-Signal Measurements

Devices and amplifiers are often characterized in other than class-A linear operation. A technique called load-pull is one way to observe the effect of changing device parameters as a function of load impedance and delivered power. The load-pull measurement system is shown in Fig. 43. The output tuner realizes most positive real load conditions. The power delivered to the device and load can be measured by power meters connected to the coupler side arms. The impedance of the load can be measured with a network analyzer. Fig. 44 shows contours of constant delivered power as a function of load impedance. These plots can be generated for the fundamental or the harmonics to give good insight into the nonlinear behavior. With these data,

matching networks can be designed that will optimize the delivered power under nonlinear operating conditions.

SIGNAL ANALYSIS

Analysis of signals in the frequency domain is an important technique to determine the characteristics of audio, RF, and microwave signals. While the oscilloscope is the basic tool for time-domain analysis, the spectrum analyzer provides a display of signal amplitude as a function of frequency and is the basic tool for frequency-domain analysis. The relationship between the time and frequency domains is illustrated in Fig. 45 for the case of two sine waves. Signal amplitude vs time and frequency is shown in the three-dimensional representation of Fig. 45A. In the time-domain representation of Fig. 45B, the two signal components add at each instant of time, producing the composite as would be viewed on an oscilloscope. Fig. 45C is the frequency-domain view. Each frequency is represented by a vertical line, with the height representing the amplitude and the horizontal position representing the frequency. Although the information about the signal is the same in either domain, the frequency domain provides a tool to observe small but important signal characteristics such as a small amount of harmonic distortion.

Conceptually, a spectrum analyzer could consist of a parallel bank of rectangular bandpass filters each followed by an envelope detector as in Fig. 46. The filters cover adjacent frequency bands and do not overlap. The detector outputs are sequentially scanned to provide an amplitude-vs-frequency display on a cathode-ray tube. The resolution of the spectrum analyzer, that is, its

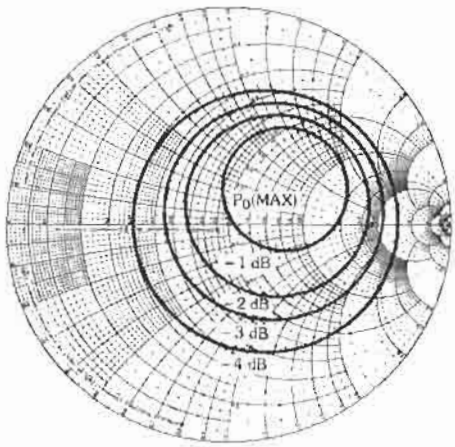

Fig. 44. Contours of constant delivered power vs load impedance under large-signal conditions.

ability to resolve closely spaced spectral lines, is determined by the width of the filter bandpass. Obviously, a very large number of filters would be required to obtain wide frequency spans with narrow resolution. Practical filters would have long time constants, thereby requiring a long time for their outputs to reach a steady-state value.

Another type of spectrum analyzer uses digital signal-processing techniques. Called a Fourier analyzer or dynamic signal analyzer, it is shown in Fig. 47. The input waveform is sampled, and each sample is digitized. The fast Fourier transform (FFT) is used to compute the spectrum from the sampled data. This type of analyzer solves the complexity and response-time problems of the parallel filter analyzer; however, ADC and computation speeds limit the input frequency to about 10 MHz.

The most common form of spectrum analyzer for RF and microwave frequencies is the swept superheterodyne receiver shown in simplified form in Fig. 48. A sweep ramp provides the tuning voltage for a voltage-tuned oscillator and is simultaneously applied to the horizontal-deflection system of a cathode-ray-tube display. The local-oscillator frequency is mixed with the input signal to produce an intermediate frequency (IF). The IF is detected, filtered, and applied to the vertical-deflection plates of the CRT. To achieve broad frequency coverage with a single local oscillator, harmonic mixing is often used so that

$$f_s = nf_{LO} \pm f_{IF}$$

where,

f_s = signal frequency,
f_{LO} = local-oscillator frequency,
f_{IF} = intermediate frequency,
n = 1, 2, 3, ...

A tracking preselector filter at the input selects the desired response.

Amplitude Measurement Range

The range of amplitudes that may be measured on a spectrum analyzer depends on several factors and is diagrammed in Fig. 49. The minimum signal level is limited by the displayed noise that is a function of the noise figure and the IF bandwidth:

$$N = kT_0B$$

where,

N = displayed noise level, in watts,
T_0 = absolute temperature, in kelvins,
k = Boltzmann's constant,
F = spectrum-analyzer noise figure,
B = IF bandwidth.

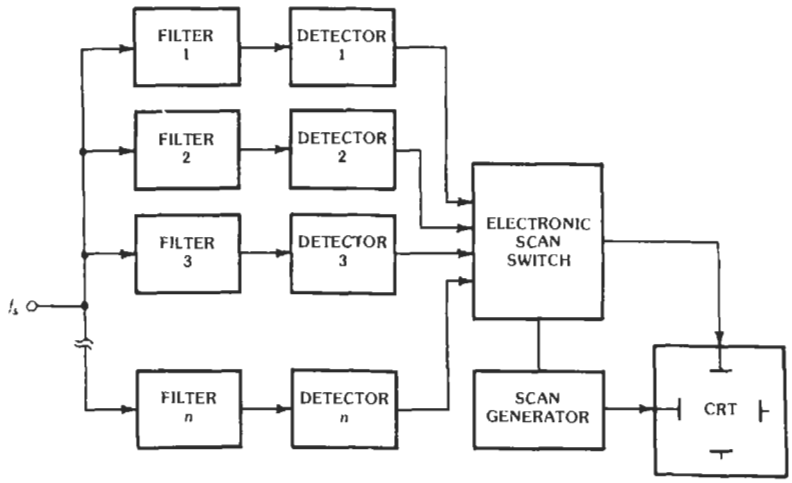

Fig. 46. A multiple-filter spectrum analyzer. (*From Hewlett-Packard Application Note No. 150 on Spectrum Analysis.* © *Hewlett-Packard. used with permission.*)

For example, a noise factor of 100 (20 dB) and an IF bandwidth of 10 kHz give a displayed noise level of 41 $\times 10^{-15}$ watt (−114 dBm).

The maximum signal level is the damage level of the input circuitry, which is typically +13 dBm for an input mixer and +30 dBm for an attenuator. Below that level, the input mixer compresses the input signal, causing an amplitude inaccuracy. The maximum signal at the input mixer for less than 1 dB of gain compression is typically 0 dBm (1 milliwatt).

Distortion products produced within the spectrum analyzer pose yet another constraint on maximum signal amplitude. For a specified spurious level, the signal level to the mixer must not exceed a given level. The dynamic range is the ratio of the largest to the smallest signal amplitudes that can be displayed simultaneously with no internally generated spurious products being present. Dynamic range depends on the display range, the distortion characteristics, and the noise level.

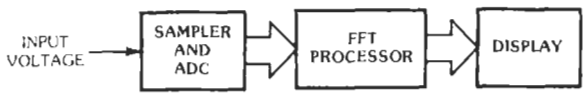

Fig. 47. Block diagram of a Fourier analyzer.

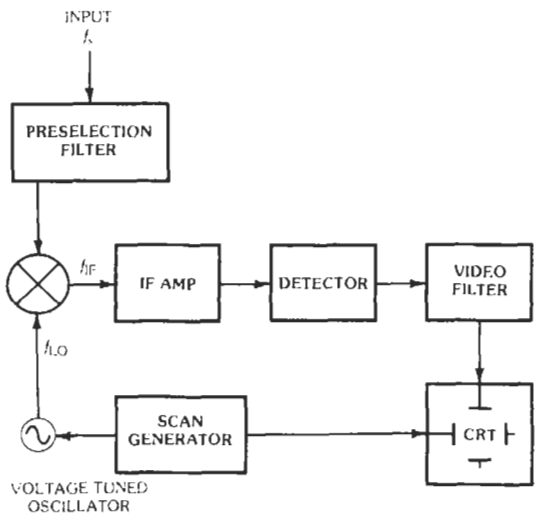

Fig. 48. Swept superheterodyne spectrum analyzer.

Signal-Analysis Characteristics as Determined by the IF Filter, Detector, and Video Amplifier

The input mixer and local oscillator translate the input frequency to a convenient intermediate frequency. Typically, several conversions are used to reduce spurious responses. The final IF filter, detector, video amplifier, and display-processing circuitry largely determine the signal-analysis characteristics of a spectrum analyzer.

The IF-filter bandwidth and shape determine the frequency resolution of the analyzer, assuming the local oscillators are sufficiently stable. Displayed CW signals have the shape of the IF filter, as shown in Fig. 50. To resolve two equal-amplitude signals, the IF 3-dB bandwidth should be less than the signal separation. Resolving unequal-amplitude signals requires narrower bandwidths or rectangularly shaped filters. Filters approximating a rectangular shape, however, have poor pulse response and limit the scan time. Filters approximating a Gaussian shape allow the shortest scan times without introducing amplitude errors due to overshoot

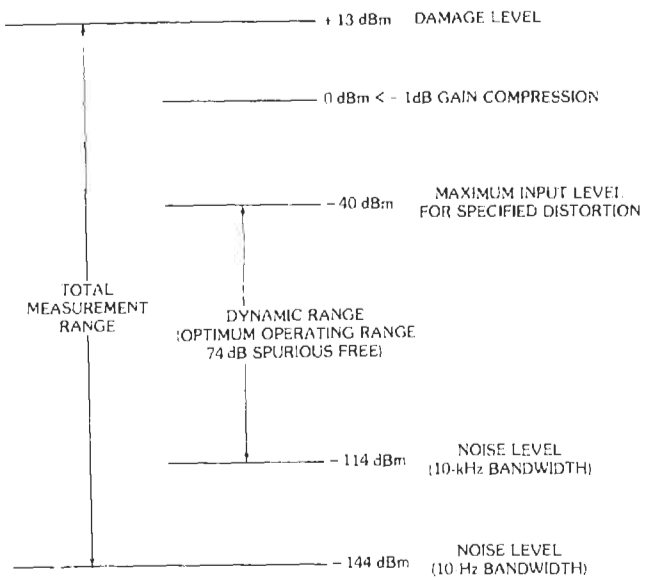

Fig. 49. Typical spectrum-analyzer input signal range.

or ringing. The fastest scan rate for Gaussian-shaped filters is approximately given by:

$$R = BW^2$$

where,

R = maximum scan rate in Hz/s,
BW = 3-dB IF filter bandwidth.

The detector following the IF amplifier is an envelope detector that provides a video signal proportional to the input RF or microwave signal. The bandwidth of the detector should exceed the widest resolution bandwidth to preserve the fidelity of signal modulation. However, post-detection low-pass filtering is often useful to provide signal integration—for example, to recover low-level signals in the presence of random noise.

While analog spectrum analyzers apply the video signal directly to the vertical-deflection system of the display, newer instrumentation using digital displays first performs an A/D conversion. Having the video data in digital form allows further opportunities for signal processing. Trace-to-trace maximums or minimums can be stored and displayed. For instance, the occupied spectrum of the FM signal shown in Fig. 51 is easily determined from the "max hold" trace.

Trace-to-trace signal averaging is possible without the sweep-time limitation associated with video filtering. Fig. 52 shows the result of digital averaging on a noise-modulated signal. The signal power distribution and average frequency are much more apparent.

Digital storage of multiple traces allows arithmetic operations among traces. Fig. 53 shows how trace arithmetic is used to correct for amplitude errors in a measurement system. Trace B may contain measurement-system correction factors, antenna factors, etc.

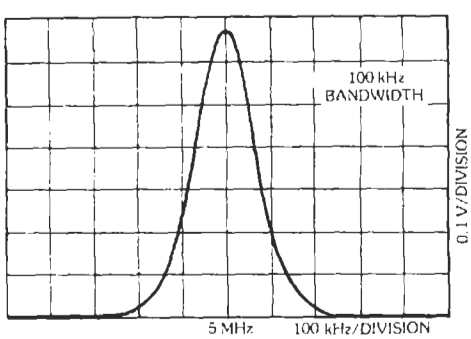

Fig. 50. Displayed CW signal has shape corresponding to IF filter bandpass.

TIME AND FREQUENCY MEASUREMENT

The measurements of time and frequency were among the first to be made in a digital form. The world standard definition of 1 second is the length of time it takes for a cesium 131 atom to "vibrate" 9 192 631 770 times, itself a digital representation. Most simply, frequency can be measured by counting the number of phase cycles taking place within a second, again a digital representation. Frequency may be measured over any interval of time, however, and not just over 1 second.

A class of instruments called counters can be used to measure time, frequency, phase, the number of events, or several other parameters. They offer a precise measurement in a relatively short measurement time, afford-

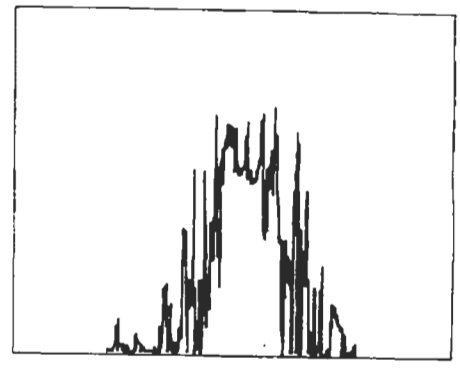
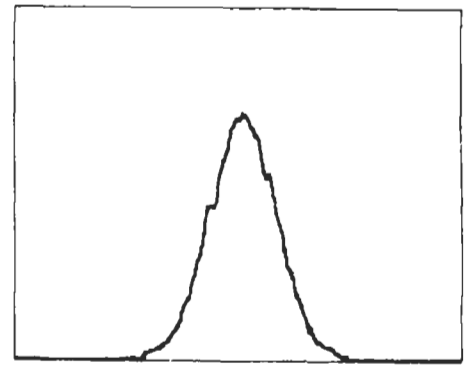
Fig. 51. Occupied spectrum of an FM signal.



(A) Normal trace.



(B) 100 digitally averaged traces.

Fig. 52. Noise-modulated FM signal.

ing good measurement throughput. Most of these measurements are accomplished by first converting the signal to be measured into a pulse train. This is done by sending the signal through a buffer amplifier and then a comparator. Once this is done, the pulse train can be counted with digital logic. The method of counting depends on the desired measurement. Also found in all counters is a time base. This is usually a signal, derived from a calibrated 10-MHz quartz crystal, which can also be counted.

Time Measurement

To measure time, the counter simply counts the number of 10-MHz time-base cycles that take place during the time to be measured. The quantization of time is the inverse of 10 MHz, or 100 ns. The start and stop signals come from the user's input signal. The length of a period can be measured by gating the time-base counter open at the start of the period and closing the gate at the end of the period. (This is shown in the shaded portion of Fig. 54.)

A time interval measurement is the time between two separate signals. The gate is opened upon receiving a signal from one input channel, and it is closed upon receiving a signal from a second input channel. The basic measurement architecture is the same as for a period measurement, except that there are now two inputs, each with its own comparator, feeding into the gating logic. Slope switches for both input channels permit use of the rising or falling edge of a signal to open or close the gate. Pulse width, rise and fall times, and relative phase also can be measured.

Resolution extension can be done in several ways. One way is to use a higher frequency time base. A 500-MHz time base gives 2-ns resolution. If the signal is repetitive, a second resolution extension method is to average. Time interval averaging is accomplished by accumulating several measurements and taking their average. Resolution is extended by the square root of the number of measurements averaged. A third method is called interpolation. This uses interpolation circuitry to measure the time between the edge of the signal pulse and the next time-base pulse edge at both the opening and closing of the gate. Extensions of 10 to 1000 times the resolution are found. By employing combinations of these techniques, the resolution can be extended to better than 1 ps.

Frequency Measurement

Simple counters measure frequency by counting input pulses during a decade value of time, such as 0.1, 1, or 10 seconds. This makes the process of dividing

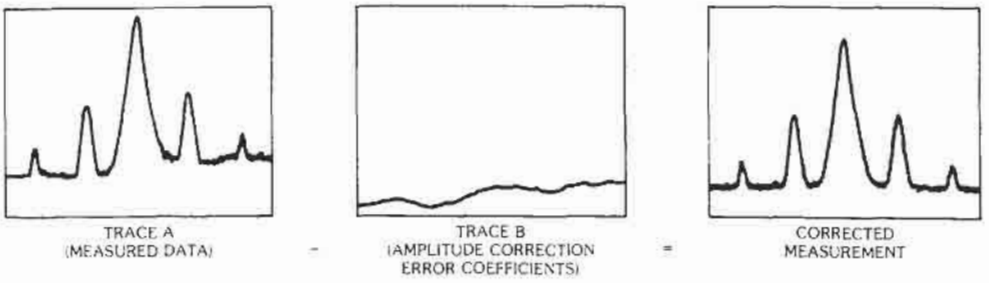


Fig. 53. Error correction by arithmetic operations on multiple traces.

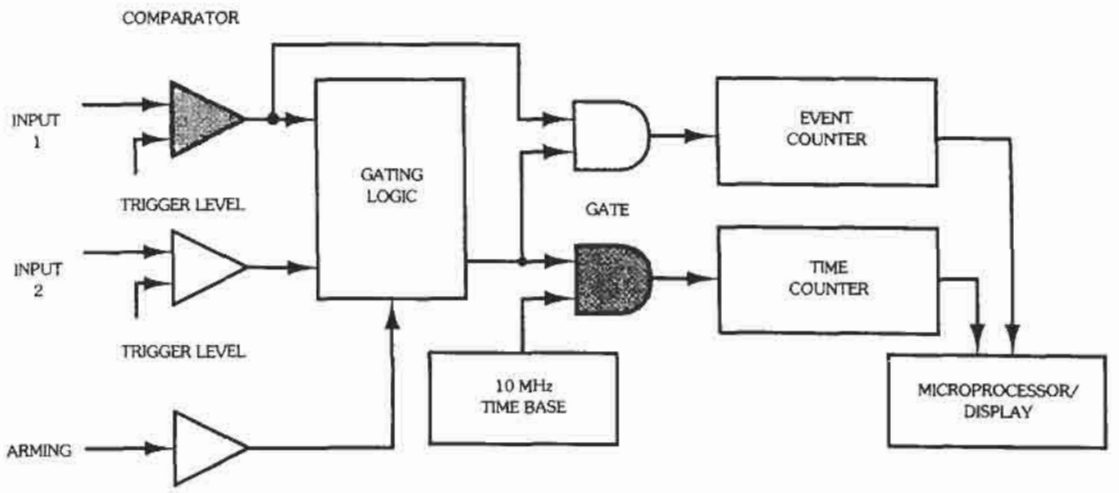

Fig. 54. Basic reciprocal counter. To make a simple period measurement, the shaded portion is used.

event pulses by time a trivial matter, and one not needing a microprocessor. Modern counters use a microprocessor to perform the division, so the gate can be open over any arbitrary time. To make the measurement, the input signal pulses are counted with one circuit while the length of time the gate was open is measured with another circuit. Additionally, an arming signal can be used to control the timing of the measurement if a particular portion of the signal is being measured. The arrangement described is called a reciprocal counter (Fig. 54).

The resolution of the frequency measurement in a reciprocal counter is determined by the resolution of a time measurement. If a counter can resolve time to 1 ns, 9 digits of frequency resolution can be displayed given a 1-second measuring time. This same counter will provide 3 digits given a 1-μs measuring time. A more recent resolution extension technique employs continuous count signal processing. A truer average of the frequency can be calculated if the signal is sampled multiple times during the measurement period; up to 12 digits of resolution in a 1-second measurement time can be obtained with 1-ns time resolution.

Microwave frequencies can be measured with the same counter architectures, but usually some form of frequency conversion needs to be used, because the counter logic typically is limited to operation below 500 MHz. One approach is to use a prescaler. This is simply a very fast counter placed between the comparator and the gating logic. A 3-GHz divide-by-32 prescaler (a five-bit counter) brings the count rate down to a maximum of below 100 MHz, and the microprocessor multiplies the count by 32 for proper display.

A sampler can also be used to mix down the signal to a more countable rate. This is a harmonic heterodyne down-conversion technique. A relatively low-frequency local-oscillator signal is sent through a step recovery diode to generate microwave-frequency harmonics for the sampler to use. The microwave input signal is mixed down, and the resulting intermediate frequency is counted. The microprocessor is used to dither the local-oscillator frequency to determine which harmonic came into play so that it can add the proper frequency offset for display. This technique can be used for microwave and millimeter-wave frequencies. It has the advantage of added frequency resolution because the

phase is preserved, but the act of finding the proper harmonic number slows the measurement. Also, confusion can be introduced if multiple signals are present, so sometimes a tuned YIG filter is used to preselect the signal. For pulsed microwave signals, a detector is added to form a signal that the counter uses to open and close the gate properly.

Frequency and Time-Interval Analysis

A new class of instruments allows further analysis of time and frequency. These instruments share similarities with the counter, but have several significant differences. First, the instrument does not have a gate, so the counter circuits are constantly counting the input and time-base signals. The contents of the counters are read synchronously and stored into memory. From two sets of these readings, a frequency measurement can be effectively constructed. This architecture is called *continuous count* (Fig. 55).

The first advantage of continuous-count architecture is that a frequency measurement can now be constructed from several *contiguous* samples, and by using a least-squares fit or other algorithm, a truer estimate of frequency can be made.

The second advantage is the ability to store these samples into a deep memory. This allows for the analysis of time-varying signals, such as the measurement of the step response of a voltage-controlled oscillator (Fig. 56A). If the signal is being frequency or phase modulated (either to carry data or to make the signal spread-spectrum), the modulation pattern can be displayed in a frequency-vs-time or phase-vs-time manner (Figs. 56B and 56C). If required, the modulation can be displayed in an eye diagram form. The maximum

Fig. 56. Continuous-count measurements.

modulation rate that can be analyzed is governed by the sample rate of the counter, or how often the counters are read into memory. Note that phase-modulation measurement is possible only because the signal is sampled continuously.

The measurements can also be stored and analyzed in histogram form (Figs. 56D and 56E). This can be useful for analyzing a frequency-agile signal. Note that these measurements cannot be easily done with a spectrum analyzer.

If the parameter being measured is time or time interval, the histogram can show information on data-to-data or clock-to-data jitter. The information in the memory can also be passed through an FFT to show jitter spectrum (Fig. 56F). These measurements are useful in the design of high-speed computers, telecommunications systems, and magnetic storage systems.

RF AND MICROWAVE POWER MEASUREMENTS

A common technique for measuring power at high frequencies is to employ a sensing element that converts the RF power to a measurable dc or low-frequency signal. The sensing element is often designed to form a termination that is matched to the characteristic impedance (Z_0) of the input transmission line. Various types of sensing elements are used.

Thermistor Sensors

Thermistor sensors provide a change of resistance. The typical power range is 1 μW to 10 mW; the maximum frequency is greater than 100 GHz. Fig. 57A shows a typical power sensor employing thermistors. The thermistors form the termination for the RF input, and dc or audio power from the self-balancing bridge in Fig. 57B raises the temperature of the thermistors until they each have a resistance of $2Z_0$. The RF impedance then becomes equal to Z_0.

Since the bridge keeps the thermistor resistance constant, any heat added by the RF power causes a corresponding reduction in bias power. The RF power level is determined by measuring this change in bias power.

Thermal Converters

Thermal converters provide a dc voltage (less than 10 mV). The typical power range is 0.1 to 100 mW; the maximum frequency is less than 1 GHz. Thermal converters employ a number of thermocouples (thermopile) mounted with good thermal contact to the RF termination (Fig. 58). The RF power heats the termination, and the thermopile output voltage is proportional to the amount of power dissipated. The converter can be calibrated by applying a precisely known dc or RF power level at the input. This calibration yields the value of C.

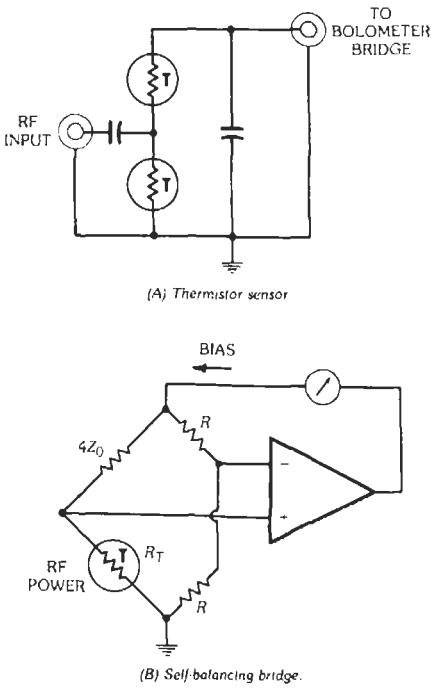

Fig. 57. Power measurement with thermistor sensor.

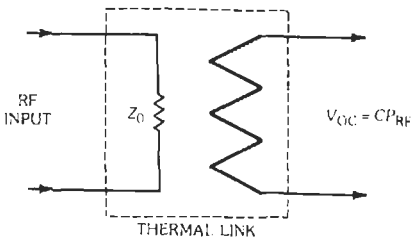

Fig. 58. Thermal converter.

Thermocouple Sensors

Thermocouple sensors provide a dc voltage (less than 10 mV). The typical power range is 0.1 μW to 100 mW; the maximum frequency is greater than 100 GHz. Thermoelectric sensors differ from thermal converters in that the thermocouples are used as the terminating resistors (Fig. 59). This type of sensor must be calibrated with a precise RF power level to determine the value of C.

Diode Sensors

Diode sensors provide a dc voltage (approximately 1 V at 10 mW). The typical power range is 0.1 nW to 10 mW; the maximum frequency is greater than 18 GHz.

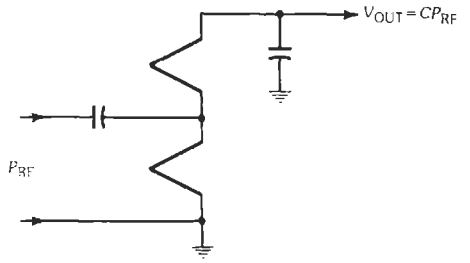

Fig. 59. Thermocouple sensor.

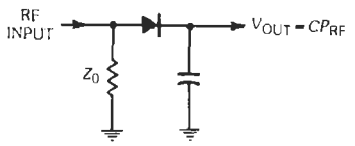

Fig. 60. Diode power sensor.

Diode power sensors (Fig. 60) use point-contact or Schottky barrier diodes to detect the RF signal. If the RF voltage is less than 20 mV, the diode output follows the square of the applied voltage, so the dc voltage is a function of RF power. At higher levels, the rectified output gradually changes to the more familiar peak-detection mode, and harmonics in the signal can cause errors in the power reading. Diode sensors must be calibrated with a precise RF signal level to determine the value of C.

Power-Measurement Definitions

Maximum Available Power, P_{avs}—The power obtainable from a source when it is terminated in a load whose impedance is the complex conjugate of the source impedance. This condition is usually obtained by installing a tuning device between the source and the power sensor and adjusting the tuner for a peak in the power reading.

Z_0 Available Power, P_{z0}—The power obtainable from a source when it is terminated with a load matched to the Z_0 of the transmission line. The Z_0 available power is related to the maximum available power by:

$$P_{z0} = P_{avs}(1 - \rho_g^2)$$

where $\rho_g = |\Gamma_g|$

Power Incident Upon the Load, P_i—The amount of power the source transmits toward the load is usually measured by use of a directional coupler connected such that its coupled output is governed by the wave emerging from the source. The incident power is related to the Z_0 available power by:

$$P_i = P_{z0}/|1 - \Gamma_g\Gamma_L|^2$$

Power Reflected by the Load, P_r—This power is usually measured by using a directional coupler connected such that its coupled output is governed by the amount of power reflected by the load. The reflected power is related to the incident power by:

$$P_r = \rho_L^2 P_i$$

Power Dissipated in a Load, P_L—The power dissipated in the load is related to the other power levels by:

$$P_L = P_i - P_r = P_i(1 - \rho_L^2)$$

$$= P_{avs}\frac{(1 - \rho_g^2)(1 - \rho_L^2)}{|1 - \Gamma_g\Gamma_L|^2}$$

Source and Load Reflection Coefficients, Γ_g and Γ_L—Some of the foregoing equations refer to the match of the source and load impedance to the characteristic impedance of the transmission line. Values of reflection coefficients Γ_g and Γ_L are given by:

$$\Gamma_g = (Z_g - Z_0)/(Z_g + Z_0)$$

$$\Gamma_L = (Z_L - Z_0)/(Z_L + Z_0)$$

$$\rho_g = |\Gamma_g|$$

$$\rho_L = |\Gamma_L|$$

Effective Efficiency, η—Efficiency of a power sensor is defined as

$$\eta = P_{sub}/P_0$$

where,

P_{sub} is the dc substituted or RF calibration power.
P_0 is the amount of power dissipated in the sensor.

Calibration Factor, K_B—Calibration factor is related to efficiency by:

$$K_B = P_{sub}/P_i = \eta(1 - \rho^2)$$

where ρ is the magnitude of the reflection coefficient of the sensor.

Multiple Mismatch Error, M_u—The precise amount of power dissipated in the sensor is a function of many variables, the largest one being the interaction of the source and load reflections. Fig. 61 can be used to estimate the worst-case uncertainty for a simple source-to-load power measurement. In the example shown, an

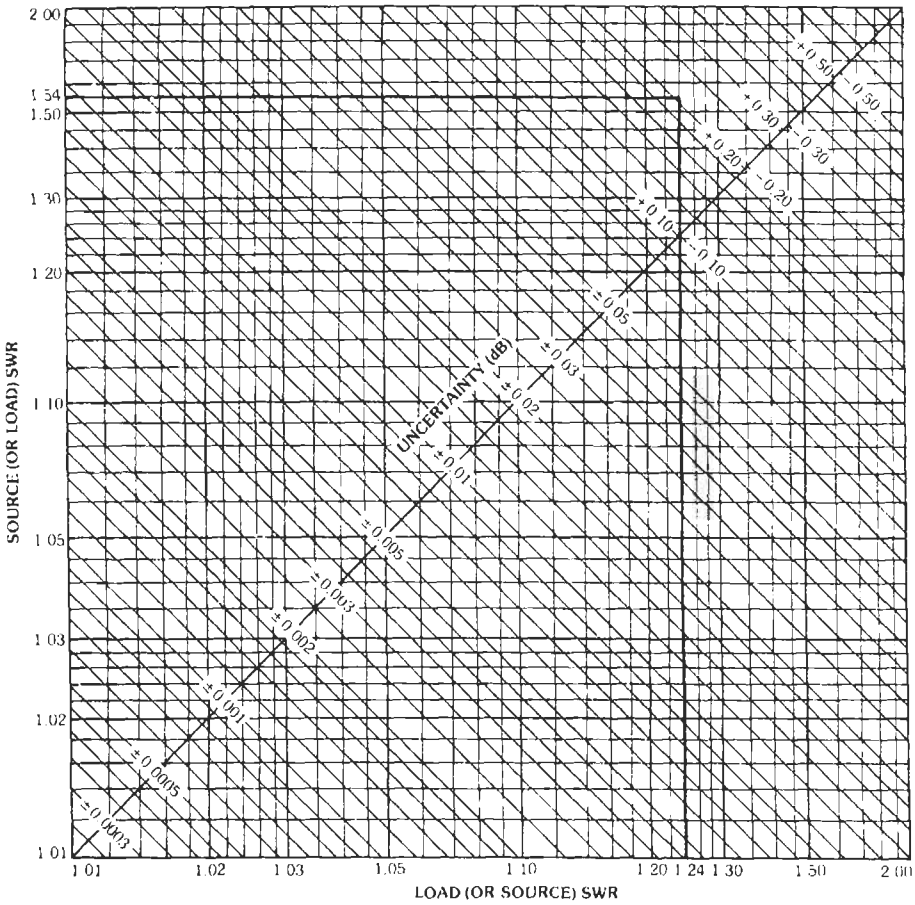

Fig. 61. Mismatch uncertainty limits.

SWR of 1.54 interacting with an SWR of 1.24 introduces about a 0.2-dB uncertainty.

$$M_u = (1 \pm \rho_g \rho_L)^{-2}$$

MICROWAVE-LINK ANALYSIS

Insertion Loss or Gain

Insertion loss or gain is defined as the loss or gain that is apparent upon inserting the network to be measured between a given source and a given receiver. In Fig. 62, P_s is the transmitted power of the source, and P_R is the received power. In Fig. 62A, it is clear that $P_R = P_s$, but in Fig. 62B, the value of P_R is modified by the insertion of the network. This change in power is the insertion loss or gain and is usually quoted in decibels:

$$\text{Insertion Loss or Gain} = 10 \log_{10}(P_R/P_s)$$

Amplitude Response

Amplitude response is sometimes referred to as "flatness" or frequency response and is the variation in gain or loss with change in frequency over a defined frequency band. While it may be thought that this

parameter is not important for frequency-modulated radio links, it generally must be well controlled, especially for high-capacity systems. Amplitude response is also very important for the RF and IF sections of digital radio links.

In order to measure amplitude response accurately, it is important that harmonics of the transmitted signal not be included in the measurement of received power. Thus the ideal measurement technique would be one using a tunable receiver. In practice, however, the measurement of radio links using intermediate frequencies of 70 MHz or 140 MHz requires a swept frequency range that allows a simple low-pass filter to remove harmonics. Additionally, errors due to the use of a broadband detector are generally low. This, then, allows a simple measurement principle to be used that lends itself to remote or "straightaway" measurements (Fig. 63).

Measurement receivers usually incorporate a frequency-tracking loop that reduces the effective sweep range in the analyzer where the benefits arising from a reduced sweep may be used for group-delay and/or linearity measurements. The frequency-tracking loop, however, also gives a recovered sweep signal that is used to drive the *X* deflection of the display and makes the "straightaway" measurement possible (Fig. 64).

The swept range of the input signal is reduced by the loop gain of the arrangement shown in Fig. 64, where the derived low-frequency signal used to drive the VCO is a facsimile of the frequency variation against time characteristic of the source signal.

These techniques are quite satisfactory when used to measure amplitude response of IF or RF sections of radio links. They are, however, generally inadequate for the measurement of baseband amplitude response, where a selective receiver should be used. This implies that the receiver should be capable of following the frequency changes of the input signal; i.e., it must "track" the input frequency. Various techniques have been developed for this, even for those measurements where frequency "stepping" synthesizers are used. These methods usually require that a receiver be programmed to tune to its next frequency only after having successfully completed a measurement at the current frequency. The method therefore usually relies on the generator stepping at a slower rate than the receiver.

Envelope-Delay Distortion (EDD)

Envelope-delay distortion is often termed group-delay distortion and is effectively the variation in the derivative of the phase-vs-frequency response. For zero group-delay distortion, the phase/frequency characteristic must be linear. This means that all frequencies are then transmitted through the system with equal time delay. Thus group delay is defined in units of time, but it is the variation that distorts broadband signals and is therefore of interest in measurement.

$$\text{Group Delay} = d\phi/df$$

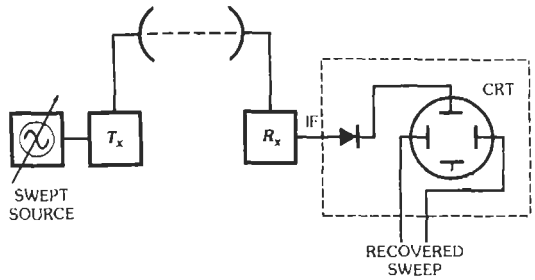

Fig. 63. Amplitude-response measurement.

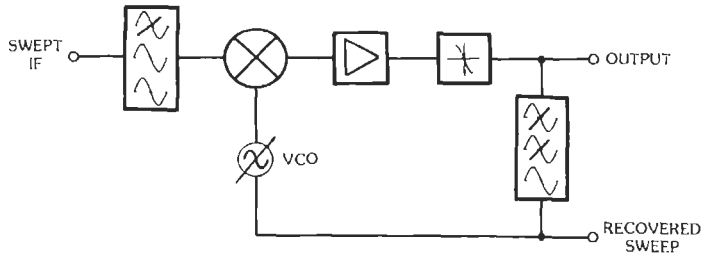

Fig. 64. Frequency-tracking loop.

The nonlinear phase characteristic of Fig. 65 will give rise to distortion of a broadband signal that will manifest itself in the form of noise and intermodulation for analog systems. The group-delay response derived from Fig. 65 will be of the form shown in Fig. 66. As can be seen, there is a mean level of group delay that is not very important; it is the variation of distortion that must be equalized.

Equalization is achieved by means of networks that give inverse group-delay variations. The most common types required are those that compensate for linear group-delay slope or parabolic group-delay distortion. It is important that equalizers be connected as close as possible to the source of group-delay distortion or at least that no nonlinear networks be connected before the equalizer. This is because nonlinearities that introduce amplitude-to-phase-modulation conversion will produce effects that cannot be removed by group-delay equalization.

Measurement of Group-Delay Distortion

There are several methods for the measurement of group-delay distortion, but the basis is usually that of comparing the phase of an output modulation envelope with the phase of a reference signal. The usual method employs a frequency-modulated signal that is swept over the frequency band of interest. Use of a phase-locked loop at the receiver makes possible the recovery of the frequency modulation, which then is used to give the variation in phase as the input signal is swept (Fig. 67).

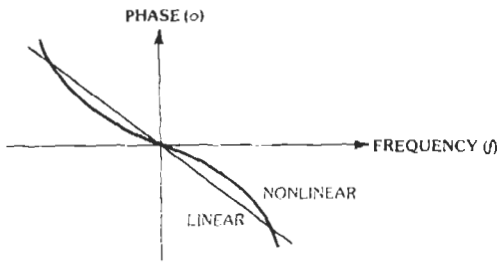

Fig. 65. Phase versus frequency slope.

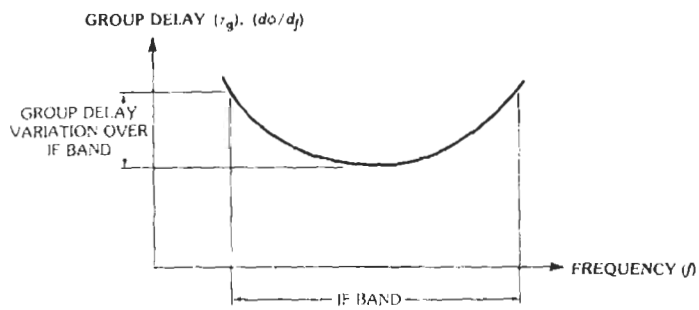

Fig. 66. Group-delay distortion.

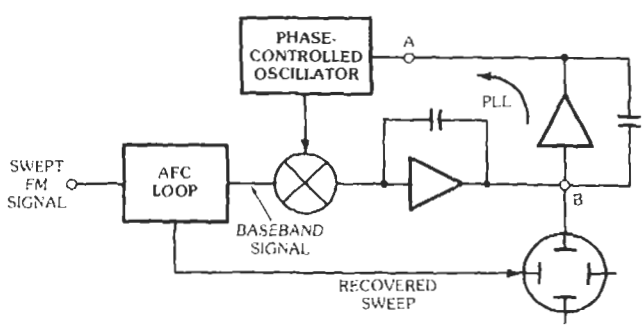

Fig. 67. Measurement of group-delay distortion.

It was shown earlier that a frequency-tracking loop could be used to recover the sweeping signal for the *X* deflection of the CRT. Additionally, the tracking loop reduces the swept range of the received IF signal so that distortions arising from the nonideal nature of networks in the receivers are minimized. For example, a signal that is used to test a radio link may sweep over a band of more than 30 MHz but will be sweep reduced in the analyzer to yield a sweep range of less than 100 kHz. Consequently, the errors introduced by the analyzer are minimized. The phase-locked loop in the group-delay measurement then uses the demodulated baseband frequency to control the phase of its reference oscillator, which will be held at the mean phase of the modulating frequency. Variations in phase are then available at point B in Fig. 67.

Another way of looking at this is to say that if point A represents the reference phase of the modulating signal, then going backward around the double integrating loop means that the signal at point B is the derivative of this phase, or $d\phi/dt$. In this system, however, time is the same as frequency, because as time proceeds, the IF is swept; hence the instantaneous value of the dc voltage at B represents the group delay ($d\phi/df$) at the instantaneous value of the IF.

The reason for using a phase-tracking detector is that it is always working very close to zero phase difference between the inputs. This means that the phase detector is always working on the central part of its dc/phase conversion slope, and nonlinearity of this response does not affect the measurement.

The measurement of group-delay distortion involves the careful selection of several test parameters:

Sweep range
Sweep rate
Modulation frequency (test tone)
Modulation index
Post-detection bandwidth

It is important to select a sweep range appropriate for the device or system under test. Some consideration should be given to the spectrum of the modulating signal, since the device under test will be subjected to the total spectrum. This is usually important only where a high-frequency test tone (> 1 MHz) is used, but it can be important for testing components such as narrowband filters with lower test-tone frequencies.

The sweep rate employed is often in the range of 50 to 100 Hz, but this range may not be suitable for systems such as satellite communication links where use of a lower sweep rate will allow a narrow bandwidth to be selected for the post-detection bandwidth. This will then enhance the measurement resolution by reducing noise power.

The modulation frequency used is a compromise between two conflicting effects:

1. Use of too high a frequency will tend to conceal rapid fluctuations in group delay such as the ripple produced by imperfect impedance matching.
2. Use of too low a frequency will produce a low voltage at the output of the group-delay detector, and the signal-to-noise ratio of the display will be poor.

It is therefore usual to select frequencies between 50 kHz and 500 kHz to give an appropriate compromise. There are cases, however, where much higher modulation frequencies can be used. This is usually true when either television or broadband telephone systems are carried and the test signal has to reveal low values of nonlinearity that produce intermodulation. In these cases, the measurement sensitivity is enhanced by using a modulation frequency between 1 MHz and 12 MHz. In using these high frequencies, it is not appropriate to refer to the measurement as a group-delay measurement, but rather as a measurement of "differential phase."

In practice, this measurement is not as important as the measurement of "differential gain," which can be very useful in tracing problems of amplitude-to-phase modulation conversion.

Television systems are often measured with a test-tone frequency equal to the television color subcarrier frequency. The measurement of differential phase is then used to define system performance.

Differential gain is an extension of the measurement of linearity that uses techniques similar to those for group delay, but, whereas this reveals how the phase for the modulation envelope varies, linearity shows how the amplitude of the envelope varies. The same measurement principle is applied to modulators and demodulators to measure nonlinearity of the voltage/frequency characteristic. It is interesting to note that for a nonlinearity occurring in a discriminator or modulator, the measured nonlinearity will be relatively independent of the modulation frequency employed. This contrasts with the case for IF nonlinearities where the distortion value changes with the square of the change in test-tone frequency. This property may then be used in analyzing system deficiencies.

It can be valuable to be able to separate key characteristics that contribute significantly to intermodulation distortion. Table 1 shows the relative effects of distortion styles to give an approximate indication of which shapes are most serious.

Table 1 does not show the effects of the "coupled" responses where amplitude-to-phase modulation conversion interacts with distortions in other parameters, but these interactions can have a serious effect in high-capacity radio systems. Additionally, nonflatness can be important, especially for digital radio systems.

Return Loss

In the alignment of microwave radio links, it is important that the impedance match of the various sections be well maintained. This is especially important where cabling is used between a source and a load, since any mismatch will produce time-delayed reflec-

TABLE 1. DISTORTION FOR 100-pW INTERMODULATION NOISE (1800-CHANNEL SYSTEM WITH PREEMPHASIS)

Parameter	Distortion Over 10 MHz	Test Tone
Differential-Gain Slope	1%	2.4 MHz
Group-Delay Slope	2 ns	—
Differential-Phase Slope	3% rad	2.4 MHz
Group Delay, Cubic	3.5 ns	—
Group Delay, Parabolic	14 ns	—

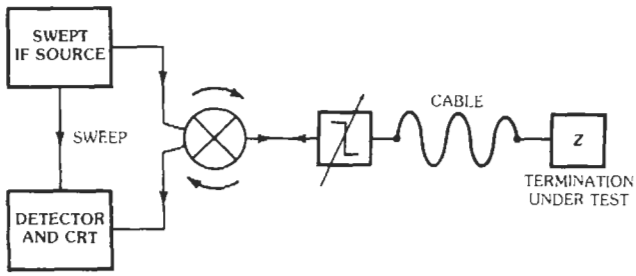

Fig. 68. Return-loss measurement by long-cable method.

tions that may impair link performance. The normal way of describing the mismatch of a source and load is by using the term "return loss." Return loss is the measure of the ratio between the transmitted and reflected signals:

$$\text{Return loss} = 20 \log_{10} |E_i/E_r|$$

where,

E_i is the incident signal,
E_r is the reflected signal.

Return loss is a measure of the magnitudes of incident and reflected signals and does not take account of phase relationships.

Measurement of Return Loss

Long-Cable Method—In this method, a "long cable" is connected to the termination under test as shown in Fig. 68. When the swept IF signal is applied to the long cable and its termination, a series of ripples will appear on the CRT display. If the test termination is removed, the open circuit produces a large amplitude of ripple that is then adjusted by the attenuator to equal the level when the termination is connected. The return loss is equal to 2 times the attenuation inserted.

Note that the cable must be long enough to produce at least one ripple over the swept range, but more than ten are required to observe variations across the band. Thus, for normal IF measurements, a length in excess of 20 meters is required.

Standard-Mismatch Method—This method (Fig. 69) relies on the measurement of power passed from a hybrid when it is terminated by a known mismatch and then by the test item. A typical mismatch of 17 dB is used to calibrate the power meter/detector, after which the actual return loss may be measured directly.

Baseband Measurements

Most of the above measurements are made at the intermediate frequency (IF) of the radio system or at the microwave carrier frequency. Obviously, some measurements such as modulator linearity also involve the direct use of baseband inputs, but there is an additional class of measurements that define system performance and are carried out at baseband level. The most obvious

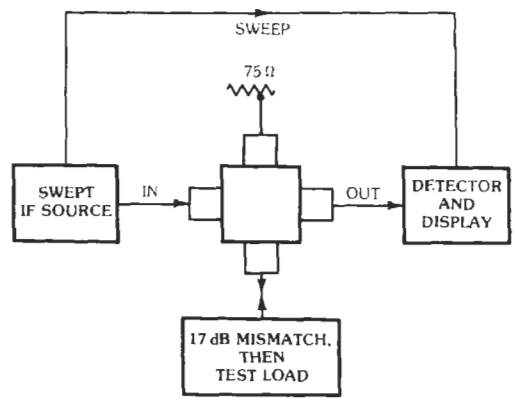

Fig. 69. Measurement of return loss by standard-mismatch method.

of these is the measurement of baseband amplitude/frequency response, but checks for spurious frequencies should also be made. These measurements can be made with special instruments that provide spectrum analysis.

For multichannel telephony systems, the prime concern is to minimize the level of noise in each channel. There can be many sources of noise, but they are mainly either thermal or caused by cross talk or intermodulation. Thermal noise is not affected by the traffic level (loading) of the system, whereas intermodulation distortion is sensitive to loading. The system designer therefore attempts to define a loading level at which intermodulation noise is low and yet the ratio of signal level to thermal noise is also satisfactory.

In order to verify that the correct balance of thermal and intermodulation noise is obtained, it is necessary to be able to simulate the traffic load and then measure the effects in channels throughout the baseband. This is achieved by using a band of thermal noise to represent the traffic.

Noise Loading—Traffic simulation using a band of thermal noise is possible because the amplitude distribution of such noise is Gaussian and the power-versus-frequency spectrum is uniform. This latter characteristic is analogous to white light, so the band of noise used to simulate traffic is often referred to as "white noise."

In order to simulate a given traffic load, the formula normally used to calculate the noise power required is

$$\text{Mean noise power} = -15 + 10 \log_{10} N$$

where,

Mean noise power is in dBm0 (power in dBm referred to a point of zero relative transmission level),
N is the number of telephone channels.

For this formula to be valid, N must be greater than 240, because as the noise bandwidth is reduced to simulate high-capacity systems, the signal departs significantly from a Gaussian distribution. The formula then used is

$$\text{Mean noise power} = -1 + 4 \log_{10} N$$

where,

Mean noise power is in dBm0,
N is less than 240.

Modern systems may, of course, be loaded with data. In this case, a modified formula is used:

$$\text{Mean noise power} = -10 + 10 \log_{10} N$$

where,

Mean noise power is in dBm0,
Data loading N is greater than 12 channels.

It is necessary to limit the noise bandwidth to represent the bandwidth of the system. Filters for controlling noise bandwidth are prescribed by the various telecommunications authorities.

Noise Power Ratio—When the system has been loaded with noise to simulate traffic, it is then necessary to measure intermodulation noise. This is done by introducing a quiet "slot" into the noise band. This slot is then inspected to determine the level of noise introduced by intermodulation. This is known as the measurement of noise power ratio (NPR), which may be defined as the ratio of the noise power in a measurement channel with the baseband fully loaded to the noise power in that channel when the baseband is noise-loaded except for the measurement channel. In Fig. 70, P_1 (Fig. 70A) represents the power in the measurement channel due to the loading signal, P_2 (Fig. 70B) would equal zero for the ideal case where there is no thermal noise or intermodulation noise, and P_3 (Fig. 70C) shows the effect that these noise components will have. Thus,

$$\text{NPR} = P_1/P_3$$

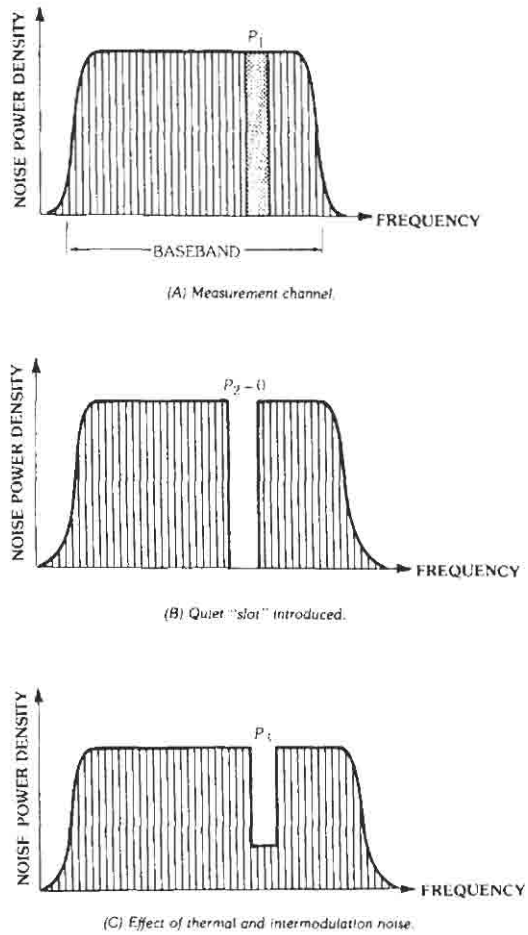

Fig. 70. Principle of NPR measurement.

If the noise load is removed, the thermal noise component in the measurement channel can be measured. (Thermal noise is sometimes referred to as basic noise or intrinsic noise.) Then if the noise load is added, the additional noise introduced by intermodulation and cross talk can be measured.

By varying the level of the baseband noise loading signal, it is possible to explore the combined effects of thermal noise and intermodulation noise to determine the optimum operating point for the system.

The NPR curve is often referred to as a "*V*" curve because of the characteristic shape (Fig. 71). At low loading levels, thermal noise will predominate, and NPR will simply be proportional to the loading power level. Thus this part of the characteristic is linear. As intermodulation noise rises, however, the noise power ratio will fall rapidly and give the shape of Fig. 71. It is possible to gain troubleshooting information by inspecting the *V* curve for slots placed at different frequencies throughout the baseband. The method employed is to select a slot and observe the change in NPR for a 1-dB change in noise loading. In the linear region of the curve, a 1-dB change in load will give a 1-dB change in NPR. For the nonlinear segment of the V curve, the change in NPR can then be used to determine the order of the nonlinearity involved.* For example, a 2-dB change in NPR will indicate that third-order nonlinearity is the cause.

The conventional form of test set† for carrying out NPR measurements is shown in Fig. 72. Fixed filters are used at both transmit and receive points in the system. This form of test set has the advantage that

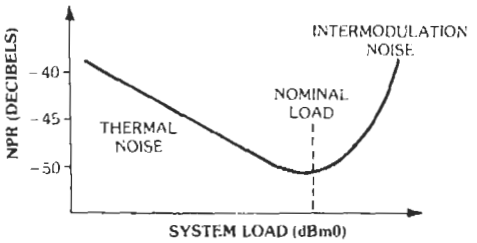

Fig. 71. NPR curve for a multichannel radio system.

intermodulation in its receive mixer is not important since bandpass filters reduce the noise band presented to the mixer. Unfortunately, it is necessary to have a range of bandpass filters and oscillators to cope with all the slots and systems that may have to be measured.

The modern design of highly linear mixers, however, allows a selective receiver to make the NPR measurement. Such receivers use a synthesizer as the local oscillator, so the requirement for separate filters and oscillators is avoided.

Conversions—It is sometimes necessary to convert from NPR to other measures, such as signal-to-noise ratio (SNR). The following relations are used.

1. Weighted signal-to-noise ratio in decibels:

$$\text{Weighted SNR} = \text{NPR} + 10 \log_{10}(f/3.1) - P + W$$

where,

f = bandwidth of baseband (kHz),
P = nominal load (dBm0),
W = weighting factor (dB).

* References 24 and 25.
† Reference 24.

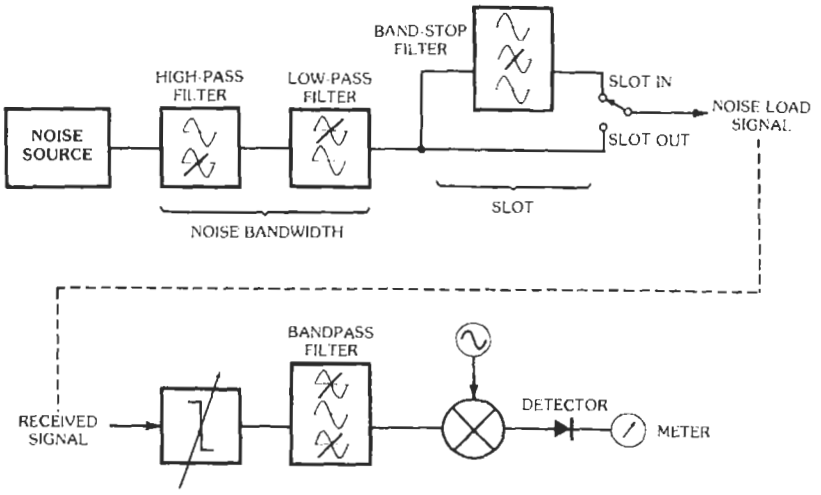

Fig. 72. NPR measurement.

When applied to systems having greater than 240 channels and using *C*-message weighting, this simplifies to

$$SNR = NPR + 17.8$$

2. The notation dBrnC0 means decibels of noise with respect to reference noise of −90 dBm and with *C* message weighting, corrected to a point of zero transmission level. Conversion to dBrnC0 for systems that have more than 240 channels is given by

$$dBrnC0 = 71.7 - NPR$$

Note that the European psophometric weighting and *C* message differ by 1 dB, but in practice the above formula is often used for psophometric weighting.

Carrier/Noise Measurement

For digital radio systems, the normal overall performance measurement is based on "bit error rate," where a pseudo-random-sequence bit pattern is applied to the system and errors are indicative of system imperfections. A more detailed analysis is made possible by inspection of the so-called "eye" diagram at the sampling stage of digital signal recovery, but measurement of error rate as the carrier-to-noise ratio is varied can be a more revealing method of analyzing system performance.

Diagnostic Measurements and System Performance

The relationships between diagnostic tests and system performance are often very complex. Thus it is difficult to relate measurements of envelope-delay distortion to the intermodulation that will be produced. It is possible to make such predictions,* but this generally requires the use of a computer. It is generally more useful to derive a clear understanding of how these measurements can best be used to optimize system performance, or at least to be able to separate those measurement responses that have a significant effect on system performance from those that have a lesser effect.

COMPUTER CONTROL OF INSTRUMENTS

A series of standards provides mechanisms for computers to communicate with instruments. IEEE 488.1 or IEC 625-1 describes a physical interface including electrical and mechanical constraints. IEEE 488.2 or IEC 625-2 describes how complete messages are formatted and exchanged. SCPI defines the semantics of the messages.

* Reference 17.

IEEE 488.1 or IEC 625-1 General Purpose Interface Bus (GPIB)*

The GPIB provides a means by which system components communicate with each other. It is analogous to the telephone system that allows one person to exchange verbal information with another person—or, in the case of a conference call, with several other people.

Every participating device in a GPIB system performs at least one of three roles: talker, listener, or controller. A talker transmits data to other devices via the bus. A listener receives data from other devices. A controller manages communications on the bus, primarily by designating which devices are to send or receive data during each measurement sequence. The controller may also interrupt and command specific actions within devices.

Many devices are both talkers and listeners. For example, a programmable multimeter or electronic counter listens when receiving its program instructions, and it talks when sending its measurements to another system component such as a printer or computer. There can be several listeners, but to avoid confusion, only one talker can be active on the bus at any one time.

In its simplest form, a GPIB system can consist of only one talker and one listener—for example, an electronic counter linked to a printer. In this application, there is no need for a controller; the counter "talks" and the printer "listens."

The full versatility of the GPIB becomes apparent when there is more stimulative interaction among the interconnected devices. To achieve this requires a controller that can schedule measurement tasks, set up instruments to perform specified tests and measurements, monitor processes on-line, and process data and analyze and interpret the results. A desktop computer, or "computing controller," is often used as a system manager to control the bidirectional data flow of the GPIB.

Interface circuitry is part of each interfaced instrument or computing controller—the GPIB cable itself is passive. Inside the cable, 16 active signal lines are grouped into three sets, according to function (Fig. 73).

The eight data lines carry coded messages—such as addresses, program data, measurements, and status bytes—among as many as 15 devices interconnected with a single bus. The same data lines are used for both input and output, and the messages are in bit-parallel, byte-serial form. Data are exchanged asynchronously, for maximum compatibility among a wide variety of devices.

For unambiguous, intelligible communication between instrument and computer devices, some rules or protocol must apply to the communication process itself. Thus, the exchange of data is controlled by the

* From Hewlett-Packard publication 5021-1927. © Hewlett-Packard, used with permission.

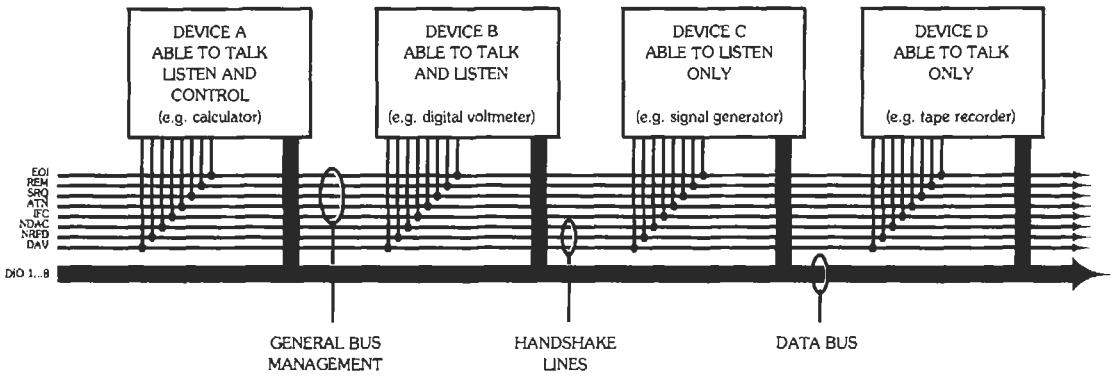

Fig. 73. General purpose interface bus. (*From Hewlett-Packard publication 5021-1927. © Hewlett-Packard, used with permission.*)

second set of signal lines, the three data byte transfer control lines. All listeners addressed on the GPIB send a signal when they are "ready for data." The talker then initiates data-byte transfer by signaling that "valid data" are on the data lines. When each listening device successfully receives the message, it acknowledges "data accepted."

When two or more devices are listening, all must acknowledge "data accepted" before new data can be transmitted on the bus. Thus, data are transferred at the rate of the slowest listener participating in the particular conversation.

High-speed and slow devices can be connected on the same bus. Data transfer between high-speed devices is not adversely affected, as long as the slow devices are not addressed or participating in the conversation.

The remaining five general interface management lines are used for such things as activating all the connected devices at once, clearing the interface, and so forth.

Up to 15 GPIB devices can be linked together on one bus. The GPIB cable connects them in parallel functionally, in either star or linear fashion physically. Total cable transmission path length on any one bus should not exceed 20 meters or 2 meters per device, whichever is less, except where the distance is extended by devices such as a common carrier interface.

A single computing controller can manage more than one bus instrument cluster at once. This is particularly useful for achieving concurrent actions at different test stations in a production test measurement application.

Interface circuitry for controllers and instruments is commercially available in integrated-circuit packages.

IEEE 488.2 or IEC 625-2

As illustrated in Fig. 74, IEEE 488.2 is a higher level standard than GPIB. It has also been used on top of IEEE 1155, VME Extensions for Instrumentation (VXI). While the physical interface provides a connection between system components, IEEE 488.2 provides rules on how the communication on the interface will take place.

The major areas covered by IEEE 488.2 are:

1. Reliable transfer of complete messages between a computer and an instrument.
2. A precise description of the syntax in those messages.
3. The form and meaning of a set of commands useful in all instruments.
4. Common status reporting capability.
5. Techniques for guaranteeing synchronization of application programs with instrument functions.

IEEE 488.1 provides a reliable means of transferring bytes between a talker and a listener. In addition, a reliable means of transferring programming commands and measurement results is needed.

A response is generated only after a query message has been received. An instrument responds only with the data asked for by the controller. An instrument is not allowed to generate arbitrary data when it is addressed to talk. Any violations of the message exchange protocol are reported as query errors in the event-status register described by the status reporting model.

IEEE 488.2 requires that devices listen in a "forgiving" manner. The level of forgiveness is, however, very precisely defined. The syntactic meaning of every data byte is well defined, even when multiple characters have the same meaning.

While the listening syntax may be very forgiving, an instrument is required to talk very precisely. As a result, the chances of a message being accepted by any controller are greatly increased.

Certain functions are useful across all types of instruments. IEEE 488.2 defines a set of commands which all instruments must implement exactly as described. Some of the more generic commands are resetting and identifying the instrument. Other commands are described which may be useful in some instruments. They are included in the standard so that if the function is implemented, implementation will be done in a standard way.

IEEE 488.2 describes a status-reporting model that is hierarchical. The contents of other data structures are

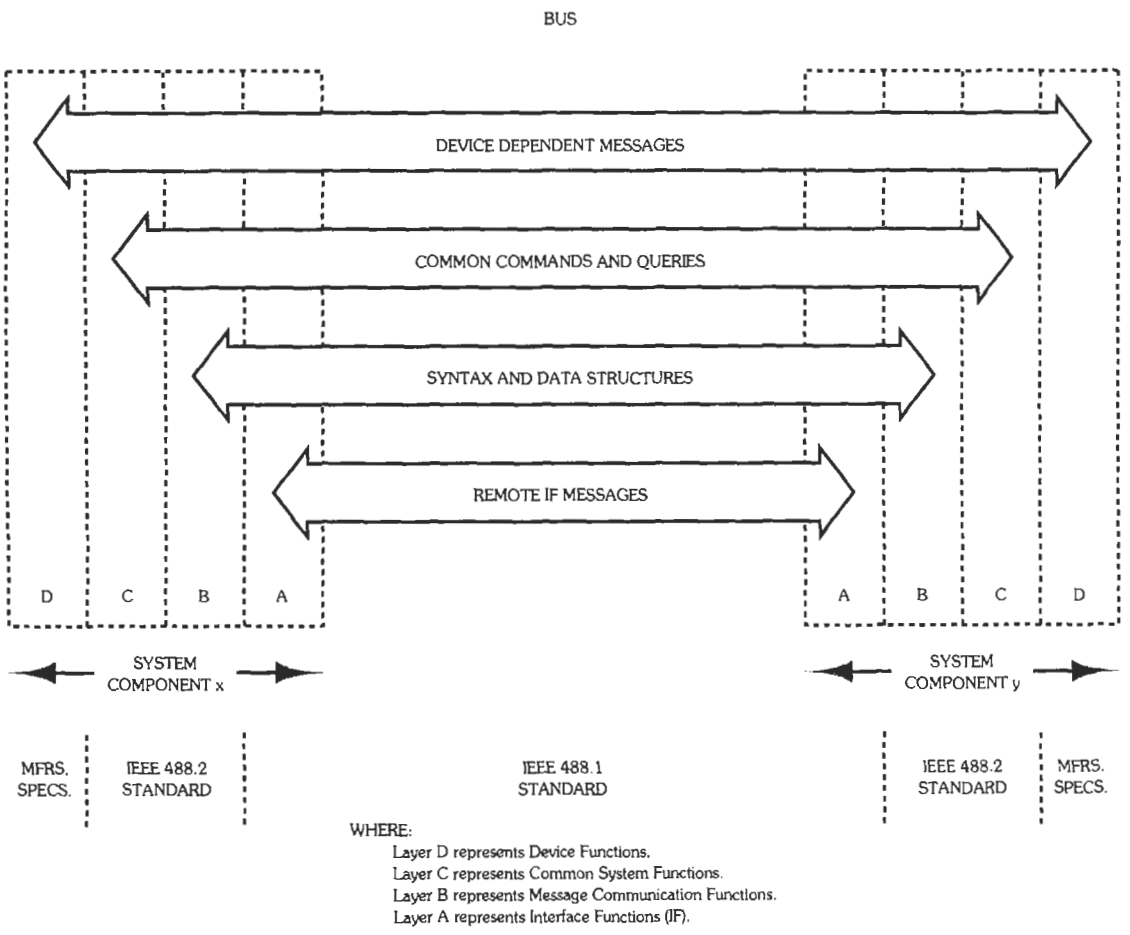

Fig. 74. IEEE 488.2 layers. (*From Hewlett-Packard publication 5021-1927. © Hewlett-Packard, used with permission.*)

summarized in the status byte. Some of the conditions required are whether a message is available and whether an error has occurred.

Instruments are often able to accept commands faster than they can be executed. While this feature can improve system throughput, it also creates a need to know when the instrument has actually completed all its commands. IEEE 488.2 requires commands which enable the application program to detect when all pending operations are complete.

Standard Commands for Programmable Instruments (SCPI)

SCPI fills in the top layer of Fig. 74 by describing the semantics of the messages. The most important objective of SCPI is to be consistently usable with a large variety of instruments. This horizontal compatibility means that a power supply can be programmed similarly to a microwave network analyzer. Even though these two instruments have very different capabilities, there is no reason to use two different programming languages. Although having a consistent style is convenient, the ability to use the exact same command for the same function (even with different hardware) is more important. Thus, a voltmeter uses the same command as an oscilloscope for measuring dc voltage.

This compatibility is derived from using a generalized model of an instrument. This model, along with the underlying standards, enforces a discipline on the language designers. In an effort to meet the needs of advancing instruments needs, a consortium of instrument manufacturers manages the growth of the language.

ELECTROMAGNETIC COMPATIBILITY, INTERFERENCE, AND SUSCEPTIBILITY

EMC/EMI/EMS

Electromagnetic compatibility (EMC) is the ability of items of electronic equipment to function properly together in the electronic environment. Most electronic

CHART 1. TYPICAL EMI/EMS MEASUREMENTS

equipment is designed to perform an assigned task. However, when improperly designed or poorly maintained, a device may emit unintentional radiation to interfere with the proper functioning of other equipment. Sometimes equipment is designed to emit radiation at designated frequencies and with prescribed bandwidths but may inadvertently emit at other frequencies or harmonics. These situations create electromagnetic interference (EMI) to other equipment.

Engineers would prefer to design equipment to survive under the most severe electromagnetic interference,* but they are often constrained by size, weight, and cost requirements. Designing equipment to work at prescribed interference levels is designing for acceptable susceptibility (EMS).

Regulations

In the United States, the Federal Communications Commission is the body responsible for the control of EMI. Part 15 (for radio-frequency devices) and Part 18 (for medical, scientific, and industrial equipment) of the FCC Rules and Regulations† contain sections on the control of interference. Devices intended for commercial and scientific applications with limited usage are governed by class A limits. Devices intended for home or consumer use are covered by class B limits, which are up to 22 dB lower in level of conducted emission and 10 dB lower in level of radiated emission. Certification from the FCC is required before equipment may be sold in the USA.

Another source of EMI regulations, particularly for builders of military equipment, is MIL-STD-461. Test methods for the frequency range 30 Hz to 40 GHz are covered in MIL-STD-462.

European Community countries use unified EMC standards (EN)§ that regulate the level of permissible electromagnetic emission and also susceptibility. These standards are based on IEC§ (International Electrotechnical Commission) and CISPR§ (International Special Committee on Radio Interference) recommendations. Certification to these regulations must be performed before the equipment is offered for sale.

Most countries in Asia and other parts of the world follow the CISPR recommendations in the development of their national EMI standards.

Other international bodies, such as the ITU (International Telecommunication Union), provide detailed limits of EMI for specialized equipment. In general, compliance with their standards is voluntary, but compliance will often mean better chances of success in interfacing with existing equipment.

Typical emission limits are shown in Fig. 75.

EMI/EMS Measurements

Chart 1 lists typical EMI/EMS measurements. An open area test site** (OATS) with little or no electromagnetic ambient noise is ideal for making emission measurements. An anechoic chamber, a shielded room with absorbent material lining all walls, is ideal for susceptibility measurements. Emission measurements in a semianechoic chamber with a conductive floor as ground plane may substitute for OATS measurements within limitations. Unlined screen rooms are afflicted with multiple reflections, which add to or subtract from the true magnitude of the radiation, and are useful only for conducted-EMC measurements.

Inexpensive techniques for the testing of radiated EMC are offered by TEM cells†† (transmission lines) if

the equipment is small relative to the dimensions of the cell. For EMI measurements, a receiver is connected as the load to the cell, and for EMS measurements, a signal generator is connected as the source. The TEM cell is completely shielded. As the cell dimensions become comparable to the wavelength, higher-order modes will affect the calibration thus creating a high-frequency usage limit known as the cutoff frequency. The cutoff frequency is raised considerably in a special form of the TEM cell* where the voltage and current on the transmission line are internally terminated and the associated electromagnetic field is absorbed.

Strip-line cells† are sometimes used for testing small electronic modules. They are inexpensive, easy to build, and economical of bench space. Unfortunately, they are not shielded, and their use is therefore limited to preliminary testing and troubleshooting.

Emission sources may be located during troubleshooting with inexpensive, small hand-held probes§ for magnetic fields. Such probes may also be used to inject fields for localized susceptibility tests.

13 Magnetic-Core Transformers and Reactors

Revised by
Charles F. Hempstead, Durwood R. Kressler, Richard W. Avery, Fred J. Banzi, Bernard D. Carniglia, Arthur Olsen, Jr., Kent W. Sternstrom, and Richard C. Walker

INTRODUCTION

Definition of Transformer and Inductor

Magnetic-core transformers are static devices containing magnetically coupled windings. They are used in power systems to change values of voltage and current at a single frequency. In communications circuits, often over a wide band of frequencies, they are used to provide direct-current isolation, signal splitting and combining functions, specific current or voltage ratios, impedance matching, and phase inversion.

The Institute of Electrical and Electronics Engineers, Inc. (IEEE) has defined a transformer as follows: "A static device consisting of a winding, or two or more coupled windings, with or without a magnetic core, for introducing mutual coupling between circuits. Note: Transformers are extensively used in electric power systems to transfer power by electromagnetic induction between circuits at the same frequency, usually with changed values of voltage and current."*

Magnetic-core inductors and reactors are static devices containing one or more windings to introduce inductance into an electric circuit. Reactors are used in power circuits primarily to filter alternating current from direct current. Inductors are used in communications systems primarily in frequency-selective circuits.

In this chapter, only those devices having magnetic cores will be considered. The type of core material is known as soft magnetic material, which is defined as ferromagnetic material which, once having been magnetized, is very easily demagnetized (i.e., requires only a slight coercive force to remove the resultant magnetism). A ferromagnetic material usually has relatively high values of specific permeability, and it exhibits hysteresis. The principal ferromagnetic materials are iron, nickel, cobalt, and certain of their alloys.†

Transformer Types and Frequency Ranges

The major types of transformers for both power and communications applications are listed below, along with the general operating frequencies for each type.

Power	
Power transformers	50, 60, and 400 Hz
Ferroresonant transformers	50, 60, and 400 Hz
Converter transformers	100 Hz to 150 kHz
Communications	
Audio-frequency transformers	20 Hz to 20 kHz
Carrier-frequency transformers	20 kHz to 20 MHz
High-frequency transformers	20 MHz to 1000 MHz
Pulse transformers	Repetition rates to 4 MHz

Inductor Types and Frequency Ranges

The major types of reactors or inductors are rectifier-filter reactors, alternating-current reactors, audio-frequency inductors, and precision adjustable inductors for filters. Inductors are used from 20 Hz to 1000 MHz or higher.

Generalized Equivalent Circuit for a Transformer

Fig. 1 shows the equivalent circuit for a generalized transformer having two windings. Commonly accepted nomenclature* is as follows:

a = turns ratio = N_p/N_s
C_p = primary equivalent shunt capacitance
C_s = secondary equivalent shunt capacitance
E_g = root-mean-square generator voltage
E_{out} = root-mean-square output voltage
k = coefficient of coupling
L_p = primary inductance
l_p = primary leakage inductance
l_s = secondary leakage inductance
R_c = core-loss equivalent shunt resistance
R_g = generator impedance
R_l = load impedance
R_p = primary-winding resistance
R_s = secondary-winding resistance

POWER TRANSFORMERS

Power transformers operate from a low source impedance at a low frequency. Depending on the source of power, the frequency may vary as much as ±5.5% at 50 or 60 Hz, and as much as ±20% at 400 Hz.

Types of Magnetic Cores

The magnetic cores used for power transformers are usually E and I laminations stamped from silicon-iron sheet when low cost is of primary importance. When

* Reference 1.
† Reference 2.
* Reference 3.

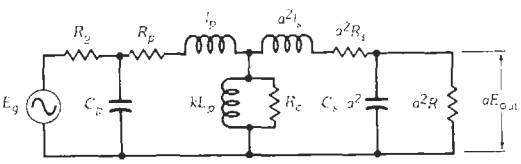

Fig. 1. Equivalent network of a transformer.

minimum size or low loss is of greatest concern, wound-cut "*C*" cores of oriented silicon steel or the more expensive Supermendur could be considered.

Table 1 lists basic properties of soft magnetic materials. Table 2 gives the maximum-flux-density operating conditions for various core materials at 60 and 400 hertz. Two types of laminations are listed as typical, although there are more types that are of both a higher and lower grade. The 0.014 M-6 material is of a higher grade than the 0.0185 M-19 material, but the cost of the former may be 50% more per pound than the cost of the latter, depending on the lamination size chosen. On the other hand, less of the better-grade material is required for the same performance. In a recent study,* it was shown that transformers and reactors constructed of the higher-grade materials were always smaller, as expected, but that in some cases the total material cost of the structures having the better-grade laminations was the lowest.

Wound-cut "*C*" cores are wound in tape form on a rectangular mandrel, impregnated, and cut into halves. These halves are then banded around the wound transformer coil.

The sheet-form magnetic materials may also be made in thin strip form and supplied as toroidal tape-wound bobbin cores for high frequencies. The 79 permalloy in 0.000 125-inch tape thickness on a bobbin core may be used at frequencies as high as 1 MHz. These cores are not cut into halves.

Tables 1 and 2 make reference to "Metallic Glass." METGLAS† is Allied Corporation's registered trademark for amorphous alloys of metals. This material is new to the list of available core materials. Its advantage is low core loss and exciting volt-amperes. It is currently manufactured in ribbon form with a nominal thickness of 0.0011 inch and widths of 1.0 to 4.0 inches. The material can be stamped into laminations, but the form lends itself best to tape-wound cores. METGLAS material was originally developed for low-frequency power transformers at a commercially competitive price compared with the standard Si-Fe material. The general-purpose alloy with the formulation Fe_{81} $B_{13.5}$ $Si_{3.5}$ C_2, known as Alloy 2605SC, is specified in Tables 1 and 2. Other alloys are available.

The approximate number of exciting volt-amperes is largely dependendent on the air gap or equivalent air gap in series with the magnetic path. The values specified in Table 2 are for the material exclusive of the air gap. Information on core loss and exciting volt-amperes for specific lamination sizes may be obtained from Thomas and Skinner.**

Similar information for cut-cores may be obtained from catalogs of the Arnold Engineering Co.

Design of Power Transformers for Rectifiers

The design of transformers for rectifiers was chosen as an example because it represents one of the more difficult transformer design problems. The reason it is difficult is that all parts of all windings are not operating continuously with a sinusoidal current. The result is that the capability of the transformer structure is not as fully utilized as it would be if the transformer supplied a nonrectified resistive load. An early paper by R. W. Armstrong* gave the effective, or rms, values of voltages and currents for the primary and secondary windings of a transformer that provides the power for various types of single-phase and polyphase rectification followed by a reactor-input filter. Table 3 lists single-phase rectifier transformer ratings for both inductive (L) and resistive (R) filter inputs. A more comprehensive listing of all the circuit parameters of these single-phase as well as polyphase rectifier circuits is found in Chapter 14 of this book. Should the input to the filter be capacitive, higher rms values of current appear in the secondary winding, resulting in a higher volt-ampere rating. A detailed analysis of the effect of the capacitor-input filter on the transformer-winding voltage and current requirements was made by O. H. Schade in 1943.† More recent analyses have been made by R. Lee** and N. R. Grossner.‡

The first step in designing a transformer is to determine its volt-ampere (VA) rating. In the case of the transformer for a rectifier,

$$VA = VA_T E_{dc}' I_{dc}$$

where,

VA_T may be obtained from Table 3,
E_{dc}' is the sum of the output dc voltage (E_{dc}), the diode drop (E_{dd}), and the reactor drop (E_{rd}).

In the case of the bridge rectifier, the current passes through two diodes on each half cycle, and it is necessary to use the value of two diode drops in the calculation of E_{dc}'.

At this point, it is handy to have a table of VA ratings versus lamination sizes, such as Table 4. Note the constraints of the 60-Hz frequency and the 75 °C winding temperature rise in an ambient of 75 °C. If a lower frequency or temperature rise is required, then the VA average will be lower for a given structure, with other parameters also being affected. It might also be noted that if a bobbin type of construction is used on the smaller structures instead of a layer-wound construction with interlayer insulation, then up to 30% more copper may be used in a given structure, resulting in up to 30% more VA average at the same frequency and temperature rise. The above calculated VA rating may be used to select a suitable structure from Table 4.

In order to determine the number of turns and wire size of each winding, it is first necessary to determine the voltage and current for each winding. Table 3 gives the relationships between the rms voltages and currents and the dc voltages and currents. The value of E_{dc}'

** Voltages, currents, and VA are based on unity dc output voltage and current. Voltage drops in transformer, diode, and inductor are neglected.

† Secondary voltage at each side of center tap.

‡ Includes second and third harmonics of ripple frequency.

calculated above is used for the dc voltage. The primary voltage, E_p, is determined by the specified input voltage. The primary rms current, I_p, is determined as follows:

$$I_p = [(\text{VA}) \ (\text{Primary VA})]/[(\text{Efficiency})(E_p)]$$

The quantities "primary VA" and "efficiency" are obtained from Tables 3 and 4, respectively. The secondary rms voltage, E_s, and the secondary rms current, I_s, are obtained from the following relationships:

$$E_s = (\text{Secondary } E_s)(E_{dc}')$$
$$I_s = (\text{Secondary } I_s)(I_{dc})$$

The quantities "Secondary E_s" and "Secondary I_s" are obtained from Table 3.

Now the number of turns in each winding can be calculated. The number of primary-winding turns, N_p, is obtained as follows:

$$N_p = (E_p \times 10^5)/(4.44 \times f \times A_c \times B_m)$$

where f is the frequency of the applied voltage, which is assumed to be sinusoidal. If the applied voltage has other than a sinusoidal waveform, then the 4.44 constant must be changed. An ASTM standard explains this.* The quantity A_c is the area of the core, and B_m is the core flux density. If the metric unit the kilogauss (kG) is used, as listed in Table 4, then A_c must be in square centimeters. If B_m is in kilolines per square inch, then the units of A_c must be square inches. The A_c of the structure selected from Table 4 may be computed by squaring the specified tongue width (in the appropriate units) and multiplying by the core manufacturer's recommended stacking factor. Although Table 4 structures are all square stacks (i.e., the stack height equals the tongue width), the stack heights are often increased or decreased for a larger or smaller VA rating.

The number of secondary-winding turns, N_s, is obtained as follows:

$$N_s = N_p(E_s/E_p)[1 + (\text{Copper Regulation} / 100)]$$

where "Copper Regulation" (in percent) is obtained from Table 4.

The wire sizes for each winding are determined by dividing the current calculated for the winding by the current density specified in Table 4. This determines the cross-sectional area needed for the conductor. A wire table, such as Table 5, will give the bare area for each wire size. This table also gives the thickness of insulation necessary to support each layer of a given wire size in the layer-wound construction, as well as the maximum diameter of the wire over its film insulation.

The next step is to design the coil that will result in the configuration shown in Fig. 2. This wound coil will then be laminated to form the finished product as shown in Fig. 3.

* Data for this table are courtesy of NEMA (ref. 12) and Phelps Dodge (ref. 13).
† Square or rectangular wire is recommended for wire sizes heavier than AWG 14. Single build is not recommended for these sizes.
** Resistance values are at 20 °C.

In designing the coil, one first selects the core tube thickness (J in Fig. 2). This thickness may vary from 0.025 to 0.050 inch for lamination stack heights (p in Fig. 3) of 0.5 to 2 inches. Next, calculate the coil-build (a in Fig. 3) for each winding, using the number of turns and wire sizes previously calculated.

$$a = 1.1[n_l(D + t) - t + t_c]$$

where,

n_l is the number of layers in the winding,
D is the diameter of the insulated wire,
t_c is the thickness of the insulation under and over the winding.

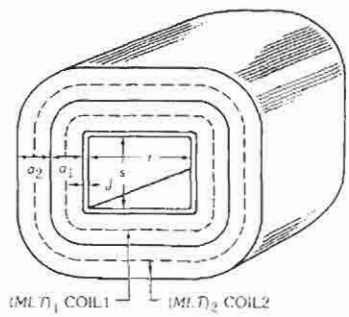

Fig. 2. Dimensions relating to coil mean length of turn (MLT).

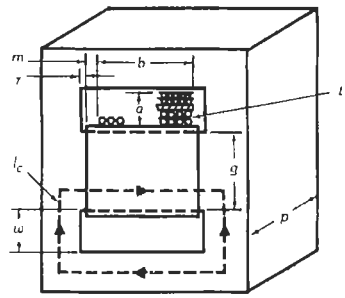

A_c = core area = $(gp)k$
a = height of coil
= coil-build
b = coil width
g = width of lamination tongue
l_c = average length of magnetic-flux path
k = stacking factor
= 0.90 for 14-mil lamination
= 0.80 for 2-mil lamination or ribbon-wound core
m = marginal space given in Table 5
p = height of lamination stack
t = thickness of interlayer insulation
w = width of core window
r = window length tolerance
= 1/16 inch, total

Fig. 3. Dimensions relating to the design of a transformer coil-build and core.

The numeric 1.1 allows for a 10% bulge factor. This factor may be reduced, depending on the winding equipment and methods of winding used. The total coil-build should not exceed 85–90% of the window width.

Compute the mean length per turn (MLT) of each winding from the geometry of the core and windings (Fig. 2).

$$(\text{MLT})_1 = 2(r + J) + 2(s + J) + \pi a_1$$
$$(\text{MLT})_2 = 2(r + J) + 2(s + J) + \pi(2a_1 + a_2)$$

where,

a_1 is the build of the first winding,
a_2 is the build of the second winding,
J is the thickness of the winding form,
r and s are the winding-form dimensions.

Calculate the total length and resistance of each winding, and determine the IR drop and I^2R loss for each winding.

Make corrections, if required, in the number of turns of the windings to allow for the IR drops, so as to have the required E_s.

$$E_s = (E_p - I_pR_p)(N_s/N_p) - I_sR_s$$

Compute the core loses from the weight of the core and Table 2 or reference 6.

Determine the percent efficiency η and voltage regulation (VR) from

$$\eta = \frac{W_{\text{out}} \times 100}{W_{\text{out}} + (\text{core loss}) + (\text{copper loss})}$$

$$(\text{VR}) = \frac{I_s[R_s + (N_s/N_p)^2R_p]}{E_s}$$

For a more accurate evaluation of voltage regulation, determine leakage-reactance drop $= I_{dc}\omega l_{sc}/2\pi$, and add to the above (VR) the value of $I_{dc}\omega l_{sc}/2\pi E_{dc}$. Here, l_{sc} = leakage inductance viewed from the secondary; see "Methods of Winding Transformers" (in this chapter) to evaluate l_{sc}.

Bring out all terminal leads. Use the wire of the coil, insulated with suitable sleevings, for all sizes of wire heavier than 21. Use 7-30 stranded and insulated wire for smaller sizes.

Effect of Duty Cycle on Design

If a transformer is operated at different loads according to a regular duty cycle, the equivalent volt-ampere (VA) rating is

$$(\text{VA})_{eq} = \left[\frac{(\text{VA})_1^2t_1 + (\text{VA})_2^2t_2 + (\text{VA})_3^2t_3 + \ldots + (\text{VA})_n^2t_n}{t_1 + t_2 + t_3 + \ldots t_n}\right]^{1/2}$$

where $(\text{VA})_1$ = output during time t_1, etc.

Example: 5 kilovolt-ampere output, 1 minute on, 1 minute off.

$$(\text{VA})_{eq} = \left[\frac{(5000)^2(1) + (0)^2(1)}{1 + 1}\right]^{1/2} = \left[\frac{(5000)^2}{2}\right]^{1/2}$$

$$= 5000/(2)^{1/2} = 3535 \text{ volt-amperes}$$

Methods of Winding Transformers

The most common methods of winding transformers are shown in Fig. 4. Leakage inductance is reduced by interleaving, i.e., by dividing the primary or secondary coil into two sections and placing the other winding between the two sections. Interleaving may be accomplished by concentric and by coaxial windings, as shown in Figs. 4B and C. Reduction of leakage inductance is computed from

$$l_{sc} = \frac{10.6\,N^2(\text{MLT})\,(2nc + a)}{n^2b \times 10^9}$$

where l_{sc} is the leakage inductance (referred to the winding having N turns) in henrys and the dimensions are in inches and to be the same for Figs. 4B and C.

Means of reducing leakage inductance are:

(A) Minimize turns by using high-permeability core.
(B) Reduce build of coil.

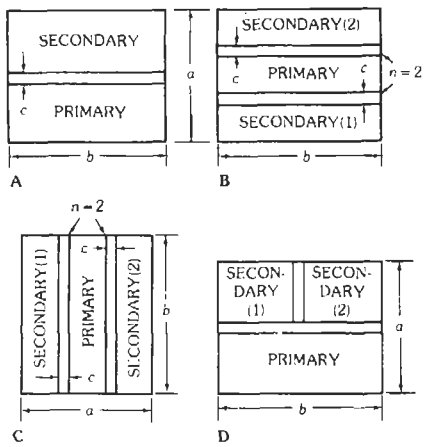

Fig. 4. Methods of winding transformers.

(C) Increase winding width.
(D) Minimize spacing between windings.
(E) Use bifilar windings.

Means of minimizing capacitance are:

(A) Increase dielectric thickness t.
(B) Reduce winding width b and thus area A.
(C) Increase number of layers.
(D) Avoid large potential differences between winding sections, as the effect of capacitance is proportional to applied potential squared.

Note: Leakage inductance and capacitance requirements must be compromised in practice since corrective measures are opposites.

Effective interlayer capacitance of a winding may be reduced by sectionalizing it as shown in Fig. 4D. This can be seen from

$$C_e = (4C_l/3n_l)(1 - 1/n_l)$$

where,

C_e = effective capacitance in picofarads,
n_l = number of layers,
C_l = capacitance of one layer to another
= $0.225\ A\epsilon/t$ picofarads,
A = area of winding layer = $(MLT)b$ inches^2,
t = thickness of interlayer insulation in inches,
ϵ = dielectric constant $\approx$ 3 for paper.

