*Basic Designations:* The aerospace metric screw thread is designated by the letters "MJ" to identify the metric J thread form, followed by the nominal size and pitch in millimeters (separated by the sign "×") and followed by the tolerance class (separated by a dash from the pitch). Unless otherwise specified in the designation, the thread helix is right hand.

*Example:* MJ6 × 1 – 4h6h

For further details concerning limiting dimensions, allowances for coating and plating, modified and special threads, etc., reference should be made to the Standard.

### Trapezoidal Metric Thread

**Comparison of ISO and DIN Standards.**— ISO metric trapezoidal screw threads standard, ISO 2904-1977, describes the system of general purpose metric threads for use in mechanisms and structures. The standard is in basic agreement with trapezoidal metric thread DIN 103. The DIN 103 standard applies a particular pitch for a particular diameter of thread, but the ISO standard applies a variety of pitches for a particular diameter. In ISO 2904-1977, the same clearance is applied to both the major diameter and minor diameter, but in DIN 103 the clearance in the minor diameter is two or three times greater than clearance in the major diameter. A comparison of DIN 103 is given in Table 1.

Metric Trapezoidal Thread, ISO 2904

**Terminology:** The term "bolt threads" is used for external screw threads, the term "nut threads" for internal screw threads.

**Calculation:** The values given in the International standards have been calculated by using the following formulas:

$$\begin{aligned}
 H_1 &= 0.5P & H_4 &= H_1 + a_c = 0.5P + a_c & H_3 &= H_1 + a_c = 0.5P + a_c \\
 D_4 &= d + 2a_c & Z &= 0.25P = H_1/2 & D_1 &= d - 2H_1 = d - p \\
 D_3 &= D - 2h_3 & d_2 &= D_2 = d - 2Z = d - 0.5P & R_{1\max.} &= 0.5a_c & R_{2\max.} &= a_c
 \end{aligned}$$

where  $a_c$  = clearance on the crest;  $D$  = major diameter for nut threads;  $D_2$  = pitch diameter for nut threads;  $D_1$  = minor diameter for nut threads;  $d$  = major diameter for bolt threads = nominal diameter;  $d_2$  = pitch diameter for bolt threads;  $d_3$  = minor diameter for bolt threads;  $h_1$  = Height of overlapping;  $h_4$  = height of nut threads;  $h_3$  = height of bolt threads; and,  $P$  = pitch.

**Table 1. Comparison of ISO Metric Trapezoidal Screw Thread ISO 2904-1977 and Trapezoidal Metric Screw Thread DIN 103**

	ISO 2904	DIN 103	Comment
Nominal Diameter	$D$	$D_s$	
Pitch	$p$	$p$	Same
Clearances (Bolt Circle)	$a_c$	$b$	Same
Clearances (Nut Circle)	$a_c$	$a$	Not same
Height of Overlapping	$h_1$	$h_e$	Same
Bolt Circle			
	$h_3 = 0.50P + a_c$	$h_s = 0.50P + a$	Same
	$h_{as} = 0.25p$	$z = 0.25p$	Same
Minor diameter for external thread	$D_3 = d - 2h_3$	$k_s = d - 2h_s$	Same
Pitch diameter for external thread	$D_2 = d - 2h_{as}$	$d_2 = d - 2z$	Same
Nut Circle			
Basic major diameter for nut thread	$D_4 = d + 2a_c$	$d_n = d + a + b$	Not same
Height of internal thread	$h_4 = h_3$	$h_n = h_3 + a$	Not same
Minor diameter of internal thread	$D_1 = D - 2h_1$	$K_n = D_n - 2h_n$	Not same

$D$  and  $d$  dimensions refer to the nut (internal) and screw (external) threads, respectively.

## British Standard ISO Metric Screw Threads

BS 3643:Part 1:1981 (R2004) provides principles and basic data for ISO metric screw threads. It covers single-start, parallel screw threads of from 1 to 300 millimeters in diameter. Part 2 of the Standard gives the specifications for selected limits of size.

**Basic Profile.**— The ISO basic profile for triangular screw threads is shown in Fig. 1. and basic dimensions of this profile are given in Table 1.

**Table 1. British Standard ISO Metric Screw Threads  
Basic Profile Dimensions BS 3643:1981 (R2004)**

8 <sup>1</sup>	6.928 203	4.330 127	2.598 076	1.732 051	0.866 025

<sup>1</sup>This pitch is not used in any of the ISO metric standard series.

All dimensions are given in millimeters.

**Tolerance System.**— The tolerance system defines *tolerance classes* in terms of a combination of a *tolerance grade* (figure) and a *tolerance position* (letter). The tolerance position is defined by the distance between the basic size and the nearest end of the tolerance zone, this distance being known as the *fundamental deviation*, EI, in the case of internal threads, and es in the case of external threads. These tolerance positions with respect to the basic size (zero line) are shown in Fig. 2 and fundamental deviations for nut and bolt threads are given in Table 2.

**Table 2. Fundamental Deviations for Nut Threads and Bolt Threads**

Pitch $P$ mm	Nut Thread $D_2, D_1$		Bolt Thread $d, d_2$				Pitch $P$ mm	Nut Thread $D_2, D_1$		Bolt Thread $d, d_2$			
	Tolerance Position							Tolerance Position

1	+26	0	-60	-40	-26	0	6	+80	0	-118	-95	-80	0

See Figs. 1 and 2 for meaning of symbols.

**Tolerance Grades.**— Tolerance grades specified in the Standard for each of the four main screw thread diameters are as follows:

Minor diameter of nut threads ( $D_1$ ): tolerance grades 4, 5, 6, 7, and 8.

Major diameter of bolt threads ( $d$ ): tolerance grades 4, 6, and 8.

Pitch diameter of nut threads ( $D_2$ ): tolerance grades 4, 5, 6, 7, and 8.

Pitch diameter of bolt threads ( $d_2$ ): tolerance grades 3, 4, 5, 6, 7, 8, and 9.

**Tolerance Positions.**— Tolerance positions are G and H for nut threads and e, f, g, and h for bolt threads. The relationship of these tolerance position identifying letters to the amount of fundamental deviation is shown in [Table 2](#).

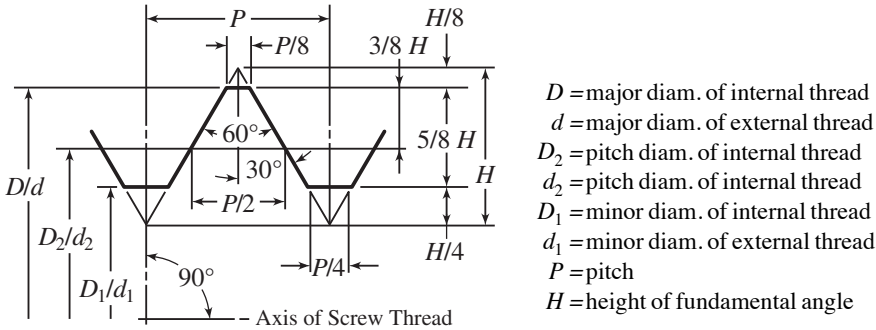

Fig. 1. Basic Profile of ISO Metric Thread

**Tolerance Classes.**— To reduce the number of gages and tools, the Standard specifies that the tolerance positions and classes shall be chosen from those listed in [Table 3](#) for short, normal, and long lengths of thread engagement. The following rules apply for the choice of tolerance quality: *Fine*: for precision threads when little variation of fit character is needed; *Medium*: for general use; and *Coarse*: for cases where manufacturing difficulties can arise as, for example, when threading hot-rolled bars and long blind holes. If the actual length of thread engagement is unknown, as in the manufacturing of standard bolts, normal is recommended.

Table 3. Tolerance Classes<sup>1,2,3</sup> for Nuts and Bolts

Tolerance Classes for Nuts												
Tolerance Quality	Tolerance Position G			Tolerance Position H								
	Short	Normal	Long	Short	Normal	Long						
Fine	...	...	...	4H <sup>2</sup>	5H <sup>2</sup>	6H <sup>2</sup>						
Medium	5G <sup>1</sup>	6G <sup>3</sup>	7G <sup>3</sup>	5H <sup>1</sup>	6H <sup>1,4</sup>	7H <sup>1</sup>						
Coarse	...	7G <sup>3</sup>	8G <sup>3</sup>	...	7H <sup>2</sup>	8H <sup>2</sup>						
Tolerance Classes for Bolts												
Tolerance Quality	Tolerance Position e			Tolerance Position f			Tolerance Position g			Tolerance Position h		
	Short	Normal	Long	Short	Normal	Long	Short	Normal	Long	Short	Normal	Long
Fine	...	...	...	...	...	...	...	...	...	3h4h <sup>3</sup>	4h <sup>1</sup>	5h4h <sup>3</sup>
Medium	...	6e <sup>1</sup>	7e6e <sup>3</sup>	...	6f <sup>1</sup>	...	5g6g <sup>3</sup>	6g <sup>1,4</sup>	7g6g <sup>3</sup>	5h6h <sup>3</sup>	6h <sup>2</sup>	7h6h <sup>3</sup>
Coarse	...	...	...	...	...	...	...	8g <sup>2</sup>	9g8g <sup>3</sup>	...	...	...

<sup>1</sup>First choice.

<sup>2</sup>Second choice.

<sup>3</sup>Third choice; these are to be avoided.

<sup>4</sup>For commercial nut and bolt threads.

*Note:* See [Table 4](#) for short, normal, and long categories. Any of the recommended tolerance classes for nuts can be combined with any of the recommended tolerance classes for bolts with the exception of sizes M1.4 and smaller for which the combination 5H/6h or finer shall be chosen. However, to guarantee a sufficient overlap, the finished components should preferably be made to form the fits H/g, H/h, or G/h.

All dimensions are given in millimeters

Fig. 2. Tolerance Positions with Respect to Zero Line (Basic Size)

**Design Profiles.**— The design profiles for ISO metric internal and external screw threads are shown in Fig. 3. These represent the profiles of the threads at their maximum metal condition. It may be noted that the root of each thread is deepened so as to clear the basic flat crest of the other thread. The contact between the thread is thus confined to their sloping flanks. However, for nut threads as well as bolt threads, the actual root contours shall not at any point violate the basic profile.

**Designation.**— Screw threads complying with the requirements of the Standard shall be designated by the letter M followed by values of the nominal diameter and of the pitch, expressed in millimeters, and separated by the sign  $\times$ . *Example:* M6  $\times$  0.75. The absence of the indication of pitch means that a coarse pitch is specified.

The complete designation of a screw thread consists of a designation for the thread system and size, and a designation for the crest diameter tolerance. Each class designation consists of: a figure indicating the tolerance grade; and a letter indicating the tolerance

position, capital for nuts, lower case for bolts. If the two class designations for a thread are the same (one for the pitch diameter and one for the crest diameter), it is not necessary to repeat the symbols. As examples, a bolt thread designated M10-6g signifies a thread of 10 mm nominal diameter in the Coarse Thread Series having a tolerance class 6g for both pitch and major diameters. A designation M10 × 1-5g6g signifies a bolt thread of 10 mm nominal diameter having a pitch of 1 mm, a tolerance class 5g for pitch diameter, and a tolerance class 6g for major diameter. A designation M10-6H signifies a nut thread of 10 mm diameter in the Coarse Thread Series having a tolerance class 6H for both pitch and minor diameters.

Fig. 3. Maximum Material Profiles for Internal and External Threads

A fit between mating parts is indicated by the nut thread tolerance class followed by the bolt thread tolerance class separated by an oblique stroke. *Examples:* M6-6H/6g and M20 × 2-6H/5g6g. For coated threads, the tolerances apply to the parts before coating, unless otherwise specified. After coating, the actual thread profile shall not at any point exceed the maximum material limits for either tolerance position H or h.

**Fundamental Deviation Formulas.**—The formulas used to calculate the fundamental deviations in Table 2 are:

$$EI_G = +(15 + 11P)$$

$$EI_H = 0$$

$$es_e = -(50 + 11P) \text{ except for threads with } P \leq 0.45 \text{ mm}$$

$$es_f = -(30 + 11P)$$

$$es_g = -(15 + 11P)$$

$$es_h = 0$$

In these formulas, EI and es are expressed in micrometers and P is in millimeters.

**Crest Diameter Tolerance Formulas.**—The tolerances for the major diameter of bolt threads ( $T_d$ ), grade 6, in **Table 5**, were calculated from the formula:

$$T_d(6) = 180 \sqrt[3]{P^2} - \frac{3.15}{\sqrt{P}}$$

In this formula,  $T_d(6)$  is in micrometers and  $P$  is in millimeters. For tolerance grades 4 and 8:  $T_d(4) = 0.63 T_d(6)$  and  $T_d(8) = 1.6 T_d(6)$ , respectively.

The tolerances for the minor diameter of nut threads ( $T_{D1}$ ), grade 6, in **Table 5**, were calculated as follows:

For pitches 0.2 to 0.8 mm,  $T_{D1}(6) = 433P - 190P^{1.22}$ .

For pitches 1 mm and coarser,  $T_{D1}(6) = 230P^{0.7}$ .

In these formulas,  $T_{D1}(6)$  is in micrometers and  $P$  is in millimeters. For tolerance grades 4, 5, 7, and 8:  $T_{D1}(4) = 0.63 T_{D1}(6)$ ;  $T_{D1}(5) = 0.8 T_{D1}(6)$ ;  $T_{D1}(7) = 1.25 T_{D1}(6)$ ; and  $T_{D1}(8) = 1.6 T_{D1}(6)$ , respectively.

<sup>1</sup> This table provides coarse- and fine-pitch series data for threads listed in Table 6 for first, second, and third choices. For constant-pitch series and for larger sizes than are shown, refer to the Standard.

<sup>2</sup> The fundamental deviation for internal threads (nuts) is zero for threads in this table.

All dimensions are in millimeters.

**Diameter/Pitch Combinations.**— Part 1 of BS 3643 provides a choice of diameter/pitch combinations shown here in Table 6. The use of first-choice items is preferred but if necessary, second, then third choice combinations may be selected. If pitches finer than those given in Table 6 are necessary, only the following pitches should be used: 3, 2, 1.5, 1, 0.75, 0.5, 0.35, 0.25, and 0.2 mm. When selecting such pitches it should be noted that there is increasing difficulty in meeting tolerance requirements as the diameter is increased for a given pitch. It is suggested that diameters greater than the following should not be used with the pitches indicated:

Pitch, mm	0.5	0.75	1	1.5	2	3
Maximum Diameter, mm	22	33	80	150	200	300

In cases where it is necessary to use a thread with a pitch larger than 6 mm, in the diameter range of 150 to 300 mm, the 8 mm pitch should be used.

**Limits and Tolerances for Finished Uncoated Threads.**— Part 2 of BS 3643 specifies the fundamental deviations, tolerances, and limits of size for the tolerance classes 4H, 5H, 6H, and 7H for internal threads (nuts) and 4h, 6g, and 8g for external threads (bolts) for coarse-pitch series within the range of 1 to 68 mm; fine-pitch series within the range of 1 to 33 mm; and constant pitch series within the range of 8 to 300 mm diameter.

The data in Table 5 provide the first, second, and third choice combinations shown in Table 6 except that constant-pitch series threads are omitted. For diameters larger than shown in Table 5, and for constant-pitch series data, refer to the Standard.

<sup>2</sup> The value shown is given in the German Standard; the value in the French Standard is 23.002; and in the Swiss Standard, 23.104.

All dimensions are in mm.

## ACME SCREW THREADS

### American National Standard Acme Screw Threads

This American National Standard ASME B1.5-1997 is a revision of American Standard ANSI B1.5-1988 and provides for two general applications of Acme threads, namely, General Purpose and Centralizing.

The limits and tolerances in this standard relate to single-start Acme threads, and may be used, if considered suitable, for multi-start Acme threads, which provide fast relative traversing motion when this is necessary. For information on additional allowances for multi-start Acme threads, see later section on page 1975.

**General Purpose Acme Threads.**— Three classes of General Purpose threads, 2G, 3G, and 4G, are provided in the standard, each having clearance on all diameters for free movement, and may be used in assemblies with the internal thread rigidly fixed and movement of the external thread in a direction perpendicular to its axis limited by its bearing or bearings. It is suggested that external and internal threads of the same class be used together for general purpose assemblies, Class 2G being the preferred choice. If less backlash or end play is desired, Classes 3G and 4G are provided. Class 5G is not recommended for new designs.

*Thread Form:* The accompanying Fig. 1 shows the thread form of these General Purpose threads, and the formulas accompanying the figure determine their basic dimensions. Table 1 gives the basic dimensions for the most generally used pitches.

*Angle of Thread:* The angle between the sides of the thread, measured in an axial plane, is 29 degrees. The line bisecting this 29-degree angle shall be perpendicular to the axis of the screw thread.

*Thread Series:* A series of diameters and associated pitches is recommended in the Standard as preferred. These diameters and pitches have been chosen to meet present needs with the fewest number of items in order to reduce to a minimum the inventory of both tools and gages. This series of diameters and associated pitches is given in Table 3.

*Chamfers and Fillets:* General Purpose external threads may have the crest corner chamfered to an angle of 45 degrees with the axis to a maximum width of  $P/15$ , where  $P$  is the pitch. This corresponds to a maximum depth of chamfer flat of  $0.0945P$ .

*Basic Diameters:* The max major diameter of the external thread is basic and is the nominal major diameter for all classes. The min pitch diameter of the internal thread is basic and is equal to the basic major diameter minus the basic height of the thread,  $h$ . The basic minor diameter is the min minor diameter of the internal thread. It is equal to the basic major diameter minus twice the basic thread height,  $2h$ .

*Length of Engagement:* The tolerances specified in this standard are applicable to lengths of engagement not exceeding twice the nominal major diameter.

*Major and Minor Diameter Allowances:* A minimum diametral clearance is provided at the minor diameter of all external threads by establishing the maximum minor diameter 0.020 inch below the basic minor diameter of the nut for pitches of 10 threads per inch and coarser, and 0.010 inch for finer pitches. A minimum diametral clearance at the major diameter is obtained by establishing the minimum major diameter of the internal thread 0.020 inch above the basic major diameter of the screw for pitches of 10 threads per inch and coarser, and 0.010 inch for finer pitches.

*Major and Minor Diameter Tolerances:* The tolerance on the external thread major diameter is  $0.05P$ , where  $P$  is the pitch, with a minimum of 0.005 inch. The tolerance on the internal thread major diameter is 0.020 inch for 10 threads per inch and coarser and 0.010 for finer pitches. The tolerance on the external thread minor diameter is  $1.5 \times$  pitch diameter tolerance. The tolerance on the internal thread minor diameter is  $0.05P$  with a minimum of 0.005 inch.

**ANSI General Purpose Acme Thread Form ASME B1.5-1997 (R2014),  
and Stub Acme Screw Thread Form ASME B1.8-1988 (R2011)**

Fig. 1. General Purpose and Stub Acme Thread Forms

**Formulas for Basic Dimensions of General Purpose and Stub Acme Screw Threads**

General Purpose	Stub Acme Threads
Pitch = $P = 1 \div \text{No. threads per inch, } n$	Pitch = $P = 1 \div \text{No. threads per inch, } n$
Basic thread height $h = 0.5P$	Basic thread height $h = 0.3P$
Basic thread thickness $t = 0.5P$	Basic thread thickness $t = 0.5P$
Basic flat at crest $F_{cn} = 0.3707P$ (internal thread)	Basic flat at crest $F_{cn} = 0.4224P$ (internal thread)
Basic flat at crest $F_{cs} = 0.3707P - 0.259 \times$ (pitch dia. allowance on ext. thd.)	Basic flat at crest $F_{cs} = 0.4224P - 0.259 \times$ (pitch dia. allowance on ext. thread)
$F_{rn} = 0.3707P - 0.259 \times$ (major dia. allowance on internal thread)	$F_{rn} = 0.4224P - 0.259 \times$ (major dia. allowance on internal thread)
$F_{rs} = 0.3707P - 0.259 \times$ (minor dia. allowance on ext. thread - pitch dia. allowance on ext. thread)	$F_{rs} = 0.4224P - 0.259 \times$ (minor dia. allowance on ext. thread - pitch dia. allowance on ext. thread)

*Pitch Diameter Allowances and Tolerances:* Allowances on the pitch diameter of General Purpose Acme threads are given in [Table 4](#). Pitch diameter tolerances are given in [Table 5](#). The ratios of the pitch diameter tolerances of Classes 2G, 3G, and 4G, General Purpose threads are 3.0, 1.4, and 1, respectively.

An increase of 10 percent in the allowance is recommended for each inch, or fraction thereof, that the length of engagement exceeds two diameters.

*Application of Tolerances:* The tolerances specified are designed to ensure interchangeability and maintain a high grade of product. The tolerances on diameters of the internal thread are plus, being applied from minimum sizes to above the minimum sizes. The tolerances on diameters of the external thread are minus, being applied from the maximum sizes to below the maximum sizes. The pitch diameter (or thread thickness) tolerances for an external or internal thread of a given class are the same. The thread thickness tolerance is 0.259 times the pitch diameter tolerance.

*Limiting Dimensions:* Limiting dimensions of General Purpose Acme screw threads in the recommended series are given in **Tables 2b** and **2c**. These limits are based on the formulas in **Table 2a**.

For combinations of pitch and diameter other than those in the recommended series, the formulas in **Table 2a** and the data in **Tables 4** and **5** make it possible to readily determine the limiting dimensions required.

A diagram showing the disposition of allowances, tolerances, and crest clearances for General Purpose Acme threads appears on page **1974**.

*Stress Area of General Purpose Acme Threads:* For computing the tensile strength of the thread section, the minimum stress area based on the mean of the minimum pitch diameter  $d_2$  min. and the minimum minor diameter  $d_1$  min. of the external thread is used:

$$\text{Stress Area} = 3.1416 \left( \frac{d_2 \text{ min.} + d_1 \text{ min.}}{4} \right)^2$$

where  $d_2$  min. and  $d_1$  min. may be computed by Formulas 4 and 6, **Table 2a** or taken from **Table 2b** or **2c**.

*Shear Area of General Purpose Acme Threads:* For computing the shear area per inch length of engagement of the external thread, the maximum minor diameter of the internal thread  $D_1$  max., and the minimum pitch diameter of the external thread  $d_2$  min., **Table 2b** or **2c**, or Formulas 12 and 4, **Table 2a**, are used:

$$\text{Shear Area} = 3.1416 D_1 \text{ max.} [0.5 + n \tan 14\frac{1}{2}^\circ (d_2 \text{ min.} - D_1 \text{ max.})]$$

**Acme Thread Abbreviations.**—The following abbreviations are recommended for use on drawings and in specifications, and on tools and gages:

*ACME* = Acme threads

*G* = General Purpose

*C* = Centralizing

*P* = pitch

*L* = lead

*LH* = left hand

**Designation of General Purpose Acme Threads.**—The examples listed below are given here to show how General Purpose Acme threads are designated on drawings and tools:

1.750-4 ACME-2G indicates a General Purpose Class 2G Acme thread of 1.750-inch major diameter, 4 threads per inch, single thread, right hand. The same thread, but left hand, is designated 1.750-4 ACME-2G-LH.

2.875-0.4P-0.8L-ACME-3G indicates a General Purpose Class 3G Acme thread of 2.875-inch major diameter, pitch 0.4 inch, lead 0.8 inch, double thread, right hand.

**Multiple Start Acme Threads.**—The tabulated diameter-pitch data with allowances and tolerances relate to single-start threads. These data, as tabulated, may be and often are used for two-start Class 2G threads but this usage generally requires reduction of the full working tolerances to provide a greater allowance or clearance zone between the mating threads to assure satisfactory assembly.

When the class of thread requires smaller working tolerances than the 2G class or when threads with 3, 4, or more starts are required, some additional allowances or increased tolerances or both may be needed to ensure adequate working tolerances and satisfactory assembly of mating parts.

It is suggested that the allowances shown in **Table 4** be used for all external threads and that allowances be applied to internal threads in the following ratios: for two-start threads, 50 percent of the allowances shown in the Class 2G, 3G and 4G columns of **Table 4**; for

All dimensions in inches. It is recommended that the sizes given in Table 3 be used whenever possible.

<sup>1</sup> The values in columns for Classes 2G, 3G, and 4G are to be used for any size within the nominal size range shown. These values are calculated from the mean of the range.

<sup>2</sup> An increase of 10 percent in the allowance is recommended for each inch, or fraction thereof, that the length of engagement exceeds two diameters.

<sup>3</sup> Allowances for the 2G Class of thread in this table also apply to American National Standard Stub Acme threads ASME/ANSI B 1.8-1988.

three-start threads, 75 percent of these allowances; and for four-start threads, 100 percent of these same values.

These values will provide for a 0.25-16 ACME-2G thread size, 0.002, 0.003, and 0.004 inch additional clearance for 2-, 3-, and 4-start threads, respectively. For a 5-2 ACME-3G thread size the additional clearances would be 0.0091, 0.0136, and 0.0181 inch, respectively. GO thread plug gages and taps would be increased by these same values. To maintain the same working tolerances on multi-start threads, the pitch diameter of the NOT GO thread plug gage would also be increased by these same values.

For multi-start threads with more than four starts, it is believed that the 100 percent allowance provided by the above procedures would be adequate as index spacing variables would generally be no greater than on a four-start thread.

In general, for multi-start threads of Classes 2G, 3G, and 4G the percentages would be applied, usually, to allowances for the same class, respectively. However, where exceptionally good control over lead, angle, and spacing variables would produce close to theoretical values in the product, it is conceivable that these percentages could be applied to Class 3G or Class 4G allowances used on Class 2G internally threaded product. Also, these percentages could be applied to Class 4G allowances used on Class 3G internally threaded product. It is not advocated that any change be made in externally threaded products.

Designations for gages or tools for internal threads could cover allowance requirements as follows:

GO and NOT GO thread plug gages for: 2.875-0.4P-0.8L-ACME-2G with 50 percent of the 4G internal thread allowance.

**Centralizing Acme Threads.**— The three classes of Centralizing Acme threads in American National Standard ASME B1.5-1988 (R2014), designated as 2C, 3C, and 4C, have limited clearance at the major diameters of internal and external threads so that a bearing at the major diameters maintains approximate alignment of the thread axis and prevents wedging on the flanks of the thread. An alternative series having centralizing control on the

For any particular size of thread, the pitch diameter tolerance is obtained by adding the *diameter increment* from the upper half of the table to the *pitch increment* from the lower half of the table. *Example:* A  $\frac{1}{4}$ -16 Acme-2G thread has a pitch diameter tolerance of  $0.00300 + 0.00750 = 0.0105$  inch.

The equivalent tolerance on thread thickness is 0.259 times the pitch diameter tolerance.

<sup>1</sup>For a nominal diameter between any two tabulated nominal diameters, use the diameter increment for the larger of the two tabulated nominal diameters.

<sup>2</sup>Columns for the 2G Class of thread in this table also apply to American National Standard Stub Acme threads, ASME B1.8-1988 (R2011).

<sup>3</sup>All other dimensions are given in inches.

*minor* diameter is described on page 1991. For any combination of the three classes of threads covered in this standard some end play or backlash will result. Classes 5C and 6C are not recommended for new designs.

*Application:* These three classes together with the accompanying specifications are for the purpose of ensuring the interchangeable manufacture of Centralizing Acme threaded parts. Users are free to select the classes best adapted to their particular needs. It is suggested that external and internal threads of the same class be used together for centralizing assemblies, Class 2C providing the maximum end play or backlash. If less backlash or end play is desired, Classes 3C and 4C are provided. The requirement for a centralizing fit is that the sum of the major diameter tolerance plus the major diameter allowance on the

Fig. 2. Disposition of Allowances, Tolerances, and Crest Clearances for General Purpose Single-start Acme Threads (All Classes)

internal thread, and the major diameter tolerance on the external thread shall equal or be less than the pitch diameter allowance on the external thread. A Class 2C external thread, which has a larger pitch diameter allowance than either a Class 3C or 4C, can be used interchangeably with a Class 2C, 3C, or 4C internal thread and fulfill this requirement. Similarly, a Class 3C external thread can be used interchangeably with a Class 3C or 4C internal thread, but only a Class 4C internal thread can be used with a Class 4C external thread.

**Thread Form:** The thread form is the same as the General Purpose Acme Thread and is shown in Fig. 3. The formulas in Table 7 determine the basic dimensions, which are given in Table 6 for the most generally used pitches.

**Angle of Thread:** The angle between the sides of the thread measured in an axial plane is 29 degrees. The line bisecting this 29-degree angle shall be perpendicular to the axis of the thread.

**Chamfers and Fillets:** External threads have the crest corners chamfered at an angle of 45 degrees with the axis to a minimum depth of  $P/20$  and a maximum depth of  $P/15$ . These modifications correspond to a minimum width of chamfer flat of  $0.0707P$  and a maximum width of  $0.0945P$  (see Table 6, columns 6 and 7).

External threads for Classes 2C, 3C, and 4C may have a fillet at the minor diameter not greater than  $0.1P$

All dimensions in inches. See Fig. 3.

<sup>1</sup> Allowance is 0.020 inch for 10 or less threads per inch and 0.010 inch for more than 10 threads per inch.

Fig. 3. Centralizing Acme Screw Thread Form

**Thread Series:** A series of diameters and pitches is recommended in the Standard as preferred. These diameters and pitches have been chosen to meet present needs with the fewest number of items in order to reduce to a minimum the inventory of both tools and gages. This series of diameters and associated pitches is given in Table 9.

**Table 7. Formulas for Finding Basic Dimensions of Centralizing Acme Screw Threads**

Pitch = $P = 1 \div$ No. threads per inch, $n$ :	Basic thread height $h = 0.5P$
Basic thread thickness $t = 0.5P$	
Basic flat at crest $F_{cn} = 0.3707P + 0.259 \times$ (minor diameter allowance on internal threads) (internal thread)	
Basic flat at crest $F_{cs} = 0.3707P - 0.259 \times$ (pitch diameter allowance on external thread) (external thread)	
$F_{rn} = 0.3707P - 0.259 \times$ (major dia. allowance on internal thread)	
$F_{rs} = 0.3707P - 0.259 \times$ (minor dia. allowance on external thread — pitch dia. allowance on external thread)	

Fig. 4. Disposition of Allowances, Tolerances, and Crest Clearances for Centralizing Single-Start Acme Threads—Classes 2C, 3C, and 4C

**Basic Diameters:** The maximum major diameter of the external thread is basic and is the nominal major diameter for all classes.

The minimum pitch diameter of the internal thread is basic for all classes and is equal to the basic major diameter  $D$  minus the basic height of thread,  $h$ . The minimum minor diameter of the internal thread for all classes is  $0.1P$  above basic.

**Length of Engagement:** The tolerances specified in this Standard are applicable to lengths of engagement not exceeding twice the nominal major diameter.

**Pitch Diameter Allowances:** Allowances applied to the pitch diameter of the external thread for all classes are given in Table 10.

**Major and Minor Diameter Allowances:** A minimum diametral clearance is provided at the minor diameter of all external threads by establishing the maximum minor diameter  $0.020$  inch below the basic minor diameter for 10 threads per inch and coarser, and  $0.010$  inch for finer pitches and by establishing the minimum minor diameter of the internal thread  $0.1P$  greater than the basic minor diameter.

**Table 8a. American National Standard Centralizing Acme Single-Start Screw Threads — Formulas for Determining Diameters** *ASME B1.5-1988 (R2014)*

$D$ = Nominal Size or Diameter in Inches $P$ = Pitch = $1 \div$ Number of Threads per Inch	
No.	Classes 2C, 3C, and 4C External Threads (Screws)
1	Major Dia., Max = $D$ (Basic).
2	Major Dia., Min = $D$ minus tolerance from Table 12, columns 7, 8, or 10.
3	Pitch Dia., Max = Int. Pitch Dia., Min (Formula 9) minus allowance from the appropriate Class 2C, 3C, or 4C column of Table 10.
4	Pitch Dia., Min = Ext. Pitch Dia., Max (Formula 3) minus tolerance from Table 11.
5	Minor Dia., Max = $D$ minus $P$ minus allowance from Table 12, column 3.
6	Minor Dia., Min = Ext. Minor Dia., Max (Formula 5) minus $1.5 \times$ Pitch Dia. tolerance from Table 11.
Classes 2C, 3C, and 4C Internal Threads (Nuts)	
7	Major Dia., Min = $D$ plus allowance from Table 12, column 4.
8	Major Dia., Max = Int. Major Dia., Min (Formula 7) plus tolerance from Table 12, columns 7, 9, or 11.
9	Pitch Dia., Min = $D$ minus $P/2$ (Basic).
10	Pitch Dia., Max = Int. Pitch Dia., Min (Formula 9) plus tolerance from Table 11.
11	Minor Dia., Min = $D$ minus $0.9P$ .
12	Minor Dia., Max = Int. Minor Dia., Min (Formula 11) plus tolerance from Table 12, column 6.

A minimum diametral clearance at the major diameter is obtained by establishing the minimum major diameter of the internal thread  $0.001 \sqrt{D}$  above the basic major diameter. These allowances are shown in Table 12.

*Major and Minor Diameter Tolerances:* The tolerances on the major and minor diameters of the external and internal threads are listed in Table 12 and are based upon the formulas given in the column headings.

An increase of 10 percent in the allowance is recommended for each inch or fraction thereof that the length of engagement exceeds two diameters.

For information on gages for Centralizing Acme threads the Standard ASME/ANSI B1.5 should be consulted.

*Pitch Diameter Tolerances:* Pitch diameter tolerances for Classes 2C, 3C and 4C for various practicable combinations of diameter and pitch are given in Table 11. The ratios of the pitch diameter tolerances of Classes 2C, 3C, and 4C are 3.0, 1.4, and 1, respectively.

*Application of Tolerances:* The tolerances specified are such as to insure interchangeability and maintain a high grade of product. The tolerances on the diameters of internal threads are plus, being applied from the minimum sizes to above the minimum sizes. The tolerances on the diameters of external threads are minus, being applied from the maximum sizes to below the maximum sizes. The pitch diameter tolerances for an external or internal thread of a given class are the same.

*Limiting Dimensions:* Limiting dimensions for Centralizing Acme threads in the preferred series of diameters and pitches are given in Tables 8b and 8c. These limits are based on the formulas in Table 8a.

For combinations of pitch and diameter other than those in the preferred series the formulas in Tables 8b and 8c and the data in the tables referred to therein make it possible to readily determine the limiting dimension required.

All dimensions are given in inches.

It is recommended that the sizes given in Table 9 be used whenever possible.

<sup>1</sup>The values in columns for Classes 2C, 3C, and 4C are to be used for any size within the nominal size range columns. These values are calculated from the mean of the range.

<sup>2</sup>An increase of 10 percent in the allowance is recommended for each inch, or fraction thereof, that the length of engagement exceeds two diameters.

5	.01342	.00626	.00447	1	.03000	.01400	.01000

All dimensions are given in inches.

For any particular size of thread, the pitch diameter tolerance is obtained by adding the *diameter increment* from the upper half of the table to the *pitch increment* from the lower half of the table. *Example:* A 0.250-16-ACME-2C thread has a pitch diameter tolerance of  $0.00300 + 0.00750 = 0.0105$  inch.

The equivalent tolerance on thread thickness is 0.259 times the pitch diameter tolerance.

<sup>1</sup>For a nominal diameter between any two tabulated nominal diameters, use the diameter increment for the larger of the two tabulated nominal diameters.

**Table 12. American National Standard Centralizing Acme Single-Start Screw Threads — Tolerances and Allowances for Major and Minor Diameters ASME B1.5-1988 (R2014)**

Size (Nom.)	Thds <sup>1</sup> per Inch	Allowance From Basic Major and Minor Diameters (All Classes)			Tolerance on Minor Diam, <sup>2,3</sup> All Internal Threads, (Plus 0.05P)	Tolerance on Major Diameter Plus on Internal, Minus on External Threads				
		Minor Diam, <sup>4</sup> All External Threads (Minus)	Internal Thread			Class 2C	Class 3C		Class 4C	
			Major Diam, <sup>5</sup> (Plus $0.0010\sqrt{D}$ )	Minor Diam, <sup>4</sup> (Plus 0.1P)		External and Internal Threads, $0.0035\sqrt{D}$	External Thread, $0.0015\sqrt{D}$	Internal Thread, $0.0035\sqrt{D}$	External Thread, $0.0010\sqrt{D}$	Internal Thread, $0.0020\sqrt{D}$

5	2	0.020	0.0022	0.0500	0.0250	0.0078	0.0034	0.0078	0.0022	0.0045

<sup>1</sup> All other dimensions are given in inches. Intermediate pitches take the values of the next coarser pitch listed. Values for intermediate diameters should be calculated from the formulas in column headings, but ordinarily may be interpolated.

<sup>2</sup> To avoid a complicated formula and still provide an adequate tolerance, the pitch factor is used as a basis, with the minimum tolerance set at 0.005 in.

<sup>3</sup> Tolerance on minor diameter of all external threads is  $1.5 \times$  pitch diameter tolerance.

<sup>4</sup> The minimum clearance at the minor diameter between the internal and external thread is the sum of the values in columns 3 and 5.

<sup>5</sup> The minimum clearance at the major diameter between the internal and external thread is equal to column 4.

**Designation of Centralizing Acme Threads.**— The following examples are given to show how these Acme threads are designated on drawings, in specifications, and on tools and gages:

*Example, 1.750-6-ACME-4C:* Indicates a Centralizing Class 4C Acme thread of 1.750-inch major diameter, 0.1667-inch pitch, single thread, right-hand.

*Example, 1.750-6-ACME-4C-LH:* Indicates the same thread left-hand.

*Example, 2.875-0.4P-0.8L-ACME-3C (Two Start):* Indicates a Centralizing Class 3C Acme thread with 2.875-inch major diameter, 0.4-inch pitch, 0.8-inch lead, double thread, right-hand.

*Example, 2.500-0.3333P-0.6667L-ACME-4C (Two Start):* Indicates a Centralizing Class 4C Acme thread with 2.500-inch nominal major diameter (basic major diameter 2.500 inches), 0.3333-inch pitch, 0.6667-inch lead, double thread, right-hand. The same thread left-hand would have LH at the end of the designation.

**Acme Centralizing Threads—Alternative Series with Minor Diameter Centralizing Control.**— When Acme centralizing threads are produced in single units or in very small quantities (and principally in sizes larger than the range of commercial taps and dies) where the manufacturing process employs cutting tools (such as lathe cutting), it may be economically advantageous and therefore desirable to have the centralizing control of the mating threads located at the *minor diameters*.

Particularly under the above-mentioned type of manufacturing, the two advantages cited for minor diameter centralizing control over centralizing control at the major diameters of the mating threads are: 1) Greater ease and faster checking of machined thread dimensions. It is much easier to measure the minor diameter (root) of the external thread and the mating minor diameter (crest or bore) of the internal thread than it is to determine the major diameter (root) of the internal thread and the major diameter (crest or turn) of the external thread; and 2) better manufacturing control of the machined size due to greater ease of checking.

In the event that minor diameter centralizing is necessary, recalculate all thread dimensions, reversing major and minor diameter allowances, tolerances, radii, and chamfer.

**American National Standard Stub Acme Threads.**— This American National Standard ASME B1.8-1988 (R2011) provides a Stub Acme screw thread for those unusual applications where, due to mechanical or metallurgical considerations, a coarse-pitch thread of shallow depth is required. The fit of Stub Acme threads corresponds to the Class 2G General Purpose Acme thread in American National Standard ANSI B1.5-1988. For a fit having less backlash, the tolerances and allowances for Classes 3G or 4G General Purpose Acme threads may be used.

*Thread Form:* The thread form and basic formulas for Stub Acme threads are given on page 1974 and the basic dimensions in Table 13.

*Allowances and Tolerances:* The major and minor diameter allowances for Stub Acme threads are the same as those given for General Purpose Acme threads on page 1973.

Pitch diameter allowances for Stub Acme threads are the same as for Class 2G General Purpose Acme threads and are given in Table 4. Pitch diameter tolerances for Stub Acme threads are the same as for Class 2G General Purpose Acme threads given in Table 5.

*Limiting Dimensions:* Limiting dimensions of American Standard Stub Acme threads may be determined by using the formulas given in Table 14a, or directly from Table 14b. The diagram below shows the limits of size for Stub Acme threads.

*Thread Series:* A preferred series of diameters and pitches for General Purpose Acme threads (Table 15) is recommended for Stub Acme threads.

**Table 13. American National Standard Stub Acme Screw Thread Form — Basic Dimensions ASME B1.8-1988 (R2011)**

<sup>1</sup> All other dimensions are given in inches.

Limits of Size, Allowances, Tolerances, and Crest Clearances for American National Standard Stub Acme Threads

**Stub Acme Thread Designations.**— The method of designation for Standard Stub Acme threads is illustrated in the following examples: 0.500-20 Stub Acme indicates a  $\frac{1}{2}$ -inch major diameter, 20 threads per inch, right hand, single thread, Standard Stub Acme thread. The designation 0.500-20 Stub Acme-LH indicates the same thread except that it is left hand.

**Alternative Stub Acme Threads.**— Since one Stub Acme thread form may not meet the requirements of all applications, basic data for two of the other commonly used forms are included in the appendix of the American Standard for Stub Acme Threads. These so-called Modified Form 1 and Modified Form 2 threads utilize the same tolerances and allowances as Standard Stub Acme threads and have the same major diameter and basic thread thickness at the pitchline ( $0.5P$ ). The basic height of Form 1 threads,  $h$ , is  $0.375P$ ; for Form 2 it is  $0.250P$ . The basic width of flat at the crest of the internal thread is  $0.4030P$  for Form 1 and  $0.4353P$  for Form 2.