Dielectric Insulation and Corona

For class A (Table 6), a maximum dielectric strength of 40 volts/mil is considered safe for small thicknesses of insulation. At high operating voltages, due regard must be paid to corona that occurs before dielectric breakdown and will in time deteriorate insulation and cause dielectric failure. Best practice is to operate insulation at least 25 percent below the corona starting voltage. Approximate 60-hertz rms corona voltage V is

$$\log \frac{V \text{ (in volts)}}{800} = (\tfrac{2}{3}) \log (100t)$$

where t = total insulation thickness in inches. This may be used as a guide in determining the thickness of insulation. With the use of varnishes that require no solvents, but solidify by polymerization, the bubbles present in the usual varnishes are eliminated, and much higher operating voltages and, hence, reduction in the size of high-voltage units may be obtained. Epoxy resins and some polyesters belong in this group. In the design of high-voltage transformers, the creepage distance required between wire and core may necessitate the use of insulating channels covering the high-voltage coil, or taping of the latter. For units operating at 10 kilovolts or higher, oil insulation will greatly reduce creepage and, hence, the size of the transformer.

Temperature and Humidity

Table 6 lists the standard classes of insulating materials and their limiting operating temperatures. Table 7 compares the properties of four high-temperature wire-insulating coatings.

Open-type constructions generally permit greater cooling than enclosed types, thus allowing smaller sizes for the same power ratings. Moderate humidity protection may be obtained by impregnating and dip-coating or molding transformers in polyester or epoxy resins; these units provide good heat dissipation but are not as good in this respect as completely open transformers.

Protection against the detrimental effects of humidity is commonly obtained by enclosing transformers in hermetically sealed metal cases. This is particularly important if very fine wire, high output voltage, or direct-current potentials are involved. Heat conductivity to the case exterior may be improved by the use of asphalt or thermosetting resins as filling materials. Best conductivity is obtained with high-melting-point silica-filled asphalts or resins of the polyester or epoxy types. Coils impregnated with these resins dissipate heat best, since voids in the heat path may be eliminated.

Immersion in oil is an excellent means of removing heat from transformers. An air space or bellows must be provided to accommodate expansion of oil when heated.

FERRORESONANT TRANSFORMERS

Ferroresonant transformers, also known as constant-voltage transformers or ferroresonant voltage regulators, make use of an alternating-current phenomenon involving at least one magnetic component in combination with a suitable capacitor to provide stabilized voltage to a load when the source voltage fluctuates. A

TABLE 6. CLASSIFICATION OF ELECTRICAL INSULATING MATERIALS†

Class	Insulating Material	Limiting Insulation Temperature (Hottest Spot) in °C
O	Materials or combinations of materials such as cotton, silk, and paper without impregnation*	90
A	Materials or combinations of materials such as cotton, silk, and paper when suitably impregnated or coated or when immersed in a dielectric liquid*	105
B	Materials or combinations of materials such as mica, glass fiber, asbestos, etc., with suitable bonding substances*	130
F	Same as for Class B	155
H	Materials or combinations of materials such as silicone elastomer, mica, glass fiber, etc., with suitable bonding substances such as appropriate silicone resins*	180
C	*	220
Over C	Materials consisting entirely of mica, porcelain, glass, quartz, and similar inorganic materials*	Over 220

* (Other) materials or combinations of materials may be included in this class if by experience or accepted tests they can be shown to have comparable thermal life at the temperature given in the right-hand column.

These temperatures are, and have been in most cases over a long period of time, benchmarks descriptive of the various classes of insulating materials, and various accepted test procedures have been or are being developed for use in their identification. They should not be confused with the actual temperatures at which these same classes of insulating materials may be used in the various specific types of equipment nor with the temperatures on which specified temperature rise in equipment standards are based.

In the above definitions the words "accepted tests" are intended to refer to recognized test procedures established for the thermal evaluation of materials by themselves or in simple combinations. Experience or test data, used in classifying insulating materials, are distinct from the experience or test data derived for the use of materials in complete insulation systems. The thermal endurance of complete systems may be determined by suitable test procedures.

A material that is classified as suitable for a given temperature may be found suitable for a different temperature, either higher or lower, by an insulation system test procedure. For example, it has been found that some materials suitable for operation at one temperature in air may be suitable for a higher temperature when used in a system operated in an inert gas atmosphere. Likewise some insulating materials when operated in dielectric liquids will have lower or higher thermal endurance than in air.

It is important to recognize that other characteristics (in addition to thermal endurance) such as mechanical strength, moisture resistance, and corona endurance are required in varying degrees in different applications for the successful use of insulating materials.

†From "Insulation class ratings," *IEEE Standard Dictionary of Electrical and Electronics Terms*, IEEE Std. 100-1972

magnetic component must have a magnetization characteristic that is sharply nonlinear, and it must operate above the "knee" of the characteristic, where the change in voltage across it is small compared to the change in current through it. A set of design equations for commonly used ferroresonant regulators and regulated rectifiers are derived in a paper by Hart and Kakalec.* These equations are for the basic open-loop type of ferroresonant voltage regulator.

A more recent development is the closed-loop, or feedback-controlled, ferroresonant voltage regultor.† Whereas the regulating function of the open-loop type depends on the stability of the frequency of the source and the magnetic characteristics of the core, the regulating function of the closed-loop type is dependent on the voltage stability of the reference in the control circuit, and also on the gain of the feedback loop. Regulation better than 0.5% for line, load, frequency, and temperature changes can be attained. The circuit of reference 15 requires the use of a magnetic component, an inductor, in the control circuit. A later development** eliminates the need for this inductor as a separate component by the use of a double-shunt feedback ferroresonant transformer.

CONVERTER/INVERTER TRANSFORMERS

The IEEE‡ defines a converter as a machine that changes alternating-current power to direct-current

power or vice versa, or from one frequency to another. It also defines an inverter as a machine, device, or system that changes direct-current power to alternating-current power.

Transformers are used in static dc-to-dc converters and dc-to-ac inverters. The core materials in these types of transformers may or may not be driven to a saturation flux density, depending on the control circuits involved. Also, the core may operate in a double-ended (bipolar) or single-ended (unipolar) mode, again dependent on the external circuitry. Bipolar is also known and defined by ASTM* as a symmetrically cyclically magnetized condition (SCM); unipolar is defined as a cyclically magnetized condition (CM). The latter has flux-current loops that are not symmetrical with respect to the origin of the axes.

Details of how to design the circuitry and the magnetics (transformer and inductor) may be found in reference 17. Details on the selection of magnetic materials for static converter and inverter transformers may be found in reference 18.

* Reference 11.

AUDIO-FREQUENCY TRANSFORMERS

Audio-frequency transformers are used mainly for matching impedances and transmitting audio frequencies. They also provide isolation from direct currents and present balanced impedances to lines or circuits.

Types of Magnetic Cores

The magnetic core for this type of transformer is usually an EI or EE type using either audio-grade silicon steel or nickel-alloy steel (refer to Tables 1 and 10). High-permeability nickel-alloy tape cores in toroidal form are used for extreme bandwidths. High-permeability ferrite cores with highly polished mating surfaces are also used to obtain wide bandwidths.

If there is no direct current in the windings, it is possible to design a small, high-quality audio transformer with a high-permeability ferrite core. Material with initial permeability above 10 000 is available. To minimize the air gap in the assembled core, the mating surfaces are ground flat and polished to a mirror finish. Because of the small core volume, when these transformers are used at low frequencies care must be taken

to avoid core saturation. The maximum flux density in a core is given by:

$$B_{max} = (3.49 \times 10^6)\, E/fNA_c$$

where,

B_{max} = maximum flux density (gauss),
E = rms volts,
f = frequency (hertz),
N = number of winding turns,
A_c = cross section of core (square inches).

Design of Audio-Frequency Transformers

Important Parameters—Important parameters are generator and load impedances, R_g and R_l, respectively; generator voltage E_g; frequency band to be transmitted; harmonic distortion; and operating voltages (for adequate insulation). See Fig. 1. Refer to the section on power-transformer design for details about physical design, cores, winding, and so forth.

Midband Frequencies—The relative low- and high-frequency responses are taken with reference to midband frequencies where

$$aE_{out}/E_g = [(1 + R_s/R_l) + R_l/a^2R_l]^{-1}$$

Low Frequencies—At low frequencies, the equivalent unity-ratio network of a transformer becomes approximately as shown in Fig. 5.

$$\text{Amplitude} = [1 + (R'_{par}/X_m)^2]^{-1/2}$$

$$\text{Phase angle} = \tan^{-1}(R'_{par}/X_m)$$

where,

$R'_{par} = (R_1R_2a^2)/(R_1 + R_2a^2)$
$R_1 = R_g + R_p$
$R_2 = R_l + R_s$
$X_m = 2\pi fL_p$

In a good output transformer, R_p, R_s, and R_c may be neglected. In input or interstage transformers, R_c may be omitted.

High Frequencies—At high frequencies, neglecting the effect of winding and other capacitances, the equivalent unity-ratio network becomes approximately as in Fig. 6.

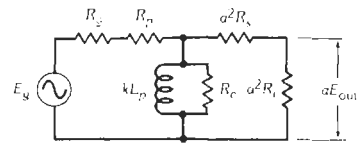

Fig. 5. Equivalent network of an audio-frequency transformer at low frequencies.

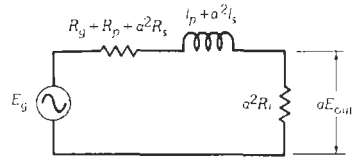

Fig. 6. Equivalent network of an audio-frequency transformer at high frequencies, neglecting the effect of the winding shunt capacitances.

$$\text{Amplitude} = [1 + (X_l/R'_{sc})^2]^{-1/2}$$

$$\text{Phase angle} = \tan^{-1}(X_l/R'_{sc})$$

where,

$R'_{sc} = R_1 + R_2a^2$,
$X_l = 2\pi fl_{scp}$,
l_{scp} = inductance measured across primary with secondary short-circuited $= l_p + a^2l_s$.

The low- and high-frequency responses are shown by the curves of Fig. 7.

If at high frequencies the effect of winding and other capacitances is appreciable, the equivalent network on a 1:1-turns-ratio basis becomes as shown in Fig. 8. In a step-up transformer, C_2 = equivalent shunt capacitances of both windings. In a step-down transformer, C_2 shunts both leakage inductances and R_2. The relative high-frequency response of this network is given by

$$\frac{(R_1 + R_2)/R_2}{[(R_1/X_c + X_l/R_l)^2 + (X_l/X_c - R_g/R_l - 1)^2]^{1/2}}$$

This high-frequency response is plotted in Fig. 9 for $R_2 = R_1$ (matched impedances), based on simplified equivalent networks as indicated. At frequency f_r $X_l = X_c$ and $B = X_c/R_l$.

Harmonic Distortion—Harmonic distortion requirements may constitute a deciding factor in the design of transformers. Such distortion is caused by either variations in load impedance or nonlinearity of magnetizing current. The percent harmonic voltage appearing in the output of a loaded transformer is given by

(Percent harmonics)
$= 100E_h/E_f = 100I_h/I_f(R'_{par}/X_m)[1 - (R'_{par}/4X_m)]$

where $100I_h/I_f$ = percent of harmonic current measured with a zero-impedance source (values in Table 8 are for a 4-percent silicon-steel core).*

* N. Partridge, "Harmonic Distortion in Audio-Frequency Transformers," *Wireless Engineer*, Vol. 19; September, October, and November 1942.

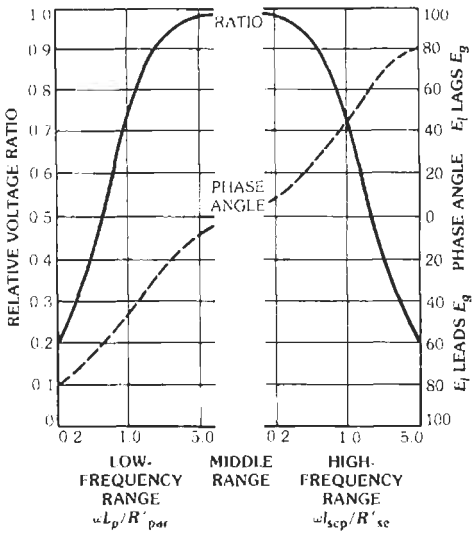

Fig. 7. Universal frequency and phase response characteristics of output transformers. (*Courtesy McGraw-Hill Book Co.*)

Insertion Loss—Insertion loss is the loss introduced into the circuit by addition of the transformer. At midband, the loss is caused by winding resistance and core loss. Frequency discrimination adds to this at low and high frequencies. Insertion loss is input divided by output expressed in decibels, or (in terms of measured voltages and impedance)

$$(\text{dB insertion loss}) = 10 \log[(E_g^2 R_l)/(4E_0^2 R_g)]$$

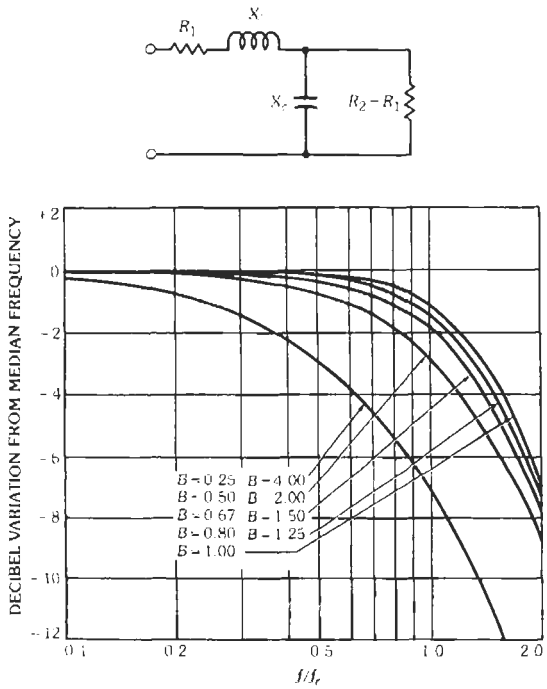

Fig. 9. Transformer characteristics at high frequencies for matched impedances. At frequency f_r, $X_l = X_c$ and $B = X_c/R_1$. (*Reprinted from* Electronic Transformers and Circuits, *by R. Lee, 2nd ed., p. 151, 1955; by permission, John Wiley & Sons, New York.*)

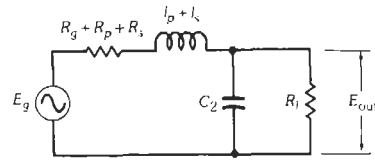

Fig. 8. Equivalent network of a 1:1-turns-ratio audio-frequency transformer at high frequencies when effect of winding shunt capacitances is appreciable.

Impedance Match—For maximum power transfer, the reflected load impedance should equal the generator impedance. Winding resistance should be included in this calculation: For matching

$$R_g = a^2(R_l + R_s) + R_p$$

Also, in a properly matched transformer

$$R_g = a^2 R_l = (Z_{oc} \times Z_{sc})^{1/2}$$

where,

Z_{oc} = transformer primary open-circuit impedance,
Z_{sc} = transformer primary impedance with secondary winding short-circuited.

If more than one secondary is used, the turns ratio to match impedances properly depends on the power delivered from each winding.

$$N_s/N_p = [(R_n/R_g)(W_n/W_p)]^{1/2}$$

Example: Using Fig. 10

$$N_2/N_p = [(10/600)(10/16)]^{1/2} = 0.102$$
$$N_3/N_p = [(50/600)(5/16)]^{1/2} = 0.161$$
$$N_4/N_p = [(100/600)(1/16)]^{1/2} = 0.102$$

WIDEBAND TRANSFORMERS

Wideband transformers operate over a range of one to three or more frequency decades without significant attenuation. The frequency band of interest can be considered to lie between 20 kHz and 1 GHz. This frequency range can be broken into two subranges: carrier frequency (20 kHz to 20 MHz) and high frequency (20 MHz to 1 GHz). Wideband transformers are used to provide impedance matching, voltage or current ratios, dc isolation, connection of balanced to unbalanced circuits, power splitting, and phase inversion.

Maximum bandwidth is achieved when the ratio of shunt inductance to leakage inductance is maximized, neglecting the effect of shunt capacitance. To increase this ratio, we must use the highest μ_e possible and make the ratio of winding width to core length approach unity. The latter occurs for a toroidal core, but is smaller for spool-wound structures. Modern wideband transformers utilize ferrite cores. Some commonly used core shapes are EE, EI, EP, RM, pot, Q, toroid, and X.

Core-Material Considerations

Carrier-frequency transformers often use cores of MnZn ferrite having material permeability (μ) in the 1000 to 20 000 range. High-frequency transformers sometimes use NiZn ferrite cores having material permeability as low as 15, especially when low core loss is important. Most high-frequency transformers operate at relatively low impedance levels. To obtain effective permeability above about 10 000, either toroidal cores or split cores having extremely small air gaps are needed. Highly polished, clean, and coplanar core mating surfaces can achieve air gaps as small as 0.2 μm. Even at such small air gaps, μ_e can be considerably reduced from μ and is given by:

$$\mu_e = l_e\mu/[l_e + (\mu - 1)l_g]$$

where,

μ_e = effective permeability,
μ = material permeability,
l_e = effective core magnetic path length,
l_g = length of air gap.

Electrical loss in ferrite material is usually expressed as a relative loss coefficient, $\tan \delta/\mu = \omega L_p/R_p$. It has three components: hysteresis loss, eddy-current loss, and residual loss. The effect in transformer cores can be more conveniently expressed as a parallel resistance per turn squared in ohms (R_c/N^2) and plotted as a function of frequency. Ferrite core loss is a frequency-dependent nonlinear resistance; hence it cannot be equalized easily by a simple reactive network, should its effects be significant.

The Curie temperature of the core material can be a consideration when transformers are operated at high ambient temperatures. High-permeability materials tend to have lower Curie temperatures. Core temperature and disaccommodation factors are usually not as critical in wideband transformers as in stable filter-class inductors.

Design Example for Carrier Frequencies

Assume the following problem: Design a 75-to-150-ohm unbalanced transformer to operate over a frequency range of 50 kHz to 10 MHz. In-band loss shall be less than 0.1 dB, and loss shaping at band ends shall be less than 0.1 dB. The transformer will not carry any direct current and should be small in size (less than 0.75 in^2 in area and less than 0.60 in high).

The initial step is to determine the minimum inductance for low-frequency loss shaping.

$$\text{Loss in dB} = 10 \log_{10} [1 + (R/\omega L_p)^2]$$

where,

$R = (R_g R')/(R_g + R')$,
R_g = 75 ohms,
R_l = 150 ohms,
$R' = a^2 R_l$,
a = turns ratio = N_p/N_s

For a loss of 0.1 dB maximum

$$1 + (37.5/\omega L_p)^2 = 10^{0.1/10}$$

From this, it is found that ωL_p = 245.7 ohms minimum at 50 kHz, and L_p therefore must be greater than 0.782 millihenries.

A minimum value for L_p could also be determined from a return-loss requirement:

$$\text{Return loss in dB} = 10 \log_{10} [1 + (2\omega L_p/R')^2]$$

The minimum inductance previously selected for loss shaping would provide a return loss relative to R' of only 16.4 dB. If a greater return loss were specified, L_p minimum would have to be larger. Return-loss requirements for wideband transformers frequently cause more severe constraints than transformer loss shaping. Transformer loss is related to return loss by the expression:

$$\text{Transformer loss} = -10 \log_{10} (1 - 10^{-RL/10})$$

The expression is applicable when the equivalent circuit is considered to contain pure reactances.

The EP13 core is a small, efficient core that meets the size constraints of this example. It is available with an A_L value of 3500 nH/N^2. With no direct current, no air gap is required between the core halves, and the full 3500 nH/N^2 may be utilized.

$$N_p = (782/3.5)^{1/2} = 14.9 \text{ turns minimum}$$
$$Ns/Np = (150/75)^{1/2} = 1.41$$

Primary turns of 17 and secondary turns of 24 will closely approximate the 1.41 ratio. This number of primary turns results in a minimum shunt inductance of 1.012 millihenrys ($17^2 \times 3.5$ μH/N^2), providing an inductance margin to allow for variations in assembly.

High-frequency loss shaping is controlled by both leakage inductance and effective shunt capacitance. Interleaved windings reduce leakage inductance but cause increased shunt capacitance. For a low-impedance transformer, the leakage inductance dominates, while in a high-impedance transformer the shunt capacitance is controlling. Windings usually can be oriented to balance and minimize the total contributions to shaping loss from leakage inductance and shunt capacitance. As a starting point, allocate half the requirement to each effect; thus, assume 0.05 dB caused by the leakage inductance.

The leakage inductance of the primary winding with the secondary winding shorted (l_{sc}) is that of both primary and secondary windings referred to the primary.

$$\text{Loss in dB} = 10 \log_{10} [1 + (\omega l_{sc})^2/(R_g + R')^2]$$
$$1 + (\omega l_{sc}/150)^2 = 10^{0.05/10}$$
$$\omega l_{sc} = 16.14 \text{ ohms maximum}$$
$$l_{sc} = 0.257 \ \mu\text{H max. at 10 MHz}$$

By singly interleaving the secondary around the primary, leakage can be reduced to a sufficiently low value. The primary is a single layer of 34 AWG wire wound as a parallel pair to achieve a smooth full single layer. Each secondary section is wound as a single layer of 31 AWG wire. Two layers of 2.5-mil Mylar tape are applied between windings. From the winding geometry, the leakage inductance referred to the primary is calculated to be 0.18 microhenry.

The loss contribution from effective shunt capacitance is also allowed to be 0.05 dB.

$$\text{Loss in dB} = 10 \log_{10}[1 + (\omega RC)^2]$$
$$1 + (\omega RC)^2 = 10^{0.05/10}$$
$$\omega RC = 0.1076$$
$$C = 45.7 \text{ pF max. at 10 MHz}$$

The direct capacitance between each secondary interleaved winding and the primary is calculated to be 32.8 pF. Each is reflected to the primary as (C direct)/3 with appropriate corrections made for turns ratio, relative winding direction, and reversing or nonreversing circuit connection. The effective shunt capacitance is calculated to be less than 40 pF.*

Midband loss results from both core and copper losses. Core loss (R_c) is a minimum of 22 ohms/N^2. Therefore, R_c is ($17^2 \times 22$), or 6358 ohms minimum.

$$\text{Loss in dB} = 20 \log_{10} (1 + R/R_c)$$
$$= 0.051 \text{ dB max.}$$

The series ac resistances of the primary and secondary windings are R_p and a^2R_s when referred to the primary winding. The value of R_p is calculated to be 0.177 ohm maximum, and the value of a^2R_s is calculated to be 0.062 ohm maximum. These values lead to a copper loss of

$$\text{Loss in dB} = 20 \log_{10} [1 + (R_p + a^2R_s) / (R_g + R')]$$
$$= 0.014 \text{ dB max.}$$

The total midband loss should be less than 0.065 decibel.

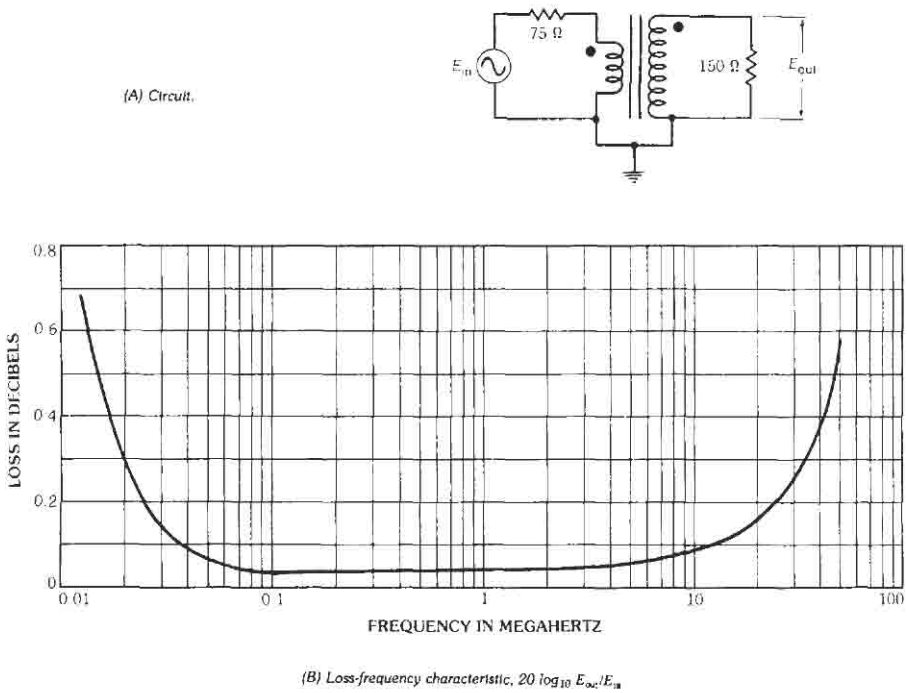
This transformer design was realized. The loss-frequency characteristic is shown in Fig. 11B. Loss shaping at the band ends, 50 kHz and 10 MHz, is 0.04 dB and 0.07 dB, respectively. Midband loss is 0.035 dB.

High-Frequency Wideband Transformers

Circuit impedances are usually low at high frequencies (20 MHz to 1 GHz). Transformer designs typically require only a few turns because shunt inductances are small and leakage inductances must be kept low. Transformers are small in size, which is compatible with low leakage inductance and low effective shunt capacitance. Winding dc resistances are usually negligible, but core loss can be important for low turns and some core materials. Small toroidal cores are often used because of their ability to achieve low leakage inductance.

Transmission-line techniques can be applied to transformer windings at high frequencies by tightly coupling the primary and secondary windings to form a transmission line having a particular characteristic impedance. The overall characteristic impedance (Z) of a transformer is approximately equal to $(Z_pZ_s)^{1/2}$. This impedance is matched as nearly as possible to a transmission-line winding whose characteristic impedance (Z_0) is equal to $(L/C)^{1/2}$. In this expression, L is the inductance of the transmission line when the far ends are shorted, and C is the effective capacitance of the transmission line with the far ends open. Windings are typically wound tightly coupled as parallel or twisted groups of

* Reference 19.



(A) Circuit.

(B) Loss-frequency characteristic, 20 $\log_{10} E_{out}/E_{in}$

Fig. 11. Response of transformer in example.

two, three, or four wires to obtain a particular ratio. Only a few integer turns ratios are easily obtainable; ratios of 1:1, 1:2, and 1:3 are the most common. Tightly coupled windings produce low leakage inductance. By controlling wire size, wire insulation, and degree of twisting, various uniform characteristic impedances can be obtained. Values of Z_0 between 50 and 100 ohms are most easily made.

Autotransformers provide very low leakage inductances and lend themselves well to a distributed transmission-line analysis. They are preferred in applications where direct-current isolation of windings is not a factor.

Use of NiZn cores, which have lower permeability than MnZn cores, will restrict low-end response considerably. However, NiZn cores usually have lower core loss at high frequencies, which is important when only a few turns are required.

PULSE TRANSFORMERS

Pulse transformers are designed to transmit rectangular waves or trains of pulses while maintaining as closely as possible the original shape. Functions performed by pulse transformers are similar to those of broadband analog transformers. Examples include impedance conversion, dc isolation, coupling between balanced and unbalanced circuits, voltage transformation, and phase inversion. Analytical design is usually done in the time domain instead of the frequency domain, and transient considerations become important.

Pulse waveshapes contain a wide range of frequencies. Lower frequencies relate to pulse duration and repetition rate, while higher frequencies determine the shape of pulse edges. Core and winding parameters limit both extremes of the frequency response of a transformer. Fig. 12 portrays a typical transformer output pulse compared with the corresponding input pulse. (In the strictest sense, pulse rise and decay times are measured between the 10- and 90-percent values; width is measured between the 50-percent values.) Pulse transformers can be analyzed by considering the leading edge, top, and trailing edge of the pulse separately. Fig. 13 illustrates simplified equivalent circuits applicable to each time interval.

As shown in Fig. 13A, leading-edge reproduction is controlled by leakage inductance, L_{scp}, winding capacitances C_p and C_s, and external impedances. Analysis for step-up and step-down transformers varies slightly, as shown in Figs. 13B and 13C. Leakage inductance and winding capacitance must be minimized to achieve a sharp rise; however, output voltage may overshoot input voltage (Fig. 12), and oscillation may be encountered where very abrupt rise times are invoked. Rise time T_r may be related to the high-frequency 3-dB loss point f_h of a wideband analog transformer as follows:*

$$f_h = 0.382/T_r$$

* Reference 20.

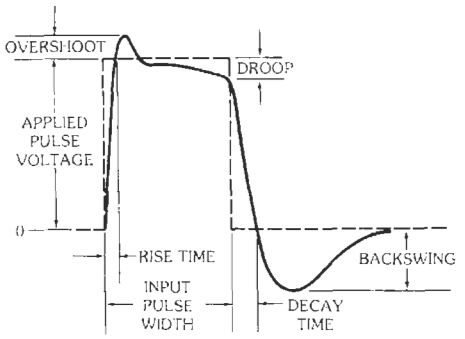


Fig. 12. Output pulse shape.

A graphical solution of rise time may be found in additional references.*

Pulse-top response (droop, Fig. 12) depends on the magnitude of open-circuit inductance L_p and external impedances as shown in Fig. 13D. A greater magnitude of L_p results in reduced droop. The circuit is similar to the low-frequency equivalent circuit for wideband analog transformers. However, the value of open-circuit inductance is proportional to the average slope of the part of the *B-H* loop traversed and may differ when measured under continuous-wave and pulse conditions. A CW input signal generally is sinusoidal, and the core *B-H* loop traversed is symmetrical about the origin. As shown in Fig. 14A, a unipolar pulse traverses a smaller, asymmetrical portion of the *B-H* loop, resulting in a lower average slope. Fig. 14B shows the *B-H* loop generated with bipolar pulse excitation (see reference 20).

Trailing-edge response is controlled by the dissipation of energy stored in the transformer after the supporting pulse voltage has been removed. It depends on the open-circuit inductance, secondary winding capacitance, and external impedances as shown in Fig. 13E. A lower capacitance results in a faster rate of voltage decay. Negative backswing is proportional to the magnitude of the transformer magnetizing current. A graphical analysis of trailing-edge response can be found in reference 10.

Choice of a pulse-transformer core is usually determined by the *Et* product, which refers to the pulse voltage *E* and the duration *t* in microseconds. The core should not saturate, so *Et* is proportional to the flux swing traversed on the *B-H* loop just below saturation and to core cross-sectional area.†

Ferrite materials, specified in terms of pulse excitation, are typically used for pulse-transformer cores. Gaps may be used to provide greater flux swing for unipolar pulse applications. Core configurations may be toroidal where self-shielding and low leakage inductance are paramount, "E" shape for typically lower-cost bobbin winding techniques, and cup-core or RM type for greater magnetic efficiency with bobbin windings.

MAGNETIC-CORE REACTORS

The purpose of a reactor is to introduce reactance into a circuit. Inasmuch as this reactance is inductive, this device is also called an inductor. Reactors consist of one or more windings and may or may not have a

* Reference 10.
† Reference 10.

(B) Bipolar pulse.

Fig. 14. Traverses of *B-H* loop.

magnetic core. This section is concerned with those reactors that have magnetic cores. A filter reactor is defined* as ". . . a reactor used to reduce harmonic voltage in alternating-current or direct-current circuits."

Rectifier-Filter Reactors

The rectifier-filter reactor is used mainly in direct-current power supplies to smooth the output ripple voltage. It carries all the direct current of the rectifier filter and must be designed not to saturate with direct current in the reactor winding.

Optimum design data may be obtained from Hanna curves, Fig. 15. These curves relate direct-current energy stored in the core per unit volume, LI_{dc}^2/V, to magnetizing field NI_{dc}/l_c (where l_c = average length of flux path in core), for an appropriate air gap. Heating is seldom a factor, but direct-current-resistance requirements affect the design; however, the transformer equivalent volt-ampere ratings of chokes given in Table 9 should be useful in determining their sizes. This is based on the empirical relationship $(VA)_{eq} = 188LI_{dc}^2$.

As an example, take the design of a choke that is to have an inductance of 10 henrys with a superimposed direct current of 0.225 ampere and a direct-current resistance ≤ 125 ohms. This reactor is to be used for suppressing harmonics of 60 hertz, where the alternating-current ripple voltage (second harmonic) is about 35 volts.

(**A**) $LI^2 = 0.51$. Based on the data of Table 9, try a 4% silicon-steel core, type EI-125 lamination, with a core buildup of 1.5 inches.

(**B**) From Table 9: $V = (11.4/1.25) \times 1.5 = 13.7$ in^3, $l_c = 7.50$, $LI^2/V = 0.51/13.7 = 0.037$. From Fig. 15: $NI/l_c = 88$ ampere-turns per inch, $N = 88l_c/I = (88 \times 7.5)/0.225 = 2930$ turns, $l_g/l_c = 0.0032$, the length of air gap $l_g = 0.0032 \times 7.5 = 0.024$ inch.

(**C**) From Table 9, coil (MLT) = (7.21 + 0.5)/12 = 0.643 foot, and length of coil = $N \times$ (MLT) = 2930 × 0.643 = 1884 feet. Since the maximum resistance is 125 ohms, the maximum ohms/ft = 125/1884 = 0.0663, or 66.3 ohms/1000 ft. From Table 5, the nearest size of wire is No. 28.

(**D**) Now see if 2930 turns of No. 28 single-insulated wire will fit in the window space of the core. (Determine turns per layer, number of layers, and coil-build, as explained in the design of power transformers.)

(**E**) This is an actual coil design; in case the lamination window space is too small (or too large), change stack of laminations, or size of laminations, so that the coil meets the electrical requirements and the total coil-build ≈ 0.85 to 0.90 × (window width).

Note: To allow for manufacturing variations in permeability of cores and resistance of wires, use at least 10-percent tolerance.

Swinging reactors are used where the direct current in the rectifier circuit varies. These reactors are designed to saturate under full load current while providing adequate inductance for filtering. At light load current, higher inductance is available to perform proper filtering and prevent "capacitor effect." The equivalent reactor size is determined from:

$$LI^2 = (L_{max} \times L_{min})^{1/2} I_{dc(max)}^2$$

The design is similar to that of a normal reactor and is based on meeting both L and I_{dc} extremes. The typical swing in inductance is 4:1 for a current swing of 10:1.

AC-Filter Reactors

In the rectifier-filter reactor, the amount of ac flux in the magnetic core is small in comparison to the dc flux. With the ac-filter reactor, there is no dc flux, and the ac flux is large. In the rectifier-filter reactor, the direct current through the coil causes the core to operate in a unipolar, or CM, mode, which necessitates the use of an air gap as calculated from the Hanna curves. In the ac-filter reactor, the core operates in a bipolar, or SCM, mode, but the peak values of the alternating current are large, which also necessitates the use of an air gap in the core to prevent it from saturating.

A method for designing ac-filter reactors may be found in Chapter VIII of reference 18.

MAGNETIC-CORE INDUCTORS

Magnetic-core inductors used in frequency-selective filters must provide a specific inductance value, a high

L = calculated inductance based on turns and magnetic-core constant
C_d = distributed capacitance of winding
R_w = copper losses in winding
R_c = magnetic-core losses reflected in series with winding
Q = quality factor $= \omega L/(R_w + R_c)$, $\omega = 2\pi f$

Fig. 16. Equivalent network of an audio filter coil.

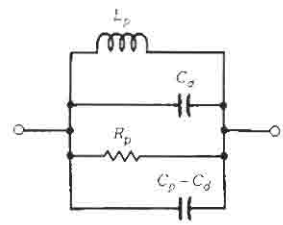
Q value (ratio of reactance to effective resistance), and stable parameter values in the operating environment. The inductance value depends on the core inductance coefficient, $A_L = L/N^2$, and the number of turns in the winding. The A_L values for specific cores are a function of the effective permeability, μ_e, and the core geometry; core manufacturers tabulate these data in their catalogs. Achieving high Q is more complex. The inductor is modeled with a set of independent loss tangent ($1/Q$) values that together describe all the loss mechanisms for the inductor. An attempt is made to minimize the major contributors at a given frequency. At the same time, the designer must also attempt to minimize distributed capacitance, μ_e, and mechanical stresses on the cores in order to promote stable performance. The completed structure must be mechanically sound to minimize the effects of shock and vibration on the parameter values.

Audio-Frequency Inductors

Audio-frequency inductors operate in the frequency band of about 200 Hz to 20 kHz. At the lowest frequencies, laminated cores are generally used, although recent designs have used ferrite. Where low-cost, nonadjustable inductors are needed in the range 300 Hz to 10 kHz, permalloy powder toroids are often used. For frequencies above 10 kHz, or for applications requiring adjustable inductors, ferrite pot cores are preferred (see Table 10). Pot-core inductors are discussed in the section on precision adjustable inductors.

To design stable, high-Q inductors, it is necessary to understand the equivalent circuit of an inductor (Fig. 16) and its application to the parallel-tuned mesh (Fig. 17) and series-tuned mesh (Fig. 18). The distributed capacitance, C_d, is very important in series-tuned meshes, because it affects both the inductance and the Q. If possible, it is desirable to keep the distributed capacitance to one tenth of the tuning capacitance, C_s. Means of minimizing C_d are discussed in succeeding paragraphs.

The copper loss in the coil winding, R_w, is made up of the dc resistance of the wire and the eddy-current losses generated in the winding by stray flux from the core that cuts the winding. This eddy-current loss can be minimized at high frequencies by dividing the wire into many small strands. This type of wire is called litz wire.



L_p = equivalent parallel inductance
R_p = equivalent parallel resistance
C_d = distributed capacitance of winding
C_p = parallel tuning capacitance
Q_p = effective parallel Q
$L_p = L_s$ for $Q > 10$
$R_p = (R_w + R_c)(Q^2 + 1)$, for $Q_p = Q$

Fig. 17. Parallel-tuned mesh.

The loss due to the magnetic core reflected in series with the coil winding is represented by R_c. The calculation of this factor is discussed in succeeding paragraphs.

Laminated-Core Audio-Filter Inductors—Externally, a laminated-core audio-filter inductor resembles a transformer. The laminations are usually "F" in shape to create an air gap in the center leg of the core. For high Q, nickel-steel laminations either 14 or 6 mils thick are used (Table 10). The air gap in the core reduces the effective permeability, μ_e, which reduces the effective core losses and stabilizes the inductance.

The winding is usually layer wound as described in the section on methods of winding transformers. The techniques for reducing capacitance described in that section can be used to reduce the distributed capacitance of the winding. A detailed method for designing this type of inductor can be found in *High Q Reactors for Low Frequencies*, Bulletin A10, Magnetic Metals Co., Camden, N.J.

Toroidal Core Types—Toroidal coils are doughnut shaped, with the winding covering the entire core. The core is usually made of pressed molybdenum-permalloy powder, although some cores are made of carbonyl powdered iron for very-high-frequency applications (Table 10).

L_s = equivalent series inductance
R_s = equivalent series resistance
C_s = series tuning capacitance
Q_s = effective series Q

For $Q > 10$
$L_s = L/(1 - \omega^2 L C_d)$
$R_s = (R_w + R_c)/(1 - \omega^2 L C_d)^2$
$Q_s = Q(1 - \omega^2 L C_d)$
$L = L_s/(1 + \omega^2 L_s C_d)$

§ See Fig. 19.

Permalloy-powder toroidal cores are made in various sizes from 0.140 to 2.25 inches OD and with ten material compositions to change the effective permeability, μ_e, from 14 to 550 for use at different frequency ranges.

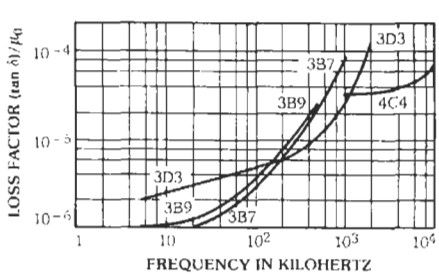

Fig. 19. Loss factor as a function of frequency. (*From* Ferrite Pot Cores, *Bulletin 220-C, Ferroxcube Corp. of America, Saugerties, N.Y.*)

Fig. 20 gives the Q-vs-frequency characteristics of four sizes of toroids with five different effective permeabilities. In addition, the inductance in millihenrys per 1000 turns, A_L, is given for each size of core.

Fig. 21 gives the number of turns of various sizes of enameled wire that can be placed on the toroid as well as the mean length of turn (MLT) for the respective toroidal cores of Fig. 20. These curves are based on a single winding wound with 180° traverse using commercially available toroidal winding machines.

Fig. 22 gives the core-loss factor in ohms per millihenry for various effective permeabilities and frequencies. This factor is multiplied by the inductance in millihenrys to determine R_c. The curves are based on a magnetic induction of 100 gauss. For other levels, R_c can be calculated from the Legg coefficients given in Table 10.

Table 11 gives an approximate value of distributed capacitance C_d that can be expected for the different sizes of cores and winding methods.

When maximum temperature stability of inductance is required, most manufacturers of permalloy toroidal cores can provide various types of stabilized cores. The stabilizations most used are listed in Table 12.

Since the distributed capacitance changes rapidly with temperature, it should be kept to a minimum to avoid changing the inductance.

Fig. 23 illustrates the most common methods of winding toroids. In Fig. 23A the toroid is rotated over a 360° arc for every layer of the winding (called 360° traverse winding). In Fig. 23B, the toroid is rotated over a 180° arc for each layer until half the coil is wound. The other half of the winding is similarly wound. This is called 180° traverse winding. In Fig. 23C the toroid is rotated over only 90° until one quarter is wound. The other three quarters are wound in the same manner. This winding method is called 90° traverse or quadrature winding.

Since most toroid cores are made with a tolerance of ±8% on the A_L (millihenrys/1000 turns), it is usually necessary to adjust the inductance after winding. This is done by winding about 5% more turns than calculated on the core and removing turns until the inductance reaches the desired value. Coils for series-tuned meshes should be adjusted to the resonance frequency of the mesh with the tuning capacitor in series to eliminate the effect of distributed capacitance. Coils for parallel tuned meshes should be adjusted at low frequency in such a way that the tuning capacitance is 1000 times the distributed capacitance for 0.1% accuracy.

Toroidal Core Design Example—It is desired to design an inductor of 100 millihenrys for a series-tuned mesh that resonates at 10 kilohertz. The Q must be 150 minimum and the size as small as possible.

(**A**) Consulting the Q curves of Fig. 20B shows that a 1.06-inch OD toroid core with $\mu_e = 125$ is the smallest core that will meet the Q requirements. This has an A_L value of 157 millihenrys per 1000 turns.

(**B**) From Table 11, $C_d \approx 200$ picofarads. Calculate L from Fig. 18:

$$L = \frac{L_s}{1 + \omega^2 L_s C_d}$$

$$= \frac{100}{1 + (2\pi 10\,000)^2 \times 0.1 \times 200 \times 10^{-12}}$$

$$= 92.68 \text{ millihenrys}$$

(**C**) Compute the number of turns required from

$$N = 1000(L_{\text{millihenrys}}/A_L)^{1/2}$$
$$= 1000(92.68/157)^{1/2}$$
$$= 768 \text{ turns}$$

(**D**) Fig. 21 gives the maximum size of wire and mean length of turn. Use No. 30 heavy enameled wire for 768 turns. On a 1.06-inch OD core the (MLT) is 1.57 inches.

(**E**) Calculate R_w from (MLT), N, and Table 5.

$$R_w = \frac{(\text{MLT}) \times N \times \text{ohms/1000 ft}}{12\,000}$$

$$= \frac{1.57 \times 768 \times 103.2}{12\,000}$$

$$= 10.36 \text{ ohms}$$

(**F**) Calculate R_c from R/L values of Fig. 22 for $\mu_e = 125$ and $f = 10$ kilohertz. $R/L = 0.23$ ohm/millihenry. $R_c = (R/L)L = 0.23 \times 92.68 = 21.32$ ohms.

(**G**) Calculate Q per Fig. 16.

$$Q = \frac{\omega L}{R_w + R_c} = \frac{2\pi 10 \times 92.68}{10.36 + 21.32} = 183.8$$

(**H**) Calculate Q_s per Fig. 18.

$$Q_s = Q(1 - \omega^2 L C_d)$$
$$= 183.8[1 - (2\pi 10\,000)^2 \times 0.09268 \times 200 \times 10^{-12}]$$
$$= 170.4$$

This should approximate the measured Q.

(**I**) The coil is wound using 360° traverse winding, and, since no special temperature stability is required, a standard unstabilized core is used.

Precision Adjustable Inductors

Pot Cores—Filter-class inductors are precision, adjustable devices designed to provide high Q values at a particular frequency. Although Q is often the greatest concern, the temperature and time stability are usually also important. While round pot-core structures are very popular, other core shapes such as RM, X, and Q are used to improve packing densities or magnetic performance.

A cross-section of a typical pot-core inductor is shown in Fig. 24. The two core halves are clamped or cemented around a bobbin that contains the winding. The ceramic ferrite cores are chosen specifically for particular performance characteristics. A wide range of permeabilities, loss characteristics, and stability performance exists. The information is available in ferrite-supplier catalogs.

The cores have a recessed center post so that when they are mated, an air gap exists. Although the gap reduces the effective permeability, μ_e, more importantly it reduces the core loss and temperature coefficient of inductance. The gap is used to control the A_L value (in nanohenrys per turn squared), a most important inductor design parameter. Inductors operating at low frequencies have relatively high values of μ_e and A_L. As the operating frequency is increased, lower values of these parameters usually are adequate.

Loss Mechanisms and Q—Inductor Q, the ratio of reactance to effective resistance at a given frequency, is controlled by four loss factors: core loss, winding resistance loss, capacitance loss, and proximity-effect loss. These are expressed in terms of loss tangents. Inductor Q is the reciprocal of the sum of these four loss tangents. Many inductor-loss equations are given by Snelling,* but only four equations are needed in practice. Optimization equations are given by Banzi.†

Most manufacturers of inductor cores list the core-material loss, tan δ_m, which has been normalized with respect to the core-material permeability μ_i. To calculate the effective core-loss tangent, it is necessary only to multiply the advertised value by the effective permeability, μ_e, listed separately in the core literature for specific geometries and inductance factors (A_L values). The effective magnetic core-loss equation is

$$\tan \delta_{m_e} = (\tan \delta_m)(\mu_e/\mu_i) = \mu_e/\mu_i Q_m$$

where Q_m is the core-material Q. While it is apparent that a low ratio of μ_e/μ_i (implying a large air gap) would reduce the effective core loss, a large gap results in higher winding losses because of flux fringing at the gap.

Although coils generally have associated capacitances that are distributed in nature, a single lumped capacitance shunting the winding may be considered a sufficiently accurate model for most Q calculations. The capacitive loss is the product of a ratio and a constant, as shown in the equation below. The ratio is the parallel winding capacitance, C_p, divided by the capacitance,

TABLE 12. STABILIZATION OF TOROIDAL CORES

Identification	Inductance Temperature Stability (%)	Temperature Range (°C)
B	±0.1	+13 to +35
D	±0.1	0 to +55
W	±0.25	−55 to +85

$$\tan \delta_c = (C_p/C_r)K_D$$

Experimental work has shown the value of K_D to be 0.02 for nylon-served litz wire (groups of individually insulated wires twisted into a bundle that is then wrapped in nylon yarn) and 0.01 for polyurethane-coated solid wire. It is not necessarily advantageous to use solid wire to minimize capacitive losses. For multiple-layer windings, litz wire usually results in lower capacitance than does solid wire because litz-wire insulation provides more separation between layers. The high loss associated with the nylon serving, then, tends to be offset by the lower value of C_p. For single-layer windings, though, there may be very little difference in capacitance between the two wire types, depending on the number of turns used, so that here solid wire presents an advantage in minimizing capacitive loss.

The winding-resistance loss tangent, tan δ_r, is the ratio of the ac resistance of the winding, R_{ac}, to the coil reactance, ωL, at the frequency of interest:

$$\tan \delta_r = R_{ac}/\omega L$$

Because the dc resistance can be determined, it would be convenient to calculate the ac resistance in terms of the dc resistance. The skin-effect factor, SEF, is the ratio of ac to dc resistance. The SEF versus d/Δ (wire diameter/skin depth) characteristic is used in conjunction with the skin depth versus frequency characteristic. These characteristics are plotted by Snelling.* The ac resistance is thus the dc resistance times SEF. This can be rewritten in more useful terms:

$$\tan \delta_r = [K_R\ (N/n)/\omega L](\text{SEF})$$

† Reference 1.

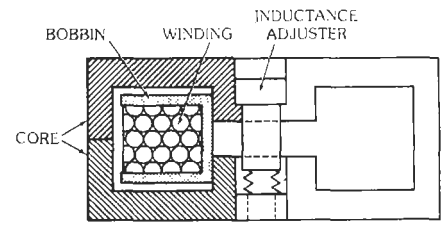

Fig. 24. Typical pot-core coil.

where,

K_R = dc resistance per strand turn of wire,
N = number of turns of wire,
n = number of wire strands,
SEF = skin-effect factor.

The proximity-effect loss-tangent formula is

$$\tan \delta_{pe} = K_E f N n d^4 \text{ (PEF)}/A_L$$

where,

K_E = a constant that is geometry dependent,
f = frequency of operation in hertz,
N = number of winding turns,
n = number of strands of wire,
d = bare diameter of an individual strand of wire in millimeters,
PEF = proximity-effect factor, which is frequency dependent,
A_L = inductance factor in nH/N^2

The value of K_E depends on the winding configuration and core type and must be determined experimentally; it varies slowly with frequency. Snelling gives typical values of K_E as well as means for obtaining PEF.*

Combining these effects:

$$Q = 1/(\tan \delta_{m_e} + \tan \delta_c + \tan \delta_r + \tan \delta_{pe})$$

For details see reference 21.

Inductor Q values as high as 1000 are obtainable with proper design and at frequencies in the range around 100 kHz. Modern designs use cores with a high A_L value and low mean length of turn to achieve high Q; unfortunately, this choice leads to higher effective permeability, which adversely affects stability of inductance.

Stability Considerations—Temperature stability of inductance may be critical for a precision adjustable inductor. The inductor is part of a tuned LC circuit in which the temperature coefficient (TC) of the inductor may be compensated by that of the capacitor to give a net TC near zero. The TC of an inductor is roughly proportional to the effective permeability of its core. Core temperature factors as low and tight as 0.7 ± 0.3 ppm/°C near room temperature are available. With an effective permeability of 100 for its core, an inductor would have a TC of 70 ± 30 ppm/°C. Ferrite cores exhibit magnetostrictive effects, so care must be taken to avoid stress on the core halves when bonding or clamping them together. A properly designed adjuster assembly is also critical for good temperature stability.

A slow decrease of inductance value with time, calling aging, is characteristic of ferrite-cored inductors. Described in terms of a disaccommodation factor, this aging usually manifests itself as a linear decrease in inductance per decade of time, on a semilog plot. Manufacturers usually measure disaccommodation factor between 10 and 100 minutes, but an extrapolation to years of life is risky, since the longer-term slope may increase above that measured over a few hours. Inductor aging of less than 0.5% over a 20-year life is achievable.

Inductance variation is usually obtained by the use of a threaded ferrite adjustment mechanism in the center hole of the core. As the ferrite slug bridges the air gap in the center leg of the core (Fig. 24), μ_e is increased, and hence inductance increases. In many applications, an adjustment range of greater than ± 8%, with a sensitivity of 0.1%, is possible. Most ferrite inductor cores have preadjusted air gaps that result in an A_L tolerance of ±3%; thus guaranteed inductor adjustment ranges of about ±2% are practical, even with a small number of turns.

14 Power Electronics—Rectifiers, Filters, and Power Supplies

Fred G. Turnbull
Revised by Ondrej Pauk

CHARACTERISTICS OF POWER SEMICONDUCTOR DEVICES

This section briefly describes the terminal properties of various types of power semiconductor devices to aid in understanding their operation in power conversion equipment. Power semiconductor devices discussed are rectifiers, including fast recovery and Schottky; bipolar, field-effect, and insulated-gate transistors; thyristors, MOS-controlled thyristors, and triacs; and voltage transient clippers.

Rectifiers

Voltage and Current Ratings—Silicon-rectifier ratings* are generally expressed in terms of reverse-voltage ratings and of mean-forward-current ratings in a half-wave circuit operating from a 60-hertz sinusoidal supply and into a purely resistive load.

There are three reverse-voltage ratings of importance:

Peak transient reverse voltage	V_{RM}
Maximum repetitive reverse voltage	$V_{RM(\text{rep})}$
Working peak reverse voltage	$V_{RM(\text{wkg})}$

Peak transient reverse voltage (V_{RM}) is the rated maximum value of any nonrecurrent surge voltage, and this value must not be exceeded under any circumstances, even for a microsecond. Maximum repetitive reverse voltage ($V_{RM(\text{rep})}$) is the maximum value of reverse voltage that may be applied recurrently, e.g., in every cycle, and will include any circuit oscillatory voltage that may appear on the sinusoidal supply voltage. Working peak reverse voltage ($V_{RM(\text{wkg})}$) is the crest value of the sinusoidal voltage of the supply at its maximum limit. The manufacturer generally recommends a $V_{RM(\text{wkg})}$ that has an appreciable safety margin in relation to the V_{RM} to allow for the commonly experienced transient overvoltages on power mains.

Three forward-current ratings are similarly of importance:

Nonrecurrent surge current	$I_{FM(\text{surge})}$
Repetitive peak forward current	$I_{FM(\text{rep})}$
Average forward current	$I_{F(\text{av})}$

Silicon diodes have comparatively small thermal mass, and care must be taken to ensure that short-term overload currents are limited. The nonrecurrent surge current is sometimes given as a single value that must not be exceeded at any time, but it is more generally given in the form of a graph of permissible surge current versus time. It is important to observe whether the surge-current scale is marked in peak, rms, or average value for the data to be correctly interpreted. The repetitive peak forward current is the peak value of the forward current reached in every cycle and excludes random peaks caused by transients. Its relation to the average forward current depends on the circuit used and on the load that is applied. For example, the repetitive peak is about three times the average for a half-wave or bridge circuit working into a resistive load; it may be many times greater when the same circuits work into capacitive loads.

Forward Characteristics—The manufacturer generally supplies curves of instantaneous forward voltage versus instantaneous forward current at one or more operating temperatures; a typical characteristic is shown by the solid curve in Fig. 1. Such curves are not exact for all rectifiers of a given type but are subject to normal production spreads. They are of particular importance in determining the power dissipated by the rectifier under given working conditions.

Calculation of power dissipation from the voltage–current curves need not be done in every instance, since the manufacturer gives curves of power dissipation versus forward current for a limited number of commonly used circuits. However, cases do arise for which the particular form of circuit or load is not covered, and it is then necessary to calculate the dissipation for these particular conditions. The calculation can be greatly simplified, with little loss of accuracy in most cases, by approximating the actual *V–I* character-

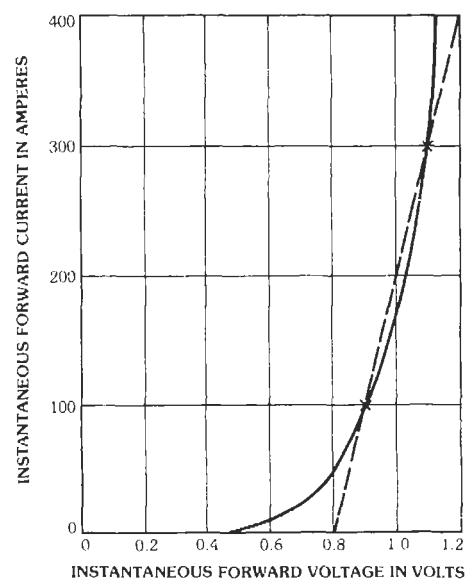

Fig. 1. Instantaneous forward voltage–current characteristic for a typical 100-ampere diode operated at 100°C junction temperature. The ideal threshold forward voltage V_f is the value where the broken line intercepts zero forward current.

* For a complete list of silicon-rectifier ratings, refer to the EIA-JEDEC *Recommendations for Letter Symbols, Abbreviations, Terms and Definitions for Semiconductor Device Data Sheets and Specifications*, published by Electronic Industries Association, 2001 I Street, NW, Washington, DC 20006.

istic curve to a straight line, as shown by the broken line in Fig. 1. The approximate characteristic corresponds to that of a fixed voltage (the threshold voltage) plus a fixed resistance (the slope resistance). For any shape of current waveform, the power dissipated at constant voltage is the product of the average current and this fixed voltage, while the power dissipated at constant resistance is the product of the square of the rms current and this fixed resistance. Thus, the following simple equation can be used:

$$P = I_{F(av)} \times V_T + I^2_{F(rms)} \times R_S \qquad \text{(Eq. 1)}$$

where,

P is the forward power dissipation,
$I_{F(av)}$ is the average forward current through the rectifier, averaged over one complete cycle,
$I_{F(rms)}$ is the rms value of the forward current through the rectifier,
V_T is the threshold voltage, and
R_S is the slope resistance.

For the best accuracy, the straight-line approximation should be drawn through points on the current curve corresponding to 50% and 150% of the peak current at which the rectifier is to be used. Thus, in Fig. 1 the broken line would correspond to a peak working current of 200 amperes.

Carrier Storage—On switching from forward conduction to reverse blocking, a silicon diode cannot immediately revert to its blocking state because of the presence of the stored carriers in the junction. These have the effect of allowing current to flow in reverse, as through a forward-biased junction, when reverse voltage is applied. The current is limited only by the external voltage and circuit parameters. However, the carriers are rapidly removed from the junction both by internal recombination and by the sweep-out effect of the reverse current, and when this has happened, the diode reverts to its blocking condition in which only a low leakage current flows. This sudden cessation of a large reverse current can cause objectionable voltage transients if there is appreciable circuit inductance and surge-suppression components have not been included. The reverse current due to carrier storage is not excessive in normal operation of power rectifier circuits and does not in itself constitute a hazard; however, its effect can sometimes lead to complications in switching arrangements. For example, in an inductively loaded circuit, the current will "free-wheel" through the diodes after the supply has been removed until the inductive energy has been discharged. Should the supply be reapplied while this process is going on, some of the diodes will be required to conduct in a forward direction, but others will be required to block; while the latter are recovering from the carrier storage injected by the free-wheeling current, the short-circuit across the supply can cause a damaging surge current to flow.

A technique for reducing this problem is to use "fast-recovery" rectifiers. These rectifiers are tailored to operate in high-frequency circuits with reduced and specified amounts of recovered charge. The devices change from conducting reverse current to leakage current in a "nonabrupt" manner. The finite rate of change in current reduces the transient voltages that appear on the power semiconductors and other circuit elements.

Schottky Rectifiers

The Schottky rectifier has the same terminal characteristics as do conventional and fast-recovery rectifiers; that is, it conducts current in one direction and blocks voltage of one polarity. Rather than rely on a pn junction for rectification, the Schottky diode uses a metal-to-semiconductor contact. Depending on the metal, the forward voltage drop is typically one-half that of a conventional silicon pn rectifier. The reverse voltage rating is lower than that of a pn rectifier, being on the order of 50 to 200 volts. The rectifying action of the Schottky rectifier depends upon the majority carriers, so there is very little reverse current caused by minority-carrier recombination. Therefore, these devices are characterized by very low recovered charge and as such are suitable for high-frequency rectification, up to typically 1 to 5 MHz. The devices are used extensively as rectifiers on the low-voltage windings of high frequency switching mode power supplies. The output voltage of these systems is typically 5 volts dc, and they operate typically at 20 kHz to 1 MHz. The Schottky rectifiers operate in these systems with considerably lower conduction and switching losses than silicon pn rectifiers.

Zener Diodes

"Zener" is the name given to a class of silicon diodes having a sharp turnover characteristic at a particular reverse voltage, as shown in Fig. 2. If such a diode is operated on this part of its characteristic, no breakdown (in the sense of dielectric breakdown) occurs, and the process is reversible without damage. The steepness of the reverse part of the current–voltage characteristic in the turnover region makes these diodes excellent elements for voltage reference and voltage regulation.

The temperature coefficient for a typical range of zener diodes is shown in Fig. 3. It will be seen that the coefficient changes from negative to positive in the region of 5 volts. Use is sometimes made of this phenomenon to match diodes of opposite coefficient to produce a series pair having a low effective temperature coefficient in combination.

Zener diodes are used to provide stable reference voltages for electronic control circuits and as a voltage reference for closed-loop regulating systems in which the actual voltage is compared to the reference voltage in order to develop an error signal. They are available

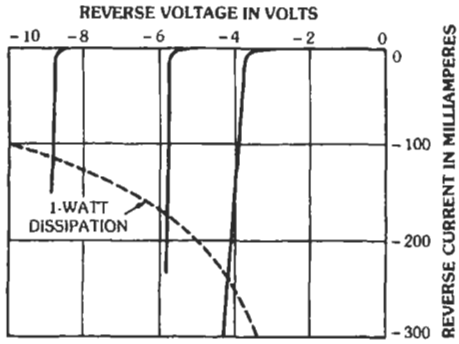

Fig. 2. Typical reverse characteristics for three low-voltage zener diodes of 1-watt rating. (From J. M. Waddell and D. R. Coleman, "Zener Diodes—Their Properties and Applications," *Wireless World*, Vol. 66, No. 1, p. 18, Fig. 2; January 1960. © 1959, Iliffe Electrical Publications, Ltd., London, England.)

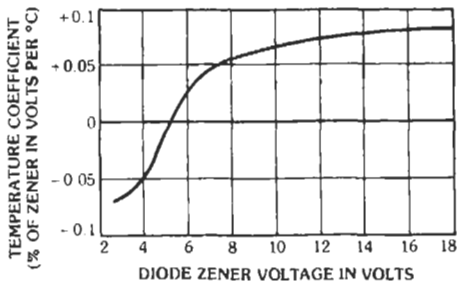

Fig. 3. Temperature coefficient for a typical range of low-voltage zener diodes. (From J. M. Waddell and D. R. Coleman, "Zener Diodes—Their Properties and Applications," *Wireless World*, Vol. 66, No. 1, p. 18, Fig. 4; January 1960. © 1959, Iliffe Electrical Publications, Ltd., London, England.)

in voltage ratings from 3 to 200 volts and power ratings from less than a watt to 50 watts. The voltage tolerance can be specified as ±20%, ±10%, ±5%, and, with further selection, to closer tolerances. Special units designed for transient voltage clipping are discussed in the section on transient-voltage suppressors.

Power Transistors

Power transistors are three-terminal semiconductor devices that are widely used in power supplies and other power conversion equipment. The addition of a third terminal allows the device to have the capability of electronic control of its impedance to the flow of current. The device impedance can range from a very low forward voltage drop, called *saturation voltage*, with the current limited by the external load to a very low leakage current during its off condition. The transistor can operate in its linear region with a simultaneous high voltage across the device and a high current flowing through the device. This linear mode is used in the linear regulated power supplies described in a later section. The power transistor can also be operated in the switching mode, where it is either on or off with the shortest possible times to accomplish the turn-on and turn-off. To increase the gain defined as the ratio of collector current to base current, two transistors are arranged in a Darlington connection in which the collector current of one transistor provides the base current to the output transistor. This connection increases the collector-to-emitter saturation voltage. Silicon high-voltage transistors useful for high-frequency switching circuits are characterized by a set of voltage, current-gain, and switching characteristics that are briefly discussed below.

Breakdown Sustaining Voltages—Power transistors during conditions of turn-off are required to withstand immediately a forward collector-to-emitter voltage. Because of the rapid change from forward conduction to forward blocking, the sustaining voltages are less than the steady-state forward blocking voltage ratings.

The collector-to-emitter sustaining-voltage rating is specified as a function of the base-to-emitter voltage conditions:

$V_{CEO(SUS)}$ = collector-emitter sustaining voltage, base open

$V_{CER(SUS)}$ = collector-emitter sustaining voltage, base-emitter resistor

$V_{CES(SUS)}$ = collector-emitter sustaining voltage, base-emitter reverse-bias voltage

The $V_{CEO(SUS)}$ rating is the lowest of the three ratings and is specified at a low level of collector current. It is important in switching inductive loads, and this voltage should not be exceeded during the switching interval.

DC Current Gain and Saturation Voltage—The collector-emitter saturation voltage is the voltage drop that occurs when the transistor is carrying current. It is specified at a given collector current and a given base current or as a gain that is the ratio of collector current to base current. The saturation voltage is also a function of junction temperature. The gain has a peak value at nominal current levels and decreases at both lower and higher values of collector current. The typical value of saturation voltage for single transistors is one volt. This voltage drop times the collector current represents a major part of the conduction losses in the transistor. The collector-emitter saturation-voltage versus collector-current characteristics of a Darlington power transistor are plotted in Fig. 4 for a 500-volt, 50-ampere NPN power transistor.

Forward- and Reverse-Biased Second Breakdown—When transistors are being turned on and off, the possibility for simultaneous high currents and high voltages exists. This results in localized high power dissipation in the transistor, leading to increasing tem-

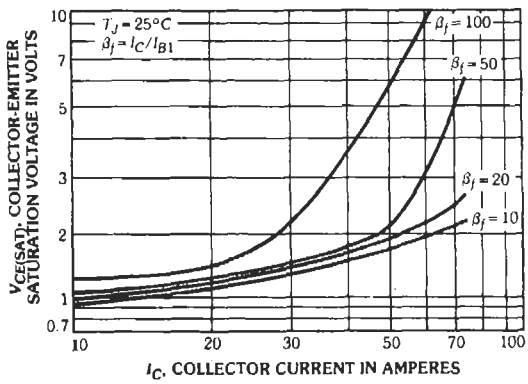

Fig. 4. Plots of $V_{CE(SAT)}$ versus I_C. T_J = 25°C. (From *Transistors-Diodes*. Auburn, NY: General Electric Co., Semiconductor Products Dept., 1982.)

perature rise and potential device failure. This failure is described as "second breakdown." Power-transistor manufacturers present a family of curves outlining a safe operating area for the device. The actual device switching locus should remain within the designated area. Two sets of curves are provided, one with forward bias on the base and the other with reverse bias on the base (turn-off). The forward-biased safe operating area for a 500-volt, 100-ampere Darlington transistor is shown in Fig. 5. The curves are bounded by peak current limits, peak voltage limits, thermal limits, and second breakdown limits. The safe operating area increases as the switching times decrease. The reverse-biased safe operating area for a 500-volt, 100-ampere Darlington transistor is shown in Fig. 6. The curve shown is for turn-off with a voltage clamp on the maximum collector-to-emitter voltage.

Switching Times—The switching times, both on and off, are important during high-frequency switching because both voltage and current are high, resulting in high peak power dissipation. Reduction in these switching times results in less average power dissipation due to switching losses. The turn-on time is composed of two parts, delay time and rise time. With inductive loads, these times are quite short, typically less than 1 microsecond. The turn-off time is also composed of two parts, a storage time and a fall time. Fall time is the most important parameter because the peak device power dissipation is high and the heat generated is nonuniform owing to current crowding. The switching times are functions of turn-on base current, turn-off base current, base-to-emitter reverse voltage, junction temperature, and device design. Typical values are from 0.1 to 15 microseconds.

Reverse Voltage Operation—If the emitter is biased positive with respect to the collector and current is supplied to the base, then the device will conduct in the "inverted mode." The gain is low, and there exists a possibility that the current capability of the device is low. In normal practice, a rectifier is placed in inverse parallel with the collector and emitter of the transistor so that the rectifier instead of the transistor carries the reverse current.

Insulated-Gate Bipolar Transistors

The insulated-gate bipolar transistor (IGBT) is a power semiconductor device used as a controlled switch. A bipolar transistor section carries the load current, and a field-effect transistor is connected to the base of the bipolar section; the field-effect transistor is an integral part of the bipolar transistor. The equivalent circuit is shown in Fig. 7. The addition of the field-effect transistor allows the IGBT to be turned on and off with a voltage signal rather than by supplying turn-on and turn-off base current as in a conventional power transistor. The device can be driven from logic-level signals. The power portion of the device, shown as a PNP transistor in Fig. 7, has all of the features described in the previous section on power transistors.

The saturation characteristic of an IGBT rated at 600 volts and 100 amperes is shown in Fig. 8. The safe-operating-area curve for the same device is shown in Fig. 9. The IGBT switching times can be controlled by selecting an appropriate value of gate resistor. The IGBT gate-to-emitter junction appears as a capacitance; decreasing the series gate resistor decreases the

time to reach the switching voltage. The change in switching times for the 600-volt, 100-ampere IGBT is shown in Fig. 10.

Modules with current ratings of 400 amperes are currently available. Voltage ratings of 1200 volts are available. Growth in both current and voltage ratings is anticipated. Switching speeds range from less than a microsecond to 10 microseconds, resulting in operating frequencies up to 20 kHz.

Field-Effect Transistors

The field-effect transistor is also used as a controlled switch in high-voltage and high-frequency power circuits. The three terminals, drain, gate, and source, in an n-channel device bear the same relationship as the collector, base, and emitter in an NPN bipolar transistor. That is, a positive signal from gate to source causes the device to conduct a positive drain current.

The advantages of power field-effect transistors over bipolar transistors are:

(1) Field-effect transistors have faster switching speeds with reduced delay, rise, storage, and fall times.
(2) Devices are voltage controlled rather than current controlled and can be driven from logic-level signals.
(3) The second-breakdown failure mechanism of bipolar transistors is absent in field-effect transistors.
(4) Field-effect transistors, because of the conduction voltage drop versus temperature characteristic, tend to share current when operated directly in parallel.
(5) The device does not block reverse voltage but has a "built-in" rectifier that has a current rating equivalent to the drain current rating.

A disadvantage of present field-effect transistors is the higher conduction voltage drop when compared with a bipolar transistor of the same current rating. The value of "on" resistance is a function of the drain-source voltage rating of the device. Higher-voltage devices have higher on resistances and therefore lower drain currents for the same temperature rise. The voltage drop can be comparable with the voltage drop of a Darlington transistor.

At present, the voltage and current ratings of field-effect transistors are not as high as those available in bipolar transistors. Field-effect transistors have replaced some bipolar transistors in switching power supplies at generally higher operating frequencies, typically over 50 kHz. Fig. 11 shows the drain-to-source voltage, during saturation, versus drain current characteristic for a 500-volt, 10-ampere n-channel field-effect transistor. The safe operating region for the same field-effect transistor is plotted in Fig. 12.

Thyristors (Silicon Controlled Rectifiers)

The thyristor* is much like a normal rectifier that has been modified to "block" in the forward direction

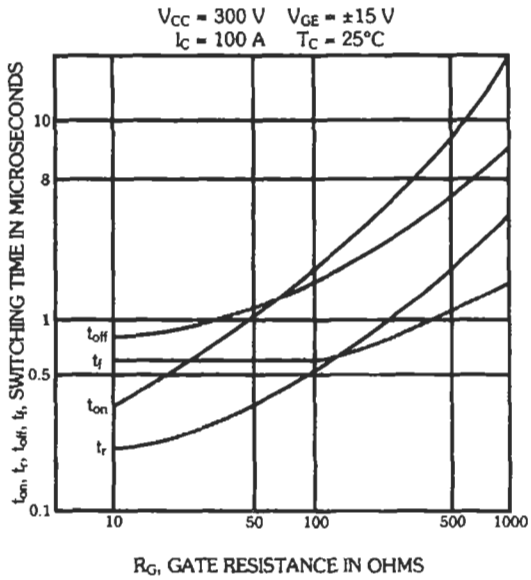

Fig. 10. Switching time versus gate resistance for an IGBT. (From *Fuji IGBT Application Manual*. Fuji Electric, 1989.)

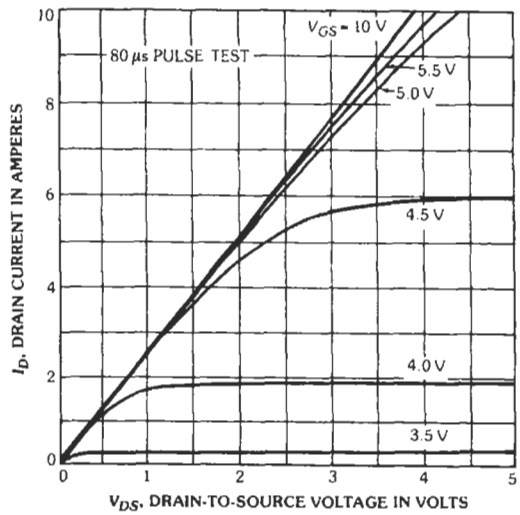

Fig. 11. Typical saturation characteristics for a 10-ampere FET. (From *HEXFET Databook*. El Segundo, CA: International Rectifier Corp., Semiconductor Div., 1981.)

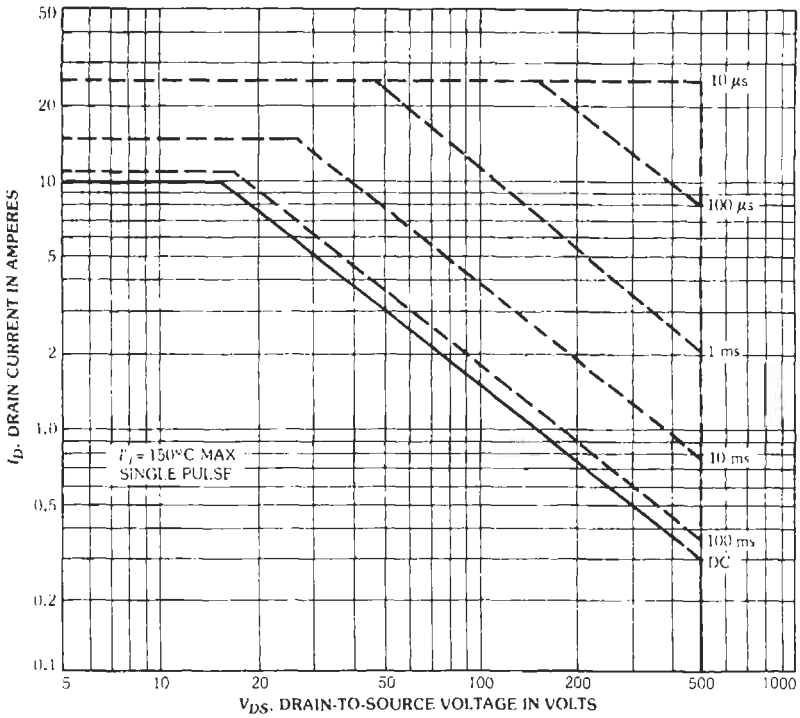

Fig. 12. Maximum safe operating area for a 10-ampere FET. (From *HEXFET Databook*. El Segundo, CA: International Rectifier Corp., Semiconductor Div., 1981.)

until a small signal is applied to the control (gate) electrode. After the signal is applied, the device conducts in the forward direction with a forward characteristic very similar to that of a normal silicon rectifier. It continues to conduct even after the control signal has been removed.

A small pulse is required at the gate electrode to switch a thyristor on, and the anode supply must be removed, reduced, or reversed to switch the thyristor off. If proportional control is required, means must be provided for adjusting the phase of the trigger pulse with respect to the supply to control the proportion of the cycle during which the thyristor is permitted to conduct. In ac circuit applications, the turn-off is obtained by the natural reversal of the supply voltage every half-cycle; in dc circuits it is usual to charge a "commutating" capacitor during the "on" period and to apply this charge in negative polarity between the anode and cathode when it is desired to turn the thyristor off.

---

* This term, which indicates a general class of solid-state controlled rectifiers, is used throughout this section instead of the term "silicon controlled rectifier" (a four-layer PNPN device that is the most common member of the class).

Ratings—Voltage and current ratings are generally expressed in terms similar to those for silicon rectifiers, as discussed in a previous section. It is necessary, however, to add the following ratings.

Peak forward blocking voltage is the maximum safe value that may be applied, under recurrent or nonrecurrent transient conditions, while the thyristor is in the blocking state. The thyristor may break over into a conducting state regardless of gate drive if either (A) too high a positive voltage is applied between anode and cathode or (B) a positive anode–cathode voltage is applied too quickly (*dv/dt* firing). Even small voltage pulses, if their leading edges are sufficiently steep at the anode, can turn the thyristor on. Firing by condition (A) is generally avoided by making the peak forward blocking voltage lower than the breakover voltage of any thyristor of a particular type and by seeing that this voltage is not exceeded in practice. Trouble from *dv/dt* effects may be minimized by locating the gate wires to avoid stray coupling between anode and gate, by use of negative bias on the gate during blocking, and by use of R-C damping circuits between anode and cathode to slow down the rate of change of applied voltage.

Continuous forward blocking voltage covers operation under dc conditions, with forward voltage from anode to cathode.

Peak forward gate voltage is quoted for the anode positive with respect to the cathode and for the anode negative with respect to the cathode. The voltage rating is quite low in the latter case (typically 0.25 V), since the reverse voltage rating is reduced by forward gate current.

Peak reverse gate voltage is generally the same whether the anode is positive or negative with respect to the cathode.

Peak forward gate current involves several factors. Forward gate impedance is a finite value subject to quite large variations between samples and over a temperature range. It is usually necessary to plot a load line on the gate current–voltage characteristics to determine the gate current that may flow due to a given external gate voltage and source resistance. Care must be taken that the rating is not exceeded with all known spreads of gate-cathode characteristic and temperature.

Gate dissipation is generally given in terms both of average rating and of peak rating.

Characteristics—Characteristics of the thyristor important for circuit design are as follows:

Leakage currents are specified for both forward and reverse blocking, at maximum applied voltage and at maximum rated temperature. Although these currents are low in comparison with forward conducting currents and can be neglected in assessing power losses, they must be taken into account in certain circumstances. An example would be a circuit in which a capacitor is slowly charged from an external source and then suddenly discharged through a thyristor into a second circuit (as in pulse modulators); the capacitor charging operation may be affected by the amount of forward leakage current conducted by the thyristor in its blocking state.

Holding current is the minimum anode–cathode current that will keep the thyristor conducting after it has been switched on. In some applications, a thyristor with a high holding current is wanted so that it can be turned off easily without the need for reducing the anode current to a very low level. In other applications, where a low load current is normal, it might be desirable to have a low holding current to ensure that the thyristor latches on reliably with light loading.

Forward voltage drop is important in assessing power loss. The same methods of assessing power loss in terms of the forward current–voltage characteristic apply as in the case of silicon rectifiers. It is impracticable to measure the junction temperature under working conditions, and therefore the manufacturers list maximum values of stud or case temperature related to the forward current. This relationship is expressed in the form of a graph, as shown in Fig. 13.

Note that since the ratio of rms to average forward current varies with the angle of conduction, the power dissipation for any average current also varies with this angle. Fig. 13 is drawn for fractional sine waves, as would apply to the cases of single-phase half-wave or bridge rectifier circuits working into a resistive load.

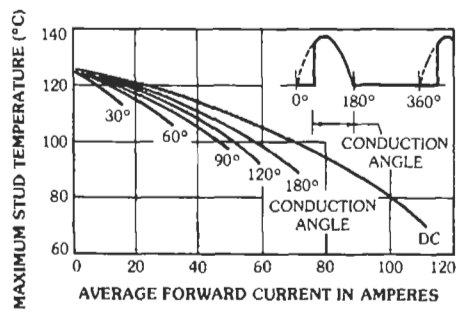

Fig. 13. Maximum permitted stud temperature vs average thyristor forward current in single-phase half-wave or bridge circuit feeding a resistive load. (70-ampere average rated thyristor.)

Fig. 14 shows a typical relationship between power dissipation and average current for a 70-ampere thyristor under the same circuit conditions. The two types of graphs illustrated by Figs. 13 and 14 together enable one to calculate the thermal resistance of heat sink required to keep the thyristor below its maximum temperature ratings when it is used under given working conditions of current and ambient temperature.

Gate trigger sensitivity is specified in terms of a minimum voltage and/or current that must be applied to ensure that all samples of a particular type of thyristor will be triggered into conduction. The minimum voltage is not temperature sensitive, but the minimum trigger current varies considerably with temperature, more current being required to turn on at low temperature than at high. The basic requirements of a gate drive circuit are therefore that the driving voltage and source resistance must be such that either the mini-

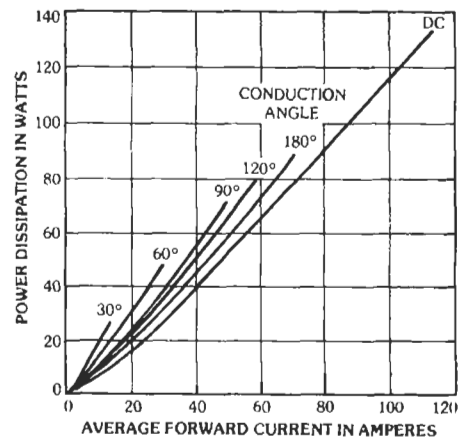

Fig. 14. Power dissipation vs average thyristor forward current in single-phase half-wave or bridge circuit feeding a resistive load. (70-ampere average rated thyristor.)

mum voltage or the minimum current (or both) is exceeded but that the rated gate dissipation is not exceeded.

Switching times of importance are the turn-on and turn-off times, the latter generally being at least one order of magnitude greater than the former. When a gate signal is applied to the thyristor, there is a finite delay time during which the anode current remains at its normal blocking level; this is followed by a "rise time" during which the anode current increases from its blocking level to a value determined by the external load circuit. Turn-on time is the sum of these two times. For a given thyristor, the turn-on time is influenced by the magnitude of gate drive, the load current to be achieved, and, to a lesser extent, the applied anode supply voltage. The time is reduced by high gate drive, low load current, and high anode supply voltage. Turn-off time is similarly composed of two individual periods; the first is a storage time, analogous to that obtained with a saturated transistor, and the second is a recovery time. Forward voltage may not be reapplied before the completion of both phases of the turn-off process, or the thyristor may conduct load current again. After this period, however, forward voltage may be applied, and the thyristor will remain in its blocking state provided that the rate of rise of anode voltage is not allowed to exceed the specified maximum *dv/dt*, as already discussed.

Gate Turn-Off Thyristors—These devices are fabricated to be able to turn off and interrupt the anode current by extracting current from the gate-to-cathode terminals. The ratio of controllable anode current to gate current is from 3/1 to 5/1. However, the reverse gate voltage is low, yielding a high power gain. These thyristors are rated up to 4500 volts and 2500 amperes.

MOS-Controlled Thyristors

The MOS-controlled thyristor is a four-layer, three-junction semiconductor similar to the thyristor described in the preceding section, except that an integral field-effect transistor has been added in parallel with the anode and the anode gate. The equivalent circuit is shown in Fig. 15. The addition of the field-effect structures allows the device to be turned on and off by a logic-level voltage signal. Reference 1 describes the device structure and features. Devices in a TO-218 plastic package are available with ratings of 600 volts and 50 amperes. Growth in voltage and current ratings is anticipated. Higher-current modules have been fabricated using selected lower-current devices operating in parallel. Switching times are currently in the range from 0.5 to 3 microseconds.

Triacs

A triac is a three-terminal ac semiconductor switch that is triggered into conduction by a gate signal much as a thyristor is. The triac was developed to provide a single device that could control current flow in both directions with the application of a gate signal. This allowed for the replacement of two inverse-parallel thyristors and the complex gate-drive circuit they require with a single device that has a single gate.

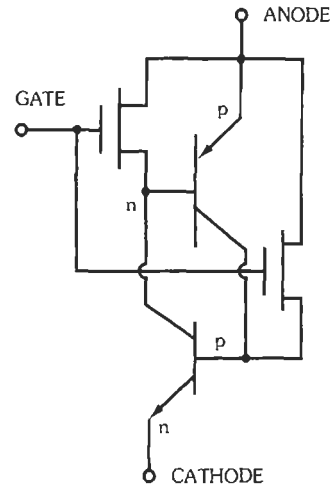

Fig. 15. Equivalent circuit of a MOS-controlled thyristor.

The terms "anode" and "cathode" are not used; instead, the power terminals are numbered MT_1 and MT_2. The gate terminal is associated with MT_1. The triggering characteristics are such that with MT_2 positive with respect to MT_1, either positive or negative gate current will trigger the device into conduction. With MT_1 positive with respect to MT_2, again either positive or negative gate current will trigger the device into conduction. However, positive gate current should be used only if needed, because the gain is lower.

The other major difference from two inverse thyristors is in the commutating *dv/dt* rating. When two thyristors are connected in inverse parallel and operating with a lagging-power-factor load, one device ceases to conduct, and the voltage rises on the previously conducting device in the reverse or non-turn-on direction. The other device sees a positive *dv/dt* in the turn-on direction, but it has had an entire half-cycle for turn-off or commutation. In a triac, the only period for turn-off occurs when the current goes through zero and a pulse of recovery current is conducted through the device. The voltage rises to the circuit voltage level in the turn-on direction very rapidly, and the device does not have an entire half-cycle to regain its forward blocking capability. A suitable R-C snubber is generally provided.

Triacs are available for standard ac voltages (120, 240, and some higher voltages) and up to 40–100 amperes operating at 50, 60, or 400 hertz. The remainder of their ratings are consistent with thyristor ratings.

Transient-Voltage Suppressors

Transient-voltage suppressors have a terminal characteristic such that, above a certain voltage level, the voltage drop across the device increases slightly for large changes in current magnitude. Some of these devices exhibit voltage clamping characteristics for both voltage polarities, whereas others exhibit clamping characteristics for only one voltage polarity. Two types are currently available. One is similar to a silicon zener diode, selected for a high-pulse-power, low-average-power duty cycle. The second type is composed of a polycrystalline nonlinear resistive material. Both of these categories of devices come in a range of voltage and power ratings. They are used as transient-voltage clippers on incoming ac or dc utility lines and as transient-voltage limiters for semiconductors and other voltage-sensitive equipment. Fig. 16 shows a comparison of several types and sizes of devices as a function of standardized pulse current waveforms and supply voltages.

AC–DC CONVERTER CIRCUITS

This section describes ac-to-dc converter circuits, both unregulated and electronically regulated, using rectifiers, phase-controlled thyristors, linear transistors, and switching-mode transistors. The basic design equations together with some of the technical advantages, disadvantages, and common applications are given and discussed.

Rectifier Circuits

Table 1 shows seven of the most commonly used power-rectifier circuits and general design information for each type. Their advantages, disadvantages, and common applications follow.

Single-Phase Half-Wave Rectifier—Since only half of the input wave is used, the efficiency is low and the regulation is relatively poor. Capacitors are commonly used in half-wave circuits to increase the output voltage and decrease the voltage ripple. The output voltage and degree of filtering are determined by the value of capacitance used in relation to the load current. Transformer design is complicated, and the unidirectional secondary current causes core saturation and poor regulation. Most half-wave circuits operate either directly from ac lines or at a high voltage with a relatively low current.

Single-Phase Full-Wave Center-Tap Rectifier—The efficiency is good, but the transformer ac voltage is approximately 2.2 times the dc output voltage. The circuit requires a larger transformer than an equivalent bridge rectifier, with the added complication of a center tap. Each arm of the center-tap circuit must block the full terminal voltage of the transformer. Because of this, center-tap connections are economical only in voltage ranges where not more than one rectifier per arm is required. If series units must be used to obtain the required output voltage, a bridge circuit is preferable. This circuit is used with low-voltage logic-level

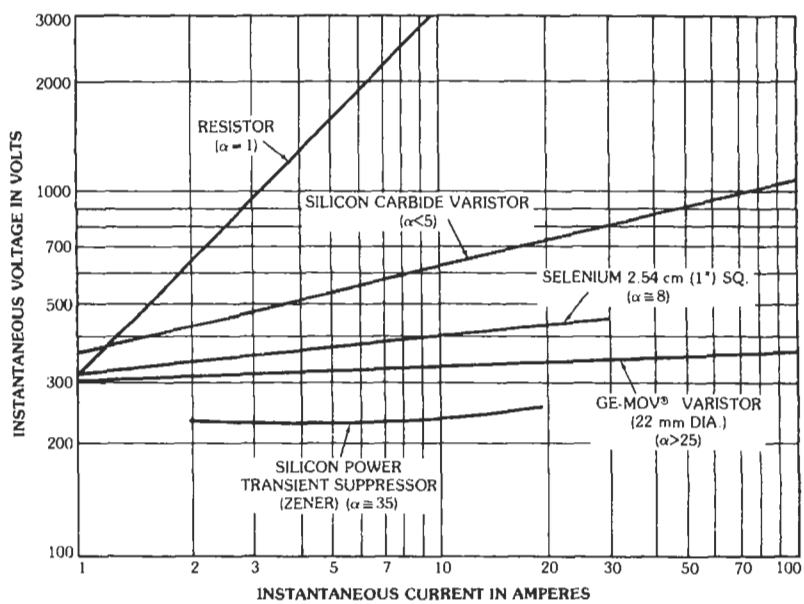

Fig. 16. Voltage–current characteristics of four transient-suppressor devices. (From *Transient Voltage Suppression*, 3rd ed. Auburn, NY: General Electric Co., Semiconductor Products Dept., 1982.)

power supplies where the efficiency is improved because there is only one diode in series with the output.