The pitch diameter and minor diameter for Form 1 threads will be smaller than similar values for the Standard Stub Acme Form and for Form 2 they will be larger owing to the differences in basic thread height  $h$ . Therefore, in calculating the dimensions of Form 1 and Form 2 threads using Formulas 1 through 12 in Table 14a, it is only necessary to substitute the following values in applying the formulas: For Form 1,  $D_2 = D - 0.375P$ ,  $D_1 = D - 0.75P$ ; for Form 2,  $D_2 = D - 0.25P$ ,  $D_1 = D - 0.5P$ .

*Thread Designation:* These threads are designated in the same manner as Standard Stub Acme threads except for the insertion of either M1 or M2 after “Acme.” Thus, 0.500-20 Stub Acme M1 for a Form 1 thread; and 0.500-20 Stub Acme M2 for a Form 2 thread.

**Former 60-Degree Stub Thread.**— Former American Standard B1.3-1941 included a 60-degree stub thread for use where design or operating conditions could be better satisfied by the use of this thread, or other modified threads, than by Acme threads. Data for 60-Degree Stub thread form are given in the accompanying diagram.

Table 15. Stub Acme Screw Thread Data ASME B1.8-1988 (R2011)

Identification		Basic Diameters			Thread Data

<sup>1</sup> All other dimensions are given in inches.

60-Degree Stub Thread

A clearance of at least  $0.02 \times \text{pitch}$  is added to depth  $h$  to produce extra depth, thus avoiding interference with threads of mating part at minor or major diameters.

Basic thread thickness at pitch line =  $0.5 \times \text{pitch } p$ ; basic depth  $h = 0.433 \times \text{pitch}$ ; basic width of flat at crest =  $0.25 \times \text{pitch}$ ; width of flat at root of screw thread =  $0.227 \times \text{pitch}$ ; basic pitch diameter = basic major diameter  $- 0.433 \times \text{pitch}$ ; basic minor diameter = basic major diameter  $- 0.866 \times \text{pitch}$ .

**Square Thread.**— The square thread is so named because the section is square, the depth, in the case of a screw, being equal to the width or one-half the pitch. The thread groove in a square-threaded nut is made a little greater than one-half the pitch in order to provide a slight clearance for the screw; hence, the tools used for threading square-threaded taps are a little less in width at the point than one-half the pitch. The pitch of a square thread is usually twice the pitch of an American Standard thread of corresponding diameter. The square thread has been superseded quite largely by the Acme form which has several advantages. See *ACME SCREW THREADS*.

*10-Degree Modified Square Thread:* The included angle between the sides of the thread is 10 degrees (see accompanying diagram). The angle of 10 degrees results in a thread which is the practical equivalent of a “square thread,” and yet is capable of economical production. Multiple thread milling cutters and ground thread taps should not be specified for modified square threads of the larger lead angles without consulting the cutting tool manufacturer.

In the following formulas,  $D$  = basic major diameter;  $E$  = basic pitch diameter;  $K$  = basic minor diameter;  $p$  = pitch;  $h$  = basic depth of thread on screw depth when there is no clearance between root of screw and crest of thread on nut;  $t$  = basic thickness of thread at pitch line;  $F$  = basic width of flat at crest of screw thread;  $G$  = basic width of flat at root of screw thread;  $C$  = clearance between root of screw and crest of thread on nut;  $E = D - 0.5p$ ;  $K = D - p$ ;  $h = 0.5p$  (see Note);  $t = 0.5p$ ;  $F = 0.4563p$ ;  $G = 0.4563p - (0.17 \times C)$ .

*Note:* A clearance should be added to depth  $h$  to avoid interference with threads of mating parts at minor or major diameters.

## BUTTRESS THREADS

## Threads of Buttress Form

The buttress form of thread has certain advantages in applications involving exceptionally high stresses along the thread axis in one direction only. The contacting flank of the thread, which takes the thrust, is referred to as the *pressure flank* and is so nearly perpendicular to the thread axis that the radial component of the thrust is reduced to a minimum. Because of the small radial thrust, this form of thread is particularly applicable where tubular members are screwed together, as in the case of breech mechanisms of large guns and airplane propeller hubs.

Fig. 1a shows a common form. The front or load-resisting face is perpendicular to the axis of the screw and the thread angle is 45 degrees. According to one rule, the pitch  $P = 2 \times \text{screw diameter} \div 15$ . The thread depth  $d$  may equal  $\frac{3}{4} \times \text{pitch}$ , making the flat  $f = \frac{1}{8} \times \text{pitch}$ . Sometimes depth  $d$  is reduced to  $\frac{2}{3} \times \text{pitch}$ , making  $f = \frac{1}{6} \times \text{pitch}$ .

Fig. 1a.

Fig. 1b.

Fig. 1c.

The load-resisting side or flank may be inclined an amount (Fig. 1b) ranging usually from 1 to 5 degrees to avoid cutter interference in milling the thread. With an angle of 5 degrees and an included thread angle of 50 degrees, if the width of the flat  $f$  at both crest and root equals  $\frac{1}{8} \times \text{pitch}$ , then the thread depth equals  $0.69 \times \text{pitch}$  or  $\frac{3}{4} d_1$ .

The saw-tooth form of thread illustrated by Fig. 1c is known in Germany as the "Sägewinde" and in Italy as the "Fillettatura a dente di Sega." Pitches are standardized from 2 millimeters up to 48 millimeters in the German and Italian specifications. The front face inclines 3 degrees from the perpendicular and the included angle is 33 degrees.

The thread depth  $d$  for the screw  $= 0.86777 \times \text{pitch } P$ . The thread depth  $g$  for the nut  $= 0.75 \times \text{pitch}$ . Dimension  $h = 0.341 \times P$ . The width  $f$  of flat at the crest of the thread on the screw  $= 0.26384 \times \text{pitch}$ . Radius  $r$  at the root  $= 0.12427 \times \text{pitch}$ . The clearance space  $e = 0.11777 \times \text{pitch}$ .

**British Standard Buttress Threads BS 1657: 1950.**— Specifications for buttress threads in this standard are similar to those in the American Standard (see page 1998) except: 1) A basic depth of thread of  $0.4p$  is used instead of  $0.6p$ ; 2) Sizes below 1 inch are not included; 3) Tolerances on major and minor diameters are the same as the pitch diameter tolerances, whereas in the American Standard separate tolerances are provided; however, provision is made for smaller major and minor diameter tolerances when crest surfaces of screws or nuts are used as datum surfaces, or when the resulting reduction in depth of engagement must be limited; and 4) Certain combinations of large diameters with fine pitches are provided that are not encouraged in the American Standard.

## American National Standard Buttress Inch Screw Threads

The buttress form of thread has certain advantages in applications involving exceptionally high stresses along the thread axis in one direction only. As the thrust side (load flank) of the standard buttress thread is made very nearly perpendicular to the thread axis, the radial component of the thrust is reduced to a minimum. On account of the small radial thrust, the buttress form of thread is particularly applicable when tubular members are

screwed together. Examples of actual applications are the breech assemblies of large guns, airplane propeller hubs, and columns for hydraulic presses.

**7°/45° Buttress Thread Form.**— In selecting the form of thread recommended as standard, ANSI B1.9-1973 (R2007), manufacture by milling, grinding, rolling, or other suitable means, has been taken into consideration. All dimensions are in inches.

*Form of Thread:* The form of the buttress thread is shown in the accompanying Figs. 2a and 2b, and has the following characteristics:

- A load flank angle, measured in an axial plane, of 7 degrees from the normal to the axis.
- A clearance flank angle, measured in an axial plane, of 45 degrees from the normal to the axis.
- Equal truncations at the crests of the external and internal threads such that the basic height of thread engagement (assuming no allowance) is equal to 0.6 of the pitch
- Equal radii, at the roots of the external and internal basic thread forms tangential to the load flank and the clearance flank. (There is, in practice, almost no chance that the thread forms will be achieved strictly as basically specified, that is, as true radii.) When specified, equal flat roots of the external and internal thread may be supplied.

**Table 1. American National Standard Diameter — Pitch Combinations for 7°/45° Buttress Threads ANSI B1.9-1973 (R2007)**

Preferred Nominal Major Diameters, Inches	Threads per Inch <sup>1</sup>	Preferred Nominal Major Diameters, Inches	Threads per Inch <sup>1</sup>
0.5, 0.625, 0.75	(20, 16, 12)	4.5, 5, 5.5, 6	12, 10, 8, (6, 5, 4), 3
0.875, 1.0	(16, 12, 10)	7, 8, 9, 10	10, 8, 6, (5, 4, 3), 2.5, 2
1.25, 1.375, 1.5	16, (12, 10, 8), 6	11, 12, 14, 16	10, 8, 6, 5, (4, 3, 2.5), 2, 1.5, 1.25

Fig. 2a. Round Root External Thread

Heavy Line Indicates Basic Form

Fig. 2b. Flat Root External Thread

Heavy Line Indicates Basic Form

**Table 3. American National Standard Buttress Inch Screw Thread Symbols and Form**

Thread Element	Max. Material (Basic)	Min. Material
Pitch	$p$	
Height of sharp-V thread	$H = 0.89064p$	
Basic height of thread engagement	$h = 0.6p$	
Root radius (theoretical)(see footnote <sup>1</sup> )	$r = 0.07141p$	Min. $r = 0.0357p$
Root truncation	$s = 0.0826p$	Min. $s = 0.5$ ; Max. $s = 0.0413p$
Root truncation for flat root form	$s = 0.0826p$	Min. $s = 0.5$ ; Max. $s = 0.0413p$
Flat width for flat root form	$S = 0.0928p$	Min. $S = 0.0464p$
Allowance	$G$ (see text)	
Height of thread engagement	$h_e = h - 0.5G$	Min. $h_e = \text{Max. } h_e - [0.5 \text{ tol. on major dia. external thread} + 0.5 \text{ tol. on minor dia. internal thread}]$ .
Crest truncation	$f = 0.14532p$	
Crest width	$F = 0.16316p$	
Major diameter	$D$	
Major diameter of internal thread	$D_n = D + 0.12542p$	Max. $D_n = \text{Max. pitch dia. of internal thread} + 0.80803p$
Major diameter of external thread	$D_s = D - G$	Min. $D_s = D - G - D \text{ tol.}$
Pitch diameter	$E$	
Pitch diameter of internal thread (see footnote <sup>2</sup> )	$E_n = D - h$	Max. $E_n = D - h + PD \text{ tol.}$
Pitch diameter of external thread (see footnote <sup>3</sup> )	$E_s = D - h - G$	Min. $E_s = D - h - G - PD \text{ tol.}$
Minor diameter	$K$	
Minor diameter of external thread	$K_s = D - 1.32542p - G$	Min. $K_s = \text{Min. pitch dia. of external thread} - 0.80803p$
Minor diameter of internal thread	$K_n = D - 2h$	Min. $K_n = D - 2h + K \text{ tol.}$
Height of thread of internal thread	$h_n = 0.66271p$	
Height of thread of external thread	$h_s = 0.66271p$	
Pitch diameter increment for lead	$\Delta EI$	
Pitch diameter increment for 45° clearance flank angle	$\Delta E\alpha_1$	
Pitch diameter increment for 7° load flank angle	$\Delta E\alpha_2$	
Length of engagement	$L_e$	

<sup>1</sup> Unless the flat root form is specified, the rounded root form of the external and internal thread shall be a continuous, smoothly blended curve within the zone defined by 0.07141*p* maximum to 0.0357*p* minimum radius. The resulting curve shall have no reversals or sudden angular variations, and shall be tangent to the flanks of the thread. There is, in practice, almost no chance that the rounded thread form will be achieved strictly as basically specified, that is, as a true radius.

<sup>2</sup> The pitch diameter *X* tolerances for GO and NOT GO threaded plug gages are applied to the internal product limits for  $E_n$  and Max.  $E_n$ .

<sup>3</sup> The pitch diameter *W* tolerances for GO and NOT GO threaded setting plug gages are applied to the external product limits for  $E_s$  and Min.  $E_s$ .

**Buttress Thread Tolerances.**—Tolerances from basic size on external threads are applied in a minus direction and on internal threads in a plus direction.

*Pitch Diameter Tolerances:* The following formula is used for determining the pitch diameter product tolerance for Class 2 (standard grade) external or internal threads:

$$\text{PD tolerance} = 0.002 \sqrt[3]{D} + 0.00278 \sqrt{L_e} + 0.00854 \sqrt{p}$$

where  $D$  = basic major diameter of external thread (assuming no allowance)

$L_e$  = length of engagement

$p$  = pitch of thread

When the length of engagement is taken as  $10p$ , the formula reduces to

$$0.002 \sqrt[3]{D} + 0.0173 \sqrt{p}$$

It is to be noted that this formula relates specifically to Class 2 (standard grade) PD tolerances. Class 3 (precision grade) PD tolerances are two-thirds of Class 2 PD tolerances. Pitch diameter tolerances based on this latter formula, for various diameter pitch combinations, are given in [Table 4](#).

*Functional Size:* Deviations in lead and flank angle of product threads increase the functional size of an external thread and decrease the functional size of an internal thread by the cumulative effect of the diameter equivalents of these deviations. The functional size of all buttress product threads shall not exceed the maximum-material limit.

*Tolerances on Major Diameter of External Thread and Minor Diameter of Internal Thread:* Unless otherwise specified, these tolerances should be the same as the pitch diameter tolerance for the class used.

*Tolerances on Minor Diameter of External Thread and Major Diameter of Internal Thread:* It will be sufficient in most instances to state only the maximum minor diameter of the external thread and the minimum major diameter of the internal thread without any tolerance. However, the root truncation from a sharp V should not be greater than  $0.0826p$  nor less than  $0.0413p$ .

*Lead and Flank Angle Deviations for Class 2:* The deviations in lead and flank angles may consume the entire tolerance zone between maximum and minimum material product limits given in [Table 4](#).

*Diameter Equivalents for Variations in Lead and Flank Angles for Class 3:* The combined diameter equivalents of variations in lead (including helix deviations), and flank angle for Class 3, shall not exceed 50 percent of the Class 2 pitch diameter tolerances given in [Table 4](#).

*Tolerances on Taper and Roundness:* There are no requirements for taper and roundness for Class 2 buttress screw threads.

The major and minor diameters of Class 3 buttress threads shall not taper nor be out of round to the extent that specified limits for major and minor diameter are exceeded. The taper and out-of-roundness of the pitch diameter for Class 3 buttress threads shall not exceed 50 percent of the pitch-diameter tolerances.

**Allowances for Easy Assembly.**—An allowance (clearance) should be provided on all external threads to secure easy assembly of parts. The amount of the allowance is deducted from the nominal major, pitch, and minor diameters of the external thread when the maximum material condition of the external thread is to be determined.

The minimum internal thread is basic.

The amount of the allowance is the same for both classes and is equal to the Class 3 pitch-diameter tolerance as calculated by the formulas previously given. The allowances for various diameter-pitch combinations are given in [Table 5](#).

1.0	1.0000	....	....	....	....	....	....	....	....	.0152	

<sup>1</sup> For threads with pitches not shown in this table, pitch increment to be used in tolerance formula is to be determined by use of formula  $PD \text{ Tolerance} = 0.002\sqrt[3]{D} + 0.00278\sqrt{L_e} + 0.00854\sqrt{p}$ , where:  $D$  = basic major diameter of external thread (assuming no allowance),  $L_e$  = length of engagement, and  $p$  = pitch of thread. This formula relates specifically to Class 2 (standard grade) PD tolerances. Class 3 (precision grade) PD tolerances are two-thirds of Class 2 PD tolerances. See text

<sup>2</sup> When the length of engagement is taken as  $10p$ , the formula reduces to:  $0.002\sqrt[3]{D} + 0.0173\sqrt{p}$

<sup>3</sup> Diameter  $D$ , used in diameter increment formula, is based on the average of the range.

**Table 5. American National Standard External Thread Allowances for Classes 2 and 3 Buttress Inch Screw Threads ANSI B1.9-1973 (R2007)**

Threads per Inch	Pitch, $p$ Inch	Basic Major Diameter, Inch

**Example Showing Dimensions for a Typical Buttress Thread.**— The dimensions for a 2-inch diameter, 4 threads per inch, Class 2 buttress thread with flank angles of 7 degrees and 45 degrees are

$$h = \text{basic thread height} = 0.1500 \text{ (Table 2)}$$

$$h_s = h_n = \text{height of thread in external and internal threads} = 0.1657 \text{ (Table 2)}$$

$$G = \text{pitch-diameter allowance on external thread} = 0.0074 \text{ (Table 5)}$$

$$\text{Tolerance on PD of external and internal threads} = 0.0112 \text{ (Table 4)}$$

$$\text{Tolerance on major diameter of external thread and minor diameter of internal thread} = 0.0112 \text{ (Table 4)}$$

#### Internal Thread:

$$\text{Basic Major Diameter: } D = 2.0000$$

$$\text{Min. Major Diameter: } D - 2h + 2h_n = 2.0314 \text{ (see Table 2)}$$

$$\text{Min. Pitch Diameter: } D - h = 1.8500 \text{ (see Table 2)}$$

$$\text{Max. Pitch Diameter: } D - h + \text{PD Tolerance} = 1.8612 \text{ (see Table 4)}$$

$$\text{Min. Minor Diameter: } D - 2h = 1.7000 \text{ (see Table 2)}$$

$$\text{Max. Minor Diameter: } D - 2h + \text{Minor Diameter Tolerance} = 1.7112 \text{ (see Table 4)}$$

#### External Thread:

$$\text{Max. Major Diameter: } D - G = 1.9926 \text{ (see Table 5)}$$

$$\text{Min. Major Diameter: } D - G - \text{Major Diameter Tolerance} = 1.9814 \text{ (see Tables 4 and 5)}$$

$$\text{Max. Pitch Diameter: } D - h - G = 1.8426 \text{ (see Tables 2 and 5)}$$

$$\text{Min. Pitch Diameter: } D - h - G - \text{PD Tolerance} = 1.8314 \text{ (see Table 4)}$$

$$\text{Max. Minor Diameter: } D - G - 2h_s = 1.6612 \text{ (see Tables 2 and 5)}$$

**Buttress Thread Designations.**— When only the designation, BUTT is used, the thread is “pull” type buttress (external thread pulls) with the clearance flank leading and the 7-degree pressure flank following. When the designation, PUSH-BUTT is used, the thread is a push type buttress (external thread pushes) with the 7-degree load flank leading and the 45-degree clearance flank following. Whenever possible this description should be con-

firmed by a simplified view showing thread angles on the drawing of the product that has the buttress thread.

*Standard Buttress Threads:* A buttress thread is considered to be standard when: 1) opposite flank angles are 7-degrees and 45-degrees; 2) basic thread height is  $0.6p$ ; 3) tolerances and allowances are as shown in **Tables 4** and **5**; and 4) length of engagement is  $10p$  or less.

*Thread Designation Abbreviations:* In thread designations on drawings, tools, gages, and in specifications, the following abbreviations and letters are to be used:

BUTT	for buttress thread, pull type	
PUSH-BUTT	for buttress thread, push type	
LH	for left-hand thread	<i>Note:</i> Absence of LH indicates that the thread is a right-hand thread.
P	for pitch	
L	for lead	
A	for external thread	<i>Note:</i> Absence of A or B after thread class indicates that designation covers both the external and internal threads.
B	for internal thread	
Le	for length of thread engagement	
SPL	for special	
FL	for flat root thread	
E	for pitch diameter	
TPI	for threads per inch	
THD	for thread	

*Designation Sequence for Buttress Inch Screw Threads:* When designating single-start standard buttress threads the nominal size is given first, the threads per inch next, then PUSH if the internal member is to push, but nothing if it is to pull, then the class of thread (2 or 3), then whether external (A) or internal (B), then LH if left-hand, but nothing if right-hand, and finally FL if a flat root thread, but nothing if a radiused root thread; thus, 2.5-8 BUTT-2A indicates a 2.5 inch, 8 threads per inch buttress thread, Class 2 external, right-hand, internal member to pull, with radiused root of thread. The designation 2.5-8 PUSH-BUTT-2A-LH-FL signifies a 2.5 inch size, 8 threads per inch buttress thread with internal member to push, Class 2 external, left-hand, and flat root.

A multiple-start standard buttress thread is similarly designated but the pitch is given instead of the threads per inch, followed by the lead and the number of starts is indicated in parentheses after the class of thread. Thus, 10-0.25P-0.5L - BUTT-3B (2 start) indicates a 10-inch thread with 4 threads per inch, 0.5 inch lead, buttress form with internal member to pull, Class 3 internal, 2 starts, with radiused root of thread.

## WHITWORTH THREADS

**British Standard Whitworth (BSW) and British Standard Fine (BSF) Threads**

The BSW is the Coarse Thread series and the BSF is the Fine Thread series of British Standard 84:1956—Parallel Screw Threads of Whitworth Form. The dimensions given in the tables on the following pages for the major, effective, and minor diameters are, respectively, the maximum limits of these diameters for bolts and the minimum limits for nuts. Formulas for the tolerances on these diameters are given in the table below.

**Whitworth Standard Thread Form.**— This thread form is used for the British Standard Whitworth (BSW) and British Standard Fine (BSF) screw threads. More recently, both threads have been known as parallel screw threads of Whitworth form. With standardization of the Unified thread, the Whitworth thread form is expected to be used only for replacements or spare parts. Tables of British Standard Parallel Screw Threads of Whitworth Form will be found on the following pages; tolerance formulas are given in the table below. The form of the thread is shown by the diagram. If  $p$  = pitch,  $d$  = depth of thread,  $r$  = radius at crest and root, and  $n$  = number of threads per inch, then

$$d = \frac{1}{2}p \times \cot 27^{\circ} 30' = 0.640327p = 0.640327 \div n$$

$$r = 0.137329p = 0.137329 \div n$$

It is recommended that stainless steel bolts of nominal size  $\frac{3}{4}$  inch and below should not be made to Close Class limits but rather to Medium or Free Class limits. Nominal sizes above  $\frac{3}{4}$  inch should have maximum and minimum limits 0.001 inch smaller than the values obtained from the table.

*Tolerance Classes : Close Class bolts.* Applies to screw threads requiring a fine snug fit, and should be used only for special work where refined accuracy of pitch and thread form are particularly required. *Medium Class bolts and nuts.* Applies to the better class of ordinary interchangeable screw threads. *Free Class bolts.* Applies to the majority of bolts of ordinary commercial quality. *Normal Class nuts.* Applies to ordinary commercial quality nuts; this class is intended for use with Medium or Free Class bolts.

**Table 1. Tolerance Formulas for BSW and BSF Threads**

	Class or Fit	Tolerance in inches <sup>1</sup> (+ for nuts, - for bolts)		
		Major Dia.	Effective Dia.	Minor Dia.
Bolts	Close	$\frac{2}{3}T + 0.01\sqrt{p}$	$\frac{2}{3}T$	$\frac{2}{3}T + 0.013\sqrt{p}$
	Medium	$T + 0.01\sqrt{p}$	$T$	$T + 0.02\sqrt{p}$
	Free	$\frac{3}{2}T + 0.01\sqrt{p}$	$\frac{3}{2}T$	$\frac{3}{2}T + 0.02\sqrt{p}$
Nuts	Close	...	$\frac{2}{3}T$	$0.2p + 0.004^2$
	Medium	...	$T$	$0.2p + 0.005^3$
	Normal	...	$\frac{3}{2}T$	$0.2p + 0.007^4$

<sup>1</sup>The symbol  $T = 0.002\sqrt[3]{D} + 0.003\sqrt{L} + 0.005\sqrt{p}$ , where  $D$  = major diameter of thread in inches;  $L$  = length of engagement in inches;  $p$  = pitch in inches. The symbol  $p$  signifies pitch.

<sup>2</sup>For 26 threads per inch and finer.

<sup>3</sup>For 24 and 22 threads per inch.

<sup>4</sup>For 20 threads per inch and coarser.

Dimensions are in inches.

**Allowances:** Only Free Class and Medium Class bolts have an allowance. For nominal sizes of  $\frac{3}{4}$  inch down to  $\frac{1}{4}$  inch, the allowance is 30 percent of the Medium Class bolt effective-diameter tolerance ( $0.3T$ ); for sizes less than  $\frac{1}{4}$  inch, the allowance for the  $\frac{1}{4}$ -inch size applies. Allowances are applied minus from the basic bolt dimensions; the tolerances are then applied to the reduced dimensions.

<sup>1</sup>To be dispensed with wherever possible.<sup>2</sup>The use of number 2 BA threads is recommended in place of 3/16-inch BSF thread, see page 2033.

## PIPE AND HOSE THREADS

The types of threads used on pipe and pipe fittings may be classed according to their intended use: 1) threads that when assembled with a sealer will produce a pressure-tight joint; 2) threads that when assembled without a sealer will produce a pressure-tight joint; 3) threads that provide free- and loose-fitting mechanical joints without pressure tightness; and 4) threads that produce rigid mechanical joints without pressure tightness.

### American National Standard Pipe Threads

American National Standard pipe threads described in the following paragraphs provide taper and straight pipe threads for use in various combinations and with certain modifications to meet these specific needs.

**Thread Designation and Notation.**— American National Standard Pipe Threads are designated by specifying in sequence the nominal size, number of threads per inch, and the symbols for the thread series and form, as:  $\frac{3}{8}$ —18 NPT. The symbol designations are as follows: NPT—American National Standard Taper Pipe Thread; NPTR—American National Standard Taper Pipe Thread for Railing Joints; NPSC—American National Standard Straight Pipe Thread for Couplings; NPSM—American National Standard Straight Pipe Thread for Free-fitting Mechanical Joints; NPSL—American National Standard Straight Pipe Thread for Loose-fitting Mechanical Joints with Locknuts; and NPSH—American National Standard Straight Pipe Thread for Hose Couplings.

**American National Standard Taper Pipe Threads.**— The basic dimensions of the ANSI Standard taper pipe thread are given in [Table 1a](#).

*Form of Thread:* The angle between the sides of the thread is 60 degrees when measured in an axial plane, and the line bisecting this angle is perpendicular to the axis. The depth of the truncated thread is based on factors entering into the manufacture of cutting tools and the making of tight joints and is given by the formulas in [Table 1a](#) or the data in [Table 2](#) obtained from these formulas. Although the standard shows flat surfaces at the crest and root of the thread, some rounding may occur in commercial practice, and it is intended that the pipe threads of product shall be acceptable when crest and root of the tools or chasers lie within the limits shown in [Table 2](#).

*Pitch Diameter Formulas:* In the following formulas, which apply to the ANSI Standard taper pipe thread,  $E_0$  = pitch diameter at end of pipe;  $E_1$  = pitch diameter at the large end of the internal thread and at the gaging notch;  $D$  = outside diameter of pipe;  $L_1$  = length of hand-tight or normal engagement between external and internal threads;  $L_2$  = basic length of effective external taper thread; and  $p$  = pitch =  $1 \div$  number of threads per inch.

$$E_0 = D - (0.05D + 1.1)p$$

$$E_1 = E_0 + 0.0625L_1$$

*Thread Length:* The formula for  $L_2$  determines the length of the effective thread and includes approximately two usable threads that are slightly imperfect at the crest. The normal length of engagement,  $L_1$ , between external and internal taper threads, when assembled by hand, is controlled by the use of the gages.

$$L_2 = (0.80D + 6.8)p$$

*Taper:* The taper of the thread is 1 in 16, or 0.75 inch per foot, measured on the diameter and along the axis. The corresponding half-angle of taper or angle with the center line is 1 degree, 47 minutes.

**Table 1a. Basic Dimensions, American National Standard Taper Pipe Threads, NPT  
ANSI/ASME B1.20.1-1983 (R2006)**

For all dimensions, see corresponding reference letter in table.

Angle between sides of thread is 60 degrees. Taper of thread, on diameter, is  $\frac{3}{4}$  inch per foot. Angle of taper with center line is  $1^{\circ}47'$ .

The basic maximum thread height,  $h$ , of the truncated thread is  $0.8 \times$  pitch of thread. The crest and root are truncated a minimum of  $0.033 \times$  pitch for all pitches. For maximum depth of truncation, see Table 2.

Nominal Pipe Size	Outside Dia. of Pipe, $D$	Threads per Inch, $n$	Pitch of Thread, $p$	Pitch Diameter at Beginning of External Thread, $E_0$	Handtight Engagement		Effective Thread, External

<sup>1</sup>The length  $L_5$  from the end of the pipe determines the plane beyond which the thread form is imperfect at the crest. The next two threads are perfect at the root. At this plane the cone formed by the crests of the thread intersects the cylinder forming the external surface of the pipe.  $L_5 = L_2 - 2p$ .

<sup>2</sup>Given as information for use in selecting tap drills.

<sup>3</sup>Three threads for 2-inch size and smaller; two threads for larger sizes.

<sup>4</sup>Military Specification MIL—P—7105 gives the wrench makeup as three threads for 3 in. and smaller. The  $E_3$  dimensions are then as follows: Size 2 1/2 in., 2.69609 and size 3 in., 3.31719.

All dimensions given in inches.

Increase in diameter per thread is equal to  $0.0625/n$ .

The basic dimensions of the ANSI Standard Taper Pipe Thread are given in inches to four or five decimal places. While this implies a greater degree of precision than is ordinarily attained, these dimensions are the basis of gage dimensions and are so expressed for the purpose of eliminating errors in computations.

**Engagement Between External and Internal Taper Threads.**—The normal length of engagement between external and internal taper threads when screwed together handtight is shown as  $L_1$  in Table 1a. This length is controlled by the construction and use of the pipe thread gages. It is recognized that in special applications, such as flanges for high-pressure work, longer thread engagement is used, in which case the pitch diameter  $E_1$  (Table 1a) is maintained and the pitch diameter  $E_0$  at the end of the pipe is proportionately smaller.

**Tolerances on Thread Elements.**—The maximum allowable variation in the commercial product (manufacturing tolerance) is one turn large or small from the basic dimensions.

The permissible variations in thread elements on steel products and all pipe made of steel, wrought iron, or brass, exclusive of butt-weld pipe, are given in Table 3. This table is a

guide for establishing the limits of the thread elements of taps, dies, and thread chasers. These limits may be required on product threads.

On pipe fittings and valves (not steel) for steam pressures 300 pounds and below, it is intended that plug and ring gage practice as set up in the Standard ANSI/ASME B1.20.1 will provide for a satisfactory check of accumulated variations of taper, lead, and angle in such product. Therefore, no tolerances on thread elements have been established for this class.

For service conditions where a more exact check is required, procedures have been developed by industry to supplement the regulation plug and ring method of gaging.

**Table 2. Limits on Crest and Root of American National Standard External and Internal Taper Pipe Threads, NPT ANSI/ASME B1.20.1-1983 (R2006)**

INTERNAL THREAD							
EXTERNAL THREAD							
Threads per Inch	Height of Sharp V Thread, $H$	Height of Pipe Thread, $h$		Truncation, $f$		Width of Flat, $F$ , Equivalent to Truncation	
		Max.	Min.	Min.	Max.	Min.	Max.
27	0.03208	0.02963	0.02496	0.0012	0.0036	0.0014	0.0041
18	0.04811	0.04444	0.03833	0.0018	0.0049	0.0021	0.0057
14	0.06186	0.05714	0.05071	0.0024	0.0056	0.0027	0.0064
11½	0.07531	0.06957	0.06261	0.0029	0.0063	0.0033	0.0073
8	0.10825	0.10000	0.09275	0.0041	0.0078	0.0048	0.0090

All dimensions are in inches and are given to four or five decimal places only to avoid errors in computations, not to indicate required precision.

**Table 3. Tolerances on Taper, Lead, and Angle of Pipe Threads of Steel Products and All Pipe of Steel, Wrought Iron, or Brass ANSI/ASME B1.20.1-1983 (R2006) (Exclusive of Butt-Weld Pipe)**

Nominal Pipe Size	Threads per Inch	Taper on Pitch Line ( $\frac{3}{4}$ in/ft)		Lead in Length of Effective Threads	60 Degree Angle of Threads, Degrees
		Max.	Min.		
$\frac{1}{16}, \frac{1}{8}$	27	$+\frac{1}{8}$	$-\frac{1}{16}$	$\pm 0.003$	$\pm 2\frac{1}{2}$
$\frac{1}{4}, \frac{3}{8}$	18	$+\frac{1}{8}$	$-\frac{1}{16}$	$\pm 0.003$	$\pm 2$
$\frac{1}{2}, \frac{3}{4}$	14	$+\frac{1}{8}$	$-\frac{1}{16}$	$\pm 0.003^1$	$\pm 2$
1, 1¼, 1½, 2	11½	$+\frac{1}{8}$	$-\frac{1}{16}$	$\pm 0.003^1$	$\pm 1\frac{1}{2}$
2½ and larger	8	$+\frac{1}{8}$	$-\frac{1}{16}$	$\pm 0.003^1$	$\pm 1\frac{1}{2}$

<sup>1</sup>The tolerance on lead shall be  $\pm 0.003$  in. per inch on any size threaded to an effective thread length greater than 1 in.

For tolerances on height of thread, see [Table 2](#).

The limits specified in this table are intended to serve as a guide for establishing limits of the thread elements of taps, dies, and thread chasers. These limits may be required on product threads.

**Table 4. Internal Threads in Pipe Couplings, NPSC for Pressure-tight Joints with Lubricant or Sealer ANSI/ASME B1.20.1-1983 (R2006)**

1 1/4	11 1/2	1.506	1.5752	1.5915		...	...	...	...	...	

<sup>1</sup> As the ANSI Standard Pipe Thread form is maintained, the major and minor diameters of the internal thread vary with the pitch diameter. All dimensions are given in inches.

<sup>2</sup> The actual pitch diameter of the straight tapped hole will be slightly smaller than the value given when gaged with a taper plug gage as called for in ANSI/ASME B1.20.1.

**Railing Joint Taper Pipe Threads, NPTR.**— Railing joints require a rigid mechanical thread joint with external and internal taper threads. The external thread is basically the same as the ANSI Standard Taper Pipe Thread, except that sizes 1/2 through 2 inches are shortened by 3 threads and sizes 2 1/2 through 4 inches are shortened by 4 threads to permit the use of the larger end of the pipe thread. A recess in the fitting covers the last scratch or imperfect threads on the pipe.

**Straight Pipe Threads in Pipe Couplings, NPSC.**— Threads in pipe couplings made in accordance with the ANSI/ASME B1.20.1 specifications are straight (parallel) threads of the same thread form as the ANSI Standard Taper Pipe Thread. They are used to form pressure-tight joints when assembled with an ANSI Standard external taper pipe thread and made up with lubricant or sealant. These joints are recommended for comparatively low pressures only.

**Straight Pipe Threads for Mechanical Joints, NPSM, NPSL, and NPSH.**— While external and internal taper pipe threads are recommended for pipe joints in practically every service, there are mechanical joints where straight pipe threads are used to advantage. Three types covered by ANSI/ASME B1.20.1 are:

*Loose-fitting Mechanical Joints With Locknuts (External and Internal), NPSL:* This thread is designed to produce a pipe thread having the largest diameter that it is possible to cut on standard pipe. The dimensions of these threads are given in [Table 5](#). It will be noted that the maximum major diameter of the external thread is slightly greater than the nominal outside diameter of the pipe. The normal manufacturer's variation in pipe diameter provides for this increase.

*Loose-fitting Mechanical Joints for Hose Couplings (External and Internal), NPSH:*

Hose coupling joints are ordinarily made with straight internal and external loose-fitting threads. There are several standards of hose threads having various diameters and pitches. One of these is based on the ANSI Standard pipe thread and by the use of this thread series, it is possible to join small hose couplings in sizes 1/2 to 4 inches, inclusive, to ends of standard pipe having ANSI Standard External Pipe Threads, using a gasket to seal the joints. For the hose coupling thread dimensions see *ANSI Standard Hose Coupling Screw Threads* starting on page [2020](#).

*Free-fitting Mechanical Joints for Fixtures (External and Internal), NPSM:* Standard iron, steel, and brass pipe are often used for special applications where there are no internal pressures. Where straight thread joints are required for mechanical assemblies, straight pipe threads are often found more suitable or convenient. Dimensions of these threads are given in [Table 5](#).

**Table 5. American National Standard Straight Pipe Threads for Mechanical Joints, NPSM and NPSL ANSI/ASME B1.20.1-1983 (R2006)**

Nominal Pipe Size	Threads per Inch	External Thread				Internal Thread				
		Allowance	Major Diameter		Pitch Diameter		Minor Diameter		Pitch Diameter

<sup>1</sup> As the ANSI Standard Straight Pipe Thread form of thread is maintained, the major and the minor diameters of the internal thread and the minor diameter of the external thread vary with the pitch diameter. The major diameter of the external thread is usually determined by the diameter of the pipe. These theoretical diameters result from adding the depth of the truncated thread ( $0.666025 \times p$ ) to the maximum pitch diameters, and it should be understood that commercial pipe will not always have these maximum major diameters.

<sup>2</sup> This is the same as the pitch diameter at end of internal thread,  $E_1$  Basic. (See Table 1a.)

All dimensions are given in inches.

*Notes for Free-fitting Fixture Threads:* The minor diameters of external threads and major diameters of internal threads are those as produced by commercial straight pipe dies and commercial ground straight pipe taps.

The major diameter of the external thread has been calculated on the basis of a truncation of  $0.10825p$ , and the minor diameter of the internal thread has been calculated on the basis of a truncation of  $0.21651p$ , to provide no interference at crest and root when product is gaged with gages made in accordance with the Standard.

*Notes for Loose-fitting Locknut Threads:* The locknut thread is established on the basis of retaining the greatest possible amount of metal thickness between the bottom of the thread and the inside of the pipe. In order that a locknut may fit loosely on the externally threaded part, an allowance equal to the "increase in pitch diameter per turn" is provided, with a tolerance of  $1\frac{1}{2}$  turns for both external and internal threads.

**American National Standard Dryseal Pipe Threads for Pressure-Tight Joints.—**

Dryseal pipe threads are based on the USA (American) pipe thread; however, they differ in that they are designed to seal pressure-tight joints without the necessity of using sealing compounds. To accomplish this, some modification of thread form and greater accuracy in manufacture is required. The roots of both the external and internal threads are truncated slightly more than the crests, i.e., roots have wider flats than crests so that metal-to-metal contact occurs at the crests and roots coincident with, or prior to, flank contact. Thus, as the threads are assembled by wrenching, the roots of the threads crush the sharper crests of the mating threads. This sealing action at both major and minor diameters tends to prevent spiral leakage and makes the joints pressure-tight without the necessity of using sealing compounds, provided that the threads are in accordance with standard specifications and tolerances and are not damaged by galling in assembly. The control of crest and root truncation is simplified by the use of properly designed threading tools. Also, it is desirable that both external and internal threads have full thread height for the length of hand engagement. Where not functionally objectionable, the use of a compatible lubricant or sealant is permissible to minimize the possibility of galling. This is desirable in assembling Dryseal pipe threads in refrigeration and other systems to effect a pressure-tight seal. The crest and root of Dryseal pipe threads may be slightly rounded, but are acceptable if they lie within the truncation limits given in [Table 6](#).

**Table 6. American National Standard Dryseal Pipe Threads—Limits on Crest and Root Truncation ASME B1.20.3-1976 (R2013)**

Threads Per Inch	Height of Sharp V Thread ( <i>H</i> )	Truncation							
		Minimum				Maximum			
		At Crest		At Root		At Crest		At Root	
		Formula	Inch	Formula	Inch	Formula	Inch	Formula	Inch

18	0.04811	$0.047p$	0.0026	$0.078p$	0.0043	$0.078p$	0.0043	$0.109p$	0.0061
14	0.06180	$0.036p$	0.0026	$0.060p$	0.0043	$0.060p$	0.0043	$0.085p$	0.0061
11½	0.07531	$0.040p$	0.0035	$0.060p$	0.0052	$0.060p$	0.0052	$0.090p$	0.0078
8	0.10825	$0.042p$	0.0052	$0.055p$	0.0069	$0.055p$	0.0069	$0.076p$	0.0095

All dimensions are given in inches. In the formulas,  $p$  = pitch.

**Types of Dryseal Pipe Thread.—** American National Standard ASME B1.20.3-1976 (R2013) covers four types of standard Dryseal pipe threads:

NPTF, Dryseal USA (American) Standard Taper Pipe Thread

PTF-SAE SHORT, Dryseal SAE Short Taper Pipe Thread

NPSF, Dryseal USA (American) Standard Fuel Internal Straight Pipe Thread

NPSI, Dryseal USA (American) Standard Intermediate Internal Straight Pipe Thread

**Table 7. Recommended Limitation of Assembly among the Various Types of Dryseal Threads**

External Dryseal Thread		For Assembly with Internal Dryseal Thread	
Type	Description	Type	Description
1	NPTF (tapered), ext thd	1	NPTF (tapered), int thd
		2 <sup>1,2</sup>	PTF-SAE SHORT (tapered), int thd
		3 <sup>1,3</sup>	NPSF (straight), int thd
		4 <sup>1,3,4</sup>	NPSI (straight), int thd
2 <sup>1,5</sup>	PTF-SAE SHORT (tapered) ext thd	4	NPSI (straight), int thd
		1	NPTF (tapered), int thd

<sup>1</sup> Pressure-tight joints without the use of a sealant can best be ensured where both components are threaded with NPTF (full length threads), since theoretically interference (sealing) occurs at all threads, but there are two less threads engaged than for NPTF assemblies. When straight internal threads are used, there is interference only at one thread depending on ductility of materials.

<sup>2</sup>PTF-SAE SHORT internal threads are primarily intended for assembly with type 1-NPTF external threads. They are not designed for, and at extreme tolerance limits may not assemble with, type 2-PTF-SAE SHORT external threads.

<sup>3</sup>There is no external straight Dryseal thread.

<sup>4</sup>NPSI internal threads are primarily intended for assembly with type 2-PTF-SAE SHORT external threads but will also assemble with full length type 1 NPTF external threads.

<sup>5</sup>PTF-SAE SHORT external threads are primarily intended for assembly with type 4-NPSI internal threads but can also be used with type 1-NPTF internal threads. They are not designed for, and at extreme tolerance limits may not assemble with, type 2-PTF-SAE SHORT internal threads or type 3-NPSF internal threads.

An assembly with straight internal pipe threads and taper external pipe threads is frequently more advantageous than an all taper thread assembly, particularly in automotive and other allied industries where economy and rapid production are major considerations. Dryseal threads are not used in assemblies in which both components have straight pipe threads.

*NPTF Threads:* This type applies to both external and internal threads and is suitable for pipe joints in practically every type of service. Of all Dryseal pipe threads, NPTF external and internal threads mated are generally conceded to be superior for strength and seal since they have the longest length of thread and, theoretically, interference (sealing) occurs at every engaged thread root and crest. Use of tapered internal threads, such as NPTF or PTF-SAE SHORT in hard or brittle materials having thin sections will minimize the possibility of fracture.

There are two classes of NPTF threads. Class 1 threads are made to interfere (seal) at root and crest when mated, but inspection of crest and root truncation is not required. Consequently, Class 1 threads are intended for applications where close control of tooling is required for conformance of truncation or where sealing is accomplished by means of a sealant applied to the threads.

Class 2 threads are theoretically identical to those made to Class 1. However, inspection of root and crest truncation is required. Consequently, where a sealant is not used, there is more assurance of a pressure-tight seal for Class 2 threads than for Class 1 threads.

*PTF-SAE SHORT Threads:* External threads of this type conform in all respects with NPTF threads except that the thread length has been shortened by eliminating one thread from the small (entering) end. These threads are designed for applications where clearance is not sufficient for the full length of the NPTF threads or for economy of material where the full thread length is not necessary.

Internal threads of this type conform in all respects with NPTF threads, except that the thread length has been shortened by eliminating one thread from the large (entry) end. These threads are designed for thin materials where thickness is not sufficient for the full thread length of the NPTF threads or for economy in tapping where the full thread length is not necessary.

Pressure-tight joints without the use of lubricant or sealer can best be ensured where mating components are both threaded with NPTF threads. This should be considered before specifying PTF-SAE SHORT external or internal threads.

*NPSF Threads:* Threads of this type are straight (cylindrical) instead of tapered and are internal only. They are more economical to produce than tapered internal threads, but when assembled do not offer as strong a guarantee of sealing since root and crest interference will not occur for all threads. NPSF threads are generally used with soft or ductile materials which will tend to adjust at assembly to the taper of external threads, but may be used in hard or brittle materials where the section is thick.

*NPSI Threads:* Threads of this type are straight (cylindrical) instead of tapered, are internal only and are slightly larger in diameter than NPSF threads but have the same tolerance and thread length. They are more economical to produce than tapered threads and may be used in hard or brittle materials where the section is thick or where there is little expansion at assembly with external taper threads. As with NPSF threads, NPSI threads when assembled do not offer as strong a guarantee of sealing as do tapered internal threads.

For more complete specifications for production and acceptance of Dryseal pipe threads, see ASME B1.20.3 (Inch) and ANSI B1.20.4 (Metric Translation), and for gaging and inspection, see ANSI B1.20.5 (Inch) and ANSI B1.20.6M (Metric Translation).

*Designation of Dryseal Pipe Threads:* The standard Dryseal pipe threads are designated by specifying in sequence nominal size, thread series symbol, and class:

*Examples:*  $\frac{1}{8}$ -27 NPTF-1;  $\frac{1}{8}$ -27 PTF-SAE SHORT; and  $\frac{3}{8}$ -18 NPTF-1 AFTER PLATING.

**Table 8. Suggested Tap Drill Sizes for Internal Dryseal Pipe Threads**

Size	Probable Drill Oversize Cut (Mean)	Taper Pipe Thread				Straight Pipe Thread		
		Minor Diameter At Distance		Drill Size <sup>1</sup>		Minor Diameter		Drill Size <sup>1</sup>
		$L_1$ From Large End	$L_1 + L_3$ From Large End	Without Reamer	With Reamer	NPSF	NPSI

<sup>1</sup> Some drill sizes listed may not be standard drills.

All dimensions are given in inches.

**Special Dryseal Threads.**— Where design limitations, economy of material, permanent installation, or other limiting conditions prevail, consideration may be given to using a special Dryseal thread series.

*Dryseal Special Short Taper Pipe Thread, PTF-SPL SHORT:* Threads of this series conform in all respects to PTF-SAE SHORT threads except that the full thread length has been further shortened by eliminating one thread at the small end of internal threads or one thread at the large end of external threads.

*Dryseal Special Extra Short Taper Pipe Thread, PTF-SPL EXTRA SHORT:* Threads of this series conform in all respects to PTF-SAE SHORT threads except that the full thread length has been further shortened by eliminating two threads at the small end of internal threads or two threads at the large end of external threads.

*Limitations of Assembly:* Table 9 applies where Dryseal Special Short or Extra Short Taper Pipe Threads are to be assembled as special combinations.

**Table 9. Assembly Limitations for Special Combinations of Dryseal Threads**

Thread	May Assemble with <sup>1</sup>	May Assemble with <sup>2</sup>
PTF SPL SHORT EXTERNAL PTF SPL EXTRA SHORT EXTERNAL	PTF-SAE SHORT INTERNAL NPSF INTERNAL PTF SPL SHORT INTERNAL PTF SPL EXTRA SHORT INTERNAL	NPTF or NPSI INTERNAL
PTF SPL SHORT INTERNAL PTF SPL EXTRA SHORT INTERNAL	PTF-SAE SHORT EXTERNAL	NPTF EXTERNAL

<sup>1</sup> Only when the external thread or the internal thread or both are held closer than the standard tolerance, the external thread toward the minimum and the internal thread toward the maximum pitch diameter to provide a minimum of one turn hand engagement. At extreme tolerance limits the shortened full-thread lengths reduce hand engagement and the threads may not start to assemble.

<sup>2</sup> Only when the internal thread or the external thread or both are held closer than the standard tolerance, the internal thread toward the minimum and the external thread toward the maximum pitch diameter to provide a minimum of two turns for wrench make-up and sealing. At extreme tolerance limits the shortened full-thread lengths reduce wrench make-up and the threads may not seal.

*Dryseal Fine Taper Thread Series, F-PTF:* The need for finer pitches for nominal pipe sizes has brought into use applications of 27 threads per inch to  $\frac{1}{4}$ - and  $\frac{3}{8}$ -inch pipe sizes. There may be other needs that require finer pitches for larger pipe sizes. It is recommended that the existing threads per inch be applied to the next larger pipe size for a fine thread series, thus:  $\frac{1}{4}$ -27,  $\frac{3}{8}$ -27,  $\frac{1}{2}$ -18,  $\frac{3}{4}$ -18, 1-14,  $1\frac{1}{4}$ -14,  $1\frac{1}{2}$ -14, and 2-14. This series applies to external and internal threads of full length and is suitable for applications where threads finer than NPTF are required.

*Dryseal Special Diameter-Pitch Combination Series, SPL-PTF:* Other applications of diameter-pitch combinations have come into use where taper pipe threads are applied to nominal size thin wall tubing. These combinations are:  $\frac{1}{2}$ -27,  $\frac{5}{8}$ -27,  $\frac{3}{4}$ -27,  $\frac{7}{8}$ -27, and 1-27. This series applies to external and internal threads of full length and is applicable to thin wall nominal diameter outside tubing.

*Designation of Special Dryseal Pipe Threads:* The designations used for these special dryseal pipe threads are as follows:

$\frac{1}{8}$ -27 PTF-SPL SHORT

$\frac{1}{8}$ -27 PTF-SPL EXTRA SHORT

$\frac{1}{2}$ -27 SPL PTF, OD 0.500

Note that in the last designation the OD of tubing is given.

### British Standard Pipe Threads

**British Standard Pipe Threads for Non-pressure-tight Joints.**—The threads in BS 2779:1973, “Specifications for Pipe Threads where Pressure-tight Joints are not Made on the Threads”, are Whitworth form parallel fastening threads that are generally used for fastening purposes such as the mechanical assembly of component parts of fittings, cocks and valves. They are not suitable where pressure-tight joints are made on the threads.

The crests of the basic Whitworth thread form may be truncated to certain limits of size given in the Standard except on internal threads, when they are likely to be assembled with external threads conforming to the requirements of BS 21 “British Standard Pipe Threads for Pressure-tight Joints” (see page 2018).

For external threads two classes of tolerance are provided and for internal, one class. The two classes of tolerance for external threads are Class A and Class B. For economy of manufacture the class B fit should be chosen whenever possible. The class A is reserved for those applications where the closer tolerance is essential. Class A tolerance is an entirely negative value, equivalent to the internal thread tolerance. Class B tolerance is an entirely negative value twice that of class A tolerance. Tables showing limits and dimensions are given in the Standard.

The thread series specified in this Standard shall be designated by the letter "G". A typical reference on a drawing might be "G $\frac{1}{2}$ ", for internal thread; "G $\frac{1}{2}$ A", for external thread, class A; and "G  $\frac{1}{2}$ B", for external thread, class B. Where no class reference is stated for external threads, that of class B will be assumed. The designation of truncated threads shall have the addition of the letter "T" to the designation, i.e., G  $\frac{1}{2}$ T and G  $\frac{1}{2}$ BT.

<sup>1</sup> The thread pitches in millimeters are as follows: 0.907 for 28 threads per inch, 1.337 for 19 threads per inch, 1.814 for 14 threads per inch, and 2.309 for 11 threads per inch.

Each basic metric dimension is given in roman figures (nominal sizes excepted) and each basic inch dimension is shown in italics directly beneath it.

**British Standard Pipe Threads for Pressure-tight Joints.**—The threads in BS 21:1973, "Specification for Pipe Threads where Pressure-tight Joints are Made on the Threads", are based on the Whitworth thread form and are specified as:

1) *Jointing threads:* These relate to pipe threads for joints made pressure-tight by the mating of the threads; they include taper external threads for assembly with either taper or parallel internal threads (parallel external pipe threads are not suitable as jointing threads).

2) *Longscrew threads:* These relate to parallel external pipe threads used for longscrews (connectors) specified in BS 1387 where a pressure-tight joint is achieved by the compression of a soft material onto the surface of the external thread by tightening a back nut against a socket.

<sup>1</sup> In the Standard BS 21:1973 the thread pitches in millimeters are as follows: 0.907 for 28 threads per inch, 1.337 for 19 threads per inch, 1.814 for 14 threads per inch, and 2.309 for 11 threads per inch.

<sup>2</sup> This is the minimum number of useful threads on the pipe for the basic gage length; for the maximum and minimum gage lengths, the minimum numbers of useful threads are, respectively, greater and less by the amount of tolerance in the column to the left. The design of internally threaded parts shall make allowance for receiving pipe ends of up to the minimum number of useful threads corresponding to the maximum gage length; the minimum number of useful *internal* threads shall be no less than 80 percent of the minimum number of useful external threads for the minimum gage length.

Each basic metric dimension is given in roman figures (nominal sizes excepted) and each basic inch dimension is shown in italics directly beneath it. Figures in ( ) are numbers of turns of thread with metric linear equivalents given beneath. Taper of taper thread is 1 in 16 on diameter.

### Hose Coupling Screw Threads

**ANSI Standard Hose Coupling Screw Threads.**— Threads for hose couplings, valves, and all other fittings used in direct connection with hose intended for domestic, industrial, and general service in sizes  $\frac{1}{2}$ ,  $\frac{5}{8}$ ,  $\frac{3}{4}$ , 1,  $1\frac{1}{4}$ ,  $1\frac{1}{2}$ , 2,  $2\frac{1}{2}$ , 3,  $3\frac{1}{2}$ , and 4 inches are covered by American National Standard ASME B1.20.7-1991. These threads are designated as follows:

NH — Standard hose coupling threads of full form as produced by cutting or rolling.

NHR — Standard hose coupling threads for garden hose applications where the design utilizes thin walled material which is formed to the desired thread.

NPSH — Standard straight hose coupling thread series in sizes  $\frac{1}{2}$  to 4 inches for joining to American National Standard taper pipe threads using a gasket to seal the joint.

Thread dimensions are given in [Table 1](#) and thread lengths in [Table 2](#).

Fig. 1. Thread Form for ANSI Standard Hose Coupling Threads, NPSH, NH, and NHR. Heavy Line Shows Basic Size.

All dimensions are given in inches.

Dimensions given for the maximum minor diameter of the nipple are figured to the intersection of the worn tool arc with a centerline through crest and root. The minimum minor diameter of the nipple shall be that corresponding to a flat at the minor diameter of the minimum nipple equal to  $\frac{1}{2}p$ , and may be determined by subtracting  $0.7939p$  from the minimum pitch diameter of the nipple. (See Fig. 1)

Dimensions given for the minimum major diameter of the coupling correspond to the basic flat,  $\frac{1}{2}p$ , and the profile at the major diameter produced by a worn tool must not fall below the basic outline. The maximum major diameter of the coupling shall be that corresponding to a flat at the major diameter of the maximum coupling equal to  $\frac{1}{2}p$  and may be determined by adding  $0.7939p$  to the maximum pitch diameter of the coupling. (See Fig. 1)

NH and NHR threads are used for garden hose applications. NPSH threads are used for steam, air and all other hose connections to be made up with standard pipe threads. NH (SPL) threads are used for marine applications.

**Table 2. ANSI Standard Hose Coupling Screw Thread Lengths**

All dimensions are given in inches. For thread designation see Table 1.

**American National Fire Hose Connection Screw Thread.**— This thread is specified in the National Fire Protection Association's Standard NFPA No. 194-1974. It covers the dimensions for screw thread connections for fire hose couplings, suction hose couplings, relay supply hose couplings, fire pump suction, discharge valves, fire hydrants, nozzles, adaptors, reducers, caps, plugs, wyes, siamese connections, standpipe connections, and sprinkler connections.

*Form of Thread:* The basic form of thread is as shown in Fig. 1. It has an included angle of 60 degrees and is truncated top and bottom. The flat at the root and crest of the basic thread form is equal to  $\frac{1}{8}$  (0.125) times the pitch in inches. The height of the thread is equal to 0.649519 times the pitch. The outer ends of both external and internal threads are terminated by the blunt start or "Higbee Cut" on full thread to avoid crossing and mutilation of thread.

*Thread Designation:* The thread is designated by specifying in sequence the nominal size of the connection, number of threads per inch followed by the thread symbol NH.

Thus, .75-8NH indicates a nominal size connection of 0.75 inch diameter with 8 threads per inch.

*Basic Dimensions:* The basic dimensions of the thread are as given in **Table 1**.

**Table 1. Basic Dimensions of NH Threads NFPA 1963-1993 Edition**

Nom. Size	Threads per Inch (tpi)	Thread Designation	Pitch, $p$	Basic Thread Height, $h$	Minimum Internal Thread Dimensions

$4\frac{1}{2}$	4	4.5-4 NH	0.25000	0.0250	5.7609	5.5985	5.4361
5	4	5-4 NH	0.25000	0.0250	6.2600	6.0976	5.9352
6	4	6-4 NH	0.25000	0.0250	7.0250	6.8626	6.7002

All dimensions are in inches.

*Thread Limits of Size:* Limits of size for NH external threads are given in **Table 2**. Limits of size for NH internal threads are given in **Table 3**.

*Tolerances:* The pitch-diameter tolerances for mating external and internal threads are the same. Pitch-diameter tolerances include lead and half-angle deviations. Lead deviations consuming one-half of the pitch-diameter tolerance are 0.0032 inch for  $\frac{3}{4}$ -, 1-, and  $1\frac{1}{2}$ -inch sizes; 0.0046 inch for  $2\frac{1}{2}$ -inch size; 0.0052 inch for 3-, and  $3\frac{1}{2}$ -inch sizes; and 0.0072 inch for 4-,  $4\frac{1}{2}$ -, 5-, and 6-inch sizes. Half-angle deviations consuming one-half of the pitch-diameter tolerance are 1 degree, 42 minutes for  $\frac{3}{4}$ - and 1-inch sizes; 1 degree, 54 minutes for  $1\frac{1}{2}$ -inch size; 2 degrees, 17 minutes for  $2\frac{1}{2}$ -inch size; 2 degrees, 4 minutes for 3- and  $3\frac{1}{2}$ -inch size; and 1 degree, 55 minutes for 4-,  $4\frac{1}{2}$ -, 5-, and 6-inch sizes.

Tolerances for the external threads are:

Major diameter tolerance =  $2 \times$  pitch-diameter tolerance

Minor diameter tolerance = pitch-diameter tolerance +  $2h/9$

The minimum minor diameter of the external thread is such as to result in a flat equal to one-third of the  $p/8$  basic flat, or  $p/24$ , at the root when the pitch diameter of the external thread is at its minimum value. The maximum minor diameter is basic, but may be such as results from the use of a worn or rounded threading tool. The maximum minor diameter is shown in **Fig. 1** and is the diameter upon which the minor diameter tolerance formula shown above is based.

Tolerances for the internal threads are:

Minor diameter tolerance =  $2 \times$  pitch-diameter tolerance

The minimum minor diameter of the internal thread is such as to result in a basic flat,  $p/8$ , at the crest when the pitch diameter of the thread is at its minimum value.

Major diameter tolerance = pitch-diameter tolerance -  $2h/9$

**Table 2. Limits of Size and Tolerances for NH External Threads (Nipples)**  
NFPA 1963, 1993 Edition

Nom. Size	Threads per Inch (tpi)	External Thread (Nipple)

<sup>1</sup> Dimensions for the minimum major diameter of the coupling correspond to the basic flat ( $p/8$ ), and the profile at the major diameter produced by a worn tool must not fall below the basic outline. The maximum major diameter of the coupling shall be that corresponding to a flat at the major diameter of the maximum coupling equal to  $p/24$  and may be determined by adding  $11h/9$  (or  $0.7939p$ ) to the maximum pitch diameter of the coupling.

All dimensions are in inches.

**Gages and Gaging:** Full information on gage dimensions and the use of gages in checking the NH thread are given in NFPA Standard No. 1963, 1993 Edition, published by the National Fire Protection Association, Batterymarch Park, Quincy, MA 02269.

The information and data taken from this standard are reproduced with the permission of the NFPA.

## OTHER THREADS

### Interference-Fit Threads

**Interference-Fit Threads.**— Interference-fit threads are threads in which the externally threaded member is larger than the internally threaded member when both members are in the free state and that, when assembled, become the same size and develop a holding torque through elastic compression, plastic movement of material, or both. By custom, these threads are designated Class 5.

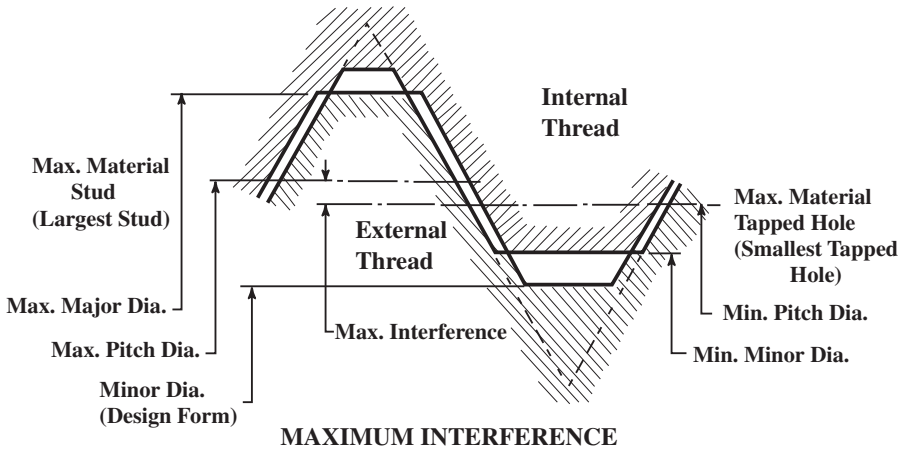

The data in **Tables 1, 2, and 3**, which are based on years of research, testing and field study, represent an American standard for interference-fit threads that overcomes the difficulties experienced with previous interference-fit recommendations such as are given in Federal Screw Thread Handbook H28. These data were adopted as American Standard ASA B1.12-1963. Subsequently, the standard was revised and issued as American National Standard ANSI B1.12-1972. More recent research conducted by the Portsmouth Naval Shipyard has led to the current revision ASME B1.12-1987 (R2013).

The data in **Tables 1, 2, and 3** provide dimensions for external and internal interference-fit (Class 5) threads of modified American National form in the Coarse Thread series, sizes  $\frac{1}{4}$  inch to  $1\frac{1}{2}$  inches. It is intended that interference-fit threads conforming with this standard will provide adequate torque conditions which fall within the limits shown in **Table 3**. The minimum torques are intended to be sufficient to ensure that externally threaded members will not loosen in service; the maximum torques establish a ceiling below which seizing, galling, or torsional failure of the externally threaded components is reduced.

**Tables 1 and 2** give external and internal thread dimensions and are based on engagement lengths, external thread lengths, and tapping hole depths specified in **Table 3** and in compliance with the design and application data given in the following paragraphs. **Table 4** gives the allowances and **Table 5** gives the tolerances for pitch, major, and minor diameters for the Coarse Thread Series.

Basic Profile of American National Standard Class 5 Interference Fit Thread

Note: Plastic flow of interference metal into cavities at major and minor diameters is not illustrated.

Maximum and Minimum Material Limits for Class 5 Interference-Fit Thread

**Design and Application Data for Class 5 Interference-Fit Threads.**— Following are conditions of usage and inspection on which satisfactory application of products made to dimensions in [Tables 1, 2, and 3](#) are based.

*Thread Designations:* The following thread designations provide a means of distinguishing the American Standard Class 5 Threads from the tentative Class 5 and alternate Class 5 threads, specified in Handbook H28. They also distinguish between external and internal American Standard Class 5 Threads.

Class 5 External Threads are designated as follows:

NC-5 HF—For driving in hard ferrous material of hardness over 160 BHN.

NC-5 CSF—For driving in copper alloy and soft ferrous material of 160 BHN or less.

NC-5 ONF—For driving in other nonferrous material (nonferrous materials other than copper alloys), any hardness.

Class 5 Internal Threads are designated as follows:

NC-5 IF—Entire ferrous material range.

NC-5 INF—Entire nonferrous material range.

**Table 1. External Thread Dimensions for Class 5 Interference-Fit Threads  
ASME B1.12-1987 (R2013)**

Nominal Size	Major Diameter, Inches						Pitch Diameter, Inches		Minor Diameter, Inches
	NC-5 HF for driving in ferrous material with hardness greater than 160 BHN $L_e = 1\frac{1}{4}$ Diam.		NC-5 CSF for driving in brass and ferrous material with hardness equal to or less than 160 BHN $L_e = 1\frac{1}{4}$ Diam.		NC-5 ONF for driving in nonferrous except brass (any hardness) $L_e = 2\frac{1}{2}$ Diam.

<sup>1</sup> Fourth decimal place is 0 for all sizes.

All dimensions are in inches, unless otherwise specified.

**Externally Threaded Products:** Points of externally threaded components should be chamfered or otherwise reduced to a diameter below the minimum minor diameter of the thread. The limits apply to bare or metallic coated parts. The threads should be free from excessive nicks, burrs, chips, grit or other extraneous material before driving.

**Table 3. Torques, Interferences, and Engagement Lengths for Class 5 Interference-Fit Threads ASME B1.12-1987 (R2013)**

Nominal Size	Interference on Pitch Diameter		Engagement Lengths, External Thread Lengths and Tapped Hole Depths <sup>1</sup>						Torque at 1-1/4D Engagement in Ferrous Material

<sup>1</sup> $L_e$  = Length of engagement.  $T_s$  = External thread length of full form thread.  $T_h$  = Minimum depth of full form thread in hole.

All dimensions are inches.

**Materials for Externally Threaded Products:** The length of engagement, depth of thread engagement and pitch diameter in Tables 1, 2, and 3 are designed to produce adequate torque conditions when heat-treated medium-carbon steel products, ASTM A-325 (SAE Grade 5) or better, are used. In many applications, case-carburized and nonheat-treated medium-carbon steel products of SAE Grade 4 are satisfactory. SAE Grades 1 and 2 may be usable under certain conditions. This standard is not intended to cover the use of products made of stainless steel, silicon bronze, brass or similar materials. When such materials are used, the tabulated dimensions will probably require adjustment based on pilot experimental work with the materials involved.

**Lubrication:** For driving in ferrous material, a good lubricant sealer should be used, particularly in the hole. A non-carbonizing type of lubricant (such as a rubber-in-water dispersion) is suggested. The lubricant must be applied to the hole and it may be applied to the male member. In applying it to the hole, care must be taken so that an excess amount of lubricant will not cause the male member to be impeded by hydraulic pressure in a blind hole. Where sealing is involved, the lubricant selected should be insoluble in the medium being sealed.

For driving, in nonferrous material, lubrication may not be needed. The use of medium gear oil for driving in aluminum is recommended. American research has observed that the minor diameter of lubricated tapped holes in non-ferrous materials may tend to close in, that is, be reduced in driving; whereas with an unlubricated hole the minor diameter may tend to open up.

**Driving Speed:** This standard makes no recommendation for driving speed. Some opinion has been advanced that careful selection and control of driving speed is desirable to obtain optimum results with various combinations of surface hardness and roughness. Experience with threads made to this standard may indicate what limitations should be placed on driving speeds.

<sup>1</sup> National Class 3 pitch diameter tolerance from ASA B1.1-1960.

<sup>2</sup> Twice the NC-3 pitch diameter tolerance.

<sup>3</sup> National Class 3 minor diameter tolerance from ASA B1.1-1960.

All dimensions are in inches.

*Relation of Driving Torque to Length of Engagement:* Torques increase directly as the length of engagement and this increase is proportionately more rapid as size increases. The standard does not establish recommended breakloose torques.

*Surface Roughness:* Surface roughness is not a required measurement. Roughness between 63 and 125  $\mu\text{in}$ . Ra is recommended. Surface roughness greater than 125  $\mu\text{in}$ . Ra may encourage galling and tearing of threads. Surfaces with roughness less than 63  $\mu\text{in}$ . Ra may hold insufficient lubricant and wring or weld together.

**Lead and Angle Variations:** The lead variation values tabulated in **Table 6** are the maximum variations from specified lead between any two points not farther apart than the length of the standard GO thread gage. Flank angle variation values tabulated in **Table 7** are maximum variations from the basic 30° angle between thread flanks and perpendiculars to the thread axis. The application of these data in accordance with ANSI/ASME B1.3M, the screw thread gaging system for dimensional acceptability, is given in the Standard. Lead variation does not change the volume of displaced metal, but it exerts a cumulative unilateral stress on the pressure side of the thread flank. Control of the difference between pitch diameter size and functional diameter size to within one-half the pitch diameter tolerance will hold lead and angle variables to within satisfactory limits. Both the variations may produce unacceptable torque and faulty assemblies.

**Table 6. Maximum Allowable Variations in Lead and Maximum Equivalent Change in Functional Diameter ASME B1.12-1987 (R2013)**

Nominal Size	External and Internal Threads	
	Allowable Variation in Axial Lead (Plus or Minus)	Max Equivalent Change in Functional Diam. (Plus for Ext, Minus for Int)
0.2500-20	0.0008	0.0013
0.3125-18	0.0009	0.0015
0.3750-16	0.0009	0.0016

0.7500-10	0.0013	0.0022
0.8750- 9	0.0014	0.0024
1.0000- 8	0.0016	0.0027
1.1250- 7	0.0017	0.0030
1.2500- 7	0.0017	0.0030
1.3750- 6	0.0020	0.0036
1.5000- 6	0.0020	0.0036

All dimensions are in inches.

Note: The equivalent change in functional diameter applies to total effect of form errors.

Maximum allowable variation in lead is permitted only when all other form variations are zero.

For sizes not tabulated, maximum allowable variation in lead is equal to 0.57735 times one-half the pitch diameter tolerance.

**Table 7. Maximum Allowable Variation in 30° Basic Half-Angle of External and Internal Screw Threads ASME B1.12-1987 (R2013)**

TPI	Allowable Variation in Half-Angle of Thread (Plus or Minus)	TPI	Allowable Variation in Half-Angle of Thread (Plus or Minus)	TPI	Allowable Variation in Half-Angle of Thread (Plus or Minus)
32	1° 30'	14	0° 55'	8	0° 45'

### Spark Plug Threads

**British Standard for Spark Plugs BS 45:1972 (withdrawn).**— This revised British Standard refers solely to spark plugs used in automobiles and industrial spark ignition internal combustion engines. The basic thread form is that of the ISO metric (see page 1964). In assigning tolerances to the threads of the spark plug and the tapped holes, full consideration has been given to the desirability of achieving the closest possible measure of interchangeability between British spark plugs and engines, and those made to the standards of other ISO Member Bodies.

#### Basic Thread Dimensions for Spark Plug and Tapped Hole in Cylinder Head

Nom. Size	Pitch	Thread	Major Dia.		Pitch Dia.		Minor Dia.	
			Max.	Min.	Max.	Min.	Max.	Min.
14	1.25	Plug	13.937 <sup>1</sup>	13.725	13.125	12.993	12.402	12.181
14	1.25	Hole		14.00	13.368	13.188	12.912	12.647
18	1.5	Plug	17.933 <sup>1</sup>	17.697	16.959	16.819	16.092	15.845
18	1.5	Hole		18.00	17.216	17.026	16.676	16.376

<sup>1</sup> Not specified

All dimensions are given in millimeters.

The tolerance grades for finished spark plugs and corresponding tapped holes in the cylinder head are: for 14 mm size, 6e for spark plugs and 6H for tapped holes which gives a minimum clearance of 0.063 mm; and for 18 mm size, 6e for spark plugs and 6H for tapped holes which gives a minimum clearance of 0.067 mm.

These minimum clearances are intended to prevent the possibility of seizure, as a result of combustion deposits on the bare threads, when removing the spark plugs and applies to both ferrous and non-ferrous materials. These clearances are also intended to enable spark plugs with threads in accordance with this standard to be fitted into existing holes.

**SAE Spark-Plug Screw Threads.**— The SAE Standard includes the following sizes:  $\frac{7}{8}$ -inch nominal diameter with 18 threads per inch; 18-millimeter nominal diameter with a 18-millimeter nominal diameter with 1.5-millimeter pitch; 14-millimeter nominal diameter with a 1.25-millimeter pitch; 10-millimeter nominal diameter with a 1.0 millimeter pitch;  $\frac{3}{8}$ -inch nominal diameter with 24 threads per inch; and  $\frac{1}{4}$ -inch nominal diameter with 32 threads per inch. During manufacture, in order to keep the wear on the threading tools within permissible limits, the threads in the spark plug GO (ring) gage should be truncated to the maximum minor diameter of the spark plug; and in the tapped hole GO (plug) gage to the minimum major diameter of the tapped hole.

#### SAE Standard Threads for Spark Plugs

Size <sup>1</sup> Nom. × Pitch	Major Diameter		Pitch Diameter		Minor Diameter	
	Max.	Min.	Max.	Min.	Max.	Min.
Spark Plug Threads, mm (inches)						
M18 × 1.5	17.933 (0.07060)	17.803 (0.7009)	16.959 (0.6677)	16.853 (0.6635)	16.053 (0.6320)	...
M14 × 1.25	13.868 (0.5460)	13.741 (0.5410)	13.104 (0.5159)	12.997 (0.5117)	12.339 (0.4858)	...
M12 × 1.25	11.862 (0.4670)	11.735 (0.4620)	11.100 (0.4370)	10.998 (0.4330)	10.211 (0.4020)	...
M10 × 1.0	9.974 (0.3927)	9.794 (0.3856)	9.324 (0.3671)	9.212 (0.3627)	8.747 (0.3444)	...

## SAE Standard Threads for Spark Plugs (Continued)

Size <sup>1</sup> Nom. × Pitch	Major Diameter		Pitch Diameter		Minor Diameter	
	Max.	Min.	Max.	Min.	Max.	Min.
Tapped Hole Threads, mm (inches)						
M18 × 1.5	...	18.039 (0.7102)	17.153 (0.6753)	17.026 (0.6703)	16.426 (0.6467)	16.266 (0.6404)
M14 × 1.25	...	14.034 (0.5525)	13.297 (0.5235)	13.188 (0.5192)	12.692 (0.4997)	12.499 (0.4921)
M12 × 1.25	...	12.000 (0.4724)	11.242 (0.4426)	11.188 (0.4405)	10.559 (0.4157)	10.366 (0.4081)
M10 × 1.0	...	10.000 (0.3937)	9.500 (0.3740)	9.350 (0.3681)	9.153 (0.3604)	8.917 (0.3511)

<sup>1</sup>M14 and M18 are preferred for new applications.

In order to keep the wear on the threading tools within permissible limits, the threads in the spark plug GO (ring) gage shall be truncated to the maximum minor diameter of the spark plug, and in the tapped hole GO (plug) gage to the minimum major diameter of the tapped hole. The plain plug gage for checking the minor diameter of the tapped hole shall be the minimum specified. The thread form is that of the ISO metric (see page 1964).

## Lamp Base and Electrical Fixture Threads

**Lamp Base and Socket Shell Threads.**— The “American Standard” threads for lamp base and socket shells are sponsored by the American Society of Mechanical Engineers, the National Electrical Manufacturers’ Association and by most of the large manufacturers of products requiring rolled threads on sheet metal shells or parts, such as lamp bases, fuse plugs, attachment plugs, etc. There are five sizes, designated as the “miniature size,” the “candelabra size,” the “intermediate size,” the “medium size” and the “mogul size.”

Rolled Threads for Screw Shells of  
Electric Sockets and Lamp Bases— American Standard

Male or Base Screw Shells Before Assembly								
Size	Threads per Inch	Pitch $P$	Depth of Thread $D$	Radius Crest Root $R$	Major Dia.		Minor Diam.	
					Max. $A$	Min. $a$	Max. $B$	Min. $b$
Miniature	14	0.07143	0.020	0.0210	0.375	0.370	0.335	0.330
Candelabra	10	0.10000	0.025	0.0312	0.465	0.460	0.415	0.410
Intermediate	9	0.11111	0.027	0.0353	0.651	0.645	0.597	0.591
Medium	7	0.14286	0.033	0.0470	1.037	1.031	0.971	0.965
Mogul	4	0.25000	0.050	0.0906	1.555	1.545	1.455	1.445
Socket Screw Shells Before Assembly								
Miniature	14	0.07143	0.020	0.0210	0.3835	0.3775	0.3435	0.3375
Candelabra	10	0.10000	0.025	0.0312	0.476	0.470	0.426	0.420

Medium	7	0.14286	0.033	0.0470	1.053	1.045	0.987	0.979
Mogul	4	0.25000	0.050	0.0906	1.577	1.565	1.477	1.465

All dimensions are in inches.

**Base Screw Shell Gage Tolerances:** Threaded ring gages—"Go," Max. thread size to minus 0.0003 inch; "Not Go," Min. thread size to plus 0.0003 inch. Plain ring gages—"Go," Max. thread O.D. to minus 0.0002 inch; "Not Go," Min. thread O.D. to plus 0.0002 inch.

**Socket Screw Shell Gages:** Threaded plug gages—"Go," Min. thread size to plus 0.0003 inch; "Not Go," Max. thread size to minus 0.0003 inch. Plain plug gages—"Go," Min. minor dia. to plus 0.0002 inch; "Not Go," Max. minor dia. to minus 0.0002 inch.

**Check Gages for Base Screw Shell Gages:** Threaded plugs for checking threaded ring gages—"Go," Max. thread size to minus 0.0003 inch; "Not Go," Min. thread size to plus 0.0003 inch.

**Electric Fixture Thread.**—The special straight electric fixture thread consists of a straight thread of the same pitches as the American standard pipe thread, and having the regular American or U. S. standard form; it is used for caps, etc. The male thread is smaller, and the female thread larger than those of the special straight-fixture pipe threads. The male thread assembles with a standard taper female thread, while the female thread assembles with a standard taper male thread. This thread is used when it is desired to have the joint "make up" on a shoulder. The gages used are straight-threaded limit gages.

### Instrument and Microscope Threads

**British Association Standard Thread (BA).**—This form of thread is similar to the Whitworth thread in that the root and crest are rounded (see illustration). The angle, however, is only 47 degrees 30 minutes and the radius of the root and crest are proportionately larger. This thread is used in Great Britain and, to some extent, in other European countries for very small screws. Its use in the United States is practically confined to the manufacture of tools for export. This thread system was originated in Switzerland as a standard for watch and clock screws, and it is sometimes referred to as the "Swiss small screw thread standard." See also *Swiss Screw Thread*.

This screw thread system is recommended by the British Standards Institution for use in preference to the BSW and BSF systems for all screws smaller than  $\frac{1}{4}$  inch except that the use of the "0" BA thread be discontinued in favor of the  $\frac{1}{4}$ -in. BSF. It is further recommended that in the selection of sizes, preference be given to even numbered BA sizes. The thread form is shown by the diagram.

British Association Thread

$$H = 1.13634 \times p$$

$$h = 0.60000 \times p$$

$$r = 0.18083 \times p$$

$$s = 0.26817 \times p$$

It is a symmetrical V-thread, of  $47\frac{1}{2}$  degree included angle, having its crests and roots rounded with equal radii, such that the basic depth of the thread is 0.6000 of the pitch. Where  $p$  = pitch of thread,  $H$  = depth of V-thread,  $h$  = depth of BA thread,  $r$  = radius at root and crest of thread, and  $s$  = root and crest truncation.

**British Association (BA) Standard Thread, Basic Dimensions**  
*BS 93:1951 (obsolescent)*

Designation Number	Pitch, mm	Depth of Thread, mm	Bolt and Nut			Radius, mm	Threads per Inch (approx.)

15	0.2100	0.125	0.90	0.775	0.65	0.0380	121
16	0.1900	0.115	0.79	0.675	0.56	0.0344	134

*Tolerances and Allowances:* Two classes of bolts and one for nuts are provided: *Close Class bolts* are intended for precision parts subject to stress, no allowance being provided between maximum bolt and minimum nut sizes. *Normal Class bolts* are intended for general commercial production and general engineering use; for sizes 0 to 10 BA, an allowance of 0.025 mm is provided.

**Tolerance Formulas for British Association (BA) Screw Threads**

	Class or Fit	Tolerance (+ for nuts, - for bolts)		
		Major Dia.	Effective Dia.	Minor Dia.
Bolts	Close Class 0 to 10 BA incl.	0.15 <i>p</i> mm	0.08 <i>p</i> + 0.02 mm	0.16 <i>p</i> + 0.04 mm
	Normal Class 0 to 10 BA incl.	0.20 <i>p</i> mm	0.10 <i>p</i> + 0.025 mm	0.20 <i>p</i> + 0.05 mm
	Normal Class 11 to 16 BA incl.	0.25 <i>p</i> mm	0.10 <i>p</i> + 0.025 mm	0.20 <i>p</i> + 0.05 mm
Nuts	All Classes		0.12 <i>p</i> + 0.03 mm	0.375 <i>p</i> mm

In these formulas, *p* = pitch in millimeters.

**Instrument Makers' Screw Thread System.**— The standard screw system of the Royal Microscopical Society of London, also known as the “Society Thread,” is employed for microscope objectives and the nose pieces of the microscope into which these objectives screw. The form of the thread is the standard Whitworth form. The number of threads per inch is 36. There is one size only. The maximum pitch diameter of the objective is 0.7804 inch and the minimum pitch diameter of the nose-piece is 0.7822 inch. The dimensions are as follows:

Male thread	outside dia. root dia.	max., 0.7982 inch max., 0.7626 inch	min., 0.7952 inch min., 0.7596 inch
Female thread	root of thread top of thread	max., 0.7674 inch max., 0.8030 inch	min., 0.7644 inch min., 0.8000 inch

The Royal Photographic Society Standard Screw Thread ranges from 1-inch diameter upward. For screws less than 1 inch, the Microscopical Society Standard is used. The British Association thread is another thread system employed on instruments abroad.

**American Microscope Objective Thread (AMO).**— The standard, ANSI B1.11-1958 (R2011), describes the American microscope objective thread, AMO, the screw thread form used for mounting a microscope objective assembly to the body or lens turret of a microscope. This screw thread is also recommended for other microscope optical assem-

bles as well as related applications such as photomicrographic equipment. It is based on, and intended to be interchangeable with, the screw thread produced and adopted many years ago by the Royal Microscopical Society of Great Britain, generally known as the RMS thread. While the standard is almost universally accepted as the basic standard for microscope objective mountings, formal recognition has been extremely limited.

The basic thread possesses the overall British Standard Whitworth form. (See *Whitworth Standard Thread Form* starting on page 2005). However, the actual design thread form implementation is based on the WWII era ASA B1.6-1944 "Truncated Whitworth Form" in which the rounded crests and roots are removed. ASA B1.6-1944 was withdrawn in 1951. However, ANSI B1.11-1958 (R2011) is still active for new design.

*Design Requirements of Microscope Objective Threads:* Due to the inherent longevity of optical equipment and the repeated use to which the objective threads are subjected, the following factors should be considered when designing microscope objective threads:

Adequate clearance to afford protection against binding due to the presence of foreign particles or minor crest damage.

Sufficient depth of thread engagement to assure security in the short lengths of engagement commonly encountered.

Allowances for limited eccentricities so that centralization and squareness of the objective are not influenced by such errors in manufacture.

*Deviation from the Truncated Whitworth Thread Form:* Although ANSI B1.11-1958 (R2011) is based on the withdrawn ASA B1.6-1944 truncated Whitworth standard, the previously described design requirements necessitate a deviation from the truncated Whitworth thread form. Some of the more significant modifications are:

A larger allowance on the pitch diameter of the external thread.

Smaller tolerances on the major diameter of the external thread and minor diameter of the internal thread.

The provision of allowances on the major and minor diameters of the external thread.

*Thread Overview:* The thread is a single start type. There is only one class of thread based on a basic major diameter of 0.800 in. and a pitch,  $p$ , of 0.027778 inch (36 threads per inch). The AMO thread shall be designated on drawings, tools and gages as "0.800-36 AMO." Thread nomenclature, definitions and terminology are based on ANSI B1.7-1965 (R1972), "Nomenclature, Threads, and Letter Symbols for Screw Threads."