Single-Phase Full-Wave Bridge Rectifier—If single-phase full-wave output is required, a bridge circuit is commonly used. Efficiency is good and transformer design is easy. Filtering is simplified because the ripple frequency is twice the input frequency.

Three-Phase Wye (or Star) Half-Wave Rectifier—This circuit is commonly used if dc output-voltage requirements are relatively low and current requirements are moderately large. The dc output voltage is approximately equal to the phase voltage. However, each of the three arms must block the line-to-line voltage, which is approximately 2.5 times the phase voltage. For this reason, it is desirable to use a three-phase half-wave connection only where one series unit per arm will provide the required dc output. The transformer design and utilization are somewhat complicated because there is a tendency to saturate the core with unidirectional current in each winding.

Three-Phase Full-Wave Bridge Rectifier—This circuit is commonly used if high dc power is required and if efficiency must be considered. The ripple component in the load is 4.2% at a frequency six times the input frequency, and so additional filtering is not required in most applications. The dc output voltage is approximately 25% higher than the phase voltage, and each arm must block only the phase voltage. Transformer utilization is good. This is the most common three-phase rectifier connection.

Three-Phase Diametric Half-Wave Rectifier—The characteristics of this circuit approximate those of the three-phase double-wye circuit without an interphase transformer. Popular applications include requirements for very high dc load currents in low-to-medium voltage ranges (approximately 6 to 125 volts dc).

Three-Phase Double-Wye Half-Wave Rectifier—A three-phase double-wye connection is recommended if a very high direct current is required at a relatively low dc voltage. Each arm is required to block the full phase voltage of the secondary windings. The dc output current rating is double that of a three-phase bridge or half-wave connection. However, the output voltage is only 75% of the phase voltage. The transformer design is complicated by additional connections and extra insulation, and an interphase transformer (or balance coil) is required.

Single-Phase Voltage Multipliers

These circuits use the principle of charging capacitors in parallel from the ac input and adding the voltages across them in series to obtain dc voltages higher than the source voltage. Filtering must be of the capacitor-input type.

Conventional and Cascade Voltage Doublers—In the conventional circuit (Fig. 17), capacitors C_1 and C_2 are each charged, during alternate half-cycles, to the peak value of the alternating input voltage. The capacitors are discharged in series into load R_L, thus producing an output across the load of approximately twice the ac peak voltage.

In the cascade circuit (Fig. 18), C_1 is charged to the peak value of the ac input voltage through rectifier CR_2 during one half-cycle, and during the other half-cycle it discharges in series with the ac source through CR_1 to charge C_2 to twice the ac peak voltage.

The "conventional" circuit has slightly better regulation, and, since the ripple frequency is twice the supply frequency, the output is easier to filter, the percentage ripple being approximately the same in both circuits. In addition, both capacitors are rated at the peak ac voltage, whereas C_2 in the cascade circuit must be rated at twice this value. With both circuits, the peak inverse voltage across each rectifier is twice the ac peak. The cascade circuit, however, has the advantage of a common input and output terminal and, therefore, permits the combination of units to give higher-order voltage multiplications. The regulation of both circuits is poor, so that only small load currents can be drawn.

Bridge Rectifier or Voltage Doubler—If SW in Fig. 19 is open, the circuit is a bridge rectifier; if the peak ac applied voltage is $2E_p$, the dc output voltage is $2E_p$. If SW is closed, the circuit is a voltage doubler; an ac input of E_p gives a dc output of $2E_p$. This circuit is used if the same dc voltage is desired and the input voltage can be either 115 or 230 volts ac.

Further Voltage Multiplication—The cascade voltage doubler shown in Fig. 18 can be combined several times to obtain higher dc voltages, as shown in Fig. 20. The voltage ratings of all the capacitors and rectifiers are twice the ac peak voltage, but the capacitors must have the values shown. The value of C will be the same as that for the cascade voltage doubler (Fig. 18), which is the basic unit for the circuit in Fig. 20. The load current must be small. The increasing size of capacitors and the deterioration in regulation limit the voltages that can be obtained from this type of circuit.

Phase-Controlled Thyristor Circuits

As described earlier, the thyristor can block forward voltage until it is triggered into conduction. The delay angle of gating the thyristor into conduction is designated as alpha (α). With $\alpha = 0$, the thyristor behaves like a rectifier. As the delay angle is increased, the average dc output voltage decreases, and therefore

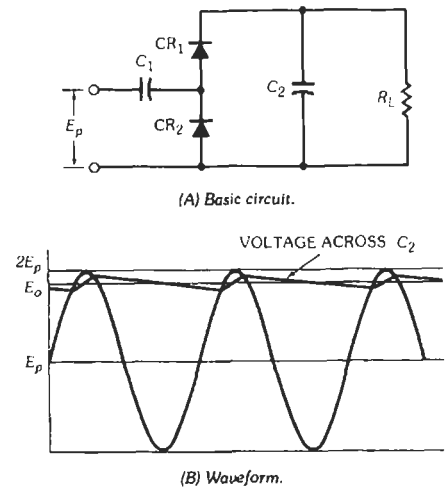

Fig. 18. Cascade voltage doubler.

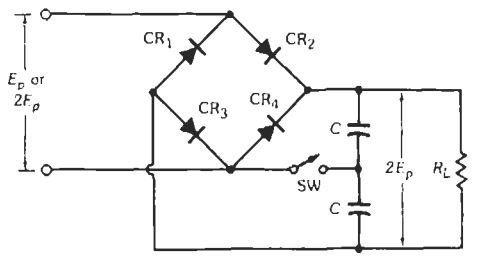

Fig. 19. Bridge rectifier or voltage doubler.

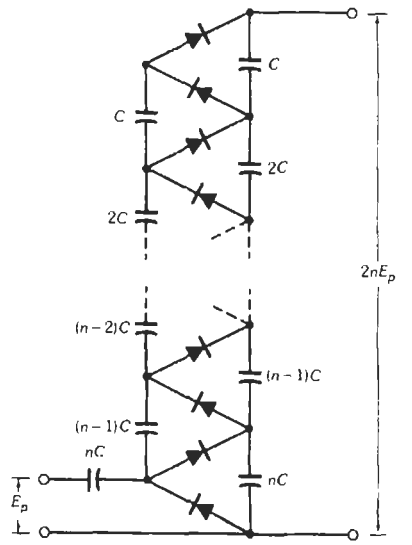

Fig. 20. Circuit for high-order voltage multiplication.

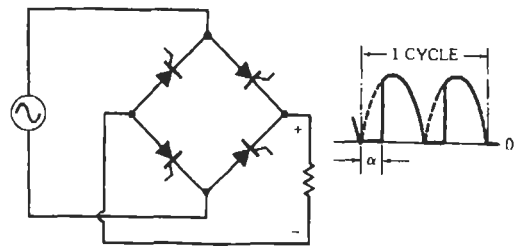

Fig. 21. Full-controlled single-phase thyristor bridge. The broken lines indicate the path of the normal waveform at full conduction, i.e., where $\alpha = 0°$ and the circuit behaves like a diode rectifier. The quantity α is the firing angle delay. Delay range required for this circuit is 0° to 180°.

these circuits provide electronic regulation of the dc output voltage.

Figs. 21 through 26 are basic circuits of thyristors used as controlled rectifiers. In many applications, it is not necessary for all rectifier elements to be controllable, and it is common to find bridges composed of thyristors and ordinary diodes in equal numbers; such circuits are called *half-controlled*, whereas those containing only thyristors are termed *full-controlled*.

Figs. 21 and 22 show a full-controlled single-phase thyristor bridge, the thyristor circuit being the same whether a resistive or inductive load is being driven. The voltage waveforms are different, however, in the two cases. The principal difference of practical importance is that the range of firing-pulse phase control is required to be different in the two cases. For the resis-

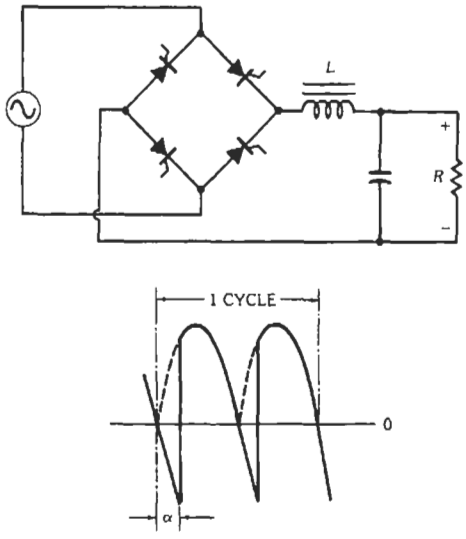

Fig. 22. Full-controlled single-phase thyristor bridge working into an inductive load where $\omega L >> R$. Delay range required is 0° to 90°.

tive load, phase control over the range 0° to 180° is necessary to obtain full control from maximum output voltage down to zero; for an almost pure inductive load (*i.e.*, a very high $\omega L/R$ ratio), full-phase control is obtained with a range of only 0° to 90°.

Fig. 23 shows a half-controlled single-phase rectifier driving an inductive load. For such loads a bypass diode,* CR_3, must be added at the output: at the end of a voltage half-cycle, current still flows in the choke, but in this circuit the current is transferred at the end of the voltage half-cycle to the bypass diode. The two important effects of this diode are (A) that the output voltage is clamped to zero while this inductively maintained current flows, so that the output waveform is the same as that of Fig. 21 (having the characteristic flat portion), and (B) that the transfer of load current from the thyristor to the diode turns the thyristor off. If CR_3 were not present, the waveform would still be the same, since a zero voltage clamp would exist through a series combination CR_1–Q_1 or CR_2–Q_2, depending on which thyristor was conducting during the previous half-cycle. However, this flow of uncontrolled current through the thyristor, bypassing the supply, is undesirable; for example, should it be required that the output voltage be turned off by removal of gate pulses, this action may prove to be impossible. The thyristor can be held on continuously through the negative half-cycle by inductive circulating current and is then ready to conduct on the next positive half-cycle. Thus the gate has lost control, and a continuous half-wave output is produced. The bypass diode overcomes these difficulties by ensuring thyristor turn-off at the end of each voltage half-cycle.

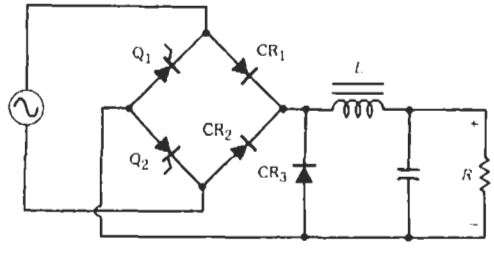

Fig. 23. Half-controlled single-phase thyristor bridge working into inductive load. Common-anode thyristor connection. Waveform and delay range as for Fig. 21.

* Sometimes called a "commutating," "freewheel," or "flyback" diode.

Fig. 24 is a push–pull controlled rectifier circuit. Fig. 25 is a three-phase full-controlled rectifier circuit. Fig. 26 shows the circuit of a three-phase half-controlled rectifier, the bypass diode being necessary only for inductive loads.

In all the cases illustrated in which a bypass diode is used, this diode must be rated continuously for a maximum average current equal to the load current if the full load current is to be drawn when the average output voltage is reduced almost to zero. In practice, a larger diode is often used in this position than in the bridge arms, or several diodes may be used in parallel.

For each of the circuits illustrated in Figs. 21 through 26, Table 2 gives equations for the average dc output voltage, $V_{d\alpha}$, at any angle α in terms of the maximum average dc output voltage, V_{do}, obtained at $\alpha = 0°$. The table also shows the value of V_{do} for each circuit in terms of the peak sinusoidal input voltage, E_p. For the single-phase push–pull circuit, the peak input voltage is E_p–0–E_p, and for all the three-phase circuits E_p is defined as the peak value of the line-to-line voltage.

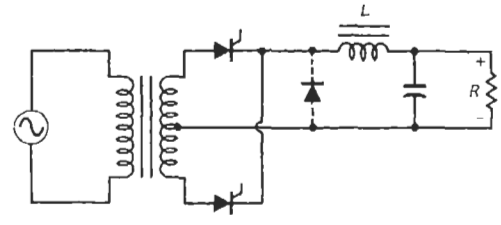

Fig. 24. Full-controlled single-phase push–pull thyristor rectifier working into inductive load. With diode connected, waveform and delay range are as for Fig. 21. Without diode, waveform and delay range are as for Fig. 22 (if $\omega L >> R$). Addition of diode reduces critical inductance of L for continuous current.

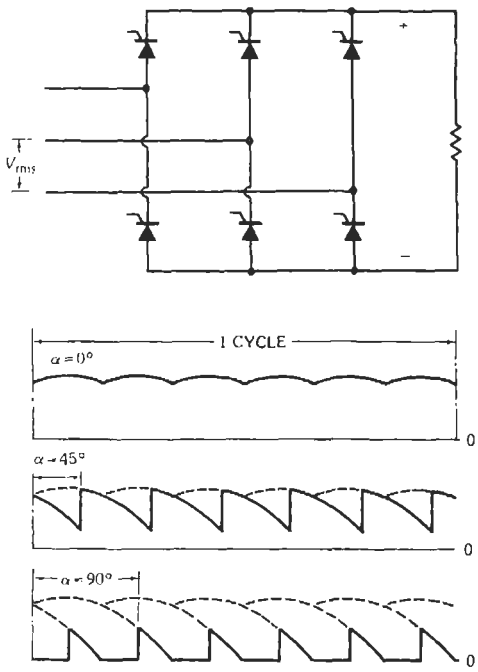

Fig. 25. Full-controlled three-phase thyristor bridge working into resistive load; waveforms of voltage output are shown for three values of α. Waveform develops characteristic flat portion when $\alpha \geq 60°$. Delay range required is 0° to 120°.

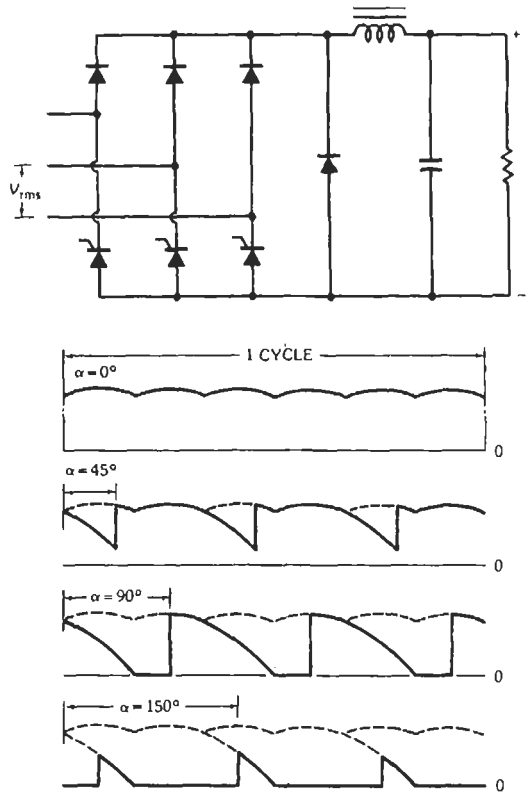

Fig. 26. Half-controlled three-phase thyristor bridge. The bypass diode is necessary only when feeding an inductive load. The waveforms are the same for resistive or inductive load. Delay range required is 0° to 180°.

Linear Transistor Circuits

A block diagram of a series voltage regulator is shown in Fig. 27. The regulator is composed of three basic parts, a comparator, an amplifier, and a series pass transistor. The purpose of the comparator is to compare the actual load voltage with a reference voltage and develop an error signal proportional to the difference between the two. This error voltage is amplified and level shifted to provide base current to a series transistor operating in its linear region. The advantages of this system are its simplicity, its current availability as a complete integrated circuit from several manufacturers, its fast response, and its low switching noise. Its disadvantage is its power dissipa-

tion, since the series transistor operates as a linear resistive element. Series pass transistors can be provided external to available integrated circuits for higher-voltage and higher-current applications. These integrated control circuits can be provided with load-current limit, remote start-up and shut-down, and over-temperature limits.

Switch-Mode Power Supplies

To achieve higher output power capability, transistor switch-mode power circuits have been developed. The transistor is operated either in its saturated state or its cutoff state. Switching frequencies can range from 2 kHz up to several megahertz. Load-voltage control is provided by adjustment of the repetition rate, pulse width, or on-to-off ratio. A functional block diagram of a switching regulator is shown in Fig. 28. An input and output filter are shown to reduce the ripple current in the source and load, respectively. The transistor either is on, connecting the source and the load, or is cut off, disconnecting the source and the load.

Basic Converters

There are three basic dc-to-dc switching converter configurations: the step-down (buck), the step-up

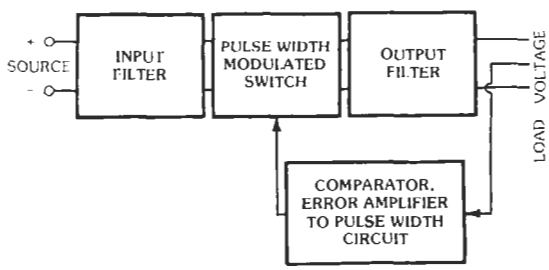

Fig. 28. Block diagram of switch-mode power supply.

(boost), the step-down/step-up (buck/boost), and two additional nonisolated converter topologies: the SEPIC and the Cuk converter. These five circuits do not provide ohmic isolation between the input and the output. Several other circuits have been developed that do provide transformer isolation between input and output. The typical examples are the flyback converter, the forward converter, the half-bridge, the full-bridge, the push–pull, and the Cuk converter with isolation transformer. Table 3 shows these circuits, their schematic diagrams, transfer functions, device rating equations, circuit waveforms, and advantages and disadvantages.

The vast majority of contemporary designs of both isolated and nonisolated converters is based upon the application of two basic concepts: the forward-mode and a flyback or boost-mode converter.

Forward-Mode Converter Basics

The *buck* or *step-down converter,* which can be seen in Fig. 29, is the basic forward-mode converter. Its operation period—one switching cycle—has two distinct parts, which occur when the series power switch is on and when it is off. When the power switch is on, the input voltage is connected to the input of the inductor. The output of the inductor is the output voltage, and the rectifier is back-biased. During this part of the switching period, since there is a constant voltage source connected across the inductor, the inductor current begins to linearly ramp upward, which is described by

$$i_{L(\text{on})} = \frac{(V_{\text{in}} - V_{\text{out}}) \times t_{\text{on}}}{L}$$

where t_{on} is the on-time of the switching cycle when the power switch Q is on.

During the on-time, energy is being stored within the inductor core material in the form of magnetic flux. In steady-state operation, there is sufficient energy stored to carry the requirements of the load during the next off-time, when the input voltage source (V_{in}) is not connected with the load. The next off-time is the "off" period of the power switch. When the power switch turns off, the input voltage of the inductor flies below ground and is clamped at one diode drop below ground by the *catch diode.* The energy stored in the inductor core causes the current continue to flow in its previous direction through the inductor and the catch diode, thus maintaining the load current loop. This removes the stored energy from the inductor. The inductor current during this time is

$$i_{L(\text{off})} = \frac{(V_{\text{out}} - V_D) \times t_{\text{off}}}{L}$$

where t_{off} is the off-time of the switching cycle when the power switch Q is off.

This period ends when the power switch is once again turned on. Regulation is accomplished by varying the on-to-off duty cycle of the power switch. The

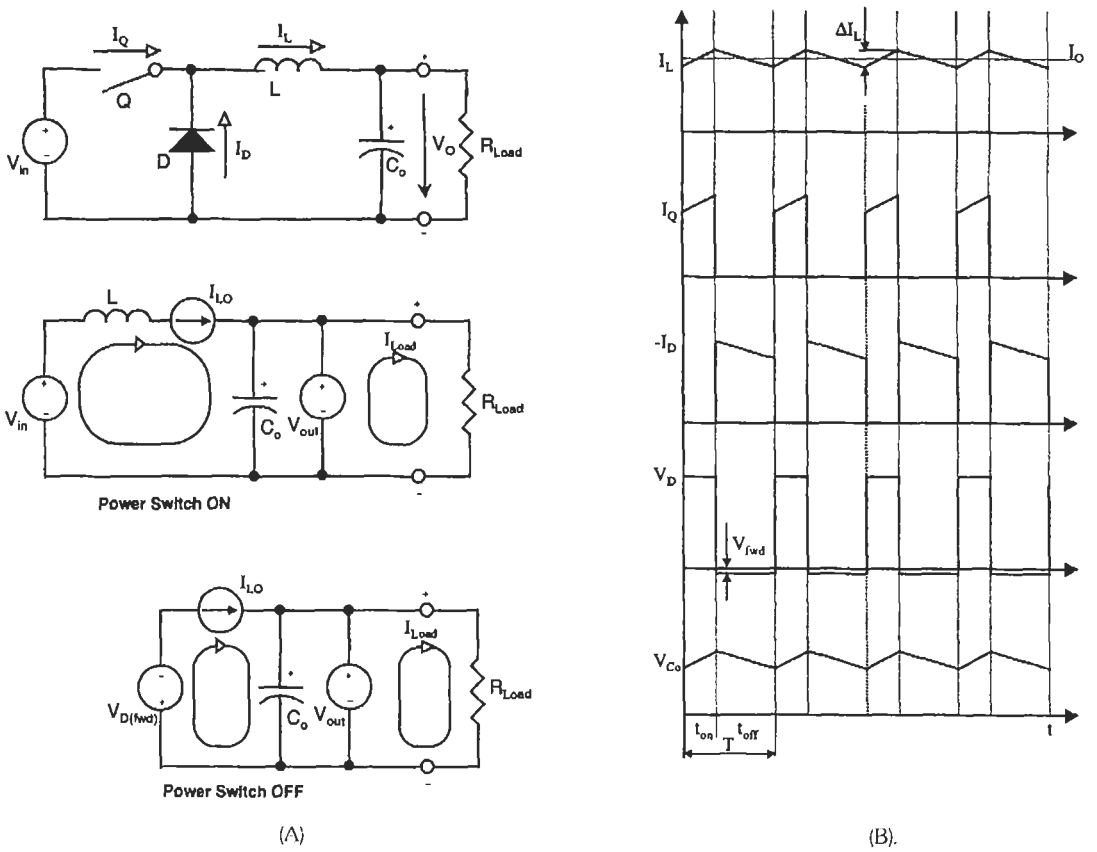
Switching losses low. Drive current referenced to ground. Highest operating frequency.
Disadvantages	High collector current. C_1 has high ripple current requirement. High voltage required for Q_1. Power output limited.	C_1 and C_2 have high ripple current requirements. Transformer design critical. Power output is limited.

* From Application Note 200.87. Auburn, NY: General Electric Co., Semiconductor Products Dept., 1979.

† For reliable operation, it is suggested and recommended that all voltage and current ratings be increased to 125% of the required maximum.



(A) (B).

Fig. 29. Buck regulator principle of operation (A) and its waveforms (B).

relationship that approximately describes its operation is

$$V_{out} = d \times V_{in}$$

Here d is the duty cycle, $d = t_{on}/(t_{on} + t_{off}) = t_{on}/T$, where T is the period of one switching cycle, or $T = 1/f_{sw}$, and f_{sw} is the frequency of operation.

The buck converter is capable of kilowatts of output power. However, it suffers from one serious shortcoming: If the power switch were to fail short-circuited, the input power source would be connected directly to the load circuitry, which usually produces catastrophic results. The buck converter should only be used for board-level regulation. The most common buck derived transformer isolated converter topologies are: forward converter, two-transistor forward converter, push–pull converter, half-bridge and full-bridge converters.

Flyback or Boost-Mode Converters Basics

The most elementary flyback or boost-mode converter is the *boost* or *step-up converter.* Its schematic can be seen in Fig. 30. Its operation can also be broken into two distinct parts, one where the power switch is on and another when it is off. When the power switch turns on, the input voltage source is placed directly across the inductor. This causes the current to begin linearly ramping upwards and is described by

$$i_{L(on)} = \frac{V_{in} \times t_{on}}{L}$$

where t_{on} is the on-time of the switching cycle when the power switch Q is on.

Once again, energy is being stored within the inductor core material. To maintain its steady-state operation the amount of energy stored during each switching cycle times the frequency of operation must be higher than the power demands of the load, or

$$P_{sto} = \frac{1}{2} L I_{pk}^2 \times f_{sw} > P_{out}$$

The power switch then turns off and the inductor voltage flies back above the input voltage and is clamped by the rectifier at the output voltage. The current then begins to linearly ramp downward until the new on-time begins. Its waveform, which is shown in Fig. 30, is determined by

$$i_{L(off)} = \frac{(V_{out} - V_{in}) \times t_{off}}{L}$$

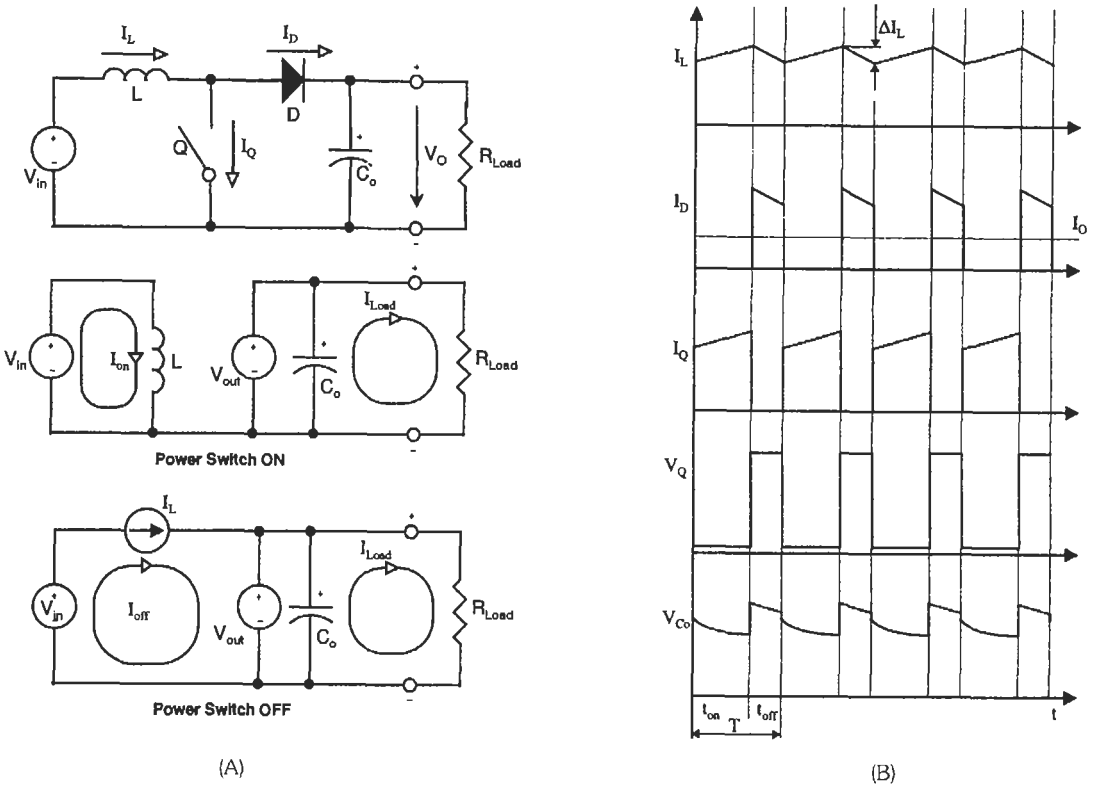


Fig. 30. Boost regulator principle of operation (A) and its waveforms (B).

where t_{off} is the on-time of the switching cycle when the power switch Q is off.

The operation of the boost converter can be approximately described by the following relation:

$$V_{in}V_{out} = (1-d)$$

Here d is the duty cycle, $d = t_{on}/(t_{on} + t_{off}) = t_{on}/T$, where T is the period of one switching cycle, or $T = 1/f_{sw}$, and f_{sw} is the frequency of operation.

The boost converter should also be only used for board-level regulation.

Table 3 shows the most common switching converter topologies, their schematic diagrams, transfer functions, device rating equations, circuit waveforms, and advantages and disadvantages.

Power Semiconductors in Switch-Mode Power Supplies

The power semiconductors used in switch-mode power supplies are thoroughly described in the previous sections. Therefore the following paragraphs summarize their properties in relation to the switch-mode power supplies.

Power MOSFETs

Power MOSFETs are very popular for use as power switches within switch-mode power supplies. MOSFETs have some advantages over the bipolar transistor, such as switching five to ten times faster than bipolar transistors and being easier to drive and use. The drive source, however, must be a well-bypassed low-impedance voltage source. This is because the gate of a MOSFET resembles a capacitor, which must be charged and discharged. Fig. 31 shows several power MOSFET gate drive circuits.

Bipolar Power Transistors

Bipolar power transistors offer several advantages over power MOSFETs: They have higher breakdown voltages, and they are somewhat less expensive for devices greater than 500 volts.

Bipolar power transistors are current-driven devices. That is, in order to have a current flowing from the col-

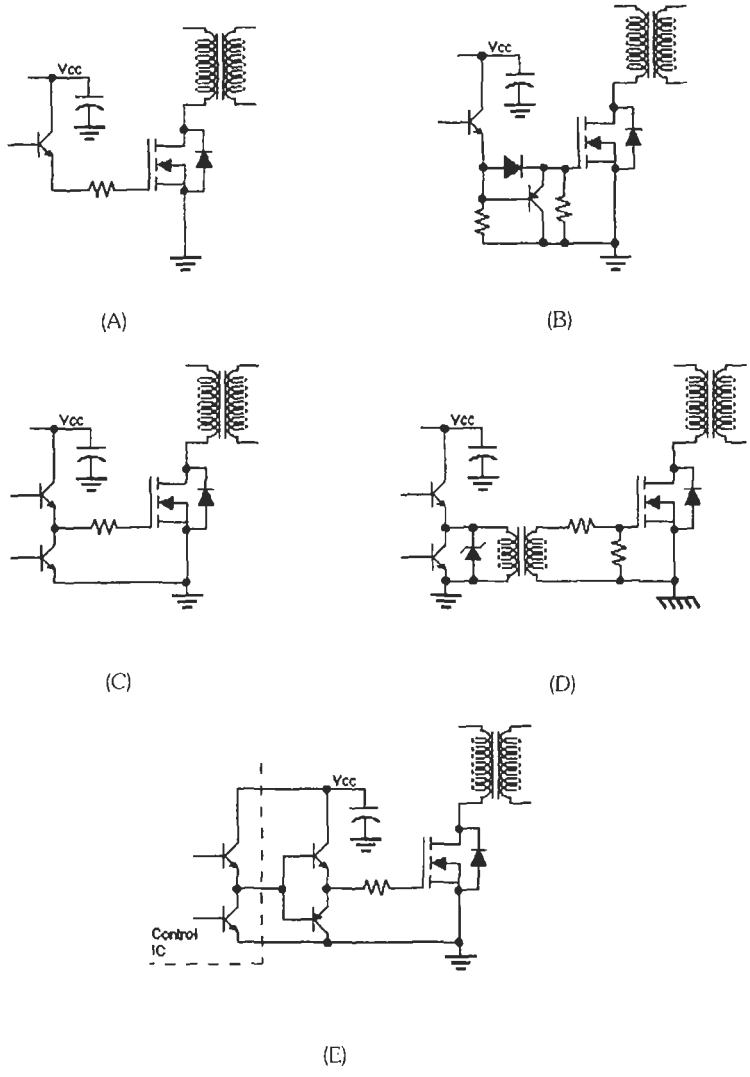

Fig. 31. Power MOSFET gate drive circuits: (A) passive base drive, (B) quasi-totem-pole, (C) totem-pole, (D) transformer-coupled totem-pole, (E) buffered totem-pole to drive MOSFETs with large gate-source capacitance.

lector to the emitter, one must drive current into the base. Within switch-mode power supplies, the objective is to have as small a collector-to-emitter voltage as possible when the transistor is "on." To do this the designer strives to have the transistor operate in, or close to, a saturated state. The saturation of bipolar transistors is defined as

$$I_B \geq \frac{I_{C(max)}}{h_{FE(min)}}$$

For the transistor to switch fast, the drive current should enter and exit the transistor fast. To accomplish this, special attention should be given to the drive circuitry.

Fig. 32. shows some common base drive circuits.

IGBTs

The insulated-gate bipolar transistor (IGBT) has gained popularity in the off-line, high-power switch-mode power supplies, because of its high voltage and current handling capabilities. It drives identically as a power MOSFET. It switches faster than the power bipolar transistor but still slower than a power MOSFET. The drive circuits are identical to those of power MOSFETs shown in Fig. 31.

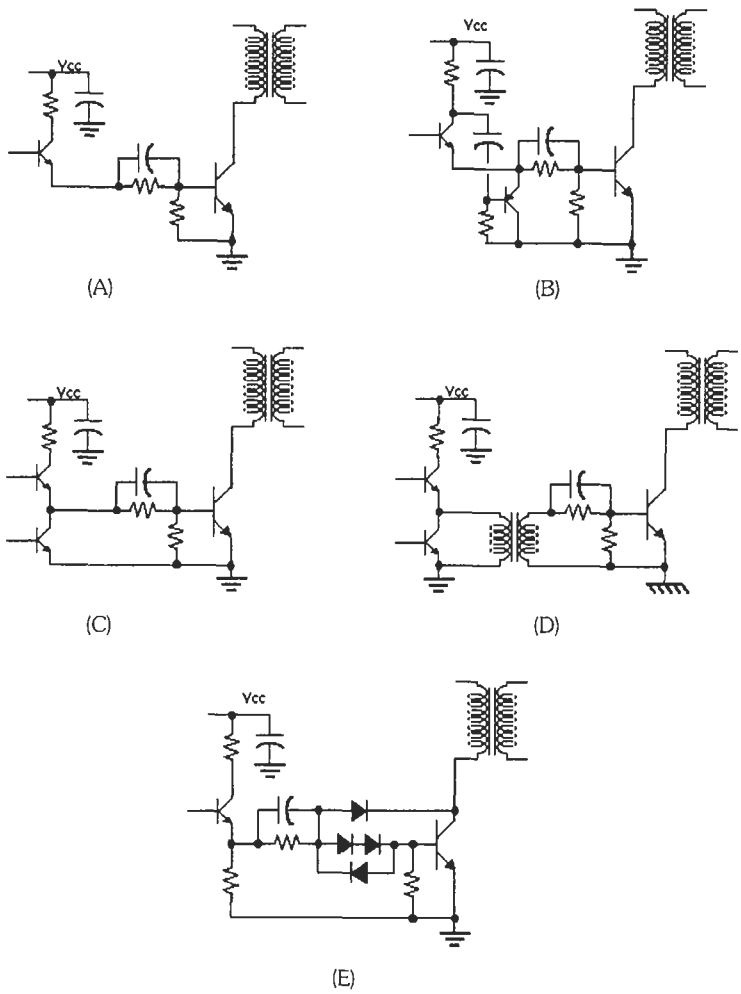

Fig. 32 Bipolar power transistor base drive circuits: (A) passive base drive, (B) quasi totem-pole, (C) totem-pole. (D) transformer-coupled totem-pole, (E) Baker clamp.

Rectifiers

Rectifiers are the largest source of loss within switch-mode power supplies. To choose the best rectifier, one must understand the parameters that affect their efficiency. The most important rectifier parameters are the *forward voltage drop* (V_f) and the *reverse recovery time* (t_{rr}). The reverse recovery loss is where the rectifier becomes reverse biased, and current appears to actually flow backward through the rectifier. It is actually the minority carriers being swept from the P-N junction. Nonetheless, it is a significant loss. This loss is minimized by selecting the rectifier with the shortest reverse recovery time (t_{rr}).

The summarized comparison of switching converter power semiconductors is given in Table 4.

Table 5 gives a comparison of power semiconductors in different switching converter applications.

Power Losses in Power Semiconductors

Conduction losses occur during the conducting period of the power semiconductor.

They can be roughly estimated as follows:

MOSFET:

$$P_{MOS(cond)} = I_{avg}^2 \times R_{DS(on)}$$

Since the $R_{DS(on)}$ increases with temperature, more conservative estimation can be made by doubling the $R_{DS(on)}$ value.

TABLE 4. COMPARISON OF VARIOUS TRANSISTORS AND RECTIFIERS

Transistors	Advantages	Disadvantages
Bipolars	Low $V_{ce(sat)}$ voltage	Low gain
	High voltage capability	Base drive is difficult
	Relatively inexpensive	Limited to approximately 75 kHz due to switching losses
		Nonsquare SOA*
MOSFETs	Easily driven	High voltage device
	Shares current well	Relatively high on-voltage
	Wide bandwidth	
	Low on-resistance for low voltage devices	
	Square SOA*	
IGBT	Easily driven	Existing devices only applicable up to 100 kHz. $T_f < 80$ ns
	High current capability	Future demands > 100 kHz and $T_f < 50$ ns
	Uses silicon more efficiently than MOSFETS	
	High voltage capability	
	Square SOA*	
Rectifiers	**Advantages**	**Disadvantages**
Schottky	Low V_f	200 V performance is marginal
	Very fast	High leakage
	No stored charge	High capacitance
Ultra-Fast	High voltage capability	Stored charge
	Low leakage	Very snappy reverse recovery

* SOA = safe operating area.

Bipolar and IGBT:

$$P_{BJT(cond)} = I_{avg} \times V_{CE(sat)}$$

Power rectifier:

$$P_{RECT} = I_{avg} \times V_f$$

Switching losses in power semiconductors occur during the transient turn-on and turn-off time. Switching losses are proportional to the switching frequency. Therefore to increase the switching frequency the turn-on and turn-off losses must be decreased.

Turn-on Losses

Fig. 33 shows the losses at turn-on. The rectifier reverse recovery effect puts stress upon the switching transistor. It is apparent that increasing *di/dt* in an attempt to reduce switching losses increases the severity of diode snap and current ringing; electromagnetic interference (EMI) is of great concern. The turn-on losses can be decreased by employing a fast power switch and a fast soft recovery rectifier.

Turn-off Losses

Turn-off losses are caused by the fact that the transistor current will not fall until an output rectifier is forward biased. It is preferable to turn-off as fast as the circuit parasitics allow, to reduce turn-off losses (see Fig. 34). Forward recovery of the output rectifier is very important.

Snubbers and Clamps

Snubber and clamp circuits are intended to reduce voltage spikes caused by parasitic elements of switching converters.

A *snubber* is used for reducing the level of a voltage spike and decreasing the rate of change of a voltage waveform. This has benefits in the Safe Operating Area (SOA) of semiconductors, and it lowers the spectral content of any conduced or radiated interference and thus less RF energy is radiated.

A *soft clamp* returns the spike energy to a medium-sized pulse capacitor. The capacitor is then discharged through the parallel resistor.

TABLE 5. COMPARISON OF POWER SEMICONDUCTORS IN DIFFERENT SWITCHING CONVERTER APPLICATIONS

Performance/ Topology	Bipolar < 80 kHz	MOSFET > 50 kHz	IGBT < 100 kHz	Schottky > 50 kHz	Ultra-Fast < 80 kHz

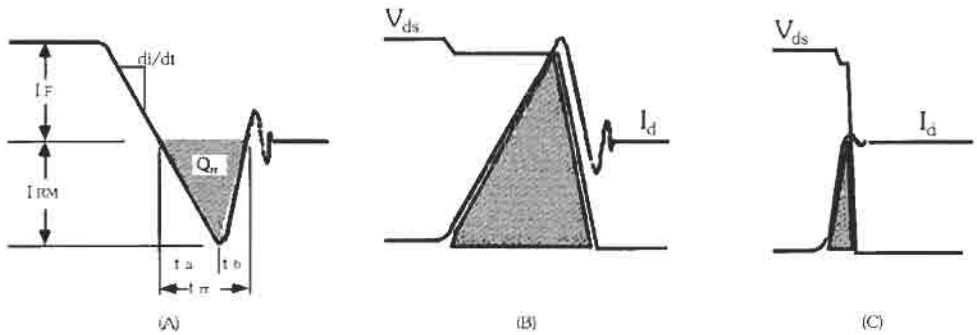

Fig. 33. The turn-on switching losses: (A) The rectifier reverse recovery effect. (B) The typical turn-on losses caused by slow *di/dt* and slow *dv/dt*. (C) Turn-on losses decreased by implementing a fast soft recovery rectifier.

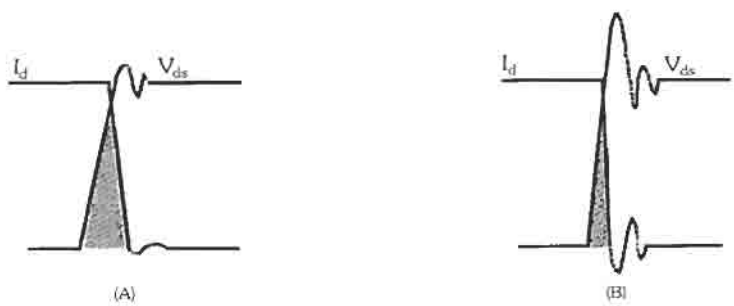

Fig. 34. (A) Losses during the turn-off. (B) Parasitic circuit inductances cause voltage overshoots at high *di/dt*.

A *hard clamp* is used only for reducing the level of a voltage spike. It has no effect on the *dV/dt* of the transition. Therefore it is not very useful for reducing EMI/RFI .* It is useful for preventing components such as semiconductors and capacitors from entering avalanche breakdown.

Typical snubber and clamp circuits are shown in Fig. 35. Their effects on a representative switching waveform are shown in Fig. 36.

* EMI—electromagnetic interference
RFI—radiated frequency interference

Switch-Mode Converter Control

Integrated circuits are available to control these various circuits properly. These signal-level integrated circuits contain reference voltages, voltage-error amplifiers, current-error amplifiers, linear timing ramps, error-voltage-to-pulse-width circuits, remote on–off, synchronization, and power-transistor base-drive signals. Only a few external components are required to set the basic operating frequency and voltage scaling to provide a complete control circuit. Isolation between the output voltage and the input voltage can be provided with optical couplers. Isolation of the

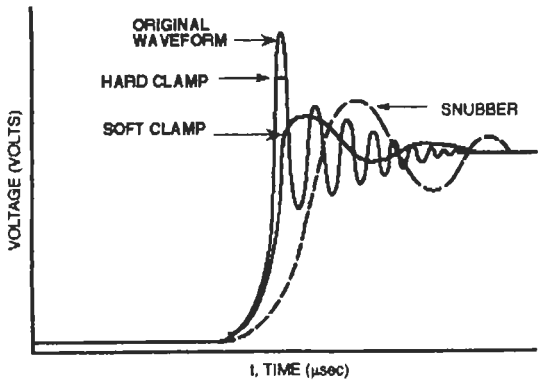

Fig. 36. The effect of snubbers and clamps upon a representative switching waveform.

power-transistor base-drive signals can be accomplished by pulse transformers with energy-storage capacitors to provide a reverse pulse of base current for fast turn-off of the power transistor or field-effect transistor. Refer to Figs. 31 and 32 for different drivers for bipolar switch-mode transistors and switch-mode power MOSFETs.

Different switching converters utilize different types of error voltage-to-switching pulse modulation. Refer to Fig. 37, which describes a basic switching converter control system.

In a Pulse-Width-Modulated (PWM) controller, the switching frequency is constant. The dc output voltage is determined by the ratio of pulse width to switching period.

In a Variable-Frequency-Modulated (VFM) controller, the pulse width is constant. The Off time will change with load and input voltage changes. Therefore, the switching period is *not* constant. It is the sum of On time and Off time. The output voltage will be the ratio of pulse width to the sum of On time and Off time.

In a Pulse-Frequency-Modulated (PFM) converter, also called Pulse-Skipping or Cycle-Skipping Modulation or Ripple Mode converter, the switching frequency, On-time and Off-time are usually all variable with line and voltage changes and have relaxed stability criterion. At very light loads, its cycle-skipping characteristic consumes less power than the other methods while maintaining a regulated output voltage. However, the ripple on the output voltage is slightly higher than with PWM or VFM converters.

In noise-sensitive applications, the PWM controller is usually preferred because the switching frequency is constant and easier to filter out. PWM controllers are also preferred in systems using more than one switching converter in the equipment.

Voltage-Mode Control

Voltage-mode control is a single-loop control method. Only the output voltage of the converter is sensed and compared to the reference voltage in order to control the duty cycle of the power switch. Voltage-mode control provides fairly good control for the power supply but has a poor load transient response and line regulation. Another drawback is that it cannot protect against instantaneous overcurrent conditions in the power switch caused by transformer core saturation.

The voltage-mode control can be easily recognized by a comparator comparing the sawtooth ramp signal from the oscillator with the feedback signal from the error amplifier, thus creating a pulse-width modulated signal for the power switch driver. The typical voltage-mode controller is shown in Fig. 38.

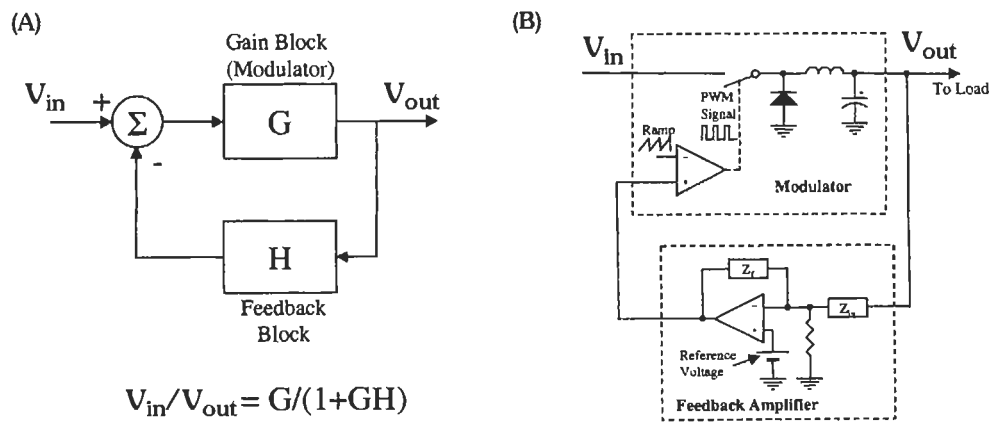

Fig. 37. Basic switching converter control system (A) and its principal block diagram (B).

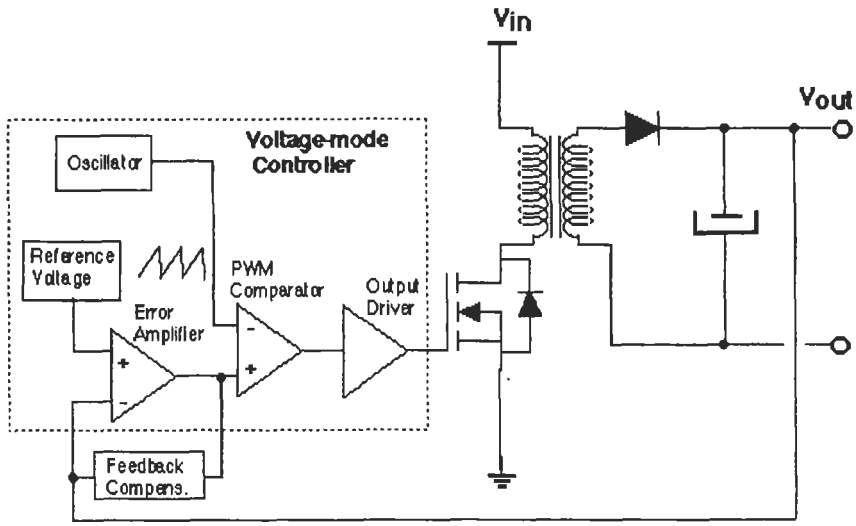

Fig. 38. Basic voltage-mode control.

Because of its simplicity this control method is still very popular among the power supply designers as well as among the manufacturers of switch-mode power supply (SMPS) control integrated circuits.

Current-Mode Control

Current-mode control adds a second control loop to the voltage feedback loop. Now, instead of the ramp from the oscillator, as in the voltage mode control, the current ramp created by magnetic elements is used for error-voltage-to-PWM conversion. The oscillator only serves to fix the frequency of operation. The basic current-mode controller diagram is shown in Fig. 39. This method of control offers significant improvements in terms of line regulation and load transient response as well as inherent cycle-by-cycle overcurrent protection.

Resonant Transistor Circuits

Unavoidable switching losses occur during each turn-on and turn-off switching event in a pulse-width-modulated power supply. In an effort to reduce the size and weight of power supplies, the frequency of operation has been increased up to the point that the switching losses are increasingly important. In an effort to reduce these switching losses, resonant circuits have been developed. Two general categories are: zero-voltage switching (ZVS), where the voltage across the switch is brought to zero before the switch is turned on, and zero-current switching (ZCS), where the power semiconductor does not switch unless the current through the switch is zero. With the switching losses greatly reduced, the frequency of operation can be increased up to, at present, 1 to 10 Mhz. The resonant operation requires inductors and capacitors to set the resonant frequency. If the frequency is high enough, the capacitances of the semiconductor junctions and the leakage reactance of the transformers can be used as the resonant elements. The actual operating frequency can be higher or lower than the *LC* resonant frequency, depending on the characteristics of the power switches. Rather than use pulse-width modulation as a means for controlling the output voltage, many resonant converters vary the frequency of operation to control their output voltage. This area of the technology is the subject of ongoing research. Chapter 7 of Reference 2 provides additional discussion of resonant converters. Fig. 40 is a block diagram of a resonant converter configured as a dc-to-dc power supply.

Power Factor Correction Circuits

As stated in previous paragraphs, switch-mode power supplies, motor control frequency inverters, and lighting electronics pull current in narrow, high-amplitude pulses rather than sinusoidally from the ac mains. In switch-mode power supplies the problem lies in the input rectification and filter network. The typical input circuit and its associated waveforms are shown in Fig. 41. The input rectifiers can only conduct current when the ac line voltage exceeds the voltage on the bulk input filter capacitor. This typically occurs within 15 degrees of the crest of the ac voltage waveform. The resulting current pulses can be 5–10 times higher than the expected average current draw. This also can lead to distortion of the ac voltage waveform and an imbalance of the three-phase power lines feeding the circuits.

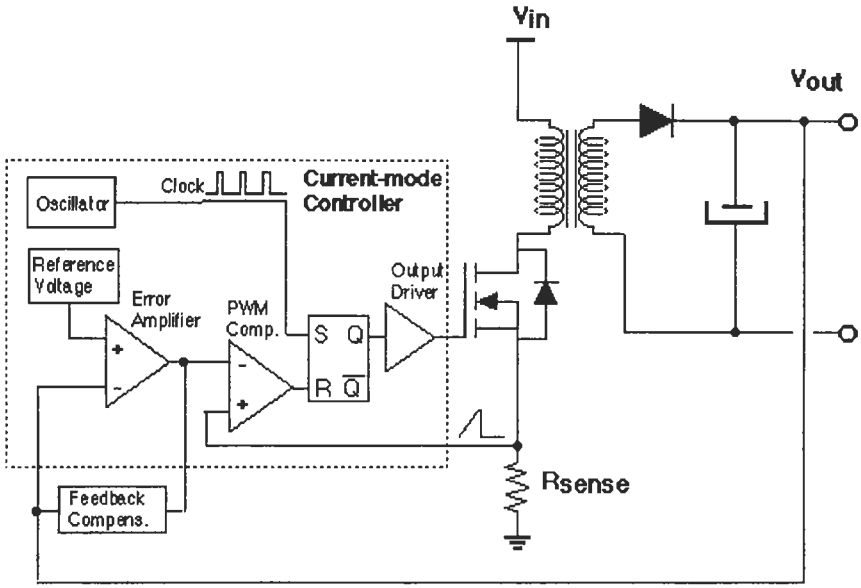

Fig. 39. Basic current-mode control.

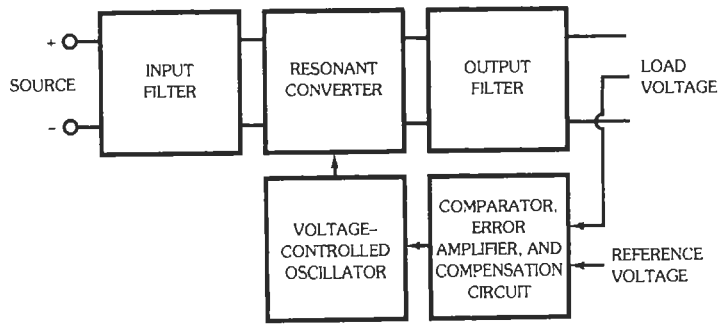

Fig. 40. Block diagram of resonant-mode power supply.

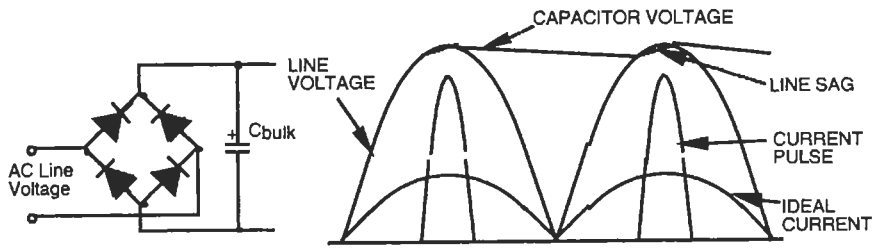

Fig. 41. Capacitive input filter and its waveforms.

Power Factor Definition

Ideally the ac current provided by local utilities should be purely sinusoidal and free of surges, transients, and electrical noise (see Fig. 42). The power factor (PF) is defined by the ratio of the real power P_R to the total apparent power P_A:

$$PF = \frac{P_R}{P_A} \qquad \text{(Eq. 2)}$$

The real power P_R can be calculated as the average of the instantaneous product of voltage and current taken at each instance in time over the full period, T:

$$P_R = \frac{1}{T}\int_0^T e \cdot i\,dt \qquad \text{(Eq. 3)}$$

where e = voltage and i = current. The apparent power, a sum of the real power and reactive power, is calculated as the product of the rms current measured over the full period and the rms voltage measured over the same full period:

$$P_A = V_{\text{RMS}} \cdot I_{\text{RMS}} \qquad \text{(Eq. 4)}$$

In the case of an uncorrected switch-mode power supply, the current and voltage can be nearly in phase as the result of the capacitor charging near the peak of the voltage waveform (see Fig. 43(A)). Therefore using the definition $PF = \cos\phi$ would misleadingly yield a PF of 1.0 when the PF may be very low.

Probably the clearest definition of the power factor can be made by following way. For sinusoidal input voltage:

$$PF = \frac{P_R}{P_A} = \frac{P_{\text{INPUT}}}{V_{\text{rms}} \cdot I_{\text{rms}}} = \frac{V_1 I_1 \cos\phi}{V_1 \cdot I_{i,\text{rms}}} \qquad \text{(Eq. 5)}$$

where

$\frac{I_1}{I_{i,\text{rms}}} = DF$ is the distortion factor,

I_1 is the first harmonic of the input current,

$I_{i,\text{rms}}$ is the total harmonic current, and

$\cos\phi$ is the displacement factor.

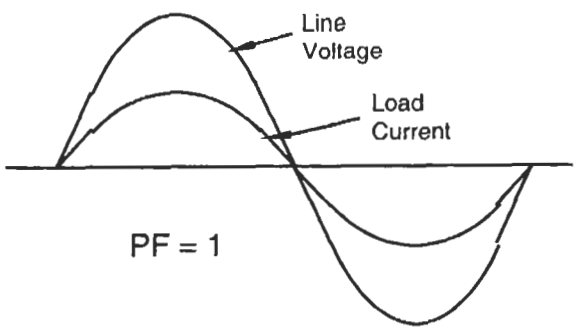

Fig. 42. The ac input current is sinusoidal and in phase with the voltage waveform. Power factor = 1.0

Then the distortion factor DF can be defined as follows:

$$DF = \frac{1}{\sqrt{1+(THD)^2}} \qquad \text{(Eq. 6)}$$

where the total harmonic distortion THD equals

$$THD = \frac{\sqrt{I_{i,\text{rms}}^2 - I_1^2}}{I_1} \qquad \text{(Eq. 7)}$$

The situation is even more clearly seen in Figs. 43(A) and 43(B). In both cases the power factor does not equal 1.0.

International Regulatory Standards

The harmonic-current problems addresses the international community in the IEC 1000-3-2 document (the successor of the IEC 555-2), which establishes requirements that limit harmonic-current injection into the public supply system. The IEC 1000-3-2 addresses equipment with nominal line-to-neutral voltages of 220 V and higher. The aim of the standard is to prevent power-control devices from generating low-frequency harmonics.

IEC 1000-3-2 categorizes devices into four classes. Each class has unique limits. Class A covers balanced three-phase equipment and all others except those defined in specialized classes B, C, and D. Class B covers portable tools, Class C sets the limits for lighting equipment. Those devices that have a special "wave shape" (see Fig. 44) and are not motor driven or do not fit into Class A, B, or C are considered Class D.

Active Power Factor Correction

To improve power quality the mains power source should see a sinusoidal load current that appears resistive. Therefore an ideal power factor correction stage should appear as a resistive load to the ac line, pulling current sinusoidally and storing the power for the main converter so that the regulated voltage exists while the

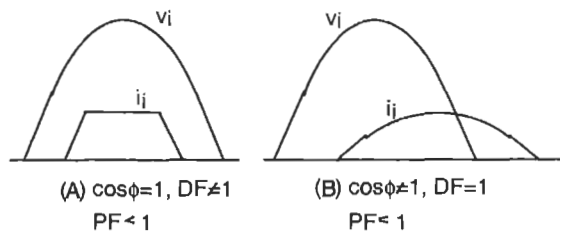

Fig. 43. Examples of non-unity power factor.

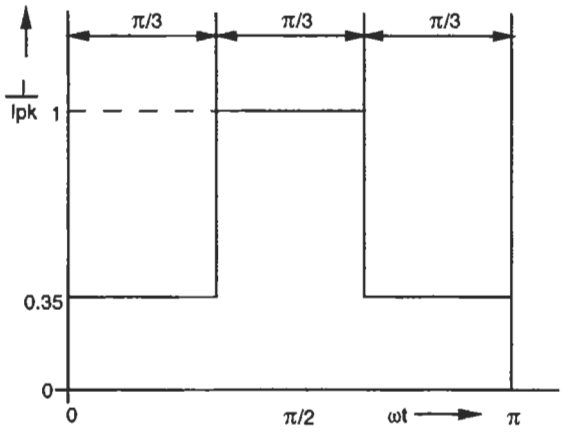

Fig. 44. Class D defines a "special wave shape" of the envelope of the input current.

line voltage sinusoidally varies. This can be approached actively or passively.

Active power factor correction circuits usually take the form of a modified boost converter (refer to Table 3, Column B, and Fig. 45). Three of these circuits can be arranged in a bridge circuit to shape the currents drawn from a multiphase ac supply.

There are several main implementations in the control of power factor correction (PFC) circuits: the fixed-frequency average current sensing method widely implemented by Unitrode under the Pioneer Magnetics patent (UC3854 control integrated circuit); the fixed-frequency, peak current sensing method by Micro Linear (ML4812); hysteretic control used by Cherry Semiconductor (CS3810); and the borderline or critical conduction, peak current sensing method used by Siemens (TDA4818), Silicon General (SG3561), and Motorola (MC34262, MC33368). Fig. 46 shows current waveforms of two typical PFC control techniques.

FILTER CIRCUITS AND DESIGN

Rectifier filters may be classified into three types:

(1) *Inductor Input* (Fig. 47): Have good voltage regulation, high transformer utilization factor, and low rectifier peak currents, but also give relatively low output voltage.

(2) *Capacitor Input* (Fig. 48): Have high output voltage, but poor regulation, poor transformer utilization factor, and high peak currents. Used mostly in television and radio receivers.

(3) *Resistor Input* (Fig. 49): Used for low-current and low-power applications.

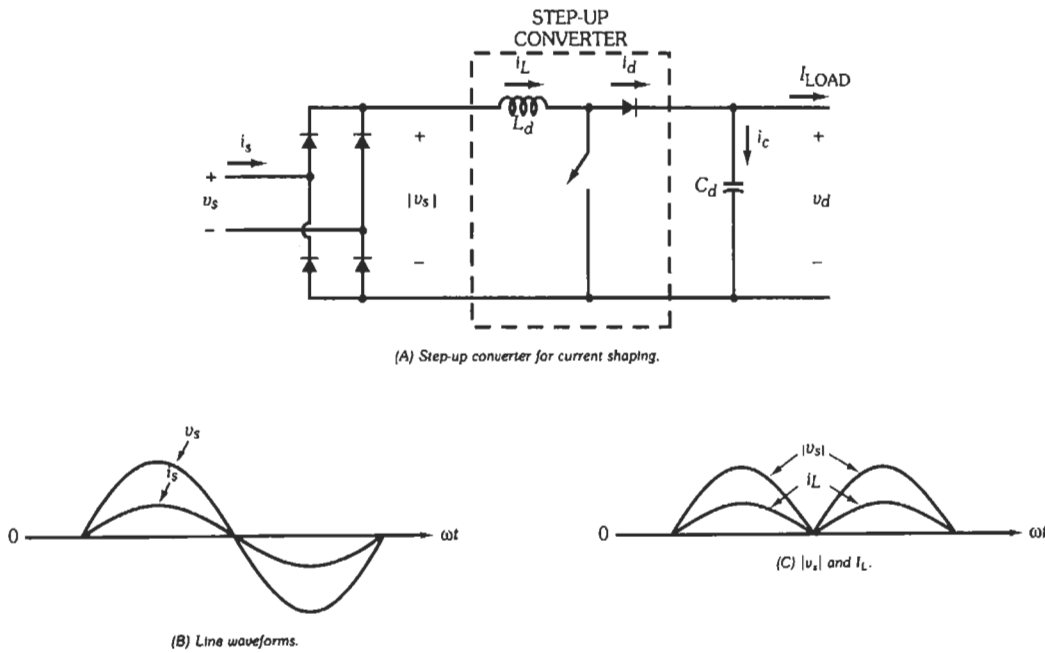

Fig. 45. Active power factor correction and harmonic filtering. (From Mohan, N., et al. *Power Electronics—Converters, Applications and Design*. New York: John Wiley & Sons, Inc., 1989.)

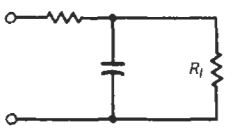

Fig. 49. Resistor-input filter.

Inductor-Input Filter Design

The constants of Fig. 47 are determined from the following considerations:

(A) There must be sufficient inductance to ensure continuous operation of rectifiers and good voltage regulation. When this critical value of inductance is increased by a 25-percent safety factor, the minimum value becomes

$$L_{\min} = (K/f_s)R_l \text{ henry} \qquad \text{(Eq. 8)}$$

where

f_s = frequency of source in hertz,
R_l = maximum total load resistance in ohms,
K = 0.060 for full-wave single-phase circuits
= 0.0057 for full-wave two-phase circuits
= 0.0017 for full-wave three-phase circuits.

At 60 hertz, single-phase full-wave

$$L_{\min} = R_l/1000 \text{ henry} \qquad \text{(Eq. 8a)}$$

(**B**) The LC product must exceed a certain minimum, to ensure a required ripple voltage factor

$$r = E_r/E_{dc} = \left[\sqrt{2}/(p^2-1)\right]\left[10^6/(2\pi f_s p)^2 L_1 C_1\right] = K'/L_1 C_1 \quad \text{(Eq. 9)}$$

where, except for single-phase half-wave,

p = effective number of phases of rectifier,
E_r = root-mean-square ripple voltage appearing across C_1,
E_{dc} = direct-current voltage on C_1,
L_1 is in henrys,
C_1 is in microfarads.

For single-phase full-wave, $p = 2$ and

$$r = (0.83/L_1 C_1)(60/f_s)^2 \quad \text{(Eq. 9a)}$$

For three-phase full-wave, $p = 6$ and

$$r = (0.0079/L_1 C_1)(60/f_s)^2 \quad \text{(Eq. 9b)}$$

Equations (8) and (9) define the constants L_1 and C_1 of the filter, in terms of load resistor R_l and allowable ripple voltage factor r.

Swinging Chokes—Swinging chokes have inductances that vary with the load current. When the load resistance varies through a wide range, a swinging choke, with a bleeder resistor R_b (10 000 to 20 000 ohms) connected across the filter output, is used to guarantee efficient operation; i.e., $L_{min} = R_l'/1000$ for all loads, where $R_l' = (R_l R_b)/(R_l + R_b)$. Swinging chokes are economical because of their smaller relative size and result in adequate filtering in many cases.

Two-Section Filters—For further reduction of ripple voltage E_{r1}, a smoothing section (Fig. 46) may be added and will result in output ripple voltage E_{r2}.

$$E_{r2}/E_{r1} \approx 10^6/(2\pi f_r)^2 L_2 C_2 \quad \text{(Eq. 10)}$$

where f_r = ripple frequency.

Capacitor-Input Filter Design

The constants of the input capacitor (Fig. 47) are determined from the following:

(**A**) Degree of filtering required.

$$r = E_r/E_{dc} = \sqrt{2}/2\pi f_r C_1 R_l = (0.00188/C_1 R_l)(120/f_r) \quad \text{(Eq. 11)}$$

where $C_1 R_l$ is in microfarads × megohms or farads × ohms.

(**B**) A maximum allowable C_1 (so as not to exceed the maximum allowable peak-current rating of the rectifier).

Unlike the inductor-input filter, the source impedance (transformer and rectifier) affects output dc and ripple voltages and the peak currents. The equivalent network is shown in Fig. 48.

Neglecting leakage inductance, the peak output ripple voltage E_{r1} (across the capacitor) and the peak rectifier current for varying effective load resistance are given in Fig. 50. If the load current is small, there may be no need to add the L-section consisting of an inductor and a second capacitor. Otherwise, with the completion of an L_2C_2 or RC_2 section (Fig. 48), greater filtering is obtained, the peak output-ripple voltage E_{r2} being given by Eq. 10 or by

$$E_{r2}/E_{r1} = 1/2\pi f_r R C_2 \quad \text{(Eq. 12)}$$

Harmonic Currents and Power Factor

In the case of the inductor-, resistor- and capacitor-input filters, the current drawn from the ac supply is nonsinusoidal. Since the definition of power factor includes a term associated with harmonic distortion, the power factor of all of the circuits is less than unity. The power factor given for the various rectifier circuits (Table 1) assumes that the inductance of the filter choke is infinite. For finite values of inductance, the power factor is decreased. With a three-phase supply, reducing the inductance of the filter reactor reduces the power factor and increases harmonic currents. The power factor as a function of filter inductance for a single-phase rectifier is shown in Fig. 51. The power factor as a function of filter inductance for a three-phase rectifier is shown in Fig. 52. The asymptote of 0.955 is the value given in Table 1, column 5. Standards are currently being prepared in Europe to limit the harmonic currents that can be drawn from the supply network. One approach to meeting these standards is to provide a pulse-width-modulated rectifier (Fig. 45).

Phase-Controlled-Thyristor Filter Design

The same general principles apply to filters for controlled rectifier circuits as to those for ordinary rectifier circuits. Capacitive-input filters, however, are rarely used, since a capacitive load restricts the range of conduction-angle control that it is possible to obtain with thyristors and results in large values of current at the instant of thyristor turn-on.

The two main differences to consider in filter design for controlled rectifiers, compared with that for ordinary rectifiers, are (A) the greatly increased values of critical inductance for the input choke and (B) the larger input ripple voltages.

Empirical equations for the critical inductance L_{min} were given that apply to various configurations of diode rectifiers. In controlled rectifiers, L_{min} rises as the conduction angle is decreased by gate control, *i.e.*,

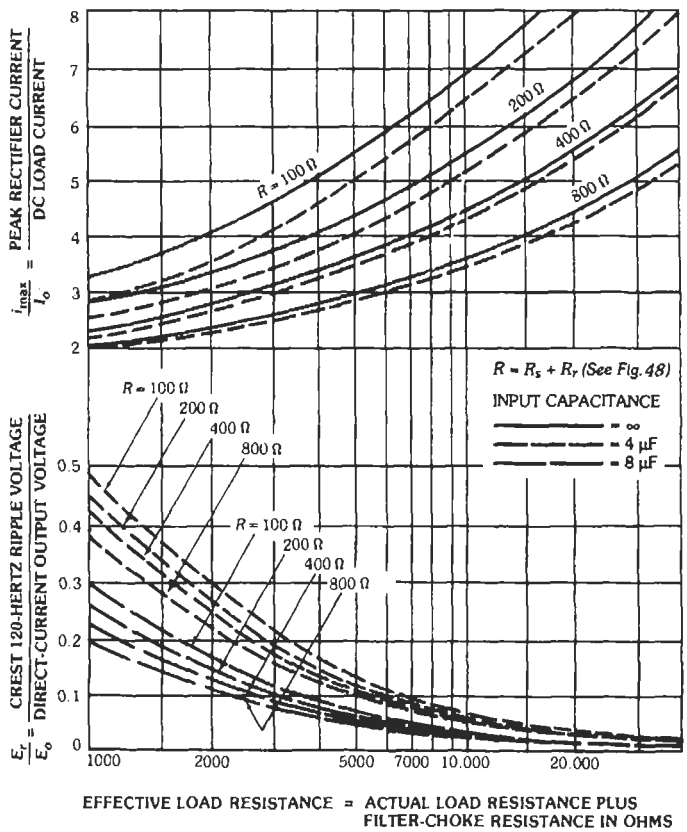

Fig. 50. Performance of capacitor-input filter for 60-hertz full-wave rectifier, assuming negligible leakage-inductance effect. (Adapted from *Radio Engineers Handbook*, by F. E. Terman, 1st ed., p. 603; 1943. By permission McGraw-Hill Book Co., New York.)

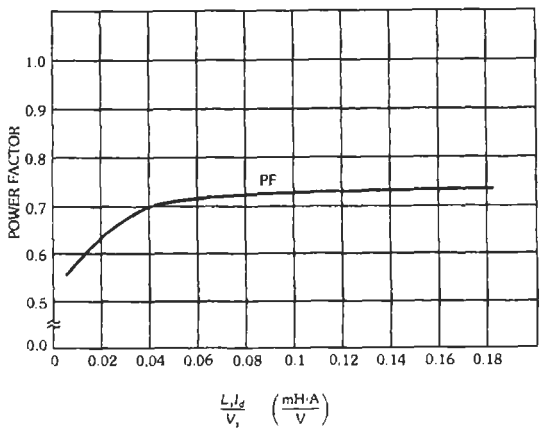

Fig. 51. Effect of L_s on power factor for a single-phase rectifier. L_s is in millihenries, I_d is the average current, and V_s is the rms voltage. (From Mohan, N., et al. *Power Electronics—Converters, Applications and Design*. ©1989. Reprinted by permission of John Wiley & Sons, Inc.)

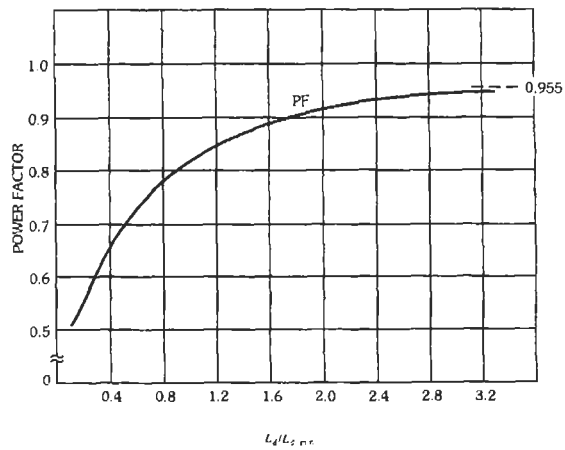

Fig. 52. Effect of L_d on power factor for three-phase rectifier. (From Mohan, N., et al. *Power Electronics—Converters, Applications and Design*. ©1989. Reprinted by permission of John Wiley & Sons, Inc.)

as the firing-angle delay, α, is increased. Fig. 53 shows the ratio L_{min}/R as a function of the percentage of maximum output voltage obtained from half- and full-controlled rectifier types discussed in the section on thyristors. Scales are included to show the corresponding values of α for various percentage outputs.

The ripple from a controlled rectifier is generally larger than that obtained from a conventional diode rectifier, and its value varies with the firing angle, α. Reference 3 provides graphs of the ripple voltage as a function of firing angle for the various single- and three-phase controlled rectifier circuits.

Resonant-Filter Design

Resonant filters are designed to reduce a specific frequency component of the waveform. A parallel-resonant section is placed in series with the load, and a series-resonant section is placed in parallel with the load. Fig. 54 shows a resonant filter. Both L_1 and C_1 and L_2 and C_2 are selected to resonate at the unwanted frequency. These systems are applied to power-system filters where additional losses cannot be tolerated.

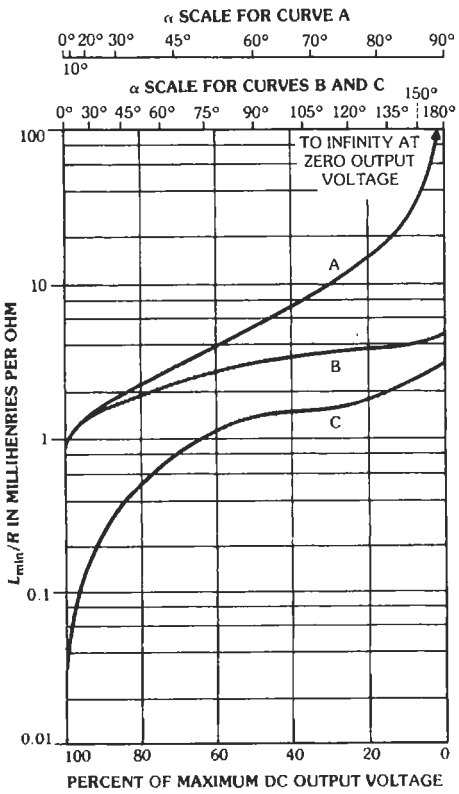

Fig. 53. L_{min}/R as a function of the percentage of maximum dc output voltage for thyristor rectifiers. The values of L_{min}/R given by the curves apply to a supply frequency of 60 hertz. Curve A is for full-controlled single-phase rectifiers such as those in Fig. 22 and in Fig. 24 with the bypass diode omitted. Curve B is for half-controlled single-phase rectifiers such as those in Fig. 23 and in Fig. 24 with the bypass diode included. Curve C is for a half-controlled three-phase rectifier such as that in Fig. 26.

DC-OUTPUT POWER SUPPLIES

The previous sections described the various types of semiconductor devices, ac-to-dc converter circuits, and filter circuits. This section assembles these subsystems into complete dc power supplies. Block diagrams illustrate the various approaches to dc power supplies.

Unregulated Power Supplies

The most common type of unregulated power supply is the ac-to-dc rectifier with uncontrolled rectifiers followed by a suitable filter. Polyphase power produces less dc ripple voltage, less input harmonic current, and reduced dc voltage regulation. A power transformer allows for voltage matching between the incoming ac and the dc load voltage. If the load requires high-voltage dc, then a voltage-multiplier circuit can be chosen, since the design of the step-up transformer is more difficult with a large step-up ratio and severe insulation requirements. Load-voltage adjustment can be provided by transformer taps or an adjustable-voltage transformer.

Linear Regulated Power Supplies

A block diagram of a low-voltage linear regulated power supply is shown in Fig. 55. A utility-frequency transformer provides voltage matching between the incoming ac voltage and the desired load voltage. A diode rectifier converts the secondary ac voltage to dc voltage. A filter provides coarse filtering and fills in the gaps in the dc voltage caused by the rectification of single-phase power. The series transistor, operating in its linear region, absorbs the difference between its input voltage and the load voltage. The load voltage is sensed and fed back to the closed-loop voltage regulator. Load current limiting can also be provided to protect the series pass transistor from excessive power

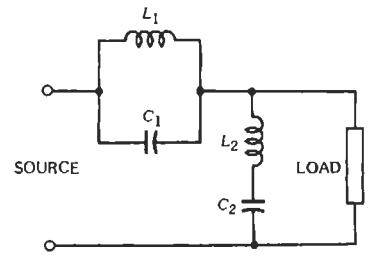

Fig. 54. Resonant filter circuit.

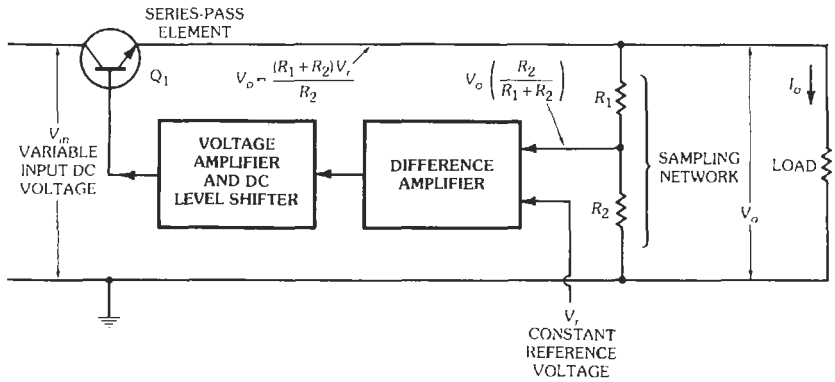

Fig. 55. Basic series-pass voltage regulator. Transistor Q_1 is an electronically controlled variable resistance in series with the load. (From Pressman, A. I. *Switching and Linear Power Supply, Power Converter Design.* Rochelle Park, NJ: Hayden Book Co., Inc., 1997.)

dissipation. Integrated and hybrid control circuits provide these and other functions in a single package. Instead of sensing output voltage, the output current can be sensed, and the system can provide a constant current to a variable load. A diode is sometimes provided to prevent load-voltage reversals caused by inductive energy in the load. Linear power supplies are used at low power (less than 50–100 watts); where multiple output voltages must be regulated; and where low noise, low ripple voltage, and fast response are essential.

Phase-Control Power Supplies

Two basic dc power-supply systems are configured with phase-controlled thyristors either on the primary or the secondary side of the isolation transformer. Figs. 56 and 57 show these two versions. The choice between the two systems is dependent on the cost of thyristors as a function of their voltage and current ratings. The usual configuration is for the ac input to be high voltage and the dc load to be low voltage and high current. Placing the thyristors in the primary allows high-voltage, low-current thyristors to provide the control of the output voltage. If the thyristors are located on the low-voltage side of the transformer, they must be rated at high current and low voltage. The efficiencies of the two systems are comparable, as the double power conversion of one system balances the losses associated with a high-current, low-voltage phase-controlled rectifier. Control of the transformer primary voltage requires that the gating signals be symmetrical to avoid transformer saturation.

Systems without isolation transformers are used to supply adjustable dc voltage to dc motor armatures and field supplies. Isolation transformers are provided in general-purpose laboratory power supplies in the range of 1–50 kW.

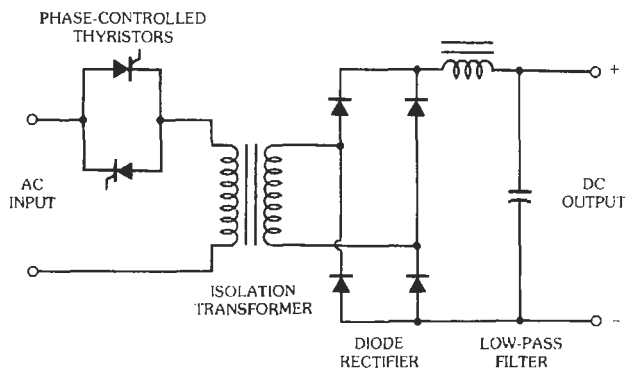

Fig. 56. Adjustable dc power supply with primary voltage control.

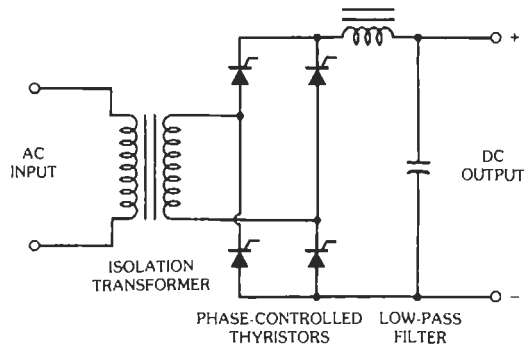

Fig. 57. Adjustable dc power supply with secondary voltage control.

Switching Power Supplies

Switching type power supplies are currently used for general-purpose dc power supplies in the 100–3000-watt range. It is expected that this range will increase in the future as the result of the technical features and cost reductions associated with this approach. Table 3 provides the design equations and device requirements for the most common types of dc-to-dc converters. To achieve small size and light weight, a 60-hertz isolation transformer is not provided. An uncontrolled diode rectifier and small capacitor filter provide an approximately 130-volt dc supply from 115-volt single-phase ac power. At light load, this voltage can increase to approximately 170–180 volts. A block diagram of this approach is shown in Fig. 58. A high-frequency pulse-width-modulated chopper or inverter is provided to regulate the voltage applied to the high-frequency transformer. The high-frequency transformer (20–500 kHz) provides voltage isolation and voltage matching at low weight, small size, and high efficiency. An uncontrolled ac-to-dc rectifier, at low voltages using Schottky diodes, converts from ac to dc. A low-pass filter removes the high-frequency (40–1000 kHz) ripple from the output voltage. A closed-loop voltage regulator is provided by sensing the output voltage, comparing it to a reference, and controlling the on–off ratio of the primary transistors. Isolation of the feedback signal can be provided by optical couplers or voltage-to-frequency converters, pulse transformers, and frequency-to-voltage converter circuits.

A second approach is to separate the regulation and transformer functions into two separate circuits. A block diagram is shown in Fig. 59. Voltage control is provided by a series dc/dc chopper operating at high frequency followed by a low-pass filter. The dc-to-ac inverter operates with a fixed 180° waveform that allows the use of a lightweight non-air-gap transformer. After rectification, the output filter needs to provide only a small amount of high-frequency filtering. This system is useful when the output voltage is low and the current is high, so that a large filter inductor is indicated.

In addition to the pulse-width-modulated switching power supplies, resonant converters based on either zero-voltage switching or zero-current switching can be provided. These circuits can operate a very high frequency (1–5 MHz). These circuits are generally configured as dc–dc converters operating as part of a distributed power supply.

Distributed Power Supplies

Large electronic systems composed of many circuit cards containing digital logic chips require regulated dc power at 5 volts dc. Newer types of digital logic will require 3.3 volts dc. The connected load can require dc currents in the range of hundreds of amperes. It is difficult to supply this amount of current without resorting to large, heavy, and complex bus structures. The area of conductor must be sufficient to keep the load regulation less than the lowest voltage required by the digital logic. A way to reduce this

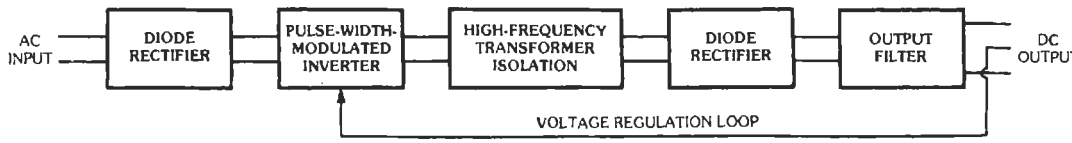

Fig. 58. Block diagram of dc power supply with pulse-width-modulated inverter for voltage control.

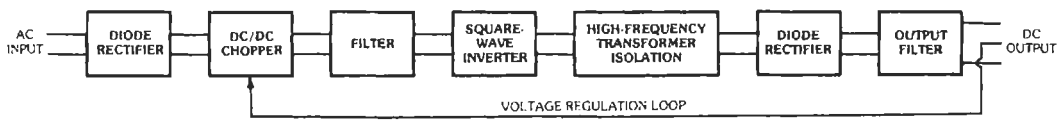

Fig. 59. Block diagram of dc power supply with dc/dc chopper for voltage control.

problem has been to use distributed power supplies. A block diagram is shown in Fig. 60. A bulk ac-to-dc converter, rated for full power, perhaps using a unity-power-factor ac-dc circuit, provides a regulated high-voltage dc output, in the range of 50 to 270 volts dc. For higher reliability, multiple converters can be connected to the high-voltage dc bus with diodes. This high-voltage dc power is supplied to the back plane of all of the electronic circuit cards and is brought on each printed circuit card. Each card has its own dc–dc converter to convert the 50 volts dc to 5 volts dc for that card. The power requirements for each card would be in the range of 10 to 100 watts, resulting in greatly reduced current demands. These "on-card" dc–dc converters operate at the highest possible frequency in order to reduce their size. Their aspect is such that their height is generally limited to less than 0.5 inch, so that the printed circuit cards can be closely stacked in their card rack.

Electromagnetic interference (EMI) can be controlled by shielding the dc–dc converter mounted on the printed circuit card. Conducted EMI can be controlled with series and parallel connected input filters. Heat rejection is accomplished by designing the converter to have the highest possible efficiency, providing fins for a larger heat surface, or conducting the heat from the printed circuit card to a cold plate.

AC-OUTPUT POWER SUPPLIES

The previous sections have discussed the aspects of converter and filter circuits and dc-output power supplies. This section describes some of the various types of power supplies that provide an alternating voltage and alternating current output. Some of the specific problem areas with an alternating output are associated with the power factor of ac loads, ac voltage magnitude control, polyphase output, adjustable-frequency output, and reverse power flow. Three basic ac-output power supplies are described, the ac voltage regulator, the dc-to-ac inverter, and the ac-to-ac cycloconverter. Greater detail and design equations for these generally complex systems are contained in References 2, 5, and 10–21.

AC Voltage Regulators

The ac voltage regulator is a static circuit that accepts a variable ac voltage input and produces a regulated ac voltage output. The output voltage is maintained for changes in input voltage, output load current, and load power factor. The input frequency is not changed, nor is the basic sinusoidal waveform modified. Since the input and output voltage is ac, thyristors with line commutation have been utilized. Fig. 61 shows a simple ac voltage-regulator circuit. This circuit is the static equivalent of the mechanical on-load tap changer. The thyristors are connected in inverse-parallel and provide a bidirectional connection from the tap on the autotransformer to the load. One tap is at a voltage lower than the input voltage; the other tap is at a higher voltage. In this manner, the input voltage can be either increased or decreased to produce a fixed voltage output. Output voltage control is provided by a closed-loop regulator that adjusts the firing angle of the two thyristors connected to the higher-voltage transformer tap. The gating on of these thyristors reverse biases the lower two thyristors, causing them to cease conducting the load current and transferring the load current to the higher-tap thyristors. More than two taps can be provided to develop a regulated output voltage with reduced harmonic content. The gating of the lower two thyristors is accomplished at the zero crossing of the load current. In this manner, the load current is initially in the lower tap irrespective of the load power factor. The transfer of load current at current zero allows the upper-tap thyristors to turn off and allows the lower-tap thyristors to conduct the load current. This transfer from upper to lower tap is at load-current zero crossing and is dependent on the load power factor. Therefore, the output voltage waveform and magnitude change with respect to the load power factor, putting an additional burden on the ac voltage regulator. Both three-phase and single-phase circuits with full isolation transformers have been fabricated. Where low harmonic distortion is required, an output filter can be provided.

DC–AC Inverters

This broad class of circuits is characterized by a dc input voltage and an ac output voltage. Since the input is dc, commutation of thyristors must be provided by techniques other than the reversal of the input voltage. Transistors are widely used in lower-power inverters because of their self-commutation capability. Four major classes of inverters are described in this section: first, a system called an "uninterruptible power supply (UPS)," which provides a fixed-voltage, fixed-frequency output; second, an adjustable-voltage, adjustable-frequency system for an adjustable-speed motor drive; third, an induction-heating supply with a high-frequency output; and fourth, an adjustable-ac-current, adjustable-frequency synchronous-motor drive operating at a leading power factor. These constitute typical applications for dc-to-ac inverters. Design equations and discussions of operating conditions in greater depth can be obtained in References 2, 5, and 10–14.