It should also be noted that ISO 8038-1:1997 "Screw threads for objectives and related nosepieces" is also based on the 0.800 inch, 36 tpi RMS thread form.

*Tolerances and Allowances:* Tolerances are given in **Table 2**. A positive allowance (minimum clearance) of 0.0018 in. is provided for the pitch diameter  $E$ , major diameter  $D$ , and minor diameter,  $K$

If interchangeability with full-form Whitworth threads is not required, the allowances for the major and minor diameters are not necessary, because the forms at the root and crest are truncated. In these cases, either both limits or only the maximum limit of the major and minor diameters may be increased by the amount of the allowance, 0.0018 inch.

*Lengths of Engagement:* The tolerances specified in **Table 2** are applicable to lengths of engagement ranging from  $\frac{1}{8}$  in. to  $\frac{3}{8}$  inch, approximately 15% to 50% of the basic diameter. Microscope objective assemblies generally have a length of engagement of  $\frac{1}{8}$  inch. Lengths exceeding these limits are seldom employed and not covered in this standard.

*Gage testing:* Recommended ring and plug testing gage dimensions for the 0.800-36 AMO thread size can be found in ANSI B1.11-1958 (R2011), Appendix.

*Dimensional Terminology:* Because the active standard ANSI B1.11-1958 (R2011) is based on the withdrawn ASA Truncated Whitworth standard, dimensional nomenclature is described below.

MICROSCOPE OBJECTIVE THREAD

Tolerances, Allowances and Crest Clearances for Microscope Objective Thread (AMO) ANSI B1.11-1958 (R2011)

**Table 1. Definitions, Formulas, Basic and Design Dimensions**  
ANSI B1.11-1958 (R2011)

Symbol	Property	Formula	Dimension
Basic Thread Form			
$\alpha$	Half angle of thread	...	27°30'
$2\alpha$	Included angle of thread	...	55°00'
$n$	Number of threads per inch	...	36
$p$	Pitch	$1/n$	0.027778
$H$	Height of fundamental triangle	$0.960491p$	0.026680
$h_b$	Height of basic thread	$0.640327p$	0.0178
$r$	Radius at crest and root of British Standard Whitworth basic thread (not used)	$0.137329p$	0.0038

**Table 1. (Continued) Definitions, Formulas, Basic and Design Dimensions  
ANSI B1.11-1958 (R2011)**

Symbol	Property	Formula	Dimension
Design Thread Form			
$k$	Height of truncated Whitworth thread	$h_b - U = 0.566410p$	0.0157
$F_c$	Width of flat at crest	$0.243624p$	0.0068
$F_r$	Width of flat at root	$0.166667p$	0.0046
$U$	Basic truncation of crest from basic Whitworth form	$0.073917p$	0.00205
Basic and Design Sizes			
$D$	Major diameter, nominal and basic	...	0.800
$D_n$	Major diameter of internal thread	$D$	0.800
$D_s$	Major diameter of external thread <sup>1</sup>	$D - 2U - G$	0.7941
$E$	Pitch (effective) diameter, basic	$D - h_b$	0.7822
$E_n$	Pitch (effective) diameter of internal thread	$D - h_b$	0.7822
$E_s$	Pitch (effective) diameter of external thread <sup>2</sup>	$D - h_b - G$	0.7804
$K$	Minor diameter, basic	$D - 2h_b$	0.7644
$K_n$	Minor diameter of internal thread	$D - 2k$	0.7685
$K_s$	Minor diameter of external thread <sup>1</sup>	$D - 2h_b - G$	0.7626
$G$	Allowance at pitch (effective) diameter <sup>1,2</sup>	...	0.0018

<sup>1</sup> An allowance equal to that on the pitch diameter is also provided on the major and minor diameters of the external thread for additional clearance and centralizing.

<sup>2</sup> Allowance (minimum clearance) on pitch (effective) diameter is the same as the British RMS thread.

All dimensions are in inches.

**Table 2. Limits of Size and Tolerances — 0.800-36 AMO Thread  
ANSI B1.11-1958 (R2011)**

Element	Major Diameter, $D$			Pitch Diameter, $E$			Minor Diameter, $K$		
	Max.	Min.	Tol.	Max.	Min.	Tol.	Max.	Min.	Tol.
External thread	0.7941	0.7911	0.0030	0.7804	0.7774	0.0030	0.7626	0.7552 <sup>1</sup>	...
Internal thread	0.8092 <sup>2</sup>	0.8000	...	0.7852	0.7822	0.0030	0.7715	0.7685	0.0030

<sup>1</sup> Extreme minimum minor diameter produced by a new threading tool having a minimum flat of  $p/12 = 0.0023$  inch. This minimum diameter is not controlled by gages but by the form of the threading tool.

<sup>2</sup> Extreme maximum major diameter produced by a new threading tool having a minimum flat of  $p/20 = 0.0014$  inch. This maximum diameter is not controlled by gages but by the form of the threading tool.

Tolerances on the internal thread are applied in a plus direction from the basic and design size and tolerances on the external thread are applied in a minus direction from its design (maximum material) size.

All dimensions are in inches.

**Lowenherz or Löwenherz Thread.**— The Lowenherz thread is intended for the fine screws of instruments and is based on the metric system. It is a symmetrical thread, not a buttress thread. The Löwenherz thread has flats at the top and bottom the same as the U.S. standard buttress form, but the angle is 53 degrees 8 minutes. The depth equals  $0.75 \times$  the pitch, and the width of the flats at the top and bottom is equal to  $0.125 \times$  the pitch. This screw thread is used for the fine threads of measuring instruments, optical apparatus, etc., especially in Germany.

**Löwenherz Thread**

**Swiss Screw Thread.**— This is a thread system originated in Switzerland as a standard for screws used in watch and clock making. The angle between the two sides of the thread is 47 degrees 30 minutes, and the top and bottom of the thread are rounded. This system has been adopted by the British Association as a standard for small screws, and is known as the British Association thread. See *British Association Standard Thread (BA)* on page 2033.

**Historical and Miscellaneous Threads**

**Aero-Thread.**— The name “Aero-thread” has been applied to a patented screw thread system that is specially applicable in cases where the nut or internally threaded part is made from a soft material, such as aluminum or magnesium alloy, for the sake of obtaining lightness, as in aircraft construction, and where the screw is made from a high-strength steel to provide strength and good wearing qualities. The nut or part containing the internal thread has a 60-degree truncated form of thread. See Fig. 1. The screw, or stud, is provided with a semi-circular thread form, as shown. Between the screw and the nut there is an intermediary part known as a thread lining or insert, which is made in the form of a helical spring, so that it can be screwed into the nut. The stud, in turn, is then screwed into the thread formed by the semicircular part of the thread insert. When the screw is provided with a V-form of thread, like the American Standard, frequent loosening and tightening of the screw would cause rapid wear of the softer metal from which the nut is made; furthermore, all the threads might not have an even bearing on the mating threads. By using a thread insert which is screwed into the nut permanently, and which is made from a reasonably hard material like phosphor bronze, good wearing qualities are obtained. Also, the bearing or load is evenly distributed over all the threads of the nut since the insert, being in the form of a spring, can adjust itself to bear on all of the thread surfaces.

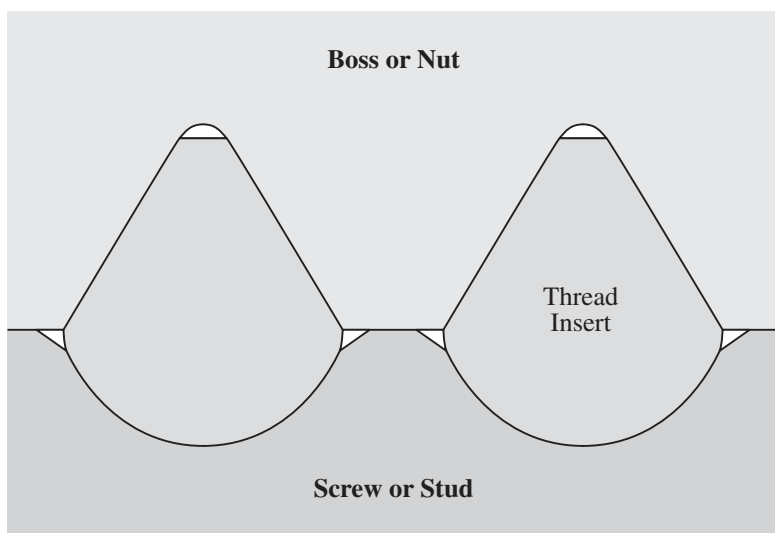

Fig. 1. The Basic Thread Form Used in the Aero-Thread System

**Briggs Pipe Thread.**— The Briggs pipe thread (now known as the American Standard) is used for threaded pipe joints and is the standard for this purpose in the United States. It derives its name from Robert Briggs.

**Casing Thread.**— The standard casing thread of the American Petroleum Institute has an included angle of 60 degrees and a taper of  $\frac{3}{4}$  inch per foot.

The fourteen casing sizes listed in the 1942 revision have outside diameters ranging from  $4\frac{1}{2}$  to 20 inches. All sizes have 8 threads per inch.

*Rounded Thread Form:* Threads for casing sizes up to  $13\frac{3}{8}$  inches, inclusive, have rounded crests and roots, and the depth, measured perpendicular to the axis of the pipe, equals  $0.626 \times \text{pitch} - 0.007 = 0.07125$  inch.

*Truncated Form:* Threads for the 16- and 20-inch casing sizes have flat crests and roots. The depth equals  $0.760 \times \text{pitch} = 0.0950$  inch. This truncated form is designated in the A.P.I. Standard as a “sharp thread.”

**Cordeaux Thread.**— The Cordeaux screw thread derives its name from John Henry Cordeaux, an English telegraph inspector who obtained a patent for this thread in 1877. This thread is used for connecting porcelain insulators with their stalks by means of a screw thread on the stalk and a corresponding thread in the insulator. The thread is approximately a Whitworth thread, 6 threads per inch, the diameters most commonly used being  $\frac{5}{8}$  or  $\frac{3}{4}$  inch outside diameter of thread;  $\frac{5}{8}$  inch is almost universally used for telegraph purposes, while a limited number of  $\frac{3}{4}$ -inch sizes are used for large insulators.

**Dardelet Thread.**— The Dardelet patented self-locking thread is designed to resist vibrations and remain tight without auxiliary locking devices. The locking surfaces are the tapered root of the bolt thread and the tapered crest of the nut thread. The nut is free to turn until seated tightly against a resisting surface, thus causing it to shift from the free position (indicated by dotted lines) to the locking position. The locking is due to a wedging action between the tapered crest of the nut thread and the tapered root or binding surface of the bolt thread. This self-locking thread is also applied to set-screws and cap-screws. The holes must, of course, be threaded with Dardelet taps. The abutment sides of the Dardelet thread carry the major part of the tensile load. The nut is unlocked simply by turning it backward with a wrench. The Dardelet thread can either be cut or rolled, using standard equipment provided with tools, taps, dies, or rolls made to suit the Dardelet thread profile. The included thread angle is 29 degrees; depth  $E = 0.3P$ ; maximum axial movement = 0.28

*P*. The major internal thread diameter (standard series) equals major external thread diameter plus 0.003 inch except for  $\frac{1}{4}$ -inch size which is plus 0.002 inch. The width of both external and internal threads at pitch line equals  $0.36 P$ .

**“Drunken” Thread.**— A “drunken” thread, according to prevalent usage of this expression by machinists, etc., is a thread that does not coincide with a true helix or advance uniformly. This irregularity in a taper thread may be due to the fact that in taper turning with the tailstock set over, the work does not turn with a uniform angular velocity, while the cutting tool is advancing along the work longitudinally with a uniform linear velocity. The change in the pitch and the irregularity of the thread is so small as to be imperceptible to the eye, if the taper is slight, but as the tapers increase to, say,  $\frac{3}{4}$  inch per foot or more, the errors become more pronounced. To avoid this defect, a taper attachment should be used for taper thread cutting.

**Echols Thread.**— Chip room is of great importance in machine taps and taper taps where the cutting speed is high and always in one direction. The tap as well as the nut to be threaded is liable to be injured, if ample space for the chips to pass away from the cutting edges is not provided. A method of decreasing the number of cutting edges, as well as increasing the amount of chip room, is embodied in the “Echols thread,” where every alternate tooth is removed. If a tap has an even number of flutes, the removal of every other tooth in the lands will be equivalent to the removal of the teeth of a continuous thread. It is, therefore, necessary that taps provided with this thread be made with an odd number of lands, so that removing the tooth in alternate lands may result in removing every other tooth in each individual land. Machine taps are often provided with the Echols thread.

**French Thread (S.F.).**— The French thread has the same form and proportions as the American Standard (formerly U. S. Standard). This French thread is being displaced gradually by the International Metric Thread System.

**Harvey Grip Thread.**— The characteristic feature of this thread is that one side inclines 44 degrees from a line at right angles to the axis, whereas the other side has an inclination of only 1 degree. This form of thread is sometimes used when there is considerable resistance or pressure in an axial direction and when it is desirable to reduce the radial or bursting pressure on the nut as much as possible. See *BUTTRESS THREADS*.

**Lloyd & Lloyd Thread.**— The Lloyd & Lloyd screw thread is the same as the regular Whitworth screw thread in which the sides of the thread form an angle of 55 degrees with one another. The top and bottom of the thread are rounded.

**Lock-Nut Pipe Thread.**— The lock-nut pipe thread is a straight thread of the largest diameter which can be cut on a pipe. Its form is identical with that of the American or Briggs standard taper pipe thread. In general, “Go” gages only are required. These consist of a straight-threaded plug representing the minimum female lock-nut thread, and a straight-threaded ring representing the maximum male lock-nut thread. This thread is used only to hold parts together, or to retain a collar on the pipe. It is never used where a tight threaded joint is required.

**Philadelphia Carriage Bolt Thread.**— This is a screw thread for carriage bolts which is somewhat similar to a square thread, but having rounded corners at the top and bottom. The sides of the thread are inclined to an inclusive angle of  $3\frac{1}{2}$  degrees. The width of the thread at the top is 0.53 times the pitch.

**SAE Standard Screw Thread.**— The screw thread standard of the Society of Automotive Engineers (SAE) is intended for use in the automotive industries of the United States. The SAE Standard includes a Coarse series, a Fine series, an 8-thread series, a 12-thread series, a 16-thread series, an Extra-fine series, and a Special-pitch series. The Coarse and Fine series, and also the 8-, 12- and 16-thread series, are exactly the same as corresponding series in the American Standard. The Extra-fine and Special-pitch series are SAE Standards only.

The American Standard thread *form* (or the form previously known as the U. S. Standard) is applied to all SAE Standard screw threads. The Extra-fine series has a total of six pitches ranging from 32 down to 16 threads per inch. The 16 threads per inch in the Extra-fine series applies to all diameters from  $1\frac{3}{4}$  up to 6 inches. This Extra-fine series is intended for use on relatively light sections; on parts requiring fine adjustment; where jar and vibration are important factors; when the thickness of a threaded section is relatively small as in tubing, and where assembly is made without the use of wrenches.

The SAE Special pitches include some which are finer than any in the Extra-fine series. The special pitches apply to a range of diameters extending from No. 10 (0.1900 inch) up to 6 inches. Each diameter has a range of pitches varying from five to eight. For example, a  $\frac{1}{4}$ -inch diameter has six pitches ranging from 24 to 56 threads per inch, whereas a 6-inch diameter has eight pitches ranging from 4 to 16 threads per inch. These various SAE Standard series are intended to provide adequate screw thread specifications for all uses in the automotive industries.

**Sellers Screw Thread.**— The Sellers screw thread, later known as the ‘United States standard thread,’ and now as the ‘American Standard,’ is the most commonly used screw thread in the United States. It was originated by William Sellers, of Philadelphia, and first proposed by him in a paper read before the Franklin Institute, in April, 1864. In 1868, it was adopted by the United States Navy and has since become the generally accepted standard screw thread in the United States.

**Worm Threads.**— The included angle of worm threads range from  $29^\circ$  to  $60^\circ$ ; for single-threaded worms  $29^\circ$  is common; multiple-threaded type must have larger helix and thread angles to avoid excessive under-cutting in hobbing the worm-wheel teeth. AGMA recommends  $40^\circ$  included thread angle for triple- and quadruple-thread worms, but many speed reducers and transmissions have  $60^\circ$  thread angles. The  $29^\circ$  angle is the same as the Acme thread, but worm thread depth is greater and widths of the flats at the top and bottom are less. If lead angle is larger than  $20^\circ$ , an increase in included thread angle is desirable. Worm gearing reaches maximum efficiency when lead angle is  $45^\circ$ , thus explaining the  $60^\circ$  thread angle. Thread parts of a  $29^\circ$  worm thread are:  $p$  = pitch;  $d$  = depth of thread =  $0.6866p$ ;  $t$  = width, top of thread =  $0.335p$ ;  $b$  = width, bottom of thread =  $0.310p$ .

## MEASURING SCREW THREADS

### Measuring Screw Threads

**Pitch and Lead of Screw Threads.**— The *pitch* of a screw thread is the distance from the center of one thread to the center of the next thread. This applies no matter whether the screw has a single, double, triple or quadruple thread. The *lead* of a screw thread is the distance the nut will move forward on the screw if it is turned around one full revolution. In a single-threaded screw, the pitch and lead are equal, because the nut would move forward the distance from one thread to the next, if turned around once. In a double-threaded screw, the nut will move forward two threads, or twice the pitch, so that in this case the lead equals twice the pitch. In a triple-threaded screw, the lead equals three times the pitch, and so on.

The word “pitch” is often, although improperly, used to denote the *number of threads per inch*. Screws are spoken of as having a 12-pitch thread, when twelve threads per inch is what is really meant. The number of threads per inch equals 1 divided by the pitch, or expressed as a formula:

$$\text{Number of threads per inch} = \frac{1}{\text{pitch}}$$

The pitch of a screw equals 1 divided by the number of threads per inch, or:

$$\text{Pitch} = \frac{1}{\text{number of threads per inch}}$$

If the number of threads per inch equals 16, the pitch =  $\frac{1}{16}$ . If the pitch equals 0.05, the number of threads equals  $1 \div 0.05 = 20$ . If the pitch is  $\frac{2}{5}$  inch, the number of threads per inch equals  $1 \div \frac{2}{5} = 2 \frac{1}{2}$ .

Confusion is often caused by the indefinite designation of multiple-thread screws (double, triple, quadruple, etc.). The expression, “four threads per inch, triple,” for example, is not to be recommended. It means that the screw is cut with four triple threads or with twelve threads per inch, if the threads are counted by placing a scale alongside the screw. To cut this screw, the lathe would be geared to cut four threads per inch, but they would be cut only to the depth required for twelve threads per inch. The best expression, when a multiple-thread is to be cut, is to say, in this case, “ $\frac{1}{4}$  inch lead,  $\frac{1}{12}$  inch pitch, triple thread.” For single-threaded screws, only the number of threads per inch and the form of the thread are specified. The word “single” is not required.

**Measuring Screw Thread Pitch Diameters by Thread Micrometers.**— As the pitch or angle diameter of a tap or screw is the most important dimension, it is necessary that the pitch diameter of screw threads be measured, in addition to the outside diameter.

Fig. 1.

One method of measuring in the angle of a thread is by means of a special screw thread micrometer, as shown in the accompanying engraving, Fig. 1. The fixed anvil is W-shaped to engage two thread flanks, and the movable point is cone-shaped so as to enable it to enter the space between two threads, and at the same time be at liberty to revolve. The contact

points are on the sides of the thread, as they necessarily must be in order that the pitch diameter may be determined. The cone-shaped point of the measuring screw is slightly rounded so that it will not bear in the bottom of the thread. There is also sufficient clearance at the bottom of the V-shaped anvil to prevent it from bearing on the top of the thread. The movable point is adapted to measuring all pitches, but the fixed anvil is limited in its capacity. To cover the whole range of pitches, from the finest to the coarsest, a number of fixed anvils are therefore required.

To find the theoretical pitch diameter, which is measured by the micrometer, subtract twice the addendum of the thread from the standard outside diameter. The addendum of the thread for the American and other standard threads is given in the section on screw thread systems.

**Ball-point Micrometers.**— If standard plug gages are available, it is not necessary to actually measure the pitch diameter, but merely to compare it with the standard gage. In this case, a ball-point micrometer, as shown in Fig. 2, may be employed. Two types of ball-point micrometers are ordinarily used. One is simply a regular plain micrometer with ball points made to slip over both measuring points. (See B, Fig. 2.) This makes a kind of combination plain and ball-point micrometer, the ball points being easily removed. These ball points, however, do not fit solidly on their seats, even if they are split, as shown, and are apt to cause errors in measurements. The best, and, in the long run, the cheapest, method is to use a regular micrometer arranged as shown at A. Drill and ream out both the end of the measuring screw or spindle and the anvil, and fit ball points into them as shown. Care should be taken to have the ball point in the spindle run true. The holes in the micrometer spindle and anvil and the shanks on the points are tapered to insure a good fit. The hole *H* in spindle *G* is provided so that the ball point can be easily driven out when a change for a larger or smaller size of ball point is required.

Fig. 2.

A ball-point micrometer may be used for comparing the *angle* of a screw thread, with that of a gage. This can be done by using different sizes of ball points, comparing the size first near the root of the thread, then (using a larger ball point) at about the point of the pitch diameter, and finally near the top of the thread (using in the latter case, of course, a much larger ball point). If the gage and thread measurements are the same at each of the three points referred to, this indicates that the thread angle is correct.

**Measuring Screw Threads by Three-wire Method.**— The *effective* or *pitch diameter* of a screw thread may be measured very accurately by means of some form of micrometer and three wires of equal diameter. This method is extensively used in checking the accuracy of threaded plug gages and other precision screw threads. Two of the wires are placed in contact with the thread on one side and the third wire in a position diametrically opposite as illustrated by the diagram, (see table “*Formulas for Checking Pitch Diameters of Screw Threads* on page 2048”) and the dimension over the wires is determined by means of a micrometer. An ordinary micrometer is commonly used but some form of “floating micrometer” is preferable, especially for measuring thread gages and other precision work. The floating micrometer is mounted upon a compound slide so that it can move freely in directions parallel or at right angles to the axis of the screw, which is held in a hor-

horizontal position between adjustable centers. With this arrangement the micrometer is held constantly at right angles to the axis of the screw so that only one wire on each side may be used instead of having two on one side and one on the other, as is necessary when using an ordinary micrometer. The pitch diameter may be determined accurately if the correct micrometer reading for wires of a given size is known.

**Classes of Formulas for Three-Wire Measurement.**— Various formulas have been established for checking the pitch diameters of screw threads by measurement over wires of known size. These formulas differ with regard to their simplicity or complexity and resulting accuracy. They also differ in that some show what measurement  $M$  over the wires should be to obtain a given pitch diameter  $E$ , whereas others show the value of the pitch diameter  $E$  for a given measurement  $M$ .

*Formulas for Finding Measurement  $M$ :* In using a formula for finding the value of measurement  $M$ , the required pitch diameter  $E$  is inserted in the formula. Then, in cutting or grinding a screw thread, the actual measurement  $M$  is made to conform to the calculated value of  $M$ . Formulas for finding measurement  $M$  may be modified so that the basic major or outside diameter is inserted in the formula instead of the pitch diameter; however, the pitch-diameter type of formula is preferable because the pitch diameter is a more important dimension than the major diameter.

*Formulas for Finding Pitch Diameters  $E$ :* Some formulas are arranged to show the value of the pitch diameter  $E$  when measurement  $M$  is known. Thus, the value of  $M$  is first determined by measurement and then is inserted in the formula for finding the corresponding pitch diameter  $E$ . This type of formula is useful for determining the pitch diameter of an existing thread gage or other screw thread in connection with inspection work. The formula for finding measurement  $M$  is more convenient to use in the shop or tool room in cutting or grinding new threads, because the pitch diameter is specified on the drawing and the problem is to find the value of measurement  $M$  for obtaining that pitch diameter.

**General Classes of Screw Thread Profiles.**— Thread profiles may be divided into three general classes or types as follows:

*Screw Helicoid:* Represented by a screw thread having a straight-line profile in the axial plane. Such a screw thread may be cut in a lathe by using a straight-sided single-point tool, provided the top surface lies in the axial plane.

*Involute Helicoid:* Represented either by a screw thread or a helical gear tooth having an involute profile in a plane perpendicular to the axis. A rolled screw thread, theoretically at least, is an exact involute helicoid.

*Intermediate Profiles:* An intermediate profile that lies somewhere between the screw helicoid and the involute helicoid will be formed on a screw thread either by milling or grinding with a straight-sided wheel set in alignment with the thread groove. The resulting form will approach closely the involute helicoid form. In milling or grinding a thread, the included cutter or wheel angle may either equal the standard thread angle (which is always measured in the axial plane) or the cutter or wheel angle may be reduced to approximate, at least, the thread angle in the normal plane. In practice, all these variations affect the three-wire measurement.

**Accuracy of Formulas for Checking Pitch Diameters by Three-Wire Method.**— The exact measurement  $M$  for a given pitch diameter depends upon the lead angle, the thread angle, and the profile or cross-sectional shape of the thread. As pointed out in the preceding paragraph, the profile depends upon the method of cutting or forming the thread. In a milled or ground thread, the profile is affected not only by the cutter or wheel angle, but also by the diameter of the cutter or wheel; hence, because of these variations, an absolutely exact and reasonably simple general formula for measurement  $M$  cannot be established; however, if the lead angle is low, as with a standard single-thread screw, and especially if the thread angle is high like a 60-degree thread, simple formulas that are not arranged to compensate for the lead angle are used ordinarily and meet most practical

requirements, particularly in measuring 60-degree threads. If lead angles are large enough to greatly affect the result, as with most multiple threads (especially Acme or 29-degree worm threads), a formula should be used that compensates for the lead angle sufficiently to obtain the necessary accuracy.

The formulas that follow include 1) a very simple type in which the effect of the lead angle on measurement  $M$  is entirely ignored. This simple formula usually is applicable to the measurement of 60-degree single-thread screws, except possibly when gage-making accuracy is required; 2) formulas that do include the effect of the lead angle but, nevertheless, are approximations and not always suitable for the higher lead angles when extreme accuracy is required; and 3) formulas for the higher lead angles and the most precise classes of work.

Where approximate formulas are applied consistently in the measurement of both thread plug gages and the thread "setting plugs" for ring gages, interchangeability might be secured, assuming that such approximate formulas were universally employed.

**Wire Sizes for Checking Pitch Diameters of Screw Threads.**— In checking screw threads by the 3-wire method, the general practice is to use measuring wires of the so-called "best size." The "best-size" wire is one that contacts at the pitch line or midslope of the thread because then the measurement of the pitch diameter is least affected by an error in the thread angle. In the following formula for determining approximately the "best-size" wire or the diameter for pitch-line contact,  $A$  = one-half included angle of thread in the axial plane.

$$\text{Best-size wire} = \frac{0.5 \times \text{pitch}}{\cos A} = 0.5 \text{ pitch} \times \sec A$$

For 60-degree threads, this formula reduces to

$$\text{Best-size wire} = 0.57735 \times \text{pitch}$$

### Diameters of Wires for Measuring American Standard and British Standard Whitworth Screw Threads

Threads per Inch	Pitch, Inch	Wire Diameters for American Standard Threads			Wire Diameters for Whitworth Standard Threads		
		Max.	Min.	Pitch-Line Contact	Max.	Min.	Pitch-Line Contact

22	0.0454	0.0409	0.0254	0.0262	0.0345	0.0245	0.0256
24	0.0417	0.0375	0.0233	0.0240	0.0317	0.0225	0.0235
28	0.0357	0.0321	0.0200	0.0206	0.0271	0.0193	0.0201
32	0.0312	0.0281	0.0175	0.0180	0.0237	0.0169	0.0176
36	0.0278	0.0250	0.0156	0.0160	0.0211	0.0150	0.0156
40	0.0250	0.0225	0.0140	0.0144	0.0190	0.0135	0.0141

These formulas are based upon a thread groove of zero lead angle because ordinary variations in the lead angle have little effect on the wire diameter and it is desirable to use one wire size for a given pitch regardless of the lead angle. A theoretically correct solution for finding the *exact* size for pitch-line contact involves the use of cumbersome indeterminate equations with solution by successive trials. The accompanying table gives the wire sizes for both American Standard (formerly, U.S. Standard) and the Whitworth Standard Threads. The following formulas for determining wire diameters do not give the extreme theoretical limits, but the smallest and largest practicable sizes. The diameters in the table are based upon these approximate formulas.

	Smallest wire diameter = $0.56 \times \text{pitch}$
American Standard	Largest wire diameter = $0.90 \times \text{pitch}$
	Diameter for pitch-line contact = $0.57735 \times \text{pitch}$
	Smallest wire diameter = $0.54 \times \text{pitch}$
Whitworth	Largest wire diameter = $0.76 \times \text{pitch}$
	Diameter for pitch-line contact = $0.56369 \times \text{pitch}$

**Measuring Wire Accuracy.**— A set of three measuring wires should have the same diameter within 0.0002 (5.08  $\mu\text{m}$ ) inch. To measure the pitch diameter of a screw-thread gage to an accuracy of 0.0001 inch (2.54  $\mu\text{m}$ ) by means of wires, it is necessary to know the wire diameters to 0.00002 (0.51  $\mu\text{m}$ ) inch. If the diameters of the wires are known only to an accuracy of 0.0001 (2.54  $\mu\text{m}$ ) inch, an accuracy better than 0.0003 (7.62  $\mu\text{m}$ ) inch in the measurement of pitch diameter cannot be expected. The wires should be accurately finished hardened steel cylinders of the maximum possible hardness without being brittle. The hardness should not be less than that corresponding to a Knoop indentation number of 630. A wire of this hardness can be cut with a file only with difficulty. The surface should not be rougher than the equivalent of a deviation of 3 microinches (0.0762  $\mu\text{m}$ ) from a true cylindrical surface.

**Measuring or Contact Pressure.**— In measuring screw threads or screw-thread gages by the 3-wire method, variations in contact pressure will result in different readings. The effect of a variation in contact pressure in measuring threads of fine pitches is indicated by the difference in readings obtained with pressures of 2 and 5 pounds (0.91 and 2.27 kg) in checking a thread plug gage having 24 threads per inch. The reading over the wires with 5 pounds (2.27 kg) pressure was 0.00013 inch (3.302  $\mu\text{m}$ ) less than with 2 pounds (0.91 kg) pressure. For pitches finer than 20 threads per inch (0.05 inch or 1.27 mm pitch), a pressure of 16 ounces (0.45 kg) is recommended by the National Bureau of Standards, now National Institute of Standards and Technology (NIST). For pitches of 20 threads per inch and coarser, a pressure of 2  $\frac{1}{2}$  pounds (1.13 kg) is recommended.

For Acme threads, the wire presses against the sides of the thread with a pressure of approximately twice that of the measuring instrument. To limit the tendency of the wires to wedge in between the sides of an Acme thread, it is recommended that pitch-diameter measurements be made at 1 pound on 8 threads per inch and finer, and at 2  $\frac{1}{2}$  pounds for pitches coarser than 8 threads per inch (0.125 inch or 3.175 mm pitch).

**Approximate Three-Wire Formulas That Do Not Compensate for Lead Angle.**— A general formula in which the effect of lead angle is ignored is as follows (see accompanying notation used in formulas):

$$M = E - T \cot A + W(1 + \csc A) \quad (1)$$

This formula can be simplified for any given thread angle and pitch. To illustrate, because  $T = 0.5P$ ,  $M = E - 0.5P \cot 30^\circ + W(1 + 2)$ , for a 60-degree thread, such as the American Standard,

$$M = E - 0.866025P + 3W$$

The accompanying table contains these simplified formulas for different standard threads. Two formulas are given for each. The upper one is used when the measurement over wires,  $M$ , is known and the corresponding pitch diameter,  $E$ , is required; the lower formula gives the measurement  $M$  for a specified value of pitch diameter. These formulas are sufficiently accurate for checking practically all standard 60-degree single-thread screws because of the low lead angles, which vary from  $1^\circ 11'$  to  $4^\circ 31'$  in the American Standard Coarse-Thread Series.

**Bureau of Standards (now NIST) General Formula.**—**Formula (2)**, which follows, compensates quite largely for the effect of the lead angle. It is from the National Bureau of Standards Handbook H 28 (1944), now FED-STD-H28. The formula, however, as here given has been arranged for finding the value of  $M$  (instead of  $E$ ).

$$M = E - T \cot A + W(1 + \csc A + 0.5 \tan^2 B \cos A \cot A) \quad (2)$$

This expression is also found in ANSI/ASME B1.2-1983 (R2007). The Bureau of Standards uses **Formula (2)** in preference to **Formula (1)** when the value of  $0.5W \tan^2 B \cos A \cot A$  exceeds 0.00015, with the larger lead angles. If this test is applied to American Standard 60-degree threads, it will show that **Formula (1)** is generally applicable; but for 29-degree Acme or worm threads, **Formula (2)** (or some other that includes the effect of lead angle) should be employed.

#### Notation Used in Formulas for Checking Pitch Diameters by Three-Wire Method

$A$  = one-half included thread angle in the axial plane

$A_n$  = one-half included thread angle in the normal plane or in plane perpendicular to sides of thread = one-half included angle of cutter when thread is milled ( $\tan A_n = \tan A \times \cos B$ ). (Note: Included angle of milling cutter or grinding wheel may equal the nominal included angle of thread, or may be reduced to whatever normal angle is required to make the thread angle standard in the axial plane. In either case,  $A_n$  = one-half cutter angle.)

$B$  = lead angle at pitch diameter = helix angle of thread as measured from a plane perpendicular to the axis,  $\tan B = L \div 3.1416E$

$D$  = basic major or outside diameter

$E$  = pitch diameter (basic, maximum, or minimum) for which  $M$  is required, or pitch diameter corresponding to measurement  $M$

$F$  = angle required in **Formulas (4b)**, **(4d)**, and **(4e)**

$G$  = angle required in **Formula (4)**

$H$  = helix angle at pitch diameter and measured from axis =  $90^\circ - B$  or  $\tan H = \cot B$

$H_b$  = helix angle at  $R_b$  measured from axis

$L$  = lead of thread = pitch  $P \times$  number of threads  $S$

$M$  = dimension over wires

$P$  = pitch =  $1 \div$  number of threads per inch

$R_b$  = radius required in **Formulas (4)** and **(4e)**

$S$  = number of "starts" or threads on a multiple-threaded worm or screw

$T = 0.5P$  = width of thread in axial plane at diameter  $E$

$T_a$  = arc thickness on pitch cylinder in plane perpendicular to axis

$W$  = wire or pin diameter

### Formulas for Checking Pitch Diameters of Screw Threads

The formulas below do not compensate for the effect of the lead angle upon measurement  $M$ , but they are sufficiently accurate for checking standard single-thread screws unless exceptional accuracy is required. See accompanying information on effect of lead angle; also matter relating to measuring wire sizes, accuracy required for such wires, and contact or measuring pressure.

The approximate best wire size for pitch-line contact may be obtained by the formula

$$W = 0.5 \times \text{pitch} \times \sec \frac{1}{2} \text{ included thread angle}$$

For 60-degree threads,  $W = 0.57735 \times \text{pitch}$ .

Form of Thread	Formulas for determining measurement $M$ corresponding to correct pitch diameter and the pitch diameter $E$ corresponding to a given measurement over wires. <sup>1</sup>
American National Standard Unified	When measurement $M$ is known, $E = M + 0.86603P - 3W$ When pitch diameter $E$ is used in formula, $M = E - 0.86603P + 3W$ The American Standard formerly was known as U.S. Standard.
British Standard Whitworth	When measurement $M$ is known, $E = M + 0.9605P - 3.1657W$ When pitch diameter $E$ is used in formula, $M = E - 0.9605P + 3.1657W$
British Association Standard	When measurement $M$ is known, $E = M + 1.1363P - 3.4829W$ When pitch diameter $E$ is used in formula, $M = E - 1.1363P + 3.4829W$
Lowenherz Thread	When measurement $M$ is known, $E = M + P - 3.2359W$ When pitch diameter $E$ is used in formula, $M = E - P + 3.2359W$
Sharp V-Thread	When measurement $M$ is known, $E = M + 0.86603P - 3W$ When pitch diameter $E$ is used in formula, $M = E - 0.86603P + 3W$
International Standard	Use the formula above for the American National Standard Unified Thread.
Pipe Thread	See accompanying paragraph on <i>Buckingham Exact Involute Helicoid Formula Applied to Screw Threads</i> .
Acme and Worm Threads	See Buckingham Formulas page 2052; also <i>Three-wire Measurement of Acme and Stub Acme Thread Pitch Diameter</i> .
Buttress Form of Thread	Different forms of buttress threads are used. See paragraph on <i>Three-Wire Method Applied to Buttress Threads</i> .

<sup>1</sup> The wires must be lapped to a uniform diameter and it is very important to insert in the rule or formula the wire diameter as determined by precise means of measurement. Any error will be multiplied. See paragraph on *Wire Sizes for Checking Pitch Diameters of Screw Threads* on page 2045.

**Why Small Thread Angle Affects Accuracy of Three-Wire Measurement.**— In measuring or checking Acme threads, or any others having a comparatively small thread angle  $A$ , it is particularly important to use a formula that compensates largely, if not entirely, for the effect of the lead angle, especially in all gage and precision work. The effect of the lead angle on the position of the wires and upon the resulting measurement  $M$  is much greater in a 29-degree thread than in a higher thread angle such, for example, as a 60-degree thread. This effect results from an increase in the cotangent of the thread angle as this angle becomes smaller. The reduction in the width of the thread groove in the normal plane due

to the lead angle causes a wire of given size to rest higher in the groove of a thread having a small thread angle  $A$  (like a 29-degree thread) than in the groove of a thread with a larger angle (like a 60-degree American Standard).

*Acme Threads:* Three-wire measurements of high accuracy require the use of **Formula (4)**. For most measurements, however, **Formula (2)** or **(3)** gives satisfactory results. The table on page 2055 lists suitable wire sizes for use in **Formulas (2)** and **(4)**.

**Buckingham Simplified Formula which Includes Effect of Lead Angle.**— The **Formula (3)** which follows gives very accurate results for the lower lead angles in determining measurement  $M$ . However, if extreme accuracy is essential, it may be advisable to use the involute helicoid formulas as explained later.

$$M = E + W(1 + \sin A_n) \quad (3) \quad \text{where} \quad W = \frac{T \times \cos B}{\cos A_n} \quad (3a)$$

Theoretically correct equations for determining measurement  $M$  are complex and cumbersome to apply. **Formula (3)** combines simplicity with a degree of accuracy which meets all but the most exacting requirements, particularly for lead angles below 8 or 10 degrees and the higher thread angles. However, the wire diameter used in **Formula (3)** must conform to that obtained by **Formula (3a)** to permit a direct solution or one not involving indeterminate equations and successive trials.

*Application of Buckingham Formula:* In the application of **Formula (3)** to screw or worm threads, two general cases are to be considered.

*Case 1:* The screw thread or worm is to be milled with a cutter having an included angle equal to the nominal or standard thread angle that is assumed to be the angle in the axial plane. For example, a 60-degree cutter is to be used for milling a thread. In this case, the

All dimensions are given in inches.

thread angle in the plane of the axis will exceed 60 degrees by an amount increasing with the lead angle. This variation from the standard angle may be of little or no practical importance if the lead angle is small or if the mating nut (or teeth in worm gearing) is formed to suit the thread as milled.

*Case 2:* The screw thread or worm is to be milled with a cutter reduced to whatever normal angle is equivalent to the standard thread angle in the axial plane. For example, a 29-degree Acme thread is to be milled with a cutter having some angle smaller than 29 degrees (the reduction increasing with the lead angle) to make the thread angle standard in the plane of the axis. Theoretically, the milling cutter angle should always be corrected to suit the normal angle; but if the lead angle is small, such correction may be unnecessary.

If the thread is cut in a lathe to the standard angle as measured in the axial plane, Case 2 applies in determining the pin size  $W$  and the overall measurement  $M$ .

In solving all problems under Case 1, angle  $A_n$  used in **Formulas (3)** and **(3a)** equals one-half the included angle of the milling cutter.

When Case 2 applies, angle  $A_n$  for milled threads also equals one-half the included angle of the cutter, but the cutter angle is reduced and is determined as follows:

$$\tan A_n = \tan A \times \cos B$$

The included angle of the cutter or the normal included angle of the thread groove =  $2A_n$ . Examples 1 and 2, which follow, illustrate Cases 1 and 2.

*Example 1 (Case 1):* Take, for example, an Acme screw thread that is milled with a cutter having an included angle of 29 degrees; consequently, the angle of the thread exceeds 29 degrees in the axial section.

The outside or major diameter is 3 inches; the pitch,  $\frac{1}{2}$  inch; the lead, 1 inch; the number of threads or "starts," 2. Find pin size  $W$  and measurement  $M$ .

Pitch diameter  $E = 2.75$ ;  $T = 0.25$ ;  $L = 1.0$ ;  $A_n = 14.50^\circ$   $\tan A_n = 0.258618$ ;  $\sin A_n = 0.25038$ ; and  $\cos A_n = 0.968148$ .

$$\tan B = \frac{1.0}{3.1416 \times 2.75} = 0.115749 \quad B = 6.6025^\circ$$

$$W = \frac{0.25 \times 0.993368}{0.968148} = 0.25651 \text{ inch}$$

$$M = 2.75 + 0.25651 \times (1 + 0.25038) = 3.0707 \text{ inches}$$

*Note:* This value of  $M$  is only 0.0001 inch larger than that obtained by using the very accurate involute helicoid **Formula (4)** discussed on the following page.

*Example 2 (Case 2):* A triple-threaded worm has a pitch diameter of 2.481 inches, pitch of 1.5 inches, lead of 4.5 inches, lead angle of 30 degrees, and nominal thread angle of 60 degrees in the axial plane. Milling cutter angle is to be reduced.  $T = 0.75$  inch;  $\cos B = 0.866025$ ; and  $\tan A = 0.57735$ . Again use **Formula (3)** to see if it is applicable.

$\tan A_n = \tan A \times \cos B = 0.57735 \times 0.866025 = 0.5000$ ; hence  $A_n = 26.565^\circ$ , making the included cutter angle  $53.13^\circ$ , thus  $\cos A_n = 0.89443$  and  $\sin A_n = 0.44721$ .

$$W = \frac{0.75 \times 0.866025}{0.89443} = 0.72618 \text{ inch}$$

$$M = 2.481 + 0.72618 \times (1 + 0.44721) = 3.532 \text{ inches}$$

*Note:* If the value of measurement  $M$  is determined by using the following **Formula (4)** it will be found that  $M = 3.515$  inches; hence the error equals  $3.532 - 3.515 = 0.017$  inch approximately, which indicates that **Formula (3)** is not accurate enough here. The application of this simpler **Formula (3)** will depend upon the lead angle and thread angle (as previously explained) and upon the class of work.

**Buckingham Exact Involute Helicoid Formula Applied to Screw Threads.**— When extreme accuracy is required in finding measurement  $M$  for obtaining a given pitch diameter, the equations that follow, although somewhat cumbersome to apply, have the merit of providing a direct and very accurate solution; consequently, they are preferable to the indeterminate equations and successive trial solutions heretofore employed when extreme precision is required. These equations are exact for involute helical gears and, consequently, give theoretically correct results when applied to a screw thread of the involute helicoidal form; they also give very close approximations for threads having intermediate profiles.

*Helical Gear Equation Applied to Screw Thread Measurement:* In applying the helical gear equations to a screw thread, use either the axial or normal thread angle and the lead angle of the helix. To keep the solution on a practical basis, either thread angle  $A$  or  $A_n$ , as the case may be, is assumed to equal the cutter angle of a milled thread. Actually, the pro-

file of a milled thread will have some curvature in both axial and normal sections; hence angles  $A$  and  $A_n$  represent the angular approximations of these slightly curved profiles. The equations that follow give the values needed to solve the screw thread problem as a helical gear problem.

$$M = \frac{2R_b}{\cos G} + W \quad (4)$$

$$\tan F = \frac{\tan A}{\tan B} = \frac{\tan A_n}{\sin B} \quad (4a) \quad R_b = \frac{E}{2} \cos F \quad (4b)$$

$$T_a = \frac{T}{\tan B} \quad (4c) \quad \tan H_b = \cos F \times \tan H \quad (4d)$$

$$\text{inv } G = \frac{T_a}{E} + \text{inv } F + \frac{W}{2R_b \cos H_b} - \frac{\pi}{S} \quad (4e)$$

The tables of involute functions starting on page 106 provide values for angles from 14 to 51 degrees, used for gear calculations. The formula for involute functions on page 105 may be used to extend this table as required.

*Example 3:* To illustrate the application of **Formula (4)** and the supplementary formulas, assume that the number of starts  $S = 6$ ; pitch diameter  $E = 0.6250$ ; normal thread angle  $A_n = 20^\circ$ ; lead of thread  $L = 0.864$  inch;  $T = 0.072$ ;  $W = 0.07013$  inch.

$$\tan B = \frac{L}{\pi E} = \frac{0.864}{1.9635} = 0.44003 \quad B = 23.751^\circ$$

$$\text{Helix angle } H = 90^\circ - 23.751^\circ = 66.249^\circ$$

$$\tan F = \frac{\tan A_n}{\sin B} = \frac{0.36397}{0.40276} = 0.90369 \quad F = 42.104^\circ$$

$$R_b = \frac{E}{2} \cos F = \frac{0.6250}{2} \times 0.74193 = 0.23185$$

$$T_a = \frac{T}{\tan B} = \frac{0.072}{0.44003} = 0.16362$$

$$\tan H_b = \cos F \tan H = 0.74193 \times 2.27257 = 1.68609 \quad H_b = 59.328^\circ$$

The involute function of  $G$  is found next by **Formula (4e)**.

$$\text{inv } G = \frac{0.16362}{0.625} + 0.16884 + \frac{0.07013}{2 \times 0.23185 \times 0.51012} - \frac{3.1416}{6} = 0.20351$$

Since 0.20351 is outside the values for involute functions given in the tables on pages 106 through 109 use the formula for involute functions on page 105 to extend these tables as required. It will be found that 44 deg. 21 min. or 44.350 degrees is the angular equivalent of 0.20351; hence,  $G = 44.350$  degrees.

$$M = \frac{2R_b}{\cos G} + W = \frac{2 \times 0.23185}{0.71508} + 0.07013 = 0.71859 \text{ inch}$$

**Accuracy of Formulas (3) and (4) Compared.**— With the involute helicoid **Formula (4)** any wire size that makes contact with the flanks of the thread may be used; however, in the preceding example, the wire diameter  $W$  was obtained by **Formula (3a)** in order to compare **Formula (4)** with (3). If Example (3) is solved by **Formula (3)**,  $M = 0.71912$ ; hence the difference between the values of  $M$  obtained with **Formulas (3) and (4)** equals  $0.71912 - 0.71859 = 0.00053$  inch. The included thread angle in this case is 40 degrees. If **Formulas**

(3) and (4) are applied to a 29-degree thread, the difference in measurements  $M$  or the error resulting from the use of Formulas (3) will be larger. For example, with an Acme thread having a lead angle of about 34 degrees, the difference in values of  $M$  obtained by the two formulas equals 0.0008 inch.

**Three-wire Measurement of Acme and Stub Acme Thread Pitch Diameter.**— For single- and multiple-start Acme and Stub Acme threads having lead angles of less than 5 degrees, the approximate three-wire formula given on page 2046 and the best wire size taken from the table on page 2055 may be used.

Multiple-start Acme and Stub Acme threads commonly have a lead angle of greater than 5 degrees. For these, a direct determination of the actual pitch diameter is obtained by using the formula:  $E = M - (C + c)$  in conjunction with the table on page 2056. To enter the table, the lead angle  $B$  of the thread to be measured must be known. It is found by the formula:  $\tan B = L \div 3.1416E_1$  where  $L$  is the lead of the thread and  $E_1$  is the nominal pitch diameter. The best wire size is now found by taking the value of  $w_1$  as given in the table for lead angle  $B$ , with interpolation, and dividing it by the number of threads per inch. The value of  $(C + c)_1$  given in the table for lead angle  $B$  is also divided by the number of threads per inch to get  $(C + c)$ . Using the best size wires, the actual measurement over wires  $M$  is made and the actual pitch diameter  $E$  found by using the formula:  $E = M - (C + c)$ .

*Example:* For a 5 tpi, 4-start Acme thread with a 13.952° lead angle, using three 0.10024-inch wires,  $M = 1.1498$  inches, hence  $E = 1.1498 - 0.1248 = 1.0250$  inches.

Under certain conditions, a wire may contact one thread flank at two points, and it is then advisable to substitute balls of the same diameter as the wires.

**Checking Thickness of Acme Screw Threads.**— In some instances it may be preferable to check the thread thickness instead of the pitch diameter, especially if there is a thread thickness tolerance.

A direct method, applicable to the larger pitches, is to use a vernier gear-tooth caliper for measuring the thickness in the *normal* plane of the thread. This measurement, for an American Standard General Purpose Acme thread, should be made at a distance below the *basic* outside diameter equal to  $p/4$ . The thickness at this basic pitch-line depth and in the axial plane should be  $p/2 - 0.259 \times$  the pitch diameter allowance from the table on page 1975 with a tolerance of *minus*  $0.259 \times$  the pitch diameter tolerance from the table on page 1980. The thickness in the normal plane or plane of measurement is equal to the thickness in the axial plane multiplied by the cosine of the helix angle. The helix angle may be determined from the formula:

$$\text{tangent of helix angle} = \text{lead of thread} \div (3.1416 \times \text{pitch diameter})$$

**Three-Wire Method for Checking Thickness of Acme Threads.**— The application of the 3-wire method of checking the thickness of an Acme screw thread is included in the Report of the National Screw Thread Commission. In applying the 3-wire method for checking thread thickness, the procedure is the same as in checking pitch diameter (see *Three-wire Measurement of Acme and Stub Acme Thread Pitch Diameter*), although a different formula is required. Assume that  $D$  = basic major diameter of screw;  $M$  = measurement over wires;  $W$  = diameter of wires;  $S$  = tangent of helix angle at pitch line;  $P$  = pitch;  $T$  = thread thickness at depth equal to  $0.25P$ .

$$T = 1.12931 \times P + 0.25862 \times (M - D) - W \times (1.29152 + 0.48407S^2)$$

This formula transposed to show the correct measurement  $M$  equivalent to a given required thread thickness is as follows:

$$M = D + \frac{W \times (1.29152 + 0.48407S^2) + T - 1.12931 \times P}{0.25862}$$

**Wire Sizes for Three-Wire Measurement of Acme Threads  
with Lead Angles of Less than 5 Degrees**

Threads per Inch	Best Size	Max.	Min.	Threads per Inch	Best Size	Max.	Min.
1	0.51645	0.65001	0.48726	5	0.10329	0.13000	0.09745
1½	0.38734	0.48751	0.36545	6	0.08608	0.10834	0.08121
1½	0.34430	0.43334	0.32484	8	0.06456	0.08125	0.06091
2	0.25822	0.32501	0.24363	10	0.05164	0.06500	0.04873
2½	0.20658	0.26001	0.19491	12	0.04304	0.05417	0.04061
3	0.17215	0.21667	0.16242	14	0.03689	0.04643	0.03480
4	0.12911	0.16250	0.12182	16	0.03228	0.04063	0.03045

Wire sizes are based upon zero helix angle. Best size =  $0.51645 \times \text{pitch}$ ; maximum size =  $0.650013 \times \text{pitch}$ ; minimum size =  $0.487263 \times \text{pitch}$ .

*Example:* An Acme General Purpose thread, Class 2G, has a 5-inch basic major diameter, 0.5-inch pitch, and 1-inch lead (double thread). Assume the wire size is 0.258 inch. Determine measurement  $M$  for a thread thickness  $T$  at the basic pitch line of 0.2454 inch. ( $T$  is the maximum thickness at the basic pitch line and equals  $0.5P$ , the basic thickness,  $-0.259 \times \text{allowance}$  from Table 4, page 1980.)

$$M = 5 + \frac{0.258 \times [1.29152 + 0.48407 \times (0.06701)^2] + 0.2454 - 1.12931 \times 0.5}{0.25862}$$

$$= 5.056 \text{ inches}$$

**Testing Angle of Thread by Three-Wire Method.**—The error in the angle of a thread may be determined by using sets of wires of two diameters, the measurement over the two sets of wires being followed by calculations to determine the amount of error, assuming that the angle cannot be tested by comparison with a standard plug gage, known to be correct. The diameter of the small wires for the American Standard thread is usually about 0.6 times the pitch and the diameter of the large wires, about 0.9 times the pitch. The total difference between the measurements over the large and small sets of wires is first determined. If the thread is an American Standard or any other form having an included angle of 60 degrees, the difference between the two measurements should equal three times the difference between the diameters of the wires used. Thus, if the wires are 0.116 and 0.076 inch in diameter, respectively, the difference equals  $0.116 - 0.076 = 0.040$  inch. Therefore, the difference between the micrometer readings for a standard angle of 60 degrees equals  $3 \times 0.040 = 0.120$  inch for this example. If the angle is incorrect, the amount of error may be determined by the following formula, which applies to any thread regardless of angle:

$$\sin a = \frac{A}{B - A}$$

where  $A$  = difference in diameters of the large and small wires used

$B$  = total difference between the measurements over the large and small wires

$a$  = one-half the included thread angle

*Example:* The diameter of the large wires used for testing the angle of a thread is 0.116 inch and of the small wires 0.076 inch. The measurement over the two sets of wires shows a total difference of 0.122 inch instead of the correct difference, 0.120 inch, for a standard angle of 60 degrees when using the sizes of wires mentioned. The amount of error is determined as follows:

$$\sin a = \frac{0.040}{0.122 - 0.040} = \frac{0.040}{0.082} = 0.4878$$

A table of sines shows that this value (0.4878) is the sine of 29 degrees 12 minutes, approximately. Therefore, the angle of the thread is 58 degrees 24 minutes or 1 degree 36 minutes less than the standard angle.

**Measuring Taper Screw Threads by Three-Wire Method.**— When the 3-wire method is used in measuring a taper screw thread, the measurement is along a line that is not perpendicular to the axis of the screw thread, the inclination from the perpendicular equaling one-half the included angle of the taper. The formula that follows compensates for this inclination resulting from contact of the measuring instrument surfaces, with two wires on one side and one on the other. The taper thread is measured over the wires in the usual manner except that the single wire must be located in the thread at a point where the effective diameter is to be checked (as described more fully later). The formula shows the dimension equivalent to the correct pitch diameter at this given point. The general formula for taper screw threads follows:

$$M = \frac{E - (\cot a)/2N + W(1 + \csc a)}{\sec b}$$

where  $M$  = measurement over the 3 wires

$E$  = pitch diameter

$a$  = one-half the angle of the thread

$N$  = number of threads per inch

$W$  = diameter of wires; and

$b$  = one-half the angle of taper.

This formula is not theoretically correct but it is accurate for screw threads having tapers of  $\frac{3}{4}$  inch per foot or less. This general formula can be simplified for a given thread angle and taper. The simplified formula following (in which  $P$  = pitch) is for an American National Standard pipe thread:

$$M = \frac{E - (0.866025 \times P) + 3 \times W}{1.00049}$$

Standard pitch diameters for pipe threads will be found in the section "American Pipe Threads," which also shows the location, or distance, of this pitch diameter from the end of the pipe. In using the formula for finding dimension  $M$  over the wires, the single wire is placed in whatever part of the thread groove locates it at the point where the pitch diameter is to be checked. The wire must be accurately located at this point. The other wires are then placed on each side of the thread that is diametrically opposite the single wire. If the pipe thread is straight or without taper,

$$M = E - (0.866025 \times P) + 3 \times W$$

*Application of Formula to Taper Pipe Threads:* To illustrate the use of the formula for taper threads, assume that dimension  $M$  is required for an American Standard 3-inch pipe thread gage. Table 1a starting on page 2009 shows that the 3-inch size has 8 threads per inch, or a pitch of 0.125 inch, and a pitch diameter at the gaging notch of 3.3885 inches. Assume that the wire diameter is 0.07217 inch: Then when the pitch diameter is correct

$$M = \frac{3.3885 - (0.866025 \times 0.125) + 3 \times 0.07217}{1.00049} = 3.495 \text{ inches}$$

*Pitch Diameter Equivalent to a Given Measurement Over the Wires:* The formula following may be used to check the pitch diameter at any point along a tapering thread when measurement  $M$  over wires of a given diameter is known. In this formula,  $E$  = the effective or pitch diameter at the position occupied by the single wire. The formula is not theoretically correct but gives very accurate results when applied to tapers of  $\frac{3}{4}$  inch per foot or less.

$$E = 1.00049 \times M + (0.866025 \times P) - 3 \times W$$

*Example:* Measurement  $M = 3.495$  inches at the gaging notch of a 3-inch pipe thread and the wire diameter = 0.07217 inch. Then

$$E = 1.00049 \times 3.495 + (0.866025 \times 0.125) - 3 \times 0.07217 = 3.3885 \text{ inches}$$

*Pitch Diameter at Any Point Along Taper Screw Thread:* When the pitch diameter in any position along a tapering thread is known, the pitch diameter at any other position may be determined as follows:

Multiply the distance (measured along the axis) between the location of the known pitch diameter and the location of the required pitch diameter, by the taper per inch or by 0.0625 for American National Standard pipe threads. Add this product to the known diameter, if the required diameter is at a large part of the taper, or subtract if the required diameter is smaller.

*Example:* The pitch diameter of a 3-inch American National Standard pipe thread is 3.3885 at the gaging notch. Determine the pitch diameter at the small end. The table starting on page 2009 shows that the distance between the gaging notch and the small end of a 3-inch pipe is 0.77 inch. Hence the pitch diameter at the small end =  $3.3885 - (0.77 \times 0.0625) = 3.3404$  inches.

**Three-Wire Method Applied to Buttress Threads.**—The angles of buttress threads vary somewhat, especially on the front or load-resisting side. **Formula (1)**, which follows, may be applied to any angles required. In this formula,  $M$  = measurement over wires when pitch diameter  $E$  is correct;  $A$  = included angle of thread and thread groove;  $a$  = angle of front face or load-resisting side, measured from a line perpendicular to screw thread axis;  $P$  = pitch of thread; and  $W$  = wire diameter.

$$M = E - \left[ \frac{P}{\tan a + \tan(A - a)} \right] + W \left[ 1 + \cos\left(\frac{A}{2} - a\right) \times \csc\frac{A}{2} \right] \quad (1)$$

For given angles  $A$  and  $a$ , this general formula may be simplified as shown by **Formulas (3)** and **(4)**. These simplified formulas contain constants with values depending upon angles  $A$  and  $a$ .

*Wire Diameter:* The wire diameter for obtaining pitch-line contact at the back of a buttress thread may be determined by the following general **Formula (2)**:

$$W = P \left( \frac{\cos a}{1 + \cos A} \right) \quad (2)$$

*45-Degree Buttress Thread:* The buttress thread shown by the diagram at the left, has a front or load-resisting side that is perpendicular to the axis of the screw. Measurement  $M$  equivalent to a correct pitch diameter  $E$  may be determined by **Formula (3)**:

$$M = E - P + (W \times 3.4142) \quad (3)$$

Wire diameter  $W$  for pitch-line contact at back of thread =  $0.586 \times$  pitch.

*50-Degree Buttress Thread with Front-face Inclination of 5 Degrees:* This buttress thread form is illustrated by the diagram at the right. Measurement  $M$  equivalent to the correct pitch diameter  $E$  may be determined by **Formula (4)**:

$$M = E - (P \times 0.91955) + (W \times 3.2235) \quad (4)$$

Wire diameter  $W$  for pitch-line contact at back of thread =  $0.606 \times$  pitch. If the width of flat at crest and root =  $\frac{1}{8} \times$  pitch, depth =  $0.69 \times$  pitch.

*American National Standard Buttress Threads ANSI B1.9-1973:* This buttress screw thread has an included thread angle of 52 degrees and a front face inclination of 7 degrees. Measurements  $M$  equivalent to a pitch diameter  $E$  may be determined by **Formula (5)**:

$$M = E - 0.89064P + 3.15689W + c \quad (5)$$

The wire angle correction factor  $c$  is less than 0.0004 inch for recommended combinations of thread diameters and pitches and may be neglected. Use of wire diameter  $W = 0.54147P$  is recommended.

**Measurement of Pitch Diameter of Thread Ring Gages.**—The application of direct methods of measurement to determine the pitch diameter of thread ring gages presents serious difficulties, particularly in securing proper contact pressure when a high degree of precision is required. The usual practice is to fit the ring gage to a master setting plug. When the thread ring gage is of correct lead, angle, and thread form, within close limits, this method is quite satisfactory and represents standard American practice. It is the only method available for small sizes of threads. For the larger sizes, various more or less satisfactory methods have been devised, but none of these have found wide application.

**Screw Thread Gage Classification.**—Screw thread gages are classified by their degree of accuracy, that is, by the amount of tolerance afforded the gage manufacturer and the wear allowance, if any.

There are also three classifications according to use: 1) Working gages for controlling production; 2) inspection gages for rejection or acceptance of the finished product; and 3) reference gages for determining the accuracy of the working and inspection gages.

**American National Standard for Gages and Gaging for Unified Inch Screw Threads ANSI/ASME B1.2-1983 (R2007).**—This standard covers gaging methods for conformance of Unified Screw threads and provides the essential specifications for applicable gages required for unified inch screw threads.

The standard includes the following gages for *Product Internal Thread*:

*GO Working Thread Plug Gage* for inspecting the maximum-material GO functional limit.

*NOT GO (HI) Thread Plug Gage* for inspecting the NOT GO (HI) functional diameter limit.

*Thread Snap Gage—GO Segments or Rolls* for inspecting the maximum-material GO functional limit.

*Thread Snap Gage—NOT GO (HI) Segments or Rolls* for inspecting the NOT GO (HI) functional diameter limit.

*Thread Snap Gages—Minimum Material: Pitch Diameter Cone Type and Vee and Thread Groove Diameter Type* for inspecting the minimum-material limit pitch diameter.

*Thread-Setting Solid Ring Gage* for setting internal thread indicating and snap gages.

*Plain Plug, Snap, and Indicating Gages* for checking the minor diameter of internal threads.

*Snap and Indicating Gages* for checking the major diameter of internal threads.

*Functional Indicating Thread Gage* for inspecting the maximum-material GO functional limit and size and the NOT GO (HI) functional diameter limit and size.

*Minimum-Material Indicating Thread Gage* for inspecting the minimum-material limit and size.

*Indicating Runout Thread Gage* for inspecting runout of the minor diameter to pitch diameter.

In addition to these gages for product internal threads, the Standard also covers differential gaging and such instruments as pitch micrometers, thread-measuring balls, optical comparator and toolmaker's microscope, profile tracing instrument, surface roughness measuring instrument, and roundness measuring equipment.

The Standard includes the following gages for *Product External Thread*:

*GO Working Thread Ring Gage* for inspecting the maximum-material GO functional limit.

*NOT GO (LO) Thread Ring Gage* for inspecting the NOT GO (LO) functional diameter limit.

*Thread Snap Gage—GO Segments or Rolls* for inspecting the maximum-material GO functional limit.

*Thread Snap Gage—NOT GO (LO) Segments or Rolls* for inspecting the NOT GO (LO) functional diameter limit.

*Thread Snap Gages—Cone and Vee Type and Minimum Material Thread Groove Diameter Type* for inspecting the minimum-material pitch diameter limit.

*Plain Ring and Snap Gages* for checking the major diameter.

*Snap Gage* for checking the minor diameter.

*Functional Indicating Thread Gage* for inspecting the maximum-material GO functional limit and size and the NOT GO (LO) functional diameter limit and size.

*Minimum-Material Indicating Thread Gage* for inspecting the minimum-material limit and size.

*Indicating Runout Gage* for inspecting the runout of the major diameter to the pitch diameter.

*WTolerance Thread-Setting Plug Gage* for setting adjustable thread ring gages, checking solid thread ring gages, setting thread snap limit gages, and setting indicating thread gages.

*Plain Check Plug Gage for Thread Ring Gage* for verifying the minor diameter limits of thread ring gages after the thread rings have been properly set with the applicable thread-setting plug gages.

*Indicating Plain Diameter Gage* for checking the major diameter.

*Indicating Gage* for checking the minor diameter.

In addition to these gages for product external threads, the Standard also covers differential gaging and such instruments as thread micrometers, thread-measuring wires, optical comparator and toolmaker's microscope, profile tracing instrument, electromechanical lead tester, helical path attachment used with GO type thread indicating gage, helical path analyzer, surface roughness measuring equipment, and roundness measuring equipment.

The standard lists the following for use of Threaded and Plain Gages for verification of product internal threads:

*Tolerance*: Unless otherwise specified all thread gages which directly check the product thread shall be X tolerance for all classes.

*GO Thread Plug Gages*: GO thread plug gages must enter and pass through the full threaded length of the product freely. The GO thread plug gage is a cumulative check of all thread elements except the minor diameter.

*NOT GO (HI) Thread Plug Gages:* NOT GO (HI) thread plug gages when applied to the product internal thread may engage only the end threads (which may not be representative of the complete thread). Entering threads on product are incomplete and permit gage to start. Starting threads on NOT GO (HI) plugs are subject to greater wear than the remaining threads. Such wear in combination with the incomplete product threads permits further entry of the gage. NOT GO (HI) functional diameter is acceptable when the NOT GO (HI) thread plug gage applied to the product internal thread does not enter more than three complete turns. The gage should not be forced. Special requirements such as exceptionally thin or ductile material, small number of threads, etc., may necessitate modification of this practice.

*GO and NOT GO Plain Plug Gages for Minor Diameter of Product Internal Thread:* (Recommended in Class Z tolerance.) GO plain plug gages must completely enter and pass through the length of the product without force. NOT GO cylindrical plug gage must not enter.

The standard lists the following for use of Thread Gages for verification of product external threads:

*GO Thread Ring Gages:* Adjustable GO thread ring gages must be set to the applicable W tolerance setting plugs to assure they are within specified limits. The product thread must freely enter the GO thread ring gage for the entire length of the threaded portion. The GO thread ring gage is a cumulative check of all thread elements except the major diameter.

*NOT GO (LO) Thread Ring Gages:* NOT GO (LO) thread ring gages must be set to the applicable W tolerance setting plugs to assure that they are within specified limits. NOT GO (LO) thread ring gages when applied to the product external thread may engage only the end threads (which may not be representative of the complete product thread).

Starting threads on NOT GO (LO) rings are subject to greater wear than the remaining threads. Such wear in combination with the incomplete threads at the end of the product thread permit further entry in the gage. NOT GO (LO) functional diameter is acceptable when the NOT GO (LO) thread ring gage applied to the product external thread does not pass over the thread more than three complete turns. The gage should not be forced. Special requirements such as exceptionally thin or ductile material, small number of threads, etc., may necessitate modification of this practice.

*GO and NOT GO Plain Ring and Snap Gages for Checking Major Diameter of Product External Thread:* The GO gage must completely receive or pass over the major diameter of the product external thread to ensure that the major diameter does not exceed the maximum-material-limit. The NOT GO gage must not pass over the major diameter of the product external thread to ensure that the major diameter is not less than the minimum-material-limit.

Limitations concerning the use of gages are given in the standard as follows:

*Product threads* accepted by a gage of one type may be verified by other types. It is possible, however, that parts which are near either rejection limit may be accepted by one type and rejected by another. Also, it is possible for two individual limit gages of the same type to be at the opposite extremes of the gage tolerances permitted, and borderline product threads accepted by one gage could be rejected by another. For these reasons, a product screw thread is considered acceptable when it passes a test by any of the permissible gages in ANSI B1.3 for the gaging system that are within the tolerances.

*Gaging large product external and internal threads* equal to above 6.25-inch nominal size with plain and threaded plug and ring gages presents problems for technical and economic reasons. In these instances, verification may be based on use of modified snap or indicating gages or measurement of thread elements. Various types of gages or measuring

devices in addition to those defined in the Standard are available and acceptable when properly correlated to this Standard. Producer and user should agree on the method and equipment used.

**Thread Forms of Gages.**— Thread forms of gages for product internal and external threads are given in [Table 1](#). The Standard ANSI/ASME B1.2-1983 (R2007) also gives illustrations of the thread forms of truncated thread setting plug gages, the thread forms of full-form thread setting plug gages, the thread forms of solid thread setting ring gages, and an illustration that shows the chip groove and removal of partial thread.

**Building Up Worn Plug Gages.**— Plug gages which have been worn under size can be built up by chromium plating and then lapped to size. Any amount of metal up to 0.004 or 0.005 inch can be added to a worn gage. Chromium oxide is used in lapping chromium plated gages, or other parts, to size and for polishing. When the chromium plating of a plug gage has worn under size, it may be removed by subjecting it to the action of muriatic acid. The gage is then built up again by chromium plating and lapped to size. When removing the worn plating the gage should be watched carefully and the action of the acid stopped as soon as the plating has been removed in order to avoid the roughening effect of the acid on the steel.

**Thread Gage Tolerances.**— Gage tolerances of thread plug and ring gages, thread setting plugs, and setting rings for Unified screw threads, designated as W and X tolerances, are given in [Table 4](#). W tolerances represent the highest commercial grade of accuracy and workmanship, and are specified for thread setting gages; X tolerances are larger than W tolerances and are used for product inspection gages. Tolerances for plain gages are given in [Table 2](#).

*Determining Size of Gages:* The three-wire method of determining pitch diameter size of plug gages is recommended for gages covered by American National Standard B1.2, described in Appendix B of the 1983 issue of that Standard.

Size limit adjustments of thread ring and external thread snap gages are determined by their fit on their respective calibrated setting plugs. Indicating gages and thread gages for product external threads are controlled by reference to appropriate calibrated setting plugs.

Size limit adjustments of internal thread snap gages are determined by their fit on their respective calibrated setting rings. Indicating gages and other adjustable thread gages for product internal threads are controlled by reference to appropriate calibrated setting rings or by direct measuring methods.

*Interpretation of Tolerances:* Tolerances on lead, half-angle, and pitch diameter are variations which may be taken independently for each of these elements and may be taken to the extent allowed by respective tabulated dimensional limits. The tabulated tolerance on any one element must not be exceeded, even though variations in the other two elements are smaller than the respective tabulated tolerances.

*Direction of Tolerance on Gages:* At the maximum-material limit (GO), the dimensions of all gages used for final conformance gaging are to be within limits of size of the product thread. At the functional diameter limit, using NOT GO (HI and LO) thread gages, the standard practice is to have the gage tolerance within the limits of size of the product thread.

*Formulas for Limits of Gages:* Formulas for limits of American National Standard Gages for Unified screw threads are given in [Table 5](#). Some constants which are required to determine gage dimensions are tabulated in [Table 3](#).

**Table 1. Thread Forms of Gages for Product Internal and External Threads**

**Table 2. American National Standard Tolerances for Plain Cylindrical Gages**  
*ANSI/ASME B1.2-1983 (R2007)*

Size Range		Tolerance Class <sup>1</sup>				
Above	To and Including	XX	X	Y	Z	ZZ
		Tolerance				
0.020	0.825	.00002	.00004	.00007	.00010	.00020
0.825	1.510	.00003	.00006	.00009	.00012	.00024

<sup>1</sup> Allowable variation in lead between any two threads not farther apart than the length of the standard gage as shown in ANSI B47.1. The tolerance on lead establishes the width of a zone, measured parallel to the axis of the thread, within which the actual helical path must lie for the specified length of the thread. Measurements are taken from a fixed reference point, located at the start of the first full thread, to a sufficient number of positions along the entire helix to detect all types of lead variations. The amounts that these positions vary from their basic (theoretical) positions are recorded with due respect to sign. The greatest variation in each direction ( $\pm$ ) is selected, and the sum of their values, disregarding sign, must not exceed the tolerance limits specified for W gages.

<sup>2</sup> Tolerances apply to designated size of thread. The application of the tolerances is specified in the Standard.

<sup>3</sup> Above 12 in. the tolerance is directly proportional to the tolerance given in this column below, in the ratio of the diameter to 12 in.

All dimensions are given in inches unless otherwise specified.

**Table 5. Formulas for Limits of American National Standard Gages for Unified Inch Screw Threads ANSI/ASME B1.2-1983 (R2007)**

Thread Gages for External Threads	
1	GO Pitch Diameter = Maximum pitch diameter of external thread. Gage tolerance is <i>minus</i> .
2	GO Minor Diameter = Maximum pitch diameter of external thread minus $H/2$ . Gage tolerance is <i>minus</i> .
3	NOT GO (LO) Pitch Diameter (for plus tolerance gage) = Minimum pitch diameter of external thread. Gage tolerance is <i>plus</i> .
4	NOT GO (LO) Minor Diameter = Minimum pitch diameter of external thread minus $H/4$ . Gage tolerance is <i>plus</i> .
Plain Gages for Major Diameter of External Threads	
5	GO = Maximum major diameter of external thread. Gage tolerance is <i>minus</i> .
6	NOT GO = Minimum major diameter of external thread. Gage tolerance is <i>plus</i> .
Thread Gages for Internal Threads	
7	GO Major Diameter = Minimum major diameter of internal thread. Gage tolerance is <i>plus</i> .
8	GO Pitch Diameter = Minimum pitch diameter of internal thread. Gage tolerance is <i>plus</i> .
9	NOT GO (HI) Major Diameter = Maximum pitch diameter of internal thread plus $H/2$ . Gage tolerance is <i>minus</i> .
10	NOT GO (HI) Pitch Diameter = Maximum pitch diameter of internal thread. Gage tolerance is <i>minus</i> .
Plain Gages for Minor Diameter of Internal Threads	
11	GO = Minimum minor diameter of internal thread. Gage tolerance is <i>plus</i> .
12	NOT GO = Maximum minor diameter of internal thread. Gage tolerance is <i>minus</i> .
Full Form and Truncated Setting Plugs	
13	GO Major Diameter (Truncated Portion) = Maximum major diameter of external thread (= minimum major diameter of full portion of GO setting plug) minus $(0.060\sqrt[3]{p^2} + 0.017p)$ . Gage tolerance is <i>minus</i> .
14	GO Major Diameter (Full Portion) = Maximum major diameter of external thread. Gage tolerance is <i>plus</i> .
15	GO Pitch Diameter = Maximum pitch diameter of external thread. Gage tolerance is <i>minus</i> .
16	<sup>1</sup> NOT GO (LO) Major Diameter (Truncated Portion) = Minimum pitch diameter of external thread plus $H/2$ . Gage tolerance is <i>minus</i> .
17	NOT GO (LO) Major Diameter (Full Portion) = Maximum major diameter of external thread provided major diameter crest width shall not be less than 0.001 in. (0.0009 in. truncation). Apply W tolerance <i>plus</i> for maximum size except that for 0.001 in. crest width apply tolerance <i>minus</i> . For the 0.001 in. crest width, major diameter is equal to maximum major diameter of external thread plus $0.216506p$ minus the sum of external thread pitch diameter tolerance and 0.0017 in.
18	NOT GO (LO) Pitch Diameter = Minimum pitch diameter of external thread. Gage tolerance is <i>plus</i> .
Solid Thread-setting Rings for Snap and Indicating Gages	
19	<sup>2</sup> GO Pitch Diameter = Minimum pitch diameter of internal thread. W gage tolerance is <i>plus</i> .
20	GO Minor Diameter = Minimum minor diameter of internal thread. W gage tolerance is <i>minus</i> .
21	<sup>2</sup> NOT GO (HI) Pitch Diameter = Maximum pitch diameter of internal thread. W gage tolerance is <i>minus</i> .
22	NOT GO (HI) Minor Diameter = Maximum minor diameter of internal thread. W gage tolerance is <i>minus</i> .

<sup>1</sup>Truncated portion is required when optional sharp root profile is used.

<sup>2</sup>Tolerances greater than W tolerance for pitch diameter are acceptable when internal indicating or snap gage can accommodate a greater tolerance and when agreed upon by supplier and user.

See data in Screw Thread Systems section for symbols and dimensions of Unified Screw Threads.

## TAPPING AND THREAD CUTTING

**Selection of Taps.**— For most applications, a standard tap supplied by the manufacturer can be used, but some jobs may require special taps. A variety of standard taps can be obtained. In addition to specifying the size of the tap it is necessary to be able to select the one most suitable for the application at hand.

The elements of standard taps that are varied are: the number of flutes; the type of flute, whether straight, spiral pointed, or spiral fluted; the chamfer length; the relief of the land, if any; the tool steel used to make the tap; and the surface treatment of the tap.

Details regarding the nomenclature of tap elements are given in the section *TAPS* starting on page 943, along with a listing of the standard sizes available.

Factors to consider in selecting a tap include: the method of tapping, by hand or by machine; the material to be tapped and its heat treatment; the length of thread, or depth of the tapped hole; the required tolerance or class of fit; and the production requirement and the type of machine to be used.

The diameter of the hole must also be considered, although this action is usually only a matter of design and the specification of the tap drill size.

*Method of Tapping:* The term *hand tap* is used for both hand and machine taps, and almost all taps can be applied by the hand or machine method. While any tap can be used for hand tapping, those having a concentric land without the relief are preferable. In hand tapping the tool is reversed periodically to break the chip, and the heel of the land of a tap with a concentric land (without relief) will cut the chip off cleanly or any portion of it that is attached to the work, whereas a tap with an eccentric or con-eccentric relief may leave a small burr that becomes wedged between the relieved portion of the land and the work. This wedging creates a pressure towards the cutting face of the tap that may cause it to chip; it tends to roughen the threads in the hole, and it increases the overall torque required to turn the tool. When tapping by machine, however, the tap is usually turned only in one direction until the operation is complete, and an eccentric or con-eccentric relief is often an advantage.

*Chamfer Length:* Three types of hand taps, used both for hand and machine tapping, are available, and they are distinguished from each other by the length of chamfer. *Taper taps* have a chamfer angle that reduces the height about 8-10 teeth; *plug taps* have a chamfer angle with 3-5 threads reduced in height; and *bottoming taps* have a chamfer angle with 1½ threads reduced in height. Since the teeth that are reduced in height do practically all the cutting, the chip load or chip thickness per tooth will be least for a taper tap, greater for a plug tap, and greatest for a bottoming tap.

For most through hole tapping applications it is necessary to use only a plug type tap, which is also most suitable for blind holes where the tap drill hole is deeper than the required thread. If the tap must bottom in a blind hole, the hole is usually threaded first with a plug tap and then finished with a bottoming tap to catch the last threads in the bottom of the hole. Taper taps are used on materials where the chip load per tooth must be kept to a minimum. However, taper taps should not be used on materials that have a strong tendency to work harden, such as the austenitic stainless steels.

*Spiral Point Taps:* Spiral point taps offer a special advantage when machine tapping through holes in ductile materials because they are designed to handle the long continuous chips that form and would otherwise cause a disposal problem. An angular gash is ground at the point or end of the tap along the face of the chamfered threads or lead teeth of the tap. This gash forms a left-hand helix in the flutes adjacent to the lead teeth which causes the chips to flow ahead of the tap and through the hole. The gash is usually formed to produce a rake angle on the cutting face that increases progressively toward the end of the tool. Since the flutes are used primarily to provide a passage for the cutting fluid, they are usually made narrower and shallower thereby strengthening the tool. For tapping thin work-

pieces short fluted spiral point taps are recommended. They have a spiral point gash along the cutting teeth; the remainder of the threaded portion of the tap has no flute. Most spiral pointed taps are of plug type; however, spiral point bottoming taps are also made.

*Spiral Fluted Taps:* Spiral fluted taps have a helical flute; the helix angle of the flute may be between 15 and 52 degrees and the hand of the helix is the same as that of the threads on the tap. The spiral flute and the rake that it forms on the cutting face of the tap combine to induce the chips to flow backward along the helix and out of the hole. Thus, they are ideally suited for tapping blind holes and they are available as plug and bottoming types. A higher spiral angle should be specified for tapping very ductile materials; when tapping harder materials, chipping at the cutting edge may result and the spiral angle must be reduced.

Holes having a pronounced interruption such as a groove or a keyway can be tapped with spiral fluted taps. The land bridges the interruption and allows the tap to cut relatively smoothly.

*Serial Taps and Close Tolerance Threads:* For tapping holes to close tolerances a set of serial taps is used.

They are usually available in sets of three: the No. 1 tap is undersize and is the first rougher; the No. 2 tap is of intermediate size and is the second rougher; and the No. 3 tap is used for finishing.

The different taps are identified by one, two, and three annular grooves in the shank adjacent to the square. For some applications involving finer pitches only two serial taps are required. Sets are also used to tap hard or tough materials having a high tensile strength, deep blind holes in normal materials, and large coarse threads. A set of more than three taps is sometimes required to produce threads of coarse pitch. Threads to some commercial tolerances, such as American Standard Unified 2B, or ISO Metric 6H, can be produced in one cut using a ground tap; sometimes even closer tolerances can be produced with a single tap. Ground taps are recommended for all close tolerance tapping operations. For much ordinary work, cut taps are satisfactory and more economical than ground taps.

*Tap Steels:* Most taps are made from high speed steel. The type of tool steel used is determined by the tap manufacturer and is usually satisfactory when correctly applied except in a few exceptional cases. Typical grades of high speed steel used to make taps are M-1, M-2, M-3, M-42, etc. Carbon tool steel taps are satisfactory where the operating temperature of the tap is low and where a high resistance to abrasion is not required as in some types of hand tapping.

*Surface Treatment:* The life of high speed steel taps can sometimes be increased significantly by treating the surface of the tap. A very common treatment is oxide coating, which forms a thin metallic oxide coating on the tap that has lubricity and is somewhat porous to absorb and retain oil. This coating reduces the friction between the tap and the work and it makes the surface virtually impervious to rust. It does not increase the hardness of the surface but it significantly reduces or prevents entirely galling, or the tendency of the work material to weld or stick to the cutting edge and to other areas on the tap with which it is in contact. For this reason oxide coated taps are recommended for metals that tend to gall and stick such as non-free cutting low carbon steels and soft copper. It is also useful for tapping other steels having higher strength properties.

Nitriding provides a very hard and wear resistant case on high speed steel. Nitrided taps are especially recommended for tapping plastics; they have also been used successfully on a variety of other materials including high strength high alloy steels. However, some caution must be used in specifying nitrided taps because the nitride case is very brittle and may have a tendency to chip.

Chrome plating has been used to increase the wear resistance of taps but its application has been limited because of the high cost and the danger of hydrogen embrittlement which can cause cracks to form in the tool. A flash plate of about .0001 in. or less in thickness is applied to the tap. Chrome-plated taps have been used successfully to tap a variety of fer-

rous and nonferrous materials including plastics, hard rubber, mild steel, and tool steel. Other surface treatments that have been used successfully to a limited extent are vapor blasting and liquid honing.

**Rake Angle:** For the majority of applications in both ferrous and nonferrous materials the rake angle machined on the tap by the manufacturer is satisfactory. This angle is approximately 5 to 7 degrees. In some instances it may be desirable to alter the rake angle of the tap to obtain beneficial results and **Table 1** provides a guide that can be used. In selecting a rake angle from this table, consideration must be given to the size of the tap and the strength of the land. Most standard taps are made with a curved face with the rake angle measured as a chord between the crest and root of the thread. The resulting shape is called a hook angle.