Uninterruptible Power Supply (UPS)—The purpose of this equipment is to provide a source of ac power during outages of the normal source of utility supply. Uninterruptible power supplies are used in computer installations where power outages can mean loss of stored data (for example, in on-line reservations systems). Lower-power systems are provided to maintain continuous power to critical instrumentation (for example, a boiler-flame detector in a power plant). The source of power for these UPS installations is a battery that is kept charged from the utility. When the utility voltage is lost, the battery supplies power to the inverter and the connected load. These installations range in size from 1 kVA single-phase to 1000 kVA three-phase. The output frequency is generally 60 hertz, and the output voltage is the normal utilization voltage in order to use conventional ac-operated equipment and in some cases to operate in parallel with the ac utility.

Fig. 62 shows a block diagram of a large UPS installation. The separate battery charger, battery, inverter, utility bypass connection, and critical loads are shown.

High-power UPS systems use thyristors with forced commutation circuits as the power switches. Systems

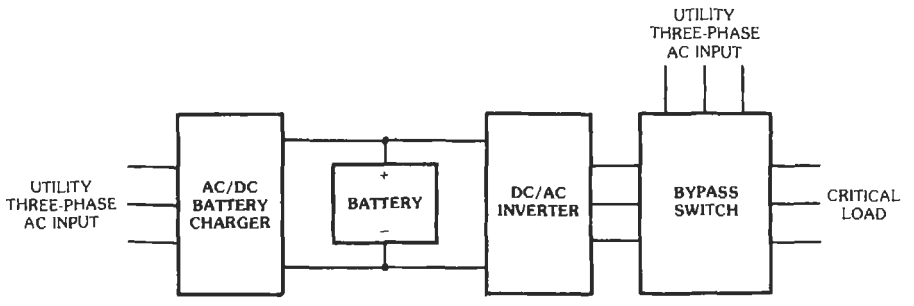

Fig. 62. Block diagram of UPS with utility bypass switch.

with ratings less than 200 kVA now use power transistors or insulated-gate bipolar transistors as the power switches. Fig. 63 shows a circuit diagram for a UPS system using a three-phase, pulse-width-modulated inverter supplied from a battery and feeding a transformer and filter. The transformer provides isolation and voltage matching. The filter reduces the harmonic content of the output voltage. A static bypass switch is shown. If the inverter must be taken off-line, the critical load can be supplied directly from the utility.

Drive for Adjustable-Speed AC Motor—A second application for an ac-output system is an adjustable-voltage, adjustable-frequency inverter operating from a dc source and providing power to an adjustable-speed ac motor. To operate at high efficiency over a wide range of speed, the ac motor must be provided with adjustable-voltage and adjustable-frequency power. The voltage and the frequency are not totally independent and are generally varied in such a way as to maintain a constant ratio of voltage to frequency. That is, higher ac voltage and higher frequency result in higher motor speed. Since the source is dc and induction motors operate at lagging power factor, forced commutation must be provided for the switching devices used in the inverter. If thyristors are used, they must be provided with auxiliary components to reduce the thyristor current to zero and provide a reverse voltage on the previously conducting device. Transistors with their self-commutation capability are becoming popular in inverters below 200 horsepower. The inverter operates from a relatively fixed source of dc voltage; therefore control of the output voltage must be provided in the inverter. The preferred technique is to pulse-width modulate the output voltage by operating the transistors in an on–off mode many times during a given half-cycle of the motor fundamental frequency. Power transistors, with turn-on and turn-off times measured in microseconds, can be switched on and off many times during one half-cycle of a 60-hertz voltage, corresponding to a 3600-rpm synchronous speed with a two-pole induction motor. Various forms of pulse-width modulation (PWM) have been proposed, with a form of sine-wave shaping being a preferred approach. Rapid advancements in microprocessor-based control systems and stored-program memory devices have reduced their cost and complexity to the point where they are used to generate the pulse-width-modulation switching times.

A three-phase full-bridge inverter is shown in Fig. 64. Transistors T_1–T_6, together with feedback diodes D_1–D_6, operate in a pulse-width-modulated manner to generate a load voltage as shown in Fig. 65. The motor leakage reactance acts as a filter for the motor current. For industrial applications, the source of dc voltage shown in Fig. 64 is an uncontrolled diode rectifier from either a single-phase or polyphase ac supply.

Induction-Heating Supply—In this application, a source of high-frequency ac power is converted to localized heating for melting and heat treating metals and ferrous parts. The frequency is relatively fixed and is dependent on the application. Low frequency, 60–180 hertz, is used for large ferrous heating and melting applications, whereas 10–50 kHz is used for surface hardening of metallic parts and in ultrasonic cleaning tanks. This application requires that the ac power be coupled into the load with an induction coil or trans-

ducer. Because of the lagging power factor of the work coil, a capacitor, either fixed or adjustable in steps, is provided to increase the power factor. High-power applications require the use of thyristors, and forced commutation is required because the operating frequency is higher than 60 hertz. The inductance of the work coil, an external capacitance, and the load resistor are selected to form an underdamped resonant circuit. Changes in the load resistance only change the damping ratio and barely affect the resonant frequency. The sinusoidal current waveform in the thyristors allows them to operate at higher frequencies with reduced losses. Fig. 66 shows an induction-heating inverter operating from a three-phase ac supply and supplying a single-phase load. High-power systems use this technique to balance the load on the three-phase supply.

Synchronous-Motor Drive—This system illustrates a fourth commutation technique for thyristors. In this case, the synchronous machine is operated at a leading fundamental-frequency power factor provided by overexciting the field of the machine. An adjustable-speed drive system of this type is shown in Fig. 67. The source of supply is an adjustable dc current supply. Thyristors T_1–T_6 steer the dc current into the motor windings in sequence to provide the ac-motor line current. A suitable control system turns on the thyristors at the proper time with respect to the back electromotive force in the motor to provide a reverse voltage for commutation of the thyristors. Shaft-position sensors or electrical signal processing is used to determine the correct time to gate the thyristors. The source of adjustable dc current for the inverter is an ac-to-dc phase-controlled rectifier. Special commutating

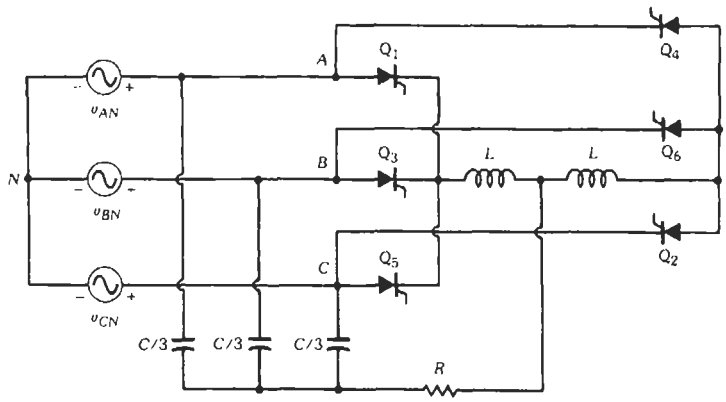

Fig. 66. Modified frequency multiplier with load commutation. (From Dewan, S. B., and Straughen, A. *Power Semiconductor Circuits*. New York: John Wiley & Sons, Inc., 1975.)

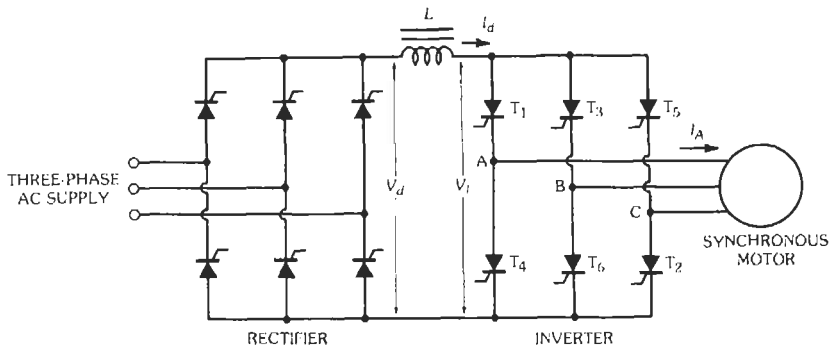

Fig. 67. Six-thyristor load-commutated inverter/synchronous-motor drive. (From Bose, Bimal K., ed. *Adjustable Speed AC Drive Systems*. New York: IEEE Press, 1981.)

circuits or turn-off intervals in the dc supply current are necessary to provide thyristor commutation during initial start-up and low-speed operation of the motor when the back emf is insufficient to commutate the thyristors. These drives have been fabricated to supply large synchronous machines up to 10 000 horsepower.

Cycloconverters

The preceding sections have described power-conversion systems that operate from dc power and produce an ac output. In industrial applications, the source is usually ac, thereby requiring a two-step conversion process from ac to dc to ac. The cycloconverter allows for a one-step conversion process from ac of a given voltage and frequency to adjustable-voltage ac (within limits) and adjustable-frequency ac (also within limits). This system uses the reversal of the line voltage to commutate the thyristors. The output voltage can be controlled by retarding the thyristor firing angle as in the phase-controlled rectifier. A second set of thyristors provides a path for the negative half-cycle of the load current. A three-phase to single-phase cycloconverter is shown in Fig. 68. The firing angle of the thyristors is modulated in a sinusoidal manner to generate a cycle of the desired output frequency. The inverse-parallel connection of the thyristors provides a bidirectional path for current flow at any power factor. Since the commutation of the thyristors is provided by the input frequency, the maximum output frequency must be less than the input frequency. The maximum output voltage is also less than the input voltage because of the need to generate a sinusoidal output voltage waveform.

There are two major applications for cycloconverters. The first is very high horsepower, very low speed, multiple-pole induction and synchronous motors. The maximum frequency for these motors can be less than 5 hertz in the case of an 8000-hp motor enclosing a rotary cement ball mill. The second application is for variable-speed constant-frequency (VSCF) systems in aircraft. The speed of the aircraft generator, and hence its generated frequency, is a function of the engine speed. A cycloconverter is provided at the output of the

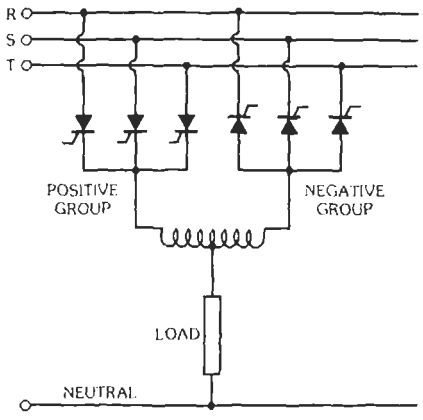

Fig. 68. Three-phase to single-phase cycloconverter power circuit. (From Murphy, J. M. D. *Thyristor Control of A.C. Motors*. New York: Pergamon Press, 1973.)

generator to convert the varying frequency into a fixed 400-hertz frequency for the aircraft power system. The adjustment of the thyristor gating times generates a sinusoidal output voltage waveform with minimum filtering. Output voltage regulation is provided by both the adjustment in thyristor gating times and adjustment of the field excitation on the synchronous generator.

15 Feedback Control Systems

Revised by
*William R. Perkins**

* This revision draws heavily upon the previous version of this chapter prepared by B. C. Kuo.

Control is the use of feedback to achieve desired response of dynamic systems in the presence of uncertainties, disturbances, and constraints. Control systems are found widely in many processes and products, and include industrial and chemical process control; vehicle, aircraft, and spacecraft control; automation and manufacturing systems; and robotics, to name only a few. Even some issues in economic and social systems can be approached from the control system viewpoint. And feedback control systems exist naturally in many living systems, such as blood-pressure regulation and heart-rate control. Fig. 1 gives a simple block-diagram representation of a controlled process. For example, in a motor-speed control problem, the controlled process is the motor, the actuating signal is the voltage or current input to the motor, and the output in this case is the motor speed. The controlled process is called the "plant." Load disturbances may be present. The objective, then, is to produce a control input that causes the controlled output to respond in a desired manner, in the presence of disturbance inputs and uncertainties in the plant description.

A typical closed-loop (feedback) control system structure is shown in Fig. 2. In this system, the output is measured with sensors and is "fed back" to the controller. The controller generates an input to the actuator, which provides an actuating input to the plant. An actuator is needed in many systems because the controller signal cannot drive the plant directly. For example, consider an antenna position control system, in which the antenna is driven by a motor, which is the actuator for this case.

MODELS OF CONTROL SYSTEM COMPONENTS

For system analysis and design, the plant, sensors, actuators, and controllers must be modeled appropriately. Differential equations or transfer functions are frequently used as models. For digital (computer) control, the controller may be modeled by difference equations. As examples, we consider several components found frequently in electromechanical control systems.

Error-Measuring Systems: Potentiometers, Synchros, Incremental Encoders

Commonly used error-measuring systems, or comparators, are shown in Fig. 3. Rotary potentiometers are

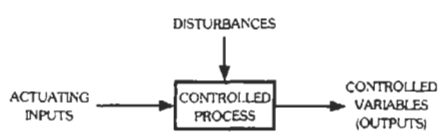

Fig. 1. Block diagram of a controlled process.

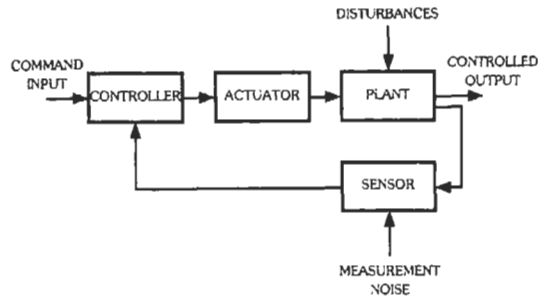

Fig. 2. Block diagram of a feedback control system.

available commercially in single-revolution or multi-revolution form. The potentiometers are commonly made with wirewound or conductive plastic resistance elements. Linear-motion potentiometers are also available for measuring linear motion properties.

The input-output relation of a potentiometer error detector is

$$e(t) = K_s[r(t) - c(t)]$$

where,

$e(t)$ is the output voltage,
$r(t)$ is the reference input,
$c(t)$ is the controlled variable,
K_s is the gain of the error detector,

Synchros are used in control systems as detectors and encoders due to their ruggedness of construction and high reliability. A synchro is basically a rotary device that operates on the same principle as a transformer and produces a correlation between an angular position and a voltage or set of voltages. See Fig. 3B.

Incremental encoders are available for rotary or linear motion. These devices typically convert linear or rotary displacement into digitally coded signals.

DC Motors

Types of dc motors include straight-series motors, split-series motors, shunt motors, compound motors (series-shunt fields), and permanent-magnet (PM) motors. Due to the advancements made in permanent-magnet materials, PM dc motors are one of the most widely used prime movers in industry today. The speed-torque characteristics of a PM dc motor are quite linear. However, the speed-torque characteristics of other types of dc motors are usually nonlinear.

The following variables and parameters are defined (SI units):

θ_m = motor angular position in radians
θ_l = load angular position in radians
ω = angular velocity in radians/second = $d\theta/dt$
T_m = motor-developed torque in Newton-meters
J_m = motor moment of inertia in kilogram-meters^2

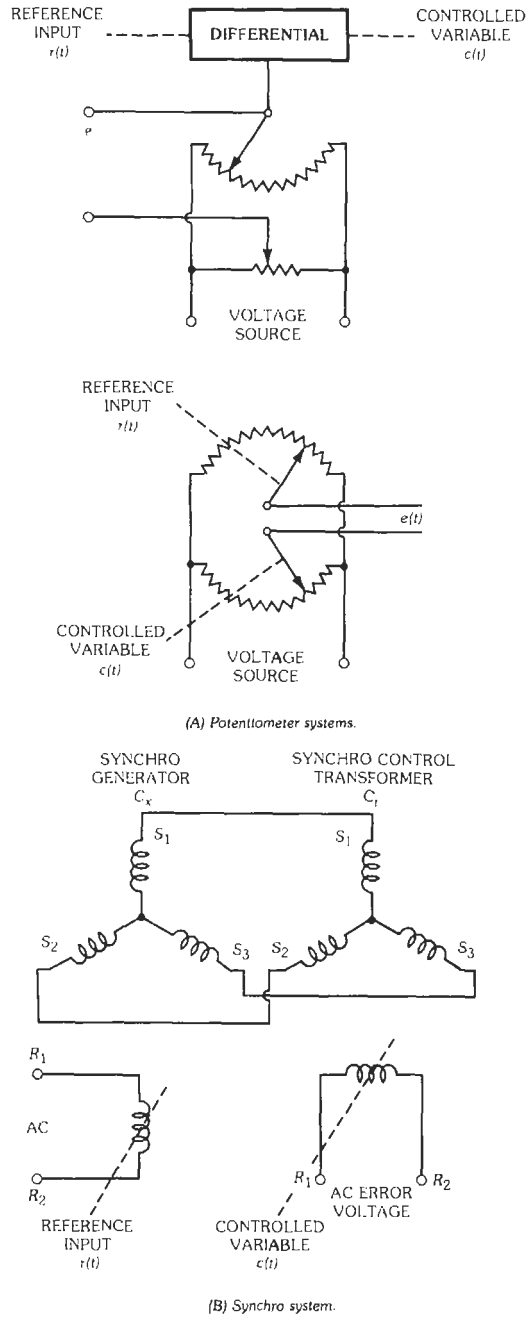

Fig. 3. Error-measuring systems.

J_1 = load moment of inertia in kilogram-meters^2
E_m = applied voltage in volts
K_m = motor torque constant in Newton-meters/ampere
K_b = motor back emf constant in V/rad/s
B_m = motor viscous-friction coefficient in Nm/rad/s
B_1 = load viscous-friction coefficient in Nm/rad/s
N = load-to-motor gear ratio = θ_l/θ_m
B_{me} = viscous-friction coefficient reflected to motor shaft = $B_m + N^2B_l$
J_{me} = inertia reflected to motor shaft = $K_m + N^2J_1$
R_a = armature resistance of motor in ohms
L_a = armature inductance of motor in henrys

The transfer function between the motor displacement and input voltage is

$$\theta_m(s)/E_m(s) = K_m/\{s[L_aJ_{me}s^2 + (R_aJ_{me} + B_{me}L_a)s + (K_bK_m + R_aB_{me})]\}$$

Two-Phase Servomotors

For low-power applications in control systems, ac motors are sometimes used because of their rugged construction. Most ac motors used in control systems are of the two-phase induction type. One of the two phases is excited from a constant-voltage source (the reference winding). The speed-torque curves shown in Fig. 4 are linearized for analytical purposes. Let

$$k = \frac{\text{Blocked-rotor torque at rated } E_m}{\text{Rated control voltage } E_1}$$

$$= T_0/E_1$$

$$m = -\frac{\text{Blocked-rotor torque}}{\text{No-load speed}} = -T_0/\Omega_0$$

The transfer function between the control voltage and the motor displacement is

$$\theta_m(s)/E_m(s) = K_m/[s(1 + \tau_m s)]$$

where,

$$K_m = k/(B_{me} - m)$$

$$\tau_m = J_{me}/(B_{me} - m)$$

Step Motors

Step motors are electromechanical incremental actuators that convert digital pulse inputs to analog output shaft motion. The advantage of a step motor is that the

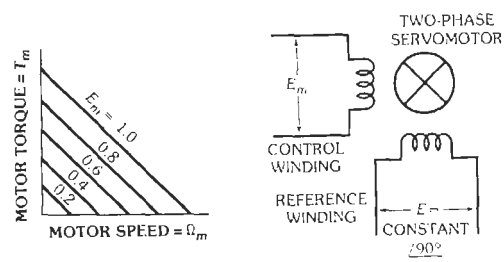

Fig. 4. Diagram of a two-phase servomotor and idealized torque-speed curves.

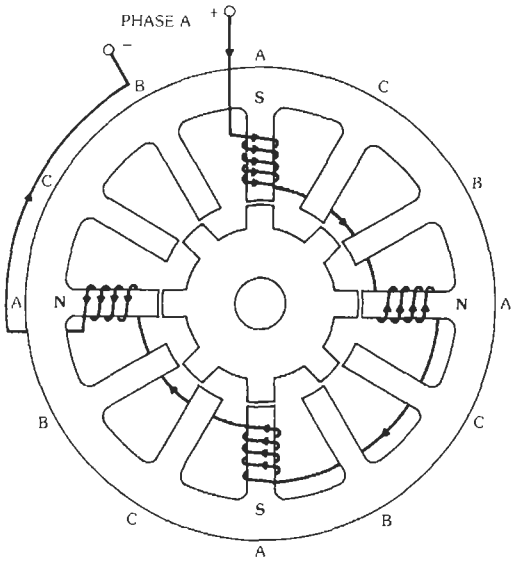

Fig. 5. Schematic diagram of a three-phase single-stack variable-reluctance step motor.

motor can be driven directly by digital inputs through the power drive, and no interface D/A conversion is necessary. In a rotary step motor, the output shaft of the motor rotates in equal increments in response to a train of input pulses.

The three most popular types of step motors are the variable-reluctance motor, the permanent-magnet motor, and the hybrid permanent-magnet motor. The latter two types have a permanent magnet in the rotor assembly.

Fig. 5 shows the schematic diagram of a single-stack three-phase variable-reluctance step motor. The stator in this case has 12 teeth, and the rotor has 8 teeth. There are four teeth per phase, and only the windings of phase A are shown. The rotor is shown to be at the detent position when phase A is energized with a dc current. If the dc excitation is shifted to the windings of phase B, the rotor will rotate 15 degrees in the clockwise direction. If, instead, phase C is energized, the rotor will make a 15-degree step in the counterclockwise direction. Therefore, the motor illustrated is a 24-step-per-revolution step motor.

Rate Generators

A rate generator (or tachometer) is a precision electromechanical component resembling a small motor and having an output voltage proportional to its shaft rotational speed. Rate generators have extensive applications both as computing instruments and as stabilizing components of feedback control systems. An example of the latter is illustrated in Fig. 6. The use of the rate generator produces an effective viscous damping and also tends to linearize the servomechanism by inserting damping of such magnitude that it is much larger than the nonlinear damping of the motor. Rate generators and servomotors are often constructed as integral units having a common shaft to eliminate the backlash. These units are available for dc or ac (either 400- or 60-hertz) operation.

SYSTEM PERFORMANCE

The performance of a closed-loop system (Fig. 2) is evaluated with respect to several desired objectives. These include:

A. *Stability*. The system is bounded-input bounded-output (BIBO) stable if its output is bounded for any bounded input (zero initial conditions).
B. *Steady-state tracking accuracy*. Frequently it is desired that the output $y(t)$ "follow," or track, a command or reference input $r(t)$, in the steady state ($t \to \infty$).
C. *Transient response*. Usually "fast" transients are desirable, provided the control inputs remain realistic (satisfy amplitude, energy, or other constraints).
D. *Disturbance rejection*. Ideally, the system should not respond to disturbance inputs. Such a goal is

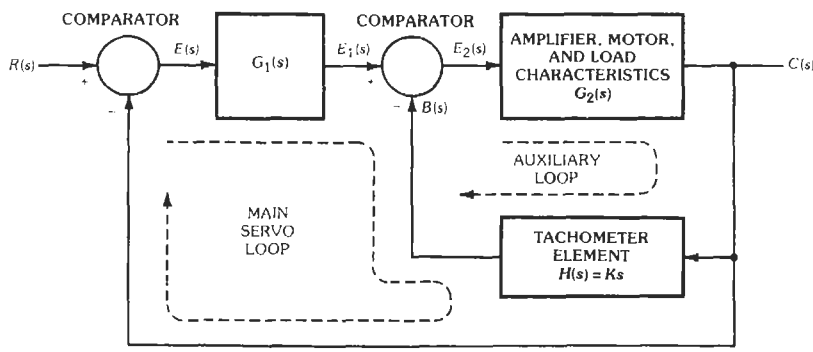

Fig. 6. Positioning servo.

unrealistic, and small (or zero) steady-state effects are sought, following rapid transients.

E. *Sensitivity and robustness.* The system should perform well in the presence of uncertain plant models. Such modeling inaccuracies are always present, and a central purpose of feedback is to obtain satisfactory performance in the presence of such inaccuracies and uncertainties.

We consider each of these objectives in detail.

Stability of Linear Time-Invariant Systems

A linear time-invariant system is BIBO stable if and only if all roots of the characteristic equation lie strictly in the left-half s-phase. The location of these roots can be determined directly by finding the roots numerically (with computer assistance, if necessary), if all system parameter values are known. Several other methods are available for investigating stability. These methods also provide additional information concerning system performance that is useful in both analysis and design. We outline here the following methods:

1. Routh-Hurwitz criterion
2. Nyquist criterion
3. Root locus diagram
4. Bode diagram

Routh-Hurwitz Criterion—The stability of the common unity feedback signal-loop linear system modeled in Fig. 7 can be investigated by referring to the closed-loop transfer function

$$C(s)/R(s) = G(s)/[1 + G(s)]$$

The stability of the system depends on the location of the poles of $C(s)/R(s)$ or the zeros of $1 + G(s)$ in the complex s-plane. The zeros of $1 + G(s)$ are also known as the roots of the *characteristic equation,* which can be written

$$D(s) = \sum_{i=0}^{n} a_i s^i$$

where all the coefficients are real.

A *necessary* condition for $D(s)$ to have no roots on the imaginary axis or in the right half of the s-plane are that all the coefficients of the equation must be of the same sign and that none of the coefficients is zero. This condition is not in general *sufficient,* however.

To check the necessary and sufficient conditions, we form the following Routh-Hurwitz tabulation:

a_n	a_{n-2}	a_{n-4}	a_{n-6}	.	.	.
a_{n-1}	a_{n-3}	a_{n-5}	a_{n-7}	.	.	.
b_1	b_2	b_3	b_4	.	.	.
c_1	c_2	c_3	c_4	.	.	.
d_1	d_2	d_3	.	.	.	.
e_1	e_2	.	.	.	.	.
f_1	.	.	.	.	.	.
.	.	.	.	.	.	.
.	.	.	.	.	.	.
.	.	.	.	.	.	.

where

$$b_1 = (a_{n-1}a_{n-2} - a_{n-3}a_n)/a_{n-1}$$
$$b_2 = (a_{n-1}a_{n-4} - a_{n-5}a_n)/a_{n-1}$$
$$b_3 = (a_{n-1}a_{n-6} - a_{n-7}a_n)/a_{n-1}$$
$$c_1 = (b_1a_{n-3} - b_2a_{n-1})/b_1$$
$$c_2 = (b_1a_{n-5} - b_3a_{n-1})/b_1$$
$$c_3 = (b_1a_{n-7} - b_4a_{n-1})/b_1$$
$$d_1 = (c_1b_2 - b_1c_2)/c_1$$
$$d_2 = (c_1b_3 - b_1c_3)/c_1$$
$$d_3 = (c_1b_4 - b_1c_4)/c_1$$
$$\vdots$$

The table will consist of n rows.

The system is stable, i.e., the characteristic polynomial has no zeros on the imaginary axis or in the right half of the s-plane, if every entry in the first column of the table has the same sign. The number of consecutive sign changes in the elements of the first column is equal to the number of zeros that are in the right half-plane.

A singular case develops when the first element in any one row is zero, or an entire row contains all zeros. Under such conditions, the table cannot be compiled by using the equations given above, and the tabulation must be modified.

Nyquist Stability Criterion—A second method for determining stability is known as the Nyquist stability criterion. This method involves obtaining the locus of the transfer function $G(s)$ in the complex G plane for values of $s = j\omega$ for ω from $-\infty$ to $+\infty$. Since the locus is always symmetrical about the real axis, it is sufficient to draw the locus for positive values of ω only. Fig. 8 shows loci for several simple systems. BIBO

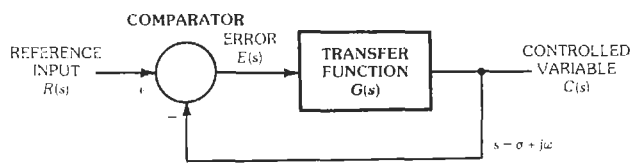

Fig. 7. Unity feedback single-loop system.

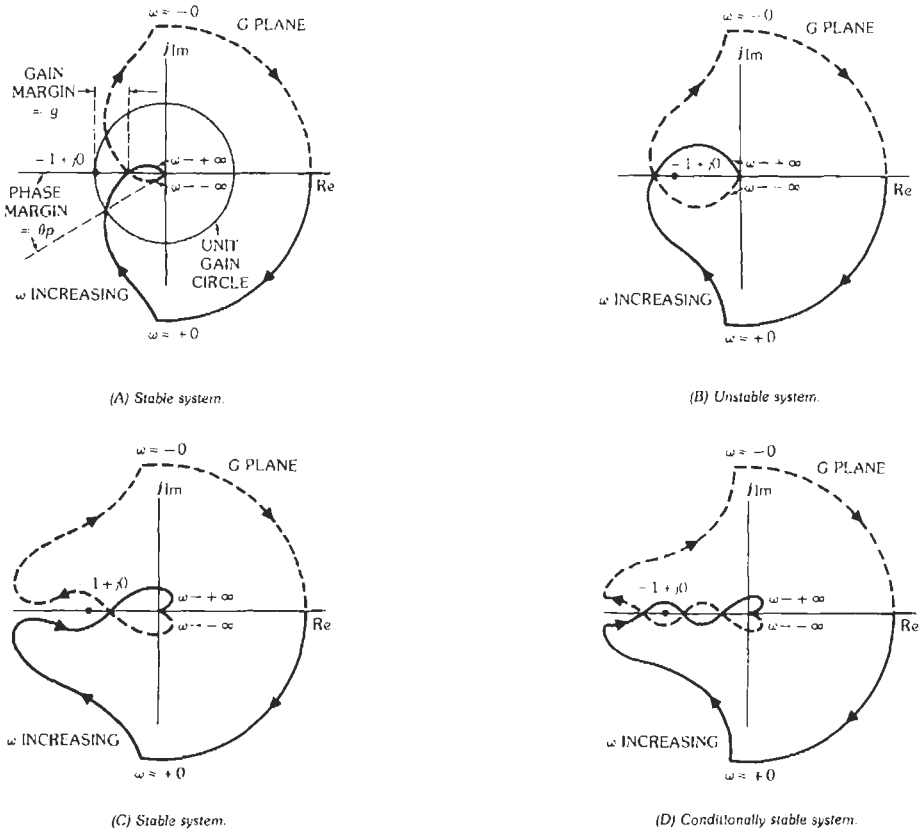

Fig. 8. Typical Nyquist loci.

stability can be determined from these plots by using the Nyquist stability criterion:

$$N = Z - P$$

where,

N = number of counterclockwise encirclements of the point $-1 + j0$ in the G-plane,
Z = number of zeros of $1 + G(s)$ in the right-half s-plane (same as number of poles of C/R in RHP),
P = number of *open-loop* poles of $G(s)$ in RHP.

Clearly for BIBO stability, Z must be zero.

The curves in Figs. 8A and 8C represent stable systems (assuming $P = 0$) and are typical of the type-1 system;* the curve in Fig. 8C represents an unstable system. The system represented in Fig. 8D is conditionally stable; that is, for a particular range of values of gain K it is unstable. The system is stable for larger and smaller values of gain. *Note*: It is unstable as shown.

The *phase margin* θ_p and *gain margin* g are also illustrated in Fig. 8A. The former is the angle between the negative real axis and $G(j\omega)$ at the point where the locus intersects the unit-gain circle. It is positive when measured as shown.

The gain margin g (in dB) is the negative dB value of $G(j\omega)$ corresponding to the frequency at which the phase angle is 180° (i.e., where $G(j\omega)$ intersects the negative real axis). Typical satisfactory values are -10 dB for g and an angle of 30° for θ_p. These values are selected on the basis of a good compromise between speed of response and reasonable overshoot. Note that for conditionally stable systems, the terms "gain margin" and "phase margin" may not have a simple interpretation.

Logarithmic Plots (Bode Diagrams)—The transfer function of a feedback control system can be described by separate plots of gain and phase versus frequency. Use of a logarithmic frequency scale permits simple straight-line (asymptotic) approximations for each curve. Fig. 9 illustrates the method for a transfer function with a single time constant. A comparison between approximation and actual values is included.

Transfer functions of the form $G = (1 + j\omega T)$ have similar approximations except that the attenuation curve slop is inverted upward (+20 dB/decade) and the values of phase are positive.

* System types are defined in the subsection "Tracking Accuracy."

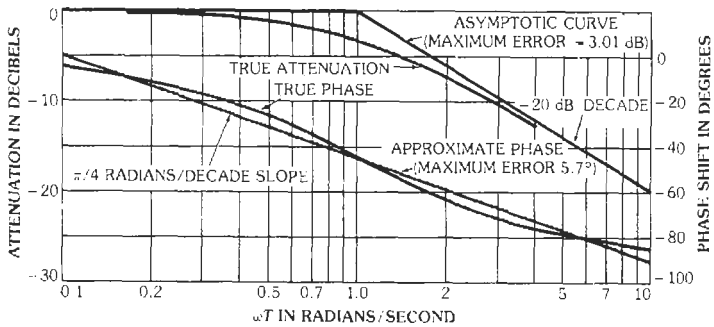

Fig. 9. Transfer-function plot. $G(j\omega) = 1/(1 + j\omega T)$.

The transfer function of feedback control systems can often be expressed as a fraction with the numerator and denominator each composed of linear factors of the form $(Ts + 1)$. Certain types of control systems, such as hydraulic motors where compressibility of the oil in the pipes is appreciable or some steering problems where the viscous damping is small, give rise to transfer functions in which quadratic factors occur in addition to the linear factors. The process of taking logarithms (as in making a dB plot) facilitates computation because only the addition of product terms is involved. The associated phase angles are directly additive. For example,

$$G(j\omega) = \frac{K(1 + j\omega T_2)}{[T^2(j\omega)^2 + 2\zeta T(j\omega) + 1](1 + j\omega T_1)(1 + j\omega T_3)}$$

where $s = j\omega$. The exact magnitude of G in decibels is

$$20 \log_{10}|G| = 20 \log_{10} K + 20 \log_{10} |1 + j\omega T_2| - 20 \log_{10} |1 + j\omega T_1| - 20 \log_{10} |1 + j\omega T_3| - 20 \log_{10} |T^2(j\omega)^2 + 2\zeta T(j\omega) + 1|$$

Plots of attenuation and phase for quadratic factors as a function of the *relative damping ratio* ζ are given in Figs. 10 and 11. The low-frequency asymptote is 0 dB, but the high-frequency asymptote has a slope of ±40 dB/decade (the positive slope applied to zero quadratic factors), twice the slope of the simple pole or zero case. The two asymptotes intersect at $\omega = 1/T$.

The difference between the asymptotic plot and the actual curves depends on the value of ζ with a variety of shapes realizable for the actual curve. Regardless of the value of ζ, the actual curve approaches the asymptotes at both low and high frequencies. In addition, the error between the asymptotic plot and the actual curve is geometrically symmetrical about the break frequency $\omega = 1/T$. As a result of this symmetry, the curves of Fig. 10 are plotted only for $\omega T \leq 1$. The error for $\omega = \alpha/T$ is identical with the error at $\omega = 1/\alpha T$.

From Bode plots, system stability can be determined by noting gain and phase margins. Nyquist diagrams can be constructed for confusing cases, such as conditionally stable systems.

Nyquist diagrams and Bode plots can also be constructed with the use of computer-aided analysis software. (See the section "Computer-Aided Analysis and Design" at the end of this chapter.)

Root-Locus Method—Root locus is a method of design due to Evans. It is based on the relation between the poles and zeros of the closed-loop system function and those of the open-loop transfer function. The rapidity and ease with which the loci can be constructed form the basis for the success of root-locus design methods, in much the same way that the simplicity of the gain and phase plots (Bode diagrams) make design in the frequency domain so attractive. The root-locus plots can be used to adjust system gain, guide the design of compensation networks, or study the effects of changes in system parameters.

In linear time-invariant "lumped" systems, $G(s)$ is a rational algebraic function, the ratio of two polynomials in s:

$$G(s) = m(s)/n(s)$$

From Fig. 7

$$(C/R)(s) = G(s)/[1 + G(s)] = \frac{m(s)/n(s)}{1 + [m(s)/n(s)]} = m(s)/[m(s) + n(s)]$$

The zeros of the closed-loop system are identical with those of the open-loop system function. The closed-loop poles are the values of s at which $m(s)/n(s) = -1$. The root-locus method is a graphical technique for determination of the zeros of $m(s) + n(s)$ from the zeros of $m(s)$ and $n(s)$. Root loci are plots in the complex s plane of the variations of the poles of the closed-loop system function with changes in the open-loop gain. For the single-loop system of Fig. 7, the root loci constitute all s-plane points at which

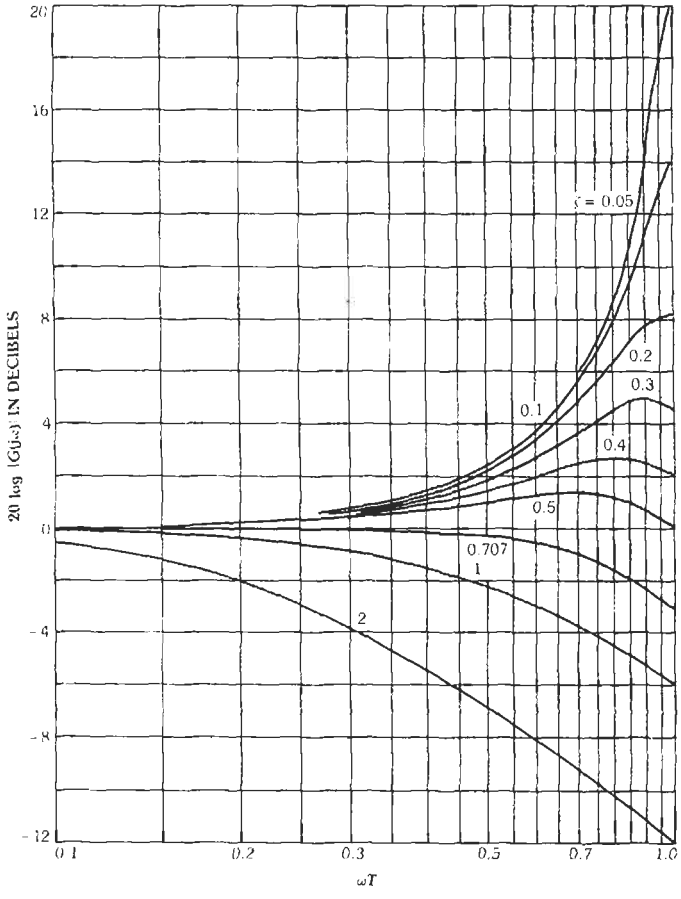

Fig. 10. Attenuation curve for quadratic factor. $G(j\omega) = 1/[T^2(j\omega^2) + 2\zeta T(j\omega) + 1]$. (*By permission from* Automatic Feedback Control System Synthesis, *by J. G. Truxal. Copyright 1955, McGraw-Hill Book Co.*)

$$\angle G(s) = 180° + n360°$$

where n is any integer including zero. A graphical interpretation for

$$G(s) = \frac{K(s + z_1)(s + z_2)}{s(s + p_1)(s + p_2)(q + p_3)}$$

is given in Fig. 12. Examples of root loci are given in Fig. 13 and 14.

For the example of Fig. 14, $K = K_1$ produces the case of critical damping. An increase in gain somewhat beyond this value causes a damped oscillation to appear. The latter increases in frequency (and decreases in damping) with further increase in gain. At gain K_3, a sustained oscillation will result. Instability exists for gain greater than K_3, as at K_4. This corresponds to poles in the right half of the s plane for the closed-loop transfer function.

Various rules are available as aids in sketching root locus plots by hand. (Computer-aided packages can also be used; see section "Computer-Aided Analysis and Design.")

Intervals Along the Real Axis: The simplest portions of the plot to establish are the intervals along the negative real ($-\sigma$) axis, because then all angles are either 0° or 180°. Complex pairs of zeros or poles contribute no net angle for points along the real axis. Along the real axis, the locus will exist for intervals that have an *odd* number of zeros and poles to the right of the interval (Fig. 15).

Asymptotes: For very large values of s, $G(s) \sim K/s^{n-m}$. The locus will thus finally approach $(n - m)$ asymptotes at the angles (Fig. 16) given by the expression

$$(180° + k360°/(n - m)$$

These asymptotes meet at a point s_1 (on the negative real axis) given by

$$s_1 = \frac{\Sigma(\text{poles}) - \Sigma(\text{zeros})}{(\text{finite poles}) - (\text{finite zeros})}$$

The other m branches of the locus will approach the zeros of $G(s)$, which are the zeros of $n(s)$.

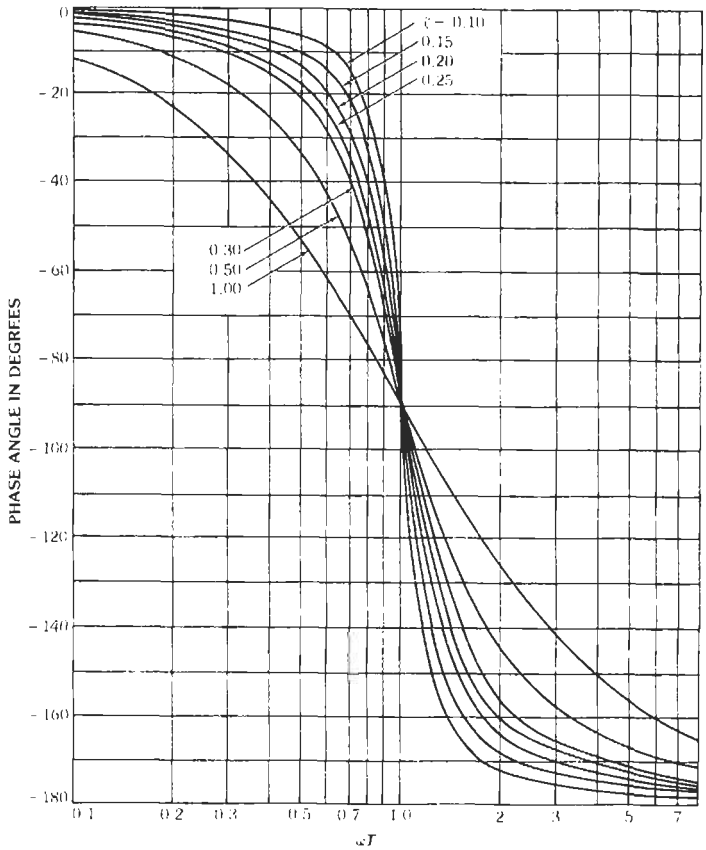

Fig. 11. Phase characteristics. (*By permission from* Theory of Servomechanisms, *by H. M. James, N. B. Nichols, and R. S. Phillips. Copyright 1947, McGraw-Hill Book Co.*)

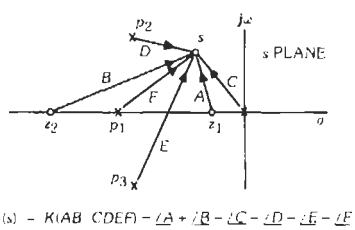
Breakaway Points: Breakaway points from the real axis occur where the net change in angle caused by a small vertical displacement is zero. In Fig. 17, point p satisfies this condition at $1/x_0 = (1/x_1) + (1/x_2)$.

Intersections With jω Axis: The Routh-Hurwitz test applied to the polynomial $m(s) + n(s)$ frequently permits rapid determination of the points at which the loci cross the $j\omega$ axis and the value of gain at these intersections.

Angles of Departure and Arrival: The angles at which the loci leave the poles and arrive at the zeros are readily evaluated from

$$\sum \angle \text{vectors from zeros to } s - \sum \angle \text{vectors from poles to } s = 180° + n360°$$

For example, consider Fig. 18. The angle of departure of the locus from the pole at $(-1 + j1)$ is desired. If a test point is assumed only slightly displaced from the pole, the angles contributed by all critical frequencies (except the pole in question) are determined approximately by the vectors from these poles and zeros



$G(s) = K/AB\ CDEF = \angle A + \angle B - \angle C - \angle D - \angle E - \angle F$

Fig. 12. Graphical interpretation of $G(s)$.

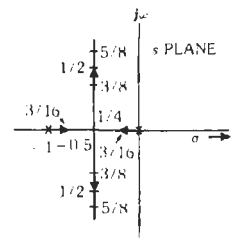


Fig. 13. Root locus for $G(s) = K/[s(s + 1)]$. Values of K as indicated by fractions.

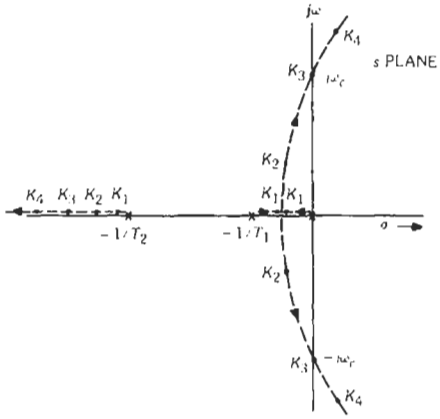

Fig. 14. Root locus for $G(s) = K/[s(T_1s + 1)(T_2s + 2)]$.

to $(-1 + j1)$. The angle contributed by the pole at $(-1 + j1)$ is then just sufficient to make the total angle 180°. In the example shown in the figure, the departure angle is found from the relation

$$\underbrace{+\ 45°}_{s+2} - \left(\underbrace{135°}_{s} + \underbrace{90°}_{s+1+j1} + \underbrace{26.6°}_{s+3} + \underbrace{\theta}_{s+1-j1}\right)$$

$$= 180° + n360°$$

Hence, $\theta = -26.6°$, the angle at which the locus leaves $(-1 + j1)$.

Tracking Accuracy

The tracking accuracy of various types of feedback control systems can be described most effectively in terms of the simple closed-loop unit-feedback system. Fig. 19 shows such a system; $R(s)$, $C(s)$, and $E(s)$ are the Laplace transforms of the reference input, controlled variable, and error signal, respectively.

For a typical linear system, $G(s)$ might appear as

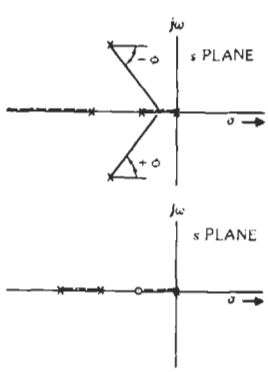

Fig. 15. Root-locus intervals along the real axis.

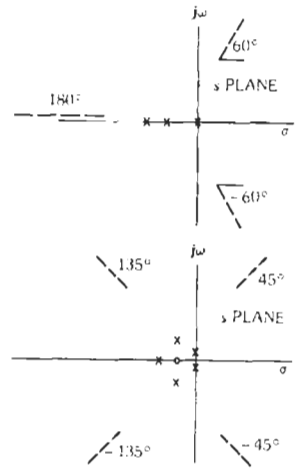

Fig. 16. Final asymptotes for root loci. Top, 60° asymptotes for system having three poles. Bottom, 45° asymptotes for system having an excess of four poles over zeros.

$$C(s)/E(s) = G(s) = [K(T_1s + 1)(T_3s + 1)]/[s^k(T_2s + 1)(T_4s + 1)]$$

The value of exponent k, an integer, designates the *type* of the system. This in turn reveals the nature of the steady-state performance of the system as follows:

For a type-0 system, a constant value of the controlled variable requires a constant error signal under steady-state conditions. A feedback control system of this type is generally referred to as a regulator system.

For a type-1 system, a constant rate of change of the controlled variable requires a constant error signal under steady-state conditions. A type-1 feedback control system is generally referred to as a servomechanism system. For reference inputs that change with time at a constant rate, a constant error is required to produce the same steady-state rate of the controlled variable. When applied to positions control, type-1 systems may also be referred to as "zero-displacement-error" systems. Under steady-state conditions, it is possible for the reference signal to have any desired constant position or displacement and the feedback signal or controlled variable to have the same displacement.

For a type-2 system, a constant acceleration of the controlled variable requires a constant error under steady-state conditions. Since these systems can main-

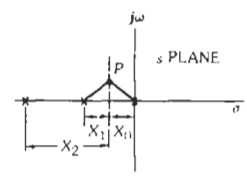

Fig. 17. Breakaway point.

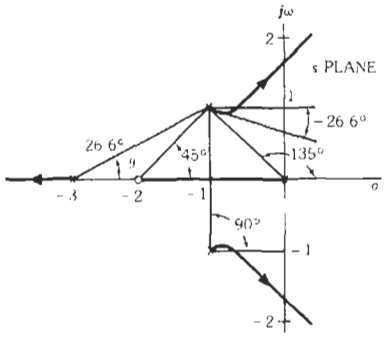

Fig. 18. Loci for $G(s) = K(s + 2)/[s(s + 3)(s^2 + 2s + 2)]$.

tain a constant value of controlled variable and a constant controlled variable speed with no actuating error, they are sometimes referred to as "zero-velocity-error" systems.

It is common to evaluate the steady-state tracking effectiveness using *error constants*. For unity feedback system (Fig. 19), these constants are defined as follows:

Positive Error Constant:

$$K_p = \lim_{s\to 0} [C(s)/E(s)] = \lim_{s\to 0} G(s)$$

Velocity Error Constant:

$$K_v = \lim_{s\to 0} [sC(s)/E(s)] = \lim_{s\to 0} sG(s)$$

Acceleration Error Constant:

$$K_a = \lim_{s\to 0} [s^2C(s)/E(s)] = \lim_{s\to 0} s^2G(s)$$

Disturbance Inputs

Frequently, systems are subjected to unwanted signals entering the system at points other than the input. Examples are load-torque disturbances, noise generated at a point within the system, etc. These may be represented as additional inputs to the system. Fig. 20 is a block diagram of such a situation. Transfer functions from the disturbance inputs to the output (with other inputs set to zero) can be found and used to analyze transient and steady-state disturbance responses, as has been done above for the command input transfer function.

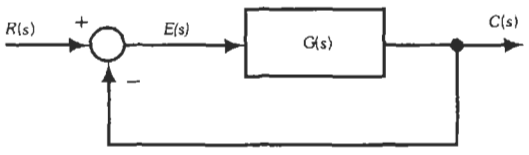

Fig. 19. Single-loop tracking system. $e = r - y$.

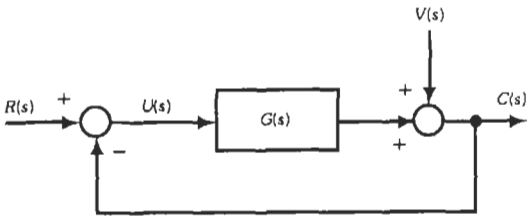

Fig. 20. Plant with "load disturbance" $v(t)$.

Sensitivity and Robustness

All system models used for analysis and design are approximations of the actual physical system. Ideally, the performance of the real physical system should be close to that predicted by our analysis and design methods, and it should be *insensitive* to the modeling approximations. A major reason for using feedback is the *potential* insensitivity of the performance of feedback structures to some variations in the plant. Bode suggested quantifying the study of plant parameter variations by defining the Bode Sensitivity Function,

$$S \triangleq (G/T)(dT/dG)$$

where T is the system transfer function and G is the plant transfer function. Notice that S is the ratio of the percent (or logarithmic) change in T, with respect to the percent change in G. Ideally S should be "small"; that is, the (percent) change in the overall transfer function should be less than the (percent) change in the plant.

For the common "single-degree-of-freedom" unity feedback structure of Fig. 21,

$$S = 1/(1 + GG_c)$$

The quantity

$$GG_c \triangleq L$$

is called the *loop gain*, and $(1 + L)$ is the *return difference*. For S to be "small" (e.g., $|S(j\omega)| < 1$), the loop gain L should be "large." Notice that

$$S + T = 1$$

This relationship provides a fundamental design constraint: S and T cannot be manipulated independently by

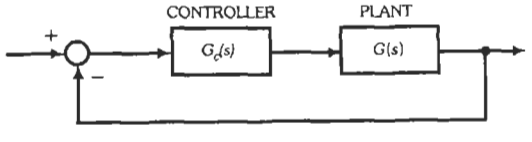

Fig. 21. Unity feedback "single-degree-of-freedom" structure.

choice of controller transfer function G_c for the system of Fig. 21.

Bode developed several other sensitivity results, of which two are especially important. One result reveals that S cannot be small for all frequencies. Suppose that $L = GG_c$ is of relative degree (number of poles − number of zeros) of at least 2, and that G and G_c are open-loop stable (no RHP poles). Then

$$\int_0^\infty \log_{10} |S(j\omega)| d\omega = 0$$

That is, the area under the sensitivity magnitude curve (in dB) is zero. Thus it is not possible for $|S(j\omega)| < 1$ (0 dB) for all frequencies. Typically $|S| < 1$ for low frequencies, but it becomes > 1 for higher frequencies.

The second important result relates the *slope* of the loop gain to stability. The exact statement of this result involves a complicated integral which is never evaluated directly. An accurate approximation, which is widely applied, is:

$$\angle L(j\omega) \cong n \times 90°$$

where n is the slope of the loop amplitude curve in units of decade of amplitude per decade of frequency. Thus, if the phase margin is to be positive (stability), $\angle L(j\omega)$ must be greater than $-180°$ at crossover, and so $n = 1$ (a slope of -20 dB/decade) at crossover. Greater slopes will produce unstable closed-loop systems.

Methods of Controller Design: Classical Design

The objective of controller design is to choose a controller transfer function to achieve desirable performance as described above. In the *classical design* approach, parameters are adjusted in several standard controller structures in an effort to meet performance specifications. Effects of parameter adjustments are commonly evaluated by using frequency response or root locus plots.

Methods of controller design for improving feedback-control-system response fall into the following basic categories:

A. Series (cascade) compensation
B. Feedback (parallel) compensation
C. Load compensation

In many cases, any one of the above methods may be used to advantage, and it is largely a question of practical consideration as to which is selected. Fig. 22 illustrates the three methods.

Many systems can be controlled satisfactorially by using a proportional-integral-derivative (PID) controller:

$$G_c(s) = K[1 + (1/T_i)(1/s) + T_d s]$$

where K, T_i, and T_d are parameters to be adjusted. Such PID controllers are very common in process control and in many other control applications. The transfer function is easily implemented through analog or digital technology and can be obtained from many vendors in the form of an "off-the-shelf" controller.

Two other common classical controllers are the *lead* and the *lag* controllers. For the lead controller,

$$G_c(s) = K(T_s + 1)/(\alpha T_s + 1)$$

where $\alpha < 1$. The lag controller has the same transfer function, but with $\alpha > 1$. Passive networks having these transfer functions are shown in Fig. 23. Op-amp–based active circuits for the same controllers are given in Fig. 24. Asymptotic attenuation and phase curves are shown in Fig. 25 and 26. The positive values of phase angle are to be associated with the phase-lead network, whereas the negative values are to be applied to the phase-lag network. Fig. 27 is a plot of the maximum phase shift for lag and lead networks as a function of the time-constant ratio.

Instead of direct feedback, the feedback path may contain frequency-sensitive elements. Typical of such frequency-sensitive elements are tachometers or other rate- or acceleration-sensitive devices that may be used for feedback directly or through suitable stabilizing circuitry.

The most common form of load stabilization involves the addition of an oscillation damper (tuned or untuned) to change the apparent characteristics of the load. Oscillation dampers can be used to obtain the equivalent of tachometric feedback. The primary advantages of load stabilization are the simplicity of instrumentation and the fact that the compensating action is independent of drift or the carrier frequency in ac systems.

STATE SPACE ANALYSIS AND DESIGN TECHNIQUES

State-variable methods are a modern approach to the analysis and design of control systems.

For linear time-invariant systems, the dynamic equations may be written in the following vector-matrix form:

$$\dot{x} = dx(t)/dt = Ax(t) + Bu(t)$$

$$y(t) = Cx(t) + Du(t)$$

where

$$x(t) = \begin{bmatrix} x_1(t) \\ x_2(t) \\ \cdot \\ \cdot \\ x_n(t) \end{bmatrix} = \text{state vector}$$

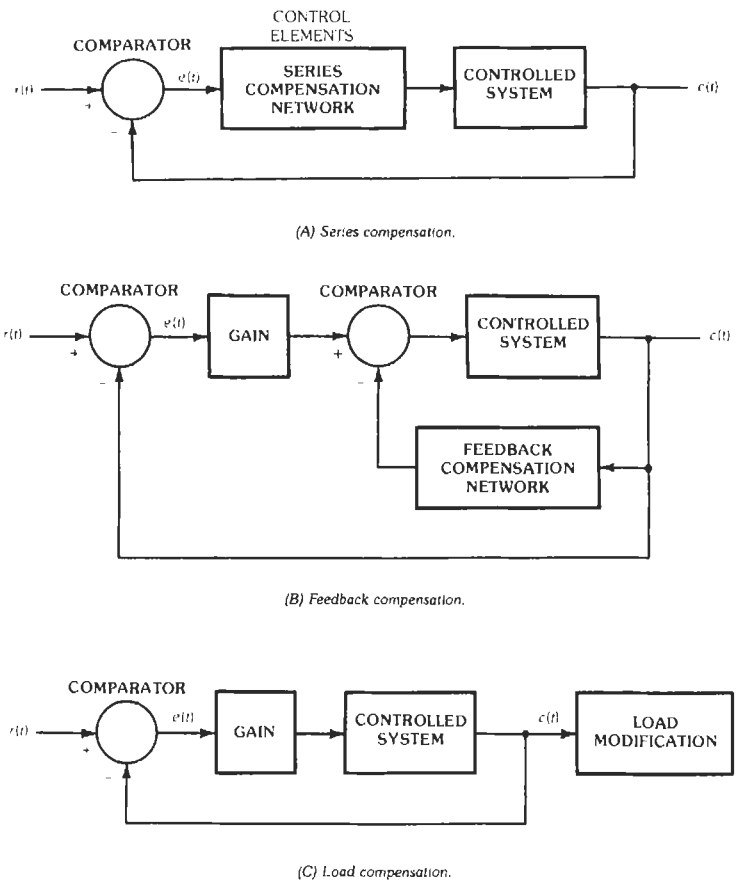

Fig. 22. Simple schemes for compensation.

$$u(t) = \begin{bmatrix} u_1(t) \\ u_2(t) \\ \vdots \\ u_m(t) \end{bmatrix} = \text{input vector}$$

$$y(t) = \begin{bmatrix} y_1(t) \\ y_2(t) \\ \vdots \\ y_p(t) \end{bmatrix} = \text{output vector}$$

$$A = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & & & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix}$$

$= n \times n$ coefficient matrix

$$B = \begin{bmatrix} b_{11} & b_{12} & \cdots & b_{1p} \\ b_{21} & b_{22} & \cdots & b_{2p} \\ \vdots & & & \vdots \\ b_{n1} & b_{n2} & \cdots & b_{nm} \end{bmatrix}$$

$= n \times m$ coefficient matrix.

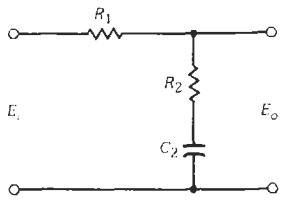
Similarly, C is a $p \times n$ coefficient matrix, and D is $q \times m$. The solution of the state equations is

$$x(t) = \phi(t - t_0)\xi(t_0) + \int_{t_0}^{t} \phi(t - \tau)Bu(\tau)d\tau$$

where $u(t)$ is the input applied at $t = t_0$, and $x(t_0)$ denotes the initial state vector. The $n \times n$ matrix $\phi(t)$ is the *state transition matrix*, and is defined as

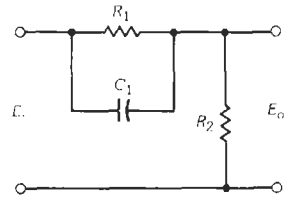
$$\phi(t) = I + At + A^2t^2/2! + \cdots A^kt^k/k! + \cdots$$

where I is the $n \times n$ identity matrix.



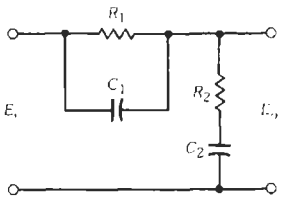
$E_o/E_i = (T_2s + 1)/(T_1s + 1)$
where,
$T_2 = R_2C_2$
$T_1 = (R_1 + R_2)C_2$

(A) Phase-lag network.



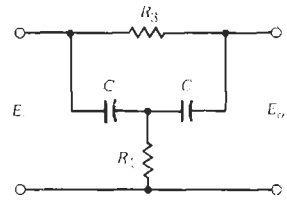
$E_o/E = (T_2/T_1)[(T_1s + 1)/(T_2s + 1)]$
where,
$T_1 = R_1C_1$
$T_2 = R_2R_1C_1/(R_1 + R_2)$

(B) Phase-lead network.



$$E_o/E_i = \frac{(T_1s + 1)(T_2s + 1)}{T_1T_{12}s^2 + (T_1 + T_2 + T_{12})s + 1}$$
where,
$T_1 = R_1C_1$
$T_2 = R_2C_2$
$T_{12} = R_1C_2$
$G_1 = (T_1 + T_2)/(T_1 + T_2 + T_{12})$

(C) Lead-lag network



$$E_o/E_i = \frac{T_1T_3s^2 + 2T_3s + 1}{T_1T_3s^2 + (2T_3 + T_3)s + 1}$$
where
$T_1 = R_1C$
$T_3 = R_3C$

(D) Bridged-T network.

Fig. 23. Passive lead, lag, and lead-lag networks.

The state transition matrix has the following properties:

$$\phi(0) = I$$

$$\phi^{-1}(t) = \text{matrix inverse of } \phi(t) = \phi(-t)$$

$$\phi(t_2 - t_1)\phi(t_1 - t_0) = \phi(t_2 - t_0) \quad \text{for any } t_0, t_1, t_2$$

$$\phi(t) = \mathcal{L}^{-1}[sI - A)^{-1}]$$

where $\mathcal{L}^{-1}$ denotes the "inverse Laplace transform of." The *characteristic* polynomial of A is defined as

$$\Delta = \text{determinant of } sI - A = |sI - A|$$

The roots of the *characteristic equation* $\Delta(s) = 0$ are the eigenvalues of A.

Controller Design: Pole Placement

One approach to control design is to feed back the state variables of the plant to adjust the closed-loop system eigenvalues to obtain stability and desired transient response. State feedback is described by

$$u(t) = -Kx(t) + r(t)$$

where K is a $m \times n$ constant matrix of feedback controller gains, and $r(t)$ is an external command input. Then the closed-loop system is described by

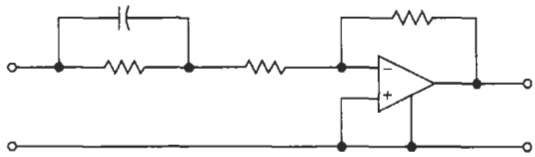
$$\dot{x} = (A - BK)x + Br$$

The eigenvalues of the closed-loop system are given by

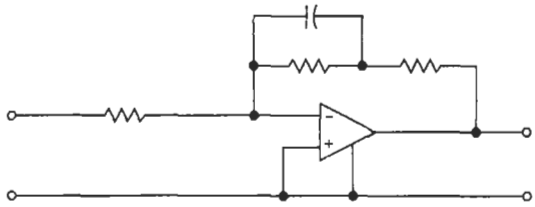
$$det[sI - (A - BK)] = 0$$

and depend on K. These eigenvalues can be placed *arbitrarily* by choice of K if and only if the open-loop system is "controllable," that is, if

$$\text{rank } [B \; AB \; A^2B \cdots A^{n-1}B] = n$$



(A) Lead network.



(B) Lag network.

Fig. 24. Active lead and lag networks.

Controller Design: LQ-Optimal Control

In the optimum control approach to design, the system performance is manifested through a scalar *performance index* selected by the designer to reflect desired performance characteristics. In the LQ-optimal control approach, the linear plant is described in state form:

$$\dot{x} = Ax + Bu \qquad x(0) = x_0$$

and the performance index is

$$J = \tfrac{1}{2}\int_0^\infty [x^T(t)Qx(t) + u^T(t)Ru(t)]dt$$

This *integral* performance index *weights* quadratic forms in the state x and control u by symmetric constant matrices Q and R. The goal is to force the state from the initial state x_0 to the state $x = 0$ (a regulator problem) by *minimizing* J. That is, from among all possible controls u, the "best" or "optimum" control is that which results in the least value for J.

The weighting matrix Q is chosen to be positive-semidefinite, so that $x^TQx \geq 0$. Thus a positive penalty is incurred in J for values of x (positive or negative) different from zero. The weighting matrix R, chosen to be positive definite, reflects a penalty for use of control. Typically, the designer would try various weightings Q and R until a desired state performance $x(t)$ was obtained, using an acceptable control $u(t)$.

The solution of this optimum control problem can be expressed in state feedback form,

$$u = -Kx$$

where $K = -R^{-1}B^TP$, the matrix P being the unique positive definite solution of the matrix algebraic Riccati equation (ARE):

$$A^TP + PA - PBR^{-1}B^TP + Q = 0$$

DIGITAL CONTROL SYSTEMS

Digital control systems differ from continuous-data, or analog, systems in that the signals in one or more parts of the system are in the form of either pulses or

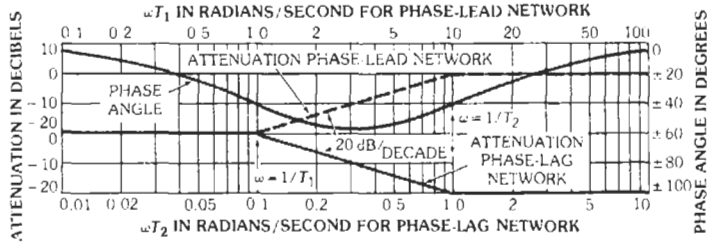


Fig. 25. Phase and magnitude for phase-lead and phase-lag networks. $T_1 = 10T_2$.

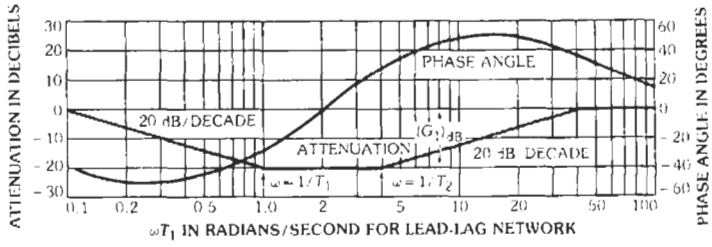

Fig. 26. Phase and magnitude for lead-lag network.

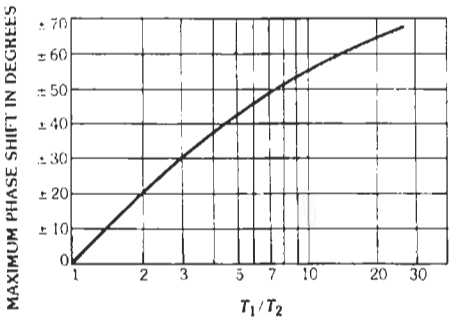

Fig. 27. Maximum phase shift for phase-lead (use positive angles) and phase-lag (negative angles) networks.

digitally coded signals. Due to the advances made in microcomputers, digital controllers have become very popular in control systems.

Fig. 28 shows the block diagram of a typical digital control system. Typically, the controlled process (plant) is an analog device, but the controller is digital. In this case, the reference input is shown to be an analog signal. The analog-to-digital converter (A/D) converts the analog signal into a digitally coded signal. The output of the digital controller is a digitally coded (such as binary-coded) signal. The digital-to-analog converter (D/A) converts the digital signal into an analog one for the controlled process.

From the analytical standpoint, the A/D operation can be represented by a *sampler* having T as the sampling period. The D/A operation can be represented by a sample-and-hold device. The block diagram representation of the sample-and-hold is shown in Fig. 29. The hold device simply holds the output of the sampler for one sampling period, T. Fig. 30 illustrates a typical set of waveforms of the inputs and the outputs of the sampler and the hold device.

The sampler defines the values of the function $f(t)$ at the sampling instants. In the time domain, the input-output relation of the sampler is written:

$$f^*(t) = \sum_{k=0}^{\infty} f(kT)\delta(t - kT)$$

where $\delta(t)$ is the unit impulse function.

The Laplace transform of the last equation is

$$F^*(s) = \sum_{k=0}^{\infty} f(kT)e^{-kTs}$$

The transfer function of the hold device is

$$G_h(s) = (1 - e^{-Ts})/s$$

The *z*-Transform

Since the transfer functions of digital systems contain exponential terms of s, it is desirable to introduce the z-transform:

$$z = e^{Ts}$$

or

$$s = (1/T)\ \ln z$$

The z-transform of the sampled signal $f^*(t)$ is written:

$$\mathfrak{Z}[f^*(t)] = F(z) = \sum_{k=0}^{\infty} f(kT)z^{-k}$$

The z-transforms of some common functions are given in Table 1. The role of the z-transform with respect to digital systems is similar to that of the Laplace transform with respect to continuous-data systems.

The *z*-Transfer Function

Fig. 31 shows the block diagram of a typical open-loop digital control system with a sample-and-hold. The transfer-function relation in the s-domain is written as:

$$C^* = [G_h(s)G_p(s)]^*F^*(s)$$

$$= \{[(1 - e^{-Ts})/s]G_p(s)\}^*F^*(s)$$

Thus, in terms of the z-transform,

$$C(z) = (1 - z^{-1})\mathfrak{Z}[G_p(s)/s]F(z)$$

The open-loop transfer function is defined as

$$C(z)/F(z) = (1 - z^{-1})\mathfrak{Z}[G_p(s)/s]$$

For the closed-loop digital control system shown in Fig. 32, the closed-loop transfer function is

$$C(z)/R(z) = G(z)/[1 + G(z)]$$

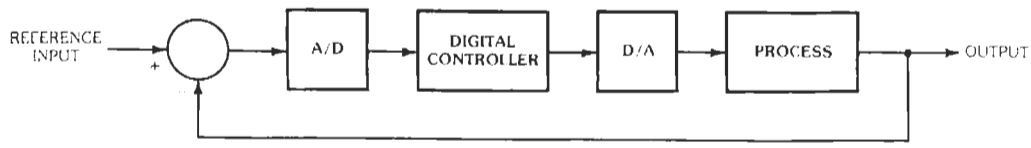

Fig. 28. Typical digital control system.

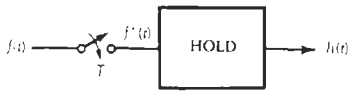

Fig. 29. Sample-and-hold.

where

$$G(z) = (1 - z^{-1})\mathfrak{Z}[G_p(s)/s]$$

The Inverse z-Transform

There are three methods of evaluating the inverse z-transform. These are the partial-fraction expansion method, the power-series method, and the inverse formula method.

Partial-Fraction Expansion Method—The function $F(z)/z$ is expanded into the form

$$F(z)/a = K_1/(z + a) + K_2/(z + b) + \cdots$$

by partial-fraction expansion. Then

$$F(z)/a = K_1 z/(z + a) + K_2 z/(z + b) + \cdots$$

The inverse z-transform of $F(z)$ is then taken term by term.

Power-Series Method—The function $F(z)$ is expanded into a power series in z^{-1}, i.e.,

$$F(z) = \sum_{k=0}^{\infty} f(kT)z^{-k}$$

Then, by the definition of the z-transform, the coefficient of z^{-k}, $k = 0, 1, 2, 3, \ldots$ is $f(kT)$.

The Inversion Formula Method—The inverse z-transform of $F(z)$ can be expressed as the inversion formula

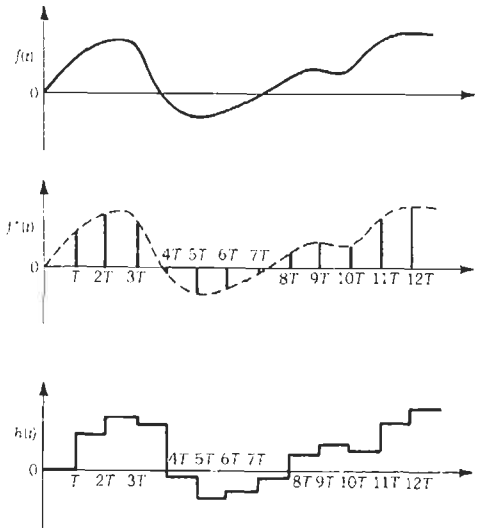

Fig. 30. Input-output relation of sample-and-hold.

$$f(kT) = (1/2\pi j)\oint F(z)z^{k-1}dz$$

where the integral is taken over a circle that encloses all the singularities of $F(z)z^{k-1}$. By use of the residue theorem of complex variable theory:

$$f(kT) = \sum \text{Residues of } F(z)z^{k-1} \text{ at the poles of } F(z)z^{k-1}$$

State Variable Analysis of Digital Control Systems

The state equations for continuous-data systems can be applied directly to digital systems with the input defined as

TABLE 1. z-TRANSFORMS

Time Function	Laplace Transform	z-Transform
$u(t)$ Unit-step function	$1/s$	$z/(z - 1)$
t	$1/s^2$	$Tz/(z - 1)^2$
$t^2/2$	$1/s^3$	$\dfrac{T^2z(z + 1)}{2(z - 1)^3}$
e^{-at}	$1/(s + a)$	$z/(z - e^{-aT})$
te^{-at}	$1/(s + a)^2$	$(Tze^{-aT})/(z - e^{-aT})^2$
$\sin\omega t$	$\omega/(s^2 + \omega^2)$	$\dfrac{z\sin\omega T}{z^2 - 2z\cos\omega T + 1}$
$\cos\omega t$	$s/(s^2 + \omega^2)$	$\dfrac{z(z - \cos\omega T)}{z^2 - 2z\cos\omega T + 1}$

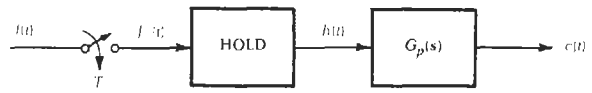

Fig. 31. Open-loop digital control system.

$$u(t) = u(kT) \qquad kT \le t < (k+1)T$$

due to the action of the sample-and-hold. Thus, the state equations of an n^{th}-order digital system are written as

$$dx(t)/dt = Ax(t) + Bu(kT) \qquad kT \le t < (k+1)T$$

The solution of the state equation, the state transition equation, is

$$x(t) = \phi(t - kT)x(kT) + \int_{kT}^{t} \phi(t - \tau)Bd\tau \cdot u(kT)$$

Let

$$\theta(t - kT) = \int_{kT}^{t} \phi(t - \tau)Bd\tau$$

Then,

$$x(t) = \psi(t - kT)x(kT) + \theta(t - kT)u(kT)$$

To describe the state variables only at the sampling instants, let $t = (k+1)T$. The last equation becomes

$$x[(k+1)T] = \phi(T)x(kT) + \theta(T)u(kT)$$

which is the form of a vector-matrix difference equation with constant coefficients. The solution of this difference equation is

$$x(NT) =$$

$$[\phi(T)]^N x(0) + \sum_{k=0}^{N-1} \phi[(N-k-1)T]\phi(T)r(kT)$$

$$= \phi(NT)x(0) + \sum_{k=0}^{N-1} \phi[N-k-1)T]\phi(t)r(kT)$$

where,

$$\phi(NT) = \phi(T) \cdot \phi(T) \cdot \cdots \phi(T) = [\phi(T)]^N$$

and

$$\phi(T) = e^{AT} = I + AT + \frac{A^2T^2}{2!} + \frac{A^3T^3}{3!} + \cdots$$

Stability of Linear Time-Invariant Digital Systems

The stability-analysis methods devised for linear continuous-data systems can all be extended to the stability study of digital systems. Since the z-transformation $z = e^{Ts}$ maps the imaginary axis in the s-plane onto the unit circle, $|z| = 1$, in the z-plane, the stability criterion of linear time-invariant digital systems is that all the roots of the characteristic equation must be found inside the unit circle in the z-plane.

The stability of the digital control system shown in Fig. 32 depends on the location of the poles of the closed-loop transfer function

$$C(z)/R(z) = G(z)/[1 + G(z)]$$

or of the zeros of $1 + G(z)$ in the complex z-plane.

The zeros of $1 + G(z)$ are also known as the roots of the characteristic equation, which can be written as

$$F(z) = a_n z^n + a_{n-1} z^{n-1} + \cdots + a_2 z^2 + a_0 = 0$$

where all the coefficients are real.

The tabulation in Chart 1, known as the Jury Table, can be formed to check the necessary and sufficient conditions for the roots of the characteristic equations to be inside the unit circle.

The conclusion are:

Number of *positive* calculated elements in the first column, $(b_0, c_0, \ldots, p_0, q_0, r_0)$ = number of roots inside the unit circle.

Number of *negative* calculated elements in the first column, $(b_0, c_0, \ldots, p_0, q_0, r_0)$ = number of roots outside the unit circle.

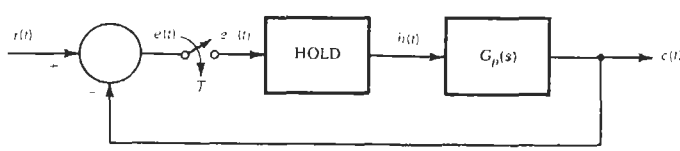

Fig. 32. Closed-loop digital control system.

q_0 q_1k_q	q_1				$k_q = q_1q_0$
r_0					

The Nyquist stability criterion can be applied directly to determine the stability of digital control systems. The method involves the construction of the Nyquist locus of $G(z)$, with $z = e^{j\omega T}$, in the complex $G(z)$ plane for values of ω from $-\infty$ to $+\infty$. Actually, the locus of $G(z)$ repeats for every sampling frequency $\omega_s = 2\pi/T$. Thus, it is necessary to obtain only the locus of $G(z)$ for $0 \leq \omega \leq \omega_s$.

Fig. 33 shows the Nyquist loci of $G(z)$ of the system in Fig. 34. The open-loop transfer function is

$$G(z) = \frac{T^2K_p(z + 1)}{2J_vz^2 + (2K_rT - 4J_v)z + 2J_v - 2K_rT}$$

with $J_v = 41\ 822$, $K_r = 317\ 000$, and $T = 0.1$ second. Or,

$$G(z) = \frac{1.2 \times 10^{-7}K_p(z + 1)}{(z - 1)(z - 0.242)}$$

Frequency response plots for the digital case present some difficulties not present in the continuous-time case. This is because the z-transform, with $z = e^{sT}$, is rational in z but not in s. So $s = j\omega$ leads to $z = e^{j\omega T}$, which means the frequency response transfer function is not rational in ω. Thus the Bode straight line approximations do not apply directly, making more difficult the sketching of the response curve by hand. Computer aids can be used to advantage. As an alternative, the Bode diagram of a digital control system can be obtained by use of the bilinear transformation

$$z = (1 + W)/(1 - W)$$

where W is a complex variable. For $z = e^{j\omega T}$,

$$W = j\tan(\omega T/2) = \sigma_W + j\omega_W$$

Thus,

$$\omega_W = \tan(\omega T/2)$$

Then the Bode plot of $G(z)$ can be made in the logarithmetic coordinates using the definition of ω_W. For the system shown in Fig. 34,

$$G(j\omega_W) = \frac{1.583 \times 10^{-7}K_p(1 - j\omega_W)}{j\omega_W(1 + j1.636\omega_W)}$$

The Bode diagram of $G(j\omega_W)$ is shown in Fig. 35.

The rules on the construction of root loci in the s-plane for continuous-data systems can be applied

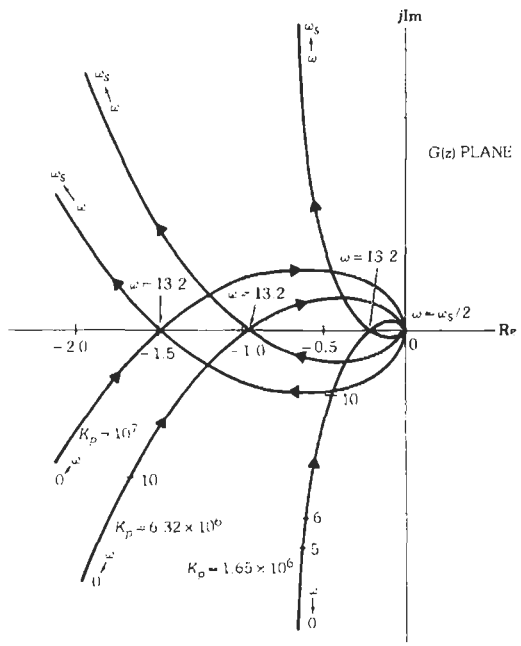

Fig. 33. Nyquist plot for system of Fig. 34.

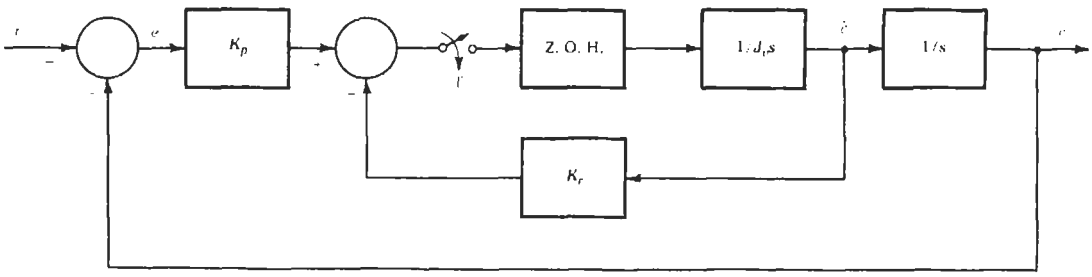

Fig. 34. Digital control of $1/s^2$ plant.

directly to the root loci in the z-plane. The only difference is that in the z-plane the stability of the digital control system must be investigated with respect to the unit circle $|z| = 1$.

For the digital control system in Fig. 34, the open-loop transfer function $G(z)$ has a zero at $z = -1$, and two poles at $z = 1$ and $z = 0.242$. The root loci of the characteristic equation for $0 \leq K_p < \infty$ are constructed as shown in Fig. 36.

State Variable Design Methods: The Digital Case

Both the pole placement and LQ-optimal control approaches can be applied to the digital control case. The results are similar to those for continuous-time. State feedback is given by

$$u(kT) = -Kx(kT) + r(kT)$$

and so, from

$$x[(k + 1)T] = \phi(T)x(kT) + \theta(T)u(kT)$$

The closed-loop system is described in state form by

$$x[(k + 1)T] = [\phi(T) - \theta(t)K]x(kT) + \theta(T)r(kT)$$

Thus the closed-loop eigenvalues can be placed arbitrarily by choice of K if and only if $[\phi(T), \theta(T)]$ satisfy the controllability condition

$$\text{rank}[\theta(T)\phi(T)\theta(T) \cdots \phi(T)^{n-1}\theta(T)] = n$$

For LQ design, the quadratic index to be minimized in the discrete (digital) case is

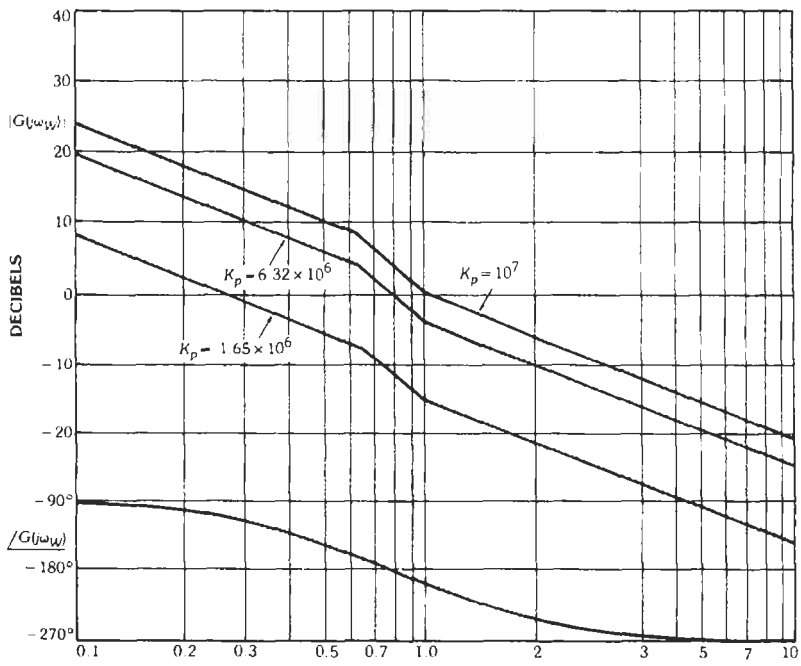

Fig. 35. Bode diagram of the digital control system in Fig. 34.

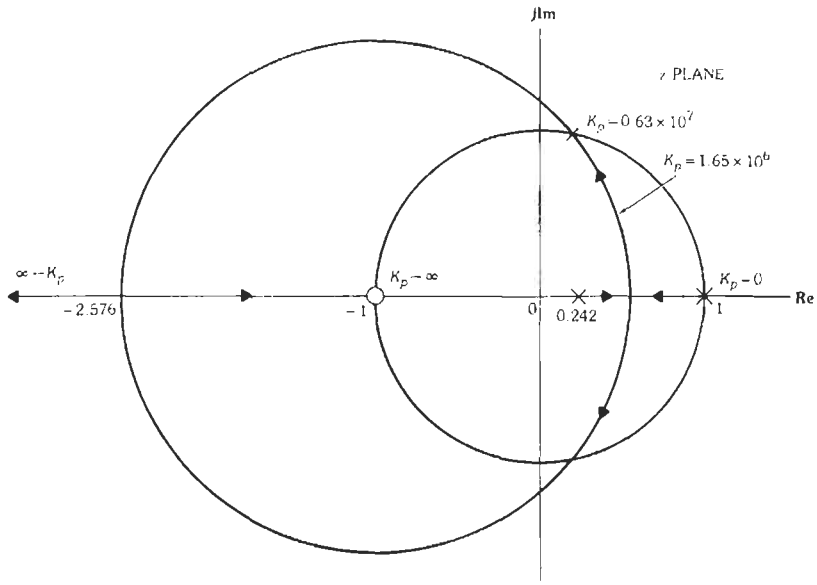

Fig. 36. Root locus for $G(z) = [(1.2 \times 10^{-7})(z + 1)K_p]/[(z - 1)(z - 0.242)]$.

$$J = \tfrac{1}{2} \sum_{k=0}^{\infty} [x^T(kT)Qx(kT) + u^T(kT)Ru(kT)],$$

where $Q \geq 0$, $R \geq 0$. (Note that, for the digital case, we require only positive *semidefiniteness* for R, in contrast to the positive definite requirement in the analog case). The optimum control is

$$u(kT) = -Kx(kT)$$

where

$$K = (\theta^T \theta + R)^{-1} \theta^T P\phi$$

with P being the unique positive definite solution of the discrete algebraic Riccati equation (DARE)

$$P = \phi^T[P - P\theta(\theta^T P\theta + R)^{-1}\theta^T P]\phi + Q$$

PHASE-LOCKED LOOP SERVO SYSTEMS

A phase-locked loop servo is a closed-loop control system that is used widely in communication systems for frequency demodulation and bit synchronization. Phase-locked loop servos are also used for velocity control, especially when a high degree of speed regulation and accuracy is desired.

A phase-locked loop in its basic form is represented by the block diagram of Fig. 37. The input signal and the feedback signal are sinusoidal, and, upon locking, both signals will have the same frequency and a constant phase difference. Any deviation from the desired phase difference is detected by the phase detector and is transmitted to the voltage-controlled oscillator (VCO) to correct the error. Since the phase difference is constant, the frequencies of the input and the feedback signals are the same. This principle can be applied to servo systems for which the control objective is speed regulation.

In the case of a phase-locked loop servo for speed control, the VCO is replaced by an amplifier-motor-encoder combination. The output of the encoder is a sinusoidal signal with a frequency proportional to the angular velocity of the motor. Fig. 38 shows the block diagram of a phase-locked loop servo.

The main difference between a phase-locked servo and the conventional servo systems is that the reference input for a phase-locked servo is a periodic signal rather than a fixed voltage. The feedback signal from the encoder is a pulse train whose frequency is proportional to the speed of the motor. The phase detector compares the frequencies or phases of the reference and feedback signals, and generates an error voltage proportional to the difference. The error voltage is then filtered and sent to the motor; the motor speed changes to reduce the

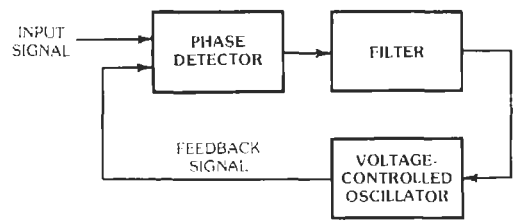

Fig. 37. Phase-locked loop.