**Table 1. Tap Rake Angles for Tapping Different Materials**

Material	Rake Angle, Degrees	Material	Rake Angle, Degrees
Cast Iron	0-3	Aluminum	8-20
Malleable Iron	5-8	Brass	2-7
Steel		Naval Brass	5-8
AISI 1100 Series	5-12	Phosphor Bronze	5-12
Low Carbon (up to .25 percent)	5-12	Tobin Bronze	5-8
Medium Carbon, Annealed (.30 to .60 percent)	5-10	Manganese Bronze	5-12
Heat Treated, 225-283 Brinell (.30 to .60 percent)	0-8	Magnesium	10-20
High Carbon and High Speed	0-5	Monel	9-12
Stainless	8-15	Copper	10-18
Titanium	5-10	Zinc Die Castings	10-15
		Plastic	
		Thermoplastic	5-8
		Thermosetting	0-3
		Hard Rubber	0-3

**Cutting Speed.**— The cutting speed for machine tapping is treated in detail on page 1114. It suffices to say here that many variables must be considered in selecting this cutting speed and any tabulation may have to be modified greatly. Where cutting speeds are mentioned in the following section, they are intended only to provide a guideline to show the possible range of speeds that could be used.

**Tapping Specific Materials.**— The work material has a great influence on the ease with which a hole can be tapped. For production work, in many instances, modified taps are recommended; however, for toolroom or short batch work, standard hand taps can be used on most jobs, providing reasonable care is taken when tapping. The following concerns the tapping of metallic materials; information on the tapping of plastics is given on page 589.

**Low Carbon Steel (Less than 0.15% C):** These steels are very soft and ductile resulting in a tendency for the work material to tear and to weld to the tap. They produce a continuous chip that is difficult to break and spiral pointed taps are recommended for tapping through holes; for blind holes a spiral fluted tap is recommended. To prevent galling and welding, a liberal application of a sulfur base or other suitable cutting fluid is essential and the selection of an oxide coated tap is very helpful.

**Low Carbon Steels (0.15 to 0.30% C):** The additional carbon in these steels is beneficial as it reduces the tendency to tear and to weld; their machinability is further improved by cold drawing. These steels present no serious problems in tapping provided a suitable cutting fluid is used. An oxide coated tap is recommended, particularly in the lower carbon range.

*Medium Carbon Steels (0.30 to 0.60% C):* These steels can be tapped without too much difficulty, although a lower cutting speed must be used in machine tapping. The cutting speed is dependent on carbon content and heat treatment. Steels that have a higher carbon content must be tapped more slowly, especially if the heat treatment has produced a pearlitic microstructure. The cutting speed and ease of tapping is significantly improved by heat treating to produce a spheroidized microstructure. A suitable cutting fluid must be used.

*High Carbon Steels (More than 0.6% C):* Usually these materials are tapped in the annealed or normalized condition although sometimes tapping is done after hardening and tempering to a hardness below 55 Rc. Recommendations for tapping after hardening and tempering are given under High Tensile Strength Steels. In the annealed and normalized condition these steels have a higher strength and are more abrasive than steels with a lower carbon content; thus, they are more difficult to tap. The microstructure resulting from the heat treatment has a significant effect on the ease of tapping and the tap life, a spheroidite structure being better in this respect than a pearlitic structure. The rake angle of the tap should not exceed 5 degrees and for the harder materials a concentric tap is recommended. The cutting speed is considerably lower for these steels and an activated sulfur-chlorinated cutting fluid is recommended.

*Alloy Steels:* This classification includes a wide variety of steels, each of which may be heat treated to have a wide range of properties. When annealed and normalized they are similar to medium to high carbon steels and usually can be tapped without difficulty, although for some alloy steels a lower tapping speed may be required. Standard taps can be used and for machine tapping a con-eccentric relief may be helpful. A suitable cutting fluid must be used.

*High-Tensile Strength Steels:* Any steel that must be tapped after being heat treated to a hardness range of 40-55 Rc is included in this classification. Low tap life and excessive tap breakage are characteristics of tapping these materials; those that have a high chromium content are particularly troublesome. Best results are obtained with taps that have concentric lands, a rake angle that is at or near zero degrees, and 6 to 8 chamfered threads on the end to reduce the chip load per tooth. The chamfer relief should be kept to a minimum. The load on the tap should be kept to a minimum by every possible means, including using the largest possible tap drill size; keeping the hole depth to a minimum; avoidance of bottoming holes; and, in the larger sizes, using fine instead of coarse pitches. Oxide coated taps are recommended although a nitrided tap can sometimes be used to reduce tap wear. An active sulfur-chlorinated oil is recommended as a cutting fluid and the tapping speed should not exceed about 10 feet per minute (3.0 m/min).

*Stainless Steels:* Ferritic and martensitic type stainless steels are somewhat like alloy steels that have a high chromium content, and they can be tapped in a similar manner, although a slightly slower cutting speed may have to be used. Standard rake angle oxide coated taps are recommended and a cutting fluid containing molybdenum disulphide is helpful to reduce the friction in tapping. Austenitic stainless steels are very difficult to tap because of their high resistance to cutting and their great tendency to work harden. A work-hardened layer is formed by a cutting edge of the tap and the depth of this layer depends on the severity of the cut and the sharpness of the tool. The next cutting edge must penetrate below the work-hardened layer, if it is to be able to cut. Therefore, the tap must be kept sharp and each succeeding cutting edge on the tool must penetrate below the work-hardened layer formed by the preceding cutting edge. For this reason, a taper tap should not be used, but rather a plug tap having 3-5 chamfered threads. To reduce the rubbing of the lands, an eccentric or con-eccentric relieved land should be used and a 10-15 degree rake angle is recommended. A tough continuous chip is formed that is difficult to break. To control this chip, spiral pointed taps are recommended for through holes and low-helix angle spiral fluted taps for blind holes. An oxide coating on the tap is very helpful and a sulfur-chlorinated mineral lard oil is recommended, although heavy duty soluble oils have also been used successfully.

*Free Cutting Steels:* There are large numbers of free cutting steels, including free cutting stainless steels, which are also called free machining steels. Sulfur, lead, or phosphorus are added to these steels to improve their machinability. Free machining steels are always easier to tap than their counterparts that do not have the free machining additives. Tool life is usually increased and a somewhat higher cutting speed can be used. The type of tap recommended depends on the particular type of free machining steel and the nature of the tapping operation; usually a standard tap can be used.

*High Temperature Alloys:* These are cobalt or nickel base nonferrous alloys that cut like austenitic stainless steel, but are often even more difficult to machine. The recommendations given for austenitic stainless steel also apply to tapping these alloys but the rake angle should be 0 to 10 degrees to strengthen the cutting edge. For most applications a nitrided tap or one made from M41, M42, M43, or M44 steel is recommended. The tapping speed is usually in the range of 5–10 ft/min (1.5–3.0 m/min).

*Titanium and Titanium Alloys:* Titanium and its alloys have a low specific heat and a pronounced tendency to weld on to the tool material; therefore, oxide coated taps are recommended to minimize galling and welding. The rake angle of the tap should be from 6 to 10 degrees. To minimize the contact between the work and the tap an eccentric or con-eccentric relief land should be used. Taps having interrupted threads are sometimes helpful. Pure titanium is comparatively easy to tap but the alloys are very difficult. The cutting speed depends on the composition of the alloy and may vary from 10–40 ft/min (3.0–12.2 m/min). Special cutting oils are recommended for tapping titanium.

*Gray Cast Iron:* The microstructure of gray cast iron can vary, even within a single casting, and compositions are used that vary in tensile strength from about 20,000–60,000 psi (138–414 MPa) and 160 to 250 Bhn. Thus, cast iron is not a single material, although in general it is not difficult to tap. The cutting speed may vary from 90 ft/min (27.4 m/min) for the softer grades to 30 ft/min (9.1 m/min) for the harder grades. The chip is discontinuous and straight fluted taps should be used for all applications. Oxide coated taps are helpful and gray cast iron can usually be tapped dry, although water soluble oils and chemical emulsions are sometimes used.

*Malleable Cast Iron:* Commercial malleable cast irons are also available having a rather wide range of properties, although within a single casting they tend to be quite uniform. They are relatively easy to tap and standard taps can be used. The cutting speed for ferritic cast irons is 60–90 ft/min (18.3–27.4 m/min), for pearlitic malleable irons 40–50 ft/min (12.2–15.2 m/min), and for martensitic malleable irons 30–35 ft/min (9.1–10.7 m/min). A soluble oil cutting fluid is recommended except for martensitic malleable iron where a sulfur base oil may work better.

*Ductile or Nodular Cast Iron:* Several classes of nodular iron are used having a tensile strength varying from 60,000–120,000 psi (414–827 MPa). Moreover, the microstructure in a single casting and in castings produced at different times vary rather widely. The chips are easily controlled but have some tendency to weld to the faces and flanks of cutting tools. For this reason oxide coated taps are recommended. The cutting speed may vary from 15 fpm (4.6 m/min) for the harder martensitic ductile irons to 60 fpm (18.3 m/min) for the softer ferritic grades. A suitable cutting fluid should be used.

*Aluminum:* Aluminum and aluminum alloys are relatively soft materials that have little resistance to cutting. The danger in tapping these alloys is that the tap will ream the hole instead of cutting threads, or that it will cut a thread eccentric to the hole. For these reasons, extra care must be taken when aligning the tap and starting the thread. For production tapping a spiral pointed tap is recommended for through holes and a spiral fluted tap for blind holes; preferably these taps should have a 10 to 15 degree rake angle. A lead screw tapping machine is helpful in cutting accurate threads. A heavy duty soluble oil or a light base mineral oil should be used as a cutting fluid.

*Copper Alloys:* Most copper alloys are not difficult to tap, except beryllium copper and a few other hard alloys. Pure copper is difficult because of its ductility and the ductile continuous chip formed, which can be hard to control. However, with reasonable care and the use of medium heavy duty mineral lard oil it can be tapped successfully. Red brass, yellow brass, and similar alloys containing not more than 35 percent zinc produce a continuous chip. While straight fluted taps can be used for hand tapping these alloys, machine tapping should be done with spiral pointed or spiral fluted taps for through and blind holes respectively. Naval brass, leaded brass, and cast brasses produce a discontinuous chip and a straight fluted tap can be used for machine tapping. These alloys exhibit a tendency to close in on the tap and sometimes an interrupted thread tap is used to reduce the resulting jamming effect. Beryllium copper and the silicon bronzes are the strongest of the copper alloys. Their strength combined with their ability to work harden can cause difficulties in tapping. For these alloys plug type taps should be used and the taps should be kept as sharp as possible. A medium or heavy duty water soluble oil is recommended as a cutting fluid.

**Other Tapping Lubricants.**— The power required in tapping varies considerably with different lubricants. The following lubricants reduce the resistance to the cut when threading forged nuts and hexagon drawn material: stearine oil, lard oil, sperm oil, rape oil, and 10 percent graphite with 90 percent tallow. A mixture of cutting emulsion (soluble oil) with water reduces resistance to threading action well. A few emulsions are almost as good as animal and vegetable oils, but the emulsion used plays an important part; the majority of emulsions do not give good results. A large volume of lubricant gives somewhat better results than a small quantity, especially in the case of the thinner oils. Kerosene, turpentine, and graphite proved unsuitable for tapping steel. Mineral oils not mixed with animal and vegetable oils, and ordinary lubricating and machine oils, are wholly unsuitable.

For aluminum, kerosene is recommended. For tapping cast iron use a strong solution of emulsion; oil has a tendency to make cast-iron chips clog in the flutes, preventing the lubricant from reaching the tap cutting teeth. For tapping copper, milk is a good lubricant.

### Diameter of Tap Drill

Tapping troubles are sometimes caused by tap drills that are too small in diameter. The tap drill should not be smaller than is necessary to give the required strength to the thread as even a very small decrease in the diameter of the drill will increase the torque required and the possibility of broken taps. Tests have shown that any increase in the percentage of full thread over 60 percent does not significantly increase the strength of the thread. Often, a 55 to 60 percent thread is satisfactory, although 75 percent threads are commonly used to provide an extra measure of safety. The present thread specifications do not always allow the use of the smaller thread depths. However, the specification given on a part drawing must be adhered to and may require smaller minor diameters than might otherwise be recommended.

The depth of the thread in the tapped hole is dependent on the length of thread engagement and on the material. In general, when the engagement length is more than one and one-half times the nominal diameter a 50 or 55 percent thread is satisfactory. Soft ductile materials permit a slightly larger tapping hole than brittle materials such as gray cast iron.

It must be remembered that a twist drill is a roughing tool that may be expected to drill slightly oversize and that some variations in the size of the tapping holes are almost inevitable. When a closer control of the hole size is required it must be reamed. Reaming is recommended for the larger thread diameters and for some fine pitch threads.

For threads of Unified form (see *American National and Unified Screw Thread Forms* on page 1858) the selection of tap drills is covered in **Table 2**, and the hole size limits are given in **Table 3**. See the section *Factors Influencing Minor Diameter Tolerances of Tapped Holes* on page 2089. Tap drill sizes for American National Form threads based on 75 percent of full thread depth are given in **Tables 4** and **5**. For smaller-size threads the use of slightly larger drills, if permissible, will reduce tap breakage. The selection of tap drills for

these threads also may be based on the hole size limits given in [Table 3](#), page 2080 for Unified threads that take lengths of engagement into account. See *Recommended Hole Sizes before Tapping* on page 2090. (Text continues on page 2074.)

The size of the tap drill hole for any desired percentage of full thread depth can be calculated by the formulas below. In these formulas the Percent Full Thread is expressed as a decimal; e.g., 75 percent is expressed as .75. The tap drill size is the size nearest to the calculated hole size.

For American Unified Thread form:

$$\text{Hole Size} = \text{Basic Major Diameter} - \frac{1.08253 \times \text{Percent Full Thread}}{\text{Number of Threads per Inch}}$$

For ISO Metric threads (all dimensions in millimeters):

$$\text{Hole Size} = \text{Basic Major Diameter} - (1.08253 \times \text{Pitch} \times \text{Percent Full Thread})$$

The constant 1.08253 in the above equation represents  $5H/8$  where  $H$  is the height of a sharp V-thread (see page 1858). The pitch is taken to be 1.

*Hole Sizes for Tapping Unified Miniature Screw Threads* are given on page 2091 and [Table 6](#).

*Theoretical and Tap Drill or Core Hole Sizes for Cold Form Tapping Unified Threads* are given in [Table 9](#), page 2095 and for ISO metric threads are given in [Table 10](#), page 2096.

**Reaming Allowance.**—Reaming is a secondary operation that slightly enlarges previously drilled or bored hole. Reamed holes are very accurate with a smooth surface finish.

The reaming allowance is amount of material left in the hole after drilling. A properly sharpened drill produces a hole that is about 0.002–0.008 inch (0.050–0.203mm) oversize. For accurate diameters, a common practice is to rough out the hole with a smaller drill, then size the hole with the proper drill, leaving the correct reaming allowance.

Use the following table to determine the drill size used prior to reaming the hole.

Size of Reamer		Reaming Allowance		Size of Reamer		Reaming Allowance	
inch	mm	inch	mm	inch	mm	inch	mm
$\frac{1}{32}$ – $\frac{1}{8}$	0.79–3.18	0.003–0.005	0.076–0.127	$\frac{3}{8}$ – $\frac{1}{2}$	9.53–12.70	0.010–0.015	0.254–0.381
$\frac{1}{8}$ – $\frac{1}{4}$	3.18–6.35	0.004–0.008	0.101–0.203	$\frac{1}{2}$ – $\frac{3}{4}$	12.70–19.05	0.015–0.03	0.381–0.762
$\frac{1}{4}$ – $\frac{3}{8}$	6.35–9.53	0.006–0.010	0.152–0.254	$\frac{3}{4}$ –1.00	19.05–25.40	0.03	0.762

*Example:* A finished bore of 1.000 inches after reaming is required. Select the drill size for predrilling that allows adequate allowance for reaming.

*Solution:* According to the table above, a 1-inch drilled hole needs to be approximately 0.03 inch undersize to allow sufficient allowance for reaming, thus the hole size prior to reaming should be approximately  $1.000 - 0.03 = 0.97$  inch.

A  $\frac{31}{32}$  drill can be expected to produce a slightly oversize hole, say 0.971 to 0.977 inch. The  $\frac{31}{32}$  drill provides a reaming allowance of 0.023 to 0.029 inch.

<sup>1</sup>This is the minimum minor diameter specified in the thread tables, page 1869.

<sup>2</sup>This is the maximum minor diameter specified in the thread tables, page 1869.

All dimensions are in inches.

For basis of recommended hole size limits see accompanying text.

As an aid in selecting suitable drills, see the listing of American Standard drill sizes starting on page 907 in the twist drill section. For amount of expected drill over-size, see page 936.

<sup>1</sup> These tap drill diameters allow approximately 75 percent of a full thread to be produced. For small thread sizes in the first column, the use of drills to produce the larger hole sizes shown in Table 3 will reduce defects caused by tap problems and breakage.

<sup>1</sup>These screws are not in the American Standard but are from the former A.S.M.E. Standard.

**Factors Influencing Minor Diameter Tolerances of Tapped Holes.**—As stated in the Unified screw thread standard, the principle practical factors that govern minor diameter tolerances of internal threads are tapping difficulties, particularly tap breakage in the small sizes, availability of standard drill sizes in the medium and large sizes, and depth (radial) of engagement. Depth of engagement is related to the stripping strength of the thread assembly, and thus also to the length of engagement. It also has an influence on the tendency toward disengagement of the threads on one side when assembly is eccentric. The amount of possible eccentricity is one-half of the sum of the pitch diameter allowance and tolerances on both mating threads. For a given pitch, or height of thread, this sum increases with the diameter, and accordingly this factor would require a decrease in minor diameter tolerance with increase in diameter. However, such decrease in tolerance would often require the use of special drill sizes; therefore, to facilitate the use of standard drill sizes, for any given pitch the minor diameter tolerance for Unified thread classes 1B and 2B threads of  $\frac{1}{4}$  inch diameter and larger is constant, in accordance with a formula given in the American Standard for Unified Screw Threads.

*Effect of Length of Engagement of Minor Diameter Tolerances:* There may be applications where the lengths of engagement of mating threads is relatively short or the combination of materials used for mating threads is such that the maximum minor diameter tolerance given in the Standard (based on a length of engagement equal to the nominal diameter) may not provide the desired strength of the fastening. Experience has shown that for lengths of engagement less than  $\frac{2}{3}D$  (the minimum thickness of standard nuts) the

minor diameter tolerance may be reduced without causing tapping difficulties. In other applications the length of engagement of mating threads may be long because of design considerations or the combination of materials used for mating threads. As the threads engaged increase in number, a shallower depth of engagement may be permitted and still develop stripping strength greater than the external thread breaking strength. Under these conditions the maximum tolerance given in the Standard should be increased to reduce the possibility of tapping difficulties. The following paragraphs indicate how the aforementioned considerations were taken into account in determining the minor diameter limits for various lengths of engagement given in [Table 3](#).

**Recommended Hole Sizes before Tapping.**— Recommended hole size limits before threading to provide for optimum strength of fastenings and tapping conditions are shown in [Table 3](#) for classes 1B, 2B, and 3B. The hole size limit before threading, and the tolerances between them, are derived from the minimum and maximum minor diameters of the internal thread given in the dimensional tables for Unified threads in the screw thread section using the following rules:

1) For lengths of engagement in the range to and including  $\frac{1}{3}D$ , where  $D$  equals nominal diameter, the minimum hole size will be equal to the minimum minor diameter of the internal thread and the maximum hole size will be larger by one-half the minor diameter tolerance.

2) For the range from  $\frac{1}{3}D$  to  $\frac{2}{3}D$ , the minimum and maximum hole sizes will each be one quarter of the minor diameter tolerance larger than the corresponding limits for the length of engagement to and including  $\frac{1}{3}D$ .

3) For the range from  $\frac{2}{3}D$  to  $1\frac{1}{2}D$  the minimum hole size will be larger than the minimum minor diameter of the internal thread by one-half the minor diameter tolerance and the maximum hole size will be equal to the maximum minor diameter.

4) For the range from  $1\frac{1}{2}D$  to  $3D$  the minimum and maximum hole sizes will each be one-quarter of the minor diameter tolerance of the internal thread larger than the corresponding limits for the  $\frac{2}{3}D$  to  $1\frac{1}{2}D$  length of engagement.

From the foregoing it will be seen that the difference between limits in each range is the same and equal to one-half of the minor diameter tolerance given in the Unified screw thread dimensional tables. This is a general rule, except that the minimum differences for sizes below  $\frac{1}{4}$  inch are equal to the minor diameter tolerances calculated on the basis of lengths of engagement to and including  $\frac{1}{3}D$ . Also, for lengths of engagement greater than  $\frac{1}{3}D$  and for sizes  $\frac{1}{4}$  inch and larger the values are adjusted so that the difference between limits is never less than 0.004 inch.

For diameter-pitch combinations other than those given in [Table 3](#), the foregoing rules should be applied to the tolerances given in the dimensional tables in the screw thread section or the tolerances derived from the formulas given in the Standard to determine the hole size limits.

*Selection of Tap Drills:* In selecting standard drills to produce holes within the limits given in [Table 3](#) it should be recognized that drills have a tendency to cut oversize. The material on pages [935](#) and [936](#) may be used as a guide to the expected amount of oversize.

As an aid in selecting suitable drills, see the listing of American Standard drill sizes in the twist drill section. Thread sizes in heavy type are preferred sizes.

**Hole Sizes for Tapping Unified Miniature Screw Threads.**— **Table 6** indicates the hole size limits recommended for tapping. These limits are derived from the internal thread minor diameter limits given in the American Standard for Unified Miniature Screw Threads ASA B1.10-1958 and are disposed so as to provide the optimum conditions for tapping. The maximum limits are based on providing a functionally adequate fastening for the most common applications, where the material of the externally threaded member is of a strength essentially equal to or greater than that of its mating part. In applications where, because of considerations other than the fastening, the screw is made of an appreciably weaker material, the use of smaller hole sizes is usually necessary to extend thread engagement to a greater depth on the external thread. Recommended minimum hole sizes are greater than the minimum limits of the minor diameters to allow for the spin-up developed in tapping.

In selecting drills to produce holes within the limits given in [Table 6](#) it should be recognized that drills have a tendency to cut oversize. The material on page [936](#) may be used as a guide to the expected amount of oversize.

**British Standard Tapping Drill Sizes for Screw and Pipe Threads.**— British Standard BS 1157:1975 (2004) provides recommendations for tapping drill sizes for use with fluted taps for various ISO metric, Unified, British Standard fine, British Association, and British Standard Whitworth screw threads as well as British Standard parallel and taper pipe threads.

<sup>1</sup> These tapping drill sizes are for fluted taps only.

<sup>2</sup> For tolerance class 6H and 7H threads only.

<sup>3</sup> For tolerance class 7H threads only.

Drill sizes are given in millimeters.

In the accompanying [Table 7](#), recommended and alternative drill sizes are given for producing holes for ISO metric coarse pitch series threads. These coarse pitch threads are suitable for the large majority of general-purpose applications, and the limits and tolerances for internal coarse threads are given in the table starting on page [1971](#). It should be noted that [Table 7](#) is for fluted taps only since a fluteless tap will require for the same screw thread a different size of twist drill than will a fluted tap. When tapped, holes produced with drills of the recommended sizes provide for a theoretical radial engagement with the external thread of about 81 percent in most cases. Holes produced with drills of the alternative sizes provide for a theoretical radial engagement with the external thread of about 70 to 75 percent. In some cases, as indicated in [Table 7](#), the alternative drill sizes are suitable only for medium (6H) or for free (7H) thread tolerance classes.

When relatively soft material is being tapped, there is a tendency for the metal to be squeezed down towards the root of the tap thread, and in such instances, the minor diame-

ter of the tapped hole may become smaller than the diameter of the drill employed. Users may wish to choose different tapping drill sizes to overcome this problem or for special purposes, and reference can be made to the pages mentioned above to obtain the minor diameter limits for internal pitch series threads.

Reference should be made to this standard BS 1157:1975 (2004) for recommended tapping hole sizes for other types of British Standard screw threads and pipe threads.

All dimensions are given in millimeters.

**British Standard Clearance Holes for Metric Bolts and Screws.**— The dimensions of the clearance holes specified in this British Standard BS 4186:1967 have been chosen in such a way as to require the use of the minimum number of drills. The recommendations cover three series of clearance holes, namely close fit (H 12), medium fit (H 13), and free fit (H 14) and are suitable for use with bolts and screws specified in the following metric British Standards: BS 3692, ISO metric precision hexagon bolts, screws, and nuts; BS 4168, Hexagon socket screws and wrench keys; BS 4183, Machine screws and machine screw nuts; and BS 4190, ISO metric black hexagon bolts, screws, and nuts. The sizes are in accordance with those given in ISO Recommendation R273, and the range has been extended up to 150 millimeters diameter in accordance with an addendum to that recommendation. The selection of clearance holes sizes to suit particular design requirements can of course be dependent upon many variable factors. It is however felt that the medium fit series should suit the majority of general purpose applications. In the Standard, limiting dimensions are given in a table which is included for reference purposes only, for use in instances where it may be desirable to specify tolerances.

To avoid any risk of interference with the radius under the head of bolts and screws, it is necessary to countersink slightly all recommended clearance holes in the close and medium fit series. Dimensional details for the radius under the head of fasteners made according to BS 3692 are given on page 1681; those for fasteners to BS 4168 are given on page 1745; those to BS 4183 are given on pages 1719 through 1723.

**Cold Form Tapping.**— Cold form taps do not have cutting edges or conventional flutes; the threads on the tap form the threads in the hole by displacing the metal in an extrusion or swaging process. The threads thus produced are stronger than conventionally cut threads because the grains in the metal are unbroken and the displaced metal is work hardened. The surface of the thread is burnished and has an excellent finish. Although chip problems are eliminated, cold form tapping does displace the metal surrounding the hole and countersinking or chamfering before tapping is recommended. Cold form tapping is not recommended if the wall thickness of the hole is less than two-thirds of the nominal diameter of the thread. If possible, blind holes should be drilled deep enough to permit a cold form tap having a four thread lead to be used as this will require less torque, produce less burr surrounding the hole, and give a greater tool life.

The operation requires 0 to 50 percent more torque than conventional tapping, and the cold form tap will pick up its own lead when entering the hole; thus, conventional tapping machines and tapping heads can be used. Another advantage is the better tool life obtained. The best results are obtained by using a good lubricating oil instead of a conventional cutting oil.

The method can be applied only to relatively ductile metals, such as low-carbon steel, leaded steels, austenitic stainless steels, wrought aluminum, low-silicon aluminum die casting alloys, zinc die casting alloys, magnesium, copper, and ductile copper alloys. A higher than normal tapping speed can be used, sometimes by as much as 100 percent.

Conventional tap drill sizes should not be used for cold form tapping because the metal is displaced to form the thread. The cold formed thread is stronger than the conventionally tapped thread, so the thread height can be reduced to 60 percent without much loss of strength; however, the use of a 65 percent thread is strongly recommended. The following formula is used to calculate the theoretical hole size for cold form tapping:

$$\text{Theoretical hole size} = \text{basic tap O.D.} - \frac{0.0068 \times \text{per cent of full thread}}{\text{threads per inch}}$$

The theoretical hole size and the tap drill sizes for American Unified threads are given in Table 9, and Table 10 lists drills for ISO metric threads. Sharp drills should be used to prevent cold working the walls of the hole, especially on metals that are prone to work hardening. Such damage may cause the torque to increase, possibly stopping the machine or breaking the tap. On materials that can be die cast, cold form tapping can be done in cored holes provided the correct core pin size is used. The core pins are slightly tapered, so the theoretical hole size should be at the position on the pin that corresponds to one-half of the required engagement length of the thread in the hole. The core pins should be designed to form a chamfer on the hole to accept the vertical extrusion.

**Table 10. Tap Drill or Core Hole Sizes for Cold Form Tapping ISO Metric Threads**

Nominal Size of Tap	Pitch	Recommended Tap Drill Size
1.6 mm	0.35 mm	1.45 mm
1.8 mm	0.35 mm	1.65 mm
2.0 mm	0.40 mm	1.8 mm
2.2 mm	0.45 mm	2.0 mm
2.5 mm	0.45 mm	2.3 mm
3.0 mm	0.50 mm	2.8 mm <sup>1</sup>
3.5 mm	0.60 mm	3.2 mm
4.0 mm	0.70 mm	3.7 mm
4.5 mm	0.75 mm	4.2 mm <sup>1</sup>
5.0 mm	0.80 mm	4.6 mm
6.0 mm	1.00 mm	5.6 mm <sup>1</sup>
7.0 mm	1.00 mm	6.5 mm
8.0 mm	1.25 mm	7.4 mm
10.0 mm	1.50 mm	9.3 mm

<sup>1</sup> These diameters are the nearest stocked drill sizes and not the theoretical hole size, and may not produce 60 to 75 percent full thread.

The sizes are calculated to provide 60 to 75 percent of full thread.

**Removing a Broken Tap.**— Broken taps can be removed by electrodischarge machining (EDM), and this method is recommended when available. When an EDM machine is not available, broken taps may be removed by using a tap extractor, which has fingers that enter the flutes of the tap; the tap is backed out of the hole by turning the extractor with a wrench. Sometimes the injection of a small amount of a proprietary solvent into the hole will be helpful. A solvent can be made by diluting about one part nitric acid with five parts water. The action of the proprietary solvent or the diluted nitric acid on the steel loosens the tap so that it can be removed with pliers or with a tap extractor. The hole should be washed out afterwards so that the acid will not continue to work on the part. Another method is to add, by electric arc welding, additional metal to the shank of the broken tap, above the level of the hole. Care must be taken to prevent depositing metal on the threads in the tapped hole. After the shank has been built up, the head of a bolt or a nut is welded to it and then the tap may be backed out.

### Tap Drills for Pipe Taps

Size of Tap	Drills for Briggs Pipe Taps	Drills for Whitworth Pipe Taps	Size of Tap	Drills for Briggs Pipe Taps	Drills for Whitworth Pipe Taps	Size of Tap	Drills for Briggs Pipe Taps	Drills for Whitworth Pipe Taps

1	1 5/32	1 1/8	3	3 1/4	3 3/32	6	6 3/8	6 1/4

All dimensions are in inches.

To secure the best results, the hole should be reamed before tapping with a reamer having a taper of 3/4 inch per foot.

**Power for Pipe Taps.**— The power required for driving pipe taps is given in the following table, which includes nominal pipe tap sizes from 2 to 8 inches.

The holes to be tapped were reamed with standard pipe tap reamers before tapping. The horsepower recorded was read off just before the tap was reversed. The table gives the net horsepower, deductions being made for the power required to run the machine without a load. The material tapped was cast iron, except in two instances, where cast steel was tapped. It will be seen that nearly double the power is required for tapping cast steel. The

power varies, of course, with the conditions. More power than that indicated in the table will be required if the cast iron is of a harder quality or if the taps are not properly relieved. The taps used in these experiments were of the inserted-blade type, the blades being made of high-speed steel.

### Power Required for Pipe Taps

Nominal Tap Size		Rev. per Min.	Net Power		Thickness of Metal		Nominal Tap Size		Rev. per Min.	Net Power		Thickness of Metal	
inch	mm		H.P.	kW	inch	mm	inch	mm		H.P.	kW	inch	mm

<sup>1</sup>Tapping cast steel; other tests in cast iron.

**High-Speed CNC Tapping.**— Tapping speed depends on the type of material being cut, the type of cutting tool, the speed and rigidity of the machine, the rigidity of the part-holding fixture, and the proper use of coolants and cutting fluids. When tapping, each revolution of the tool feeds the tap a distance equal to the thread pitch. Both spindle speed and feed per revolution must be accurately controlled so that changes in spindle speed result in a corresponding change in feed rate. If the feed/rev is not right, a stripped thread or broken tap will result. NC/CNC machines equipped with the *synchronous tapping* feature are able to control the tap feed as a function of spindle speed. These machines can use rigid-type tap holders or automatic tapping attachments and are able to control depth very accurately. Older NC machines that are unable to reliably coordinate spindle speed and feed must use a tension-compression type tapping head that permits some variation of the spindle speed while still letting the tap feed at the required rate.

CNC machines capable of synchronous tapping accurately coordinate feed rate and rotational speed so that the tap advances at the correct rate regardless of the spindle speed. A canned tapping cycle (see *Right Hand Thread (G84)* and *Left Hand Thread (G74)* on page 1333 in the *CNC NUMERICAL CONTROL PROGRAMMING* section) usually controls the operation, and feed and speed are set by the machine operator or part programmer. Synchronized tapping requires reversing the tapping spindle twice for each hole tapped, once after finishing the cut and again at the end of the cycle. Because the rotating mass is fairly large (motor, spindle, chuck or tap holder, and tap), the acceleration and deceleration of the tap are rather slow and a lot of time is lost by this process. The frequent changes in cutting speed during the cut also accelerate tap wear and reduce tap life.

A self-reversing tapping attachment has a forward drive that rotates in the same direction as the machine spindle, a reverse drive that rotates in the opposite direction, and a neutral position in between the two. When a hole is tapped, the spindle feeds at a slightly slower rate than the tap to keep the forward drive engaged until the tap reaches the bottom of the hole. Through holes are tapped by feeding to the desired depth and then retracting the spindle, which engages the tapping-head reverse drive and backs the tap out of the hole—the spindle does not need to be reversed. For tapping blind holes, the spindle is fed to a depth equal to the thread depth minus the self-feed of the tapping attachment. When the spindle is retracted (without reversing), the tap continues to feed forward a short distance (the tapping head self-feed distance) before the reverse drive engages and reverse drives the tap out of the hole. The depth can be controlled to within about 1/4 revolution of the tap. The tapping cycle normally used for the self-reversing tap attachment is a standard boring cycle with feed return and no dwell. A typical programming cycle is illustrated with a G85 block on page 1333. The inward feed is set to about 95 percent of the normal tapping feed (i.e., 95

percent of the pitch per revolution). Because the tap is lightweight, tap reversal is almost instantaneous and tapping speed is very fast compared with synchronous tapping.

Tapping speeds are usually given in surface feet per minute (sfm) or the equivalent feet per minute (fpm or ft/min), so a conversion is necessary to get the spindle speed in revolutions per minute. The tapping speed in rpm depends on the diameter of the tap, and is given by the following formula:

$$\text{rpm} = \frac{\text{sfm} \times 12}{d \times 3.14159} = \frac{\text{sfm} \times 3.82}{d}$$

where  $d$  is the nominal diameter of the tap in inches. As indicated previously, the feed in in/rev is equal to the thread pitch and is independent of the cutting speed. The feed rate in inches per minute is found by dividing the tapping speed in rpm by the number of threads per inch, or by multiplying the speed in rpm by the pitch or feed per revolution:

$$\text{feed rate (in/min)} = \frac{\text{rpm}}{\text{threads per inch}} = \text{rpm} \times \text{thread pitch} = \text{rpm} \times \text{feed/rev}$$

*Example:* If the recommended tapping speed for 1020 steel is given as 45 to 60 sfm, find the required spindle speed and feed rate for tapping a 1/4-20 UNF thread in 1020 steel.

Assuming that the machine being used is in good condition and rigid, and the tap is sharp, use the higher rate of 60 sfm and calculate the required spindle speed and feed rate as follows:

$$\text{speed} = \frac{60 \times 3.82}{0.25} = 916.8 \approx 920 \text{ rpm} \quad \text{feed rate} = \frac{920}{20} = 46 \text{ in/min}$$

**Coolant for Tapping.**— Proper use of through-the-tap high-pressure coolant/lubricant can result in increased tap life, increased speed and feed, and more accurate threads. In most chip-cutting processes, cutting fluid is used primarily as a coolant, with lubrication being a secondary but important benefit. Tapping, however, requires a cutting fluid with lubricity as the primary property and coolant as a secondary benefit. Consequently, the typical blend of 5 percent coolant concentrate to 95 percent water is too low for best results. An increased percentage of concentrate in the blend helps the fluid to cling to the tap, providing better lubrication at the cutting interface. A method of increasing the tap lubrication qualities without changing the concentration of the primary fluid blend is to use a cutting fluid dispenser controlled by an M code different from that used to control the high-pressure flood coolant (for example, use an M08 code in addition to M07). The secondary coolant-delivery system applies a small amount of an edge-type cutting fluid (about a drop at a time) directly onto the tap-cutting surfaces providing the lubrication needed for cutting. The edge-type fluid applied in this way clings to the tap, increasing the lubrication effect and ensuring that the cutting fluid becomes directly involved in the cutting action at the shear zone.

High-pressure coolant fed through the tap is important in many high-volume tapping applications. The coolant is fed directly through the spindle or tool holder to the cutting zone, greatly improving the process of chip evacuation and resulting in better thread quality. High-pressure through-the-tap coolant flushes blind holes before the tap enters and can remove chips from the holes after tapping is finished. The flushing action prevents chip recutting by forcing chips through the flutes and back out of the hole, improving the surface of the thread and increasing tap life. By improving lubrication and reducing heat and friction, the use of high-pressure coolant may result in increased tap life up to five times that of conventional tapping and may permit speed and feed increases that reduce overall cycle time.

**Combined Drilling and Tapping.**— A special tool that drills and taps in one operation can save a lot of time by reducing setup and eliminating a secondary operation in some

applications. A combination drill and tap can be used for through holes if the length of the fluted drill section is greater than the material thickness, but cannot be used for drilling and tapping blind holes because the tip (drill point) must cut completely through the material before the tapping section begins to cut threads. Drilling and tapping depths up to twice the tool diameter are typical. Determine the appropriate speed by starting the tool at the recommended speed for the tap size and material, and adjust the speed higher or lower to suit the application. Feed during tapping is dependent on the thread pitch. NC/CNC programs can use a fast drilling speed and a slower tapping speed to combine both operations into one and minimize cutting time.

**Relief Angles for Single-Point Thread Cutting Tools.**— The surface finish on threads cut with single-point thread cutting tools is influenced by the relief angles on the tools. The leading and trailing cutting edges that form the sides of the thread, and the cutting edge at the nose of the tool must all be provided with an adequate amount of relief. Moreover, it is recommended that the effective relief angle,  $a_e$ , for all of these cutting edges be made equal, although the practice in some shops is to use slightly less relief at the trailing cutting edge. While too much relief may weaken the cutting edge, causing it to chip, an inadequate amount of relief will result in rough threads and in a shortened tool life. Other factors that influence the finish produced on threads include the following: the work material; the cutting speed; the cutting fluid used; the method used to cut the thread; and the condition of the cutting edge.

Two similar diagrams showing relationships of various relief angles of thread cutting tools

Relief angles on single-point thread cutting tools are often specified on the basis of experience. While this method may give satisfactory results in many instances, better results can usually be obtained by calculating these angles, using the formulas provided further on. When special high helix angle threads are to be cut, the magnitude of the relief angles should always be calculated. These calculations are based on the effective relief angle,  $a_e$ ; this is the angle between the flank of the tool and the sloping sides of the thread, measured in a direction parallel to the axis of the thread. Recommended values of this angle are 8 to 14 degrees for high speed steel tools, and 5 to 10 degrees for cemented carbide tools. The larger values are recommended for cutting threads on soft and gummy materials, and the smaller values are for the harder materials, which inherently take a better surface finish. Harder materials also require more support below the cutting edges, which is provided by using a smaller relief angle. These values are recommended for the relief angle below the cutting edge at the nose without any further modification. The angles below the leading and trailing side cutting edges are modified, using the formulas provided. The angles  $b$  and  $b'$  are the relief angles actually ground on the tool below the leading and trailing side cutting edges respectively; they are measured perpendicular to the side cutting edges. When designing or grinding the thread cutting tool, it is sometimes helpful to know the magnitude of the angle,  $n$ , for which a formula is provided. This angle would occur only in the event that the tool were ground to a sharp point. It is the angle of the edge formed by the intersection of the flank surfaces.