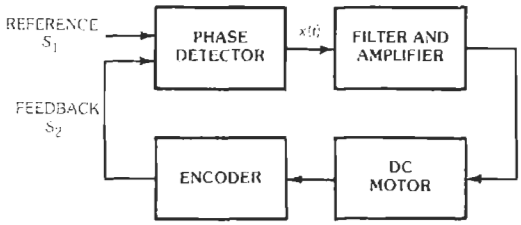

Fig. 38. Phase-locked servo system.

difference between the frequencies or phases of the two signals. Thus, the motor speed can be synchronized to the reference frequency.

A typical set of signals, $s_1(t)$ and $s_2(t)$, is shown in Fig. 39. The output of the phase detector, $x(t)$, switches between 0 and V_s as shown in Fig. 39.

The phase-locked loop servo can be modeled as a linearized digital control system as shown in Fig. 40.

The loop transfer function of the system in Fig. 40 is

$$G(z) = (V_x Tn/2\pi)\mathfrak{Z}[G_p(s)/s]$$

Let

$$G_p(s) = K_m/(1 + \tau s)$$

Then,

$$\begin{aligned}\mathfrak{Z}[G_p(s)/s] &= \mathfrak{Z}\{K_m/[s(1 + \tau s)]\} \\ &= K_m z/(z - 1) - K_m z/(z - e^{-T/\tau})\end{aligned}$$

Let

$$K = (V_x Tn/2\pi)K_m$$

Then,

$$G(z) = \frac{K_z(1 - e^{-T/\tau})}{(z - 1)(z - e^{-T/\tau})}$$

The characteristic equation of the digital phase-locked loop servo is

$$z^2 + (-1 - e^{-T/\tau} + K - Ke^{-T/\tau})z + e^{-T/\tau} = 0$$

Applying the stability test to the last equation yields the condition of stability:

$$K < 2(1 - e^{-T/\tau})/(1 - e^{-T/\tau})$$

NONLINEAR SYSTEMS

All physical systems have nonlinearities to some degree. However, there are no general methods of analysis and synthesis for nonlinear systems. Therefore, they are often treated with linear approximations, and, in many cases of small nonlinear effects, satisfactory results have been obtained. In other cases, however, linear methods become restrictive in their application and quite often unrealistic.

There are many approaches to nonlinear systems that may be applicable to a certain type of system but not to all. Among these methods, two techniques have proved especially useful. These are the describing function technique and the phase plane.

The describing-function technique was first applied to the analysis of nonlinear feedback control systems by Kochenburger. It is the object of the describing-function method of analysis to reduce the representation of the nonlinearity to an equivalent linear gain and phase angle. The representation of the nonlinearity is described in terms of the fundamental component of the distorted output waveform in response to a sinusoidal input. The result of the describing-function analysis is an approximate representation of the system in the frequency domain. The synthesis of nonlinear systems can be carried out with the describing-function technique in much the same way as is done with the linear systems.

The phase-plane method, on the other hand, is a time-domain representation of the behavior of the first- and second-order systems portrayed on the phase plane. The phase-plane diagrams are a useful tool in the study of transient response to any initial condition and in some cases to step and ramp inputs. This method can be extended conceptually to higher-order systems in the so-called phase space. However, an nth-order system in the nth-dimensional phase space compared with the phase plane is difficult to envision and interpret and may be less effective in its usefulness.

Characteristics of Nonlinear Systems

A comparison of linear and nonlinear systems yields the following representative characteristics.

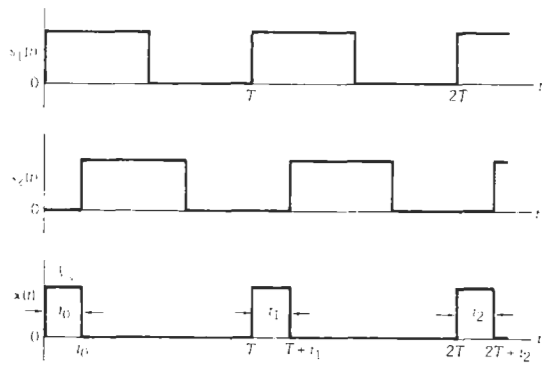

Fig. 39. Typical input and output signals of the phase detector.

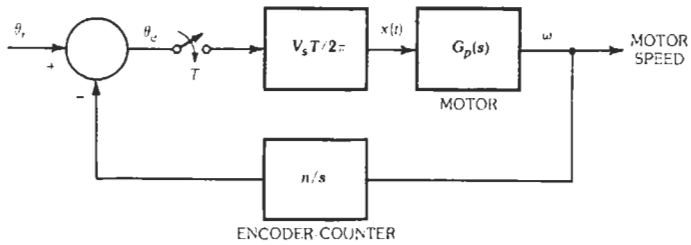

Fig. 40. Linearized model for a phase-locked loop servo.

Principle of Superposition Does not Apply—In nonlinear systems, the response to a combination of individual signals at the input will not be the same as the response to the sum of those same signals. The relationship of the impulse response (weighting function) to the frequency response in linear systems is therefore not applicable. The familiar Laplace transform operation ($s = \sigma + j\omega$) and the transfer-function concept used extensively in linear systems cannot be applied.

Nonlinear Response is Dependent on Input Signal—The response of nonlinear systems is dependent on the input-signal size and initial conditions as well as the system parameters. A stable response for one input signal may be unstable for another.

In nonlinear systems, phenomena exist that are not present in linear systems (generation of new frequencies, jump resonance, limit cycles, etc). The following are examples of such nonlinear phenomena.

Jump Resonance—The phenomenon called jump resonance is observed in certain closed-loop systems with saturation, where the input-output amplitude ratio and phase angle as a function of frequency exhibit sudden discontinuities. The typical closed-loop gain characteristics of a saturating system with jump resonance are shown in Fig. 41. Amplitude ratio $|\theta_o/\theta_i|$ is plotted as a function of frequency for fixed amplitude θ_i. As the frequency is increased from zero, the frequency response follows the curve along points A, B, and C. At point C a sudden discontinuous jump to D is observed with an incremental increase in frequency. Further increase in frequency leads to point E along the curve. If the frequency is reversed, the response retraces the path E, D and continues to point, F, at which a sudden jump to point G occurs; it then continues on through B and A of the gain curve. The phase-angle response behaves similarly. The overall response curve exhibits a hysteresis-type property or jump resonance.

Limit Cycle—Limit cycle is an oscillation peculiar to nonlinear systems. The oscillatory behavior, unexplainable in terms of linear theory, is characterized by a constant amplitude and frequency determined by the nonlinear properties of the system. Limit cycles are distinguishable from linear oscillations in that their amplitude of oscillation is independent of initial conditions. For instance, if a system has a stable limit cycle, the system will tend to fall into the limit cycle, with the output approaching the amplitude of that limit cycle regardless of the initial condition and forcing function. A limit cycle is easily recognized in the phase plane as an isolated closed path as shown in Fig. 42.

Generation of New Frequencies—In a nonlinear system, the output of the nonlinear device contains harmonic and subharmonic frequencies of the input signal. For instance, application of two sine waves of different frequencies f_1 and f_2 to the input will produce components corresponding to the input frequencies f_1, f_2, their sum and difference $f_1 \pm f_2$, their higher harmonics mf_1, nf_2, and various combinations of sums and differences $mf_1 \pm nf_2$. In a linear system, only the components of the input frequencies f_1, f_2 will be reflected in the output. Clearly, the frequency-response concept of linear systems must be modified for nonlinear applications.

Hysteresis—Multivalued functions exist when two or more function values correspond to the value of the variable. Multivalued functions are intrinsically nonlinear. Examples of this are the hysteresis curves of magnetic materials and the backlash of a gear train.

Describing-Function Technique

The object of the describing-function technique is to represent the actual nonlinearity of the system in terms of an equivalent linear system by considering only the fundamental component of the output waveform of the nonlinear element subject to a sinusoidal input. This technique is valuable in the analysis and design of an important class of nonlinear feedback control systems, in which the output of the nonlinear element is acted upon as it travels around the closed loop by a linear low-pass filter.

The describing-function analysis is made on the following basic assumptions.

A. The input to the nonlinear element n is a sinusoidal signal, and only the fundamental component of the output of n contributes to the input. The output response of a nonlinear element to a periodic signal consists of the fundamental frequency components of the input signal and its harmonics. Generally, the harmonic components are smaller in amplitude compared with the fundamental component. Further, in most control systems the system behaves as a low-pass filter, and the higher harmonics are attenuated. If the higher harmonics are sufficiently small, they can be neglected, and the equivalent linear approximation may be justified.

B. There is only one nonlinear element in the system. All nonlinearities in the system are lumped into one single nonlinear element n. Fig. 43 shows a block diagram of a closed-loop system containing a nonlinear element n.

The describing function of a nonlinear element is defined as the ratio of the fundamental-frequency component of the output as a complex quantity (amplitude and phase angle) to the amplitude of the sinusoidal input signal. If the input signal as applied to the nonlinear element n is described by

$$e_{in}(t) = X\sin\omega t$$

the output response $e_0(t)$ may be expressed by the Fourier series

$$e_0(t) = (a_0X/2) + a_1X\sin\omega t + b_1\cos\omega t + \sum_{n=2}^{\infty} a_nX\sin n\omega t + \sum_{n=2}^{\infty} b_nX\cos n\omega t + \cdots$$

The $(a_0/2)$ term is the dc component; a_n and b_n are the harmonic components.

The fundamental-frequency component of the output may be expressed in terms of amplitude and phase angle as

$$e_o1 = A(\omega, X)X\sin[\omega t + \phi(\omega, X)]$$

In this expression, $A(\omega, X)X$ is the amplitude, and $\phi(\omega, X)$ is the phase angle of the fundamental component. Both amplitude and phase angle are a function of the frequency and amplitude of the input signal. The describing function $N(\omega, X)$ by definition is

$$\begin{aligned} N(\omega, X) &= \{A(\omega, X)\,X\exp[j\phi(\omega, X)]/X\} \\ &= A(\omega, X)\exp[j\phi(\omega, X)] \\ &= A(\omega, X)\cos\phi(\omega, X) \\ &\quad + jA(\omega, X)\sin\phi(\omega, X) \end{aligned} \qquad \text{(Eq. 1)}$$

The describing function $N(\omega, X)$ may be purely real or contain a phase angle depending on the type of nonlinearity. For single-valued nonlinear functions N is real, whereas for multivalued functions phase shift exists, generally lagging.

Calculation of a Describing Function—Calculation of the describing function involves performing a conventional Fourier analysis on the output waveform to obtain the fundamental component. The Fourier series expansion of the output waveform to an input sinusoidal $X\sin\omega t$ may be expressed as

$$e_0(t) = (a_0X/2) + a_1X\sin\omega t + b_1X\cos\omega t + a_2X\sin\omega t + b_2X\cos 2\omega t + \cdots$$

For the describing function, only the coefficients of the fundamental-frequency component are required. The coefficients may be obtained from the integrals

$$a_1 = (\pi X)^{-1}\int_0^{2\pi} f_0(t)\sin\omega t \cdot d(\omega t) \qquad \text{(Eq. 2)}$$

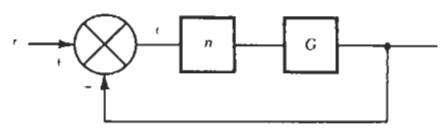

Fig. 43. Block diagram of nonlinear closed-loop system.

$$b_1 = (\pi X)^{-1} \int_0^{2\pi} f_0(t) \cos\omega t \cdot d(\omega t) \qquad \text{(Eq. 3)}$$

where $f_0(t)$ is the exact output of the nonlinear element expressed as a function of time. The describing function is then

$$|N(\omega, X)| = |a_1 + jb_1| = (a_1^2 + b_1^2)^{1/2} \angle N(\omega, X) = \tan^{-1}(b_1/a_1)$$

Where the exact output function $f_0(t)$ is known, the above method is applicable. If the function is not known, a graphical Fourier expansion can be performed on the output waveform. Two examples describing the procedure for calculation of the describing function using the graphical method are given.

Example 1: Saturation-Type Nonlinearity—A nonlinear element with saturation is shown in Fig. 44. Output y is held constant for input values greater than S. This region is called saturation or limiting. For input values less than S, the output behaves linearly with the input. The input-output relationship can be expressed by

(A) $y = kx$ for $-S < x < S$
(B) $y = kS$ for $x > S$
(C) $y = -kS$ for $x < -S$

The output is an odd function, and thus only the sine term of the fundamental equation need be calculated. Furthermore, because of symmetry only the first quarter of the integration need be evaluated as follows:

$$a_1 = (4/\pi X) \int_0^{\pi/2} f_0(t) \sin\omega t \cdot d(\omega t)$$

If the input is $x = X\sin\omega t$, then the output $f_0(t) = y$ is expressed by

$$f_0(t) = kX\sin\omega t \qquad X < S$$

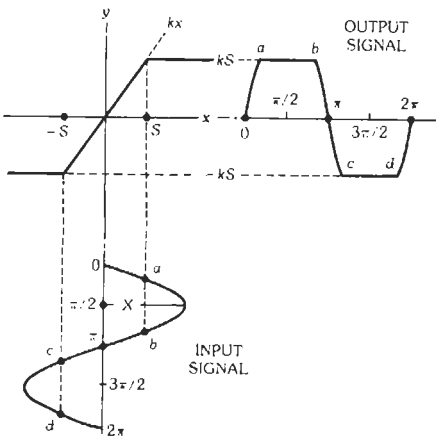

Fig. 44. Graphical representation of saturation.

and for X greater than S

$$f_0(t) = kX\sin\omega t \qquad 0 < \omega t < \sin^{-1}(S/X)$$
$$= kS \qquad \sin^{-1}(S/X) < \omega t < \pi/2$$

Therefore the coefficients a_1 are

$$a_1 = k \qquad X < S$$

and for X greater than S

$$a_1 = (4/\pi X) \int_0^{\sin^{-1}(S/X)} kX\sin^2(\omega t) \cdot d(\omega t)$$
$$+ (4/\pi X) \int_{\sin^{-1}(S/X)}^{\pi/2} kS\sin\omega t \cdot d(\omega t)$$
$$= (2k/\pi)[\phi + (\sin 2\pi)/2]$$

where $\phi = \sin^{-1}(S/X)$.

The describing function N is given by

$$N = k \qquad X < S$$
$$N = k(2/\pi)[\phi + (\sin 2\phi)/2] \qquad X > S$$

The variation of amplitude of N with respect to X/S is plotted in Fig. 45. The phase angle is zero over the entire range.

Example 2: Backlash-Type Nonlinearity—For the second example, a simple backlash-type nonlinearity (Fig. 46) is evaluated. The backlash is a multivalued nonlinearity where the input-output relationship follows a different path dependent on the input-signal amplitude (curves 1, 2, and 3). After the steady state is established, the output $f_0(t)$ corresponding to different values of X of an input signal $x = X\sin\omega t$ are:

For $X < D$ (curve 1):

$$f_0(t) = 0$$

For $D < X < 2D$ (curve 2):

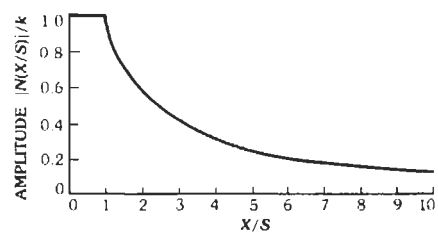

Fig. 45. Describing function for saturation (normalized amplitude).

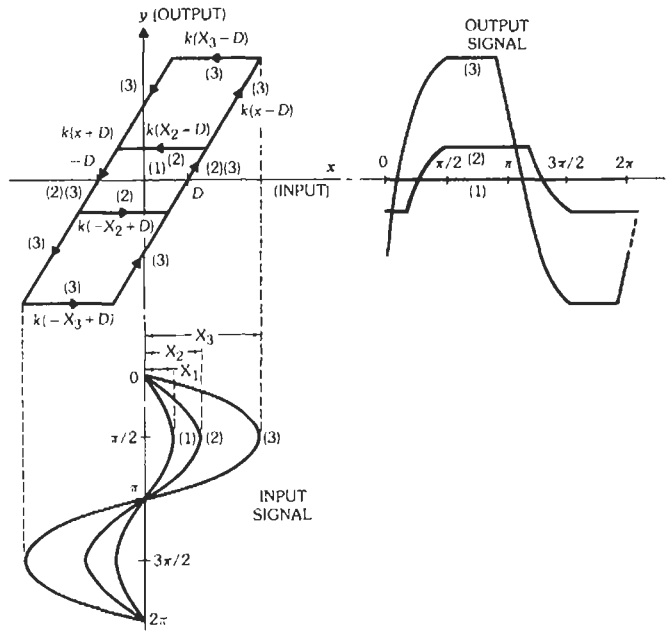

Fig. 46. Graphical representation of backlash nonlinearity. (*Levinson, E. "Nonlinear Feedback Control Systems."* Electro-Technology, *September 1962; Fig. 36, p. 139.*)

$f_0(t) = -k(X - D)$ $\quad 0 < \omega t < \sin^{-1}[(2D/X) - 1]$

$f_0(t) = k(X \sin\omega t - D)$ $\quad \sin^{-1}[(2D/X) - 1] < \omega t < \pi/2$

$f_0(t) = k(X - D)$ $\quad \pi/2 < \omega t < \pi + \sin^{-1}[(2D/X) - 1]$

$f_0(t) = k(X \sin\omega t + D)$ $\quad \pi + \sin^{-1}[(2D/X) - 1] < \omega t < 3\pi/2$

$f_0(t) = -k(X - D)$ $\quad 3\pi/2 < \omega t < 2\pi$

For $X > 2D$ (curve 3):

$f_0(t) = k(X \sin\omega t - D)$ $\quad 0 < \omega t < \pi/2$

$f_0(t) = k(X - D)$ $\quad \pi/2 < \omega t < \pi - \sin^{-1}[1 - (2D/X)]$

$f_0(t) = k(X \sin\omega t + D)$ $\quad \pi - \sin^{-1}[1 - (2D/X)] < \omega t < 3\pi/2$

$f_0(t) = -k(X - D)$ $\quad 3\pi/2 < \omega t - \sin^{-1}[1 - (2D/X)]$

$f_0(t) = k(X \sin\omega t - D)$ $\quad 2\pi - \sin^{-1}[1 - (2D/X)] < \omega t < 2\pi$

Solving for a_1 and b_1 of Eqs. 2 and 3, for the three conditions above, yields the describing-function terms

$a_1 = 0$ $\quad X < D$

$a_1 = (k/\pi)[\pi/2 + \theta + (\sin 2\theta)/2]$ $\quad X > D$

$b_1 = 0$ $\quad X < D$

$b_1 = (-k/\pi)\cos^2\theta$ $\quad X > D$

where,

$\theta = \sin^{-1}[1 - (2D/X)]$

Or in terms of amplitude and phase angle

$$|N| = (k/\pi)\{[\tfrac{1}{2}\pi + \theta + \tfrac{1}{2}(\sin 2\theta)]^2 + \cos^4\theta\}^{1/2}$$

$$\angle N = \tan^{-1}\left[-\left(\frac{\cos^2\theta}{\frac{1}{2}\pi + \theta + \frac{1}{2}(\sin 2\theta)}\right)\right]$$

The normalized amplitude and phase angle of the describing function N for different values of D/X are plotted in Fig. 47.

The describing function is calculated simply by determining the fundamental output component of the nonlinear element. Describing functions for some of the common nonlinear elements are given in Table 2.

Stability Analysis—The describing function N of the nonlinearity can be used to determine the stability of the system, providing the harmonics are sufficiently attenuated. In general, the describing function is a function of both frequency and amplitude of the input signal.

The closed-loop "transfer function" of the nonlinear feedback system in Fig. 48 is given by

$$(c/r)(\omega, X) = \frac{N(\omega, X)G(j\omega)}{1 + N(\omega, X)G(j\omega)}$$

The "characteristic equation" of the system is

$$1 + N(\omega, X)G(j\omega) = 0 \qquad \text{(Eq. 4)}$$

or

$$G(j\omega) = -[1/N(\omega, X)]$$

The condition of Eq. 4 must be satisfied for sustained oscillation of the output with zero input. Since $N(\omega, X)$ is a function of both frequency and amplitude, various combinations of ω and X can be found for oscillation. If there are no possible combinations satisfying the oscillatory condition, the system is stable. In the case of sustained oscillation, the oscillatory mode may be either stable or unstable. If a slight disturbance in amplitude or frequency occurs and the oscillation returns to its original value, the oscillation is stable (stable limit cycle). If the oscillation amplitude increases or decreases from the original value, the oscillation is unstable (unstable limit cycle). The stability of the closed-loop system may be evaluated analytically by directly solving the characteristic equation by any one of the modified linear graphical methods.

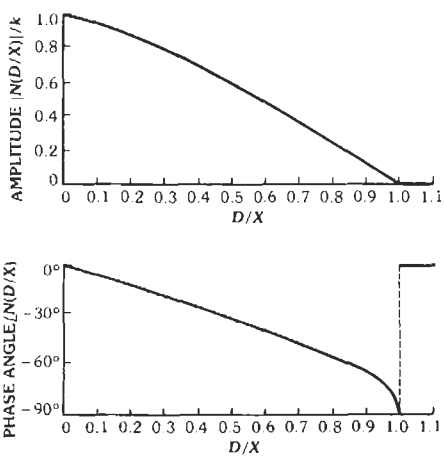

Fig. 47. Describing function for backlash (normalized amplitude and phase angle).

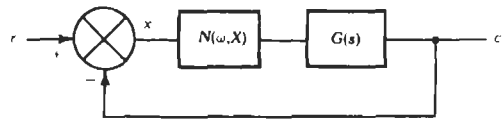

Fig. 48. Single-loop nonlinear system.

Polar Plot (Nyquist Diagram)—The conventional Nyquist diagram must be modified to apply the Nyquist stability criteria to the frequency-response plot. In a linear system, the crucial point on the Nyquist diagram is -1. For nonlinear systems the $-[1/N(\omega, X)]$ locus corresponds to the critical point -1. To evaluate the stability of the system, both $-[1/N(\omega, X)]$ and the $G(j\omega)$ function are plotted on the polar plane. The describing function $N(\omega, X)$ generally is a function of both ω and X. If N is only a function of X, there will be one locus $-[1/N(x)]$ plotted as a function of X. If N is also a function of ω, a family of constant-frequency loci are plotted for different values of ω (see Fig. 49).

The stability of the system is determined by the following relationship between the $-[1/N(\omega, X)]$ locus and the $G(j\omega)$ plot (Fig. 50). If the $-[1/N(\omega, X)]$ locus lies to the left of the $G(j\omega)$ plot or is not enclosed, the system is *stable*. Conversely, if the $-[1/N(\omega, X)]$ locus lies to the right of the $G(j\omega)$ plot or is enclosed, the system is *unstable*. If the $-[1/N(\omega, X)]$ locus intersects with the $G(j\omega)$ plot, the system may have a *sustained oscillation*. In the case where N is a function of ω, the condition for sustained oscillation is satisfied if the ω of the $G(j\omega)$ plot at the intersecting point is the same ω of the $-[1/N\omega, X)]$ locus (see Fig. 51).

The oscillation may be either stable or unstable. If the $G(j\omega)$ intersects with the $-[1/N(\omega, X)]$ locus at one point only, the oscillation is stable (stable limit cycle). If more points of intersection exist, the limit cycle may be either stable or unstable. The stability of the limit cycle is determined by the direction of the two loci at the crossover point.

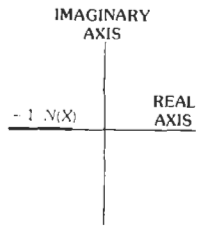
By establishing the $G(j\omega)$ locus pointing in the direction of increasing frequency as a reference, if the $-[1/N(X)]$ locus pointing in the direction of increasing amplitude X crosses the $G(j\omega)$ locus from right to left, the limit cycle is stable. If the crossover occurs from left to right, the limit cycle is unstable. A polar plot with both stable and unstable limit cycles is shown in Fig. 52.

TABLE 2. DESCRIBING FUNCTIONS FOR COMMON NONLINEAR ELEMENTS

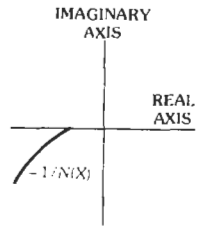
DESCRIBING FUNCTION: $N(X)=a_1+jb_1$ or $|N(X)|=(a_1^2+b1^2)^{1/2}$, $\angle N(X)=\tan^{-1}(b_1/a_1)$

Characteristic	Describing-Function Coefficients
A 	$a_1=4S/\pi X$ $b_1=0$
B 	$a_1=(4S/\pi X)\cos\theta$ $\quad\theta=\sin^{-1}(D/X)$ $b_1=0$
C 	$a_1=(2k_1/\pi)[\theta+(1/2)(\sin2\theta)]$ $\quad\theta=\sin^{-1}(S/X)$ $b_1=0$
D 	$a_1=(2k_1/\pi)[\pi/2-\theta-(1/2)(\sin2\theta)]$ $\quad\theta=\sin^{-1}(D/X)$ $b_1=0$
E 	$a_1=(2k_1/\pi)[\psi-\theta+(1/2)(\sin2\psi)-(1/2)(\sin2\theta)]$ $\quad\psi=\sin^{-1}(S/X)$ $\quad\theta=\sin^{-1}(D/X)$ $b_1=0$
F 	$a_1=k_1+(4A/\pi X)$ $b_1=0$
G 	$a_1=k_2-[(k_2-k_1)/\pi](2\theta+\sin2\theta)$ $b_1=0$ $\quad\theta=\sin^{-1}(P/X)$

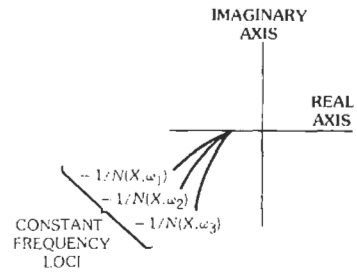
Characteristic	Describing-Function Coefficients
H 	$a_1=k_1/2$ $b_1=0$
I 	$a_1=4X/3\pi$ $b_1=0$
J 	$a_1=(k_1/\pi)[\pi/2+\theta+(1/2)(\sin2\theta)]$ $b_1=-(k_1/\pi)\cos^2\theta$ $\quad\theta=\sin^{-1}[1-(2D/X)]$
K 	$a_1=(4L/\pi X)\cos\theta$ $\quad\theta=\sin^{-1}(D/X)$ $b_1=-(4L/\pi X)\sin\theta$
L 	$a_1=(2L/\pi X)(\cos\theta+\cos\psi)$ $\quad\psi=\sin^{-1}(P/X)$ $b_1=(2L/\pi X)(\sin\psi-\sin\theta)$ $\quad\theta=\sin^{-1}(Q/X)$



(A) Plot of $-1/N(X)$, zero phase angle.



(B) Plot of $-1/N(X)$, with phase angle.



(C) Plot of $-1/N(X)$, as a function of constant ω.

Fig. 49. Typical polar plots of various $N(\omega, X)$.

Gain-Phase Plot—The gain-phase plot is the direct transfer of the polar plot from polar coordinates to rectangular coordinates. The ordinate is the gain in decibels, and the abscissa is the phase angle in degrees.

The gain and phase angle of the two functions $G(j\omega)$ and $-[1/N(\omega, X)]$ are, for $G(j\omega)$

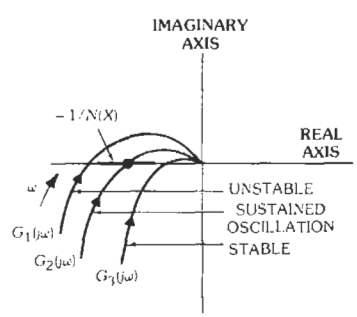


Fig. 50. Polar-plot stability criteria.

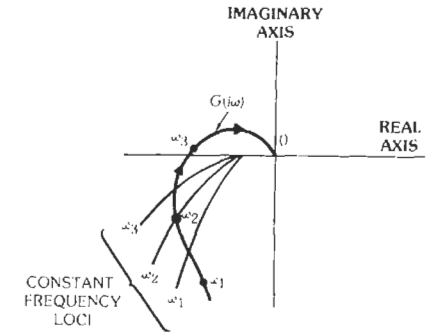

Fig. 51. Typical polar plot of $G(j\omega)$ and $-[1/N(\omega, X)]$ as a function of ω.

$$\text{Gain} \qquad 20 \log |G(j\omega)|$$

$$\text{Phase angle} \qquad \angle G(j\omega)$$

and for $N(X, \omega)$

$$\text{Gain} \qquad -20 \log_{10} |N(\omega, X)|$$

$$\text{Phase angle} \qquad -180° - \angle N(\omega, X)$$

Typical gain-phase plots for various types of $N(\omega, X)$ are given in Fig. 53.

The system is stable if the $-(1/N)$ locus does not intersect with the $G(j\omega)$ plot. If the $-(1/N)$ locus intersects with the $G(j\omega)$ plot, the system has a sustained oscillation (Fig. 54).

In the case of sustained oscillation, there may be more than one point of intersection, as shown in Fig. 55. Points A and C are stable points (stable limit cycle), and point B is an unstable point (unstable limit cycle). The stability of the limit cycle is determined in a manner similar to that of the polar plot, except that if the $-[1/N(X)]$ locus in the direction of increasing X crosses the $G(j\omega)$ locus point in the direction of increasing frequency from left to right, the limit cycle is stable; if it crosses from right to left, the limit cycle is unstable. Fig. 56 is a typical gain-phase plot of $G(j\omega)$ and $-[1/N(\omega, X)]$, where $N(\omega, X)$ is a function of ω. The family of $-(1/N)$ plots are the constant-frequency loci. Point A is the location for sustained oscillation.

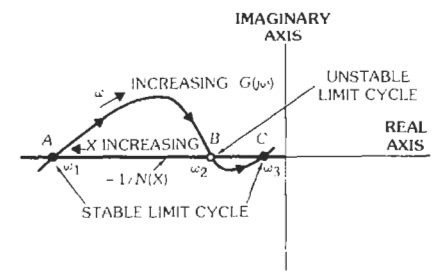

Fig. 52. Polar plot of stable and unstable limit cycles.

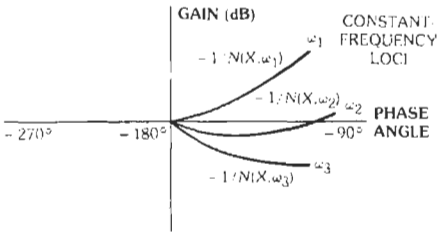
(B) Plot of $-1/N(X)$, with phase angle.



(C) Plot of $-1/N(X)$ as a function of constant ω.

Fig. 53. Typical gain-phase plots of various $N(\omega, X)$.

Phase-Plane Method

The phase-plane method of analysis is used to study the transient behavior of second-order nonlinear systems. Differential equations for systems of higher order may be solved in the phase space; however, the results are complex and unwieldy, and not suited for graphical display. (Modern high-quality computer graphics can be used to advantage for higher-order problems).

Phase Plane—The differential equation describing a time-invariant second-order system may be expressed by

$$f_1(x, dx)/dt)(d^2x/dt^2) + f_2(x, dx/dt, t)(dx/dt) + f_3(x, dx/dt, t)x = g(t) \quad \text{(Eq. 5)}$$

The equation in which t does not appear explicitly is called "autonomous." By defining

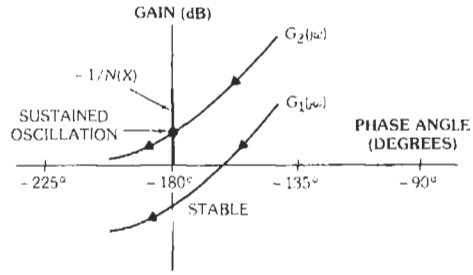


Fig. 54. Stability criteria for gain-phase plot.

$$\dot{x} = dx/dt$$

the equation may be rewritten as

$$f_1(x, \dot{x})(d\dot{x}/dt) + f_2(x, \dot{x})\dot{x} + f_3(x, \dot{x})x = 0$$

Or

$$dx/dt = P(x, \dot{x}) = \dot{x} \quad \text{(Eq. 6)}$$

$$d\dot{x}/dt = Q(x, \dot{x}) = -[f_2(x, \dot{x})\dot{x} + f_3(x, \dot{x})x]/f_1(x, \dot{x}) \quad \text{(Eq. 7)}$$

and, further:

$$(d\dot{x}/dt)/(dx/dt) = d\dot{x}/dt = Q(x, \dot{x})/P(x, \dot{x}) = -[f_2(x, \dot{x})\dot{x} + f_3(x, \dot{x})x]/\dot{x}f_1(x, \dot{x}) \quad \text{(Eq. 8)}$$

The second-order differential equation with respect to time is converted to a first-order equation of x and $\dot{x}$.

The phase-plane diagram has the $\dot{x}$ as its ordinate and x as its abscissa. The plot of $\dot{x}$ as a function of x on the phase-plane diagram is termed *phase trajectory*. A family of phase trajectories is called the *phase portrait*.

The phase trajectory originates at a point corresponding to the initial condition $(x_0, \dot{x}_0)$ and moves to a new location at each increment of time. Generally, the increments of time are not portrayed on the trajectory

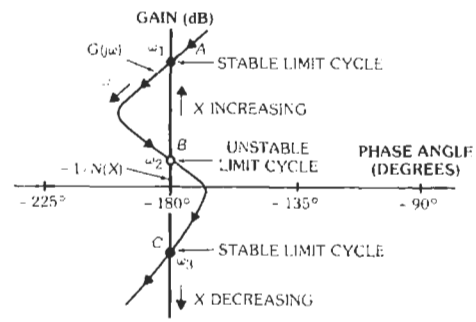

Fig. 55. Gain-phase plot of stable and unstable limit cycles.

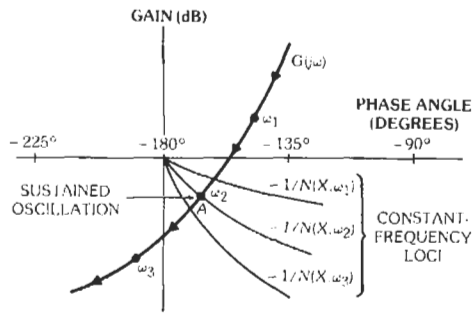

Fig. 56. Typical gain-phase plot of $G(j\omega)$ and $-[1/N(\omega, X)]$ as a function of ω.

and must be obtained by other means. If the value of time at each point on the trajectory is obtained, the time response of $\dot{x}(t)$ and $x(t)$ can be plotted. The phase trajectory has a definite direction associated with time. When $\dot{x}$ is positive the trajectory moves from left to right, and for negative values of $\dot{x}$ all paths move from right to left. If the trajectory approaches the origin or some finite point on the phase plane as time goes to ∞, the system is stable. If the trajectory goes to ∞ with time, the system is unstable. If the trajectory approaches an enclosed path in the phase plane, the system has sustained oscillation. The enclosed path is called the limit cycle.

Construction of the Phase Portrait, Method of Isoclines—The slope of $d\dot{x}/dx$ of Eq. 8 is simply the slope of the trajectory in the phase plane. The locus of constants $d\dot{x}/dx$ is termed an *isocline* corresponding to the slope α; that is

$$\alpha = d\dot{x}/dx = -[f_2(x, \dot{x})/f_1(x, \dot{x})] - [f_c(x, \dot{x})/f_1(x, \dot{x})]/(x/\dot{x}) = -g(x, \dot{x}) - h(x, \dot{x})(x/\dot{x})$$

The phase portrait is constructed by hand by plotting a large number of isoclines corresponding to the various slopes of the trajectory on the phase plane. All points located on the same isocline have the same slope α. Beginning at the location of the initial condition $(x_0, \dot{x}_0)$, the trajectory traverses in the clockwise direction, crossing each isocline at an angle corresponding to that slope α. Fig. 57 shows the isocline for a damped, linear, second-order system. Isoclines for first- and second-order linear differential equations are straight lines.

Singular Points: In a second-order system, the differential equation of the system may be described by two variables x and $\dot{x}$ in the following form:

$$dx/dt = P(x, \dot{x})$$

$$d\dot{x}/dt = Q(x, \dot{x})$$

The points where dx/dt and $d\dot{x}/dt$ vanish are called *singular points*. At a singular point, the system is in a state of equilibrium.

The importance of a singular point in the phase plane is how the trajectories of the phase portrait behave in the vicinity of the singular point. When the trajectory converges to the singular point the system is stable, whereas if it diverges the system is unstable. Typical singular points are described below.

Types of Singular Points: Besides stable and unstable equilibria, the singular points may be classified into node, focus, center, and saddle points.

Consider, for example, a singular point at $x = a$ and $\dot{x} = b$ of Eqs. 6 and 7. At a singular point the derivatives dx/dt and $d\dot{x}/dt$ are both zero, and the location may be solved in the phase plane by setting equations 6 and 7 equal to zero. A singular point exists at $x = a$, $\dot{x} = b$, and the functions P and Q can be expressed in terms of the Taylor series about those points; then

$$dx/dt = c_1(x - a) + c_2(\dot{x} - b) + c_3(x - a)^2 + c_4(x - a)(\dot{x} - b) + c_5(\dot{x} - b)^2 + \cdots$$

$$d\dot{x}/dt = d_1(x - a) + d_2(\dot{x} - b) + d_3(x - a)^2 + d_4(x - a)(\dot{x} - b) + d_5(\dot{x} - b)^2 + \cdots$$

If a sufficiently small region around the singular point is taken, the derivatives are dominated by the linear terms and hence quantities c_1, c_2, d_1, and d_2. By changing the variables, the singular point may be moved to the origin. Then the system equation may be rewritten as

$$dx/dt = p_1x + p_2\dot{x} = 0$$

$$d\dot{x}/dt = q_1x + q_2\dot{x} = 0$$

and the characteristic equation is

$$\lambda^2 - (p_1 + q_2)\lambda + (p_1q_2 - p_2q_1) = 0$$

The roots of the characteristic equation determine the nature of the critical points. The roots are

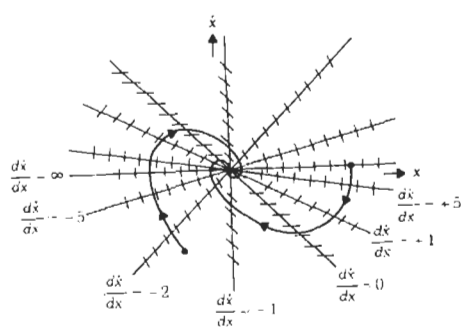

Fig. 57. Isocline method.

$$\lambda = \tfrac{1}{2}\{(p_1 + q_2) \pm [(p_1 + q_2)^2 - 4(p_1q_2 - p_2q_1)]^{1/2}\}$$

There are six possible cases for the six types of singular points.

A. The roots are real and are both negative. If the initial condition is $x_0 \neq 0$, $\dot{x}_0 = 0$, the trajectory approaches the singular point without an overshoot or oscillation and is called a *stable node* (Fig. 58A).

B. The roots are complex conjugate with negative real parts. The trajectory displays a spiraling response as it converges to the singular point as shown in Fig. 58B. This is called the *stable-focus* type of singularity.

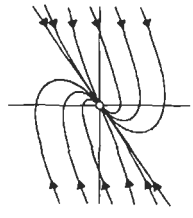
C. The roots are conjugate and pure imaginary. The response exhibits a sustained oscillatory motion with the amplitude dependent on the initial condition. The trajectory displays a family of ellipses about the singular point, and is termed *center* (Fig. 58C).

D. The roots are both positive real. The response in the time domain increases exponentially and is unstable. The portrait is the same as the stable node except the trajectory diverges from the singular point. This is termed *unstable node* (Fig. 58D).

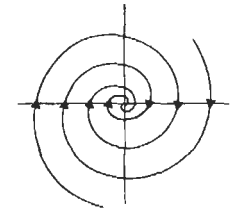
E. The roots are complex conjugate with positive real parts. The phase portrait is the same as the stable focus except the trajectory diverges from the singular point. This is termed the *unstable focus* (Fig. 58E).

F. The roots are real with one negative and the other positive. The phase portrait consists of a family of curves of the hyperbolic type having $k_1 = (\lambda_1 - p_1)/p_2$ and $k_2 = (\lambda_2 - p_1)/p_2$ for its asymptotes. The direction of the paths is toward the singular point on the negative asymptote and away from the singular point on the positive asymptote. Singular points of this type are called *saddle points* and are unstable (Fig. 58F).

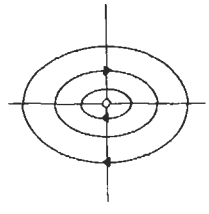
The six types of singularities correspond to the six regions of Fig. 59.



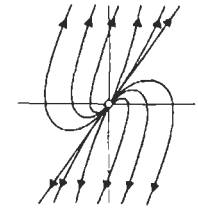
(A) Stable node.



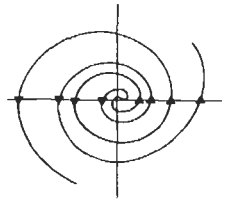
(B) Stable focus.



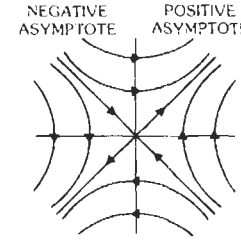
(C) Center



(D) Unstable node.



(E) Unstable focus



(F) Saddle point.

COMPUTER-AIDED ANALYSIS AND DESIGN

The development of software for computer-aided control-system analysis and design has revolutionized control engineering. Several software packages are currently available commercially for carrying out the analysis and design methodologies described in this chapter. These packages provide high-quality graphics for displaying system time responses, as well as Bode plots and root loci. User-friendly interfaces provide the ease of interaction with these packages that is essential for an efficient design environment. Typically, these packages include both classical and state-space oriented methodologies. The underlying numerical algorithms are based on the latest research in numerical analysis. Currently available packages include Matlab, Matrix-X, Program CC, Simnon, Easy-5, Ctrl-C, and L-A-S, among others. See the end of the References section for further information on software packages.

BIBLIOGRAPHY

There are many good introductory texts in the field of control. Among these are:

Kuo, B. C. *Automatic Control Systems*, 6th ed. Englewood Cliffs, NJ: Prentice Hall, 1991.

Franklin, G. F., Powell, J. D., and Emami-Naeini, A. *Feedback Control of Dynamic Systems*. Reading, MA: Addison-Wesley, 1991.

Dorf, R. C. *Modern Control Systems*, 5th ed. Reading, MA: Addison-Wesley, 1989.

Phillips, C. L., and Harbor, R. D. *Feedback Control Systems*, 2nd ed. Englewood Cliffs, NJ: Prentice-Hall, 1991.

For control system components, sensors, and actuators, see:

deSilva, C. W. *Control Sensors and Actuators*. Englewood Cliffs, NJ: Prentice-Hall, 1989.

See also the journal *Sensor and Actuators* for up-to-date developments in this rapidly-moving field.

Modeling of a variety of physical systems and components for control purposes is discussed in:

Connon, R. H., Jr. *Dynamics of Physical Systems*. New York: McGraw-Hill, 1967.

Ogata, K. *System Dynamics*. Englewood Cliffs, NJ: Prentice-Hall, 1978.

The classical reference on sensitivity is:

Bode, H. W. *Network Analysis and Feedback Amplifier Design*. New York: Van Nostrand, 1945.

See also

Horowitz, I. *Synthesis of Feedback Systems*. New York: Academic Press, 1963.

An extension of the Bode sensitivity approach to multivariable systems (comparison sensitivity) is given in

Perkins, W. R. "Sensitivity Analysis," in J. B. Cruz, Jr., ed. *Feedback Theory*. Chapter 2, pp. 19–65. New York: McGraw-Hill Book Co., 1972.

Cruz, J. B., Jr. and Perkins, W. R. "A new approach to the sensitivity problem in multivariable feedback systems design." *IEEE Trans. Automat. Control*, July 1984, pp. 216–223.

Textbooks emphasizing the state-space approach include:

Friedland, B. *Control System Design: An Intro. to State-Space Methods*. New York: McGraw-Hill, 1986.

Anderson, B. D. O., and Moore, J. B. *Optimal Control: Linear Quadratic Methods*. Englewood Cliffs, NJ: Prentice-Hall, 1990.

Lewis, F. L. *Optimal Control*. New York: Wiley-Interscience, 1986.

Digital control is the subject for the following texts:

Kuo, B. C. *Digital Control Systems*, 2nd ed. Saunders, 1992.

Åström, K., and Wittenmark, B. *Computer-Controlled Systems: Theory and Design*, 2nd ed. Englewood Cliffs, NJ: Prentice-Hall, 1990.

Franklin, G. F., Powell, J. D., and Workman, M. L., *Digital Control of Dynamic Systems*, 2nd ed. Reading, MA: Addison-Wesley, 1990.

Auslander, D. M., and Tham, C. H. *Real-Time Software for Control: Program Examples in C*. Englewood Cliffs, NJ: Prentice-Hall, 1990.

Nonlinear systems are the subject of intense current interest. Useful texts include:

Vidyasagar, M. *Nonlinear Systems Analysis*. Englewood Cliffs, NJ: Prentice-Hall, 1978.

Khalil, H. K. *Nonlinear Systems*. New York: Macmillan, 1992.

Current research in control theory and applications is reported in journals such as *IEEE Trans. on Automatic Control*, *IEEE Trans. on Industrial Electronics*, *Automatica*, and the *International Journal on Control*, as a sampling. Very useful to designers are the "trade" magazine *Control Engineering* and the *IEEE Control Systems Magazine*. These magazines contain advertisements for the computer-aided design packages mentioned in the section "Computer-Aided Analysis and Design." Some control texts provide software on back-of-the-book disks.

16 Electron Tubes

Marvin Chodorow and Robert Symons
Revised by David Abe, Richard Abrams, Bruce Danly, Henry Freund, Kevin Jensen, Baruch Levush, Robert Myers, Robert Parker, Jonathan Shaw, Arnold Shih, Joan Yater

ELECTRON EMISSION

All electron tubes* depend for their operation on the flow of electrons within the tube, through either high vacuum or an ionized gas. The electrons are emitted from a cathode surface as a result of one of four processes that are distinguished on the basis of the mechanism by which the electrons are enabled to leave the surface. These processes are elevated temperature (thermionic or primary emission); bombardment by other particles, generally electrons (secondary emission); the action of a high electric field (field emission); or the incidence of photons (photoemission).

Thermionic Emission

Thermionic emission originates from the thermally excited electrons that have sufficient kinetic energy to overcome the vacuum barrier. The sum of all these thermal electrons gives rise to the Richardson–Dushman equation, which is

$$J = AT^2 \exp(-\phi/kT) \qquad \text{(Eq. 1)}$$

where

J is emission density in amperes/cm^2,
A is 120 amperes/cm^2,
ϕ is work function in electron volts (eV),
T is temperature in kelvins (K), and
k, the Boltzmann constant, is 8.6164×10^{-5} eV K^{-1}.

Emission density is an exponential function of the work function. Between 1000 K and 2000 K, a decrease in the work function of 0.2 to 0.4 eV causes an order of magnitude increase in the emission density. The work function of commonly used thermionic cathodes varies from 4.6 eV (tungsten) to 1.5 eV (oxide-coated cathodes).

The first thermionic cathodes used in quantity were made from pure tungsten (W). Because of the high work function, a very high temperature is required to provide a reasonable emission density. For example, Eq. 1 indicates that an emission density of 0.3 A/cm^2 requires a temperature of 2150°C (or 2423 K).

To reduce the operating temperature, thoria (thorium oxide) was mixed with W. Thorium would diffuse to the surface of W and lower the work function. The cathode surface was sometimes carburized to reduce the thorium evaporation, extending the operating life. The resulting surface has a work function of ~ 3.2 eV.† For comparison with pure tungsten, the emission density of 0.3 A/ cm^2 requires 1950°C (2223 K), a 200°C reduction in temperature.

A significant reduction in work function was realized in oxide-coated cathodes. The oxide-coated cathodes consist of an alkaline-earth-oxide coating on a metal substrate, which is usually nickel (Ni). A standard ASTM (American Society for Testing and Materials) mixture of the oxide coating is 49, 44, and 7 atomic percent of Ba, Sr, and Ca oxide, respectively. The substrate can be made of either active or passive Ni, depending on whether or not it contains reducing agents. A typical active Ni contains 4% W in the bulk. The work function of a fully activated oxide-coated cathode is 1.85 eV and 1.5 eV on passive and active Ni substrates, respectively.‡

The initial alkaline earths are in carbonate form and mixed by an organic binder. The carbonates and binder are either sprayed onto the substrate or they are cut and transferred from a self-supporting sheet, which is known as a "Sarong" coating. Activation of an oxide-coated cathode requires several hours of outgassing. A copious quantity of hydrocarbon gases is released initially from the decomposition of the organic binder, and then a large amount of CO_2 is released from the decomposition of the carbonates into the respective oxides. It is advisable to raise the cathode temperature gradually during the carbonate conversion to avoid CO_2 overpressure, which could cause melting of the oxide coating. On some oxide-coated cathodes, high work function patches were observed to form, which were identified as the formation of CaO slags on the surface caused by $BaO/BaCO_3$ eutectic melting during the conversion process.§

The activation and poisoning processes of an oxide-coated cathode are explained by a semiconductor model." The oxygen vacancies in the oxide lattice act as electron donors. During activation, the reducing agents, such as W in the Ni substrate, react and bind with the oxygen atoms in the oxides and generate oxygen vacancies. The creation of these donors shifts the Fermi level up from the intrinsic mid-band gap to near the bottom of the conduction band, and consequently, the work function is lowered. Thermal excitation lifts some of the electrons in the donors to the conduction band, and the mobile electrons are needed in the electron emission process. Cathode poisoning by oxidizing gases such as O_2, H_2O, and CO_2 occurs through filling the oxygen vacancies and shifting the Fermi level back toward the mid-band gap. Sulfur, which is present on the surface of many metals, can have a detrimental effect on the oxide-coated cathodes since S can also fill the oxygen vacancies. The well-known 10-volt slump occurs when S is transferred from the metal grids to the oxide coating through electron-stimulated

§ Reference 3.

" Reference 4.

desorption. An oxide-coated cathode, once poisoned by S, cannot be reactivated.*

The major limitations of oxide-coated cathodes are low dc emission and susceptibility to damage. Because moderate electrical conductivity is inherent to semiconductive alkaline earth oxides, the dc emission of the oxide-coated cathodes is limited to less than 1 A/cm^2. Pulsed emission densities are dependent on pulse length and can be as high as tens of A/cm^2.† After the conversion from carbonates to the oxides, it is imperative to maintain a good vacuum since reactivation after exposure to oxidizing gases is often difficult.* Exposure to atmosphere is always detrimental since the coating expansion accompanying the hydroxide formation would cause the oxide coating to peel.

Dispenser cathodes are now the most commonly used high emission-density cathodes. Instead of a thick oxide coating, only a mono-layer or less of Ba and O covers the metal substrate of a dispenser cathode. Since the cathode body is made of W metal, the dc emission is no longer limited by the electrical conductivity. During the operation of a dispenser cathode, a fresh supply of active materials (Ba and O) is continuously dispensed onto the emitting surface, replenishing the loss due to evaporation. Consequently, the dispenser cathodes are quite robust in comparison to the oxide-coated cathodes. During the fabrication of a dispenser cathode, W powder with an average grain size of 4.5 μm is pressed to form the cathode body of a W-matrix with 20% porosity (i.e., 80% density of W). The pores of the W-matrix are then impregnated with a melt of mixed calcined $BaO/CaO/Al_2O_3$ drawn into the pores by capillary action in an atmosphere of dry hydrogen. Consequently, dispenser cathodes are also known as impregnated cathodes or matrix cathodes. Fig. 1 illustrates how the pores in the W-matrix form continuous paths, which allow the impregnation process to occur and which serve as a conduit in dispensing the active material. The most commonly used impregnant mixtures are B-type, S-type, and I-type.‡ The B-type impregnants consist of a mixture of 5 moles of BaO, 3 moles of CaO, and 2 moles of Al_2O_3, with a designation of 5-3-2. The S-type impregnants consist of a 4-1-1 mixture. Less frequently used are the I-type impregnants, which consist of a 6-1-2 mixture. An important effect of the difference in the impregnant mixtures is the Ba evaporation rate. The higher the BaO-to-CaO ratio, the higher the Ba evaporation rate is. In applications where a fast turn-on after shelf storage is essential (e.g., expendable decoys), it is advantageous to choose impregnants with a higher Ba evaporation rate.§ However, excessive Ba evaporation is often undesirable. Ba deposition on the grids leads to unwanted grid emission; a higher Ba ion concentration is also correlated with noisier tube performance.

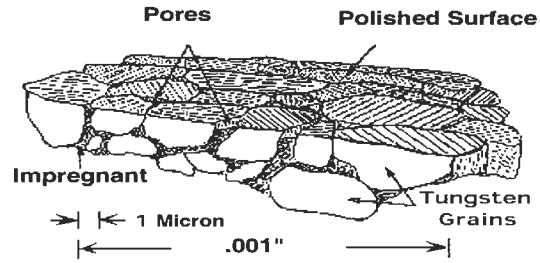

Fig. 1. Scale of dispenser-type cathode features near the emitting surface:

average W-grain diameter ~ 4.5 μm,
approximately 3×10^6 pores/cm^2,
pore equivalent diameter ~ 3 μm,
average inter-pore distance ~ 6 μm.

(From M. C. Green, "Dispenser Cathode Physics," Final Technical Report RADC-TR-81-211, July 1981, 9, Fig. 1.)

There are two types of commercially available off-the-shelf dispenser cathodes, namely the standard-type and the *M*-type. The difference lies in the absence or presence of a metallic coating. As already discussed, the standard-type dispenser cathodes are classified as B-type, S-type, and I-type cathodes, depending on the impregnant mixture. *M*-type cathodes are standard-type cathodes coated with ~ 5000 Å noble metal on top of the emitting surface. The noble metals can be Os, Os–Ru, Ir, or Re. The most common *M*-type cathode has a sputter-deposited Os/Ru coating with an atomic ratio of 80/20." At full activation, the effective work function of a standard-type dispenser cathode is about 2.1 eV and that of a *M*-type cathode is about 1.9 eV.# The low work functions are the effect of the surface layer, which consists of Ba, O, and substrate atoms. The charge transfer and the relative atomic positions result in a net dipole moment, which is directed outward from the surface and reduces the work function of the metal surface. The type of substrate atom changes the degree of charge transfer, the surface coverage, and the atomic arrangement, leading to the observed difference in the work functions.**

The emission from *M*-type cathodes can be further improved by the deposition of alloys of optimized composition, for example, 50% W and 50% Ir. The design of a structure that is stable at the optimum surface composition leads to MMM-type (Mixed Metal Matrix) or CD-type (Controlled Doping) cathodes.††

* Reference 4.
† Reference 1.
‡ Reference 5.
§ Reference 6.
" Reference 7.
Reference 7 & 8.
** Reference 9.
†† Reference 10.

The cathode body of a MMM-type cathode is a sintered plug of W and noble metal (usually Ir) particles. The surface coating of a CD-type cathode consists of deposited multiple layers of alloy material, each of different composition. However, these types of cathodes are no longer commercially available as off-the-shelf items.

Scandate cathodes have been under study for many years. In early years, their performance had not been stable or reproducible. However, recent developments at Philips Research Laboratories have demonstrated consistent emission for several thousand hours in diode tests from top-layer type scandate cathodes, which were fabricated by depositing a layer of Sc_2O_3 and W mixture on a S-type cathode. At 1030°C, emission densities of 100 A/cm^2 and 400 A/cm^2 have been demonstrated for top-layer scandate cathodes prepared by a mixed powder method* and laser ablation deposition,† respectively. These emission densities correspond to effective work functions of 1.63 eV and 1.48 eV, respectively. Even in applications that require an emission density lower than 100 A/cm^2, the use of scandate cathodes allows operation at a lower temperature, which will result in lower Ba evaporation and longer life.

Fig. 2 shows the empirical relation between the emission density and life expectancy of B-type and M-type cathodes. The major life-limiting factor of a dispenser cathode is Ba depletion from the pores. A higher emission density requires a higher operating temperature, which results in a faster rate of Ba depletion, and consequently a shorter life. Since an M-type cathode has a lower work function than a B-type cathode, at a given emission density the operating temperature of the M-type cathode is lower, resulting in a longer life. At the high emission density end of the figure, the data of B-type and M-type cathodes converge.

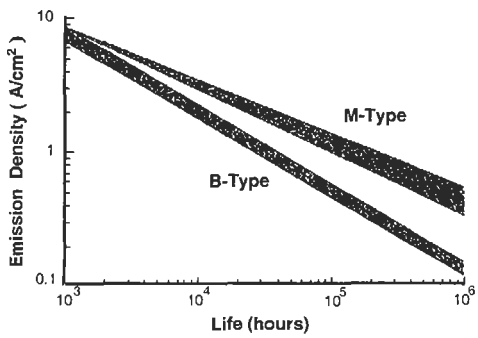

Fig. 2. Operating emission densities that can be expected as a function of desired cathode life. (From A. S. Gilmour, Jr., *Microwave Tubes*. Norwood, MA: Artech House, Inc., 1986, page 132, Fig. 5.27.)

* Reference 11.

† Reference 12.

At these operating temperatures, interdiffusion between the overlayer Os/Ru atoms and the substrate W atoms becomes rapid. The emission characteristics of *M*-type cathodes asymptotically approach that of B-type cathodes. At an emission density above 10 A/cm^2, both B-type and M-type cathodes have too short a life expectancy to be of practical use. A dispenser cathode with a lower work function such as the scandate cathode is needed. However, further developments must be made before scandate cathodes find wide applications. One of the major obstacles is its susceptibility to ion damage. Ion bombardment could cause emission degradation through sputter removal of the surface atoms. With other types of dispenser cathodes, heating to a higher temperature completely restores the original emission characteristics. It was found that thermal treatments were unable to reactivate scandate cathodes after ion beam damage because the lost surface scandium atoms were not readily replenished. A method of replenishing scandium must be developed and incorporated in the cathode fabrication for scandate cathodes to have a reliable performance in a practical tube environment.

Secondary Emission

When the surface of a solid is bombarded by charged particles having appreciable velocity, electrons are emitted from the solid. This is the process of secondary emission.‡§"# In the case where the bombarding particles are also electrons, which is the focus of this discussion, the incident and emitted electrons are differentiated by the terms primary and secondary, respectively. Secondary emission processes under electron bombardment play an essential role in vacuum electronic devices. The materials used in the devices may need to be judiciously selected in some cases to enhance the secondary emission or in other cases to suppress such emission. High secondary-emission materials are desirable for grids in electron multipliers and for cathodes in crossed-field devices, such as magnetrons and crossed-field amplifiers. In contrast, low secondary-emission materials are desirable for depressed collectors in microwave- and millimeter-wave power tubes to ensure a high efficiency in the energy conversion. Low-emission materials are also sought for coating the grids and tube walls to prevent RF vacuum breakdown.

§ O. Hackenberg and W. Brauer, *Secondary Electron Emission from Solids*, Advances in Electronics and Electron Physics, Vol. XI (New York: Academic Press, 1959).

" A. J. Dekker, *Secondary Electron Emission*, Solid State Physics, Vol. 6 (New York: Academic Press, 1958).

R. O. Jenkins and W. G. Trodden, *Electron and Ion Emission* (New York: Dover, 1965) p. 54.

The secondary emission measured from a material includes *all* electrons emitted from the surface. These electrons comprise three groups: (a) true secondaries, (b) inelastically reflected primaries, and (c) elastically reflected primaries. True secondaries are considered to be those of the solid that have been excited above the energy level required for escape across the surface barrier. The three groups are separable to a degree on the basis of energy as indicated in the energy distribution curve of Fig. 3. True secondaries constitute the bulk of emitted electrons at moderate primary energies, and their distribution is almost independent of primary energy. Electrons in the relatively flat interval between *a* and *b* constitute a mixture of true secondaries and inelastically reflected primaries. It has become customary to arbitrarily designate those emitted electrons having energies less than 50 eV as true secondaries.

In practice the secondary emission characteristics of a material are described by the secondary yield coefficient δ (defined as the ratio of the secondary-electron current to the primary-electron current) and the emitted energy distribution. These emission characteristics are influenced by the properties of both the material and the primary electrons. To understand these influences, it is necessary to consider the three-step secondary-emission process: (1) generation of internal secondary electrons by kinetic impact of the primary electrons, (2) transport of the internal secondary electrons through the bulk to the surface, and (3) escape of the secondary electrons across the solid–vacuum interface. For example, the energy-dependent yield is a product of the competing generation and escape processes. First, primary electrons penetrate into the material and lose energy through collisions with electrons and ions. In the process, kinetic energy is transferred to internally generated secondary electrons. Each primary electron is able to generate more secondary electrons as its energy increases, and consequently the secondary yield exhibits an initial increase with increasing primary energy. However, as the primary energy increases, the primary electrons penetrate deeper into the material where most of the secondary electrons are generated. The secondary electrons cannot escape if they are generated too deeply in the material, and hence the yield exhibits a decrease at very high primary energies. The resulting bell-shaped yield curve is seen in Fig. 4 and is observed for most materials. Significant points on the yield curve are the maximum yield, which occurs at a primary energy for which the penetration depth is approximately equal to the escape depth, and the first and second crossovers at which the yield becomes unity. The secondary yield also varies with incident angle, and this variation can be understood from the same process described above. If the primary electron is incident at an angle θ to the surface, the maximum penetration depth is reduced by a factor $\cos\theta$ relative to that at normal incidence ($\theta = 0$), assuming a forward path for the primary electron. Consequently, the yields are larger at more oblique angles, with this enhancement most pronounced at higher primary energies.

Energetic primary electrons generate many internal secondary electrons in all materials. However, high yields are not observed from most materials because the internal secondary electrons lose energy through collisions with electrons and ions and fall below the vacuum level. The dominant energy-loss mechanisms differ in metals and insulators, which results in different secondary emission characteristics for the two types of materials. In metals, secondary electrons lose energy primarily through strong inelastic scattering with conduction electrons. As a result, very few secondary electrons reach the surface with a sufficient kinetic energy to overcome the work function (~ 4–5 eV). The secondary yields from metals are therefore small, with the maximum yield being on the order of unity and varying between 0.5 (for Li) and 1.8 (for Pt).* Because the yield is relatively insensitive to changes in the metallic work function,† the secondary

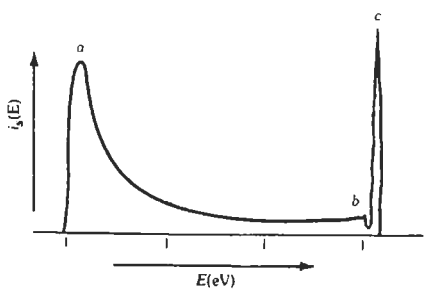

Fig. 3. Total energy distribution of secondary electrons.

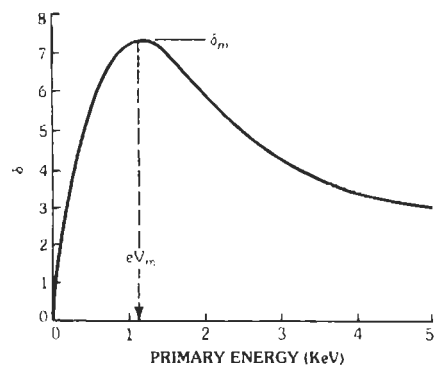

Fig. 4. Secondary-emission yield curve.

* A. J. Dekker, *Secondary Electron Emission*, Solid State Physics, Vol. 6 (New York: Academic Press, 1958).

† R. O. Jenkins and W. G. Trodden, *Electron and Ion Emission* (New York: Dover, 1965) p. 54.

emission from metals is relatively stable and long lived. Low yields ($\delta < 1$) are also obtained from semimetallic graphite and amorphous carbon, and these materials are commonly used in low-yield applications.

Very few conduction electrons are present in insulators, and therefore secondary electrons lose energy primarily through the excitation of valence electrons into the conduction band. This electron–electron scattering interaction becomes forbidden if the secondary–electron energy is less than the energy gap, which is very large in insulators (~ 5–10 eV). As a result, secondary electrons lose energy more slowly as they move through insulators than they do through metals, and the escape depth becomes large. Upon reaching the surface, secondary electrons must have sufficient kinetic energy to overcome the electron affinity, which is the difference between the vacuum level and the conduction-band minimum. In insulators, the electron affinity is typically on the order of 1 eV. Because of the larger escape depth and lower surface barrier, the secondary yields from insulators are generally higher than from metals; for example, the maximum yield is 6.8 for NaCl and 25 for single-crystal MgO.*

The energy distribution of secondary electrons emitted from metals and insulators has generally been assumed to resemble the measurements shown in Fig. 3. From this curve, the secondary-electron energies appear to be relatively high (~ tens of eV) and very broadly distributed. In the case of metals, this energy distribution is consistent with the broad internal distribution produced by inelastic scattering with conduction electrons. However, recent studies have revealed that secondary electrons generated in nonmetals (e.g., wide band gap materials) have a very narrow, low-energy distribution, and the emitted energy distribution depends strongly on the energy barrier at the surface. For example, in secondary emission measurements from diamond surfaces having *no* energy barrier (i.e., a negative electron affinity), the energy distribution is sharply peaked less than 1 eV above the conduction-band minimum with a FWHM of ~ 0.5 eV.† For primary energies above 1000 eV, the low-energy peak contains more than 90% of the total emitted electrons, and yields greater than 100 are measured. Once the electron affinity becomes greater than 1 eV, however, the very low energy electrons are blocked from emission and the yields decrease to values of about 1–3. In this case, only the high-energy tail of the low energy peak is able to escape and the emitted electron energy distribution resembles the "typical" distribution shown in Fig. 3.

It is clear that the secondary emission from insulators depends strongly on the nature of the surface barrier, unlike the case of secondary emission from metals. At some insulator surfaces, the electron affinity can be made small or even negative, in which case the yields become extremely high. However, the secondary emission from such surfaces is very sensitive to surface contamination or damage and may not be stable or long lived. Secondary emission from insulators can also be affected by charging problems. Unlike metals, insulators do not have sufficient electrical conductivity to replenish the emitted electrons, and sample charging decreases the secondary yield to 1. To overcome charging problems, different approaches can be used to provide electrical conductivity in insulator materials. These include the fabrication of a thin insulator layer (e.g., < 50 Å metal-oxide film) on a metal substrate, the incorporation of metallic crystallites in the insulator bulk, and appropriate doping in single-crystal or polycrystalline insulator material. However, each of these approaches presents challenges in practical applications. For example, a thin oxide layer is eroded in the harsh environment of a crossed-field device, and hence a replenishment mechanism must be incorporated into the device. The size and distribution of crystallites in composite materials are difficult to control, and such materials suffer from erosion as well as localized charging problems. Insulator doping represents a promising approach, especially with recent advances in material growth capabilities. However, only a few selective material systems can be appropriately doped at this time, and the robustness and reliability of these materials have not yet been adequately established.

Secondary emitter materials typically used in microwave tubes include pure Pt metal and oxidized metals such as Mg, Be, and Al. For example, BeO is currently used as the secondary emission cathode in the crossed-field amplifiers of the AEGIS system. BeO produces high yields (~ 3–4), but the emitting layer must be replenished by use of an oxygen source. In other high-yield applications, Ag–Mg or Cu–Be alloys are processed to provide a high-yield, partly conductive surface film. Typical yields of 2.5 to 4 are obtained at 100 eV primary energy from the metal oxide (i.e., MgO or BeO) on the surface. In addition to these conventional materials, novel materials are being investigated for future device applications. In particular, doped semiconductor and insulator materials have produced extremely high yields (~100–1000) when the surface is prepared with a small or negative electron affinity. These include hydrogenated diamond and Cs-coated semiconductors (Si, GaAs, GaP). Although these surfaces are not sufficiently stable under heavy ion or electron bombardment, they may be suitable for operation in less harsh environments.

Field Emission

Field Emission From Metals—For current to flow from a metal into vacuum in the absence of heating (thermionic emission), an electric field must be sup-

* A. J. Dekker, *Secondary Electron Emission*, Solid State Physics, Vol. 6 (New York: Academic Press, 1958).

† J. E. Yater, A. Shih, and R. Abrams, *Phys. Rev. B* **56**, R4410 (1997).

plied of sufficient magnitude for electrons to quantum mechanically escape the surface barrier. When an electron leaves a metal surface, a redistribution of charge occurs to shield the electron's influence from the interior and maintain the surface at constant potential. The potential distribution the departing electron experiences is modified by an equal but opposite interior charge at the same distance from the surface and is called the *image charge potential*. It is given by

$$V(x) = \mu + \phi - Fx - Q/x$$

where

x = the distance from the metal surface in nm
μ = the chemical potential (approximately the Fermi energy E_F) in eV
ϕ = the work function in eV
F = the product of the electron charge and the electric field in eV/nm
$Q = e^2/(16\pi\epsilon_o)$, 0.359991 eV-nm
e = the electron charge, 1.60218×10^{-19} Coulombs
ϵ_o = the permittivity of free space, 8.85419×10^{-12} F/m

The chemical potential (Fermi energy) is related to the density of electrons in the metal (or "carrier concentration" in semiconductors) by the relationship*

$$n = N_c \frac{2}{\sqrt{\pi}} F_{1/2}(\beta\mu)$$

where

n = the number density of electrons in #/nm^3
N_c = 0.0250942 #/nm^3 for metals
β = 11604.5/T in eV^{-1}, where T is the temperature in Kelvin
$F_{1/2}(x)$ = the Fermi–Dirac integral, equal to $x^{3/2}(2 + (\pi/x)^2)/3$ when $x >> 1$

"F" is the force on an electron due to the local electric field, referred to here simply as "field." Barrier lowering by an amount $(4QF)^{1/2}$ occurs, and this increases the thermionic emission current, but the thermionic current is negligible by comparison to the tunneling current at room temperature for typical metals. The tunneling current is given by†

$$J(F) = \frac{em}{2\pi^2\beta\hbar^3}\int_0^\infty \ln\left(1 + e^{\beta[\mu - E]}\right)\exp\left(-\frac{b_{fn}}{F} + c_{fn}(E - \mu)\right)dE$$

where

J = the current density in A/cm^2
E = the energy of the incident electron in eV
m = electron rest mass, 510999 eV/c^2
c = the speed of light, 2.99792×10^{10} cm/s
$\hbar$ = Planck's constant over (2π), 6.58212×10^{-16} eV-s

The "ln" term arises from the Fermi–Dirac distribution for electron statistics, and the exponential term is from the WKB approximation to the transmission coefficient in which the log of the transmission coefficient is Taylor expanded to first order in energy about μ. The terms b_{fn} and c_{fn} are

$$b_{fn}(F) = \frac{4}{3\hbar}\sqrt{2m\phi^3}\,v(y);\; c_{fn}(F) = \frac{2}{\hbar F}\sqrt{2m\phi}\,t(y)$$

where

$v(y)$ = function of elliptical integrals, approximated to within 0.1% for $0.40 \le y \le 0.92$ by $v(y) \approx 0.13119\,(1 - y)(1.1321 + y)\,(6.9464 - y)$
$t(y)$ = function of elliptical integrals, approximated to within 0.1% for $0.24 \le y \le 1.00$ by $t(y) \approx 0.023056\,(5.0842 - y)(y^2 + 2.3317y + 8.4607)$
y = $(4QF)^{1/2}/\phi$ and ranges between 0.4 to 0.85 for generic metal field emission

For metals, the integral lower limit in $J(F)$ can be extended to $(-\infty)$ with negligible error and analytically integrated to give the *Fowler Nordheim* (FN) *Equation*‡

$$J_{fn}(F) = a_{fn}F^2\exp(-b_{fn}/F)\left[\frac{\pi c_{fn}/\beta}{\sin(\pi c_{fn}/\beta)}\right]$$

where

$$a_{fn}(F) = \frac{e}{16\pi^2\hbar\phi t(y)^2}$$

(the present form is closer to that of Murphy and Good).§ The variation of the FN parameters a_{fn}, b_{fn}, and c_{fn} are shown in Fig. 5. The term in square brack-

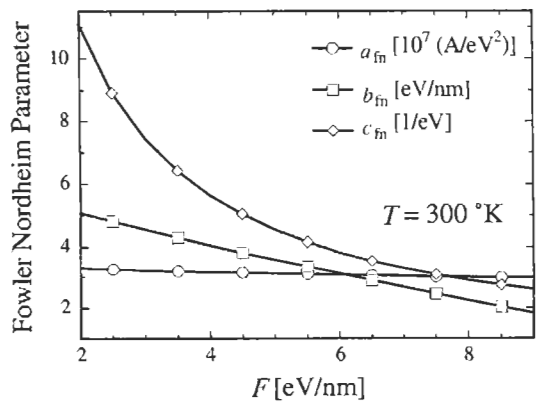

Fig 5. Variation of the Fowler–Nordheim current density parameters as a function of field F at the surface for $\phi = 4.41$ eV (photoelectric work function of Molybdenum) at room temperature. The weak dependence of a_{fn} on F motivates the common approximation that $t(y) \approx$ constant.

† Reference 14.
‡ Reference 15.
§ Reference 16.

ets in $J(F)$ is within 6% of unity for metals under common field emission conditions and is often ignored, reflecting the relative independence of the electron energy distribution from temperature unless the temperature is sufficiently high, as in Fig. 6.

The plot of $\ln(J(F)/F^2)$ versus $(1/F)$ is approximately linear and is referred to as a "Fowler–Nordheim Plot." The slope is proportional to $\phi^{3/2}/F$ and is therefore sensitive to work function changes and geometrical field enhancement. Because of the exponential dependence of $J(F)$ on b_{fn}/F, small changes in either ϕ or the local field result in substantial changes in the emitted current density, as in Fig. 7.

The function $v(y)$ is commonly taken to be linear in y^2, for then $b_{fn}(F)/F$ is linear in $(1/F)$ and $J_{fn}(F)$ on a Fowler–Nordheim plot is manifestly linear. The most widely used approximation is $t(y) \approx (1.1)^{-1/2}$ and $v(y) \approx 0.95 - y^2$.* For emission from multidimensional structures (below), such approximations are similarly expedient, but because $v(y)$ versus y^2 exhibits a weak convexity, the tangent line at a particular $y_o = y(F)$ is a better approximation, for which

$$v(y)\big|_{\text{tangent}} = v_0 - v_1 y^2$$

$$v_0 = \frac{1}{4}\left(3t(y_o) + v(y_o)\right)$$

$$v_1 = \frac{3}{4y_o^2}\left(t(y_o) - v(y_o)\right)$$

where

v_1 = the slope of the tangent line
v_0 = the intercept of the tangent line, equal to 0.9368 when $v_1 = 1$
y_o = the expansion point for a given F, equal to 0.5992 when $v_1 = 1$

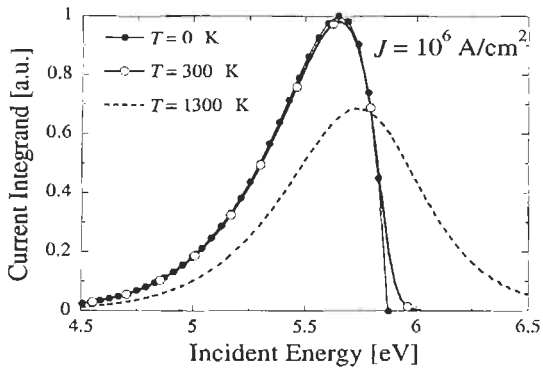

Fig. 6. Energy distribution of electrons incident on the surface barrier in the Fowler–Nordheim approximation. For a given current density, the effects of a raise in temperature are to increase the thermal "tail" near the Fermi level. At room temperature, the energy distribution for metals is well approximated by the 0 K limit.

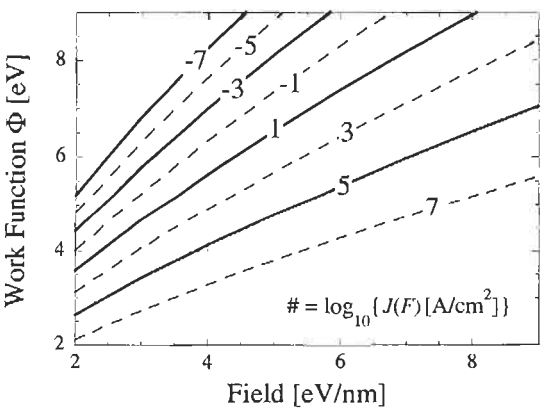

Fig. 7. Contours of constant current density, labeled by $\log_{10}(J(F)[\text{A/cm}^2])$, as a function of work function and field as evaluated using $J_{fn}(F)$.

Field Emission from Semiconductors—The carrier concentration in semiconductors is substantially less than the conduction-band electron density in metals, even under high field. Band bending occurs, so that electron affinity (energy difference between vacuum level and bottom of the conduction band) is a more useful parameter for semiconductors than work function (energy difference between vacuum level and Fermi level), as for semiconductors the latter is affected by applied field. Emission arises from either the valence or conduction band or both, as well as surface states and defects within the band gap. The nature of the current flow depends on the type of doping (n- or p-type) incorporated. Current resulting from hole transport can be significant. The effective mass in a semiconductor is generally less than the electron rest mass in vacuum, and it depends on the crystallographic plane. Surface layers, oxides, or adsorbates generally exist on the surface and contribute to emission fluctuations. If field emission is primarily from the valence band (e.g., diamond†), then the barrier height encountered by the valence electrons is augmented by the band gap. Because of these complications, a current density formula for semiconductors with the simplicity of the Fowler–Nordheim equation for metals is not available except for provisional approximations (more extensive treatments are available‡).

Electrons migrate to the surface to shield out an applied field, indicating that the electron density increases near the surface. The chemical potential is replaced by $\mu(x) = \mu_o + \phi(x)$, where μ_o is the bulk chemical potential (generally such that $\mu_o < 0$) and

* Reference 17.
† Reference 18.
‡ Reference 14.

$\phi(x)$ is the solution to Poisson's equation. $\mu(x)$ is referred to as the "electrochemical potential." If emission is primarily from the conduction band and all other complications are ignored, then the equation for $J(F)$ for semiconductors is analogous to that for metals, but with the replacements:*

$$\phi \Rightarrow \chi - \mu$$

$$Q \Rightarrow \frac{K_s - 1}{K_s + 1} Q$$

$$\frac{c_{\mathrm{fn}}\pi/\beta}{\sin(c_{\mathrm{fn}}\pi/\beta)} \Rightarrow \frac{c_{\mathrm{fn}}\pi/\beta}{\sin(c_{\mathrm{fn}}\pi/\beta)} - (1 + c_{\mathrm{fn}}\mu)\exp(-c_{\mathrm{fn}}\mu)$$

where

χ = the electron affinity in eV
K_s = dielectric constant (e.g., 11.9 for silicon)

At the surface, $\mu(x)$ is related to F_{vac} by Poisson's equation for ϕ such that $K_s\, \partial_x \phi = F_{\mathrm{vac}}$ at the surface, from which

$$F_{\mathrm{vac}(\mu)} = \begin{cases} \left(\dfrac{2\pi^2 N_c K_s}{3\beta\varepsilon_o} \left(\dfrac{\beta\mu}{\pi} \right)^{1/2} \left[\dfrac{8}{5} \left(\dfrac{\beta\mu}{\pi} \right)^2 + 1 \right] \right)^{1/2} & \beta\phi \text{ large} \\ \left(\dfrac{2N_c K_s}{\beta\varepsilon_o} \exp(\beta\mu_o) \left[\exp(\beta\phi) - \beta\phi - 1 \right] \right)^{1/2} & \beta\phi \text{ small} \end{cases}$$

where

$N_c = 2\, M_c\, (m/(2\,\pi\beta\hbar^2))^{1/2}$
M_c = number of equivalent minima in the conduction band (e.g., 6 for silicon)
m = effective electron mass in the semiconductor (e.g., 0.3283 m_o for silicon)
F_{vac} = applied field in vacuum in eV/nm

Macroscopic Current Density

Field emission sources come in a variety of geometries (e.g., conical [Spindt-type] and wedge [knife-edge], to planar thin films and mats of carbon nanotubes) and materials (e.g., metal and semiconductor with or without various coatings for robust performance or low work function). The current density is rarely uniform over extended emission areas because of geometrical and/or work function variation. The sharpest and lowest work function sites dominate, so that electron emission invariably occurs from localized emission sites of small size. For example, conical Molybdenum tips centered in gate holes of micron dimensions† can have an overall radius of curvature at the tip on the order of 25 nm, though emission appears to arise from sites of atomic dimensions.‡

The total current from a single emission site is small, but that is offset by the magnitude of the number of sites. The packing density (alternately, the Emission Site Density [ESD]) is on the order of 10^7–10^9 tips/cm^2 for field emitter arrays and 10^4 – 10^6 sites/cm^2 for various carbon-based and wide band gap emitters.§ The combination of high current density in conjunction with the large number of sites counter the small emission site area and the tendency of only a subset of emitters or sites to be active. Current densities averaged over the cathode area vary between 0.01 and 0.1 A/cm^2 for carbon-based emitters and up to 10 to 2400 A/cm^2 for field emitter arrays. Often, macroscopic fields are cited, but such fields cannot be used in the Fowler–Nordheim equation unless modified by some estimate of the field at the emission site (the macroscopic field is related by a multiplicative factor dependent upon the geometry of the emission site).

Field Emitter Arrays

Field emitter arrays (FEAs) have been extensively investigated for vacuum electronics amplifiers," space-based applications,# and flat panel displays.** An example of a molybdenum FEA cathode is shown in Fig. 8. Concepts such as emission area and field enhancement treated here for FEAs have analogs for the other cold cathodes but are more ambiguous for the latter because a wider variety of mechanisms are believed to be responsible for electron emission.

The local field F is related to an applied (gate) voltage V by the "field enhancement factor" β_g such that $F = \beta_g V$. The field generated at the emission site by the gate significantly dominates other fields (such as that due to the collection anode). The field enhancement factor varies primarily as the inverse radius of the emission site, with other geometrical parameters contributing to a lesser extent. The emission is concentrated about the nanoprotrusions and atomic-sized structures that exist on emitter surfaces.

In practice, β_g is not measured but is inferred from experimental data or simulated.†† β_g is analytically intractable for realistic configurations, but it is obtainable for idealized models. For a Spindt-type tip approximated by a gated hyperbolic cone, β_g is‡‡

$$\beta_g = \left\{ \frac{\pi}{\ln\left[\dfrac{a_g}{54 a_s} \left(86 + \dfrac{a_g}{a_s} \right) \cot(\beta_o) \right]} - \tan^2(\beta_o) \right\} \frac{e}{a_s}$$

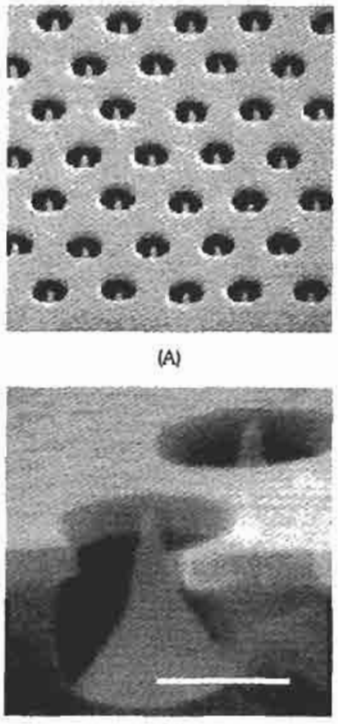

Fig. 8. (A) A 5 μm by 5 μm region of a Molybdenum field emitter array developed by SRI, corresponding to approximately 10^8 tips/cm^2. (*Photo courtesy of C. A. Spindt.*) (B) Close-up cross section of an individual SRI emitter. Bar corresponds to a length of 1 μm. (*Photo courtesy of C. A. Spindt.*)

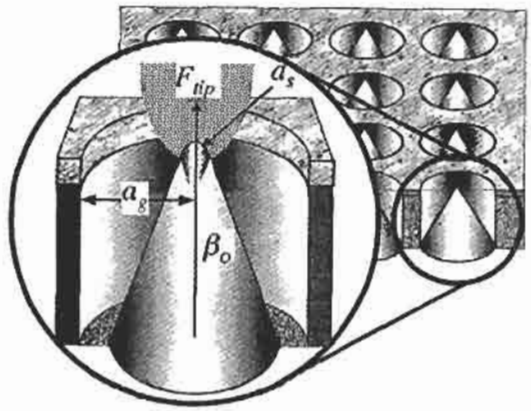

Fig. 9. Representation of an individual emitter as a hyperbolic cone, showing relevant parameters: gate radius (a_g), apex radius (a_s), and cone half-angle (β_O).

where (as shown in Fig. 9)

β_g = the field enhancement factor in eV/Volt-nm
a_s = the radius of hyperbolic apex in nm
a_g = the radius of the gate in nm
β_o = the cone half-angle in radians

The emission is concentrated at the cone's apex. The characteristic emission area factor is defined by $b_{area} = I(V)/J(F)$ and is approximated by

$$b_{\text{area}}(F) = 2\pi a_s^2 \left(\frac{F\cos^2(\beta_o)}{b_{\text{fn}}^o + F\sin^2(\beta_o)} \right)$$

where

b_{fn}^o = the intercept of $b_{\text{fn}}(y)$ as a linear function of y^2.

Because the current falls off exponentially with field, the actual emission area is about a factor of 2.7 larger than b_{area}, and the average current density is smaller by the same factor. Generic values are given in Table 1 for a single molybdenum Spindt-type emitter operating at 1 μA.

In a spherical coordinate system such that the symmetry axis of a single tip is parallel to the z axis, and the polar angle is θ, then the distribution of electrons on a hemisphere of approximately the same diameter as the gate diameter (i.e., $r \approx a_g$) is given by

$$f(\theta) = \exp(-2\chi \sin^2\theta)$$

$$\chi = \frac{1}{2}\left(1 + \frac{b_{\text{fn}}^o}{2F} + \frac{1}{2}\sin^2\beta_o\right)$$

TABLE 1: GENERIC FEA MODEL PARAMETERS

Symbol	Description	Value
Independent		
T	Temperature	300 K
Φ_o	Work Function (Mo)	4.41 eV
a_s	Emission Site Radius	4 nm
a_g	Gate Radius	0.5 μm
β_o	Cone Half-Angle	15°
V	Gate Voltage	72.2 V
Dependent		
β_g	Field Enhancement Factor	0.0867 e/nm
F	Field	6.26 eV/nm
y	Elliptical Integral Argument	0.681
b_{fn}^o	$J(F)$ Exponential Term	58.2 eV/nm
b_{area}	Area Factor	10.0 nm2
$b_{\text{area}}J_{\text{fn}}$	Single Tip Current	1.00 μA
χ	Emission Distribution Parameter	2.84
θ_{rms}	$<\theta^2>$ – rms Emission Angle	19.1°
E_t	Transverse Energy Component	7.32 eV

where

F = field at apex in [eV/nm]

The root-mean-square (rms) value of θ and the transverse energy E_t for electrons emerging from the hemisphere is then, for a single tip,

$$\langle \theta^2 \rangle = \sqrt{\frac{1}{24}\left(15 - \frac{16I_1(\chi) - I_2(\chi)}{I_0(\chi)}\right)}$$

$$E_t = \frac{1}{2}\left(1 - \frac{I_1(\chi)}{I_0(\chi)}\right)V_g$$

where

$I_n(z)$ = hyperbolic Bessel function of order n

Asymptotically, $\theta_{rms} \approx (4\chi + 2)^{1/2}/(4\chi)$ and $E_t \approx \{(4\chi + 1)/(4\chi^2\}$V. The presence of other emitters in close proximity, as in an array, will affect the electron distribution accordingly.

Current–Voltage Relationship, Transconductance, and Modulation

The proportion of active emission sites increases with applied voltage, that is, sites "turn on" as the voltage is raised. The proportion of operating tips scales approximately linearly with applied voltage* (and similarly for the emission sites of wide band gap emitters†). Further, as in b_{area}, the region over which emission occurs scales approximately linearly if the emission surface is curved. The commonly made assumption that total current $I(V)$ varies as $A\ J(F)$, where A is a constant area, is incorrect, as is the "derivation" of current–voltage relations by the substitution $J \Rightarrow I/A$ and $F \Rightarrow \beta_g V$ in $J(F)$. Nevertheless, experimental data plotted on axes defined by $\ln(I(V)/V^2)$ versus $1/V$ is more or less linear for FEAs, as well as for other field emission sources, so that

$$I(V) = A_{FN} V^2 \exp(-B_{FN}/V)$$

where

I = the current measured in amperes
V = the extraction potential in volts
A_{FN} = the "intercept" parameter in A/V^2
B_{FN} = the "slope" parameter in volts

The complex relationship between the parameters A_{FN} and B_{FN} and the parameters a_{fn} and b_{fn} is available only for idealized models, for which the majority of B_{FN}/V is due to b_{fn}/F. This implies that the slope on a Fowler–Nordheim plot of $I(V)$ data can give information about the ratio $\phi^{3/2}/\beta_g$, (but not about ϕ or β_g separately).