## THREAD CUTTING

$$\tan \phi = \frac{\text{lead of thread}}{\pi K} \quad \tan \phi' = \frac{\text{lead of thread}}{\pi D}$$

$$a = a_e + \phi$$

$$a' = a_e - \phi'$$

$$\tan b = \tan a \cos \frac{1}{2}\omega$$

$$\tan b' = \tan a' \cos \frac{1}{2}\omega$$

$$\tan n = \frac{\tan a - \tan a'}{2 \tan \frac{1}{2}\omega}$$

where  $\theta$  = helix angle of thread at minor diameter

$\theta'$  = helix angle of thread at major diameter

$K$  = minor diameter of thread

$D$  = major diameter of thread

$a$  = side relief angle parallel to thread axis at leading edge of tool

$a'$  = side relief angle parallel to thread axis at trailing edge of tool

$a_e$  = effective relief angle

$b$  = side relief angle perpendicular to leading edge of tool

$b'$  = side relief angle perpendicular to trailing edge of tool

$\omega$  = included angle of thread cutting tool

$n$  = nose angle resulting from intersection of flank surfaces

*Example:* Calculate the relief angles and the nose angle  $n$  for a single-point thread cutting tool that is to be used to cut a 1-inch diameter, 5-threads-per-inch, double Acme thread. The lead of this thread is  $2 \times 0.200 = 0.400$  inch. The included angle  $\omega$  of this thread is 29 degrees, the minor diameter  $K$  is 0.780 inch, and the effective relief angle  $a_e$  below all cutting edges is to be 10 degrees.

$$\tan \phi = \frac{\text{lead of thread}}{\pi K} = \frac{0.400}{\pi \times 0.780}$$

$$\phi = 9.27^\circ (9^\circ 16')$$

$$\tan \phi' = \frac{\text{lead of thread}}{\pi D} = \frac{0.400}{\pi \times 1.000}$$

$$\phi' = 7.26^\circ (7^\circ 15')$$

$$a = a_e + \phi = 10^\circ + 9.27^\circ = 19.27^\circ$$

$$a' = a_e - \phi' = 10^\circ - 7.26^\circ = 2.74^\circ$$

$$\tan b = \tan a \cos \frac{1}{2}\omega = \tan 19.27 \cos 14.5$$

$$b = 18.70^\circ (18^\circ 42')$$

$$\tan b' = \tan a' \cos \frac{1}{2}\omega = \tan 2.74 \cos 14.5$$

$$b' = 2.65^\circ (2^\circ 39')$$

$$\tan n = \frac{\tan a - \tan a'}{2 \tan \frac{1}{2}\omega} = \frac{\tan 19.27 - \tan 2.74}{2 \tan 14.5}$$

$$n = 30.26^\circ (30^\circ 16')$$

**Lathe Change Gears**

**Change Gears for Thread Cutting.**—To determine the change gears to use for cutting a thread of given pitch, first find what number of threads per inch will be cut when gears of the same size are placed on the lead screw and spindle stud, either by trial or by referring to the index plate; then multiply this number, called the “lathe screw constant,” by some trial number to obtain the number of teeth in the gear for the spindle stud, and multiply the threads per inch to be cut by the *same* trial number to obtain the number of teeth in the gear for the lead screw. Expressing this rule as a formula:

$$\frac{\text{Trial number} \times \text{lathe screw constant}}{\text{Trial number} \times \text{threads per inch to be cut}} = \frac{\text{teeth in gear on spindle stud}}{\text{teeth in gear on lead screw}}$$

For example, suppose the available change gears supplied with the lathe have 24, 28, 32, 36 teeth, etc., the number increasing by 4 up to 100, and that 10 threads per inch are to be cut in a lathe having a lathe screw constant of 6; then, if the screw constant is written as the numerator, the number of threads per inch to be cut as the denominator of a fraction, and both numerator and denominator are multiplied by some trial number, say, 4, it is found that gears having 24 and 40 teeth can be used. Thus:

$$\frac{6}{10} = \frac{6 \times 4}{10 \times 4} = \frac{24}{40}$$

The 24-tooth gear goes on the spindle stud and the 40-tooth gear on the lead screw.

The lathe screw constant is, of course, equal to the number of threads per inch on the lead screw, provided the spindle stud and spindle are geared in the ratio of 1 to 1, which, however, is not always so.

**Compound Gearing.**—To find the change gears used in compound gearing, place the screw constant as the numerator and the number of threads per inch to be cut as the denominator of a fraction; resolve both numerator and denominator into two factors each, and multiply each “pair” of factors by the same number, until values are obtained representing suitable numbers of teeth for the change gears. (One factor in the numerator and one in the denominator make a “pair” of factors.)

*Example:*— $1\frac{3}{4}$  threads per inch are to be cut in a lathe having a screw constant of 8; the available gears have 24, 28, 32, 36, 40 teeth, etc., increasing by 4 up to 100. Following the rule:

$$\frac{8}{1\frac{3}{4}} = \frac{2 \times 4}{1 \times 1\frac{3}{4}} = \frac{(2 \times 36) \times (4 \times 16)}{(1 \times 36) \times (1\frac{3}{4} \times 16)} = \frac{72 \times 64}{36 \times 28}$$

The gears having 72 and 64 teeth are the *driving* gears and those with 36 and 28 teeth are the *driven* gears.

**Fractional Threads.**—Sometimes the lead of a thread is given as a fraction of an inch instead of stating the number of threads per inch. For example, a thread may be required to be cut, having  $\frac{3}{8}$  inch lead. The expression “ $\frac{3}{8}$  inch lead” should first be transformed to “number of threads per inch.” The number of threads per inch (the thread being single) equals:

$$\frac{1}{\frac{3}{8}} = 1 \div \frac{3}{8} = \frac{8}{3} = 2\frac{2}{3}$$

To find the change gears to cut  $2\frac{2}{3}$  threads per inch in a lathe having a screw constant 8 and change gears ranging from 24 to 100 teeth, increasing in increments of 4, proceed as below:

$$\frac{8}{2\frac{2}{3}} = \frac{2 \times 4}{1 \times 2\frac{2}{3}} = \frac{(2 \times 36) \times (4 \times 24)}{(1 \times 36) \times (2\frac{2}{3} \times 24)} = \frac{72 \times 96}{36 \times 64}$$

**Change Gears for Metric Pitches.**— When screws are cut in accordance with the metric system, it is the usual practice to give the lead of the thread in millimeters, instead of the number of threads per unit of measurement. To find the change gears for cutting metric threads, when using a lathe having an inch lead screw, first determine the number of threads per inch corresponding to the given lead in millimeters. Suppose a thread of 3 millimeters lead is to be cut in a lathe having an inch lead screw and a screw constant of 6. As there are 25.4 millimeters per inch, the number of threads per inch will equal  $25.4 \div 3$ . Place the screw constant as the numerator, and the number of threads per inch to be cut as the denominator:

$$\frac{6}{\frac{25.4}{3}} = 6 \div \frac{25.4}{3} = \frac{6 \times 3}{25.4}$$

The numerator and denominator of this fractional expression of the change gear ratio is next multiplied by some trial number to determine the size of the gears. The first whole number by which 25.4 can be multiplied so as to get a whole number as the result is 5. Thus,  $25.4 \times 5 = 127$ . Hence, one gear having 127 teeth is always used when cutting metric threads with an inch lead screw. The other gear required has 90 teeth. Thus:

$$\frac{6 \times 3 \times 5}{25.4 \times 5} = \frac{90}{127}$$

Therefore, the following rule can be used to find the change gears for cutting metric pitches with an inch lead screw:

*Rule:* Place the lathe screw constant multiplied by the lead of the required thread in millimeters multiplied by 5 as the numerator of the fraction and 127 as the denominator. The product of the numbers in the numerator equals the number of teeth for the spindle-stud gear, and 127 is the number of teeth for the lead-screw gear.

If the lathe has a metric pitch lead screw, and a screw having a given number of threads per inch is to be cut, first find the “metric screw constant” of the lathe or the lead of thread in millimeters that would be cut with change gears of equal size on the lead screw and spindle stud; then the method of determining the change gears is simply the reverse of the one already explained for cutting a metric thread with an inch lead screw.

*Rule:* To find the change gears for cutting inch threads with a metric lead screw, place 127 in the numerator and the threads per inch to be cut, multiplied by the metric screw constant multiplied by 5, in the denominator; 127 is the number of teeth on the spindle-stud gear and the product of the numbers in the denominator equals the number of teeth in the lead-screw gear.

**Threads per Inch Obtained with a Given Combination of Gears.**— To determine the number of threads per inch that will be obtained with a given combination of gearing, multiply the lathe screw constant by the number of teeth in the *driven* gear (or by the product of the numbers of teeth in both driven gears of compound gearing), and divide the product thus obtained by the number of teeth in the *driving* gear (or by the product of the two driving gears of a compound train). The quotient equals the number of threads per inch.

**Change Gears for Fractional Ratios.**— When gear ratios cannot be expressed exactly in whole numbers that are within the range of ordinary gearing, the combination of gearing required for the fractional ratio may be determined quite easily, often by the “cancellation method.” To illustrate this method, assume that the speeds of two gears are to be in the ratio of 3.423 to 1. The number 3.423 is first changed to  $\frac{3423}{1000}$  to clear it of decimals. Then, in order to secure a fraction that can be reduced, 3423 is changed to 3420;

$$\frac{3420}{1000} = \frac{342}{100} = \frac{3 \times 2 \times 57}{2 \times 50} = \frac{3 \times 57}{1 \times 50}$$

Then, multiplying  $\frac{3}{1}$  by some trial number, say, 24, the following gear combination is obtained:

$$\frac{72}{24} \times \frac{57}{50} = \frac{4104}{1200} = \frac{3.42}{1}$$

As the desired ratio is 3.423 to 1, there is an error of 0.003. When the ratios are comparatively simple, the cancellation method is not difficult and is frequently used; but by the logarithmic method to be described, more accurate results are usually possible.

**Modifying the Quick-Change Gearbox Output.**—On most modern lathes, the gear train connecting the headstock spindle with the lead screw contains a quick-change gearbox. Instead of using different change gears, it is only necessary to position the handles of the gearbox to adjust the speed ratio between the spindle and the lead screw in preparation for cutting a thread. However, a thread sometimes must be cut for which there is no quick-change gearbox setting. It is then necessary to modify the normal, or standard, gear ratio between the spindle and the gearbox by installing modifying change gears to replace the standard gears normally used. Metric and other odd pitch threads can be cut on lathes that have an inch thread lead screw and a quick-change gearbox having only settings for inch threads by using modifying-change gears in the gear train. Likewise, inch threads and other odd pitch threads can be cut on metric lead-screw lathes having a gearbox on which only metric thread settings can be made. Modifying-change gears also can be used for cutting odd pitch threads on lathes having a quick-change gearbox that has both inch and metric thread settings.

The sizes of the modifying-change gears can be calculated by formulas to be given later; they depend on the thread to be cut and on the setting of the quick-change gearbox. Many different sets of gears can be found for each thread to be cut. It is recommended that several calculations be made in order to find the set of gears that is most suitable for installation on the lathe. The modifying-change gear formulas that follow are based on the type of lead screw, i.e., whether the lead screw has inch or metric threads.

*Metric Threads on Inch Lead-Screw Lathes:* A 127-tooth translating gear must be used in the modifying-change gear train in order to be able to cut metric threads on inch lead-screw lathes. The formula for calculating the modifying change gears is:

$$\frac{5 \times \text{gearbox setting in thds/in.} \times \text{pitch in mm to be cut}}{127} = \frac{\text{driving gears}}{\text{driven gears}}$$

The numerator and denominator of this formula are multiplied by equal numbers, called trial numbers, to find the gears. If suitable gears cannot be found with one set, then another set of equal trial numbers is used. (Because these numbers are equal, such as 15/15 or 24/24, they are equal to the number one when thought of as a fraction; their inclusion has the effect of multiplying the formula by one, which does not change its value.) It is necessary to select the gearbox setting in threads per inch that must be used to cut the metric thread when using the gears calculated by the formula. One method is to select a quick-change gearbox setting that is close to the actual number of metric threads in a 1-inch length, called the equivalent threads per inch, which can be calculated by the following formula: Equivalent thds/in. = 25.4 ÷ pitch in millimeters to be cut.

*Example:* Select the quick-change gearbox setting and calculate the modifying change gears required to set up a lathe having an inch-thread lead screw in order to cut an M12 × 1.75 metric thread.

## THREAD CUTTING

$$\begin{aligned} \text{Equivalent thds/in.} &= \frac{25.4}{\text{pitch in mm to be cut}} = \frac{25.4}{1.75} = 1.45 \text{ (use 14 thds/in.)} \\ \frac{5 \times \text{gearbox setting in thds/in.} \times \text{pitch in mm to be cut}}{127} &= \frac{5 \times 14 \times 1.75}{127} \\ &= \frac{(24) \times 5 \times 14 \times 1.75}{(24) \times 127} = \frac{(5 \times 14) \times (24 \times 1.75)}{24 \times 127} \\ &= \frac{70 \times 42}{24 \times 127} = \frac{\text{driving gears}}{\text{driven gears}} \end{aligned}$$

*Odd Inch Pitch Threads:* The calculation of the modifying change gears used for cutting odd pitch threads that are specified by their pitch in inches involves the sizes of the standard gears, which can be found by counting their teeth. Standard gears are those used to enable the lathe to cut the thread for which the gearbox setting is made; they are the gears that are normally used. The threads on worms used with worm gears are among the odd pitch threads that can be cut by this method. As before, it is usually advisable to calculate the actual number of threads per inch of the odd pitch thread and to select a gearbox setting that is close to this value. The following formula is used to calculate the modifying-change gears to cut odd inch pitch threads:

$$\begin{aligned} \frac{\text{Standard driving gear} \times \text{pitch to be cut in inches} \times \text{gearbox setting in thds/in.}}{\text{Standard driven gear}} \\ = \frac{\text{driving gears}}{\text{driven gears}} \end{aligned}$$

*Example:* Select the quick-change gearbox setting and calculate the modifying change gears required to cut a thread having a pitch equal to 0.195 inch. The standard driving and driven gears both have 48 teeth. To find equivalent threads per inch:

$$\frac{\text{Thds}}{\text{in.}} = \frac{1}{\text{pitch}} = \frac{1}{0.195} = 5.13 \quad (\text{use 5 thds/in.})$$

$$\begin{aligned} \frac{\text{Standard driving gear} \times \text{pitch to be cut in inches} \times \text{gearbox setting in thds/in.}}{\text{Standard driven gear}} \\ = \frac{48 \times 0.195 \times 5}{48} = \frac{(1000) \times 0.195 \times 5}{(1000)} = \frac{195 \times 5}{500 \times 2} = \frac{39 \times 5}{100 \times 2} = \frac{39 \times 5 \times (8)}{50 \times 2 \times 2 \times (8)} \\ = \frac{39 \times 40}{50 \times 32} = \frac{\text{driving gears}}{\text{driven gears}} \end{aligned}$$

It will be noted that in the second step above, 1000/1000 has been substituted for 48/48. This substitution does not change the ratio. The reason for this substitution is that  $1000 \times 0.195 = 195$ , a whole number. Actually,  $200/200$  might have been substituted because  $200 \times 0.195 = 39$ , also a whole number.

The procedure for calculating the modifying gears using the following formulas is the same as illustrated by the two previous examples.

*Odd Threads per Inch on Inch Lead Screw Lathes:*

$$\frac{\text{Standard driving gear} \times \text{gearbox setting in thds/in.}}{\text{Standard driven gear} \times \text{thds/in. to be cut}} = \frac{\text{driving gears}}{\text{driven gears}}$$

*Inch Threads on Metric Lead Screw Lathes:*

$$\frac{127}{5 \times \text{gearbox setting in mm pitch} \times \text{thds/in. to be cut}} = \frac{\text{driving gears}}{\text{driven gears}}$$

*Odd Metric Pitch Threads on Metric Lead Screw Lathes:*

$$\frac{\text{Standard driving gear} \times \text{mm pitch to be cut}}{\text{Standard driven gear} \times \text{gearbox setting in mm pitch}} = \frac{\text{driving gears}}{\text{driven gears}}$$

**Finding Accurate Gear Ratios.**— Tables included in the 23rd and earlier editions of this handbook furnished a series of logarithms of gear ratios as a quick means of finding ratios for all gear combinations having 15 to 120 teeth. The ratios thus determined could be factored into sets of 2, 4, 6, or any other even numbers of gears to provide a desired overall ratio.

Although the method of using logarithms of gear ratios provides results of suitable accuracy for many gear-ratio problems, it does not provide a systematic means of evaluating whether other, more accurate ratios are available. In critical applications, especially in the design of mechanisms using reduction gear trains, it may be desirable to find many or all possible ratios to meet a specified accuracy requirement. The methods best suited to such problems use *Continued Fractions* and *Conjugate Fractions* as explained starting on starting on page 3110 in the *ADDITIONAL* material on *Machinery's Handbook 30 CD* and illustrated in the worked-out example on page 3111 for a set of four change gears.

As an example, if an overall reduction of 0.31416 is required, a fraction must be found such that the factors of the numerator and denominator may be used to form a four-gear reduction train in which no gear has more than 120 teeth. By using the method of conjugate fractions discussed on page 3111, the ratios listed above and their factors are found to be successively closer approximations to the required overall gear ratio.

Ratio	Numerator Factors	Denominator	Error Factors
11/35	11	5 × 7	+0.00013
16/51	2 × 2 × 2 × 2	3 × 17	-0.00043
27/86	3 × 3 × 3	2 × 43	-0.00021
38/121	2 × 19	11 × 11	-0.00011
49/156	7 × 7	2 × 2 × 3 × 13	-0.00006
82/261	2 × 41	3 × 3 × 29	+0.00002
224/713	2 × 2 × 2 × 2 × 2 × 7	23 × 31	+0.000005
437/1391	19 × 23	13 × 107	+0.000002
721/2295	7 × 103	3 × 3 × 3 × 5 × 17	+0.000001
1360/4329	2 × 2 × 2 × 2 × 17	3 × 3 × 13 × 53	+0.0000003
1715/5459	5 × 7 × 7 × 7	53 × 103	+0.0000001
3927/12500	3 × 7 × 11 × 17	2 × 2 × 5 × 5 × 5 × 5 × 5	0

**Lathe Change-gears.**— To calculate the change gears to cut any pitch on a lathe, the “constant” of the machine must be known. For any lathe, the ratio  $C:L$  = driver:driven gear, in which  $C$  = constant of machine and  $L$  = threads per inch.

For example, to find the change gears required to cut 1.7345 threads per inch on a lathe having a constant of 4, the formula:

$$\frac{C}{L} = \frac{4}{1.7345} = 2.306140$$

may be used. The method of conjugate fractions shown on page 3111 will find the ratio,  $113/49 = 2.306122$ , which is closer than any other having suitable factors. This ratio is in error by only  $2.306140 - 2.306122 = 0.000018$ . Therefore, the driver should have 113 teeth and the driven gear 49 teeth.

**Relieving Helical-Fluted Hobs.**—Relieving hobs that have been fluted at right angles to the thread is another example of approximating a required change-gear ratio. The usual method is to change the angle of the helical flutes to agree with previously calculated change-gears. The ratio between the hob and the relieving attachment is expressed in the formula:

$$\frac{N}{(C \times \cos^2 \alpha)} = \frac{\text{driver}}{\text{driven}} \text{ gears}$$

and

$$\tan \alpha = \frac{P}{H_c}$$

in which:  $N$  = number of flutes in hob;  $\alpha$  = helix angle of thread from plane perpendicular to axis;  $C$  = constant of relieving attachment;  $P$  = axial lead of hob; and  $H_c$  = hob pitch circumference, = 3.1416 times pitch diameter.

The constant of the relieving attachment is found on its index plate and is determined by the number of flutes that require equal gears on the change-gear studs. These values will vary with different makes of lathes.

For example, what four change-gears can be used to relieve a helical-fluted worm-gear hob, of 24 diametral pitch, six starts, 13 degrees, 41 minutes helix angle of thread, with eleven helical flutes, assuming a relieving attachment having a constant of 4 is to be used?

$$\frac{N}{(C \times \cos^2 \alpha)} = \frac{11}{(4 \times \cos^2 13^\circ 41')} = \frac{11}{(4 \times 0.944045)} = 2.913136$$

Using the conjugate fractions method discussed on page 3111, the following ratios are found to provide factors that are successively closer approximations to the required change-gear ratio 2.913136.

<i>Numerator/Denominator</i>	<i>Ratio</i>	<i>Error</i>
$67 \times 78 / (39 \times 46)$	2.913043	-0.000093
$30 \times 47 / (22 \times 22)$	2.913223	+0.000087
$80 \times 26 / (21 \times 34)$	2.913165	+0.000029
$27 \times 82 / (20 \times 38)$	2.913158	+0.000021
$55 \times 75 / (24 \times 59)$	2.913136	+0.0000004
$74 \times 92 / (57 \times 41)$	2.913136	+0.00000005

## THREAD ROLLING

Screw threads may be formed by rolling either by using some type of thread-rolling machine or by equipping an automatic screw machine or turret lathe with a suitable threading roll. If a thread-rolling machine is used, the unthreaded screw, bolt, or other "blank" is placed (either automatically or by hand) between dies having thread-shaped ridges that sink into the blank, and by displacing the metal, form a thread of the required shape and pitch. The thread-rolling process is applied where bolts, screws, studs, threaded rods, etc., are required in large quantities. Screw threads that are within the range of the rolling process may be produced more rapidly by this method than in any other way. Because of the cold-working action of the dies, the rolled thread is 10 to 20 percent stronger than a cut or ground thread, and the increase may be much higher for fatigue resistance. Other advantages of the rolling process are that no stock is wasted in forming the thread, and the surface of a rolled thread is harder than that of a cut thread, thus increasing wear resistance.

**Thread-Rolling Machine of Flat-Die Type.**— One type of machine that is used extensively for thread rolling is equipped with a pair of flat or straight dies. One die is stationary and the other has a reciprocating movement when the machine is in use. The ridges on these dies, which form the screw thread, incline at an angle equal to the helix angle of the thread. In making dies for precision thread rolling, the threads may be formed either by milling and grinding after heat treatment, or by grinding "from the solid" after heat treating. A vitrified wheel is used.

In a thread-rolling machine, thread is formed in one passage of the work, which is inserted at one end of the dies, either by hand or automatically, and then rolls between the die faces until it is ejected at the opposite end. The relation between the position of the dies and a screw thread being rolled is such that the top of the thread-shaped ridge of one die, at the point of contact with the screw thread, is directly opposite the bottom of the thread groove in the other die at the point of contact. Some form of mechanism ensures starting the blank at the right time and square with the dies.

**Thread-Rolling Machine of Cylindrical-Die Type.**— With machines of this type, the blank is threaded while being rolled between two or three cylindrical dies (depending upon the type of machine) that are pressed into the blank at a rate of penetration adjusted to the hardness of the material, or wall thickness in threading operations on tubing or hollow parts. The dies have ground, or ground and lapped, threads and a pitch diameter that is a multiple of the pitch diameter of the thread to be rolled. As the dies are much larger in diameter than the work, a multiple thread is required to obtain the same lead angle as that of the work. The thread may be formed in one die revolution or even less, or several revolutions may be required (as in rolling hard materials) to obtain a gradual rate of penetration equivalent to that obtained with flat or straight dies if extended to a length of possibly 15 or 20 feet (4.6 or 6 m). Provisions for accurately adjusting or matching the thread rolls to bring them into proper alignment with each other are important features of these machines.

*Two-Roll Type of Machine:* With a two-roll type of machine, the work is rotated between two horizontal power-driven threading rolls and is supported by a hardened rest bar on the lower side. One roll is fed inward by hydraulic pressure to a depth that is governed automatically.

*Three-Roll Type of Machine:* With this machine, the blank to be threaded is held in a "floating position" while being rolled between three cylindrical dies that, through toggle arms, are moved inward at a predetermined rate of penetration until the required pitch diameter is obtained. The die movement is governed by a cam driven through change gears selected to give the required cycle of squeeze, dwell, and release.

**Rate of Production.**— Production rates in thread rolling depend upon the type of machine, the size of both machine and work, and whether the parts to be threaded are inserted by hand or automatically. A reciprocating flat die type of machine, applied to ordinary steels, may thread 30 or 40 parts per minute in diameters ranging from about  $\frac{5}{8}$  to  $1\frac{1}{2}$

inch (15.875–28.575 mm), and 150 to 175 per minute in machine screw sizes from No. 10 (.190 inch) to No. 6 (.138 inch). In the case of heat-treated alloy steels in the usual hardness range of 26 to 32 Rockwell C, the production may be 30 or 40 per minute or less. With a cylindrical die type of machine, which is designed primarily for precision work and hard metals, 10 to 30 parts per minute are common production rates, the amount depending upon the hardness of material and allowable rate of die penetration per work revolution. These production rates are intended as a general guide only. The diameters of rolled threads usually range from the smallest machine screw sizes up to 1 or 1½ inches (25.4 or 38.1 mm), depending upon the type and size of machine.

**Precision Thread Rolling.**— Both flat and cylindrical dies are used in aeronautical and other plants for precision work. With accurate dies and blank diameters held to close limits, it is practicable to produce rolled threads for American Standard Class 3 and Class 4 fits. The blank sizing may be by centerless grinding or by means of a die in conjunction with the heading operations. The blank should be round, and, as a general rule, the diameter tolerance should not exceed  $\frac{1}{2}$  to  $\frac{2}{3}$  the pitch diameter tolerance. The blank diameter should range from the correct size (which is close to the pitch diameter, but should be determined by actual trial), down to the allowable minimum, the tolerance being minus to insure a correct pitch diameter, even though the major diameter may vary slightly. Precision thread rolling has become an important method of threading alloy steel studs and other threaded parts, especially in aeronautical work where precision and high-fatigue resistance are required. Micrometer screws are also an outstanding example of precision thread rolling. This process has also been applied in tap making, although it is the general practice to finish rolled taps by grinding when the Class 3 and Class 4 fits are required.

**Steels for Thread Rolling.**— Steels vary from soft low-carbon types for ordinary screws and bolts, to nickel, nickel-chromium and molybdenum steels for aircraft studs, bolts, etc., or for any work requiring exceptional strength and fatigue resistance. Typical SAE alloy steels are No. 2330, 3135, 3140, 4027, 4042, 4640 and 6160. The hardness of these steels after heat-treatment usually ranges from 26 to 32 Rockwell C, with tensile strengths varying from 130,000 to 150,000 psi (896–1034 MPa). While harder materials might be rolled, grinding is more practicable when the hardness exceeds 40 Rockwell C. Thread rolling is applicable not only to a wide range of steels but for non-ferrous materials, especially if there is difficulty in cutting due to “tearing” the threads.

**Diameter of Blank for Thread Rolling.**— The diameter of the screw blank or cylindrical part upon which a thread is to be rolled should be less than the outside screw diameter by an amount that will just compensate for the metal that is displaced and raised above the original surface by the rolling process. The increase in diameter is approximately equal to the depth of one thread. While there are rules and formulas for determining blank diameters, it may be necessary to make slight changes in the calculated size in order to secure a well-formed thread. Blank diameter should be verified by trial, especially when rolling accurate screw threads. Some stock offers greater resistance to displacement than other stock, owing to greater hardness or tenacity of the metal. The following figures may prove useful in establishing trial sizes. The blank diameters for screws varying from  $\frac{1}{4}$  to  $\frac{1}{2}$  inch are from 0.002 to 0.0025 inch (50.8–63.5  $\mu\text{m}$ ) larger than the pitch diameter, and for screws varying from  $\frac{1}{2}$  to 1 inch (12.7–25.4 mm) or larger, the blank diameters are from 0.0025 to .003 inch (63.5–76.2  $\mu\text{m}$ ) larger than the pitch diameter. Blanks which are slightly less than the pitch diameter are intended for bolts, screws, etc., which are to have a comparatively free fit. Blanks for this class of work may vary from 0.002 to 0.003 inch (50.08–76.2  $\mu\text{m}$ ) less than the pitch diameter for screw thread sizes varying from  $\frac{1}{4}$  to  $\frac{1}{2}$  inch (6.35–12.7  $\mu\text{m}$ ), and from 0.003 to 0.005 inch (76.2–127  $\mu\text{m}$ ) less than the pitch diameter for sizes above  $\frac{1}{2}$  inch. If the screw threads are smaller than  $\frac{1}{4}$  inch, the blanks are usually from 0.001 to 0.0015 inch (25.4–38.1  $\mu\text{m}$ ) less than the pitch diameter for ordinary grades of work.

**Thread Rolling in Automatic Screw Machines.**—Screw threads are sometimes rolled in automatic screw machines and turret lathes when the thread is behind a shoulder so that it cannot be cut with a die. In such cases, the advantage of rolling the thread is that a second operation is avoided. A circular roll is used for rolling threads in screw machines. The roll may be presented to the work either in a tangential direction or radially, either method producing a satisfactory thread. In the former case, the roll gradually comes into contact with the periphery of the work and completes the thread as it passes across the surface to be threaded. When the roll is held in a radial position, it is simply forced against one side until a complete thread is formed. The method of applying the roll may depend upon the relation between the threading operation and other machining operations. Thread rolling in automatic screw machines is generally applied only to brass and other relatively soft metals, owing to the difficulty of rolling threads in steel. Thread rolls made of chrome-nickel steel containing from 0.15 to 0.20 percent of carbon have given fairly good results, however, when applied to steel. A 3 percent nickel steel containing about 0.12 percent carbon has also proved satisfactory for threading brass.

**Factors Governing the Diameter of Thread Rolling.**—The threading roll used in screw machines may be about the same diameter as the screw thread, but for sizes smaller than, say,  $\frac{3}{4}$  inch (19.05 mm), the roll diameter is some multiple of the thread diameter minus a slight amount to obtain a better rolling action. When the diameters of the thread and roll are practically the same, a single-threaded roll is used to form a single thread on the screw. If the diameter of the roll is made double that of the screw, in order to avoid using a small roll, then the roll must have a double thread. If the thread roll is three times the size of the screw thread, a triple thread is used, and so on. These multiple threads are necessary when the roll diameter is some multiple of the work, in order to obtain corresponding helix angles on the roll and work.

**Diameter of Threading Roll.**—The pitch diameter of a threading roll having a single thread is slightly less than the pitch diameter of the screw thread to be rolled, and in the case of multiple-thread rolls, the pitch diameter is not an exact multiple of the screw thread pitch diameter but is also reduced somewhat. The amount of reduction recommended by one screw machine manufacturer is given by the formula shown at the end of this paragraph. A description of the terms used in the formula is given as follows:  $D$  = pitch diameter of threading roll,  $d$  = pitch diameter of screw thread,  $N$  = number of single threads or “starts” on the roll (this number is selected with reference to diameter of roll desired),  $T$  = single depth of thread:

$$D = N\left(d - \frac{T}{2}\right) - T$$

*Example:* Find, by using above formula, the pitch diameter of a double-thread roll for rolling a  $\frac{1}{2}$ -inch American standard screw thread. Pitch diameter  $d = 0.4500$  inch and thread depth  $T = 0.0499$  inch.

$$D = 2\left(0.4500 - \frac{0.0499}{2}\right) - 0.0499 = 0.8001 \text{ inch}$$

**Kind of Thread on Roll and Its Shape.**—The thread (or threads) on the roll should be left hand for rolling a right-hand thread, and *vice versa*. The roll should be wide enough to overlap the part to be threaded, provided there are clearance spaces at the ends, which should be formed if possible. The thread on the roll should be sharp on top for rolling an American (National) standard form of thread, so that less pressure will be required to displace the metal when rolling the thread. The bottom of the thread groove on the roll may also be left sharp or it may have a flat. If the bottom is sharp, the roll is sunk only far enough into the blank to form a thread having a flat top, assuming that the thread is the American form. The number of threads on the roll (whether double, triple, quadruple, etc.) is

selected, as a rule, so that the diameter of the thread roll will be somewhere between  $1\frac{1}{4}$  and  $2\frac{1}{4}$  inches (31.75–57.15 mm). In making a thread roll, the ends are beveled at an angle of 45 degrees, to prevent the threads on the ends of the roll from chipping. Precautions should be taken in hardening, because, if the sharp edges are burnt, the roll will be useless. Thread rolls are usually lapped after hardening, by holding them on an arbor in the lathe and using emery and oil on a piece of hard wood. To give good results a thread roll should fit closely in the holder. If the roll is made to fit loosely, it will mar the threads.

**Application of Thread Roll.**— The shape of the work and the character of the operations necessary to produce it, govern, to a large extent, the method employed in applying the thread roll. Some of the points to consider are as follows:

- 1) Diameter of the part to be threaded.
- 2) Location of the part to be threaded.
- 3) Length of the part to be threaded.
- 4) Relation that the thread rolling operation bears to the other operations.
- 5) Shape of the part to be threaded, whether straight, tapered or otherwise.
- 6) Method of applying the support.

When the diameter to be rolled is much smaller than the diameter of the shoulder preceding it, a cross-slide knurl-holder should be used. If the part to be threaded is not behind a shoulder, a holder on the swing principle should be used. When the work is long (greater in length than two-and-one-half times its diameter) a swing roll-holder should be employed, carrying a support. When the work can be cut off after the thread is rolled, a cross-slide roll-holder should be used. The method of applying the support to the work also governs to some extent the method of applying the thread roll. When no other tool is working at the same time as the thread roll, and when there is freedom from chips, the roll can be held more rigidly by passing it under instead of over the work. When passing the roll over the work, there is a tendency to raise the cross-slide. Where the part to be threaded is tapered, the roll can best be presented to the work by holding it in a cross-slide roll-holder.

**Tolerances on Wire for Thread Rolling.**— The wire mills will accept a tolerance specification of plus or minus 0.002 inch (50.8 mm) on the diameter. It is particularly important that this tolerance be maintained on stock used for long screws of small diameter. On screws of short length the material will flow, and if the wire is over size little trouble will be experienced, but in the case of screws having a length greater than ten times their diameter, the material will be confined, and “burning” will take place, if the tolerance is greater than that specified. If the wire is slightly under size, the rolled threads will have a ragged appearance due to the fact that the crest is not fully formed. On screws under the No. 10-24 size, a tolerance of plus or minus 0.001 inch should be adhered to in order to ensure good results.

**Speeds and Feeds for Thread Rolling.**— When the thread roll is made from high-carbon steel and used on brass, a surface speed as high as 200 feet per minute can be used. However, better results are obtained by using a lower speed than this. When the roll is held in a holder attached to the cross-slide, and is presented either tangentially or radially to the work, a considerably higher speed can be used than if it is held in a swing tool. This is due to the lack of rigidity in a holder of the swing type. The feeds to be used when a cross-slide roll-holder is used are given in the upper half of the table “Feeds for Thread Rolling;” the lower half of the table gives the feeds for thread rolling with swing tools. These feeds are applicable for rolling threads without a support, when the root diameter of the blank is not less than five times the double depth of the thread. When the root diameter is less than this, a support should be used. A support should also be used when the width of the roll is more than two-and-one-half times the smallest diameter of the piece to be rolled, irrespective of the pitch of the thread. When the smallest diameter of the piece to be rolled is much less than the root diameter of the thread, the smallest diameter should be taken as the deciding factor for the feed to be used.

THREAD ROLLING

2111

## THREAD GRINDING

Thread grinding is employed for precision tool and gage work and also in producing certain classes of threaded parts.

Thread grinding may be utilized 1) because of the accuracy and finish obtained; 2) hardness of material to be threaded; and 3) economy in grinding certain classes of screw threads when using modern machines, wheels, and thread-grinding oils.

In some cases pre-cut threads are finished by grinding; but usually, threads are ground "from the solid," being formed entirely by the grinding process. Examples of work include thread gages and taps of steel and tungsten carbide, hobs, worms, lead-screws, adjusting or traversing screws, alloy steel studs, etc. Grinding is applied to external, internal, straight, and tapering threads, and to various thread forms.

**Accuracy Obtainable by Thread Grinding.**— With single-edge or single-ribbed wheels it is possible to grind threads on gages to a degree of accuracy that requires but very little lapping to produce a so-called "master" thread gage. As far as lead is concerned, some thread grinding machine manufacturers guarantee to hold the lead within 0.0001 inch per inch (or mm per mm) of thread; and while it is not guaranteed that a higher degree of accuracy for lead is obtainable, it is known that threads have been ground to closer tolerances than this on the lead. Pitch diameter accuracies for either Class 3 or Class 4 fits are obtainable according to the grinding method used; with single-edge wheels, the thread angle can be ground to an accuracy of within two or three minutes in half the angle.

**Wheels for Thread Grinding.**— The wheels used for steel have an aluminous abrasive and, ordinarily, either a resinoid bond or a vitrified bond. The general rule is to use resinoid wheels when extreme tolerances are not required, and it is desirable to form the thread with a minimum number of passes, as in grinding threaded machine parts, such as studs, adjusting screws which are not calibrated, and for some classes of taps. *Resinoid wheels*, as a rule, will hold a fine edge longer than a vitrified wheel but they are more flexible and, consequently, less suitable for accurate work, especially when there is lateral grinding pressure that causes wheel deflection. *Vitrified wheels* are utilized for obtaining extreme accuracy in thread form and lead because they are very rigid and not easily deflected by side pressure in grinding. This rigidity is especially important in grinding pre-cut threads on such work as gages, taps and lead-screws. The progressive lead errors in long lead-screws, for example, might cause an increasing lateral pressure that would deflect a resinoid wheel. Vitrified wheels are also recommended for internal grinding.

*Diamond Wheels:* Diamond wheels set in a rubber or plastic bond are also used for thread grinding, especially for grinding threads in carbide materials and in other hardened alloys. Thread grinding is now being done successfully on a commercial basis on both taps and gages made from carbides. Gear hobs made from carbides have also been tested with successful results. Diamond wheels are dressed by means of silicon-carbide grinding wheels which travel past the diamond-wheel thread form at the angle required for the flanks of the thread to be ground. The action of the dressing wheels is, perhaps, best described as a "scrubbing" of the bond which holds the diamond grits. Obviously, the silicon-carbide wheels do not dress the diamonds, but they loosen the bond until the diamonds no longer wanted drop out.

**Thread Grinding with Single-Edge Wheel.**— With this type of wheel, the edge is trued to the cross-sectional shape of the thread groove. The wheel, when new, may have a diameter of 18 or 20 inches (45.7 or 50.8 cm) and, when grinding a thread, the wheel is inclined to align it with the thread groove. On some machines, lead variations are obtained by means of change-gears which transmit motion from the work-driving spindle to the lead-screw. Other machines are so designed that a lead-screw is selected to suit the lead of thread to be ground and transmits motion directly to the work-driving spindle.

**Wheels with Edges for Roughing and Finishing.**— The “three-ribbed” type of wheel has a roughing edge or rib which removes about two-thirds of the metal. This is followed by an intermediate rib which leaves about 0.005 inch (127  $\mu$ m) for the third or finishing rib. The accuracy obtained with this triple-edge type compares with that of a single-edge wheel, which means that it may be used for the greatest accuracy obtainable in thread grinding.

When the accuracy required makes it necessary, this wheel can be inclined to the helix angle of the thread, the same as is the single-edge wheel.

The three-ribbed wheel is recommended not only for precision work but for grinding threads which are too long for the multi-ribbed wheel referred to later. It is also well adapted to tap grinding, because it is possible to dress a portion of the wheel adjacent to the finish rib for the purpose of grinding the outside diameter of the thread, as indicated in Fig. 1. Furthermore, the wheel can be dressed for grinding or relieving both crests and flanks at the same time.

Fig. 1. Wheel with Edges for Roughing and Finishing

Fig. 2. Multi-ribbed Type of Thread-grinding Wheel

Fig. 3. Alternate-ribbed Wheel for Grinding the Finer Pitches

**Multi-ribbed Wheels.**— This type of wheel is employed when rapid production is more important than extreme accuracy, which means that it is intended primarily for the grinding of duplicate parts in manufacturing. A wheel  $1\frac{1}{4}$  to 2 inches (3.175–5.08 cm) wide has formed upon its face a series of annular thread-shaped ridges (see Fig. 2); hence, if the length of the thread is not greater than the wheel width, a thread may be ground in one work revolution plus about one-half revolution for feeding in and withdrawing the wheel. The principle of operation is the same as that of thread milling with a multiple type cutter. This type of wheel is not inclined to the lead angle. To obtain a Class 3 fit, the lead angle should not exceed 4 degrees.

It is not practicable to use this form of wheel on thread pitches where the root is less than 0.007 inch (177.8 mm) wide, because of difficulties in wheel dressing. When this method can be applied, it is the fastest means known of producing threads in hardened materials. It is not recommended, however, that thread gages, taps, and work of this character be ground with multi-ribbed wheels. The single-ribbed wheel has a definite field for accurate, small-lot production.

It is necessary, in multi-ribbed grinding, to use more horsepower than is required for single-ribbed wheel grinding. Coarse threads, in particular, may require a wheel motor with two or three times more horsepower than would be necessary for grinding with a single-ribbed wheel.

**Alternate-ribbed Wheel for Fine Pitches.**— The spacing of ribs on this type of wheel (Fig. 3) equals twice the pitch, so that during the first revolution every other thread groove section is being ground; consequently, about two and one-half work revolutions are required for grinding a complete thread, but the better distribution of cooling oil and resulting increase in work speeds makes this wheel very efficient. This alternate-type of wheel is adapted for grinding threads of fine pitch. Since these wheels cannot be tipped to the helix angle of the thread, they are not recommended for anything closer than Class 3 fits. The “three-ribbed” wheels referred to in a previous paragraph are also made in the alternate type for the finer pitches.

**Grinding Threads “from the Solid”.**— The process of forming threads entirely by grinding, or without preliminary cutting, is applied both in the manufacture of certain classes of threaded parts and also in the production of precision tools, such as taps and thread gages. For example, in airplane engine manufacture, certain parts are heat-treated and then the threads are ground “from the solid,” thus eliminating distortion. Minute cracks are sometimes found at the roots of threads that were cut and then hardened, or ground from the solid. Steel threads of coarse pitch that are to be surface hardened, may be rough threaded by cutting, then hardened and finally corrected by grinding. Many ground thread taps are produced by grinding from the solid after heat-treatment. Hardening high-speed steel taps before the thread is formed will ensure there are no narrow or delicate crests to interfere with the application of the high temperature required for uniform hardness and the best steel structure.

**Number of Wheel Passes.**— The number of cuts or passes for grinding from the solid depends upon the type of wheel and accuracy required. In general, threads of 12 or 14 per inch and finer may be ground in one pass of a single-edge wheel unless the “unwrapped” thread length is much greater than normal. Unwrapped length = pitch circumference  $\times$  total number of thread turns, approximately. For example, a thread gage  $1\frac{1}{4}$  inches long with 24 threads per inch would have an unwrapped length equal to  $30 \times$  pitch circumference. (If more convenient, outside circumference may be used instead of pitch circumference.) Assume that there are 6 or 7 feet of unwrapped length on a screw thread having 12 threads per inch. In this case, one pass might be sufficient for a Class 3 fit, whereas two passes might be recommended for a Class 4 fit. When two passes are required, too deep a roughing cut may break down the narrow edge of the wheel. To prevent this, try a roughing cut depth equal to about two-thirds the total thread depth, thus leaving one-third for the finishing cut.

**Wheel and Work Rotation.**— When a screw thread, on the side being ground, is moving *upward* or *against* the grinding wheel rotation, less heat is generated and the grinding operation is more efficient than when wheel and work are moving in the same direction on the grinding side; however, to avoid running a machine idle during its return stroke, many screw threads are ground during both the forward and return traversing movements, by reversing the work rotation at the end of the forward stroke. For this reason, thread grinders generally are equipped so that both forward and return work speeds may be changed; they may also be designed to accelerate the return movement when grinding in one direction only.