Because current is exponentially sensitive to changes in voltage, the large transconductance of FEAs and cold cathodes is of interest to vacuum electronics devices. Transconductance is the change in current with respect to voltage, or $g_m = \partial I/\partial V$. For Class A amplifiers, in which $I \propto V^n$ (n being of order unity) the transconductance does not vary greatly over a minimum to maximum voltage sweep (it is constant if $n = 1$). For space-charge limited thermionic emitters—where $n = 3/2$, or $I(V) = C\ V^{3/2}$, C being a constant of proportionality—g_m varies by only 41% when the maximum to minimum voltage ratio is 2. In contrast, for field emission, g_m is given by

$$g_m = \frac{(B_{FN} + 2V)}{V^2} I(V)$$

where

g_m = the transconductance in siemens

Transconductance for a field emission cathode therefore varies exponentially with inverse voltage. For a common Spindt-type 100-tip FEA‡ with A_{FN} = 1.535 mA/V^2 and B_{FN} = 544 V operated between V = 40 V and 80 V, the max/min ratios for current and transconductance are 1000 and 3600, respectively, and g_m is 12 μA/V-tip for I = 110 μA/tip. Increasing g_m/C, where C is capacitance, is sought for amplifier designs that seek to modulate the electron beam.§

Three other parameters individually or in combination bear on the utility of a field emission cathode for vacuum electronic devices. They are beam turn-off conditions, average-to-peak current ratio, and pulse repetition frequency (PRF). For an emitter characterized by A_{FN} and B_{FN}, the current minimum to maximum ratio x identifies what minimum voltage is required to ensure that an electron beam is turned off. It is given by the large-n limit of x_n, defined by the recursion relation

$$x_n = \frac{\eta}{\eta - \ln\left(\dfrac{\zeta}{x_{n-1}}\right)}$$

where

ζ = current minimum to maximum ratio (I_{min}/I_{max})
$\eta = B_{FN}$ to voltage maximum V_{max} ratio B_{FN}/V_{max}
x_n = voltage minimum to voltage maximum ratio V_{min}/V_{max} (nth iteration for $n \geq 1$)
$= (\eta + 2)/(\eta + 2 - \ln(\zeta))$ ($n = 0$)

The $n = 0$ term is adequate to within 10% for general parameters. If "beam turn-off" is defined as $\zeta = 0.001$, then for $\eta = 6.8$, $V_{min} = 54.4\%$ of V_{max} (i.e., $x = 0.544$); compare to space-charge limited thermionic emitters,

* Reference 33.
† Reference 34.
‡ Reference 35.
§ Reference 36.

for which the minimum voltage is 1% of the maximum. Devices requiring beam turn-off (e.g., radar) may benefit.*

Emission gating of the electron beam is required for a class of *rf* devices known as *Inductive Output Amplifiers*.† If the extraction grid or gate potential is sinusoidally modulated, then the average-to-peak current ratio is given by

$$\frac{I_{ave}}{I_{pk}} = \frac{\frac{1}{2\pi}\int_0^{2\pi} I_{FN}\left(V(\omega t)\right)d(\omega t)}{I_{pk}}$$

$$= e^{-z} I_0(z) + \frac{\left(B_{FN}+V_{pk}\right)V_{pk}}{\left(B_{FN}+V_{pk}\right)^2}\left\{\left[(2z+1)I_1(z) - 2zI_0(z)\right]ze^{-z}\right\}$$

where

ω = the angular frequency of modulation in rad/s
$V(\omega t) = V_{pk} - V_{rf}(1-\cos(\omega t))$, with V_{pk} and V_{rf} constant voltages representing maximum and amplitude of oscillation, respectively
$I_n(z)$ = hyperbolic Bessel function of order n
$z = (V_{rf}/V_{pk}^2)[B_{FN} + 2V_{pk}]$ and is dimensionless

For generic parameters $77.5\,V_{rf} = 6.8\,V_{pk} = B_{FN}$, then $z = 0.772$, and $I_{ave}/I_{pk} \approx 0.5$.

Protective Resistance

To limit the damage caused by exponential rises in current (associated with arcing events, which can destroy an emitter) and to increase uniformity and homogenize the current density across the cathode,‡ protective resistance elements are often incorporated. Resistive protection suppresses current runaway and limits damage by providing a voltage drop in proportion to the emitted current. The $I(V)$ equation is modified according to

$$I(V) = A_{FN}\left(V - I(V)R\right)^2 \exp\left(-\frac{B_{FN}}{V - I(V)R}\right)$$

where

R = resistance in ohms

which may be solved graphically. Alternatively, an iterative solution is obtained from $I(V) = (V/R)\,z/(1+z)$, where z is the $(n \to \infty)$ limit of z_n defined by

$$z_n = \frac{RI_0(V)}{V}\frac{\exp\left(-\frac{B_{FN}}{V}z_{n-1}\right)}{\left(1+z_{n-1}\right)}$$

where

$I_0(V)$ = current in the absence of resistance in amperes, or $A_{FN}V^2\exp(-B_{FN}/V)$
V = voltage drop from gate to ground in volts
z_n = the ratio of $(I(V)R)/(V - I(V)R)$ (nth iteration for $n \geq 1$)
$= (V I_0 R)/[B_{FN} I_0 R + V(V + I_0 R)]$ ($n = 0$)

When $I(V)R << V$, z_n rapidly converges, and so the $n = 0$ term is adequate. When $I(V)R \approx V$, convergence is slow.

Field Emission Displays

Flat panel cathodoluminescent displays utilizing pixel-size, addressed cathodes are available commercially. Most of these displays are called Field Emitter Displays (FEDs) because the cathodes are field emitter arrays. Monochrome grayscale displays with diagonal dimension of 5.2" are currently available,§ and larger color displays have been developed as prototypes. Similar displays using somewhat different kinds of cathodes are also under development. In addition to being flat, these displays can be very bright and energy efficient and appear similar to standard CRT displays.

FEDs are built by fabricating a "cathode plate" filled with field emitter arrays and placing it in close proximity to a printed phosphor screen similar to those used in cathode ray tube displays (see Fig. 10). The phosphor screen and the arrays are fabricated such that each phosphor pixel will be facing a separately gated array, which produces the electrons required for cathodoluminescence. The cathode and phosphor plates are manufactured separately, bonded together at the edges (typically using glass frit), and then evacuated. The emission from each cathode is modulated as needed to produce the desired visible light intensity at the adjacent pixel. The emission time or the emission intensity or both can be modulated to produce images with desired color and brightness. Because the field emitter arrays have a highly nonlinear current–voltage characteristic, individual arrays can be addressed when all the emitters in each row and all the gates in each column are connected together. Thus there is no need to fabricate transistors to address the pixels.

Each field emitter array contains many micron-scale field emitters and apertures. Ideally, all of the field emitters would have identical I–V curves. However, state-of-the-art fabrication techniques produce emitters that vary both in shape and in surface electronic characteristics. Thus some means of homogenizing the emission is required. Many more emitters are placed at each pixel than are required, to provide a statistical distribution. In addition, the emitters are fabricated on top of a resistive film, such that excessive emission current will produce a voltage across the film. Thus the potential appearing between the gate and emission site

§ PixTech Corporation (www.pixtech.com).

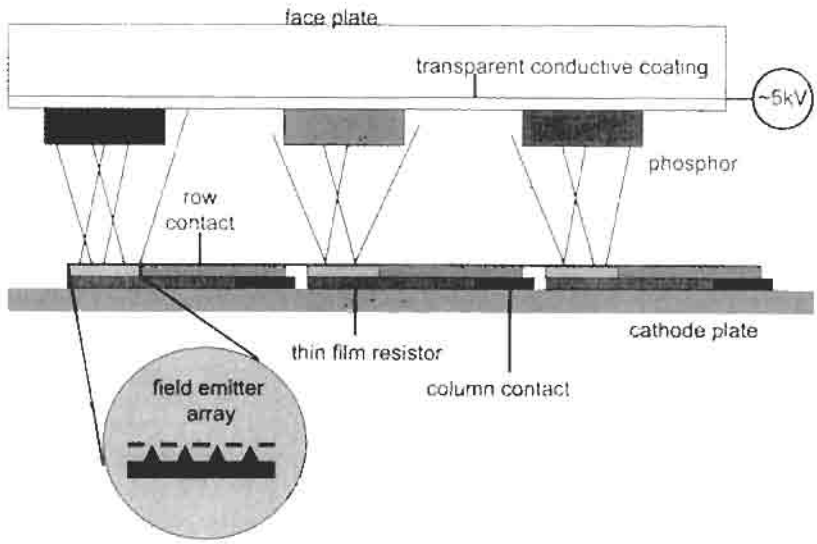

Fig. 10. Schematic diagram of a typical field emission display (FED). Individual pixels are addressed by applying positive and negative voltages to the corresponding row and column contacts. The resulting electrons strike the adjacent phosphor dots. Variations include use of a grid above the cathode plate (to partially focus the electrons), and various support structures between the cathode and face plate (not shown).

is less than the voltage applied between the row and column contacts. The emission characteristic becomes nearly linear and much more uniform from emitter to emitter as a result. Transistor structures can also be used in place of the thin-film resistors, producing saturated emission curves.

Since the thin glass plates are not mechanically strong enough to support atmospheric pressure over more than a few square inches, internal supporting structures are required. These supporting structures must not be visible to the viewer, and they must sustain the voltage applied between the cathode and phosphor plates. Slightly conductive materials can sustain high voltages more easily; however, larger currents dissipate precious power. Because the field emitter arrays emit electrons into a 20–30 degree angle, the distance between the cathode and phosphor plates must be kept small (~200 μm) to provide high resolution without crosstalk between adjacent pixels. The spacing can be increased by adding a grid to columate the beams. Typical color phosphors used in CRTs work best with electron energies large enough to penetrate several hundred nanometers inside the phosphor particle. As in CRTs, a thin layer of aluminum is often applied to the backside of the phosphor, and this requires additional electron energy to penetrate. These issues translate to phosphor plate potentials of at least 5 kV. Thus the requirements on the support structures are severe.

Significant pressures of reactive gases are typically present inside the displays. These gases can be evolved when electrons strike the phosphor plate. These gases can react at the emission sites, reducing the emission current. Electrons traveling through the oxide tend to break it down again, so that a kind of balance is struck between oxidation and electronic reduction. This process is poorly understood and depends on the type of phosphor as well as the emitter material.

Many of these issues could be resolved by using alternative emitter and phosphor technologies. For example, the emitter surfaces can be fabricated from less reactive materials. Some new phosphors can be excited at lower voltages and /or produce fewer reactive gases. Progress in these areas may produce improved FEDs in the future, provided that cost-effective production methods can be found.

Photocathodes

There is a renewed interest in photocathodes as electron sources for applications that require high current density and high brightness.* The primary focus of current research in photocathodes is the generation of high-brightness electron beams for either linear colliders or free electron lasers (FELs). Photocathodes are also of interest in high-power RF devices. Laser-driven photocathodes allow precise control over the electron peak current and the spatial and temporal profiles of the electron beam. Consequently, laser-driven photocathodes reduce the demands placed on beam structures and lead to a compact design.

Two types of materials have been used for photocathodes: metals and semiconductors. The primary advantages of metal photocathodes are fast response

* Reference 40.

time, tolerance to relatively poor vacuum (10^{-6} – 10^{-7} torr), and long lifetime (> 1 year). However, the main drawback is the low photoelectric yield, which is measured by the quantum efficiency (QE), i.e., the number of electrons produced per incident photon. The QE for metals is typically 10^{-5}–10^{-7}*. Semiconductor photocathodes, in contrast, have higher QE, with the highest QE being around 10^{-1}. However, they are extremely sensitive to contamination and require an ultra-high vacuum (UHV) of 10^{-9} to 10^{-10} torr. Even then, the lifetimes are short, namely 1 to 100 hours.† Research efforts are ongoing to improve both types of photocathodes.

The characteristics of metal and semiconductor photocathodes can be understood by examining the photoemission process. Similar to the secondary-electron-emission process discussed earlier, the photoemission process can be visualized as a three-step process: photoelectron generation, transmission of the electrons through the material, and emission of the electrons over the vacuum barrier. Photoelectron generation is a quantum process, i.e., the energy of the absorbed photon is converted completely into the energy of the photoexcited electron. Of course, to be emitted the photoexcited electrons need to have sufficient energy to overcome the vacuum barrier. As a result, in a metal photocathode, the photon energy must be equal to or greater than the work function of the metal to achieve a high QE. Because the metal work function is typically greater than 4 eV, UV lasers are required to drive a metal photocathode (where the wavelength of a 4-eV photon is 310 nm). Before the photoexcited electrons can be emitted, however, they need to traverse the material to reach the surface, and in the transport process they suffer energy loss from collisions with conduction electrons. Because conduction electrons are abundant in metals, the collisions are frequent and the mean free path of the photoexcited electrons is short, which limits the QE. However, the photoexcited electrons have to be generated near the emitting surface of the metal to retain sufficient energy to overcome the high vacuum barrier. Consequently, metal photocathodes offer a short delay in the photon-to-electron conversion, resulting in a fast response time and narrowly bunched beam.

In semiconductor photocathodes, the photon energy must be at least as large as the energy gap (~ 1–2 eV in commonly used semiconductors) to generate the photoexcited electrons. A long mean free path for the photo-excited electrons and a low or negative electron affinity are then required to achieve a high QE. The conduction electron population is relatively low in semiconductor materials, and hence low-energy electrons (with insufficient energy to excite valence electrons over the band gap) experience infrequent electron–electron collisions. This results in a relatively long mean free path for the low-energy electrons. Most of the high-QE semiconductor photocathodes are alkali-containing or cesiated semiconductors since the low or negative electron affinity of these materials allows the low-energy electrons that reach the surface to escape. However, adsorption of ambient gases often leads to an increase in the electron affinity, preventing many of the low-energy electrons from escaping. Because the contribution from low-energy electrons is essential to a high QE, the performance of semiconductor photocathodes is very sensitive to ambient gas adsorption.

The most promising metal photocathode materials have been Cu and Mg. They can be transported in air, are not sensitive to contaminants, and have lifetimes greater than a year. Various techniques have been used to improve the QE of metal photocathodes. High-power UV lasers are used to irradiate the sample to remove surface contamination, and the laser incident angle is near the Brewster's angle to confine the photons to the surface region. The electric field of the laser is oriented in the plane of incidence, and a high field is used to lower the work function by the Schottky effect. Recently, alkali ion implantations have also been used to reduce the work function. Among metal photocathodes, the highest QE obtained with a 266-nm (4.66 eV) laser beam has been 4×10^{-3} for a Mg photocathode, whereas the QE for Cu is 5×10^{-4}.‡

Alkali-based semiconductor cathodes, such as Na_2KSb:Cs and K_2CsSb, have been used in photomultipliers. However, their sensitivity to contaminants prevents their wide use as photocathodes. Cs_3Sb, Cs_2Te, and GaAs:Cs are some of the materials that have been investigated as photocathodes. For potential application as high-brightness, high-current-density cathodes for induction LINAC FELs, various types of cathodes have been evaluated, including *M*-type dispenser and LaB_6 thermionic cathodes, graphite cathodes, velvet cathodes, and Cs_3Sb photocathodes. Although the highest brightness has been observed from some Cs_3Sb photocathodes,§ Cs_3Sb requires a vacuum of 10^{-10} torr and the lifetime is only tens of hours. Another material evaluated as a photocathode is Cs_2Te, which is typically fabricated in situ in a UHV system. Freshly prepared Cs_2Te samples grown on Cu and Mo substrates were shown to yield a QE of 6×10^{-2}–1.2×10^{-1} and 1.6×10^{-1} using photons of 4.66 eV (266 nm) and 4.94 eV (251 nm), respectively. However, the QE decreased roughly exponentially with a decay time of about 100 hours." A very high QE (~1.4×10^{-1}) has been achieved from GaAs:Cs photocathodes with 2.55 eV (486 nm) photons. Typically, these cathodes have been used to generate polarized electrons, but recently there has been interest in using them as photocathodes in RF cavities. With the advent of GaAs:Cs photocath-

odes, it may be possible to generate electron bunches with visible photons instead of UV photons in the foreseeable future.

ELECTRODE DISSIPATION

After the electron stream has given up the useful component of its energy, the remainder is dissipated as heat in some suitable part of the tube. Five processes are commonly used to remove this heat. The amount that can be removed depends on the area available, the temperature differential, and, in the cases of forced cooling, the coolant flow.

In computing cooling-medium flow, a minimum velocity sufficient to assure turbulent flow at the dissipating surface must be maintained. The figures for specific dissipation (Table 2) apply to clean cooling surfaces and may be reduced to a small fraction of the values shown by heat-insulating coatings such as scale or dust.

Radiation Cooling

In a radiation-cooled system, that portion of the tube on which the heat is dissipated is allowed to reach a temperature such that the heat is radiated to the surroundings. The amount of heat that can be removed in this manner is given by the equation

$$P = \varepsilon_t \sigma \left(T^4 - T_o^4\right)$$

where

P = radiated power in W/cm^2
ϵ_t = total thermal emissivity of the surface
σ = Stefan–Boltzmann constant = 5.67×10^{-12} W cm^{-2} K^{-4}
T = temperature of radiating surface in kelvins
T_o = temperature of surroundings in kelvins

Total thermal emissivity varies with the degree of roughness of the surface of the material and the temperature. Values for typical surfaces are listed in Table 3.

TABLE 3. TOTAL THERMAL EMISSIVITY ϵ_t OF ELECTRON-TUBE MATERIALS

Material	Temperature (K)	Thermal Emissivity
Aluminum	450	0.1
Anode graphite	1000	0.9
Copper	300	0.07
Molybdenum	1300	0.13
Molybdenum, quartz-blasted	1300	0.5
Nickel	600	0.09
Tantalum	1400	0.18
Tungsten	2600	0.30

Water Cooling

For water cooling, the water is circulated through a suitably designed structure. The amount of heat that can be removed by this process is given by

$$P = 264 Q_w (T_2 - T_1)$$

where

P = power in watts
Q_w = flow in gallons per minute
T_2, T_1 = outlet and inlet water temperatures, respectively, in kelvins

This same relationship is given in the nomogram of Fig. 11 with the temperature rise in degrees Fahrenheit or Celsius and the power in kilowatts.

Forced-Air Cooling

With forced-air cooling, a stream of air is forced past a suitable radiator. The heat that can be removed by this process is given by

$$P = 169 Q_A [(T_2/T_1) - 1]$$

TABLE 2. TYPICAL OPERATING DATA FOR COMMON TYPES OF COOLING

Type	Average Cooling Surface Temperature (°C)	Specific Dissipation of Cooling Surface (W/cm^2)	Cooling-Medium Supply
Radiation	400–1000	4–10	
Water	30–150	30–110	0.25–0.5 gallon/minute/kilowatt
Forced air	150–200	0.5–1	50–150 ft^3/minute/kilowatt
Evaporative	100–120	80–125	Water-, air-, or convection-cooled condenser. A water-cooled condenser would require 0.07–0.1 gallon/minute/kilowatt.
Conduction	100–250	5–30	Heat sink operating at 50–100°C

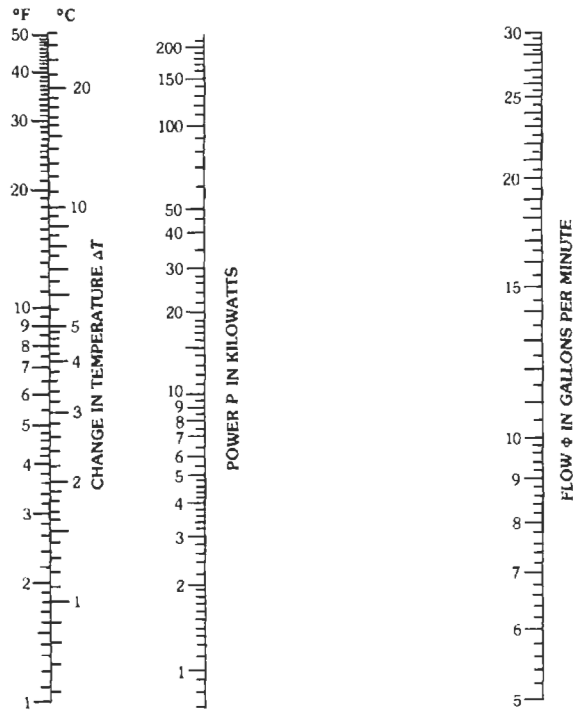

Fig. 11. Heat transfer in cooling water. $P = 0.1466\phi\Delta T$, for T in Fahrenheit. (*Courtesy Clyde G. Haehnle.*)

where

Q_A = air flow in ft^3/minute

Evaporative Cooling

A typical evaporative-cooled system consists of a tube with a specially designed anode immersed in a boiler containing distilled water. When power is dissipated on the anode, the water boils and the steam is conducted upward through an insulating pipe to a condenser. The condensate is then gravity fed back to the boiler, thus eliminating the pump required in a circulating water system.

For some transmitter applications, the steam is directed downward to leave the space above the tube available for other components. Such a system requires a pump to return the condensate to the boiler, but even then the pump has to handle only about 0.05 of the amount of water required for a water-cooled system because of the exploitation of the latent heat of steam.

The size of the heat-exchanger equipment for an evaporative-cooled system is less than one-third of that required for a water-cooled system because of the greater mean temperature differential between the cooled liquid and the secondary coolant. Typical temperature differentials for the two systems are 75°C and 30°C, respectively.

The anode dissipation should not exceed 135 watts per square centimeter of external anode surface because at this point, often referred to as the "Leidenfrost" or "calefaction" point, the surface becomes completely covered with a sheath of vapor, and the thermal conductivity between the anode and the cooling liquid drops to 30 watts per square centimeter, with resultant overheating of the anode. Special designs of the external anode surface (such as the "pineapple") allow up to 500 watts to be dissipated per square centimeter of internal anode surface.

Conduction Cooling

When an external heat sink is available, heat may be removed from the tube by conduction. Since the electrode where the heat appears is usually at an elevated potential, it is often necessary to conduct the heat through an electrical insulator.

Because of its relatively high thermal conductivity, beryllia ceramic can be used as a common insulator and thermal conductor between the anode of a tube and a heat sink. Beryllia has the following properties:

Breakdown strength = 10 kV/mm
Dielectric constant = 6–8
Thermal conductivity = 2.62 W/cm/°C at 20°C, 1.75 W/cm/°C at 200°C
Dielectric loss factor = 4×10^{-5}

Tensile strength = 18 000 lbs/square inch
Compressive strength = 150 000 lbs/square inch

The temperature drop in degrees Celsius across the beryllia ceramic is given by

$$t_1 - t_2 = dW_a/KA \text{ (for a parallel configuration)}$$

where

t_1 = temperature of tube anode (typical maximum 250°C)
t_2 = temperature of heat sink (typically 100°C)
d = thickness of beryllia in cm
A = cross-sectional area of beryllia perpendicular to direction of heat flow
K = thermal conductivity of beryllia in W/cm/°C
W_a = power dissipated on anode in watts

To the temperature drop across the beryllia ceramic must be added the temperature drop across the interfaces between the ceramic and the anode and heat sink, typically 20°C for clamped surfaces at a loading of 25 W/cm ^{2}.

Because of its toxic nature, care must be taken in handling and disposal of beryllia ceramic.

Grid Temperature

Operation of grids at excessive temperatures will result in one or more harmful effects: liberation of gas, high primary (thermal) emission, contamination of the other electrodes by deposition of grid material, and melting of the grid. Grid-current ratings should not be exceeded, even for short periods.

NOISE IN TUBES

There are several sources of noise in electron tubes,* some of which are associated with the nature of electron emission and some of which are caused by other effects in the tube.

Shot Effect

The electric current emitted from a cathode consists of a large number of electrons and consequently exhibits fluctuations that produce tube noise and set a limit to the minimum signal that can be amplified. The root-mean-square value of the fluctuating (noise) component of the plate current I_n is given in amperes by

$$I_n^2 = 2eI\Gamma^2\Delta f$$

where

I = plate direct current in amperes
e = electron charge = 1.6×10^{-19} coulomb
Δf = bandwidth in hertz
Γ^2 = space-charge reduction or smoothing factor

For temperature-limited cases, $\Gamma^2 = 1$. For space-charge-controlled regions

$$\Gamma^2 = 2kT_c g\theta / \sigma eI$$

where

k = Boltzmann's constant = 1.380×10^{-23} joule/kelvin
T_c = cathode temperature in kelvins
g = conductance or transconductance in mhos, which relates the output signal current to the input signal voltage†
θ = a factor that in most practical cases is nearly equal to its asymptotic value of $3[1 - (\pi/4)] = 0.644$
σ = a tube parameter, related to the amplification factor and electrode spacings, that has a value of unity for diodes and varies between 0.5 and 1.0 for negative-grid tubes

Partition Noise

Excess noise appears in multicollector tubes because of fluctuations in the division of the current between the different electrodes. In a grid-controlled tube, these fluctuations in current division reduce the effectiveness of the space-charge smoothing of the shot noise in the plate current. For a screen-grid tube, the root-mean-square noise currents in the cathode lead, the screen-grid lead, and the plate lead (I_{nk}, I_{nc2}, and I_n, respectively) are given by

$$I_{nk}^2 = 2eI_k\Gamma^2\Delta f$$

$$I_{nc2}^2 = 2eI_{c2}\left[\left(\Gamma^2 I_{c2} + I\right)/I_k\right]\Delta f$$

$$I_n^2 = 2eI\left[\left(\Gamma^2 I + I_{c2}\right)/I_k\right]\Delta f$$

where I_k and I_{c2} are the cathode and screen-grid currents, respectively.

Flicker Effect

The mechanism involved in the flicker effect is not completely understood but appears to depend on the field distribution in the surface layer of the cathode

* S. Goldman, *Frequency Analysis, Modulation and Noise* (New York: Dover Publications, 1967). A. van der Ziel, *Noise* (Englewood Cliffs, NJ: Prentice-Hall, 1954). L. D. Smullin and H. A. Haus, eds., *Noise in Electron Devices* (The Technology Press of Massachusetts Institute of Technology and John Wiley & Sons, New York, 1959). D. H. Bell, *Electron Noise* (London: D. Van Nostrand Co., 1960). W. R. Bennett, *Electrical Noise* (New York: McGraw-Hill Book Co., 1960). D. K. C. MacDonald, *Noise and Fluctuations: An Introduction* (New York: John Wiley & Sons, 1962).

† For diodes, g is the conductance; for triode and pentode amplifiers, g is the transconductance g_m; and for triode or pentode mixers and converters, g is the conversion conductance g_c.

resulting from its porous structure. Because this same field distribution also will influence the cathode activity and temperature, flicker noise will depend on cathode activity and temperature in a complicated manner.

The flicker noise spectrum is usually of the form f^{-a} with a close to unity and thus is important only at low frequencies. The sensitivity of audio, subaudio, and direct-current amplifiers is limited by the flicker noise generated in the first tube.

Collision Ionization

Free gas ions can be generated by collisions with the electron stream. The electrons thus liberated and collected by the anode will appear as noise in the anode circuit. The ions that travel to the cathode will travel slowly through the potential minimum and reduce the space charge, which in turn will reduce the space-charge smoothing effect. This also will increase the noise in the anode circuit.

Induced Noise

At high frequencies it is not necessary for electrons to reach an electrode for induced current to flow in the electrode leads. This noise is an important consideration in miniature tubes above 15 megahertz and becomes the principal limiting factor in low-noise amplifier design above about 100 megahertz. For microwave tubes, this is the dominant method by which beam noise is coupled to the output circuit.

Miscellaneous Noise

Other noise may be present as the result of microphonics, hum, leakage, charges on insulators, poor contacts, and secondary emission.

Microwave Tubes

The noise appearing in the output circuit of a microwave tube is due in part to induced noise from the beam. Also, some of the electrons may be intercepted by the radio-frequency structure (microwave cavity, slow-wave circuit, etc.) giving rise to partition noise. In well-designed low-noise tubes, however, the latter effect is kept negligibly small.

For lossless linear beam tubes (traveling-wave amplifiers, klystron amplifiers, backward-wave amplifiers), the minimum obtainable noise figure F_{min} for one-dimensional single-velocity small-signal theory and high gain has been found to be given by

$$F_{min} = 1 + (2\pi / kT_0)(S - \pi)$$

where $S - \pi$ is the basic noise parameter and is established in the region of the potential minimum of the beam. If certain assumptions concerning the potential minimum are made, such as full shot noise and uncorrelated current and velocity fluctuations,* then values for S and π can be obtained. They are given as

$$\pi = 0$$

$$S = \left[1 - (\pi/4)\right]^{1/2} (kT_c/\pi)$$

Therefore

$$F_{min} = 1 + (4 - \pi)^{1/2} (T_c / T_0)$$

For $T_c/T_0 = 4$, $F_{min} = 4$. The assumptions made are not entirely valid, as shown by the fact that noise figures of less than 4 have been obtained experimentally. At the present time values of S and π/S are obtained by measurement.

LOW-, MEDIUM-, AND HIGH-FREQUENCY TUBES

This section applies particularly to triodes and multigrid tubes operated at frequencies where electron-inertia effects are negligible. Traditionally, the vacuum envelope of such tubes has been of glass with metal, usually copper, for the anode in larger sizes. In recent years, the trend has been toward using ceramic in place of glass for the external insulating portions of such tubes. Fig. 12 shows a typical construction of a medium-power transmitting tube.

Ceramic-envelope tubes have the following advantage over glass tubes.

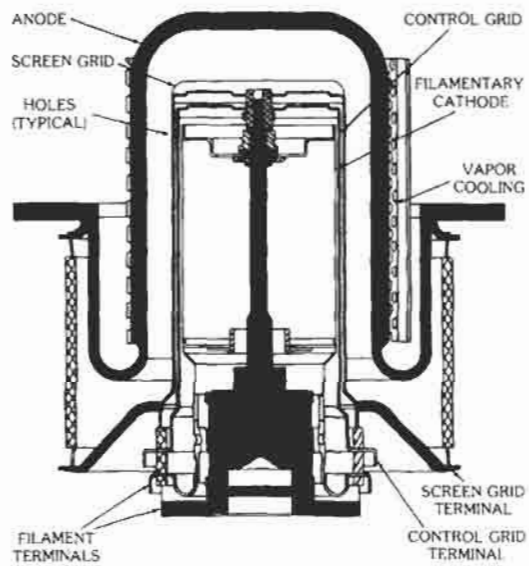

Fig. 12. Typical medium-power transmitting tube.

* J. R. Pierce, "A theorem concerning noise in electron streams," *Journal of Applied Physics*, vol. 25, p. 931, 1954.

(A) The radio-frequency loss P_{rf} in the seals of a tube is given by

$$P_{rf} = Kf^{5/2}R^{1/2}/\mu^{1/2}$$

where

K = constant
f = frequency
R = resistivity of the conducting material
μ = permeability of the conducting material.

In glass-to-metal seals, the metal is normally of a magnetic material such as Kovar. As Kovar has high resistivity and permeability, the radio-frequency losses at the seals are therefore high, and at high frequencies cracking and/or glass suck-in near the seals can result. With ceramic-to-metal seals, this problem is minimized because the radio-frequency circulating currents at the seals flow through the metallizing and plating on the ceramic. The resistivity is low, and the permeability is unity.

(B) Ceramics have a lower dielectric loss than glass. Furthermore, the loss factor of glass rapidly rises with temperature. This leads to a "runaway" condition, glass suck-in, and hence severe limitation of maximum frequency of operation of glass tubes.

(C) The safe operating temperature of a ceramic-to-metal seal may be between 220 and 250°C as against 180°C for Kovar-glass seals.

(D) The high bakeout temperature of ceramic-envelope tubes during evacuation increases reliability and life.

(E) Ceramic tubes withstand higher thermal and mechanical shocks than those with glass envelopes. They can also be manufactured to closer dimensional tolerances.

Coefficients

Amplification factor μ: Ratio of incremental plate voltage to control-electrode voltage change at a fixed plate current with constant voltage on other electrodes.

$$\mu = \left[\frac{\delta e_b}{\delta e_{c1}}\right]_{i_b=0} \quad I_b, E_{c2}, \ldots, E_{cn} \text{ constant}$$

Transconductance s_m: Ratio of incremental plate current to control-electrode voltage change at constant voltage on other electrodes.

$$s_m = \left[\frac{\delta i_b}{\delta e_{c1}}\right]_{i_b=0} \quad E_b, E_{c2}, \ldots, E_{cn} \text{ constant}$$

When electrodes are plate and control grid, the ratio is the mutual conductance g_m.

$$g_m = \mu/r_p$$

Variational (ac) plate resistance r_p: Ratio of incremental plate voltage to current change at constant voltage on other electrodes.

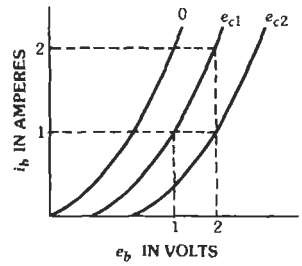
$$r_p = \left[\frac{\delta e_b}{\delta i_b}\right]_{i_b=0} \quad E_{c1}, \ldots, E_{cn} \text{ constant}$$

Total (dc) plate resistance R_p: Ratio of total plate voltage to current for constant voltage on other electrodes.

$$R_p = \left[\frac{E_b}{I_b}\right]_{i_b=0} \quad E_{c1}, \ldots, E_{cn} \text{ constant}$$

A useful approximation of these coefficients may be obtained from a family of anode characteristics, Fig. 13. Relationships between the actual geometry of a tube and its coefficients are given roughly in Table 4.

When the operating frequency is increased, the operation of triodes and multigrid tubes is affected by electron-inertia effects. The design features that distinguish the high-frequency tube shown in Fig. 15 from the lower-frequency tube (Fig. 12) are: reduced cathode-to-grid and grid-to-anode spacings, high emission density, high power density, small active and inactive capacitances, heavy terminals, short support leads, and adaptability to a cavity circuit.



Amplification factor $\mu = (e_{b2} - e_{b1})/(e_{c2} - e_{c1})$
Mutual conductance $g_m = (i_{b2} - i_{b1})/(e_{c2} - e_{c1})$
Total plate resistance $R_p = e_{b2}/i_{b2}$
Variational plate resistance $r_p = (e_{b2} - e_b)/(i_{b2} - i_{b1})$

TABLE 4. TUBE CHARACTERISTICS FOR UNIPOTENTIAL CATHODE AND NEGLIGIBLE SATURATION OF CATHODE

Function	Parallel-Plane Cathode and Anode	Cylindrical Cathode and Anode
Diode anode current (amperes)	$G_1 e_b^{3/2}$	$G_1 e_b^{3/2}$
Triode anode current (amperes)	$G_2[(e_b + \mu e_c)/(1 + \mu)]^{3/2}$	$G_2[(e_b + \mu e_c)/(1 + \mu)]^{3/2}$
Diode perveance G_1	$2.3 \times 10^{-6}(A_b/d_b^2)$	$2.3 \times 10^{-6}(A_b/\beta^2 r_b^2)$
Triode perveance G_2	$2.3 \times 10^{-6}(A_b/d_b d_c)$	$2.3 \times 10^{-6}(A_b/\beta^2 r_b r_c)$
Amplification factor μ	$2.7 d_c[(d_b/d_c) - 1]/\rho \log(\rho/2\pi r_g)]$	$(2\pi d_c/\rho)[\log(d_b/d_c)/\log(\rho/2\pi r_g)]$
Mutual conductance g_m	$1.5 G_2 \mu/(\mu + 1)](E'_g)^{1/2}$	$1.5 G_2[\mu/(\mu + 1)](E'_g)^{1/2}$
	$E'_g = (E_b + \mu E_c)/(1 + \mu)$	$E'_g = (E_b + \mu E_c)/(1 + \mu)$

A_b = effective anode area in square centimeters; d_b = anode–cathode distance in centimeters; d_c = grid–cathode distance in centimeters; β = geometric constant (a function of the ratio of anode-to-cathode radius), $\beta^2 \approx 1$ for $r_b/r_k > 10$ (Fig. 14); ρ = pitch of grid wires in centimeters; r_g = grid-wire radius in centimeters; r_b = anode radius in centimeters; r_k = cathode radius in centimeters; r_c = grid radius in centimeters.

Note:

These equations are based on theoretical considerations and do not provide accurate results for practical structures; however, they give a fair idea of the relationship between the tube geometry and the constants of the tube.

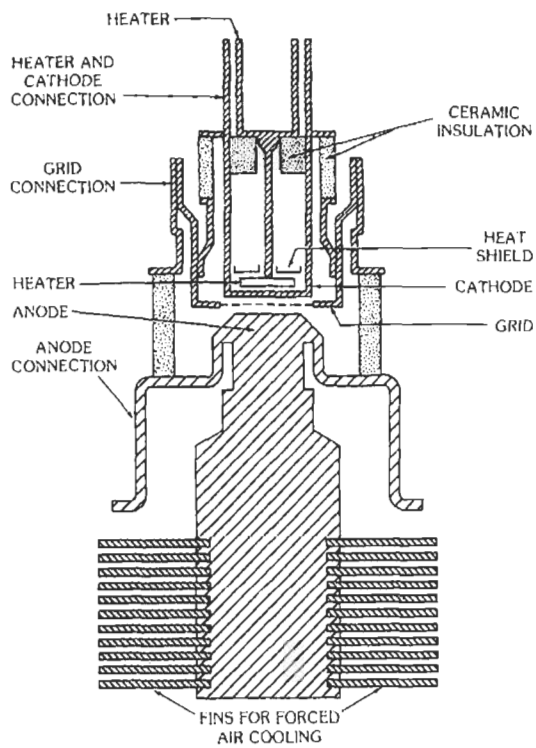

Fig. 15. Electrode arrangement of a small high-frequency external-anode triode.

MATERIALS AND STRUCTURES

Cathodes

Early cathodes were all directly heated, that is, the filament, which was heated by passing a current through it, was also the cathode. The filaments were made of mostly tungsten (W) or thoriated W (i.e., W mixed with a small percentage of thoria). Thoriated W cathodes are still commonly used in high-power switch tubes, transmitter tubes, and microwave magnetrons at operating temperatures of 1600–1900°C.

In a directly heated cathode, the heating current causes a voltage drop along the current path and across the surface. Most applications require *indirectly* heated cathodes so that the surface of the cathode is at a constant potential. Oxide-coated cathodes and dispenser-type cathodes use mostly indirect heaters, with the heater filament made of W. A potted heater, shown in Fig. 16, uses alumina (Al_2O_3) potting material to fill the space in the cavity that contains the heater, whereas a nonpotted heater has alumina coating on the surface of the heater filament only. A potted heater maintains good thermal contact with the cathode body and provides uniform heating across the cathode. A nonpotted heater has a low heat capacity and is suitable for applications that require fast warm-up. In addition, nonpotted heaters cost much less than potted heaters.

The emitting surfaces of oxide-coated cathodes are initially made of Ba, Ca, and Sr carbonates, which are converted thermally to respective oxides before electron emission can occur. The conversion occurs around 800°C and the operating temperatures are 750–800°C. The emitting surfaces of dispenser-type cathodes are made of pressed tungsten powder impregnated with BaO, CaO, and Al_2O_3. The surfaces of *M*-type dispenser cathodes are coated with ~5000 Å of noble metal, most commonly an Os/Ru mixture. The operating temperatures of dispenser-type cathodes are typically 900–1250°C.

Grids

Grids are conductors, semitransparent to electrons, usually in the form of meshes or parallel bars. Their

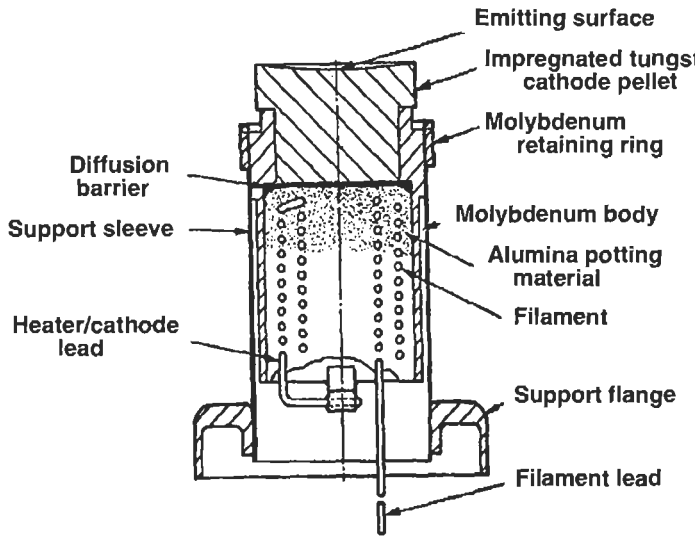

Fig. 16. Cross-sectional view of a typical cathode and heater assembly. The materials used are indicated by the labels in the figure. (From A. S. Gilmour, Jr., *Microwave Tubes*, Norwood, MA: Artech House, Inc., 1986, p. 126, fig. 5.20.

function is to control or accelerate electrons by establishing appropriate electric fields. An ideal grid would intercept no electrons; in practice, interception is minimized by careful design but still occurs, causing heating that usually sets the upper limit to power output of the tube.

In tubes with oxide cathodes, grids may be tungsten or molybdenum wire structures, coated with gold to reduce primary emission caused by deposition of material evaporated from the cathode during operation. In tubes with thoriated tungsten cathodes, grids may be made of tungsten or molybdenum coated with proprietary compounds to reduce primary emission. Relatively recently, pyrolytic graphite has been found to be an excellent grid material because of its combination of good thermal and mechanical properties and its low primary and secondary emission.* Grids made of this material behave elastically up to very high temperatures and as a result are more dimensionally stable than refractory metal wire grids. This material is anisotropic, is formed by chemical vapor deposition at high temperature (2000°C or higher), and should not be confused with ordinary graphite, which is isotropic.

Anodes

Anodes are usually made of copper, cooled by air or water. Some glass-envelope tubes have molybdenum internal anodes. Carbon has been used. Insulating structures inside the vacuum envelope are usually high-purity aluminum oxide or beryllium oxide. Conductors are molybdenum, tungsten, nickel, Kovar, cupro-nickel, Hastalloy, or copper.

Getters

Getters are used to maintain a high vacuum during the life of the tube. They are so called because they "get" or trap and hold gases that may evolve. Typical materials are zirconium, cerium, barium, and titanium.

Tube Geometry

Gridded tubes at all power levels for frequencies up to about 1 GHz are invariably cylindrical in form. The tetrode in Fig. 12 is a typical example. The anode is vapor cooled by means of a wire mesh, or "wick," held in contact with the anode. This is a substitute for the knobs or fins usually found on vapor-cooled anodes and is satisfactory at medium power density. At higher frequencies, the "planar" triode structure is almost universal. An example is shown in Fig. 15.

The number of electrodes is usually three (triode) or four (tetrode) and rarely five (pentode). That is, the number of grids may be one, two, or three. An unusual hybrid tube invented in 1939 by Haeff†‡ and recently rediscovered and improved has been named Klystrode TM. Its geometry is part triode, part klystron. Its performance is described in Chapter 17, which covers the

performance of tubes and some typical associated circuits.

MICROWAVE TUBES*

The reduced performance of space-charge control tubes in the microwave region has fostered the development of other types of tubes for use as oscillators and amplifiers at microwave frequencies. Such tubes generally function on the basis of the modulation of the velocity of an electron stream rather than of its density. They may be roughly divided simply into linear-beam devices and crossed-field devices. In the former, the electron stream flows essentially linearly, often with a collimating magnetic field to counteract space-charge spreading; in the latter, the electron stream follows a curved path under the action of orthogonal electric and magnetic fields. The linear-beam devices are often referred to as *O*-type, while the crossed-field devices are referred to as *M*-type.

Terminology

Bunching: Any process that introduces a radio-frequency conduction-current component into a velocity-modulated electron stream as a direct result of the variation in electron transit time that the velocity modulation produces.

Cavity resonator: Any region bounded by conducting walls within which resonant electromagnetic fields may be excited.

Circuit efficiency: The ratio of (A) the power of the desired frequency delivered to the output terminals of the circuit of an oscillator or amplifier to (B) the power of the desired frequency delivered by the electron stream to the circuit.

Coherent-pulse operation: Method of pulse operation in which the phase of the radio-frequency wave is maintained through successive pulses.

Drift space: In an electron tube, a region substantially free of externally applied alternating fields in which a relative repositioning of the electrons is determined by their velocity distributions and the space-charge forces.

Duty cycle: The product of the pulse duration and the pulse repetition rate. It is also the ratio of the average power output to the peak power output.

External Q: The reciprocal of the difference between the reciprocals of the loaded Q and the unloaded Q.

Frequency pulling of an oscillator: The change in the generated frequency caused by a change of the load impedance.

Frequency pushing of an oscillator: The change in frequency caused by a change in anode current (or in anode voltage).

Loaded Q of a specific mode of resonance of a system: The Q when there is external coupling to that mode. Note: When the system is connected to the load by means of a transmission line, the loaded Q is customarily determined when the line is terminated in its characteristic impedance.

Mode: One of the components of a general configuration of a vibrating system. A mode is characterized by a particular geometric pattern of the electromagnetic field and a resonant frequency (or propagation constant).

Noise Figure: The ratio in decibels of the total available output noise from an amplifier to the available noise that would be present at the output if the amplifier itself were noiseless, assuming a source temperature of 290 K.

Perveance: The ratio of electron beam current to the 3/2 power of the beam voltage ($IV^{-3/2}$), which is an invariant for a particular electron-gun design.

Pulling figure of an oscillator: The difference in megahertz between the maximum and minimum frequencies of oscillation obtained when the phase angle of the load-impedance reflection coefficient varies through 360 degrees, while the absolute value of this coefficient is constant and is normally equal to 0.20.

Pulse: Momentary flow of energy of such short time duration that it may be considered as an isolated phenomenon.

Pushing figure of an oscillator: The rate of frequency pushing in megahertz per ampere or megahertz per volt.

Q: The Q of a specific mode of resonance of a system is 2π times the ratio of the stored electromagnetic energy to the energy dissipated per cycle when the system is excited in this mode.

Reflector: Electrode whose primary function is to reverse the direction of an electron stream. It is also called a *repeller.*

Reflex bunching: Type of bunching that occurs when the velocity-modulated electron stream is made to reverse its direction by means of an opposing direct-current field.

Slow-wave structure: A microwave circuit, as used in beam-type microwave tubes, capable of propa-

gating radio-frequency waves with phase velocities appreciably less than the velocity of light.

Recent Trends

Dramatic progress in device performance and capability has been achieved in the 1980s and 1990s. These advances can be credited to a combination of device innovation, enhanced understanding gained through improved modeling and design, introduction of superior materials and subassembly components, and development of advanced vacuum processing and construction techniques. The most familiar types of microwave power tube, invented in the decade spanning the mid-1930s and 1940s, may be broadly classified as "slow-wave" devices. This description as being slow-wave emphasizes the fundamental requirement in these devices that the phase velocity of the electromagnetic wave on the interaction circuit must be approximately equal to the velocity of the electron stream if energy transfer between the beam and the wave is to occur. The electron velocity is less than the speed of light and hence the wave phase velocity must also be slower than the speed of light in free space. From the richness of device concepts investigated through the 1960s, the helix and coupled cavity traveling-wave tubes (TWTs), the klystron, magnetron, and crossed field amplifier (CFA) have emerged as the primary products of today's technology. The continuing vitality of this relatively mature segment of the technology is demonstrated by the recent development of a hybrid amplifier architecture, the microwave power module (MPM), that combines the best features of solid-state and vacuum technologies. This hybrid approach yields a cost-competitive amplifier that offers the power, efficiency, and bandwidth of a TWT with the reduced noise and functionality of a solid-state amplifier with either discrete or monolithic components. Most significantly, this performance is obtained in a miniaturized package that can be a small fraction of the size of a comparable TWT amplifier (TWTA) or an all solid-state power amplifier (SSPA).

The most dramatic of the modern trends, however, is the extension of device operation into the spectral range well beyond the microwave. Beginning in the mid-1960s, two new classes of powerful "fast-wave" device, the gyro-oscillator/amplifier and the free electron laser (FEL), have experienced ongoing development. In fast-wave devices, the phase velocity of the electromagnetic wave exceeds the speed of light in the interaction region. Although the physical interaction mechanism is not the same, gyro-devices are technologically very similar to other microwave power tubes. They differ primarily by their intrinsic need for magnetic field strengths typically available only from superconducting magnets. In recent years, gyro-oscillators have produced output powers approaching a megawatt in the frequency range of 100–200 GHz with the pulse duration nearing a second. In the guise of the ubitron, free electron masers are much akin to their slow-wave cousins. By using electrons at relativistic energies, the operational domain of the FEL is extended to much shorter wavelength. For this extension, a high-energy electron accelerator replaces the electron gun and optical cavities replace the interaction circuits of the microwave power tube. Free electron lasers are now generating usable levels of tunable power at submillimeter wavelengths and in the infrared and promise to provide high-power, continuously tunable coherent sources over a spectral range extending into the ultraviolet and eventually to x rays.

For very general comparison of device limits, the average power density, $P_{av}f^2$, in units of $(MW)(GHz)^2$, has been used as a figure of merit providing an insightful basis for comparing device types and portraying growth trends in performance. The physical significance of $P_{av}f^2$ as a figure of merit derives from the fact that the maximum beam or charge-carrier power that can be transported through a device is proportional to the circuit cross-sectional area, which is inversely proportional to the operating frequency. Upper limits in "power density" were therefore considered as intrinsic to a device design. With this in mind, the progression of power density for major device types is plotted in Fig. 17. In general, the power density profile for each device type exhibits the characteristic S-shaped curve associated with technological maturity. The slow progress typical of a period of innovation and preliminary study is followed by the rapid growth associated with intense development. As the fundamental limits of a particular device are approached, progress becomes more difficult and the curve flattens. Escape from the limits imposed by a particular device concept requires finding a better approach. Following this argument, we conclude that the vitality of a technology is measured by its ability to provide research opportunities leading to the next step.

As seen by the sustained growth in achieved power density, RF vacuum electronics continue to provide such opportunity. The history of RF vacuum electronics can be viewed as successive waves of scientific innovation driven by technical opportunity coupled with market demand. First, the gridded tube is overtaken by the magnetron under the impetus of wartime demands. Then, the high-power linear-beam tubes, the klystron and the coupled cavity TWT, move to the fore in response to accelerator and radar interests. Finally, the gyro-oscillator and the FEL surpass slow-wave devices in the mid-1970s. With these transitions, the envelope of vacuum device performance, as defined by the straight line in Fig. 17, continues to grow exponentially at an approximate rate of one-and-a-half orders of magnitude per decade, a rate sustained for the past 60 years. In contrast to the fast-wave devices, the figures of merit for the slow-wave devices have grown very little since the mid-1960s.

One significant exception to limited growth with slow-wave devices is the periodic-permanent-magnet-(PPM-) focused helix TWT, whose pace of growth

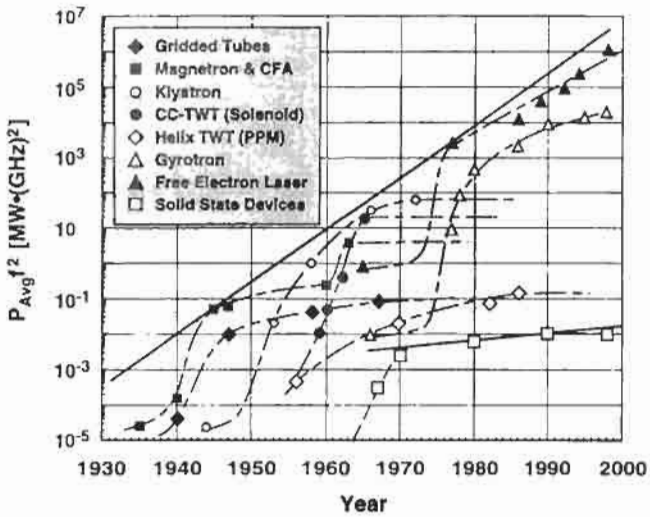

Fig. 17. Progression of device power density, $P_{av}f^2$, for major device types.

continues but at a somewhat diminished rate. This continued growth of the PPM-focused TWT is not surprising given its dominance in the marketplace. As measured in terms of the basic parameters of information theory, the capabilities of the conventional TWT are extraordinary. The TWT is a key building block in the rapidly expanding telecommunication systems and retains a major role in satellite-based transmitters. With their increasing demand for bandwidth, military radar, electronic countermeasures, and communication data links depend heavily on TWTs. In a package weighing less than a pound, the modern TWT provides average powers from tens to hundreds of watts combined with a gain of ~60 dB and an instantaneous bandwidth of well over an octave. The basic distortion parameters can satisfy the most exacting requirements and the overall efficiency can be as high as 70%. Moreover, the demonstrated mean lifetime of TWTs in the most demanding environment of space exceeds 15 years (> 130 000 hrs).

In general, the character of the research and developmental effort associated with fast- and slow-wave devices is commensurate with the relative state of maturity (as defined within the context of power density limits) and the market served. Fast-wave efforts retain a strong research flavor while having become progressively more developmental since the mid-1980s. The areas of application (thermonuclear plasma heating; high-power, millimeter-wave radar; RF drivers for high-energy particle accelerators; and biological, chemical, and medical research in the submillimeter and IR) served by fast-wave devices still require higher power performance at high frequency. Hence, market pull and technological opportunity coalesce to sustain the pursuit of power at high frequency with fast-wave devices.

In contrast, the development of conventional microwave power tubes is strongly driven by the market. Most current military, commercial, and scientific applications do not require simply power, but rather some combination of more bandwidth, efficiency, and linearity or lower noise and intermodulation. As new systems become more complex and expensive, the components must become smaller and lighter as well as more reliable. These demands have increased the importance of technology in determining the opportunity for advance. Revolutionary change has given way to iterative improvement. Although these steps may be evolutionary, the impact can be dramatic and important advances continue to be achieved within this broader view of performance. The current capabilities of the major device types is given in Fig. 18 in terms of average power with frequency.

Linear-Beam Tubes

The principal types of linear-beam tubes are the klystron, the traveling-wave amplifier, and the backward-wave oscillator.

Klystrons—A klystron* is an electron tube in which the following processes may be distinguished:

(A) Periodic variations of the longitudinal velocities of the electrons forming the beam in a region confining a radio-frequency field

* D. R. Hamilton, J. K. Knipp, and J. B. H. Kuper, *Klystrons and Microwave Triodes* (New York: McGraw-Hill Book Co., 1948); A. H. W. Beck, *Velocity-Modulated Thermionic Valves* (London: Cambridge University Press, 1948; A. H. W. Beck, *Thermionic Valves, Their Theory and Design* (London: Cambridge University Press, 1953); A. H. W. Beck, *Space-Charge Waves and Slow Electromagnetic Waves* (New York: Pergamon Press, 1958).

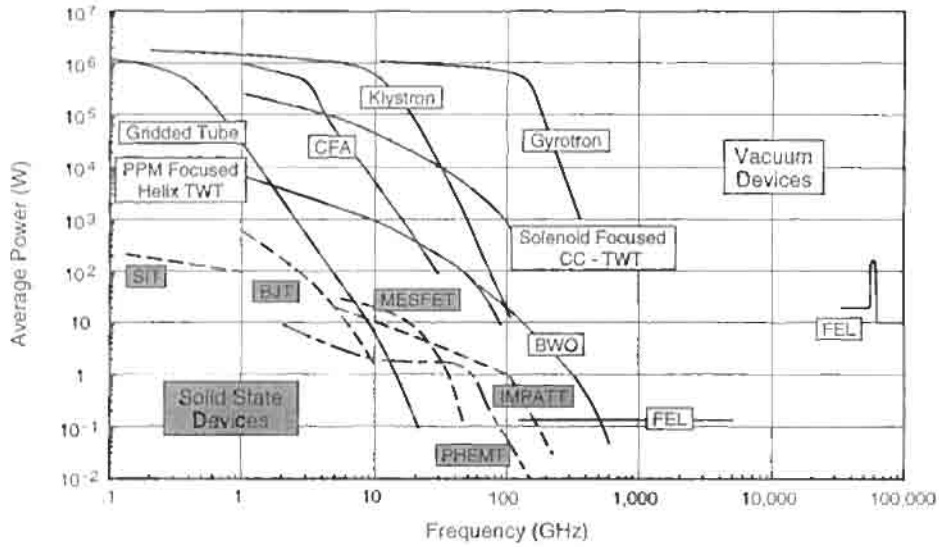

Fig. 18. RF Vacuum electronic and solid-state devices: current state of technology for single device performance.

(B) Conversion of the velocity variation into conduction-current modulation by motion in a region free from radio-frequency fields

(C) Extraction of the radio-frequency energy from the beam in another confined radio-frequency field

The transit angles in the confined fields are made short ($\delta \cong \pi/2$) so that there is no appreciable conduction-current variation while the electrons traverse them.

Several variations of the basic klystron exist. These include the two-cavity amplifier or oscillator, the reflex klystron, and the multicavity high-power amplifier.

Two-Cavity Klystron Amplifiers: An electron beam is formed in an electron gun and passed through the gaps associated with the two cavities (Fig. 19). After emerging from the second gap, the electrons pass to a collector designed to dissipate the remaining beam power without the production of secondary electrons. In the first gap, the electron beam is alternately accelerated and decelerated in succeeding half-periods of the radio-frequency cycle, the magnitude of the change in speed depending on the magnitude of the alternating voltage impressed on the cavity. The electrons then move in a drift space where there are no radio-frequency fields. Here, the electrons that were accelerated in the input gap during one half-cycle catch up with those that were decelerated in the preceding half-cycle, and a local increase of current density occurs in the beam. Analysis shows that the maximum of the current-density wave occurs at the position, in time and space, of those electrons that passed the center of the input gap as the field changed from negative to positive. There is therefore a phase difference of $\pi/2$ between the current wave and the voltage wave that produced it. Thus at the end of the drift space, the initially uniform electron beam has been altered into a beam showing periodic density variations. This beam now traverses the output gap, and the variations in density induce an amplified voltage wave in the output circuit, phased so that the negative maximum corresponds with the phase of the bunch center. The increased radio-frequency energy has been gained by conversion from the direct-current, beam energy.

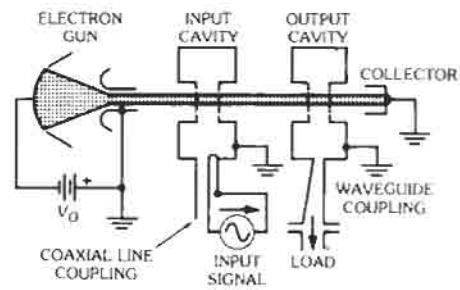

Fig. 19. Two-cavity klystron amplifier. (*From J. W. Gewartowski and H. A. Watson, Principles of Electron Tubes, 1965, p. 296. Courtesy D. Van Nostrand Co., Inc.*)

The two-cavity amplifier can be made to oscillate by providing a feedback loop from the output to the input cavity. A much simpler but less efficient structure results if the electron-beam direction is reversed by a negative electrode, termed the reflector.

*Reflex Klystrons:** A schematic diagram of a reflex klystron is shown in Fig. 20. The velocity-modulation process takes place as before, but analysis shows that in the retarding field used to reverse the direction of electron motion, the phase of the current wave is exactly opposite to that in the two-cavity klystron. When the bunched beam returns to the cavity gap, a positive field extracts maximum energy from the beam, since the direction of electron motion has now been reversed. Consideration of the phase conditions shows that for a fixed cavity potential, the reflex klystron will oscillate only near certain discrete values of reflector voltage for which the transit time measured from the gap center to the reflection point and back is given by

$$w\tau = 2\pi(N + 3/4)$$

where N is an integer called the mode number.

By varying the reflector voltage around the value corresponding to the mode center, it is possible to vary the oscillation frequency by a small percentage. This fact is made use of in providing automatic frequency control or in frequency-modulation transmission.

Reflex-Klystron Performance Data: The performance data for a reflex klystron are usually given in the form of a reflector-characteristic chart. This chart displays power output and frequency deviations as a function of reflector voltage. Several modes are often displayed on the same chart. A typical chart is shown in Fig. 21.

Table 5 shows typical reflex-klystron performance.

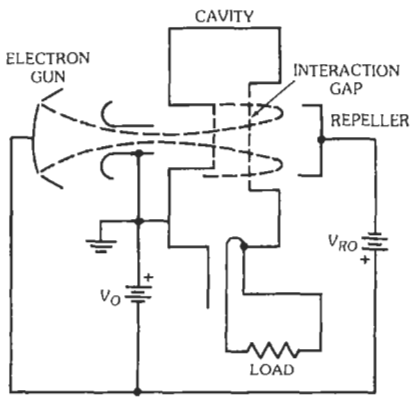

Fig. 20. Schematic diagram of reflex klystron with power supply. (*From J. W. Gewartowski and H. A. Watson, Principles of Electron Tubes, 1965; p. 311. Courtesy D. Van Nostrand Co., Inc.*)

* J. R. Pierce and W. G. Shepherd, "Reflex oscillators," *Bell System Technical Journal*, vol. 26, pp. 460–681, July, 1947.

Multicavity Klystrons: Multicavity klystrons† have been perfected for use in two rather different fields of application: 1. those requiring extremely high pulse powers and 2. continuous-wave (CW) systems in which a few kilowatts to hundreds of kilowatts are required. Examples of the first application are power sources for nuclear-particle acceleration and radar; ultra-high-frequency television, troposcatter, satellite-groundstation, and space-communication transmitters are examples of the latter.

A multicavity klystron amplifier is shown schematically in Fig. 22. The example shown has three cavities, all coupled to the same beam, although as many as seven cavities are sometimes used. The radio-frequency input modulates the beam as before. The bunched beam induces an amplified voltage across the second cavity, which is tuned to the operating frequency. This amplified voltage remodulates the beam with a certain phase shift, and the now more strongly bunched beam excites a highly amplified wave in the output circuit. It is found that the optimum power output is obtained when the second cavity is slightly detuned. When four or more cavities are used, optimum efficiency is obtained with both the penultimate and the antepenultimate cavities tuned above the operating frequency. Moreover, when increased bandwidth is required, the earlier cavities may be loaded. Modern multicavity klystrons use magnetically focused, high-perveance beams, and under these conditions high

gains, large power output, and reasonable values of efficiency are readily obtained.

Fig. 23 shows the power output and tuning range versus frequency for a number of typical CW klystrons. Efficiencies from 30% to 75% are typical. The lower efficiencies apply for high-perveance ($3 \times 10^{-6}\ A/V^{3/2}$) stagger-tuned, broad-band klystrons, and the higher efficiencies apply for narrow-band, lower-perveance ($0.5 \times 10^{-6}\ A/V^{3/2}$) klystrons. Average output power scales as about λ^3 (λ = wavelength) at constant perveance if cavity losses limit output power. At the lowest frequencies, the limit on power is imposed by single-mode-waveguide, output window capability, and power scales as A. At the highest frequencies, cathode current and cavity losses impose the limit, and the power scales as $\lambda^{9/2}$.

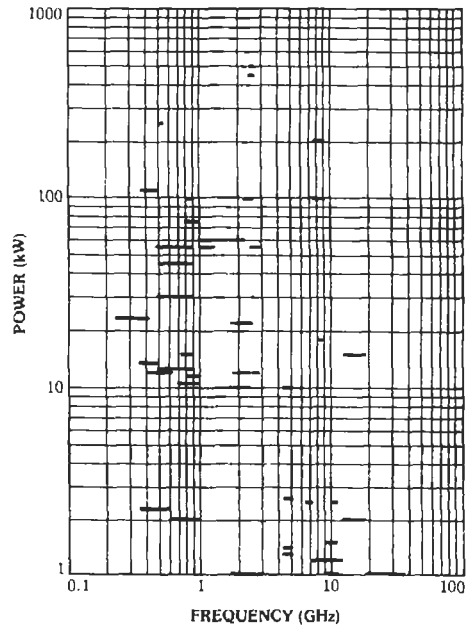

Fig. 23. Output power vs frequency for a representative group of CW klystrons.

Fig. 24 shows the power output and tuning range versus frequency for pulsed klystrons. Because most pulsed klystrons use higher-perveance beams (1.5 to 3 $\times 10^{-6}\ A/V^{3/2}$) to keep the beam voltage low, efficiencies range from 30% to 50%. As much as 11.8% band-

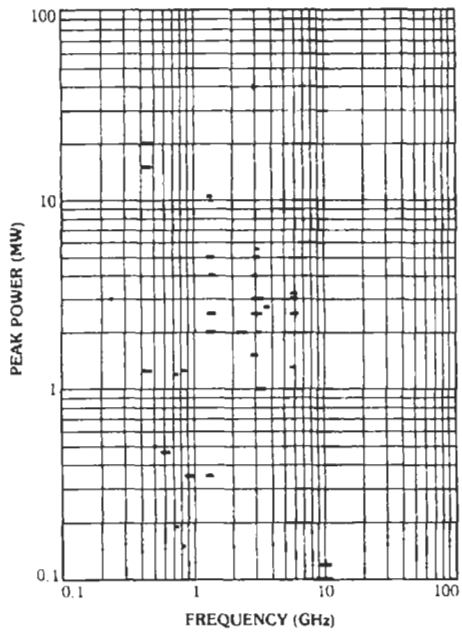

Fig. 24. Output power vs frequency for a representative group of pulsed klystrons.

width has been achieved from a 10-MW klystron with a 1000-ohm "beam impedance." Even wider bandwidth, at lower power, has been achieved recently by replacing the individual intermediate cavities along the beam of a multicavity klystron with groups or clusters of two or three closely spaced artificially loaded low-Q cavities. In this way, two or three times the bandwidth can be achieved while preserving the overall dimensions of the tube as well as the gain.*

Bandwidth scales inversely with the ratio of dc beam voltage to dc beam current, or "beam impedance," in both CW and pulse klystrons. Peak output power from pulsed klystrons is usually limited by the beam voltage that can be applied to the electron gun without giving rise to arcing problems and by the current that can be put through the beam tunnel while keeping the cathode current density reasonable. For this reason, maximum peak power from klystrons is relatively constant up to about 3000 MHz and then falls as λ^2.

Multiple-Beam Klystrons: Multiple-beam klystrons (MBKs) are useful in systems that require high peak/average power with relatively high instantaneous bandwidths (up to approximately 15%) and/or systems where relatively low operating voltages are desired. They are used in a broad range of applications, ranging from compact, low-power C-, X-, and Ku-band 10–500 watt amplifiers for communications, airborne radar, and missile seekers, to high power L-, S-, and X-band 100–1000 kilowatt amplifiers for radar and broadcasting.

The concept of the multiple-beam klystron appeared in the early 1940s,† soon after the invention of the conventional (single-beam) klystron by the Varian brothers. The development of the multiple-beam klystron was driven by the desire of microwave source developers to produce a given amount of microwave power at as low an operating voltage as possible, since, in general, lower voltages make the design of power supplies simpler, lighter, cheaper, and more reliable. However, to keep the beam power constant, any reduction in the beam voltage must be accompanied by a corresponding increase in beam current. In conventional klystrons (as well as in many other microwave tubes), an increase in electron current density increases the role of space-charge forces. When these forces are negligibly small, electrons will ballistically bunch in the drift channel of the klystron because of the initial modulation of electron velocities at the input cavity gap. At high current densities, however, space-charge forces are not negligible and the repulsive forces will interfere with the ballistic bunching, leading to a degradation in efficiency.

It occurred to klystron designers that higher current beams could be achieved by separating the single electron beam into multiple beamlets, each with a sufficiently low current density to ensure efficient electron bunching. Each beamlet is transported down its own drift channel, parallel to, but isolated from, the other beamlets. The beamlets are allowed to interact only over small axial distances corresponding to cavity gap locations. Klystrons with such an electron beam generation and transport design are termed "multiple-beam klystrons." Over the years, many multiple-beam klystron configurations have been considered.‡

An important advantage of a multiple-beam klystron is the potential for enhanced instantaneous bandwidths relative to single-beam klystrons. Since the total current and perveance of the beam is higher in multiple-beam klystrons than in conventional klystrons, the quality factors of the cavities in the multiple-beam klystrons will be lower. The lower quality factors increase the width of the resonance curves of the modes in the cavities, thus increasing the operating bandwidth.§ Another significant advantage of the multiple-beam configuration is a reduction in operating voltage relative to conventional klystrons. This reduc-

* R. S. Symons, B. Arfin, R. E. Boesenberg, P. E. Ferguson, M. Kirshner, and J. R. M. Vaughan, "An experimental clustered-cavity^{TM} klystron," Paper 7.4, *Technical Digest, International Electron Devices Meeting*, Washington, DC, Dec. 6–9, 1987, IEEE.

† J. Bernier, Patent No. 992-853, September 15, 1944 (France).

‡ M. R. Boyd, R. A. Dehn, J. S. Hickey, and T. G. Mihran, "The multiple-beam klystron," *IRE-ED* vol. 9, pp. 247–252 (1962).

tion in voltage can be illustrated by examining the cases of a multiple-beam klystron and a single-beam klystron (SBK) generating the same level of microwave power with the following assumptions: (*i*) the microperveance of a single beamlet in the multiple-beam klystron is the same as the microperveance of a whole beam in the single-beam klystron; (*ii*) the power and efficiency of the multiple-beam and single-beam klystrons are identical; and (*iii*) the electron current density in both cases is limited by space-charge effects. Under these assumptions, the voltage for the multiple-beam klystron will scale as $V_{MBK} = V_{SBK}/N^{2/5}$, where N is number of beamlets. In addition, the total length of the interaction region will scale as $V_{MBK}^{1/2}$, and so the reduced voltage also leads to a more compact device.

Traveling-Wave Tubes—The traveling-wave tube* differs from the klystron in that the radio-frequency field is not confined to a limited region but is distributed along a wave-propagating structure. A longitudinal electron beam interacts continuously with the field of a wave traveling along this wave-propagating structure. In its most common form, it is an amplifier, although there are related types of tubes that are basically oscillators.

The principle of operation may be understood by reference to Fig. 25. An electron stream is produced by an electron gun, travels along the axis of the tube, and is finally collected by a suitable electrode. Spaced closely around the beam is a circuit, in this case a helix, capable of propagating a slow wave. The circuit is proportioned so that the phase velocity of the wave is small with respect to the velocity of light. In typical low-power tubes, a value of the order of one-tenth of

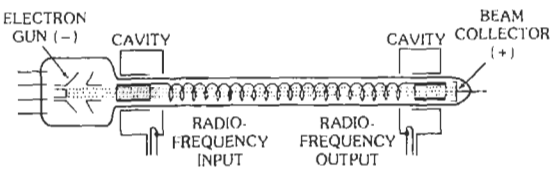

Fig. 25. Basic helix traveling-wave tube. The magnetic beam-focusing system between input and output cavities is not shown.

the velocity of light is used; for higher-power tubes the phase velocity may be two or three times higher. Suitable means are provided to couple an external radio-frequency circuit to the slow-wave structure at the input and output. The velocity of the electron stream is adjusted to be approximately the same as the axial phase velocity of the wave on the circuit.

When a wave is launched on the circuit, the longitudinal component of its field interacts with the electrons traveling in approximate synchronism with it. Some electrons will be accelerated and some will be decelerated, resulting in a progressive rearrangement in phase of the electrons with respect to the wave. The electron stream, thus modulated, in turn induces additional waves on the helix. This process of mutual interaction continues along the length of the tube with the net result that direct-current energy is given up by the electron stream to the circuit as radio-frequency energy, and the wave is thus amplified.

By virtue of the continuous interaction between a wave traveling on a broad-band circuit and an electron stream, traveling-wave tubes do not suffer the gain-bandwidth limitation of ordinary types of electron tubes. By proper circuit design, such tubes can have instantaneous bandwidths approaching three octaves.

The helix is an extremely useful form of slow-wave circuit because the impedance that it presents to the wave is relatively high and because, when properly proportioned, its phase velocity is almost independent of frequency over a wide range.

An essential feature of this type of tube is the approximate synchronism between the electron stream and the wave. For this reason, the traveling-wave tube will operate correctly over only a limited range in voltage. Practical considerations require that the operating voltages be kept as low as is consistent with obtaining the necessary beam input power; the voltage, in turn, dictates the phase velocity of the circuit. The electron velocity v in centimeters/second is determined by the accelerating voltage V in volts in accordance with

$$v = 5.93 \times 10^7 V^{1/2}$$

Fig. 26 shows a typical relationship between gain and beam voltage. The small-signal gain $G_{s.s.}$, in decibels, of a traveling-wave tube is given approximately by

$$G_{s.s.} = A + BCN$$

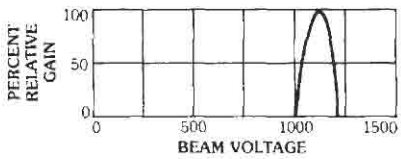

Fig. 26. Traveling-wave tube gain vs accelerating voltage.

where

A is the initial loss due to the establishment of the modes on the helix and lies in the range from –6 to –9 decibels,
B is a gain coefficient that accounts for the effect of circuit attenuation and space charge,
C is a gain parameter that depends on the impedances of the circuit and the electron stream, and
N is the number of active wavelengths in the tube.

$$C = \left\{\left[E^2/(\omega/v)^2 P\right] \times (I_0/8V_0)\right\}^{1/3}$$

and

$$N = (l/\lambda_0)(c/v)$$

where

I_0 is the beam current,
V_0 is the beam voltage,
l is the axial length of the helix,
λ_0 is the free-space wavelength,
v is the phase velocity of the wave along the tube, and
c is the velocity of light.

The term $E^2/(\omega/v)^2 P$ is a normalized wave impedance that may be defined in a number of ways.

In practice, the attenuation of the circuit will vary along the tube, and consequently the gain per unit length will not be constant. The total gain will be a summation of the gains of various sections of the tube.

Commonly, C is of the order of 0.02 to 0.2 in helix traveling-wave tubes; typical gains vary from 20 to 70 decibels, depending on the application. The gain in a tube designed to produce appreciable power will vary somewhat with signal level when the beam voltage is adjusted for optimum operation. Fig. 27 shows a typical characteristic.

To restrain the physical size of the electron stream as it travels along the tube, it is necessary to provide a focusing field, either magnetic or electrostatic, of a strength appropriate to overcome the space-charge forces that would otherwise cause the beam to spread. For tubes requiring a strong confining field (in the range of 0.5 to 2 tesla) and/or a high degree of spatial field uniformity, a solenoid electromagnet is typically used to generate the longitudinal magnetic field. Many traveling-wave tube designs (e.g., for electronic warfare, communications, and airborne/space-based applications) require more modest bore fluxes in the range of 0.2 to 0.5 tesla, allowing the use of periodic-permanent-magnet (PPM) focusing. A PPM stack consists of rings of permanent magnets with alternating axial polarities separated by iron pole pieces and/or nonconducting shims. Typically, the permanent magnets are fabricated from a rare-earth compound of samarium-cobalt or neodymium-iron-boron. The high-energy products ($|BH|_{max} > 200$ kilojoules/cubic meter) and coercivities ($H_c > 100$ amperes/meter) of these materials enable amplifier designs with substantial weight and size reductions compared to solenoid-focused systems along with improved efficiency and reliability owing to the elimination of external electromagnet power supplies.

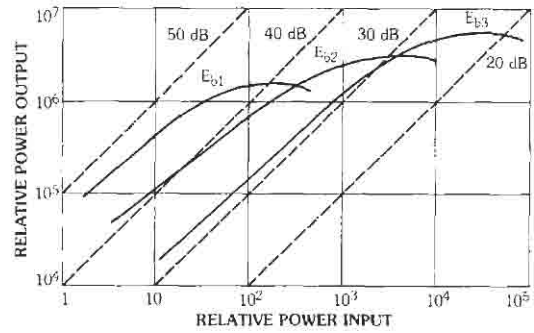

Fig. 27. Gain of traveling-wave tube as a function of input level and beam voltage. $E_{b1} < E_{b2} < E_{b3}$.

After interacting with the fields in the slow-wave circuit of the traveling-wave tube, the spent beam electrons are collected in an electron collector. If the collector is maintained at the same potential as the slow-wave circuit, the kinetic energy of the electrons will be dissipated in the walls of the collector as heat. However, if the collector is operated at a reduced (depressed) potential relative to the slow-wave circuit, much of the remaining energy in the beam can be recovered by decelerating the electrons prior to collection, greatly enhancing the efficiency of the device.

In practice, the beam–wave interaction process introduces a spread of velocities in the beam electrons; for efficient collection, the collector must have multiple electrodes (stages) maintained at a range of depressed potentials to efficiently sort electrons traveling at different velocities. With an optimized two- or three-stage depressed collector, the efficiency of the traveling-wave tube can be increased by as much as a factor of two or three. For space-based applications, where efficiency is critical, a traveling-wave tube may use up to a five-stage depressed collector to achieve narrow-band electronic efficiencies approaching 80%.

Helix traveling-wave circuits of the type shown in Fig. 25 are widely used in low- to medium-power applications (≤ 200 watts), where gain, bandwidth, and efficiency are important performance criteria. For

applications requiring high peak and/or high average power, the helix can be replaced by periodic slow-wave structures such as ring–bar, ring–loop, and coupled-cavity circuits. These structures have the advantage of being mechanically robust with high intrinsic thermal conductivities and are readily adaptable to liquid cooling. For example, ladder circuit coupled-cavity traveling-wave tubes have been built that operate at peak output powers ranging from 50 to 50,000 W at frequencies from 30 GHz to 95 GHz and bandwidths ranging from 14% to 20%. In general, the nonhelix circuits are capable of higher power operation at the expense of bandwidth.

Traveling-Wave-Tube Performance Data—Traveling-wave tubes are designed to emphasize particular inherent characteristics (e.g., gain, bandwidth, peak/average power, linearity, efficiency) for specific applications. Principle application areas include radar, electronic countermeasures, telecommunications, and satellite communications.

Radar: For this application, the traveling-wave tube may be an intermediate or final output stage of a transmitter; power output may be pulsed, continuous-wave, or dual-mode (user selectable low-power continuous-wave/high-power pulsed operation). Gains of 30 to 65 decibels are typical. Designs using coupled-cavity circuits have achieved peak output powers ranging from > 1000 kilowatts in S-band to one kilowatt in W-band; helix circuits operate at lower peak powers (ranging from tens to thousands of watts) but with broader bandwidth.

Electronic Countermeasures: In this application, the principle performance requirements are high bandwidth and low harmonic distortion at moderate output power levels; power output may be pulsed or continuous-wave. Bandwidths approaching three octaves have been achieved; gains range from 25 to 60 decibels. For applications in L-band through Ku-band, peak powers are in the several kilowatt range for pulsed tubes and in the several hundreds of watts range for continuous-wave devices.

Telecommunications: Terrestrial telecommunications applications include transmitters for satellite ground stations, point-to-point microwave links, and broadband, high-speed data transmission. Power output is typically continuous-wave and falls into one of three classes: low power (≤ 200 watts), medium power (300 to 1,200 watts), or high power (≥ 1,200 watts). All commercial/defense/scientific bands are covered, including C-, X-, Ku-, DBS, K- , Ka-, Q-, and V-bands. Gains range from 30 to 65 decibels.

Satellite Communications: Because of their reliability, lifetime, and high efficiency, traveling-wave tubes are the amplifier of choice for many space-based applications. Typical operating lifetimes for space tubes are in excess of 15 years. Power output is typically continuous-wave and can range from tens of watts to hundreds of watts depending on the application. Gains are generally high, in the range of 45 to 65 decibels, with efficiencies from 55% to approaching 80%.

Microwave Power Modules*—The microwave power module (MPM) and millimeter-wave power module (MMPM) represent a class of highly compact, fully integrated, self-contained amplifiers that combine both solid-state and vacuum electronics technologies. As shown in Fig. 28, the power module consists of a solid-state driver amplifier (constructed from either discrete or monolithic microwave integrated circuit components) combined with a highly efficient, low-gain traveling-wave tube; power conditioning is inte-

* C. R. Smith, C. M. Armstrong, and J. Duthie, "The microwave power module: A versatile RF building block for high-power transmitters," *Proceedings of the IEEE*, vol. 87, no. 5, May, 1999.

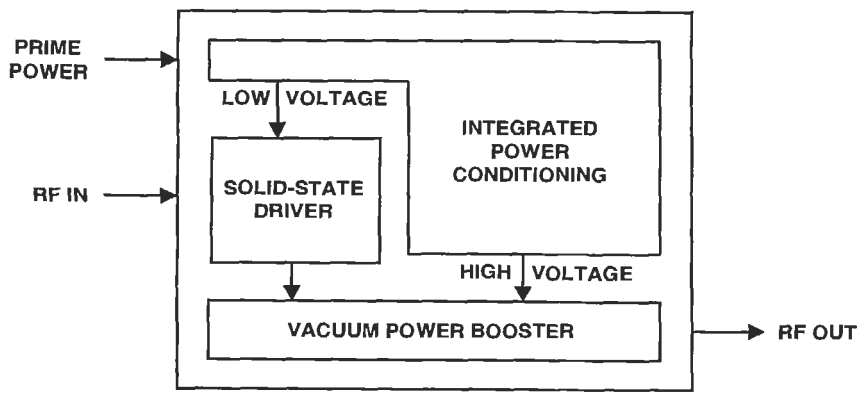

Fig. 28. Block diagram of a microwave power module.

grated with the amplifier chain. The overall gain of the power module is partitioned approximately equally between the solid-state driver and the traveling-wave tube, taking maximum advantage of the low-noise, signal conditioning capabilities of solid-state technology and the high power, high efficiency, and broad bandwidth capabilities of vacuum electronics technology. To emphasize its complementary function, the traveling-wave tube is often referred to as a "vacuum power booster" in the context of the power module.

The optimal partitioning of gain between the solid-state driver and vacuum power booster stages results in a number of performance benefits, including (*i*) reduced amplifier size and weight, owing to the reduction in gain, and hence length, of the vacuum power booster; (*ii*) increased broad-band power handling capability, again owing to the reduction in gain of the vacuum power booster; (*iii*) extremely high DC-to-RF transmitter efficiency, owing to the use of a multi-stage depressed collector in the vacuum power booster; (*iv*) improved noise performance (noise figure < 10 decibels), owing to the use of the solid-state driver; (*v*) the ability to incorporate gain and temperature compensation, as well as phase shifting, in the driver; (*vi*) the opportunity to incorporate linearization circuitry in the solid-state driver that can be matched to the characteristics of the vacuum power booster and the needs of the system; and (*vii*) an anticipated increase in reliability owing to the reduction of the high voltage required for the reduced-gain vacuum power booster. Depending on the application, power modules have been developed that can deliver 50 to 200 watts of continuous-wave radio frequency output power at power gains of > 50 decibels over bandwidths approaching three octaves. For optimized narrow-band designs, DC-to-RF conversion efficiencies of 50% have been achieved (using a multi-stage depressed collector); for multi-octave frequency designs, efficiencies of > 35% have been achieved.

Modeling of the Helix Traveling-Wave Tube—The need for experimental prototyping and testing cycles in traveling-wave tube development can be reduced or eliminated through the use of modern computer-aided design tools,* reducing the time and cost of development. The design tools are based on physical models of the interaction between the electron beam and the electromagnetic fields in the traveling-wave tube structure. Implemented into design codes using modern numerical techniques and advanced algorithms, these sophisticated models can simulate actual hardware geometries and incorporate realistic material properties. Advances in computationally efficient codes and processor speeds enable intricate three-dimensional structures with advanced, inhomogeneous, anisotropic materials to be simulated on modern desktop computers, where complex parameter optimization trade-off analyses can be made to develop tube designs that meet specific goals for frequency, bandwidth, power, efficiency,† gain, noise, and linearity.

Large-signal codes of different levels of sophistication are employed to model helix traveling-wave tube performance.‡ Electron gun design codes accurately model electron beam formation and transport to the interaction region, whereas the collector codes are used in the design of efficient multi-stage depressed collectors (examples of 2-D electron gun codes include EGUN§ and UGUN"; 3-D gun/collector codes include MICHELLE#). Sophisticated finite-element codes are employed to design magnetic circuits (e.g., MAXWELL**) and are used to address thermo-mechanical design issues (e.g., ANSYS††). The effective exercise of computational design tools can also provide insight into the dependence of device performance on the variation of critical parameters, such as dimensional variations or variations in materials properties. This information can significantly impact device design, as well as fabrication and assembly processes.

Backward-Wave Oscillators—A member of the traveling-wave-tube family, the *O*-type backward-wave oscillator‡‡ makes use of the interaction of the electron stream with a radio-frequency-circuit wave whose phase and group velocities are 180° apart. The group velocity, and thus the direction of energy flow, is

directly opposed to the direction of electron motion. Fig. 29 shows schematically a backward-wave tube with connection to both ends of the slow-wave structure, so that operation as either oscillator or amplifier could be achieved. An electron beam is produced by the electron gun, traverses the slow-wave structure, and is dissipated in the collector structure. During its transit, the beam is confined by a longitudinal magnetic field. With a beam current of sufficient magnitude, the beam-structure interaction will produce oscillations, and microwave power will be delivered from the end of the structure adjacent to the electron gun. At beam-current levels below the "start-oscillation" value, a radio-frequency signal may be introduced at the collector end of the device, and the tube will operate as an amplifier.

To improve interaction efficiency, electron beams with hollow cross sections are usually used. This places all the electrons as close as possible to the slow-wave structure in the region of maximum radio-frequency field. This is beneficial because the strength of the −1 space harmonic field goes to zero on the axis. To produce this hollow-cross-section beam, it is necessary to use magnetically confined electron flow from the cathode, and thus the electron gun is entirely immersed in the magnetic field.

An *O*-type backward-wave device is voltage tunable, with the frequency being proportional to the 1/2 power of the cathode–helix voltage as well as dependent on the dimensions of the structure. Typically, tuning over a full octave range is possible, and in special cases a range of two or more octaves can be achieved.

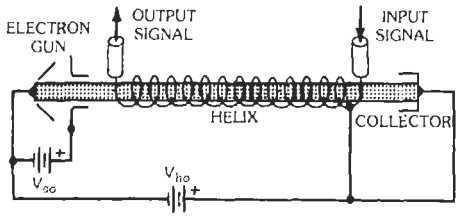

Fig. 29. A traveling-wave tube in operation as a backward-wave amplifier. A separate power supply connected to the anode permits beam-current control independent of the helix voltage. (*From J. W. Gewartowski and H. A. Watson, Principles of Electron Tubes, 1965; p. 398. Courtesy D. Van Nostrand Co., Inc.*)

Beck, *Space-Charge Wavey and Slow Electromagnetic Waves* (New York: Pergamon Press, 1958: pp. 241–255); R. Kompfner and N. T. Williams, "Backward-wave tubes," *Proceedings of the IRE*, vol. 41, pp. 1602–1611, November, 1953.

However, where confined limits are desired on power variation or other special characteristics, more restricted frequency ranges may be necessary. Where full octave tuning is used, power output variation of 6 to 10 decibels across the range is usual. In most cases, a separate control element in the gun permits adjustment of beam-current amplitude and thus provides control of power output. Oscillators of this type have very low pulling figures, but the pushing figure is often substantial. Frequency stability is generally excellent, with the achievable value normally depending on power-supply capabilities rather than on inherent tube limitations.

Generally, *O*-type backward-wave oscillators are low-power devices, with 10 to 50 milliwatts being typical. However, in the range from 1 to 4 gigahertz, up to several hundred milliwatts is feasible, while in the range from 50 to 100 gigahertz, 5 to 10 milliwatts is relatively difficult to achieve reliably. Typical performance data for low-power helix-type permanent-magnet-focused backward-wave oscillators are listed in Table 6.

Crossed-Field Tubes

Microwave crossed-field tubes are often called *M*-type devices to distinguish them from linear-beam tubes that are often called *O*-type devices. The earliest type of crossed-field tube* was the magnetron oscillator. Crossed-field amplifiers (CIA) and voltage-tunable crossed-field oscillators have been developed more recently. Crossed-field tubes generally operate with higher electronic conversion efficiency for dc power to microwave power than linear-beam tubes, so they are especially attractive for high-power applications.

Magnetrons—A magnetron is a high-vacuum tube containing a cathode and an anode, the latter usually divided into two or more segments. A constant magnetic field modifies the space-charge distribution and the current–voltage relations. In modern usage, the

TABLE 6. PERFORMANCE OF TYPICAL LOW-POWER BACKWARD-WAVE OSCILLATORS

term "magnetron" refers to the magnetron oscillator in which the interaction of the electronic space charge with the resonant system converts direct-current power into alternating-current power, usually at microwave frequencies.

Many forms of magnetrons have been made in the past, and several kinds of operation have been employed. The type of tube that is now almost universally employed is the multicavity magnetron generating traveling-wave oscillations. It possesses the advantages of good efficiency at high frequencies, capability of high outputs either in pulse or continuous-wave operation, moderate magnetic-field requirements, and good stability of operation. A section through the basic anode structure of a typical fixed-frequency, conventional magnetron is shown in Fig. 30.

In magnetrons, the operating frequency is determined by the resonant frequency of the separate cavities arranged around the central cylindrical cathode and parallel to it. A high direct-current potential is placed between the cathode and the cavities, and radio-frequency output in the conventional type of magnetron is brought out through a suitable transmission line or waveguide, usually coupled to one of the resonator cavities. Under the action of the radio-frequency voltages across these resonators and the axial magnetic field, the electrons from the cathode form a bunched space-charge cloud that rotates around the tube axis, exciting the cavities and maintaining their radio-frequency voltages.

Pulsed magnetrons have been developed to operate with peak power output from a few kilowatts to several megawatts and at frequencies from a few hundred megahertz to tens of gigahertz. The primary application for these tubes is the RF power generator for radar transmitters. Continuous-wave magnetrons have also been developed with power output of several hundred watts at frequencies from a few hundred megahertz to about 10–12 GHz. The principal use of many of these CW tubes is in countermeasure equipment used for electronic jamming. In addition, many fixed-frequency CW magnetrons at 2450 MHz have been used in microwave ovens.

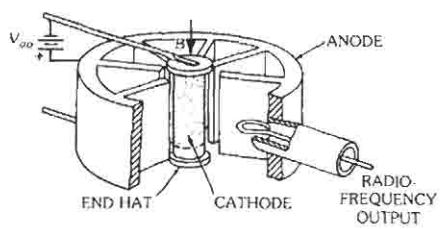

Fig. 30. Magnetron oscillator. (*From J. W. Gewartowski and H. A. Watson, Principles of Electron Tubes, 1965; p. 428. Courtesy D. Van Nostrand Co., Inc.*)

The output frequency of conventional magnetrons can be altered in an undesired fashion by variations in the microwave load impedance (frequency pulling) or by changes in cathode current (frequency pushing) caused by fluctuations in voltage applied to the magnetron. Significant improvement in operational stability for the magnetron is obtained by coupling to a high-Q stabilizing cavity. A convenient method for doing this is shown in Fig. 31. The stabilizing cavity is made an integral part of the magnetron by surrounding the magnetron anode with a resonant coaxial cavity (hence, the name "coaxial magnetron"). Alternate resonators of the anode circuit are slotted to provide coupling to excite the TEO_{01} circular electric mode in the coaxial cavity. Power output from a coaxial magnetron is obtained through a slot in the outer wall of the cavity.

The circulating space charge in both conventional and coaxial magnetrons contains wide-band noise-frequency components that can couple to the output. In conventional magnetrons, this spurious noise can couple directly to the output waveguide. Spurious noise power measured in a 1-MHz bandwidth is typically greater than 30 to 40 dB below the carrier. The coaxial cavity in the coaxial magnetron provides some isolation between the spurious noise coupled to the vanes and the output waveguide. The spurious noise power from coaxial magnetrons is typically 10 to 20 dB lower than the noise power from conventional magnetrons of comparable peak power level.

Magnetron frequencies can be tuned by various means. One method used for conventional magnetrons employs metallic probes that are inserted uniformly into the multiple resonant cavities of the anode. This changes the resonant frequency of the cavities that control the magnetron frequency. Coaxial magnetrons are usually tuned by changing the resonant frequency of the coaxial stabilizing cavity by moving an end plate in the cavity. Other methods are also used in each magnetron type.

Many conventional and coaxial magnetrons are designed for very rapid tuning. Fast frequency operation is employed in radar transmitters to improve radar signal detection and/or as an electronic countermeasure to avoid jamming. Fast tuning is performed by several methods. Some tubes have tuners that are driven mechanically by an electromagnet in a manner similar to the voice coil of a radio speaker. Tuning rates, tuning range, and oscillator frequency-versus-time profiles are determined by the waveform of the voltage applied to the electromagnet. Other tubes have a mechanical linkage between the tuner and a rotating motor and produce approximately sinusoidal variation in frequency–time profile. Tuning rates and range are limited by acceleration forces in the reciprocating tuner. For example, X-band, 200-kW tubes with narrow-band, rapid tuning of 30–50 MHz are tuned through this range at 200 Hz. Wider-band tuner excursions of 250–500 MHz are cycled at 25–40 Hz. Other tuning mechanisms in conventional and coaxial magnetrons utilize continuously rotating tuners. More

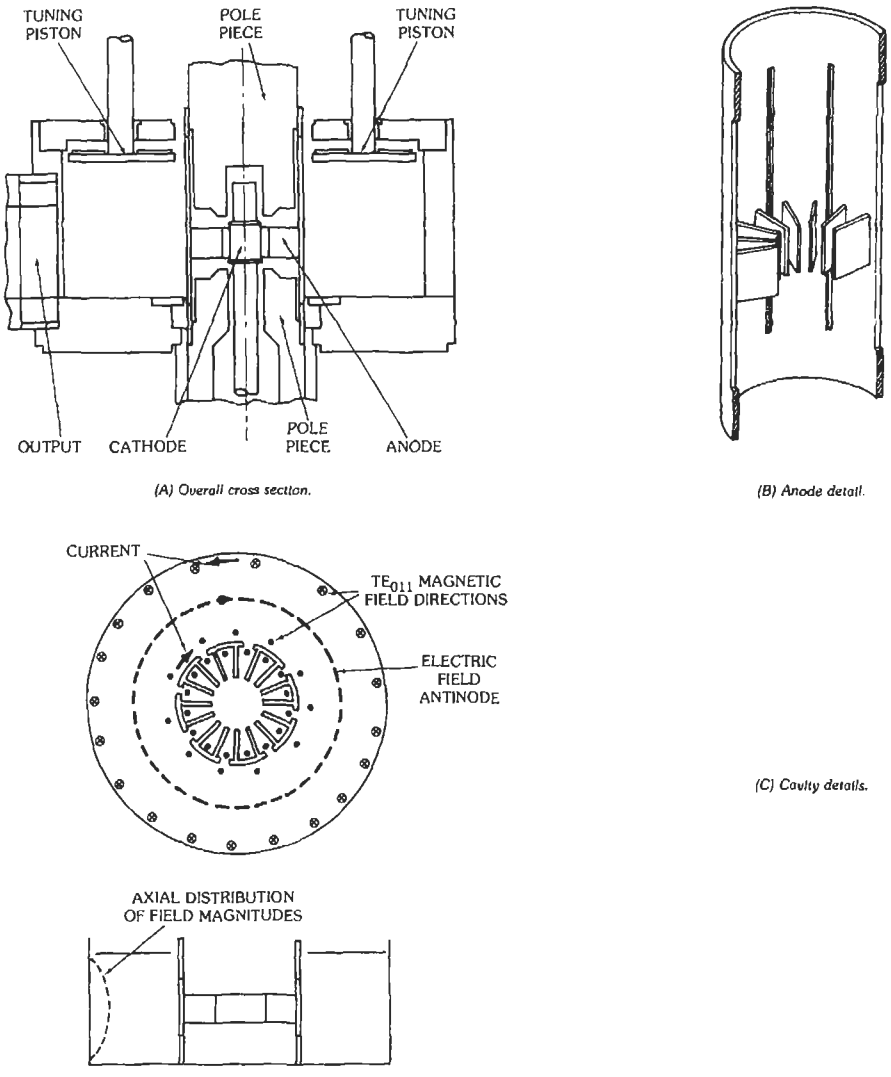

Fig. 31. Geometry of the composite anode. (*From E. Okress, Crossed-Field Microwave Devices, Vol. 2, New York: Academic Press, Inc., 1961; p. 125.*)

rapid frequency excursions through a fixed tuning range can be obtained with rotating tuners than from reciprocating tuners, but the rotational inertia of the tuners prohibits rapid changes in tuning profiles.

Voltage-Tuned Crossed-Field Oscillators—There are two types of voltage-tunable, crossed-field oscillators. These are the carcinotron and the voltage-tuned magnetrons (VTM).

The carcinotron is an *M*-type backward-wave oscillator in which the electron stream traverses the tube and interacts with the fields on the slow-wave structure under conditions where the electric and magnetic fields are perpendicular to each other. Fig. 32 shows schematically a linear version of the carcinotron. In the electron gun, current is drawn from the cathode when the accelerator voltage is applied. Because of the presence of the magnetic field, directed as shown, the electron paths are curved approximately 90° so that they enter the interaction region between the slow-wave structure and the sole. If the voltages and the magnetic field strength are proper, the electrons will travel along a path approximately parallel to the structure until they reach the collector.

Although Fig. 32 shows a linear arrangement, carcinotrons are conventionally designed in a circular arrangement to conserve magnet size and weight. In this arrangement, the sole approximates the appearance of the cathode of a magnetron, and the slow-wave structure is in the position of the magnetron anode, but neither the sole nor the structure is reentrant.

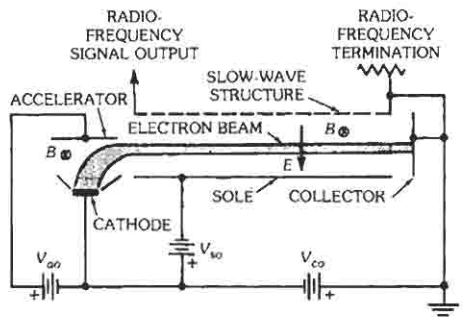

Fig. 32. Linear version of an *M*-type carcinotron oscillator. (*From J. W. Gewartowski and H. A. Watson, Principles of Electron Tubes, 1965; p. 459. Courtesy D. Van Nostrand Co., Inc.*)

The carcinotron gives performance similar to that of the *O*-type backward-wave oscillator, but it offers several of the advantages of crossed-field devices. High-efficiency operation is possible, with values of 20% to 30% being readily obtained. This efficiency capability makes the carcinotron useful as a high-power device with continuous-wave capabilities of hundreds of watts through the X-band. Its construction permits direct scaling to very high frequencies, with several milliwatts of power having been achieved at frequencies beyond 300 gigahertz.

The carcinotron, like the *O*-type backward-wave oscillator, is voltage tunable with the oscillation frequency being approximately directly proportional to the voltage between the cathode and the slow-wave structure. This linear relationship simplifies the associated electronic tuning circuit considerably. Frequency pushing is considerably lower than in *O*-type backward-wave oscillators. The *M*-type carcinotron has the disadvantage, however, that it is relatively noisy, with spurious power output often not more than 10 to 15 decibels below the main signal output.

Voltage-tuned magnetrons (VTMs) are distinguished from conventional magnetrons in two critical ways:

1. The output is coupled very heavily to the circuit, and so the loaded Q is very low, typically between 1 and 10.
2. The normal cathode is replaced by a nonemitting post, and a cylindrical beam is injected into the interaction space from an emitting filament at one end; the injected current is controlled by the voltage on a control electrode surrounding the filament.

Under these conditions, the oscillation frequency is no longer controlled by the resonator, but by the ratio of electric to magnetic fields in the interaction space. The magnetic field is held constant by a permanent magnet so that the frequency becomes directly proportional to the applied voltage, which is normally between 1 and 4 kV dc. The control–electrode voltage is normally about 20% of the cathode–anode voltage.

Power output of VTMs ranges from a few watts to a few hundred watts at frequencies from about 1 to 5 GHz. Tuning range is more than one octave at low powers (under 10 watts) but reduces to about 30% at 100 watts.

Efficiency is remarkably high, exceeding 60% in the higher-power VTMs. The tubes are more compact and more efficient that carcinotrons, but they do not reach as high an absolute power level or as high a frequency.

Because the heavy coupling would make the VTM very susceptible to load changes, a ferrite isolator is normally made an integral part of the VTM package.

The application of high-power, voltage-tuned, crossed-field oscillators is exclusively in the field of electronic countermeasures. Low-power VTMs are also used as test oscillators and are capable of extremely high modulation rates.

Crossed-Field Amplifiers—Crossed-field amplifiers (CFAs) can be divided into two general classes, injected-beam tubes and distributed-emission (or sometimes emitting-sole) tubes. The former are similar in appearance to the carcinotron in that they employ separate electron guns, interaction regions, and beam-collector elements. For amplifiers, the slow-wave circuit is provided with both input and output terminals. The RF input is close to the electron gun, and the RF wave is amplified as it travels along the slow-wave circuit to the output while maintaining synchronism with the electron stream. Most injected-beam CFAs are fabricated in a linear format and are often compared to beam-type traveling-wave tubes. The principal application of injected-beam CFAs is in electronic-countermeasures equipment.

Distributed-emission CFAs are similar to magnetrons in that electron current for interaction is obtained from the cathode (or sole electrode) throughout the interaction space. Most distributed-emission tubes are fabricated in a circular format like magnetrons. As may be seen from Fig. 33, the major difference is that the slow-wave structure is not reentrant, whereas in the magnetron both the beam and the circuit are reentrant. In Fig. 33, voltage and magnetic field are applied as for the magnetron. A radio-frequency signal is applied to the structure and progresses in a clockwise direction toward the output terminal. Current spokes, produced in the cathode-circuit region by the radio-frequency electric fields, also progress in a clockwise direction synchronously with the circuit wave. The interaction between the beam and circuit wave results in a growing circuit wave and, hence, gain. If desired, interaction with a backward mode may also be accomplished with this device.

Because the beam is reentrant, the crossed-field amplifier will oscillate if the circuit gain becomes high. Gain is usually limited to 10 to 15 decibels. If only a portion of the circumference is used for the slow-wave structure and a drift area is left between the two ends of the structure, the feedback mechanism is

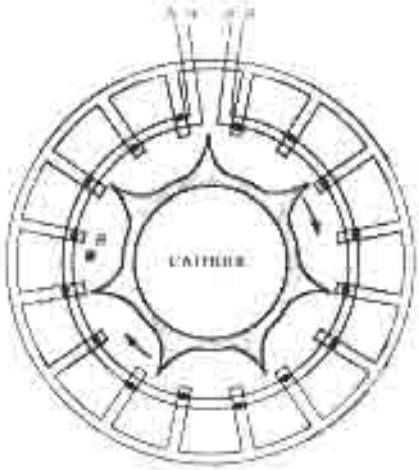

Fig. 33 Schematic drawing of a crossed-field amplifier. (*From J. W. Gewartowski and H. A. Watson, Principles of Electron Tubes, 1965, p. 349. Courtesy D. Van Nostrand Co., Inc.*)

disrupted, and gains of 15 to 20 decibels may be realized.

The power output of the crossed-field amplifier is essentially independent of the radio-frequency drive signal, and the device thus operates as a saturated amplifier. This characteristic makes it unsuitable for amplifying amplitude-modulated signals.

Distributed-emission crossed-field amplifiers offer the advantage of relatively high efficiency (40% to 60% or even higher), and they may be designed to provide very high peak output powers. Their disadvantages are their low gain, limited bandwidth, high noise, and saturated-amplifier characteristic.

CYCLOTRON RESONANCE MICROWAVE TUBES*†

One of the highest power device technologies for the generation and amplification of power in the millimeter wave bands (30–300 GHz) are the cyclotron resonance devices.

In cyclotron resonance devices (gyrotrons, gyro klystrons, gyro traveling-wave tubes, and gyro backward-wave oscillators), the electrons in the electron beam have substantial motion perpendicular to the axis of the beam and the solenoidal focusing magnetic field. They interact with radio-frequency electric fields perpendicular to the magnetic focusing field. The RF fields correspond to the fields of TE modes in cavities that, to a first approximation, are cylindrical, and the operating modes need not be the fundamental mode of the cavity. Operation of higher-order modes permits use of larger diameter cavities and the attainment of higher output power. As the electrons rotate and the fields alternate in synchronism, there is a cumulative interaction. Some electrons gain energy, and other electrons lose energy. The electrons that gain energy undergo a relativistic mass increase, and the ones that lose energy undergo a relativistic-mass decrease. Because the cyclotron frequency is equal to $\Omega_c = eB/\gamma m$, in which m is the rest mass of the electrons and γ is the relativistic factor $(\gamma = \left|1 - v^2/c^2\right|^{-1/2})$, where v is the electron velocity), electrons that gain energy have larger gyromagnetic and thus smaller angular rotation rates, and electrons that lose energy have larger angular rotation rates. Hence, the electrons gather into rod-like bunches parallel to the axis of the helical electron trajectories. As a result of this bunching, there is a net exchange of energy between the electron beam and the resonant electromagnetic field. This resonance condition is given by

$$\omega = s\Omega_c$$

where

$$\omega = 2\pi f$$

f is the frequency, and
s is the harmonic number ($s = 1, 2, 3$).

In most instances gyro devices operate on the fundamental resonance ($s = 1$), but many successful devices have also been made at higher harmonics ($s > 1$). For a solenoidal magnetic field of 1 T and $\gamma = 1$, a gyro device operating on the fundamental cyclotron resonance ($s = 1$) will have a frequency of $f = \Omega_c/2\pi = 28$ GHz. The magnetic field of the solenoid serves two purposes for the cyclotron resonance maser: 1. to propagate the electron beam and 2. more importantly, to permit this resonance with a particular cavity mode. Because the resonant nature of the interaction permits the designer to select an interaction with a higher-order cavity mode without necessarily having interference from lower-order modes, cyclotron resonance devices will produce higher powers at higher frequencies than will other microwave tubes. Although the bunching in this device is based on a relativistic effect, the electron energies need not be that relativistic; electron beam kinetic energies typical in gyro devices are 20–80 keV. Some cyclotron resonance devices designed for very high peak powers do employ much higher energy beams.

Cyclotron resonance devices that have been built so far fall into four major categories: (A) gyrotron oscillators, which are single-cavity devices that oscillate because of the negative interaction impedance of the electron beam with the cavity; (B) gyro-klystrons, in which azimuthal bunching of the electrons is achieved

---

† K. L. Felch, H. G. Dandy, H. R. Jory, K. E. Kreischer, W. Lawson, B. Levush, and R. J. Temkin, "Characteristics and applications of fast-wave gyrodevices," *Proceedings of the IEEE*, vol. 87, no. 5, pp. 752–781, 1999.

by first passing them through an input cavity wherein the microwave signal to be amplified is injected, then through successive beam-excited bunching cavities, and then through a final output cavity in which the energy extraction is achieved; (C) gyro-traveling-wave tubes (gyro-TWTs), in which the electrons travel through a uniform or tapered waveguide supporting a transverse electric mode; and (D) gyro backward-wave oscillators, which are similar in structure to gyro-TWTs but in which the group velocity of the wave in the uniform waveguide is opposed to electron flow and power comes out of the circuit at the end where the electron beam enters.

Gyrotron oscillators are by far the best developed of these four categories. The principle applications are scientific and include applications to the cyclotron resonance heating of fusion plasmas and material processing. Representative of present state of the art for gyrotron oscillators is a 110-GHz gyrotron capable of operation at 1 MW for 0.6-s pulses, 400 kW for 6.5-s pulses, and 100 kW CW.* To achieve these unprecedented powers without thermal damage to the interaction circuit, this device was operated in a very high order cavity mode, the $TE_{22,6,1}$ mode. Consequently, gyrotrons often now have internal mode converters that convert the TE mode used in the interaction to a more usable output mode, such as a TEM_{00} Gaussian beam. Gyrotrons have been developed or are under development at frequencies ranging from 8 to 170 GHz. Gyrotrons at even higher frequencies (up to 800 GHz) have been developed for scientific applications.

Though they have received less development than gyrotron oscillators, gyro-amplifiers such as the gyro-klystron have been developed in several frequency bands with radar and accelerator applications as the primary motivation. As an example, a 90-kW peak power, 10-kW average power gyro-klystron amplifier has been developed at 94 GHz for radar applications. The device has an instantaneous bandwidth of 600 MHz, an efficiency of 33%, and operates with a 65-kV, 6-A electron beam.† A second device delivered the same average power at 700 MHz bandwidth, and it offers a 1-GHz bandwidth at 4-kW average power. This represents more than an order of magnitude higher average power than is available from any other amplifier technology at this frequency. Gyro-klystron amplifiers behave as coherent amplifiers of the input signal, and they have been demonstrated to have low phase noise comparable to that obtained from klystrons, with –147 dBc/Hz SSB phase noise at 10 MHz offset from the carrier in one experimental device when operated with a carrier at 200-kW output power at 35 GHz.‡

Experimental gyro-klystrons at high peak power levels in the microwave bands have also been developed for powering RF linear accelerators. Experimental devices designed for this application have achieved 27-MW peak power at 9.87 GHz at the fundamental (n = 1) cyclotron resonance device, and 32-MW peak power has been obtained at 19.76 GHz in a second harmonic (n = 2) device.§

Future efforts in the development of the cyclotron resonance or gyrotron-class of devices are directed toward higher power oscillators for fusion applications, more compact and efficient oscillators for industrial processing applications, and gyro-amplifiers such as the gyro-klystron and gyro-TWT for high-power millimeter-wave radar and accelerator applications.

FREE-ELECTRON LASERS

Free-electron lasers (which are also called ubitrons when applied to microwaves millimeter waves) consist of an electron beam propagating through a periodic transverse magnetic field (called a *wiggler* or *undulator*) that induces motion perpendicular to the axis of symmetry." A schematic illustration of a free-electron laser is shown in Fig. 34.

The wiggler and the radiation combine to produce a beat wave, which is essentially an interference pattern, that exerts a slowly varying ponderomotive force on the electrons. Because the electrons experience a near-constant field the interaction can be extremely strong. Stimulated emission occurs when electrons form coherent bunches over a wavelength. Bunching occurs because the ponderomotive wave has the same frequency (ω) as the radiation, but the wavenumber is the sum of the wavenumbers of the electromagnetic (k) and wiggler (k_w) fields. Hence, the beat wave travels more slowly than the light wave and can be in synchronism with the electrons when the phase velocity of the ponderomotive wave equals the electron beam velocity (v_b), i.e., $\omega/(k + k_w) = v_b$. The amplitude of the transverse velocity (v_w) is proportional to the product of the wiggler amplitude and period and inversely proportional to the relativistic dilation factor. Specifically,

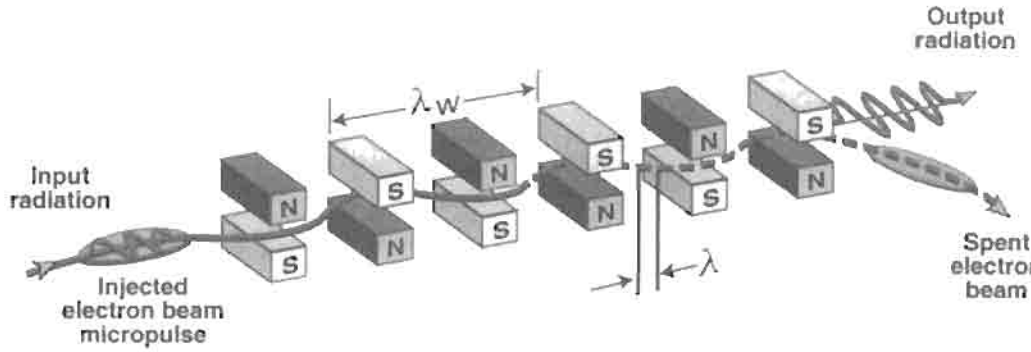

Fig. 34. A schematic of a typical free-electron laser.

$\nu_u = 0.934 B_u \lambda_u / \gamma_b$, where B_u denotes the wiggler amplitude in kG, λ_u is the wiggler period in cm, and $\gamma_b = 1 + E_b/m_e c^2$ (where E_b is the electron beam energy and $m_e c^2$ is the electron rest mass energy). As a result, for frequencies well above the waveguide cutoffs, the resonant wavelength is given by $\lambda = (1 + 0.872 B_u^2 \lambda_u^2)\lambda_u / 2\gamma_b^2$.

Because of the wavelength scaling, the free-electron laser is capable of producing very high frequency radiation when either high-energy beams or short-period wigglers are used. In practical applications, however, high gain requires high wiggler field amplitudes, which, in turn, precludes very short wiggler periods; hence, high-frequency operation can entail relatively high beam energies. This often precludes the use of standard power supplies and modulators, requiring instead relatively large and complex electron accelerators. As a result, free-electron lasers are principally useful when infrared or shorter wavelengths are needed.

At the present time, 10 free-electron laser user facilities are in operation (see Table 7) for a wide range of applications in materials and biomedical research. Most existing free-electron lasers operate at infrared wavelengths where the high-intensity picosecond pulses they produce are used to study principle excita-

tions in condensed matter systems where it is possible to access the principal excitations such as plasmons, phonons, magnons, and inter-sub-band transitions. Direct linear probing of defect modes and buried interfaces with bond specificity is possible. Free-electron lasers have been used for pump probe observation of coherent transient grating effects of narrow-gap semiconductors and third-order nonlinearity coefficients and electron relaxation times in GaAs/AlGaAs quantum wells. Studies in kinetics include vibrational energy transfers in molecules and resonant excitations of molecular vibrations. Applications to neurosurgery take advantage of particular absorption bands to produce an exceptionally fine cut in bone and tissue. At shorter wavelengths, free-electron lasers have been used to make measurements of time-resolved fluorescence decays of biological molecules, to study time-resolved photoemission, and photoionization.

There are two principal areas of future development for free-electron laser (FEL) technology: high average powers and ultra-short wavelengths. The high average power goal is several tens of kilowatts at infrared or shorter wavelengths, and the most likely configuration is an oscillator driven by a radio-frequency linear accelerator (rf linac). Rates of progress in the development of vacuum generators of coherent radiation can be gauged by using the power density (the product of the average power and the square of the frequency) as a figure of merit. The evolution of power densities in magnetrons, klystrons, gyrotrons, and FELs is shown in Fig. 35.

Significantly, although all the other vacuum tubes types listed have reached their technological limits, the ultimate limit for free-electron lasers has not yet been reached. The record FEL average power of 1.7 kilowatts at a 3-micron wavelength was achieved at the Thomas Jefferson Laboratory,* and an upgrade is currently under construction to reach 10 kW. Short-wavelength free-electron lasers are primarily directed toward research applications of X-rays at wavelengths down to 1 Å. Currently, the principal X-ray sources are synchrotrons, but FELs hold promise for substantial increases in the average brilliance. Since neither coherent sources nor mirrors exist at X-ray wavelengths, these free-electron lasers cannot operate either as coherent amplifiers or oscillators. Instead, these X-ray free-electron lasers are intended to operate in a mode referred to as self-amplified spontaneous emission (SASE) in which shot noise on the beam is amplified to high power levels during a single pass through a long undulator. Current designs† call for beam energies of the order of 14 GeV, peak beam currents of about 3400 A, and wigglers of the order of 100 m in length. Obviously, therefore, construction of these sources are clearly major financial undertakings.

GAS TUBES

A gas tube‡ is an electron tube in which the pressure of the contained gas is such as to affect substantially the electrical characteristics of the tube. Such effects are caused by collisions between moving electrons and

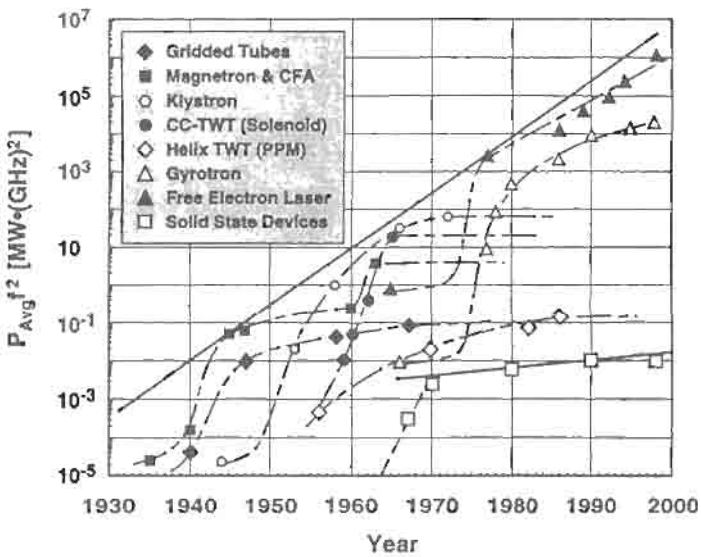

Fig. 35. Progression of device power density, $P_{av}f^2$, for major device types.

gas atoms. These collisions, if of sufficient energy, may dislodge an electron from the atom, thereby leaving the atom as a positive ion. The electron space charge is effectively neutralized by these positive ions, and comparatively high free-electron densities are easily created.

Table 8 gives the energy in electron volts necessary to produce ionization. The column headed P_c contains the kinetic-theory collision probability per centimeter of path length for an electron in a gas at 15°C at a pressure of 1 mm of mercury. The collision frequency is given by

$$\nu_c = P_c p_o v$$

where

ν_c = collisions per second
P_c = collision probability in collisions per centimeter per torr of pressure
p_o = reduced gas pressure in torr
v = electron velocity

Characteristics of Gas Tubes

Gas tubes may be generally divided into two classes, depending on whether the cathode is hot or cold and thus on the mechanism by which electrons are supplied.

Hot-Cathode Gas Tubes—The electrons in the hot-cathode gas tube are produced thermionically. The voltage drop across such tubes is that required to produce ionization of the gas and is generally a few tens of volts. The current conducted by the tube depends primarily on the emission capability of the cathode.

Fig. 37 shows the effect of the ionized gas on the voltage distribution in a hot-cathode tube.

TABLE 8. IONIZATION PROPERTIES OF GASES

Gas	Ionization Energy (eV)	Collision Probability P_c
Helium	24.5	12.7
Neon	21.5	17.5
Nitrogen	16.7	37.0
Hydrogen (H_2)	15.9	20.0
Argon	15.7	34.5
Carbon monoxide	14.2	23.8
Oxygen	13.5	34.5
Krypton	13.3	45.4
Water vapor	13.2	55.2
Xenon	11.5	62.5
Mercury	10.4	67.0

Cold-Cathode Gas Tubes—The electrons in a cold-cathode tube are produced by bombardment of the cathode by ions and/or by the action of a localized high electric field. The voltage drop across such a tube is higher than in the hot-cathode tube because of this mechanism of electron generation, and the current is limited. Fig. 38 shows the effect of tube geometry and gas pressure on the voltage required to initiate the discharge.

Fig. 39 shows a typical volt–ampere characteristic of a cold-cathode discharge. Cold-cathode gas tubes may be divided into two categories, depending on the region of this characteristic in which they operate. *Glow discharge tubes* require a drop of several hundred volts across the tube and operate in region II. The current is of the order of tens of milliamperes. *Arc discharge tubes* operate in region III. They are not, strictly speaking, cold-cathode tubes since the current is drawn from a localized spot on the cathode, which is consequently heated and provides a large thermionic current. The voltage drop is thus lowered. Such a tube is capable of conducting currents of thousands of amperes at voltage drops of tens of volts. Mercury-pool cathodes are used in one common form of arc discharge tube, supplying the electron current from an arc spot on the mercury-pool surface. The mercury vapor evaporated from the surface provides the gas atmosphere that is ionized.

Power Applications of Gas Tubes

Power rectifier and control tubes include mercury-vapor rectifiers, thyratrons, and ignitrons. These tubes employ the very high current-carrying capacity of gas discharge tubes with low power losses for rectification and control in high-power equipment. The operation of tubes depends on temperature insofar as mercury-vapor tube voltage drop and peak inverse voltages are concerned. (See Fig. 40.)

Hydrogen thyratrons are hot-cathode hydrogen-filled triodes designed for use as electronic switching devices where short anode delay time is important. In pulsing service, they are capable of switching tens of megawatts at voltages of tens of kilovolts. Anode delay time and time jitter are in the nanosecond range, and the tubes do not depend on ambient temperature for proper operation. Hydrogen thyratrons are also used in crowbar applications to protect other circuit components against fault voltages or currents and are capable of handling peak currents of several thousand amperes.

Triggered spark gaps are cold-cathode gas tubes operating in the arc discharge region (region III). The gaps contain two high-power electrodes and a trigger electrode, which is generally fired through a step-up pulse transformer by a simple low-energy pulse. The gaps are used as electronic switching devices for peak currents of tens of thousands of amperes and voltages of tens of kilovolts. They can discharge stored energies

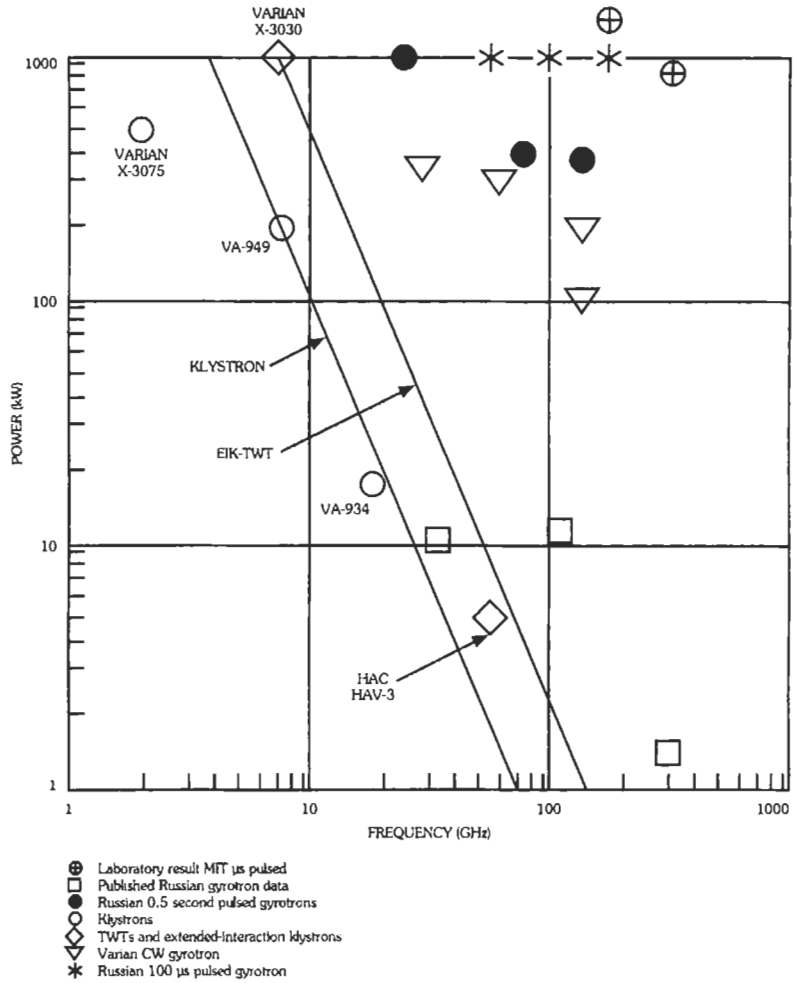

Fig. 36. Selected power output of high-frequency microwave tubes circa 1980.

(For an overview of the current state-of-the-art in high power millimeter-wave devices, see "Characteristics and applications of fast-wave gyrodevices," K. L. Felch, B. G. Danly, H. R. Jory, K. E. Kreischer, W. Lawson, B. Levush, and R. J. Temkin, *Proc. of the IEEE*, vol. 87, no. 5, pp. 752–781, May, 1999.)

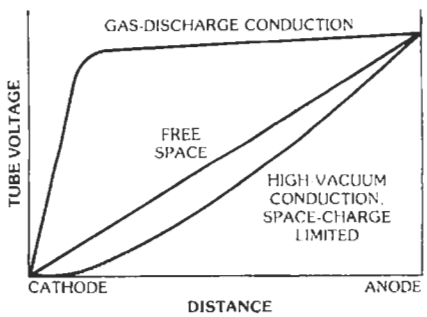

Fig. 37. Voltage distribution between plane parallel electrodes showing effect of space-charge neutralization in a hot-cathode gas tube.

of several thousand joules and are used for energy transfer in exploding-bridge-wire circuits, gas plasma discharges, spark chambers, and Keff cells. They are also used in crowbar applications for fast-acting protection of other circuit components against fault voltages and currents. Before conduction, the gap presents a low capacitance and a very high impedance to the circuit. After triggering, when the gap is conducting, the impedance drops to a few ohms or less.

Voltage regulators of the glow-discharge type take advantage of the volt–ampere characteristic in region II, where the voltage is nearly independent of the current. They operate at milliamperes and up to a few hundred volts.

Voltage regulators of the corona-discharge type operate at currents of less than a milliampere and at voltages up to several thousand volts.

Microwave Applications of Gas Tubes

Noise Sources—Gas-discharge devices possess a highly stable and repeatable effective noise temperature when in the fired condition. This feature provides a convenient and accurate means for determining the noise figure. The microwave energy radiated from a gas-discharge plasma is coupled into a radio-frequency transmission line with which it is used. The amount of radio-frequency power available from a gas-discharge tube depends mainly on the nature of the gas fill, the geometric characteristic of the discharge tube, and the electron temperature of the positive column or plasma. The design parameter that most strongly determines the noise temperature is the type of gas employed. Any of the noble gases may be used in a noise source. In practice, however, only two or three are normally used (see Table 9).

In referring to a noise source or generator, the ratio of its noise power output to thermal noise power is called the Excess Noise Ratio (ENR) and is defined by

$$F = ENR = \frac{\left[(T_2/T_0)-1\right]-Y\left[(T_1/T_0)-1\right]}{Y-1}$$

where

Y = ratio of the noise output power of the receiver with the noise generator on to that with the noise generator off
T_0 = 290 K
T_1 = temperature (in kelvins) of the termination
T_2 = effective noise temperature (in kelvins) of the noise generator in the fired condition

The expression $[(T_2/T_0)-1]$ is termed the excess noise power of the noise source. When $T_1 = T_0 = 290$ K

$$\text{ENR} = \left[(T_2/T_0)-1\right]/(Y-1)$$

$$\text{ENR(dB)} = 10\log_{10}\text{ENR}$$

The effective temperature of the noise source is equal to the temperature of the discharge only if the coupling of the transmission line to the discharge is complete. Otherwise, there is a reduction in the noise power output that can best be determined by measuring the fired and unfired insertion loss of the unit at the frequency of interest. The relation between these factors is given by

$$\left[(T_e/T_0)-1\right]/\left[(T_2/T_0)-1\right] = 1-\left(L_u/L_f\right)$$

where

$[(T_e/T_0)-1]$ is the effective excess noise power of the generator,
$[(T_2/T_0)-1]$ is the excess noise power, and
L_u and L_f are the insertion losses in the unfired and fired conditions, respectively.

TABLE 9. NOISE FIGURES FOR SOME NOBLE GASES

Gas	F = ENR(dB)

Neon	18.5
Argon	15.3

This correction should be subtracted from the apparent measured noise figure. The noise figure is always measured with reference to a standard temperature of 290 K (T_0). If the ambient temperature (T_1) of the noise-generator termination differs from the standard temperature, the noise figure calculated must be corrected. To find the correction factor, substitute the ambient temperature of the noise-generator termination for T_1, in the following equation, and add the temperature factor (F_T) to the noise figure calculated.

$$F_T = \left[Y/(Y-1)\right]\left[\left(T_1/T_0\right)-1\right]$$

TR Tubes—Transmit–receive (TR) tubes are gas-discharge devices designed to isolate the receiver section of radar equipment from the transmitter during the period of high power output. A typical TR tube and its circuit are illustrated in Fig. 41. The cones in the waveguide form a transmission cavity tuned to the transmitter frequency, and the tube conducts received low-power-level signals from the antenna to the receiver. When the transmitter is operated, however, the high-power signal causes gas ionization between the cone tips, which detunes the structure and reflects all the transmitter power to the antenna. The receiver is protected from the destructively high level of power, and all of the available transmitter power is useful output.

Microwave Gas-Discharge Circuit Elements—Because of the high free-electron density, the plasmas of gas discharges are capable of strong interaction with electromagnetic waves in the microwave region. In general, microwave phase shift and/or absorption result. If used in conjunction with a magnetic field, these effects can be increased and made nonreciprocal. Phase shift is a result of the change in dielectric constant caused by the plasma according to

$$\varepsilon_p/\varepsilon_0 = 1-\left(0.8\times10^{-4}N_0/f_s^2\right)$$

where

ϵ_p = dielectric constant in the plasma
ϵ_0 = dielectric constant in free space
N_0 = electron density in electrons/cm^3 = signal frequency in megahertz
f_s = signal frequency in megahertz

Absorption of microwave energy results when electrons, having gained energy from the electric field of the signal, lose this energy in collisions with the tube envelope or neutral gas molecules. This absorption is a maximum when the frequency of collisions is equal to the signal frequency and the absolute magnitude is proportional to the free-electron density.

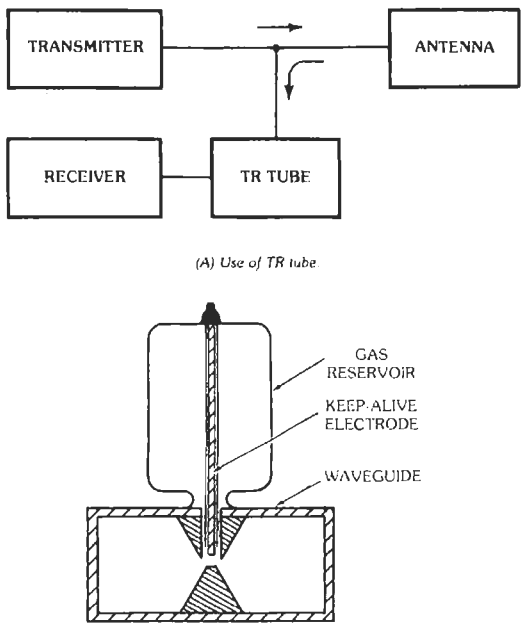

Fig. 41. Transmit–receive tube.

LIGHT-SENSING AND LIGHT-EMITTING TUBES

Radiometry and Photometry*

Radiometric and photometric systems are generally based on the concept of radiated flux, where flux is defined as the total amount of radiation passing through a unit area per unit time. If a flux is measured in terms of its thermal heating ability, the most common unit is the watt, and the resultant measurement system is referred to as radiometry. If a flux is measured in terms of its ability to stimulate the standard photopic human eye, the resultant unit is the lumen, and the resultant measurement system is called photometry. A third choice for the measurement of flux is the number of photons per unit time. These three choices, in conjunction with the mks system of units, lead to the three mutually compatible systems of units shown in Table 10. Table 11 gives equivalents among units in different photometric measurement systems.

Flux Units

The number of lumens $dL\lambda$ and the number of photons per second $dN\lambda$ associated with a monochromatic flux $dW\lambda$ in watts are given by

$$dL_\lambda = 680E_\lambda dW_\lambda \text{ and } dN_\lambda = (\lambda/hc)dW_\lambda$$

where

680 = number of lumens per watt of radiation at the peak photopic eye response

* See also Chapter 21.

TABLE 10. COMPATIBLE SYSTEMS OF RADIATION UNITS

Parameter	Radiometric System	Photometric System	Photon System
Flux	watt	lumen	photon s^{-1}
Source intensity	watt sr^{-1}	lumen sr^{-1}	photon s^{-1} sr^{-1}
Incidence	watt m^{-2} (irradiance)	lumen m^{-2} (illuminance)	photon s^{-1} m^{-2}
Excitance	watt m^{-2} (emittance)	lumen m^{-2} (emittance)	photon s^{-1} m^{-2}
Sterance	watt sr^{-1} m^{-2} (radiance)	lumen sr^{-1} m^{-2} (luminance)	photon s^{-1} sr^{-1} m^{-2}
Energy	watt second	lumen second	photon

Note: The terms in parentheses are often used to characterize a measurement as either radiometric or photometric.

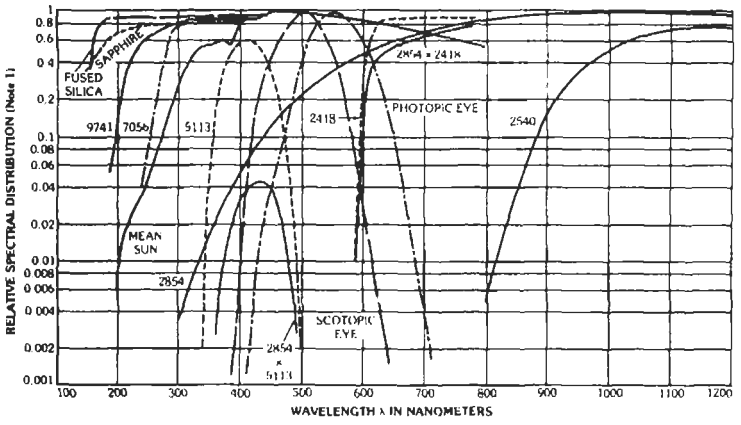
E_λ = normalized (to unity maximum) photopic human eye response (Fig. 42)
λ = wavelength of the monochromatic radiation (m)
h = Planck's constant $\simeq 6.6 \times 10^{-34}$ (J · s)
c = velocity of light $\simeq 3.0 \times 10^8$ (m/s)

The number of lumens L and the number of photons per second N between the wavelength units of λ_3 to λ_4 associated with a distributed spectral radiation source having a wattage W between the wavelength limits λ_1 and λ_2 are given by

$$L/W = 680\int_0^\infty E_\lambda w_\lambda d\lambda \Big/ \int_{\lambda_1}^{\lambda_2} w_\lambda d\lambda$$

and

$$Nhc/W = \int_{\lambda_3}^{\lambda_4} \lambda w_\lambda d\lambda \Big/ \int_{\lambda_1}^{\lambda_2} w_\lambda d\lambda$$



Fused silica: transmission through polished "Suprasil" (1 millimeter thick)
Sapphire: transmission through polished Sapphire (1 millimeter thick)
9741: transmission through polished Corning 9741 glass (1 millimeter thick)
7056: transmission through polished Corning 7056 glass (1 millimeter thick)
Mean sun: mean solar distribution at Earth's surface
5113: transmission through polished Corning 5113 filter (CS-5-58) (half-stock thickness)
2854 × 5113: product of 5113 curve and 2854 curve
2854: spectral density distribution of 2854 K color-temperature tungsten lamp
Scotopic eye: relative response of dark-adapted eye
Photopic eye: standard eye response
2418: transmission through polished Corning 2418 filter (CS-2-62) (stock thickness)
2854 × 2418: product of 2854 and 2418 curves
2540: transmission through polished Corning 2540 filter (CS-7-56) (stock thickness)

Note 1: "Relative spectral distribution" designates the relative radiant-energy density distribution w_λ for sources, the relative visual stimulation for equienergy inputs for the eye response, and the spectral transmission t_λ for windows and filters. The transmission characteristics of individual filter and window samples can be expected to depart appreciably from these typical values.

Fig. 42. Useful spectral distributions.

where

$$W = w_{\lambda\max}\int_{\lambda_1}^{\lambda_2} w_\lambda d\lambda$$

and where

$w\lambda_{max}$ = maximum spectral density in watts per unit wavelength in the spectral band between λ_1 and λ_2,
w_λ = relative spectral distribution of the radiation source on thermal-energy basis, normalized to a maximum value of unity.

Typical w_λ spectral distributions are in Fig. 42.

Optical Imaging

In an optical lens system of flux-gathering diameter D_f in meters, focal length f in meters, and optical transmittance T, the ratio $f/D_f = n_f$ is called the f-number of the lens. If the surface of an object of radiance or luminance B in flux units per steradian per meter^2 is imaged by this system with a linear magnification m, and if we assume Lambertian emittance characteristics over the solid angle subtended by the optical system, the image will be subjected to an irradiance or illuminance I_L in flux units per meter^2 given by

$$I_L = \pi BT/\left[4n_f{}^2(m+1)^2 + m^2\right]$$

For objects at infinity, $m = 0$, and

$$I_L\,(\text{object at infinity}) = \pi BT/4n_f{}^2$$

If the irradiance (or illuminance) I_L in flux units per meter^2 is allowed to fall on a nonabsorbing Lambertian diffusing surface, the resultant image radiance (or luminance) B_i in flux units per steradian per meter^2 is given by

$$\Pi B_i = I_L.$$

Any desired method of measuring flux units, such as watts, lumens, or photons/second (Table 11), can be selected for expressing the object radiance (or luminance) B in flux units steradian^{-1} meter^{-2} and the irradiance (or illuminance) I_L in flux units meter^{-2} in these relationships. Thus, a radiance B in watts steradian^{-1} meter^{-2} would be paired with an irradiance I_L in watts meter^{-2}, a luminance B in lumens steradian^{-1} meter^{-2} with an illuminance I_L, in lumens meter^{-2}, and a radi-

ance B in photons second^{-1} steradian^{-1} meter^{-2} with an irradiance I_L in photons second^{-1} meter^{-2}.

Any spectral distribution modifications, if present, would be included in the numerical magnitude of the lens transmission T, defined as the ratio of the total output flux from the optical system to the corresponding input flux.

Selection of appropriate alternative pairs of luminance and illuminance units when the flux units are not explicitly stated (first column of Table 11) must be made with care. Thus candle centimeter^{-2} (or stilb) would be paired with phot, candle meter^{-2} (or nit) with lux, and candle foot^{-2} with footcandle. Even greater difficulty arises when the factor Π in the preceding relationships is absorbed or included in the units of luminance. Thus the product ΠB in apostilbs would be paired with I_L in lux, the product ΠB in lamberts with I_L in phots, the products ΠB in millilamberts with I_L in milliphots, and the product ΠB in footlamberts with I_L in footcandles. These difficulties are avoided by the use of the compatible systems of radiation units shown in Table 10.

Typical Approximate Illumination Values at the Surface of the Earth

Sun at zenith $\simeq 10^4$ footcandles
$\simeq 10^5$ lumens meter^{-2}
Full moon $\simeq 3 \times 10^{-2}$ footcandles
$\simeq 3 \times 10^{-1}$ lumens meter^{-2}

Typical Approximate Brightness Values

	footlamberts	lm sr^{-1} m^{-2}
Highlights, 35-millimeter movie	$\simeq 4$	$\simeq 100$
Page brightness for reading fine print	$\simeq 10$	$\simeq 3 \times 10^2$
November football field	$\simeq 50$	$\simeq 1.5 \times 10^3$
Surface of moon seen from Earth	$\simeq 1.5 \times 10^3$	$\simeq 5 \times 10^4$
Summer baseball field	$\simeq 3 \times 10^3$	$\simeq 10^5$
Surface of 40-watt frosted lamp bulb	$\simeq 8 \times 10^3$	$\simeq 2.5 \times 10^5$
Crater of carbon arc	$\simeq 4.5 \times 10^7$	$\simeq 10^9$
Sun seen from Earth	$\simeq 5.2 \times 10^8$	$\simeq 1.5 \times 10^{10}$

LIGHT-SENSING TUBES

Image Tubes and Image Intensifiers

An image tube* is an optical-image-in to optical-image-out electron-tube device, combining an input photocathode and an output phosphor screen such that photoelectrons emitted from each point on the photocathode subsequently excite a corresponding individual image "point" on the phosphor screen. Various focusing means, including magnetic and electrostatic electron lenses, may be used to assure maximum point-to-point correlation between the input and output images. The principal operating requirements are a lens to form the input image and a high-voltage supply, typically 5–25 kilovolts, to provide sufficient electron-beam energy to excite the output phosphor screen.

If means are provided within the image tube to amplify the photoelectrons before they strike the output phosphor screen, or if the tube without such means produces a much brighter output image than the input image would produce on a diffusing screen, the tube is commonly called an image-intensifier tube.

Image-intensifier tubes are used to amplify the brightness of a faint input image for better visual or photographic viewing, whereas image tubes without amplification are used to convert radiation from one spectral region to another (image conversion) or to perform such control operations as optical shuttering by programming the applied high voltage.

The total output flux dW_o, in watts exiting (through 2Π steradians) from the phosphor-screen faceplate of an image-intensifier tube for an input monochromatic flux dW_λ in watts at a wavelength λ is given by

$$dW_o = s_\lambda G \mathscr{E}_w (V - V_k) dW_\lambda$$
$$= G_\lambda dW_\lambda$$

where

G_λ = monochromatic wattage gain of the image-intensifier tube at a wavelength λ-ratio of the total output flux dW_o in watts to the input monochromatic flux dW_λ in watts
s_λ = radiant sensitivity of the input photocathode in amperes per watt (see Fig. 13, Chapter 21)
G = internal current gain ratio of the image-intensifier tube = ratio of the current bombarding the output phosphor screen to the corresponding photocurrent leaving the input photocathode
$\mathscr{E}_w$ = absolute phosphor efficiency = ratio of the total radiated flux in watts to the exciting electron-beam power in watts dissipated in the particles of the output phosphor screen
V = energy of the electron beam in volts bombarding the output phosphor screen
V_k = extrapolated knee voltage of the output phosphor screen.

If the phosphor screen radiates flux according to Lambert's law (usually only approximately valid), the

---

* *Photo-Electrical Image Devices*, Advances in Electronics and Electron Physics, Vols. 12, 16, 22A, and 22B (New York and London: Academic Press, 1960, 1962, and 1966), H. V. Soule, *Electro-Optical Photography at Low Illumination Levels* (New York: John Wiley & Sons, 1968).

corresponding output image radiance R_o, in watts steradian^{-1} meter^{-2} is given by

$$R_o = G_{\lambda 1} I_{\lambda 1} / \Pi m^2$$

where

$I\lambda_1$ = input image irradiance on the photocathode expressed in watts meter^{-2} at the wavelength λ_1.
m = differential magnification ratio of the image tube = output incremental image size divided by the corresponding input incremental image size.

For a spectrally distributed input flux having a known relative spectral distribution w_λ and a known total radiated power $W_{\lambda 1 \lambda 2}$ in watts between the wavelength limits λ_1 and λ_2, the resulting total output flux W_o, in watts exiting from the image tube, is given by

$$W_o = s_{\lambda \max}\left(\int_0^\infty \sigma_\lambda w_\lambda d\lambda \Big/ \int_{\lambda_1}^{\lambda_2} w_\lambda d\lambda\right) \times G\mathscr{E}_w (V - V_k) W_{\lambda 1 \lambda 2}$$
$$= G_{\lambda 1 \lambda 2} W_{\lambda 1 \lambda 2}$$

where

$s_{\lambda_{max}}$ = peak radiant sensitivity of the input photocathode in amperes per watt
σ_λ = relative radiant sensitivity of the input photocathode as a function of wavelength λ normalized to unity maximum
w_λ = relative spectral distribution of the power density spectrum of the input flux normalized to unity maximum
$G_{\lambda_1 \lambda_2}$ = wattage gain of the image tube for the relative spectral distribution w_λ and the wavelength limits λ_1 and λ_2.

Typical values for the magnitude of the dimensionless spectral-matching-factor ratio are given by

$$\int_0^\infty \sigma_\lambda w_\lambda d\lambda \Big/ \int_{\lambda_1}^{\lambda_2} w_\lambda d\lambda$$

The total output flux L_o, in lumens exiting from an image tube, corresponding to the total output flux W_o in watts, can be computed from the flux conversion relationships given in the section on radiometry and photometry, or from the following relationship

$$L_o = s_{\lambda \max}\left(\int_0^\infty \sigma_\lambda w_\lambda d\lambda \Big/ \int_0^\infty E_\lambda w_\lambda d\lambda\right) \times G\mathscr{E}_w \left(\int_0^\infty E_\lambda w_{o\lambda} d\lambda \Big/ \int_0^\infty w_{o\lambda} d\lambda\right) (V - V_k) L_i$$
$$= G_L L_i$$

where

G_L = luminous gain of the image intensifier tube = ratio of the output flux in lumens to the corresponding input flux in lumens for the spectral input distribution w_λ
E_λ = standard tabulated average relative photopic eye response
$w_{o\lambda}$ = relative spectral density distribution of the output flux
L_i = input flux in lumens

The typical values of the dimensionless spectral matching factors can be used to determine the magnitude of the dimensionless integral ratios appearing in these relationships. For the special case where the input flux $L_i(2854)$ in lumens is generated by a 2854 K color-temperature tungsten-filament lamp, the output flux $L_o(2854)$ in lumens is given by

$$L_o(2854) = S(2854) G\mathscr{E}_w \left(\int_0^\infty w_{o\lambda} E_\lambda d\lambda \Big/ \int_0^\infty w_{o\lambda} d\lambda\right) \times (V - V_k) L_i(2854)$$
$$= G_L(2854) L_i(2854)$$

where

$G_L(2854)$ = luminous gain of the image intensifier for 2854 K tungsten-lamp radiation
$S(2854)$ = luminous sensitivity of the input photocathode for 2854 K tungsten-lamp radiation

The magnitude of the luminous gain $G_L(2854)$ is commonly used to characterize the image intensification properties of an image-intensifier tube.

If the output phosphor screen radiates flux according to Lambert's law (usually only approximately valid), the output image luminance (or brightness) B_o in lumens steradian^{-1} meter^{-2} is given by

$$B_o = G_L I_i / \pi m^2$$

where

G_L = luminous gain of the image intensifier for input spectral distribution w_λ
I_i = input illuminance (or illumination) on the photocathode in lumens meter^{-2} for the spectral distribution w_λ
m = differential magnification ratio of the image tube = output incremental image size divided by the corresponding input incremental image size

Internal current gain G of an image-intensifier tube can be obtained by the use of an internal sandwich electrode, in which an auxiliary or sandwich photocathode is mounted in close proximity to and following an auxiliary or sandwich phosphor. Photoelectrons from the input photocathode of the tube are then imaged onto this sandwich phosphor screen, and the flux from this screen is coupled to the sandwich photocathode, generating an enhanced photocurrent. The current gain ratio G of this sandwich phosphor-photocathode combination, defined

as the ratio of output photocurrent to input photocurrent, is given by

$$G = s_{\lambda\,\max,\,\text{sand}} \left(\int_0^\infty w_{\lambda(\text{sand})} \sigma_{\lambda(\text{sand})} d\lambda \Big/ \int_0^\infty w_{\lambda(\text{sand})} d\lambda \right) \mathscr{E}_{w,\,\text{sand}} \left(V_{\text{sand}} - V_{k,\,\text{sand}} \right) \gamma$$

where

$s_{\lambda\,\max,\,\text{sand}}$ = peak monochromatic responsivity of the sandwich photocathode in amperes watt^{-1}

$w_{\lambda\,(\text{sand})}$ = relative spectral distribution of the flux emitted by the sandwich phosphor screen

$\sigma_{\lambda\,(\text{sand})}$ = the relative spectral distribution of the sandwich photocathode

$\mathscr{E}_{w,\,\text{sand}}$ = absolute efficiency of the sandwich phosphor screen in watts watt^{-1}

V_{sand} = electron beam energy in volts bombarding the sandwich phosphor screen

$V_{k,\,\text{sand}}$ = extrapolated knee voltage in volts for the sandwich phosphor screen

γ = optical coupling efficiency of the sandwich electrode = ratio of the flux falling onto the sandwich photocathode to the corresponding flux emitted by the sandwich phosphor screen

The combination of a phosphor screen and a photocathode to produce current gain G can also be achieved by optically coupling the output flux from one image tube to the input of a second tube.

Resolution in image tubes and image-intensifier tubes is a subjective parameter describing the number of pairs of equally spaced illuminated and unilluminated bars per unit distance at the photocathode imaged onto the input photocathode surface that can just be distinguished visually by a trained observer under stated test conditions.

Distortion is a parameter describing any change in the geometric shape of the output image compared with the input image. Radially increasing magnification leads to "pincushion" distortion; radially decreasing magnification leads to "barrel" distortion; and radially changing image rotation leads to "S" distortion.

Gas Photodiodes

In diode phototubes not containing a high vacuum, ionization by collision of electrons with neutral molecules may occur so that more than one electron reaches the anode for each originally emitted photoelectron. This "gas amplification factor" has a value of between 3 and 5; a higher factor causes instabilities. Gas-tube operation is restricted to frequencies below about 10 000 hertz.

Image Orthicons

The image orthicon* is a camera tube that is widely used for commercial television. This fact derives from its high sensitivity, its close spectral-sensitivity match to the human eye, and its relatively fast response. Good quality commercial television pictures can be generated by an image orthicon viewing a 5-to-20-footlambert (≃15–50 lumen steradian^{-1} meter^{-2}) scene through an f/5.6 lens. The image orthicon is generally available with either S-10 or S-20 spectral response (see Fig. 13, Chapter 21) and is capable of 500 picture elements per raster height (9.9 line pairs/millimeter) at 30% video-amplitude response.

Principle of Operation—Fig. 43 is a diagram of an image orthicon. In the image section, a light image incident on the translucent photocathode liberates photoelectrons into the adjacent vacuum region in proportion to the light intensity (gamma is unity) on each

* A. Rose, P. K. Weimer, and H. B. Law, "The image orthicon—A sensitive television pickup tube," *Proceedings of the IRE*, vol. 34, no. 7, pp. 424–432, July, 1946.

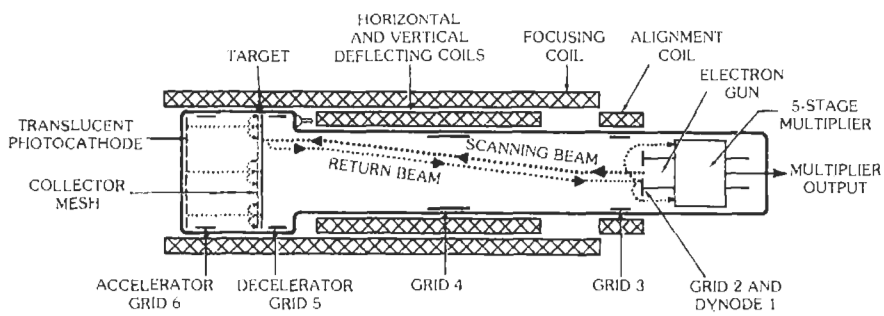


Fig. 43. Image orthicon. (*By permission of RCA, copyright proprietor.*)

element of the cathode. These photoelectrons are accelerated toward and magnetically focused onto the surface of a thin semiconducting target. Electrons strike this target with sufficient energy to liberate a larger number of secondary electrons (typically five) for each incident primary. The secondary electrons are collected by a mesh closely spaced from the target membrane. Hence, by depletion of electrons from the thin membrane, incremental areas become positive in proportion to the number of photoelectrons striking each element. In cases of high-light-level operation, parts of the target may become charged to target (collector) mesh potential, and saturation charge results. This phenomenon accounts for the so-called "knee" in the signal-versus-illumination transfer curve (Fig. 43).

Because the target membrane is very thin, of the order of microns, a charge distribution pattern formed on the image-section surface appears nearly simultaneously and identically on the scanning-section surface.

In the scanning section, an electron gun generates a highly apertured electron beam from a fraction to tens of microamperes in intensity. A solenoidal magnetic-focus coil and saddle-type deflection coils surrounding the scan section focus this beam on the insulator target and move it across the target. Scan-beam electrons impinge on the target at very low velocity, giving rise to relatively few secondary electrons. The target acts somewhat as a retarding-field electrode and reflects a large number of the beam electrons that have less than average axial velocity. These two phenomena—small but finite secondary emission and reflection of slow beam electrons—limit scan-beam modulation to a maximum of about 30% at high light levels, and to 2 orders less at threshold. As will be shown later, the large unmodulated return beam current is the primary source of noise in the image orthicon.

Another problem created by the retarding-field aspect of low-velocity target scanning appears when the deflected beam does not strike the target normally. Since the entire beam-velocity component normal to the surface is now reduced by the cosine of the angle of incidence, the effective beam impedance is greatly increased. To overcome this problem, the decelerating field between grids 4 and 5 is shaped such that the electron beam always approaches normal to the plane of the target at a low velocity. If the elemental area on the target is positive, then electrons from the scanning beam deposit until the charge is neutralized. If the elemental area is at cathode potential (corresponding to a dark picture area), no electrons are deposited. In both cases, the excess beam electrons are turned back and focused into a five-stage electron multiplier. The charges existing on either side of the semiconductive target membrane will, by conductivity, neutralize each other in less than one frame time. Electrons turned back at the target form a return beam that has been amplitude-modulated in accordance with the charge pattern of the target.

The return beam is redirected by the deflection and focus fields toward the electron gun where it originated. Atop the electron gun, and forming the final aperture for that gun, is a flat secondary-emitting surface comprising the first dynode of the electron multiplier. The return beam strikes this surface, generating secondary electrons in a ratio of approximately 4:1.

Grid 3 facilitates a more complete collection by dynode 2 of the secondary electrons emitted from dynode 1. The gain of the multiplier is high enough that in operation the limiting noise is the shot noise of the returned electron beam rather than the input noise of the video amplifier.

Signal and Noise—Typical signal output currents for tube types 5820 and 5826 are shown in Fig. 44. The tubes should be operated so that the highlights on the photocathode bring the signal output slightly over the knee of the signal-output curve.

The spectral response of type 5820 and 5826 image orthicons is shown in Fig. 45. Note that when a Wratten 6 filter is used with the tube, a spectral curve closely approximating that of the human eye is obtained.

From the standpoint of noise, the total television system can be represented as shown in Fig. 46, where I_s = signal current, I_n = total image-orthicon noise current, E_{nt} = thermal noise in R_1, E_{ns} = shot noise in the input amplifier tube, R_1 = input load, C_1 = total input shunt capacitance, and R_t = shot-noise equivalent resistance of the input amplifier = $2.5/g_m$ for triode or cascode input = $[I_b/(I_b + I_c)][(2.5/g_m) + (20I_{c2}/g_m^2)]$ for pentode input, with g_m = transconductance of input tube or cascode combination, I_b = amplifier direct plate current, and I_c = amplifier direct screen-grid current.

The noise added per stage is

$$\Delta n = \left[\sigma/(\sigma - 1)\right]^{1/2}$$

where σ = stage gain in the multiplier. For a total multiplier noise figure to be directly usable, it must be referred to the first-dynode current; therefore, for five multiplier stages

$$\overline{\Delta N} = \Delta n^2 + \frac{\Delta n^2}{\sigma^2} + \frac{\Delta n^2}{\sigma^4} + \frac{\Delta n^2}{\sigma^6} + \frac{\Delta n^2}{\sigma^8}$$

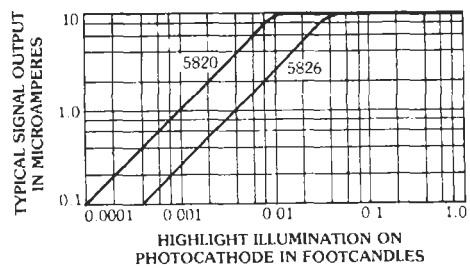

Fig. 44. Basic light-transfer characteristic for type 5820 and 5826 image orthicons. The curves are for small-area highlights illuminated by tungsten light, white fluorescent light, or daylight. (*By permission of RCA, copyright proprietor.*)

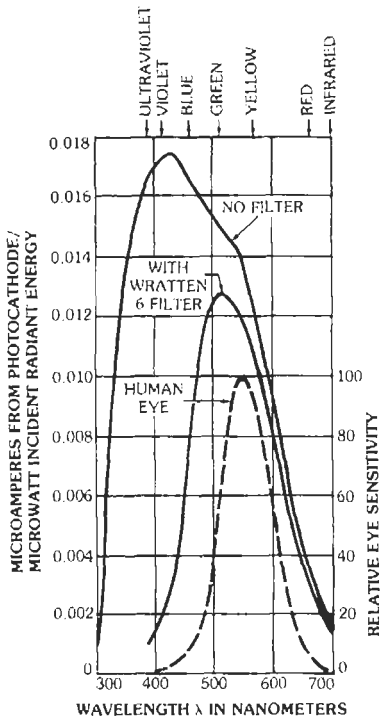

Fig. 45. Spectral sensitivity of image orthicon. (*By permission of RCA, copyright proprietor.*)

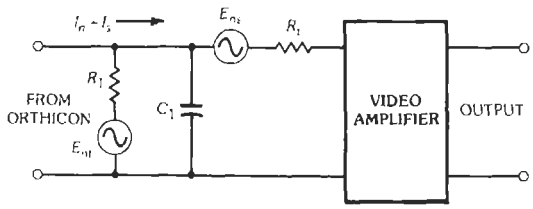

Fig. 46. Equivalent circuit for noise in orthicon and first amplifier stage.

where ΔN = electron-multiplier noise factor referred to multiplier input.

After combining all noise sources

$$\frac{S}{N} = \frac{I_s}{\left\{F\left[2eIk_m^2 + 4kT\left(\frac{1}{R_1} + \frac{R_t}{R_1^2} + \frac{\omega^2 C_1^2 R_t}{3}\right)\right]\right\}^{1/2}}$$

where

S/N = signal-to-noise ratio
F = bandwidth in hertz
e = electron charge = 1.6×10^{-19} coulomb
I = image-orthicon beam current
k_m = electron-multiplier noise factor, referred to multiplier output $m\Delta N$
k = Boltzmann's constant = 1.38×10^{-23} joule/kelvin
T = absolute temperature in kelvins
$\omega = 2\pi f$ in hertz

The signal current is an alternating-current signal superimposed on a larger direct beam current. This can be thought of as a modulation of the beam current. Properly adjusted tubes obtain as much as 30% modulation.

$$I_s = mMI$$

where

m = multiplier gain
M = percentage modulation

If S/N is now rewritten,

$$\frac{S}{N} = \frac{I_s}{\left[4kTF\left(\frac{2eI_s m\overline{\Delta N^2}}{4kTM} + \frac{1}{R_1} + \frac{R_t}{R_1^2} + \frac{\omega^2 C_1^2 R_t}{3}\right)\right]^{1/2}}$$

In typical television operation, the thermal noise of the load resistor and the shot noise of the first amplifier can be neglected.

Focusing and Scanning Fields—The electron optics of the scanning section of the tube are quite complicated, and space does not permit the inclusion of the complete equations. A simple relationship between the strength of the magnetic focusing field and the magnetic deflection field is given below.

The image orthicon is usually operated with multiple-node focus in the scanning section. Working at a multiple-node focus not only demands more focus current but also more deflection current. Note the deflection path in Fig. 47. Let H = horizontal dimension of scanned area or target, L = effective length of horizontal deflection field, H_d = horizontal deflection field (peak-to-peak value), and H_f = focusing field. Then

$$H_d = H_f H/L$$

For the image orthicon, $H \approx 1.25$ inches, and $L \approx 4$ inches. Thus $H_f \approx 75$ gauss, and $H_d \approx 23$ gauss.

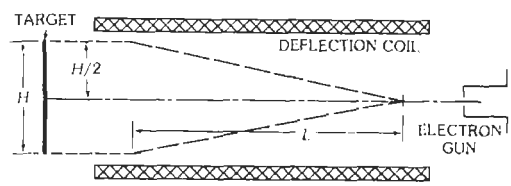

Fig. 47. Deflection in image orthicon.

Vidicons

The vidicon* is a small television camera tube that is used primarily for industrial television, space application, and studio film pickup because of its small size and simplicity.

As shown in Fig. 48, the tube consists of a signal electrode composed of a transparent conducting film on the inner surface of the faceplate, a thin layer (a few micrometers) of photoconductive material deposited on the signal electrode, a fine mesh screen (grid 4) located adjacent to the photoconductive layer, a focusing electrode (grid 3) connected to grid 4, and an electron gun.

Principle of Operation—Each elemental area of the photoconductor can be likened to a leaky capacitor with one plate electrically connected to the signal electrode that is at some positive voltage (usually about 20 volts) with respect to the thermionic cathode of the electron gun and the other plate floating except when commutated by the electron beam. Initially, the gun side of the photoconductive surface is charged to cathode potential by the electron gun, thus leaving a charge on each elemental capacitor. During the frame time, these capacitors discharge in accordance with the value of their leakage resistance, which is determined by the amount of light falling on each elemental area. Hence, there appears on the gun side of the photoconductive surface a positive-potential pattern corresponding to the pattern of light from the scene imaged on the opposite surface of the layer. Even those areas that are dark discharge slightly, since the dark resistivity of the material is not infinite.

The electron beam is focused at the surface of the photoconductive layer by the combined action of the uniform magnetic field and the electrostatic field of grid 3. Grid 4 serves to provide a uniform decelerating field between itself and the photoconductive layer such that the electron beam always approaches the surface normally and at a low velocity. When the beam scans the surface, it deposits electrons where the potential of the elemental area is more positive than that of the electron-gun cathode. At this moment the electrical circuit is completed through the signal-electrode circuit to ground. The amount of signal current depends on the amount of discharge in the elemental capacitor, which in turn depends on the amount of light falling on this area.

Alignment of the beam is accomplished by a transverse magnetic field produced by external coils located at the base end of the focusing coil.

Deflection of the beam is accomplished by the transverse magnetic fields produced by external deflecting coils.

Signal and Noise—Because the vidicon acts as a constant-current generator as far as signal current is concerned, the value of the load resistor is determined by bandpass and noise considerations in the input circuit of the video amplifier. Unlike the image orthicon, the vidicon has the signal current removed at the target, and only that portion of the scan beam actually involved in the target discharge contributes shot noise. Moreover, electron-beam contributions to noise are minimal for low-light portions of the scene.

The primary noise associated with vidicon operation is seldom scan-beam shot noise. Where the signal current is less than 1 microampere and the bandpass is relatively wide, the principal noise in the system is contributed by the input circuit and the first stage of the video amplifier. To minimize the thermal noise of the load resistor, its resistance is made much higher than flat-bandpass considerations would indicate, as signal voltage increases directly and noise voltage increases as the square root. To correct for attenuation of the signal with increasing frequency, the amplitude response of the video amplifier frequently employs high-frequency boost of the following form, where C_1 and R_1 refer to Fig. 49:

$$G = G_0\left(1+4\pi^2F^2C_1^2R_1^2\right)^{1/2}/R_1$$

A representative plot of amplitude response as a function of the number of television lines (per raster height) is shown in Fig. 50.

The vidicon has somewhat more lag or image persistence than the image orthicon. This is the result of two factors. To obtain high-sensitivity surfaces, the

photoconductive decay time is made as long as tolerable, because quantum efficiency is limited by the ratio of effective carrier lifetime to carrier transit time across the photoconductor. A second source of lag is simply the *RC* time constant of the target recharging circuit, that is, the target capacitance and the beam impedance.

The spectral response of most commercial vidicons designated S-18 is more actinic than that of the human eye. Fig. 51 compares these responses with the spectrum of a 2854 K tungsten source.

Variations of the Vidicon

Interest in optical guidance and surveillance from aircraft and spacecraft has given rise to a wide variety

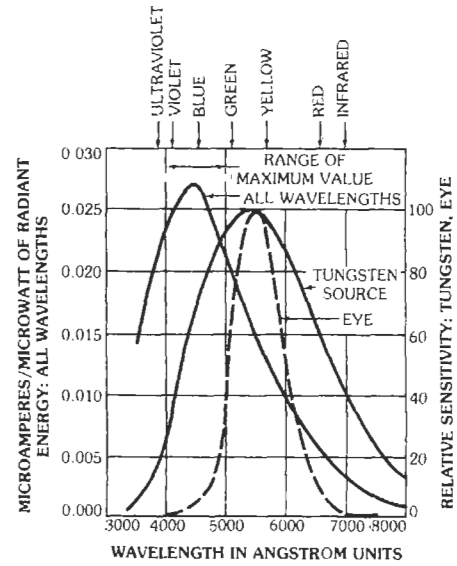

Fig. 51. Spectral response of vidicon. (*By permission of RCA, copyright proprietor.*)

of vidicon camera tubes. To treat these variations in detail becomes encyclopedic, but the following gives some indication of the choices now available to the user.

Effective Sensitivity—True photoconductive tubes now offer sensitivities of 150–200 nanoamperes for 1/2-footcandle illumination with 20 nanoamperes dark current. Improved methods of deposition of photoconductors have made possible higher-voltage operation without objectionable dark shading. Special devices using junction effects promise even better sensitivity.

Spectral Response—Available photoconductors, taken as a whole, provide sensitivity over the entire visible range with usual (7056) glass windows. Quartz-window tubes offer useful sensitivity to below 2000 angstroms. Numerous applications of direct excitation of photoconductors by X-radiation have been reported. High-velocity electron excitation (bombardment-induced conductivity) is also in use.

Size and Deflection—Vidicons are available in sizes ranging from 1/2 inch to 2 inches in diameter. Various combinations of deflection and focus are available.

Storage—A number of manufacturers have produced vidicons with long-storage characteristics. Many are merely long-lag tubes; however, a few rely on high-resistivity materials or on barrier layers to retain stored charge through minimal dark current. One such device, once exposed properly to a scene, regenerates the scene through readout over a period of the order of half an hour.

LIGHT-EMITTING TUBES

Cathode-Ray Tubes

A cathode-ray tube (CRT)* is a vacuum tube in which an electron beam, deflected by applied electric or magnetic fields, produces a trace on a fluorescent screen. Cathode-ray tubes have many uses; the most popular is the television (TV) display. Other uses include radar displays, oscillography, and visual displays for computer terminals.

Principle of Operation—The function of the cathode-ray tube is to convert an electrical signal into a visual display. The tube contains an electron-gun structure (to provide a narrow beam of electrons) and a phosphor screen. The electron beam is directed to the phosphor screen and strikes it, causing light to be emitted in a small area or spot in proportion to the intensity of the electron beam. The beam intensity varies as a function of the beam-control element in the electron gun. In a TV or computer-display CRT, the electrical signal that controls the beam intensity corresponds to the desired picture information and is referred to as the video signal. Although one spot or picture element is not enough to reproduce a picture, by moving the spot over the entire screen in a systematic manner, the complete picture can be reproduced.

For oscilloscope use, the deflection of the beam at the screen is proportional to the voltages applied to the deflection electrodes within the tube, and a visual picture of time-dependent waveforms can be produced on the screen in the same manner as a graph is drawn on paper.

Electrostatic Deflection—Electrostatic deflection is generally used in oscillography where high-frequency signals need to be analyzed. Electrostatic deflection requires little power, and deflectors can be designed to perform at extremely high frequencies. Electrodes placed within the tube (Fig. 52) form an electric field perpendicular to the electron path. Deflection is determined by the voltage across the electrodes, the accelerating voltage, and the distance to the screen. For high sensitivity, the accelerating voltage in the gun needs to be low, but for high brightness, the accelerating voltage at the screen needs to be high. Some form of post-deflection acceleration (PDA) is therefore required. The most common form of PDA uses a dome-shaped mesh at the end of the electron gun to form a scan-expansion lens. The mesh is maintained at gun voltage (2000 V), and the conductive coating in the glass envelope is maintained at a higher voltage (20 000 V). The resultant electric field between the mesh and this conducting surface causes an outward radial force on the electrons so that their angle from the gun is increased and scan magnification

occurs. A typical mesh-type PDA CRT is shown in Fig. 53.

Magnetic Deflection—Magnetic deflection (Fig. 54) is generally used with TV, computer-display, and radar CRTs, where high resolution and brightness are required. Magnetic coils are placed in pairs on the outside of the CRT to provide horizontal and vertical magnetic fields perpendicular to the electron flow. Current in these coils causes deflection of the electrons perpendicular to the magnetic field and to the direction of the electrons.

Deflection bandwidth is limited by the high deflection power required of magnetic-deflection systems. Repetitive resonant circuits are normally used. Deflection is proportional to the flux or current in the coil and inversely proportional to the accelerating voltage.

Beam Focusing—Magnetic focusing can be achieved by placing an external magnetic coil in the form of a short solenoid on the outside of the CRT over the electron gun (Fig. 55). Because of the disadvantages of weight and the difficulty in aligning the coil to the beam, most modern CRTs use electrostatic focusing. Cylindrical electrodes at differing voltages form electron lenses that focus the beam to a fine spot at the phosphor screen.

Storage Cathode-Ray Tubes

The storage cathode-ray tube† produces a visual display of controllable duration. The tube has two electron guns, a phosphor viewing screen, and two or more fine-mesh screens. One of the electron guns is referred to as the writing gun and the other as the flood gun. The screen nearest the guns is the collector mesh. The other mesh is the storage mesh and is coated with

a thin dielectric material to form a surface on which electrons store information. A typical storage tube is shown in Fig. 56.

The writing gun emits a pencil-like electron beam, which can be modulated by the information to be stored. This information is in the form of an electrical input signal that can be applied to the control grid for intensity modulation or to the deflection electrodes for spatial modulation. The storage surface is scanned by this high-resolution beam, which actually strikes the surface. A positive-charge image corresponding to the input signal pattern is created on the storage surface by secondary-emission effects. The image remains on the storage surface until it decays from the neutralizing action of gas ions or is erased intentionally. The storage screen acts as an array of elemental electron guns, with each mesh hole acting as a control element of one of the guns. The desired information is stored on the storage mesh by the action of the writing gun, and the entire surface is flooded by electrons from the flood gun. The value of the positive charge deposited at each mesh aperture controls the amount of flood-gun current that can pass through the mesh aperture to the phosphor screen. The current that passes through the mesh strikes the phosphor, and light is emitted in proportion to the current density arriving and to the landing energy of the electrons. In other words, a gray scale is reproduced in the stored image. After the stored information has been observed or recorded, it is erased from the storage surface by fully writing the whole target first with high-energy flood electrons and then with low-energy electrons. The net negative charge so deposited on the storage target causes the target to be maintained at flood-gun cathode potential. The target is then prepared for storing a new image.

Increased storage sensitivity can be obtained by the addition of a third mesh coated with a dielectric material similar to that on the storage mesh and placed between the two meshes of the standard tube. This high-speed target is optimized to have very high sensitivity, but with consequently short retention (view time). The charge pattern written on this surface is quickly transferred to the front storage mesh, on which the coating has been optimized for long retention time and low sensitivity. Such CRTs are generally referred to as transfer storage tubes and are capable of storing signals with bandwidth in excess of 400 MHz.

Bistable Storage Tube

The bistable storage tube allows storage of charge in a CRT without the complication and expense of added meshes. Two guns are used as in the mesh storage tubes, but the phosphor screen is structured to have collector islands surrounded by a phosphor layer deposited on a transparent film (Fig. 57). The phosphor itself acts as both the dielectric storage surface and the light emitter. The potential of the phosphor can be maintained at two stable potentials by the action of secondary emission from the phosphor layer. To prepare the phosphor surface for storage, the collector electrode is pulsed with the waveform shown in Fig. 58. The flood electrons strike the whole target, and because the target potential is above first crossover, the target charges positively toward the collector potential. When the collector potential is suddenly dropped to 0 volts, the phosphor follows by capacitive coupling and is maintained at 0 volts while the collector potential slowly rises to its operational voltage. At 0 volts potential, few flood-gun electrons can land on the phosphor, and the light output is low. The target is now ready to store information. The writing-gun electrons have potential energy sufficiently high to charge the phosphor particles above first-crossover potential. Once the

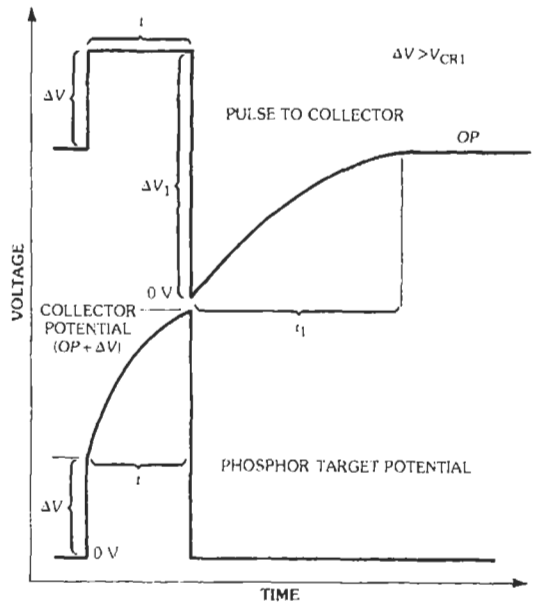

Fig. 58. Erasure waveforms.

particles are above this value, the flood-gun electrons can charge the written area to collector potential. The flood-gun electrons therefore can be made to maintain the phosphor surface at two stable potentials, flood-gun cathode and collector potential, and hence the term used is "bistable storage." At collector potential, the flood-gun electrons arrive with sufficient energy to excite the phosphor, and the stored image is clearly visible and remains as long as desired or until erased. These CRTs have enjoyed wide use in computer graphics terminals. Very high resolution can be obtained on large display tubes of 19 and 25 inches (diagonal). The 19-inch tube is capable of displaying

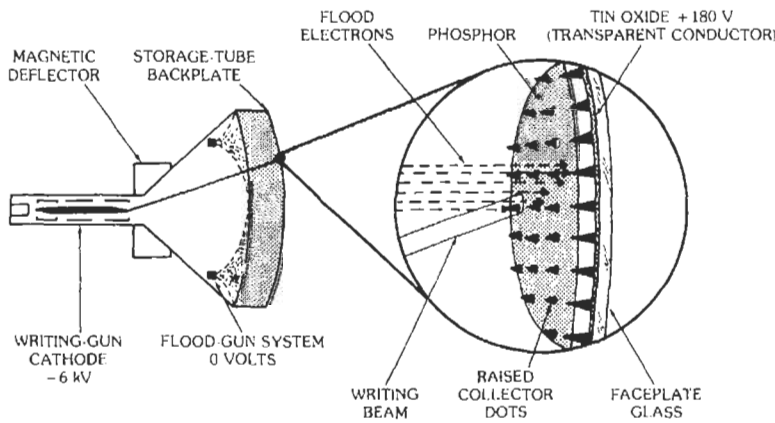

Fig 57. Typical bistable storage tube.

8500 characters, and the 25-inch CRT is capable of over 15 000 characters. Since these characters are actually stored on the face of the CRT until erased, no solid-state memory is required to refresh them. Another advantage of this type of CRT is that when a line is scanned with the writing gun at low beam current, the collector current will be a function of whether the area scanned is written or not. This signal current can be amplified and processed to produce an electronic image of the written areas. This image can be fed into a copy device for producing a hard copy of the display.

17 Power Grid-Tube Circuits

Marvin Chodorow and Donald H. Preist

It is common practice to differentiate between types of vacuum-tube circuits, particularly amplifiers, on the basis of the operating regime of the tube.

Class-A: Grid bias and alternating grid voltages such that plate current flows continuously throughout electrical cycle ($\theta_p = 360°$).

Class-AB: Grid bias and alternating grid voltages such that plate current flows appreciably more than half but less than entire electrical cycle ($360° > \theta_p > 180°$).

Class-B: Grid bias close to cutoff such that plate current flows only during approximately half of electrical cycle ($\theta_p \approx 180°$).

Class-C: Grid bias appreciably greater than cutoff so that plate current flows for appreciably less than half of electrical cycle ($\theta_p < 180°$).

A further classification between circuits in which positive grid current is conducted during some portion of the cycle and those in which it is not is denoted by subscripts 2 and 1, respectively. Thus a class-AB_2 amplifier operates with a positive swing of the alternating grid voltage such that positive electronic current is conducted and accordingly in-phase power is required to drive the tube.

GENERAL DESIGN

For quickly estimating the performance of a tube from catalog data, or for predicting the characteristics needed for a given application, the ratios given below may be used.

Table 1 gives correlating data for typical operation of tubes in the various amplifier classifications. If the maximum ratings of a tube are known, the maximum power output, currents, voltages, and corresponding load impedance may be estimated from the table. Take for example a type F-124-A water-cooled transmitting tube operated as a class-C radio-frequency power amplifier and oscillator (the constant-current characteristics are shown in Fig. 1). Published maximum ratings are as follows.

Dc plate voltage:

$$E_b = 20\,000 \text{ volts}$$

Dc grid voltage:

$$E_c = 3000 \text{ volts}$$

Dc plate current:

$$I_b = 7 \text{ amperes}$$

RF grid current:

$$I_g = 50 \text{ amperes}$$

Plate input:

$$P_i = 135\,000 \text{ watts}$$

Plate dissipation:

$$P_p = 40\,000 \text{ watts}$$

Maximum conditions may be estimated as follows. For $\eta = 75$ percent

$$P_i = 135\,000 \text{ watts}$$

$$E_b = 20\,000 \text{ volts}$$

Power output $P_o = \eta P_i = 100\,000$ watts.
Average dc plate current $I_b = P_i/E_b = 6.7$ amperes

From a tabulated typical ratio ${}^{M}i_b/I_b = 4$, the instantaneous peak plate current ${}^{M}i_b = 4I_b = 27$ amperes.*

The rms plate alternating-current component, taking the ratio $I_p/I_b = 1.2$, is

$$I_p = 1.2I_b = 8 \text{ amperes}$$

The rms value of the plate alternating-voltage component from the ratio $E_p/E_b = 0.6$ is $E_p = 0.6\ E_b = 12\,000$ volts.

* In this discussion, the superscript M indicates the use of the maximum or peak value of the varying component; i.e., ${}^{M}i_b$ = maximum or peak value of the alternating component of the plate current.

TABLE 1. TYPICAL AMPLIFIER OPERATING DATA (MAXIMUM-SIGNAL CONDITIONS, PER TUBE)

Function	Class A	Class B AF (p-p)	Class B RF	Class C RF
Plate efficiency η (percent)	20–30	35–65	60–70	65–85
Peak instantaneous to dc plate-current ratio ${}^{M}i_b/I_b$	1.5–2	3.1	3.1	3.1–4.5
Rms alternating to dc plate-current ratio I_p/I_b	0.5–0.7	1.1	1.1	1.1–1.2
Rms alternating to dc plate-voltage ratio E_p/E_b	0.3–0.5	0.5–0.6	0.5–0.6	0.5–0.6
Dc to peak instantaneous grid-current $I_c/{}^{M}i_c$		0.1–0.25	0.1–0.25	0.1–0.25

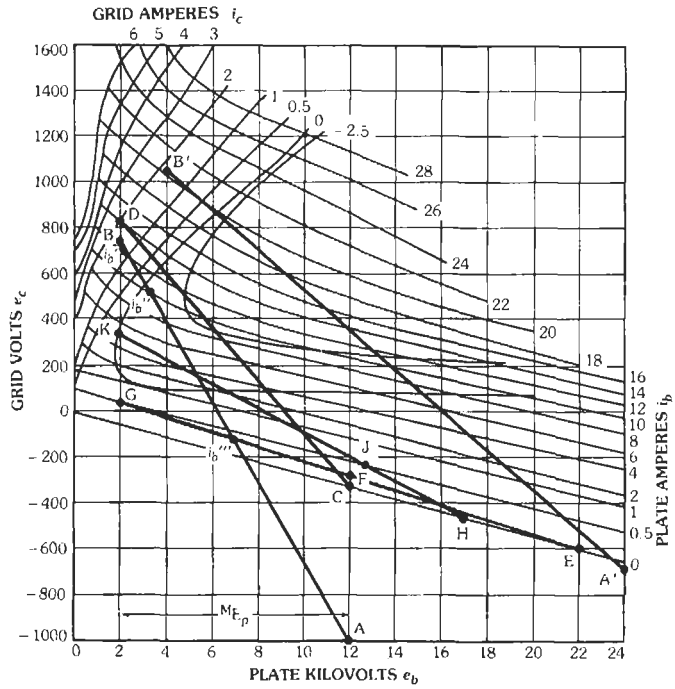

Fig. 1. Constant-current characteristics of type F-124-A tube with typical load lines: AB—class C, CD—class B, EFG—class A, HJK—class AB.

The approximate operating load resistance, R_l, is now found from

$$R_l = E_p/I_p = 1500 \text{ ohms}$$

An estimate of the grid drive power required may be obtained by reference to the constant-current characteristics of the tube and determination of the peak instantaneous positive grid current $^M i_c$ and the corresponding instantaneous total grid voltage $^M e_c$. If the value of grid bias for the given operating condition is E_c, the peak alternating grid drive voltage is

$$^M E_g = (^M e_c - E_c)$$

from which the peak instantaneous grid drive power can be determined:

$$^M P_c = {}^M E_g {}^M i_c$$

An approximation to the average grid drive power, P_g, necessarily rough due to neglect of negative grid current, is obtained from the typical ratio of dc to peak value of grid current, $I_c/^M i_c = 0.2$. The result is

$$P_g = I_c E_g = 0.2 {}^M i_c E_g \text{ watt}$$

Plate dissipation P_p may be checked with published values since

$$P_p = P_i - P_o$$

It should be borne in mind that combinations of published maximum ratings as well as each individual maximum rating must be observed. Thus, for example in this case, the maximum dc plate operating voltage of 20 000 volts does not permit operation at the maximum dc plate current of 7 amperes since this exceeds the maximum plate input rating of 135 000 watts.

Plate load resistance R_l may be connected directly in the tube plate circuit as in the resistance-coupled amplifier, through impedance-matching elements as in audio-frequency transformer coupling, or effectively represented by a loaded parallel-resonant circuit as in most radio-frequency amplifiers. In any case, calculated values apply only to effectively resistive loads, such as are normally closely approximated in radio-frequency amplifiers. With appreciably reactive loads, operating currents and voltages will in general be quite different, and their precise calculation is quite difficult.

The physical load resistance present in any given setup may be measured by audio-frequency or radio-frequency bridge methods. In many cases, the proper value of R_l is ascertained experimentally as in radio-frequency amplifiers that are tuned to the proper minimum dc plate current. Conversely, if the circuit is to be matched to the tube, R_l is determined directly as in a resistance-coupled amplifier or as

$$R_l = N^2 R_s$$

in the case of a transformer-coupled stage, where N is the primary-to-secondary voltage transformation ratio.

In a parallel-resonant circuit in which the output resistance R_s is connected directly in one of the reactance legs

$$R_l = X^2/R_s = L/Cr_s = QX$$

where,

X is the leg reactance at resonance (ohms),
L *and* C are leg inductance in henrys and capacitance in farads, respectively,
$Q = X/R_s$.

GRAPHIC DESIGN METHODS

When accurate operating data are required, more precise methods must be used. Because of the nonlinear nature of tube characteristics, graphic methods usually are most convenient and rapid. Examples of such methods are given below.

A comparison of the operating regimes of class A, AB, B, and C amplifiers is given in the constant-current-characteristics graph of Fig. 1. The lines corresponding to the different classes of operation are the loci of instantaneous grid voltage e_c and plate voltage e_b, corresponding to their respective load impedances.

For radio-frequency amplifiers and oscillators having tuned circuits that give an effectively resistive load, plate and grid tube and load alternating voltages are sinusoidal and in phase (disregarding transit time), and the loci become straight lines.

For amplifiers having nonresonant resistive loads, the loci are in general nonlinear except in the distortionless case of linear tube characteristics (constant r_p), for which they are again straight lines.

Thus, for determination of radio-frequency performance, the constant-current chart is convenient. For solution of audio-frequency problems, however, it is more convenient to use the i_b-e_c transfer characteristics of Fig. 2, on which a dynamic load line may be constructed.

Methods for calculation of the most important cases are given below.

Class-C RF Amplifier or Oscillator

Draw a straight line from A to B (Fig. 1) corresponding to the chosen dc operating plate and grid voltages, and to the desired peak alternating plate and grid voltage excursions. The projection of AB on the horizontal axis thus corresponds to ${}^{M}E_p$. Using Chaffee's 11-point method of harmonic analysis, lay out on AB points

$$e_p' = {}^{M}E_p$$

$$e_p'' = 0.866\,{}^{M}E_p$$

$$e_p''' = 0.5\,{}^{M}E_p$$

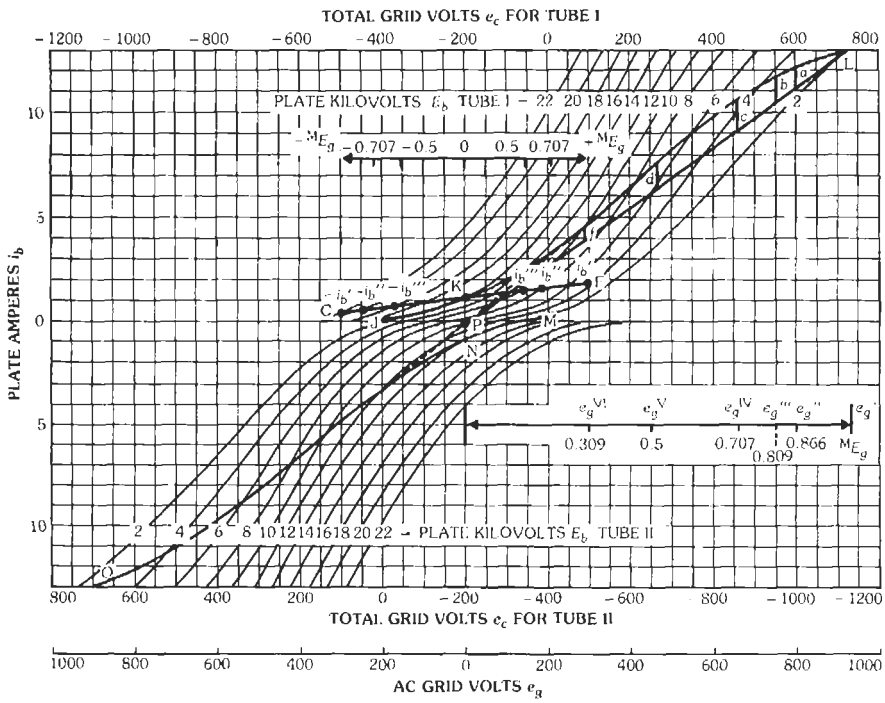

Fig. 2. Transfer characteristics i_b versus e_c with load lines; CKF—class A_2 and OPL—class B.

to each of which correspond instantaneous plate currents, i_b', i_b'', and i_b''' and instantaneous grid currents i_c', i_c'', and i_c'''. The operating currents are obtained from

$$I_b = [i_b' + 2i_b'' + 2i_b''']/12$$

$$I_c = [i_c' + 2i_c'' + 2i_c''']/12$$

$${}^{M}I_p = [i_b' + 1.73i_b'' + i_b''']/6$$

$${}^{M}I_g = [i_c' + 1.73i_c'' + i_c''']/6$$

Substitution of the above in the following gives the desired operating data.

Power output $P_o = ({}^{M}E_p\,{}^{M}I_p)/2$
Power input $P_i = E_bI_b$
Average grid excitation power $P_g = ({}^{M}E_g\,{}^{M}I_g)/2$
Peak grid excitation power ${}^{M}P_c = {}^{M}E_g i_c$
Plate load resistance $R_l = {}^{M}E_p/{}^{M}I_p$
Grid bias resistance $R_c = E_c/I_c$
Plate efficiency $\eta = P_o/P_i$
Plate dissipation $P_p = P_i - P_o$

The above procedure may also be applied to plate-modulated class-C amplifiers. Take the above data as applying to carrier conditions, and repeat the analysis for ${}^{crest}E_b = 2E_b$ and ${}^{crest}P_o = 4P_o$, keeping R_l constant. After a cut-and-try method has given a peak solution, it will often be found that combination fixed and self grid biasing as well as grid modulation are indicated to obtain linear operation.

To illustrate the preceding exposition, a typical amplifier calculation is given below.

Operating requirements (carrier condition):

E_b = 12 000 volts

P_o = 25 000 watts

η = 75 percent

Preliminary calculation (refer to Tables 1 and 2):

$E_p/E_b = 0.6$

$E_p = 0.6 \times 12\,000 = 7200$ volts

${}^{M}E_p = 1.41 \times 7200 = 10\,000$ volts

$I_p = P_o/E_p$ 25 000/7200 = 3.48 amperes

${}^{M}I_p = 4.9$ amperes

$I_p/I_b = 1.2$

$I_b = 3.48/1.2 = 2.9$ amperes

$P_i = 12\,000 \times 2.9 = 35\,000$ watts

${}^{M}i_b/I_b = 4.5$

${}^{M}i_b = 4.5 \times 2.9 = 13.0$ amperes

$R_l = E_p/I_p = 7200/3.48 = 2060$ ohms

Complete Calculation: Lay out carrier operating line AB on the constant-current graph, Fig. 1, using values of E_b, ${}^{M}E_p$, and ${}^{M}i_b$ from the preliminary calculated data. Operating carrier bias voltage E_c is chosen somewhat greater than twice the cutoff value (1000 volts) to locate point A.

The following data are taken along AB.

i_b' = 13 amperes

i_b'' = 10 amperes

TABLE 2. CLASS-C RF AMPLIFIER DATA FOR 100-PERCENT PLATE MODULATION

Symbol	Preliminary Carrier	Detailed	
		Carrier	Crest
E_b (volts)	12 000	12 000	24 000
${}^{M}E_p$ (volts)	10 000	10 000	20 000
E_c (volts)	—	−1 000	−700
${}^{M}E_g$ (volts)	—	1 740	1 740
I_b (amperes)	2.9	2.8	6.4
${}^{M}I_p$ (amperes)	4.9	5.1	10.2
I_c (amperes)	—	0.125	0.083
${}^{M}I_g$ (amperes)	—	0.255	0.183
P_i (watts)	35 000	33 600	154 000
P_o (watts)	25 000	25 500	102 000
P_g (watts)	—	220	160
η (percent)	75	76	66
R_l (ohms)	2 060	1 960	1 960
R_c (ohms)	—	7 100	7 100
E_{cc} (volts)	—	−110	−110

$i_b''' = 0.3$ ampere

$i_c' = 1.7$ amperes

$i_c'' = -0.1$ ampere

$i_c''' = 0$ ampere

$E_c = -1000$ volts

$e_c' = 740$ volts

${}^{M}E_p = 10\,000$ volts

From the equations, complete carrier data as follows are calculated.

${}^{M}I_p = [13 + 1.73 \times 10 + 0.3]/6 = 5.1$ amperes

$P_o = (10\,000 \times 5.1)/2 = 25\,500$ watts

$I_b = [13 + 2 \times 10 + 2 \times 0.3]/12 = 2.8$ amperes

$P_i = 12\,000 \times 2.8 = 33\,600$ watts

$\eta = (25\,500/33\,600) \times 100 = 76$ percent

$R_l = (10\,000/5.1) = 1960$ ohms

$I_c = [1.7 + 2(-0.1)]/12 = 0.125$ ampere

${}^{M}I_g = [1.7 + 1.7(-0.1)]/6 = 0.255$ ampere

$P_g = (1740 \times 0.255)/2 = 220$ watts

Operating data at 100-percent positive modulation crests are now calculated based on the fact that here

$E_b = 24\,000$ volts

$R_l = 1960$ ohms

and for undistorted operation

$P_o = 4 \times 25\,500 = 102\,000$ watts

${}^{M}E_p = 20\,000$ volts

The crest operating line A′B′ is now located by trial so as to satisfy the above conditions, by the use of the same equations and method as for the carrier condition.

It is seen that to obtain full-crest power output, in addition to doubling the alternating plate voltage, the peak plate current must be increased. This is accomplished by reducing the crest bias voltage with a resultant increase of current conduction period but lower plate efficiency.

The effect of grid secondary emission to lower the crest grid current is taken advantage of to obtain the reduced grid-resistance voltage drop required. By use of combination fixed and grid-resistance bias, proper variation of the total bias is obtained. The value of grid resistance required is given by

$$R_c = -({}^{\text{crest}}E_c - E_c)/({}^{\text{crest}}I_c - I_c)$$

and the value of fixed bias by

$$E_{cc} = E_c - (I_c R_c)$$

Calculations at carrier and positive crest together with the condition of zero output at negative crest give sufficiently complete data for most purposes. If accurate calculation of audio-frequency harmonic distortion is necessary, the above method may be applied to the additional points required.

Class-B RF Amplifiers

A rapid approximate method is to determine by inspection from the tube i_b-e_b characteristics the instantaneous current, i_b', and voltage, e_b', corresponding to the peak alternating voltage swing from operating voltage E_b.

Ac plate current:

$${}^{M}I_p = i_b'/2$$

Dc plate current:

$$I_b = i_b'/\pi$$

Ac plate voltage:

$${}^{M}E_p = E_b - e_b'$$

Power output:

$$P_o = [(E_b - e_b')i_b']/4$$

Power input:

$$P_i = E_b i_b'/\pi$$

Plate efficiency:

$$\eta = (\pi/4)[1 - (e_b'/E_b)]$$

Thus $\eta \approx 0.6$ for the usual crest value of ${}^{M}E_p \approx 0/8\ E_b$.

The same method of analysis used for the class-C amplifier may also be used in this case. The carrier and crest-condition calculations, however, are now made from the same E_b, the carrier condition corresponding to an alternating-voltage amplitude of ${}^{M}E_p/2$ such as to give the desired carrier power output.

For greater accuracy than the simple check of carrier and crest conditions, the radio-frequency plate currents ${}^{M}I_p'$, ${}^{M}I_p''$, ${}^{M}I_p'''$, ${}^{M}I_p^0$, $-{}^{M}I_p'''$, $-{}^{M}I_p''$, and $-{}^{M}I_p'$ may be calculated for seven corresponding selected

points of the audio-frequency modulation envelope $+{}^{M}E_g$, $+0.707{}^{M}E_g$, $+0.5{}^{M}E_g$, 0, $-0.5{}^{M}E_g$, $-0.707{}^{M}E_g$, and $-{}^{M}E_g$, where the negative signs denote values in the negative half of the modulation cycle. If the designations

$$S' = {}^{M}I_p' - (-{}^{M}I_p')$$
$$D' = {}^{M}I_p' + (-{}^{M}I_p') - 2{}^{M}I_p^{0}$$

are used, the fundamental and harmonic components of the output audio-frequency current are obtained as

$${}^{M}I_{p1} = (S'/4) + [S''/2(2)^{1/2}] \text{ (fundamental)}$$

$${}^{M}I_{p2} = (5D'/24) + (D''/4) - (D'''/3)$$

$${}^{M}I_{p3} = (S'/6) - (S'''/3)$$

$${}^{M}I_{p4} = (D'/8) - (D''/4)$$

$${}^{M}I_{p5} = (S'/12) - [S''/2(2)^{1/2}] + (S'''/3)$$

$${}^{M}I_{p6} = (D'/24) - (D''/4) + (D'''/3)$$

This detailed method of calculation of audio-frequency harmonic distortion may, of course, also be applied to calculation of the class-C modulated amplifier, as well as to the class-A modulated amplifier.

Class-A and -AB AF Amplifiers

Approximate equations assuming linear tube characteristics:

Maximum undistorted power output

$${}^{M}P_o = ({}^{M}E_p{}^{M}I_p)/2$$

when plate load resistance

$$R_l = r_p\left[\frac{E_c}{({}^{M}E_p/\mu) - E_c} - 1\right]$$

and negative grid bias

$$E_c = ({}^{M}E_p/\mu)[(R_l + r_p)/(R_l + r_p)/(R_l + 2r_p)]$$

giving maximum plate efficiency

$$\eta = {}^{M}E_p{}^{M}I_p/8E_bI_b$$

Maximum maximum undistorted power output

$${}^{MM}P_o = {}^{M}E_p^2/16r_p$$

when

$$R_l = 2r_p$$

$$E_c = \tfrac{3}{4}({}^{M}E_p/\mu)$$

An exact analysis may be obtained by use of a dynamic load line laid out on the transfer characteristics of the tube. Such a line is CKF of Fig. 2, which is constructed about operating point K for a given load resistance r_l from

$$i_b{}^{S} = [(e_b{}^{R} - e_b{}^{S})/R_l] + i_b{}^{R}$$

where R, S, etc., are successive conveniently spaced construction points.

Using the seven-point method of harmonic analysis, plot instantaneous plate currents i_b', i_b'', i_b''', i_b, $-i_b'''$, $-i_b''$, and $-i_b'$, corresponding to $+{}^{M}E_g$, $+0.707{}^{M}E_g$, $+0.5{}^{M}E_g$, 0, $-0.5{}^{M}E_g$, $-0.707{}^{M}E_g$, and $-{}^{M}E_g$, where 0 corresponds to operating point K. In addition to the equations given under class-B radio-frequency amplifiers

$$I_b \text{ average} = I_b + (D'/8) + (D''/4)$$

from which complete data may be calculated.

Class-AB and -B AF Amplifiers

Approximate equations assuming linear tube characteristics give (referring to Fig. 1, line CD) for a class-B audio-frequency amplifier

$${}^{M}I_p = i_b'$$

$$P_o = {}^{M}E_p{}^{M}I_p/2$$

$$P_i = (2/\pi)E_b{}^{M}I_p$$

$$\eta = (\pi/4)\,({}^{M}E_p/E_b)$$

$$R_{pp} = 4({}^{M}E_p/i_b') = 4R_l$$

An exact solution may be derived by use of dynamic load line JKL on the i_b-e_c characteristic of Fig. 2. This line is calculated about the operating point K for the given R_l (in the same way as for the class-A case). However, since two tubes operate in phase opposition in this case, an identical dynamic load line MNO represents the other half cycle, laid out about the operating bias abscissa point but in the opposite direction (see Fig. 2).

Algebraic addition of instantaneous current values of the two tubes at each value of e_c gives the composite dynamic characteristic OPL for the two tubes. Inasmuch as this curve is symmetrical about point P, it may be analyzed for harmonics along a single half-curve PL by use of the Mouromtseff 5-point method. A straight line is drawn from P to L, and ordinate plate-current differences *a, b, c, d, f* between this line and the curve, corresponding to e_g'', e_g''', $e_g{}^{IV}$, $e_g{}^{V}$, *and* $e_g{}^{VI}$, are measured. Ordinate distances measured upward from curve PL are taken positive.

Fundamental and harmonic current amplitudes and power are found from

$$^{M}I_{p1} = i_b' - {}^{M}I_{p3} + {}^{M}I_{p5} - {}^{M}I_{p7} + {}^{M}I_{p9} - {}^{M}I_{p11}$$

$$^{M}I_{p3} = 0.4475(b + f) + (d/3) - 0.578d - \tfrac{1}{2}\,{}^{M}I_{p5}$$

$$^{M}I_{p5} = 0.4(a - f)$$

$$^{M}I_{p7} = 0.4475(b + f) - {}^{M}I_{p3} + 0.5{}^{M}I_{p5}$$

$$^{M}I_{p9} = {}^{M}I_{p5} - \tfrac{2}{3}d$$

$$^{M}I_{p11} = 0.707c - {}^{M}I_{p3} + {}^{M}I_{p5}$$

Even harmonics are not present due to the symmetry of the dynamic characteristic. The direct-current and power-input values are found by the 7-point analysis from curve PL and doubled for two tubes.

CIRCUIT CLASSIFICATION

The classification of amplifiers in classes A, B, and C is based on the operating conditions of the tube. Another classification can be used, based on the type of circuits associated with the tube.

A tube can be considered as a four-terminal network with two input terminals and two output terminals. One of the input terminals and one of the output terminals are usually common; this common junction or point is usually called "ground."

When the common point is connected to the filament or cathode of the tube, we can speak of a grounded-cathode circuit (the most conventional type of vacuum-tube circuit). When the common point is the grid, we can speak of a grounded-grid circuit; and when the common point is the plate or anode, we can speak of a grounded-anode circuit. This last type of circuit is most commonly known by the name "cathode-follower."

A fourth and most general class of circuit is obtained when the common point or ground is not directly connected to any of the three electrodes of the tube. This is the condition encountered at UHF where the series impedances of the internal tube leads make it impossible to ground any of them. It is also encountered in such special types of circuits as the phase-splitter, in which the impedance from plate to ground and the impedance from cathode to ground are made equal to obtain an output between plate and cathode balanced with respect to ground.

Design information for the first three classifications is given in Table 3, where

Z_2 = load impedance to which output terminals of amplifier are connected,
$\mathbf{E}_1$ = phasor input voltage to amplifier,
$\mathbf{E}_2$ = phasor output voltage across load impedance Z_2,
$\mathbf{A}$ = voltage gain of amplifier = $\mathbf{E}_2/\mathbf{E}_1$,
Y_i = input admittance to input terminals of amplifier,
$\omega = 2\pi \times$ (frequency of excitation voltage $\mathbf{E}_1$),
$j = (-1)^{1/2}$.

RF AMPLIFIER CIRCUITS

The power grid tube requires external circuits. Examples are shown schematically below for each kind of tube.

Triodes

The triode has three electrodes: the thermionic cathode, which emits electrons; the control grid; and the anode, which collects most of the electrons. If the grid is "biased" to a sufficiently high negative potential (cutoff bias), no current flows. As the grid potential becomes less negative, more current flows to the anode. When the grid becomes positive with respect to the cathode, both grid and anode draw current. At some value of positive grid potential, the total space current starts to exceed the emitting capability of the cathode (cathode saturation) or the product of the grid current and grid-cathode voltage (grid dissipation) exceeds the limit above which the grid will emit electrons (primary emission). Excessive grid dissipation interferes with the desired operation of the tube or results in mechanical distortion due to excessive temperature. There is also a limit to the power dissipation of the anode, depending on the cooling method used.

In operation as an RF power amplifier, the triode must be either "neutralized" as in Fig. 3A or operated "grounded-grid" ("cathode-driven") as in Fig. 3B; otherwise, the internal capacitance between grid and anode produces positive feedback that may cause self-oscillation at a frequency close to the operating frequency. The triode may be operated as an efficient oscillator by optimizing the feedback through the addition of extra capacitance or by other means. Oscillators are used for RF heating of materials in industrial operations where precise control of frequency is not required.

Small planar triodes are used at UHF and microwave frequencies up to about 4 GHz, especially in pulse service where peak-to-average power ratios are 100–1000. The anode supply voltage is typically 1 kV or more.

Small cylindrical triodes are used mainly at VHF and UHF where CW power of a few hundred watts or pulse powers of tens of kilowatts are required. Modern triodes are designed with beam-forming cathode and control-grid geometry to allow the simplicity of design and circuit advantages of a triode with the gain of a tetrode.

Tetrodes and Pentodes

The tetrode and pentode have four or five electrodes, respectively. A tetrode has a cathode, a control grid, a screen grid, and an anode. The screen grid greatly reduces the capacitance between the anode and control

TABLE 3. DESIGN INFORMATION FOR THREE CLASSES OF AMPLIFIERS

Grounded-Cathode	Grounded-Grid	Grounded-Plate or Cathode-Follower

grid and makes neutralization unnecessary or easy to accomplish. The pentode has an additional "suppressor grid" to control secondary electrons. Modern tetrodes accomplish this control in other ways and have almost completely displaced pentodes.

Two tetrode circuits for RF amplification are shown in Fig. 4. The arrangement in Fig. 4. The arrangement in Fig. 4A is commonly used at frequencies below about 30 MHz for very large tubes and below about 400 MHz for small tubes. A power gain of 1000 (30 dB) is typical at lower frequencies.

At VHF and UHF, the cathode-lead inductance, L_k, of Fig. 4A produces excessive negative feedback, which can be overcome by incorporating the inductance into the input resonant circuit as shown in Fig. 4B. In this arrangement, both the control grid and screen grid are maintained at RF ground potential by the bypassing capacitors (C_b). In this circuit, the power gain is reduced compared to that of Fig. 4A, but 10–15 dB is typical at frequencies below about 1000 MHz.

Tetrode tubes are available in various sizes for different power levels and frequencies. Applications are radio broadcasting (AM and FM), television (VHF and UHF), communications, radar, navigational aids, and high-energy physics, including particle accelerators and thermonuclear-fusion machines. Functions are RF power

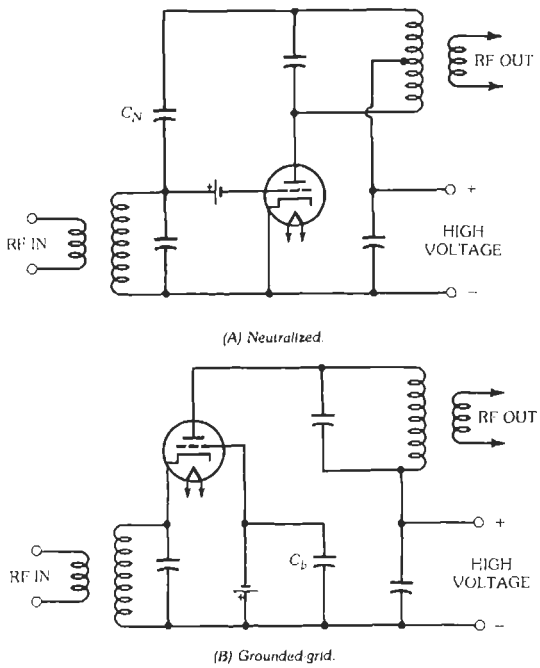

Fig. 3. Triode amplifier circuits.

generation, modulation (AM), and switching for pulse service.

UHF Operation

When the transit time of the electrons from cathode to anode is an appreciable fraction of one radio-frequency cycle:

(*A*) Input conductance due to reaction of electrons with the varying field from the grid becomes appreciable. This conductance, which increases as the square of the frequency, results in lowered gain, an increase in driving-power requirement, and loading of the input circuit.

(*B*) Grid-anode transit time introduces a phase lag between grid voltage and anode current. In oscillators, the problem of compensating for the phase lag by design and adjustment of a feedback circuit becomes difficult. Efficiency is reduced in both oscillators and amplifiers.

(*C*) Distortion of the current pulse in the grid-anode space increases the anode-current conduction angle and lowers the efficiency.

In amplifiers, the effect of cathode-lead inductance is to introduce a conductance component in the grid circuit. This effect is serious because the loading of the input circuit by the conductance current limits the gain of the stage. Cathode-grid and grid-anode capacitive reactances are of small magnitude at ultrahigh frequencies, and heavy currents flow as a result of these reactances. Tubes must be designed to carry these currents without serious loss. Coaxial cavities are used to resonate with the tube reactances and to minimize resistive and radiation losses.

Klystrode™ Amplifiers

At frequencies between about 100 and 1000 MHz, a hybrid tube, part triode, part klystron, has promise. Called a Klystrode™, it was invented in 1939 and demonstrated at low power levels, but lay dormant for over 40 years. It now appears capable of high power, somewhat greater conversion efficiency, and considerably more power gain than the conventional tetrode. It is physically shorter than a klystron because of the absence of a multicavity buncher. The Klystrode requires a resonant output cavity; in this respect it resembles the klystron. At frequencies much above 1000 MHz, the power output falls off rapidly with increasing frequency, because the device is basically a "density-modulated" or grid-controlled tube limited by electron transit time and grid limitations. A diagram of a Klystrode is shown in Fig. 5, and expected power versus frequency is shown in Fig. 9.

Circuits of Special Interest

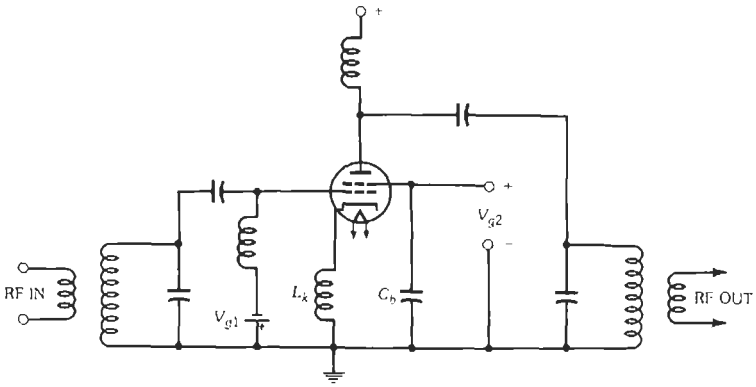
High-Efficiency Circuits for RF Amplification—Increasing energy costs have led to attempts to improve the efficiency of conversion from DC to RF, especially in very high-power equipment. Most of these attempts are based on wave shaping. It can be shown that the power lost as heat at the anode of a tetrode, for example, can be reduced as the waveforms of voltage and current approach square waves rather than sine waves or portions of sine waves. One method due to Tyler* still in use in AM broadcast transmitters is to add harmonics in the correct phase and amplitude to the original sine functions. The harmonics are generated in tuned circuits that are resonant at the harmonic frequencies and placed in series with the circuits tuned to the fundamental. The current and voltage waveforms approach square waves.

Another approach not involving extra circuits is simply to restrict the time duration of the current (class-C operation). This, however, reduces the power output or increases the cathode current density.

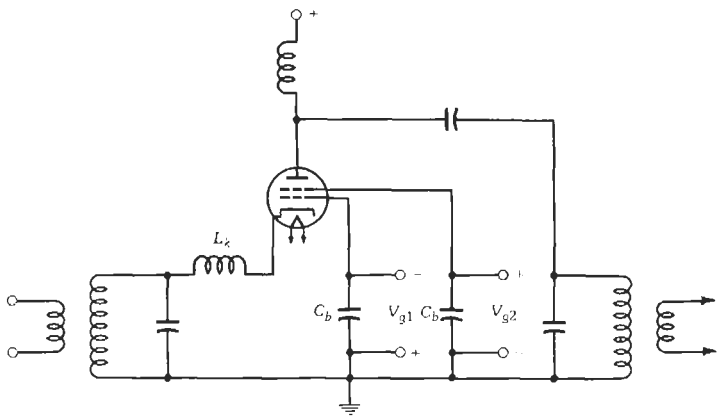
For a power amplifier at 1.5 MHz, typical efficiencies are: Class B, 75%; Class C, 80%–85%; "Tyler," 93%.

Circuits That Provide High Linearity—In some applications, for example TV visual channels, it is necessary to achieve RF power amplification with very low distortion of the modulation content, measured either as total harmonic distortion or, more often, as intermodulation distortion. Present practice is to use triodes as class-A amplifiers or tetrodes as class-B or class-AB linear amplifiers. In class-B service, grid bias

* Reference 1.



(A) Grid-driven.



(B) Cathode-driven.

Fig. 4. Tetrode amplifier circuits.

is adjusted to the value that just reduces the anode current to zero. In class-AB, a small "idling" current is allowed to flow. By careful design of the tube and circuit combination, the modulated RF output power can be a faithful copy of the input over the bandwidth required for transmission of the information contained in the modulation. In this system, the average conversion efficiency over a period of time long compared to the modulation period or cycle can be reasonably high, because power input to the tube falls when the modulation level is low (the carrier is suppressed). In contrast, an amplifier operating in class A, such as a tetrode biased so that a sinusoidal anode current waveform is produced, would draw the same dc current whether the modulation were 100% or zero. The same is true of a klystron or TWT amplifier in which the beam current does not vary with the RF drive level.

In the linear amplifier with suppressed carrier, the efficiency varies as the square root of the modulation depth. For example, if with 100% modulation the efficiency is 50%, with 30% modulation the efficiency would be $50\% \times \sqrt{0.3} = 27\%$. The corresponding klystron efficiency would be $50\% \times 0.3 = 15\%$.

Another tube-circuit combination of interest is the high-efficiency Doherty linear amplifier* shown schematically in Fig. 6. In this configuration, modulation is accomplished by causing two linear amplifiers, both driven by modulated RF grid-cathode voltages, to feed power into a common load impedance. The tubes are essentially in parallel. They are biased differently so that with no modulation the carrier power is supplied only by one (the "carrier" tube). The other ("peaking" tube) is cut off. At full modulation, both tubes deliver power. A quarter-wavelength transmission line is connected between the tubes. The impedance inverting properties of this line allow each tube to "see" a load impedance that varies with modulation depth. This arrangement is found in some AM broadcast transmitters in which the carrier and both sidebands are

* References 2 and 3.

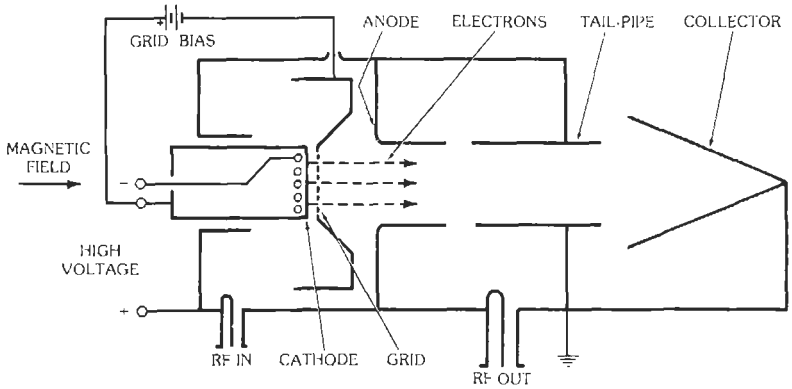


Fig. 5. Klystrode™ amplifier schematic. (*Courtesy Varian/Eimac*)

transmitted. This circuit has the advantage that efficiency tends to be high at all modulation levels, no high-level modulation transformer is required, and the peak voltage on the tubes is much lower than with conventional anode modulation.

Modulators—Modulation of the signal from a tetrode RF amplifier may be accomplished by:

A. Variation of RF drive, described above
B. Variation of screen-grid voltage, keeping drive and anode voltage constant
C. Variation of screen-grid and anode voltage together
D. Variation of control-grid voltage only

Each of these systems has advantages and disadvantages. Most transmitters today use method A or C. Pulse transmission, where essentially square pulses are required, can be accomplished by method D, with variation of the grid-bias voltage between cutoff and the value required for efficient operation when current flows.

Power grid tubes are frequently used to pulse-modulate velocity-modulated microwave tubes such as klystrons, TWTs, magnetron oscillators, and cross-field amplifiers. Simple circuits can be used because a single gridded tube can perform the pulsing function. An interesting example at high power level is the "linear beam switch tube" series modulator. This tube is a

form of tetrode in which the pseudo-screen grid is an apertured electrode and the final anode, or collector, is a reentrant chamber designed to minimize the production of secondary electrons, which would be accelerated back to the screen grid because of its higher potential. This arrangement is especially suitable for modulation of a high-power klystron that requires a high beam voltage negative in polarity with respect to ground. Fig. 7 shows this arrangement schematically. The switch tube itself uses a convergent electron beam from a concave spherical cathode and control grid in an electron gun that is similar to that of the klystron.

A relatively new modulation technique that is finding increasing use in AM broadcast transmitters is pulse duration modulation (PDM)*. An RF power amplifier is anode-modulated by a series modulator tube. The control grid of the modulator tube is pulsed by a train of rectangular pulses at a repetition frequency well above the highest modulation frequency required. The pulses are arranged to drive the modulator tube to its maximum anode current and to zero current alternately. The width of the pulses is varied at the modulation frequency. A filter tuned to the pulse repetition frequency is placed between the modulator tube and the RF amplifier tube so that only the required modulating signal is applied to the RF tube. The result is a relatively efficient system at all modulation levels because the modulator tube is either fully on or fully off, and because the efficiency of the RF tube is constant over a wide range of applied anode voltage.

Broad-Band Distributed Amplifiers—For some applications, an amplifier that covers several octaves of bandwidth is required. At microwave frequencies, a single TWT can be made to do this. At lower frequencies, from DC to several hundred megahertz, an arrangement of tetrode tubes and lumped-constant transmission lines known as a "distributed amplifier" can be used, as shown in Fig. 8. The transmission lines are terminated by load resistances of magnitude equal to their characteristic impedances. A growing wave of current is present on the output transmission line, each tube providing its contribution of current in the correct phase. Such amplifiers are quite inefficient. Typically eight to sixteen tubes are used. Tube requirements are high input impedance (there must be no grid current) and high anode dissipation capability, dictating the use of tetrodes with grounded cathodes. The upper cutoff frequency is limited mainly by cathode and grid lead inductances and grid-cathode capacitance of the tubes.*

PERFORMANCE OF ELECTRON POWER TUBES; COMPARISON WITH SOLID-STATE DEVICES

Power grid tubes are traditionally used for generation and amplification of power at radio frequencies; for modulation, switching, and rectification; and, formerly, for low-power-level applications including receivers and early computers. Solid-state devices and packages have eliminated tubes from all low-power-level applications where information processing is the objective, and they are becoming widely used where up to 2 kW of CW power is required for radio transmission below about 2 GHz. At much higher power levels, power tubes remain the economical choice and are likely to remain so for the forseeable future.

Fig. 9 shows the RF power obtainable from various devices as a function frequency. Data are taken from manufacturers' catalogs and other published information. It is clear that in terms of maximum CW power obtainable, a single power-tube device is many orders of magnitude more powerful than a single solid-state device over the whole frequency range. This situation is not likely to change. It exists because of the fundamental physical distinction between the properties of electrons moving in a vacuum and electrons moving in solid material, and the properties of the media themselves. This can be seen from the following discussion.

Radio-frequency generators are really converters of DC to RF power. The key elements are:

A. A DC power supply
B. An RF resonant circuit with Q greater than approximately 5
C. A source of electrons
D. A means of "bunching" electrons and accelerating the bunches
E. A means for interaction between the bunches of electrons and the resonant circuit so that energy is extracted from the electrons and transferred via the circuit (which, like a flywheel, stores energy) to a useful load such as an antenna or a substance to be heated. (See Fig. 10.)

* Reference 5.

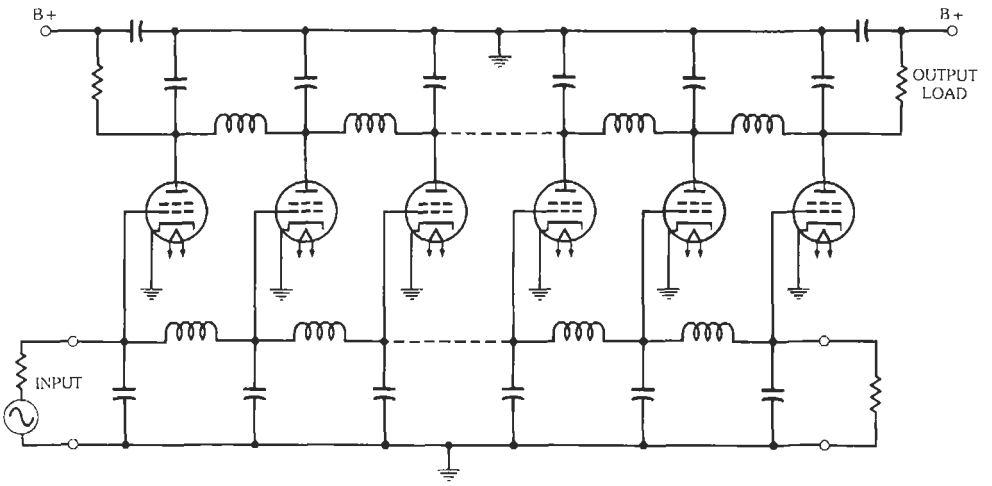

Fig. 8. Basic distributed amplifier circuit. (*Courtesy IEEE*)

More specifically, typical configurations are shown in Fig. 11. Simplified circuit diagrams are essentially the same for a triode tube and a transistor, both of which illustrate the principles involved.

Fig. 12, which illustrates current and voltage as functions of time, shows that the voltage appearing across the output region of the device is small when current is flowing, but peaks at a value roughly equal to twice the DC supply voltage half a period later. The device must withstand this voltage without internal arcing. The current waveform shown in Fig. 12 implies that the time of transit of electrons between the source (cathode or emitter) and the final electrode (anode or collector) is very small compared to the period of the radio frequency. If the transit time is large, the current waveform will depart from that shown as the solid line in Fig. 12 and will tend to be shown by the dash line. The RF component of this current will decrease as the transit time increases, and the conversion efficiency of the device will fall, eventually to zero. In quantitative terms, it can be shown that, other factors being equal, the parameter v/fd (where v is electron velocity across

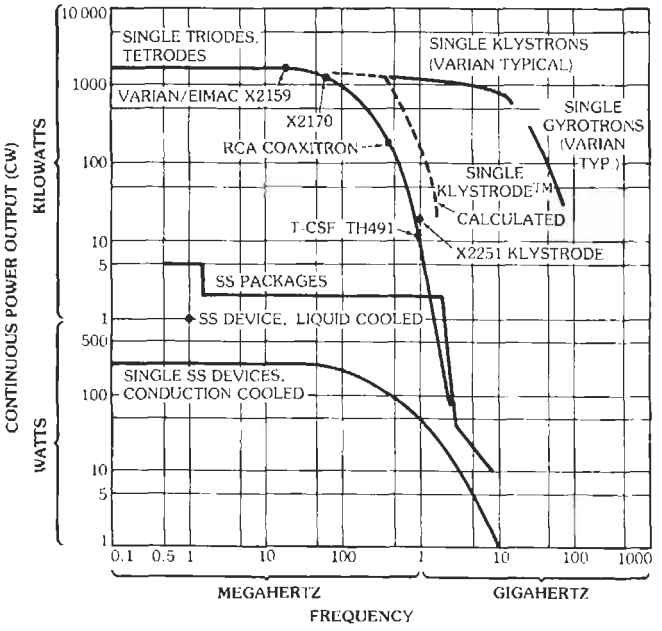

Fig. 9. Maximum CW power versus frequency from RF power sources, 1982. Available except where noted.

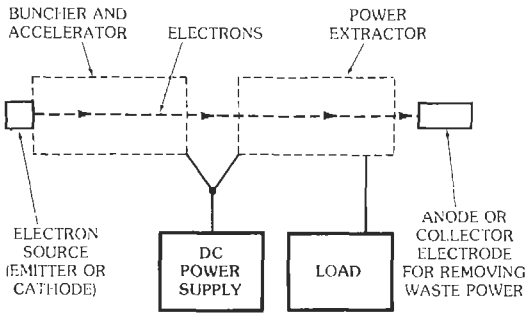

Fig. 10. Basic schematic diagram of RF amplifier using electron device.

the interelectrode gap, f is frequency, and d is gap length in the direction of electron flow) must be held constant for a given performance.

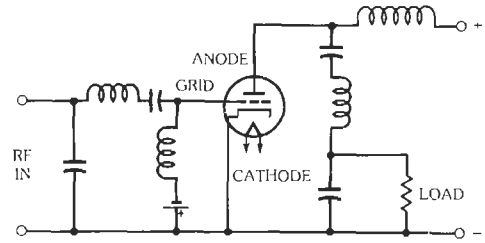
The above is true for electrons both in a vacuum and in the solid state, but if we now consider the actual values of v and d, we note a fundamental difference.

$$v \text{ in vacuum} \propto \phi^{1/2}$$

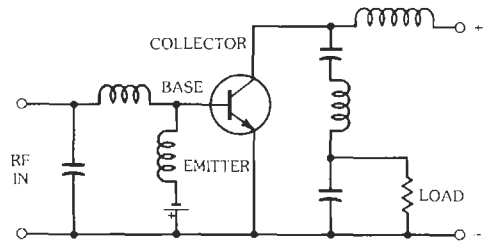
where ϕ is the potential difference through which the electron has passed. For example, if $\phi = 2000$ volts, as commonly encountered in a high-power tube, $v \simeq 2 \times 10^9$ cm/s. On the other hand, in silicon, for example, v_{max} is a constant 6×10^6 cm/s.

Assume that for efficient energy extraction an electron must pass through the output gap in a time $t = (1/2\pi) \times$ (period of radio frequency). (The output gap is grid to anode in a tube or base to collector in a transistor.) At a frequency of 100 MHz, for example, $t = (1/2\pi)10^{-8}$ s. Then the output gap length must be less than the product vt, or 10^{-2} cm for the transistor compared to 3 cm for the tube. At 1000 MHz, these dimensions would be 10^{-3} cm for the transistor and 0.3 cm for the tube.

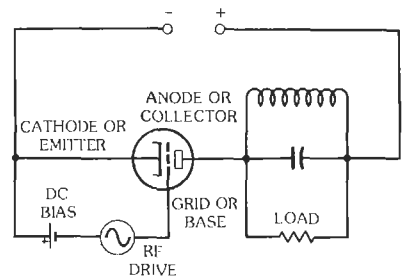
The maximum applied voltage is determined by the above dimensions and the dielectric strength of the medium. For silicon, the breakdown voltage is about 2×10^5 V/cm. In a vacuum, the situation is more complicated, but under typical conditions in a high-power tube the same number can be used. This leads to the conclusion that at 1000 MHz the maximum voltage across the tube could be $2 \times 10^5 \times 3 \times 10^{-1} = 60\,000$ V and the maximum voltage across the transistor could be 200 V. In both devices, when used in the circuits shown in Fig. 11, the peak applied voltage occurs during the half cycle when no current flows and will reach a value of about twice the DC power-supply voltage. Therefore, the DC voltage would ideally be limited, at 1000 MHz, to 100 volts for the transistor and 30 000 volts for the tube. In practice, the transistor DC voltage tends to be much lower, typically 28 volts, because the base-to-collector distance is in fact less than the distance limit determined by electron transit time (for reasons given below), and the maximum usable



(A) Using triode tube.



(B) Using transistor.



(C) Equivalent circuit for both types of device.

Fig. 11. Simplified RF amplifier circuit diagrams.

voltage remains constant as the frequency is reduced. In the tube, the voltage ideally could rise inversely with frequency, but it is limited in practice because of the cost of high-voltage power supplies and the problem of insulation outside the vacuum.

Summarizing, then, it appears that for reasons of breakdown voltage alone, the relative power levels of transistors and gridded power tubes would be in the ratio of 1 to 300, assuming the same current in both and no other limitations. In practice, the ratio is higher because the problem of heat removal in the transistor sets an upper limit to the voltage that tends to be constant at about 60 volts rather than 200 volts, so that power-supply voltages of 28 volts are typical. The heat-removal problem is severe because, unlike the case in a vacuum, heat is generated by the passage of current through the semiconductor due to collisions between electrons and atoms (the reason for the velocity limit referred to above) and also by the thermal vibration of

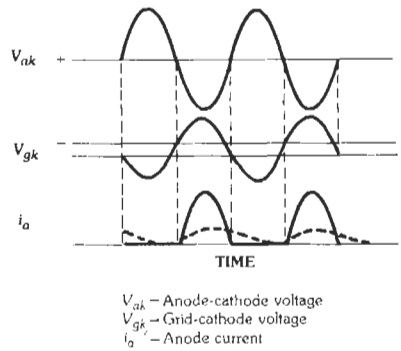


Fig. 12. Waveforms of voltage and current in class-B radio-frequency amplifier.

the atoms in the RF field (dielectric loss). In a vacuum, this is zero. The heat generated must be conducted through the semiconductor to the heat sink at the collector terminal, so the thermal conductivity of the material is critical. To add to the difficulties, semiconductor performance deteriorates as temperature increases. The heat-removal problem in fact sets an upper limit to power output well below the more basic limitation due to electron transit time.

The remaining factors that determine the power output of a device are its cross-sectional area and current density. Here again is a great distinction. The size of the solid-state device is limited by fabrication technology and cost to the order of 0.1 cm^2. The gridded power tube is limited by the more fundamental fact that its efficiency falls off if one dimension perpendicular to electron flow exceeds approximately one-tenth the operating wavelength. The other dimension may be larger. A cylindrical tube at 1000 MHz (30 cm wavelength) may be $3 \times 10 = 30$ cm^2 in area. At lower frequencies, it can be correspondingly larger, as will be seen later. The maximum current density on peaks of RF achievable in the transistor is about 200 A/cm^2 at UHF and 800 A/cm^2 at 100 MHz. In the tube, it is about 3 A/cm^2. The current per device is the product of the current density and the area.

In summary, the power output per device is proportional to applied voltage times current density times cross-sectional area times conversion efficiency. If efficiency is neglected, Table 4 is a rough guide to relative performance. From the table, it is evident that large numbers of transistors must be combined to give the power output obtainable from a single tube. Combination of transistors has been done to the extent indicated by Fig. 9, in which available power from combinations is shown.

It should be noted that the major advantage of the solid-state device, inherent long life under normal conditions, becomes less and less significant as the number of devices combined increases. This is to some extent overcome by techniques that allow complete failure of one or more devices to occur without failure of the system but with only a degradation in performance that can often be tolerated ("graceful degradation"). It is also not surprising that some performance criteria—bandwidth, for example—tend to fall off as the number of devices combined increases. This happens because the input and output impedances of the combination, which with simple paralleling are inversely proportional to the number of devices, become very low compared to the impedances of the circuits with which the combination is associated. Also, it should be noted that paralleling requires low-voltage regulated power supplies with high current capability. This is by no means easy to achieve and is very costly. One form of degradation, hardly graceful, is total failure of all devices due to a transient overcurrent or overvoltage phenomenon such as the electromagnetic pulse (emp) that can result from nearby lightning or a nuclear explosion. A less dramatic but equally fatal circumstance producing the same result is an unplanned increase in load impedance that causes the voltage to rise to the breakdown limit. It is interesting that the solid-state device and the tube device react differently to this event because of their different physical nature. In the solid-state device, the effect is a permanent breakdown, or short-circuit. In the vacuum device, the effect is a temporary breakdown followed by a resumption of full performance a short time after the transient has subsided.

In summary, then, it appears that both tubes and solid-state devices have fundamental limitations. Both have reached a stage of development where subsequent improvements will probably be small relative to those already made. Essentially, the transistor is a low-power device. The art of combining transistors may progress so that higher-power packages may become available, but at extra cost. In nonmilitary systems, it is ultimately the cost in terms of amortized capital cost plus operating and maintenance costs per unit time that governs the choice of device type.

TABLE 4. RELATIVE PERFORMANCE OF TUBE AND TRANSISTOR

Device	Volts	Area (cm^2)	Current Density (A/cm^2)	Product	Approx Ratio
Transistor at 1000 MHz	28	0.1	200	5.6×10^2	1
Transistor at 100 MHz	28	0.1	800	22.4×10^2	4
Tetrode at 1000 MHz	6000	30	3	5.4×10^5	1000
Tetrode at 100 MHz	18 000	1000	1	1.8×10^7	30 000

(It is of historical interest that before the advent of high-power velocity-modulated tubes, serious and successful attempts were made to combine triodes and tetrodes to increase RF power output at VHF and UHF, and many transmitters were built this way. As soon as tubes giving sufficient power from a single type for the application became available, these multitube equipments were superceded for economic reasons.)

Power Gain and Bandwidth of RF Amplifiers

Power gain and bandwidth of RF amplifiers depend on both device and circuit properties. As noted above, the power gain of a tetrode falls in the range between 30 dB at LF and MF and 10 dB at UHF. Power gain at UHF is limited by electron-transit-time effects and by the inevitable effect of cathode-lead inductance.

Corresponding bandwidths with conventional resonant circuits fall between about 1% (AM broadcast, UHF TV) and 10% (TV at 50 MHz) of the carrier frequency.

For a simplified ideal tube amplifier, the gain-bandwidth product tends to be constant and equal to G_m/C, where G_m is the mutual conductance (transconductance) and C is the output capacitance. This product is independent of frequency. In practice, the product is always less because of the presence of the external circuits that store energy and because the bandwidth of the input circuit may be smaller than that of the output circuit. Furthermore, the performance of the amplifier may be largely determined by the amount of feedback present. It is nevertheless true that the gain-bandwidth product will always increase with G_m/C.

This factor is related to interelectrode spacings and is approximately inversely proportional to the grid-cathode spacing. The achievement of small spacing, which implies fine grid wires and structures of high dimensional stability with respect to change of temperature, has always been a major challenge in tube design.

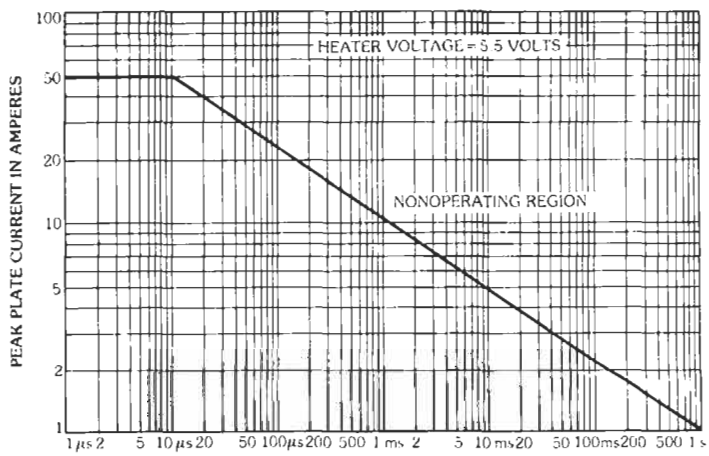
Power Output Under Pulse Conditions

Fig. 9 shows CW power available versus frequency. Under pulse conditions, gridded tubes can be made to give many times this power, depending on the pulse width and duty factor (ratio of pulse width to the interval between pulses). Tube manufacturers will supply data on the exact amount of power. A typical pulse derating chart is shown in Fig. 13. The power is limited by the thermal capacity of the grids, by the breakdown voltage between electrodes, and by the emission capability of the cathode.

Life Expectancy of Tubes

The principal factor governing tube life is the temperature of the thermionic cathode. This is related to emission and therefore to output power. In general, longer life results from lower cathode temperature. In a well designed tube, the available emission at the specified cathode heating power is many times that required for satisfactory operation. It is therefore often possible to reduce the heating power and increase the life of the tube.

Another factor affecting life is the relationship between maximum ratings and operating conditions. Exceeding ratings causes overheating, which tends to shorten life. Careful attention must be paid to manufacturers' ratings and recommendations.



Peak (pulse) plate-current capability is dependent on pulse duration (t_p) and duty factor (*Du*). Maximum peak plate current for a given value t_p is shown. Maximum *Du* may then be derived from the relationship:

$$1.0 = i_{p\max} \overline{Du}$$

Fig. 13. Pulse-derating data for triode type 3CPX1500A7, pulse modulator or regulator service. (*Courtesy Varian/Eimac*)

Life expectancy for a highly stressed oxide-cathode tube at UHF may be 2500 hours. For a thoriated-tungsten-filament tube in broadcast service, 50 000 hours is not uncommon.

Development Trends in Gridded Power Tubes

Improved performance of power grid tubes, including longer life, can be anticipated from the incorporation of improved materials and fabrication techniques. For example, the use of pyrolytic graphite for grids is becoming standard practice. Impregnated tungsten dispenser cathodes commonly found in microwave velocity-modulated tubes may find their way into gridded power tubes.

In addition, improved structural forms such as modular construction may allow the manufacture of very-high-power tubes (capable of 10 MW of CW power output) having higher gain-bandwidth products because of smaller grid-cathode spacings.

At VHF and UHF, developments of the Klystrode™ amplifier may appear in applications where the combination of small size compared to a klystron; relatively high efficiency, especially with amplitude modulation; high power capability; and interesting power gain makes it more attractive than a klystron or a conventional tetrode.

18 Semiconductors and Transistors

Ben G. Streetman

The basic building blocks of any electronic circuit or system are electronic devices—the transistors, diodes, and other elements that collectively allow the system to perform its function. These devices may be individual transistors, diodes, and passive elements soldered in appropriate interconnection. Or, the system may be a collection of complex integrated circuits, each composed of thousands of active and passive elements on a silicon chip (see Chapter 20). The system may even involve information transfer by a modulated light beam and detector (see Chapter 21). In any case, a great variety of electronic elements is available for performing the desired function, and those who design or use electronic equipment have a wide range of devices from which to choose.

Most modern electronic devices are made with semiconductor materials. The unusual properties of these solids are responsible for a revolution in electronics since the invention of the transistor. This chapter* deals with semiconductors and their applications in pn junctions, transistors, and other devices. Circuit models of transistors are discussed in Chapter 19, and fabrication methods are discussed in Chapter 20.

SEMICONDUCTORS

Semiconductors are a group of materials that have electrical conductivities intermediate between those of metals and insulators. It is significant that the conductivity of these materials can be varied considerably by changes in temperature, optical excitation, and impurity content. This variability of electrical properties makes possible the wide range of modern electronic devices.

*Much of this discussion is from Ben G. Streetman, *Solid State Electronic Devices*, 3rd ed., © 1990. Reprinted by permission of Prentice-Hall, Inc., Englewood Cliffs, N.J.

Semiconductor Materials

Semiconductors are found in column IV and neighboring columns of the periodic table (Table 1). The column-IV semiconductors silicon (Si) and germanium (Ge) are called *elemental* semiconductors because they are composed of single species of atoms. In addition to the elemental materials, compounds of column-III and column-V atoms, as well as certain combinations from columns II and VI, make up the *intermetallic*, or *compound*, semiconductors.

As Table 1 indicates, there are numerous semiconductor materials. Among these, silicon is used for the majority of semiconductor devices; rectifiers, transistors, and integrated circuits are now made mostly in silicon, although GaAs is also used in high-speed integrated circuits. The compounds are most widely used in devices requiring the emission or absorption of light. For example, semiconductor light-emitting diodes commonly are made of such compounds as GaAs, GaP, and alloys such as GaAsP. An important microwave device, the gunn diode, is usually made in GaAs. Thus, the wide range of semiconductor materials offers considerable variety in properties and provides experts in electronic circuits and systems with much flexibility in the design of electronic functions.

The electronic and optical properties of semiconductor materials are strongly affected by impurities, which may be added in precisely controlled amounts. Such impurities are used to vary the conductivities of semiconductors, and even to alter the nature of the conduction processes from conduction by negative charge carriers to conduction by positive charge carriers. For example, an impurity concentration of one part per million can change a sample of silicon from a poor conductor to a good conductor of electric current. This process of controlled addition of impurities, called *doping*, will be discussed below.

TABLE 1. COMMON SEMICONDUCTOR MATERIALS

The Portion of the Periodic Table Where Semiconductors Occur				
II	III	IV	V	VI
	B	C		
	Al	Si	P	S
Zn	Ga	Ge	As	Se
Cd	In		Sb	Te

Elemental and Compound Semiconductors			
Elemental	IV Compounds	III-V Compounds	II-VI Compounds
Si	SiC	AlP	ZnS
Ge	SiGe	AlAs	ZnSe
		AlSb	ZnTe
		GaP	CdS
		GaAs	CdSe
		GaSb	CdTe
		InP	
		InAs	
		InSb	

Virtually all semiconductor devices require single crystals of extremely pure materials. Since small concentrations of impurities can radically alter their electrical properties, device-grade semiconductor crystals are grown with greater perfection than any other materials.

Energy Bands and Charge Carriers

The atomic arrangement in most semiconductor crystals is similar to the diamond lattice, in which each atom is surrounded by four nearest neighbors. The atomic bonding in the crystal is largely covalent (as in the H_2 molecule). That is, the sharing of electrons between adjacent atoms in covalent bonds holds the crystal together. In the column-IV semiconductor silicon, for example, each atom has four valence electrons shared with four nearest neighbors.

Electrons in isolated atoms are restricted to certain discrete energy levels, predictable generally from the Bohr model and more precisely from the results of quantum mechanics. In a similar fashion, electrons in solids are restricted to certain energies and are not allowed at other energies. The basic difference between the case of an electron in a solid and that of an electron in an isolated atom is that in the solid the electron has a *range*, or *band*, of available energies. General features of the energy bands for insulators, metals, and semiconductors are shown in Fig. 1. In an insulator or semiconductor, a lower (valence) band is filled with electrons at low temperatures, and an upper (conduction) band is empty of electrons. The separation between the valence and conduction bands is called the *band gap* E_g. Insulators have a wider band gap than do semiconductors, and metals have overlapping bands.

The variety of electrical conductivities of metals, insulators, and semiconductors arises primarily from their band structures (Fig. 1). If electrons are to experience acceleration in an electric field, they must be able to move into new energy states. In a completely filled band, there are no available empty states, and therefore no net charge transport (no current) can take place. The same is true for an empty band, which contains no electrons to move. As a result, a perfect insulator does not conduct current. Metals, on the other hand, have electrons mixed with unfilled allowable

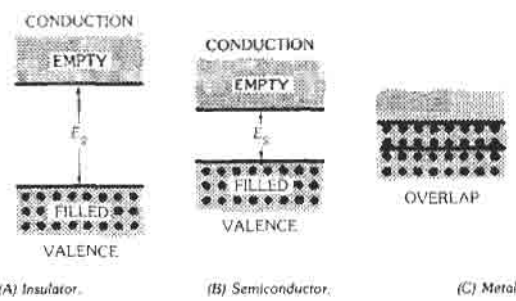

Fig. 1. Energy bands for typical materials.

energy states. Electrons are therefore available to participate in current flow, and there are plenty of energy states for the electrons to occupy in response to a field. This accounts for the high conductivity of metals.

Although semiconductors and insulators have similar band structures, there is an important difference: The band gap E_g of an insulator is several electronvolts wide,* whereas E_g for a typical semiconductor is sufficiently small (about one eV) to allow excitations of electrons from the valence band to the conduction band. These excitations can result from the application of thermal or optical energy. For example, at room temperature in a perfect silicon crystal (E_g = 1.1 eV), the equilibrium concentration of thermally generated electrons in the conduction band is about 1.5×10^{10} per cubic centimeter (cm^{-3}). Of course, there is an equal number of empty energy states in the valence band. These unoccupied valence-band states are referred to as *holes*. Electron-hole pairs (EHP) can also be created by optical excitation; for example, a quantum of light (*photon*) with energy greater than the band gap E_g can be absorbed by the semiconductor crystal, exciting a valence-band electron to the conduction band. The result is a conduction-band electron and a valence-band hole. As discussed below, this optical generation of electron-hole pairs is basic to the operation of semiconductor photoconductors and photodiodes.

At thermal equilibrium, the excitation of electrons to the conduction band is balanced by electrons falling back to the valence band (recombination). This balance of electron-hole generation and recombination results in a predictable concentration of EHP at a given temperature. Similarly, a steady optical excitation causes a new steady-state balance between generation and recombin- holes.

It is clear that electrons which have been excited to the conduction band of a semiconductor can participate in current conduction, since ample unoccupied energy states are available in that band. A less obvious but important feature of semiconductors is charge transport involving holes in the valence band. The presence of an empty state (hole) in the otherwise filled valence band allows electrons in the band to move, with a resulting net motion of charge, or current. The approach for calculating this charge transport is to sum the contributions of all electrons in a filled valence band (which results in zero net current) and then subtract the contribution of the missing electron. The result is equivalent to considering the hole as a positive charge carrier (i.e., a particle with charge $+q$, where $-q$ is the charge on an electron).† For example, a semiconductor

*The electronvolt (eV) is a particularly convenient unit of measure for the energy of an electron. One eV is defined as the energy acquired by an electron moving through a potential of one volt. Thus, 1 eV = 1.6×10^{-19} joule.

†Table 2 lists the magnitude of the electronic charge and other information.

TABLE 2.* PHYSICAL CONSTANTS AND CONVERSION FACTORS

Avogadro's number	$N_A = 6.02 \times 10^{23}$ molecules/mole
Boltzmann's constant	$k = 1.38 \times 10^{-23}$ J/K

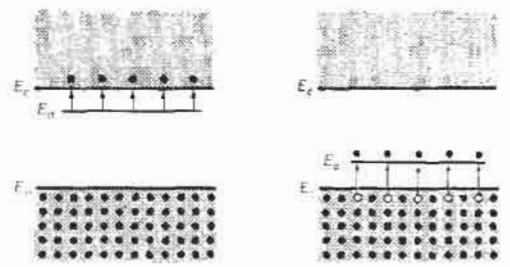
with 10^{10} electron-hole pairs per cubic centimeter contains a concentration of 10^{10} cm^{-3} negatively charged electrons in the conduction band, which drift opposite to an applied electric field, and 10^{10} cm^{-3} positively charged holes in the valence band, which drift in the direction of the field. The two current components add in the field direction to give the total current. Both electrons and holes are important charge carriers in semiconductors.

In addition to the direct excitation of electrons and holes in pairs, each type of charge carrier can be introduced by appropriate doping of the semiconductor with impurities. Impurities can be added to the crystal in the growth process or introduced later during device fabrication. By doping, a crystal can be altered so that it has a predominance of either electrons or holes. Thus there are two types of doped semiconductors, n-type (mostly electrons) and p-type (mostly holes). The designation n and p is chosen to reflect the dominance of negative or positive charge carriers.

When impurities are introduced into an otherwise perfect crystal, additional levels are created in the energy-band structure, usually within the band gap. For example, an impurity from column V of the periodic table (phosphorus, P; arsenic, As; antimony, Sb) introduces an energy level very near the conduction band in germanium or silicon. This level is filled with electrons at 0 K, and very little thermal energy is required to excite these electrons to the conduction band (Fig. 2A). Thus at room temperature virtually all of the electrons in the impurity level are "donated" to the conduction band. Such an impurity level is called a *donor* level, and the column-V impurities in germanium or silicon are called donor impurities. Material doped with donor impurities can have a considerable number of electrons in the conduction band, even when the temperature is too low for the thermally generated EHPs to be appreciable. Thus for semiconductors doped with a significant number of donor atoms, the electron concentration n will be much greater than the hole concentration p. This is n-type material.

Atoms from column III (boron, B; aluminum, Al; gallium, Ga; indium, In) introduce impurity levels in germanium or silicon near the valence band (Fig. 2B). These levels are empty of electrons at 0 K. At higher temperatures, enough thermal energy is available to excite electrons from the valence band into the impurity level, leaving behind holes in the valence band. Since this type of impurity level "accepts" electrons from the valence band, it is called an *acceptor* level, and the column-III impurities are acceptor impurities in germa-



(A) Electrons are thermally excited from a donor level to the conduction band.

(B) Valence-band electrons are excited to E_a, leaving holes in the valence band.

Fig. 2. Donor and acceptor levels (E_d and E_a) in a semiconductor.

nium and silicon. Doping with acceptor impurities can create a semiconductor with a hole density much greater than the conduction-band electron density (p-type material).

A semiconductor without doping impurities is called *intrinsic* material, and the *intrinsic carrier concentration* n_i is the concentration of thermally generated electron-hole pairs. In silicon, for example, the intrinsic concentration n_i is about 10^{10} cm^{-3} at room temperature. If silicon is doped with 10^{15} antimony atoms/cm^3, the conduction electron concentration n increases from 10^{10} to 10^{15} cm^{-3}, a change of five orders of magnitude. As a result, the resistivity of silicon changes from about 2×10^5 ohm-cm to 5 ohm-cm with this doping.

When a semiconductor is doped n-type or p-type, one type of carrier dominates. In the example given above, the conduction-band electrons outnumber the holes in the valence band by many orders of magnitude. We refer to the small number of holes in n-type material as *minority carriers* and the relatively large number of conduction electrons as *majority carriers*. Similarly, electrons are the minority carriers in p-type material and holes are the majority carriers.

Carrier Concentrations

In calculating semiconductor electrical properties and analyzing device behavior, it is often necessary to know the concentration of charge carriers in the material. The majority-carrier concentration is usually obvious in heavily doped material, since one majority carrier is obtained for each impurity atom. The concentration of minority carriers is not obvious, however, unless we consider details of the electron distribution in the solid. An important result of semiconductor statistics is that the *electron-hole product np* at equilibrium is a constant for a given material at a given temperature, whether the material is doped or not:

$$np = n_i^2 \qquad \text{(Eq. 1)}$$

where n and p are the equilibrium electron and hole concentrations, respectively. Thus, if we know the majority-carrier concentration (e.g., from the doping density) we can find the minority-carrier concentration from Eq. 1. For example, if a silicon sample ($n_i = 1.5 \times 10^{10}$ cm^{-3}) is doped with 10^{15} donors/cm^3, the electron concentration is essentially 10^{15} and the hole concentration is only 2.25×10^5 cm^{-3} at room temperature. It is interesting to note from Eq. 1 that as the majority-carrier concentration increases, the minority-carrier concentration must decrease.

If a semiconductor contains both donors and acceptors, the exact relationship among the electron, hole, donor, and acceptor concentrations can be obtained by considering the requirements for *space-charge neutrality*. If the material is to remain electrostatically neutral, the sum of the positive charges (holes and ionized donor atoms N_d^+) must balance the sum of the negative charges (electrons and ionized acceptor atoms N_a^-):

$$p + N_d^+ = n + N_a^- \qquad \text{(Eq. 2)}$$

If the material is strongly n-type ($n >> p$) and all of the impurities are ionized, we can approximate Eq. 2 by $n \cong N_d - N_a$.

Drift of Carriers

The electrons and holes in a semiconductor are in constant motion due to their thermal energy. At thermal equilibrium, the movement is random, and carriers are scattered from lattice atoms, impurities, and defects. Since the scattering is completely random, there is no net motion of the group of carriers over a period of time. On the other hand, if an electric field is applied to the sample, a net drift of carriers is superimposed on the random thermal motion. Thus, a field $\mathscr{E}_x$ applied in the direction results in a net force $q\mathscr{E}_x$ on each hole and $-q\mathscr{E}_x$ on each electron. The current resulting from this net drift is just the number of carriers crossing a given area A per unit time (number of carriers times velocity) multiplied by the charge of the carrier:

$$I = qApv_p - qAn(-v_n) \qquad \text{(Eq. 3)}$$

In this equation, v_p is the average drift velocity of holes in the x direction, and $-v_n$ is the average electron velocity, which is in the opposite direction. The resulting electrical conductivity is usually written in terms of the *mobility* of each charge carrier. This quantity measures the ease with which carriers drift in a given material. The hole mobility μ_p is the average drift velocity per unit applied field $v_p/\mathscr{E}$, and similarly for electron mobility μ_n. Thus the current is

$$I = qA(\mu_p p + \mu_n n)\mathscr{E} \equiv \sigma\mathscr{E}A \qquad \text{(Eq. 4)}$$

where the conductivity of the sample σ has the units (ohm-cm)$^{-1}$. Conductivity is determined by electron and hole concentration (n, p), and therefore by the doping of the sample, and also by the carrier mobilities.

If a semiconductor bar contains both types of carriers, holes drift as a group in the direction of the electric field, and electrons drift in the opposite direction. Both components of current are in the direction of the $\mathscr{E}$ field, however, since conventional current is positive in the direction of hole flow and opposite to the direction of electron flow.

If a magnetic field is applied perpendicular to the direction in which holes drift in a p-type bar, the path of the holes tends to be deflected (Fig. 3). In vector notation, the total force on a single hole due to the combined electric and magnetic fields is

$$\mathbf{F} = q(\mathbf{E} + \mathbf{v} \times \mathbf{B}) \qquad \text{(Eq. 5)}$$

In the y direction the force is

$$F_y = q(\mathscr{E}_y - v_x\mathscr{B}_z) \qquad \text{(Eq. 6)}$$

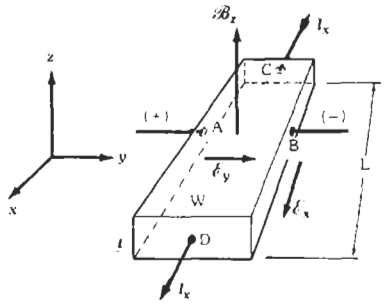


Fig. 3. A p-type semiconductor bar in a magnetic field, resulting in the production of a Hall-effect voltage.

An electric field $\mathcal{E}_y$ builds up in the y direction as holes are displaced laterally, and in steady state this field is sufficient to just balance the force due to the magnetic field ($\mathcal{E}_y = v_x \mathcal{B}_z$). The resulting voltage between A and B can be measured with a high-impedance voltmeter. This is called the Hall effect, and V_{AB} is called the Hall voltage. This effect can be used to measure magnetic fields and in a variety of other applications. An important use for the Hall effect in semiconductor research is that the Hall voltage can be easily related to the concentration of majority carriers in the sample. Although the discussion here relates to p-type material, similar results obtain for n-type samples, in which the majority carriers are electrons. By combining Hall measurements with conductivity measurements, the majority-carrier concentration and mobility can be obtained for a semiconductor sample.

Excess Carriers; Diffusion

To this point, we have discussed electron and hole carrier concentrations at thermal equilibrium or with steady fields applied. In each case, the carrier concentrations have been the equilibrium values (let us call them n_o and p_o). However, most semiconductor devices operate by the creation of carrier concentrations greater than the equilibrium values. In such cases, we can refer to the *excess* electron concentration as δn, such that the total electron concentration n is

$$n = n_o + \delta n \qquad \text{(Eq. 7A)}$$

and similarly

$$p = p_o + \delta p \qquad \text{(Eq. 7B)}$$

for holes.

The excess carrier concentrations denoted by δn and δp can arise from several causes, most commonly from *optical excitation* or from *carrier injection*, which is characteristic of pn junctions. Optical excitation is the basis of semiconductor light detectors.

When excess carriers are created at a rate g_{op} by a steady light, a steady-state balance is established between generation and recombination. That is, in steady state the EHPs recombine as fast as they are generated; otherwise, there would be a buildup of EHPs with time. Thus, the recombination rate equals the generation rate in steady state. However, the electron and hole concentrations in the illuminated sample are greater than the equilibrium values. In particular,

$$\delta n = g_{op}\tau_n, \quad \delta p = g_{op}\tau_p \qquad \text{(Eq. 8)}$$

where τ_n and τ_p are called the electron and hole *lifetimes*, respectively. The lifetime of a carrier is the average time it spends in its respective band before recombination. Thus $\delta n/\tau_n$ is the electron recombination rate, and $\delta p/\tau_p$ is the rate at which holes are generated and recombine in steady state.

The complementary mechanism to optical absorption is *radiative recombination*. In some semiconductors, the energy lost by an electron in recombining with a hole is given off by a photon of light. If the recombination takes place directly, without involving an intermediate state in which a carrier is temporarily captured, the energy of the emitted photon is equal to the band gap (see Table 3). For example, recombination of excess carriers in GaAs results in light emission with photon energies equal to the band-gap energy of about 1.4 eV. Such emission is called *luminescence*. Recombination in many semiconductors (such as silicon and germanium) takes place indirectly; for example, an electron is trapped at an impurity or lattice defect, and then a hole is captured to complete the recombination process. In such cases, the energy of the electron is given up as heat to the lattice, and no light is emitted.

If a current is passed through an illuminated semiconductor sample, we find that the conductivity has increased due to the presence of the excess carriers. From Eqs. 4 and 7, the conductivity is

$$\sigma = q(\mu_p p + \mu_n n)$$

$$= q[\mu_p(p_o + \delta p) + \mu_n (n_o + \delta n)] \qquad \text{(Eq. 9)}$$

The change in conductivity between its dark value and its value with the generation rate g_{op} is

$$\Delta\sigma = q(\mu_p \delta p + \mu_n \delta n)$$

$$= q\, g_{op}(\tau_p \mu_p + \tau_n \mu_n) \qquad \text{(Eq. 10)}$$

This increase in conductivity for the illuminated sample is called *photoconductivity*. We notice from Eq. 10 that a sensitive photoconductive detector should have reasonably long carrier lifetimes and high carrier mobilities. Carrier lifetime is determined for most semiconductors by crystal quality, doping, and other material properties.

If the excess carrier concentrations δn and δp vary with position in the sample, *diffusion* occurs. Diffusion is the familiar process by which particles migrate from regions where their concentration is high to regions of lower concentration. A simple example of this process is the opening of a perfume bottle in a closed room with

very still air. The scented air molecules soon disperse throughout the room, even if no air currents exist. The diffusion is due simply to the random thermal motion of the air molecules. The diffusion continues until the particles are evenly distributed in space. This process is described mathematically by *Fick's first law of diffusion*

$$\phi(x) = -D[dN(x)/dx] \qquad \text{(Eq. 11)}$$

for a one-dimensional problem. This relation states that the rate of particle flow in the x direction [the particle flux density $\phi(x)$] is proportional to the negative gradient of the particle concentration $N(x)$ at each point x. The proportionality constant D is called the *diffusion coefficient* (cm^2/s). Particles diffuse in the direction of decreasing particle concentration; the rate of flow depends on how steeply the concentration profile is graded; and no external driving force besides random thermal motion is involved.

The same diffusion mechanism applies to charge carriers if their concentration varies spatially, and the result is a diffusion current

$$J_n(\text{diff.}) = -(-q)\, D_n[dn(x)/dx]$$

$$= +q\, D_n[dn(x)/dx] \qquad \text{(Eq. 12A)}$$

$$J_p(\text{diff.}) = -(+q)\, D_p\, [dp(x)/dx]$$

$$= -q\, D_p\, [dp(x)/dx] \qquad \text{(Eq. 12B)}$$

In these equations J(diff.) is the current density (A/cm^2) due to diffusion, and the n and p subscripts refer to electrons and holes, respectively. The current density J is related to the particle flux density ϕ by the charge on the carrier. As a result of the opposite charge on the two types of carriers, Eqs. 12 indicate that electrons and holes diffusing together in a particle gradient give rise to currents in opposite directions.

In most cases, electric fields are present along with gradients in the carrier concentrations. We can include drift in the field along with diffusion:

$$J_n(x) = q\mu_n n(x)\mathscr{E}(x) + qD_n[dn(x)/dx] \qquad \text{(Eq. 13A)}$$

drift diffusion

$$J_p(x) = q\mu_p p(x)\mathscr{E}(x) - qD_p[dp(x)/dx] \qquad \text{(Eq. 13B)}$$

The total current density is the sum of the electron and hole components:

$$J(x) = J_n(x) + J_p(x) \qquad \text{(Eq. 14)}$$

At equilibrium, there is no net current in a semiconductor. Thus, any fluctuation that would begin a diffusion current sets up an electric field that redistributes carriers by drift. An examination of the requirements for equilibrium indicates that the diffusion coefficient and mobility must be related by

$$D/\mu = kT/q \qquad \text{(Eq. 15)}$$

for either carrier type. This important equation is called the *Einstein relation*. It allows us to measure either D or μ and calculate the other.

In many carrier-diffusion problems, a steady-state distribution is maintained by a constant generation of excess carriers at some point in the semiconductor. For example, in Fig. 4, a steady excess hole concentration Δp is maintained by the injection of holes at $x = 0$ in a long semiconductor bar. Clearly, these excess holes will diffuse into the semiconductor; but they will also recombine with a characteristic lifetime τ_p. Thus the excess hole concentration $\delta p(x)$ decreases with distance into the semiconductor. This process is governed by the *steady-state diffusion equations:*

$$d^2\delta n/dx^2 = \delta n/D_n\tau_n \equiv \delta n/L_n^2 \quad \text{(Eq. 16A)}$$

$$d^2\delta p/dx^2 = \delta p/D_p\tau_p \equiv \delta p/L_p^2 \quad \text{(Eq. 16B)}$$

where,

$L_n \equiv \sqrt{D_n\tau_n}$ is called the electron *diffusion length*, L_p is the diffusion length for holes.

For the example of Fig. 4, the solution to Eq. 16B is

$$\delta p(x) = C_1 e^{x/L_p} + C_2 e^{-x/L_p} \quad \text{(Eq. 17)}$$

We can evaluate C_1 and C_2 from the boundary conditions. Since recombination must reduce $\delta p(x)$ to zero for large values of x, $\delta p = 0$ at $x = \infty$, and therefore $C_1 = 0$. Similarly, the condition $\delta p = \Delta p$ at $x = 0$ gives $C_2 = \Delta p$, and the solution is

$$\delta p(x) = \Delta p e^{-x/L_p} \quad \text{(Eq. 18)}$$

for the steady-state hole distribution. The injected excess hole concentration dies out exponentially in x due to recombination, and the diffusion length L_p represents the average distance a hole diffuses before recombining.

The steady-state distribution of excess holes causes diffusion, and therefore a hole current, in the direction of decreasing concentration. From Eqs. 12B and 18 we have

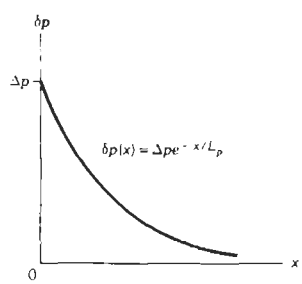

Fig. 4. Excess holes injected into a long n-type semiconductor diffuse and recombine, giving an exponential distribution.

$$J_p(x) = -qD_p(dp/dx) = -qD_p(d\delta p/dx)$$

$$= q(D_p/L_p)\Delta p e^{-x/L_p} = q(D_p/L_p)\delta p(x) \quad \text{(Eq. 19)}$$

Since $p(x) = p_o + \delta p(x)$, the space derivative involves only the excess holes. Notice that since $\delta p(x)$ is proportional to its derivative for an exponential distribution, the diffusion current at any x is just proportional to the excess density δp at that position.

Although this example seems rather restricted, it is typical of carrier injection in pn junctions. The injection of minority carriers across a junction often leads to exponential distributions as in Eq. 18, with the resulting diffusion current of Eq. 19.

pn JUNCTIONS

Most semiconductor devices contain at least one junction between p-type and n-type material. Such junctions are responsible for the injection and collection of charge carriers necessary for the operation of diodes, transistors, and other devices. Junctions are typically formed by crystal growth processes, by alloying, or by ion implantation or diffusion of doping impurities into crystals of the opposite conductivity type. We will consider here an abrupt junction between a uniformly doped p region and a uniformly doped n region of a single crystal semiconductor.

A Junction at Equilibrium

Let us consider separate regions of p- and n-type semiconductor material, brought together to form a junction (Fig. 5). Since the n material has a large concentration of electrons and few holes, and conversely for the p material, we expect considerable diffusion of carriers across the junction. Thus holes diffuse from the p side into the n side, and electrons diffuse from n to p.

Uncharged particles would diffuse throughout the material, resulting in a homogeneous distribution. This cannot occur in the case of the charged particles in a pn junction because of the development of space charge and the electric field $\mathscr{E}$ in the neighborhood of the junction. Electrons diffusing from n to p leave behind uncompensated* donor ions (N_d^+) in the n material, and holes leaving the p region leave behind uncompensated acceptors (N_a^-); thus a region of positive space charge develops near the n side of the junction, and negative charge develops near the p side. The resulting

*Neutrality is maintained in the bulk materials of Fig. 5 by the presence of one electron for each ionized donor ($n = N_d^+$) in the n material, and one hole for each ionized acceptor ($p = N_a^-$) in the p material (neglecting minority carriers). Thus, if electrons leave n, some of the positive donor ions near the junction are left uncompensated. The donors and acceptors are fixed in the lattice, in contrast to the mobile electrons and holes.

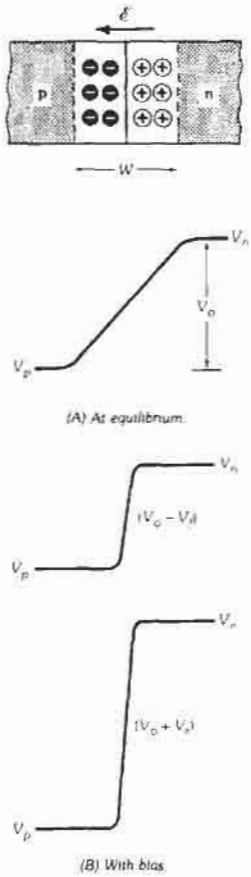

Fig. 5. A pn junction.

electric field is directed from the positive charge toward the negative charge. The influence of $\mathscr{E}$ for each type of carrier is in the direction opposite to that of diffusion current. Therefore the field creates a drift component of current from n to p, opposing the diffusion current.

Since no *net* flow of electrons or holes across the junction can take place at equilibrium, the current due to the drift of each type of carrier in the $\mathscr{E}$ field must exactly cancel the diffusion current in Eq. 13. Therefore, the electric field $\mathscr{E}$ builds up to the point that the net current is zero at equilibrium. The electric field appears in some region W about the junction, and there is an equilibrium potential difference V_o across W. We assume the electric field is zero in the neutral regions outside W. Thus there is a constant potential V_n in the neutral n material, a constant V_p in the neutral p material, and a potential difference $V_o = V_n - V_p$ between the two. The region W is called the *transition region* (also called the *depletion region*), and the potential V_o is called the *contact potential*.

If we consider the junction to be made up of material with N_a acceptors per cubic centimeter on the p side and N_d donors on the n side, we can show that the contact potential is

$$V_o = (kT/q) \ln N_a N_d / n_i^2 \qquad \text{(Eq. 20)}$$

Forward and Reverse Bias

One of the useful features of a pn junction is the fact that current flows quite freely in the p-to-n direction when the p region has a positive external voltage bias relative to n (forward bias and forward current), whereas virtually no current flows when p is made negative relative to n (reverse bias and reverse current). This current asymmetry makes the pn junction diode very useful as a rectifier of ac signals, and forms the basis for many other applications of junctions.

Assume an applied voltage bias V appears across the transition region of the junction rather than in the neutral n and p regions. In typical devices, the neutral regions have low resistance, and the space charge regions about the junction take up most of the applied voltage. Since an applied voltage changes the electrostatic potential barrier and thus the electric field within the transition region, we would expect changes in the various components of current at the junction.

The *electrostatic potential barrier* at the junction is lowered by a forward bias, V_f, from the equilibrium contact potential, V_o, to the smaller value $V_o - V_f$. This lowering of the potential barrier occurs because a forward bias (p positive with respect to n) raises the electrostatic potential on the p side relative to the n side (Fig. 5B). For a reverse bias ($V = -V_r$) the opposite occurs; the electrostatic potential of the p side is depressed relative to the n side, and the potential barrier at the junction becomes larger ($V_o + V_r$).

The *electric field* within the transition region decreases with forward bias, since the applied electric field opposes the built-in field. With reverse bias, the field at the junction is increased by the applied field.