**Wheel Speeds.**— Wheel speeds should always be limited to the maximum specified on the wheel by the manufacturer. According to the American National Standard Safety Code, resinoid and vitrified wheels are limited to 12,000 surface feet per minute (3657 m/min); however, according to Norton Co., the most efficient speeds are from 9,000 to 10,000 (2743–3048 m/min) for resinoid wheels and 7,500 to 9,500 (2286–2896 m/min) for vitrified wheels. Only tested wheels recommended by the wheel manufacturer should be used. After a suitable surface speed has been established, it should be maintained by increasing the rpm of the wheel, as the latter is reduced in diameter by wear.

Since thread grinding wheels work close to the limit of their stock-removing capacity, some adjustment of the wheel or work speed may be required to get the best results. If the wheel speed is too slow for a given job and excessive heat is generated, try an increase in speed, assuming that such increase is within the safety limits. If the wheel is too soft and the edge wears excessively, again an increase in wheel speed will give the effect of a harder wheel and result in better form-retaining qualities.

**Work Speeds.**— The work speed usually ranges from 3 to 10 fpm (0.9–3.0 m/min). In grinding with a comparatively heavy feed, and a minimum number of passes, the speed may not exceed  $2\frac{1}{2}$  or 3 fpm (0.76–0.9 m/min). If very light feeds are employed, as in grinding hardened high-speed steel, the work speed may be much higher than 3 fpm (0.9 m/min) and should be determined by test. If excessive heat is generated by removing stock too rapidly, a work speed reduction is one remedy. If a wheel is working below its normal capacity, an increase in work speed would prevent dulling of the grains and reduce the tendency to heat or “burn” the work. An increase in work speed and reduction in feed may also be employed to prevent burning while grinding hardened steel.

**Truing Grinding Wheels.**— Thread grinding wheels are trued to maintain both the required thread form and an efficient grinding surface. Thread grinders ordinarily are equipped with precision truing devices which function automatically. One type automatically dresses the wheel and also compensates for the slight amount removed in dressing, thus automatically maintaining size control of the work. While truing the wheel, a small amount of grinding oil should be used to reduce diamond wear. Light truing cuts are advisable, especially in truing resinoid wheels which may be deflected by excessive truing pressure. A master former for controlling the path followed by the truing diamond may require a modified profile to prevent distortion of the thread form, especially when the lead angles are comparatively large. Such modification usually is not required for 60-degree threads when the pitches for a given diameter are standard because then the resulting lead angles are less than  $4\frac{1}{2}$  degrees. In grinding Acme threads or 29-degree worm threads having lead angles greater than 4 or 5 degrees, modified formers may be required to prevent a bulge in the thread profile. The highest point of this bulge is approximately at the pitch line. A bulge of about 0.001 inch (25.4 mm) may be within allowable limits on some commercial worms but precision worms for gear hobbers, etc., require straight flanks in the axial plane.

*Crushing Method:* Thread grinding wheels are also dressed or formed by the crushing method, which is used in connection with some types of thread grinding machines. When this method is used, the annular ridge or ridges on the wheel are formed by a hardened steel cylindrical dresser or crusher. The crusher has a series of smooth annular ridges which are shaped and spaced like the thread that is to be ground. During the wheel dressing operation, the crusher is positively driven instead of the grinding wheel, and the ridges on the wheel face are formed by the rotating crusher being forced inward.

**Wheel Hardness or Grade.**— Wheel hardness or grade selection is based upon a compromise between efficient cutting and durability of the grinding edge. Grade selection depends on the bond and the character of the work. The following general recommendations are based upon Norton grading.

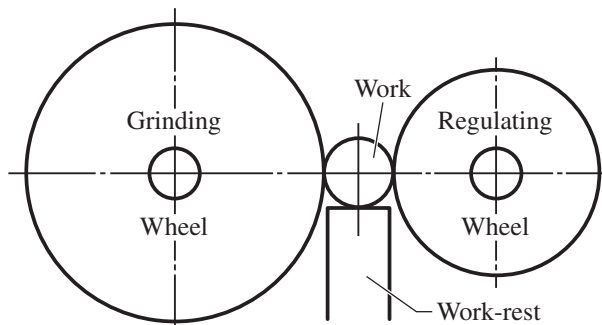

Vitrified wheels usually range from J to M, and resinoid wheels from R to U. For heat-treated screws or studs and the Unified Standard Thread, try the following. For 8 to 12

threads per inch, grade S resinoid wheel; for 14 to 20 threads per inch, grade T resinoid; for 24 threads per inch and finer, grades T or U resinoid. For high-speed steel taps 4 to 12 threads per inch, grade J vitrified or S resinoid; 14 to 20 threads per inch, grade K vitrified or T resinoid; 24 to 36 threads per inch, grade M vitrified or T resinoid.

**Grain Size.**— A thread grinding wheel usually operates close to its maximum stock-removing capacity, and the narrow edge which forms the root of the thread is the most vulnerable part. In grain selection, the general rule is to use the coarsest grained wheel that will hold its form while grinding a reasonable amount of work. Pitch of thread and quality of finish are two governing factors. Thus, to obtain an exceptionally fine finish, the grain size might be smaller than is needed to retain the edge profile. The usual grain sizes range from 120 to 150. For heat-treated screws and studs with Unified Standard Threads, 100 to 180 is the usual range. For precision screw threads of very fine pitch, the grain size may range from 220 to 320. For high-speed steel taps, the usual range is from 150 to 180 for Unified Standard Threads, and from 80 to 150 for pre-cut Acme threads.

**Thread Grinding by Centerless Method.**— Screw threads may be ground from the solid by the centerless method. A centerless thread grinder is similar in its operating principle to a centerless grinder designed for general work, in that it has a grinding wheel, a regulating or feed wheel (with speed adjustments), and a work-rest. Adjustments are provided to accommodate work of different sizes and for varying the rates of feed. The grinding wheel is a multi-ribbed type, being a series of annular ridges across the face. These ridges conform in pitch and profile with the thread to be ground. The grinding wheel is inclined to suit the helix or lead angle of the thread. In grinding threads on such work as socket type set-screws, the blanks are fed automatically and passed between the grinding and regulating wheels in a continuous stream. To illustrate production possibilities, hardened socket set-screws of  $\frac{1}{4}$ -20 size may be ground from the solid at the rate of 60 to 70 per minute and with the wheel operating continuously for 8 hours without redressing. The lead errors of centerless ground screw threads may be limited to 0.0005 inch per inch (or mm per mm) or even less by reducing the production rate. The pitch diameter tolerances are within 0.0002 to 0.0003 inch (5.08–7.62 mm) of the basic size. The grain size for the wheel is selected with reference to the pitch of the thread, the following sizes being recommended: For 11 to 13 threads per inch, 150; for 16 threads per inch, 180; for 18 to 20 threads per inch, 220; for 24 to 28 threads per inch, 320; for 40 threads per inch, 400.

**Principle of Centerless Grinding.**— Centerless grinding is the grinding of cylindrical work without supporting it on centers in the usual way. Two abrasive wheels are mounted so that their peripheries face each other, one of the wheels having its axis so arranged that it can be swung out of parallel with the axis of the other wheel by varying amounts, as required. Between these two abrasive wheels is a work-supporting member equipped with suitable guides. The grinding wheel forces the work downward against the work-rest and also against the regulating wheel. The latter imparts a uniform rotation to the work which has the same peripheral speed as the regulating wheel, the speed of which is adjustable.

Principle of the Centerless Grinding Process

## THREAD MILLING

**Single-cutter Method.**— Usually, when a single point cutter is used, the axis of the cutter is inclined an amount equal to the lead angle of the screw thread, in order to locate the cutter in line with the thread groove at the point where the cutting action takes place. Tangent of lead angle = lead of screw thread  $\div$  pitch circumference of screw.

The helical thread groove is generated by making as many turns around the workpiece diameter as there are pitches in the length of thread to be cut. For example, a 16-pitch thread, 1 inch long, would require 16 turns of the cutter around the work. The single cutter process is especially applicable to the milling of large screw threads of coarse pitch, and either single or multiple threads.

The cutter should revolve as fast as possible without dulling the cutting edges excessively, in order to mill a smooth thread and prevent the unevenness that would result with a slow-moving cutter because of the tooth spaces. As the cutter rotates, the part on which a thread is to be milled is also revolved, but at a very slow rate (a few inches per minute), since this rotation of the work is practically a feeding movement. The cutter is ordinarily set to the full depth of the thread groove and finishes a single thread in one passage, although deep threads of coarse pitch may require two or even three cuts. For fine pitches and short threads, the multiple-cutter method (described in the next paragraph) usually is preferable, because it is more rapid. The milling of taper screw threads may be done on a single-cutter type of machine by traversing the cutter laterally as it feeds along in a lengthwise direction, the same as when using a taper attachment on a lathe.

**Multiple-cutter Method.**— The multiple cutter for thread milling is practically a series of single cutters, although formed of one solid piece of steel, at least so far as the cutter proper is concerned. The rows of teeth do not lie in a helical path, like the teeth of a hob or tap, but they are annular or without lead. If the cutter had helical teeth the same as a gear hob, it would have to be geared to revolve in a certain fixed ratio with the screw being milled, but a cutter having annular teeth may rotate at any desired cutting speed, while the screw blank is rotated slowly to provide a suitable rate of feed. (The multiple thread milling cutters used are frequently called "hobs," but the term hob should be applied only to cutters having a helical row of teeth like a gear-cutting hob.)

The object in using a multiple cutter instead of a single cutter is to finish a screw thread complete in approximately one revolution of the work, a slight amount of over-travel being allowed to insure milling the thread to the full depth where the end of cut joins the starting point. The cutter, which is at least one and one half or two threads or pitches wider than the thread to be milled, is fed in to the full thread depth and then either the cutter or screw blank is moved in a lengthwise direction a distance equal to the lead of the thread during one revolution of the work.

The multiple cutter is used for milling comparatively short threads and coarse, medium or fine pitches. The accompanying illustration shows typical examples of external and internal work for which the multiple-cutter type of thread milling has proved very efficient, although its usefulness is not confined to shoulder work and "blind" holes.

In using multiple cutters either for internal or external thread milling, the axis of the cutter is set parallel with the axis of the work, instead of inclining the cutter to suit the lead angle of the thread, as when using a single cutter. Theoretically, this is not the correct position for a cutter, since each cutting edge is revolving in a plane at right angles to the screw's axis while milling a thread groove of helical form. However, as a general rule, interference between the cutter and the thread does not result in a decided change in the standard thread form. Usually the deviation is very slight and may be disregarded except when milling threads which incline considerably relative to the axis like a thread of multiple form and large lead angle. Multiple cutters are suitable for external threads having lead angles under  $3\frac{1}{2}$  degrees and for internal threads having lead angles under  $2\frac{1}{2}$  degrees. Threads which have steeper sides or smaller included angles than the American Standard or Whitworth

forms have greater limitations on the maximum helix angle and may have to be milled with a single point cutter tilted to the helix angle, assuming that the milling process is preferable to other methods. For instance, in milling an Acme thread which has an included angle between the sides of 29 degrees, there might be considerable interference if a multiple cutter were used, unless the screw thread diameter were large enough in proportion to the pitch to prevent such interference. If an attempt were made to mill a square thread with a multiple cutter, the results would be unsatisfactory owing to the interference.

Examples of External and Internal Thread Milling  
with a Multiple Thread Milling Cutter

Interference between the cutter and work is more pronounced when milling internal threads, because the cutter does not clear itself so well. It is preferable to use as small a cutter as practicable, either for internal or external work, not only to avoid interference, but to reduce the strain on the driving mechanism. Some thread milling cutters, known as “topping cutters,” are made for milling the outside diameter of the thread as well as the angular sides and root, but most are made non-tapping.

**Planetary Method.**— The planetary method of thread milling is similar in principle to planetary milling. The part to be threaded is held stationary and the thread milling cutter, while revolving about its own axis, is given a planetary movement around the work in order to mill the thread in one planetary revolution. The machine spindle and the cutter which is held by it is moved longitudinally for thread milling, an amount equal to the thread lead during one planetary revolution. This operation is applicable to both internal and external threads. Other advantages: Thread milling is frequently accompanied by milling operations on other adjoining surfaces, and may be performed with conventional and planetary methods. For example, a machine may be used for milling a screw thread and a concentric cylindrical surface simultaneously. When the milling operation begins, the cutter-spindle feeds the cutter in to the right depth and the planetary movement then begins, thus milling the thread and the cylindrical surface. Thin sharp starting edges are eliminated on threads milled by this method and the thread begins with a smooth gradual approach. One design of machine will mill internal and external threads simultaneously. These threads may be of the same hand or one may be right hand and the other left hand. The threads may also be either of the same pitch or of a different pitch, and either straight or tapered.

**Classes of Work for Thread Milling Machines.**— Thread milling machines are used in preference to lathes or taps and dies for certain threading operations.

There are four general reasons why a thread milling machine may be preferred:

- 1) Because the pitch of the thread is too coarse for cutting with a die; 2) because the milling process is more efficient than using a single-point tool in a lathe; 3) to secure a smoother and more accurate thread than would be obtained with a tap or die; and
- 4) because the thread is so located relative to a shoulder or other surface that the milling method is superior, if not the only practicable way.

A thread milling machine having a single cutter is especially adapted for coarse pitches, multiple-threaded screws, or any form or size of thread requiring the removal of a relatively large amount of metal, particularly if the pitch of the thread is large in proportion to the screw diameter, since the torsional strain due to the milling process is relatively small. Thread milling often gives a higher rate of production, and a thread is usually finished by means of a single turn of the multiple thread milling cutter around the thread diameter. The multiple-cutter type of thread milling machine frequently comes into competition with dies and taps, and especially self-opening dies and collapsing taps. The use of a multiple cutter is desirable when a thread must be cut close to a shoulder or to the bottom of a shallow recess, although the usefulness of the multiple cutter is not confined to shoulder work and "blind" holes.

**Maximum Pitches of Die-cut Threads.**— Dies of special design could be constructed for practically any pitch, if the screw blank were strong enough to resist the cutting strains and the size and cost of the die were immaterial; but, as a general rule, when the pitch is coarser than four or five threads per inch, the difficulty of cutting threads with dies increases rapidly, although in a few cases some dies are used successfully on screw threads having two or three threads per inch or less. Much depends upon the design of the die, the finish or smoothness required, and the relation between the pitch of the thread and the diameter of the screw. When the screw diameter is relatively small in proportion to the pitch, there may be considerable distortion due to the twisting strains set up when the thread is being cut. If the number of threads per inch is only one or two less than the standard number for a given diameter, a screw blank ordinarily will be strong enough to permit the use of a die.

**Changing Pitch of Screw Thread Slightly.**— A very slight change in the pitch of a screw thread may be necessary as, for example, when the pitch of a tap is increased a small amount to compensate for shrinkage in hardening. One method of obtaining slight variations in pitch is by means of a taper attachment. This attachment is set at an angle and the work is located at the same angle by adjusting the tailstock center. The result is that the tool follows an angular path relative to the movement of the carriage and, consequently, the pitch of the thread is increased slightly, the amount depending upon the angle to which the work and taper attachment are set. The cosine of this angle, for obtaining a given increase in pitch, equals the standard pitch (which would be obtained with the lathe used in the regular way) divided by the increased pitch necessary to compensate for shrinkage.

*Example:* If the pitch of a  $\frac{3}{4}$ -inch American standard screw is to be increased from 0.100 to 0.1005, the cosine of the angle to which the taper attachment and work should be set is found as follows:

$$\text{Cosine of required angle} = \frac{0.100}{0.1005} = 0.9950$$

which is the cosine of 5 degrees 45 minutes, nearly.

### Change Gears for Helical Milling

**Lead of a Milling Machine.**— If gears with an equal number of teeth are placed on the table feed-screw and the worm-gear stud, then the *lead of the milling machine* is the distance the table will travel while the index spindle makes one complete revolution. This distance is a constant used in figuring the change gears.

The lead of a helix or “spiral” is the distance, measured along the axis of the work, in which the helix makes one full turn around the work. The lead of the milling machine may, therefore, also be expressed as the lead of the helix that will be cut when gears with an equal number of teeth are placed on the feed-screw and the worm-gear stud, and an idler of suitable size is interposed between the gears.

*Rule:* To find the lead of a milling machine, place equal gears on the worm-gear stud and on the feed-screw, and multiply the number of revolutions made by the feed-screw to produce one revolution of the index head spindle, by the lead of the thread on the feed-screw. Expressing the rule given as a formula:

$$\text{lead of milling machine} = \frac{\text{rev. of feed-screw for one revolution of index spindle with equal gears}}{\text{lead of feed-screw}}$$

Assume that it is necessary to make 40 revolutions of the feed-screw to turn the index head spindle one complete revolution, when the gears are equal, and that the lead of the thread on the feed-screw of the milling machine is  $\frac{1}{4}$  inch (6.35 mm); then the lead of the machine equals  $40 \times \frac{1}{4}$  inch = 10 inches. In metric units, the lead is  $40 \times 6.35 = 254$  mm.

**Change Gears for Helical Milling.**— To find the change gears to be used in the compound train of gears for helical milling, place the lead of the helix to be cut in the numerator and the lead of the milling machine in the denominator of a fraction; divide numerator and denominator into two factors each; and multiply each “pair” of factors by the *same* number until suitable numbers of teeth for the change gears are obtained. (One factor in the numerator and one in the denominator are considered as one “pair” in this calculation.)

*Example:* Assume that the lead of a machine is 10 inches, and that a helix having a 48-inch lead is to be cut. Following the method explained:

$$\frac{48}{10} = \frac{6 \times 8}{2 \times 5} = \frac{(6 \times 12) \times (8 \times 8)}{(2 \times 12) \times (5 \times 8)} = \frac{72 \times 64}{24 \times 40}$$

The gear having 72 teeth is placed on the worm-gear stud and meshes with the 24-tooth gear on the intermediate stud. On the same intermediate stud is then placed the gear having 64 teeth, which is driven by the gear having 40 teeth placed on the feed-screw. This makes the gears having 72 and 64 teeth the driven gears, and the gears having 24 and 40 teeth the driving gears. In general, for compound gearing, the following formula may be used:

$$\frac{\text{lead of helix to be cut}}{\text{lead of machine}} = \frac{\text{product of driven gears}}{\text{product of driving gears}}$$

**Short-lead Milling.**— If the lead to be milled is exceptionally short, the drive may be direct from the table feed-screw to the dividing head spindle to avoid excessive load on feed-screw and change-gears. If the table feed-screw has 4 threads per inch (usual standard), then

$$\text{Change-gear ratio} = \frac{\text{Lead to be milled}}{0.25} = \frac{\text{Driven gears}}{\text{Driving gears}}$$

For indexing, the number of teeth on the spindle change-gear should be some multiple of the number of divisions required, to permit indexing by disengaging and turning the gear.

**Helix.**— A helix is a curve generated by a point moving about a cylindrical surface (real or imaginary) at a constant rate in the direction of the cylinder's axis. The curvature of a screw thread is one common example of a helical curve.

*Lead of Helix:* The lead of a helix is the distance that it advances in an axial direction, in one complete turn about the cylindrical surface. To illustrate, the lead of a screw thread

equals the distance that a thread advances in one turn; it also equals the distance that a nut would advance in one turn.

*Development of Helix:* If one turn of a helical curve were unrolled onto a plane surface (as shown by diagram), the helix would become a straight line forming the hypotenuse of a right angle triangle. The length of one side of this triangle would equal the circumference of the cylinder with which the helix coincides, and the length of the other side of the triangle would equal the lead of the helix.

**Helix Angles.**— The triangular development of a helix has one angle *A* subtended by the circumference of the cylinder, and another angle *B* subtended by the lead of the helix. The term “helix angle” applies to angle *A*. For example, the helix angle of a helical gear, according to the general usage of the term, is always angle *A*, because this is the angle used in helical gear-designing formulas. Helix angle *A* would also be applied in milling the helical teeth of cutters, reamers, etc. Angle *A* of a gear or cutter tooth is a measure of its inclination relative to the axis of the gear or cutter.

*Lead Angle:* Angle *B* is applied to screw threads and worm threads and is referred to as the lead angle of the screw thread or worm. This angle *B* is a measure of the inclination of a screw thread from a plane that is perpendicular to the screw thread axis. Angle *B* is called the “lead angle” because it is subtended by the lead of the thread, and to distinguish it from the term “helix angle” as applied to helical gears.

*Finding Helix Angle of Helical Gear:* A helical gear tooth has an infinite number of helix angles, but the angle at the pitch diameter or mid-working depth is the one required in gear designing and gear cutting. This angle *A*, relative to the axis of the gear, is found as follows:

$$\tan \text{ helix angle} = \frac{3.1416 \times \text{pitch diameter of gear}}{\text{Lead of gear tooth}}$$

*Finding Lead Angle of Screw Thread:* The lead or helix angle at the pitch diameter of a screw thread usually is required when, for example, a thread milling cutter must be aligned with the thread. This angle measured from a plane perpendicular to the screw thread axis is found as follows:

$$\tan \text{ lead angle} = \frac{\text{Lead of screw thread}}{3.1416 \times \text{pitch diameter of screw thread}}$$

## Change Gears for Different Leads—0.670 Inch to 2.658 Inches

Lead in Inches	Driven	Driver	Driven	Driver	Lead in Inches	Driven	Driver	Driven	Driver	Lead in Inches	Driven	Driver	Driven	Driver

**Helix Angle for Given Lead and Diameter.**— The table on this and the preceding page gives helix angles (relative to axis) equivalent to a range of leads and diameters. The expression “Diameter of Work” at the top of the table might mean pitch diameter or outside diameter, depending upon the class of work. Assume, for example, that a plain milling cutter 4 inches in diameter is to have helical teeth and a helix angle of about 25 degrees is desired. The table shows that this angle will be obtained approximately by using change-gears that will give a lead of 26.67 inches. As the outside diameter of the cutter is 4 inches,

the helix angle of  $25\frac{1}{4}$  degrees is at the top of the teeth. The angles listed for different diameters are used in setting the table of a milling machine. In milling a right-hand helix (or cutter teeth that turn to the right as seen from the end of the cutter), swivel the right-hand end of the machine table toward the rear, and, inversely, for a left-hand helix, swivel the left-hand end of the table toward the rear. The angles in the table are based upon the following formula:

$$\cot \text{ helix angle relative to axis} = \frac{\text{lead of helix}}{3.1416 \times \text{diameter}}$$

**Lead of Helix for Given Angle.**—The lead of a helix or “spiral” for given angles measured with the axis of the work is given in the table, starting on page 2132, for a diameter of 1. For other diameters, lead equals the value found in the table multiplied by the given diameter. Suppose the angle is 55 degrees, and the diameter 5 inches; what would be the lead? By referring to the table starting on page 2132, it is found that the lead for a diameter of 1 and an angle of 55 degrees 0 minutes equals 2.200. Multiply this value by 5;  $5 \times 2.200 = 11$  inches, which is the required lead. If the lead and diameter are given, and the angle is wanted, divide the given lead by the given diameter, thus obtaining the lead for a diameter equal to 1; then find the angle corresponding to this lead in the table. If the lead and angle are given, and the diameter is wanted, divide the lead by the value in the table for the angle.

**Helix Angle for Given Lead and Pitch Radius.**—To determine the helix angle for a helical gear, knowing the pitch radius and the lead, use the formula:

$$\tan \psi = \frac{2\pi R}{L}$$

where  $\psi$  = helix angle

$R$  = pitch radius of gear, and

$L$  = lead of tooth

*Example:*

$$R = 3.000, L = 21.000, \tan \psi = (2 \times 3.1416 \times 3.000) / 21.000 = 0.89760$$

$$\therefore \psi = 41.911 \text{ degrees}$$

**Helix Angle and Lead, Given Normal DP and Numbers of Teeth.**—When  $N_1$  = number of teeth in pinion,  $N_2$  = number of teeth in gear,  $P_n$  = normal diametral pitch,  $C$  = center distance,  $\psi$  = helix angle,  $L_1$  = lead of pinion, and  $L_2$  = lead of gear, then:

$$\cos \psi = \frac{N_1 + N_2}{2P_n C}, \quad L_1 = \frac{\pi N_1}{P_n \sin \psi}, \quad L_2 = \frac{\pi N_2}{P_n \sin \psi}$$

$$P_n = 6, \quad N_1 = 18, \quad N_2 = 30, \quad C = 4.500$$

$$\cos \psi = \frac{18 + 30}{2 \times 6 \times 4.5} = 0.88889, \therefore \psi = 27.266^\circ, \text{ and } \sin \psi = 0.45812$$

$$L_1 = \frac{3.1416 \times 18}{6 \times 0.45812} = 20.5728, \text{ and } L_2 = \frac{3.1416 \times 30}{6 \times 0.45812} = 34.2880$$

**Lead of Tooth Given Pitch Radius and Helix Angle.**—To determine the lead of the tooth for a helical gear, given the helix angle and the pitch radius, the formula becomes:  
 $L = 2\pi R / \tan \psi$ .

$$\psi = 22.5^\circ, \quad \therefore \tan \psi = 0.41421, \quad R = 2.500.$$

$$L = \frac{2 \times 3.1416 \times 2.500}{0.41421} = 37.9228$$

## GEARS AND GEARING

*External spur gears* are cylindrical gears with straight teeth cut parallel to the axes. Gears transmit drive between parallel shafts. Tooth loads produce no axial thrust. Excellent at moderate speeds but tend to be noisy at high speeds. Shafts rotate in opposite directions.

*Internal spur gears* provide compact drive arrangements for transmitting motion between parallel shafts rotating in the same direction.

*Helical gears* are cylindrical gears with teeth cut at an angle to the axes. Provides drive between shafts rotating in opposite directions, with superior load carrying capacity and quietness than spur gears. Tooth loads produce axial thrust.

*Crossed helical gears* are helical gears that mesh together on non-parallel axes.

*Straight bevel gears* have teeth that are radial toward the apex and are of conical form. Designed to operate on intersecting axes, bevel gears are used to connect two shafts on intersecting axes. The angle between the shafts equals the angle between the two axes of the meshing teeth. End thrust developed under load tends to separate the gears.

*Spiral bevel gears* have curved oblique teeth that contact each other smoothly and gradually from one end of a tooth to the other. Meshing is similar to that of straight bevel gears but is smoother and quieter in use. Left hand spiral teeth incline away from the axis in an anti-clockwise direction looking on small end of pinion or face of gear; right-hand teeth incline away from axis in clockwise direction. The hand of spiral of the pinion is always opposite to that of the gear and is used to identify the hand of the gear pair. Used to connect two shafts on intersecting axes as with straight bevel gears. The spiral angle does not affect the smoothness and quietness of operation or the efficiency but does affect the direction of the thrust loads created. A left-hand spiral pinion driving clockwise when viewed from the large end of the pinion creates an axial thrust that tends to move the pinion out of mesh.

*Zerol bevel gears* have curved teeth lying in the same general direction as straight bevel teeth but should be considered to be spiral bevel gears with zero spiral angle.

*Hypoid bevel gears* are a cross between spiral bevel gears and worm gears. The axes of hypoid bevel gears are non-intersecting and non-parallel. The distance between the axes is called the offset. The offset permits higher ratios of reduction than is practicable with other bevel gears. Hypoid bevel gears have curved oblique teeth on which contact begins gradually and continues smoothly from one end of the tooth to the other.

*Worm gears* are used to transmit motion between shafts at right angles, that do not lie in a common plane and sometimes to connect shafts at other angles. Worm gears have line tooth contact and are used for power transmission, but the higher the ratio the lower the efficiency.

**Definitions of Gear Terms.**— The following terms are commonly applied to the various classes of gears:

*Active face width* is the dimension of the tooth face width that makes contact with a mating gear.

*Addendum* is the radial or perpendicular distance between the pitch circle and the top of the tooth.

*Arc of action* is the arc of the pitch circle through which a tooth travels from the first point of contact with the mating tooth to the point where contact ceases.

*Arc of approach* is the arc of the pitch circle through which a tooth travels from the first point of contact with the mating tooth to the pitch point.

*Arc of recession* is the arc of the pitch circle through which a tooth travels from its contact with a mating tooth at the pitch point until contact ceases.

*Axial pitch* is the distance parallel to the axis between corresponding sides of adjacent teeth.

*Axial plane* is the plane that contains the two axes in a pair of gears. In a single gear the axial plane is any plane containing the axis and any given point.

*Axial thickness* is the distance parallel to the axis between two pitch line elements of the same tooth.

*Backlash* is the shortest distance between the non-driving surfaces of adjacent teeth when the working flanks are in contact.

*Base circle* is the circle from which the involute tooth curve is generated or developed.

*Base helix angle* is the angle at the base cylinder of an involute gear that the tooth makes with the gear axis.

*Base pitch* is the circular pitch taken on the circumference of the base circles, or the distance along the line of action between two successive and corresponding involute tooth profiles. The *normal base pitch* is the base pitch in the normal plane and the *axial base pitch* is the base pitch in the axial plane.

*Base tooth thickness* is the distance on the base circle in the plane of rotation between involutes of the same pitch.

*Bottom land* is the surface of the gear between the flanks of adjacent teeth.

*Center distance* is the shortest distance between the non-intersecting axes of mating gears, or between the parallel axes of spur gears and parallel helical gears, or the crossed axes of crossed helical gears or worm gears.

*Central plane* is the plane perpendicular to the gear axis in a worm gear, which contains the common perpendicular of the gear and the worm axes. In the usual arrangement with the axes at right angles, it contains the worm axis.

*Chordal addendum* is the radial distance from the circular thickness chord to the top of the tooth, or the height from the top of the tooth to the chord subtending the circular thickness arc.

*Chordal thickness* is the length of the chord subtended by the circular thickness arc. The dimension obtained when a gear tooth caliper is used to measure the tooth thickness at the pitch circle.

*Circular pitch* is the distance on the circumference of the pitch circle, in the plane of rotation, between corresponding points of adjacent teeth. The length of the arc of the pitch circle between the centers or other corresponding points of adjacent teeth.

*Circular thickness* is the thickness of the tooth on the pitch circle in the plane of rotation, or the length of arc between the two sides of a gear tooth measured on the pitch circle.

*Clearance* is the radial distance between the top of a tooth and the bottom of a mating tooth space, or the amount by which the dedendum in a given gear exceeds the addendum of its mating gear.

*Contact diameter* is the smallest diameter on a gear tooth with which the mating gear makes contact.

*Contact ratio* is the ratio of the arc of action in the plane of rotation to the circular pitch, and is sometimes thought of as the average number of teeth in contact. This ratio is obtained most directly as the ratio of the length of action to the base pitch.

*Contact ratio - face* is the ratio of the face advance to the circular pitch in helical gears.

*Contact ratio - total* is the ratio of the sum of the arc of action and the face advance to the circular pitch.

*Contact stress* is the maximum compressive stress within the contact area between mating gear tooth profiles. Also called the Hertz stress.

*Cycloid* is the curve formed by the path of a point on a circle as it rolls along a straight line. When such a circle rolls along the outside of another circle the curve is called an *epicycloid*, and when it rolls along the inside of another circle it is called a *hypocycloid*. These curves are used in defining the former American Standard composite Tooth Form.

*Dedendum* is the radial or perpendicular distance between the pitch circle and the bottom of the tooth space.

*Diametral pitch* is the ratio of the number of teeth to the number of inches in the pitch diameter in the plane of rotation, or the number of gear teeth to each inch of pitch diameter. Normal diametral pitch is the diametral pitch as calculated in the normal plane, or the diametral pitch divided by the cosine of the helix angle.

*Efficiency* is the torque ratio of a gear set divided by its gear ratio.

*Equivalent pitch radius* is the radius of curvature of the pitch surface at the pitch point in a plane normal to the pitch line element.

*Face advance* is the distance on the pitch circle that a gear tooth travels from the time pitch point contact is made at one end of the tooth until pitch point contact is made at the other end.

*Fillet radius* is the radius of the concave portion of the tooth profile where it joins the bottom of the tooth space.

*Fillet stress* is the maximum tensile stress in the gear tooth fillet.

*Flank of tooth* is the surface between the pitch circle and the bottom land, including the gear tooth fillet.

*Gear ratio* is the ratio between the numbers of teeth in mating gears.

*Helical overlap* is the effective face width of a helical gear divided by the gear axial pitch.

*Helix angle* is the angle that a helical gear tooth makes with the gear axis at the pitch circle, unless specified otherwise.

*Hertz stress*, see *Contact stress*.

*Highest point of single tooth contact (HPSTC)* is the largest diameter on a spur gear at which a single tooth is in contact with the mating gear.

*Interference* is the contact between mating teeth at some point other than along the line of action.

*Internal diameter* is the diameter of a circle that coincides with the tops of the teeth of an internal gear.

*Internal gear* is a gear with teeth on the inner cylindrical surface.

*Involute* is the curve generally used as the profile of gear teeth. The curve is the path of a point on a straight line as it rolls along a convex base curve, usually a circle.

*Land* The top land is the top surface of a gear tooth and the *bottom land* is the surface of the gear between the fillets of adjacent teeth.

*Lead* is the axial advance of the helix in one complete turn, or the distance along its own axis on one revolution if the gear were free to move axially.

*Length of action* is the distance on an involute line of action through which the point of contact moves during the action of the tooth profile.

*Line of action* is the portion of the common tangent to the base cylinders along which contact between mating involute teeth occurs.

*Lowest point of single tooth contact (LPSTC)* is the smallest diameter on a spur gear at which a single tooth is in contact with its mating gear. Gear set contact stress is determined with a load placed on the pinion at this point.

*Module* is the ratio of the pitch diameter to the number of teeth, normally the ratio of pitch diameter in mm to the number of teeth. Module in the inch system is the ratio of the pitch diameter in inches to the number of teeth.

*Normal plane* is a plane normal to the tooth surfaces at a point of contact and perpendicular to the pitch plane.

*Number of teeth* is the number of teeth contained in a gear.

*Outside diameter* is the diameter of the circle that contains the tops of the teeth of external gears.

*Pitch* is the distance between similar, equally-spaced tooth surfaces in a given direction along a given curve or line.

*Pitch circle* is the circle through the pitch point having its center at the gear axis.

*Pitch diameter* is the diameter of the pitch circle. The operating pitch diameter is the pitch diameter at which the gear operates.

*Pitch plane* is the plane parallel to the axial plane and tangent to the pitch surfaces in any pair of gears. In a single gear, the pitch plane may be any plane tangent to the pitch surfaces.

*Pitch point* is the intersection between the axes of the line of centers and the line of action.

*Plane of rotation* is any plane perpendicular to a gear axis.

*Pressure angle* is the angle between a tooth profile and a radial line at its pitch point. In involute teeth, the pressure angle is often described as the angle between the line of action and the line tangent to the pitch circle. *Standard pressure angles* are established in connection with standard tooth proportions. A given pair of involute profiles will transmit smooth motion at the same velocity ratio when the center distance is changed. Changes in center distance in gear design and gear manufacturing operations may cause changes in pitch diameter, pitch and pressure angle in the same gears under different conditions. Unless otherwise specified, the pressure angle is the *standard pressure angle at the standard pitch diameter*. The *operating pressure angle* is determined by the center distance at which a pair of gears operates. In oblique teeth such as helical and spiral designs, the pressure angle is specified in the transverse, normal or axial planes.

*Principle reference planes* are pitch plane, axial plane and transverse plane, all intersecting at a point and mutually perpendicular.

*Rack*: A rack is a gear with teeth spaced along a straight line, suitable for straight line motion. A basic rack is a rack that is adopted as the basis of a system of interchangeable gears. Standard gear tooth dimensions are often illustrated on an outline of a basic rack.

*Roll angle* is the angle subtended at the center of a base circle from the origin of an involute to the point of tangency of a point on a straight line from any point on the same involute. The radian measure of this angle is the tangent of the pressure angle of the point on the involute.

*Root diameter* is the diameter of the circle that contains the roots or bottoms of the tooth spaces.

*Tangent plane* is a plane tangent to the tooth surfaces at a point or line of contact.

*Tip relief* is an arbitrary modification of a tooth profile where a small amount of material is removed from the involute face of the tooth surface near the tip of the gear tooth.

*Tooth face* is the surface between the pitch line element and the tooth tip.

*Tooth surface* is the total tooth area including the flank of the tooth and the tooth face.

*Total face width* is the dimensional width of a gear blank and may exceed the effective face width as with a double-helical gear where the total face width includes any distance separating the right-hand and left-hand helical gear teeth.

*Transverse plane* is a plane that is perpendicular to the axial plane and to the pitch plane. In gears with parallel axes, the transverse plane and the plane of rotation coincide.

*Trochoid* is the curve formed by the path of a point on the extension of a radius of a circle as it rolls along a curve or line. A trochoid is also the curve formed by the path of a point on a perpendicular to a straight line as the straight line rolls along the convex side of a base curve. By the first definition, a trochoid is derived from the *cycloid*; by the second definition it is derived from the *involute*.

*True involute form diameter* is the smallest diameter on the tooth at which the point of tangency of the involute tooth profile exists. Usually this position is the point of tangency of the involute tooth profile and the fillet curve, and is often referred to as the TIF diameter.

*Undercut* is a condition in generated gear teeth when any part of the fillet curve lies inside a line drawn at a tangent to the working profile at its lowest point. Undercut may be introduced deliberately to facilitate shaving operations, as in pre-shaving.

*Whole depth* is the total depth of a tooth space, equal to the addendum plus the dedendum and equal to the working depth plus clearance.

*Working depth* is the depth of engagement of two gears, or the sum of their addendums. The standard working distance is the depth to which a tooth extends into the tooth space of a mating gear when the center distance is standard.

Definitions of gear terms are given in AGMA Standards 112.05, 115.01, and 116.01 entitled "Terms, Definitions, Symbols and Abbreviations," "Reference Information—Basic Gear Geometry," and "Glossary—Terms Used in Gearing," respectively; obtainable from American Gear Manufacturers Assn., 500 Montgomery St., Alexandria, VA 22314.

**Comparative Sizes and Shape of Gear Teeth**

Gear Teeth of Different Diametral Pitch

Shapes of Gear Teeth of Different Pressure Angles

**Nomenclature of Gear Teeth**

Terms Used in Gear Geometry from Table 1 on page 2147

**Properties of the Involute Curve.**— The involute curve is used almost exclusively for gear-tooth profiles, because of the following important properties.

1) The form or shape of an involute curve depends upon the diameter of the base circle from which it is derived. (If a taut line were unwound from the circumference of a circle—the *base circle* of the involute—the end of that line or any point on the unwound portion would describe an involute curve.)

2) If a gear tooth of involute curvature acts against the involute tooth of a mating gear while rotating at a uniform rate, the angular motion of the driven gear will also be uniform, even though the center-to-center distance is varied.

3) The relative rate of motion between driving and driven gears having involute tooth curves is established by the diameters of their base circles.

4) Contact between intermeshing involute teeth on a driving and driven gear is along a straight line that is tangent to the two base circles of these gears. This is the *line of action*.

5) The point where the line of action intersects the common center-line of the mating involute gears establishes the radii of the pitch circles of these gears; hence true pitch circle diameters are affected by a change in the center distance. (Pitch diameters obtained by dividing the number of teeth by the diametral pitch apply when the center distance equals the total number of teeth on both gears divided by twice the diametral pitch.)

6) The pitch diameters of mating involute gears are directly proportional to the diameters of their respective base circles; thus, if the base circle of one mating gear is three times as large as the other, the pitch circle diameters will be in the same ratio.

7) The angle between the line of action and a line perpendicular to the common center-line of mating gears is the *pressure angle*; hence the pressure angle is affected by any change in the center distance.

8) When an involute curve acts against a straight line (as in the case of an involute pinion acting against straight-sided rack teeth), the straight line is tangent to the involute and perpendicular to its line of action.

9) The pressure angle, in the case of an involute pinion acting against straight-sided rack teeth, is the angle between the line of action and the line of the rack's motion. If the involute pinion rotates at a uniform rate, movement of the rack will also be uniform.

*Nomenclature:*

$\phi$ = Pressure Angle		
$a$ = Addendum	$a_G$ = Addendum of Gear	$a_p$ = Addendum of Pinion
$b$ = Dedendum		
$c$ = Clearance		
$C$ = Center Distance		
$D$ = Pitch Diameter	$D_G$ = Pitch Diameter of Gear	$D_p$ = Pitch Diameter of Pinion
$D_B$ = Base Circle Diameter	$D_O$ = Outside Diameter	$D_R$ = Root Diameter
$F$ = Face Width		
$h_k$ = Working Depth of Tooth	$h_t$ = Whole Depth of Tooth	
$m_G$ = Gear Ratio		
$N$ = Number of Teeth	$N_G$ = Number of Teeth in Gear	$N_p$ = Number of Teeth in Pinion
$p$ = Circular Pitch	$P$ = Diametral Pitch	

**Diametral and Circular Pitch Systems.**— Gear tooth system standards are established by specifying the tooth proportions of the basic rack. The diametral pitch system is applied to most of the gearing produced in the United States. If gear teeth are larger than about one diametral pitch, it is common practice to use the circular pitch system. The circular pitch system is also applied to cast gearing and it is commonly used in connection with the design and manufacture of worm gearing.

**Pitch Diameters Obtained with Diametral Pitch System.**— The diametral pitch system is arranged to provide a series of standard tooth sizes, the principle being similar to the standardization of screw thread pitches. Inasmuch as there must be a whole number of

teeth on each gear, the increase in pitch diameter per tooth varies according to the pitch. For example, the pitch diameter of a gear having, say, 20 teeth of 4 diametral pitch will be 5 inches; 21 teeth, 5¼ inches; and so on, the increase in diameter for each additional tooth being equal to ¼ inch for 4 diametral pitch. Similarly, for 2 diametral pitch the variations for successive numbers of teeth would equal ½ inch, and for 10 diametral pitch the variations would equal 1/10 inch, etc. Where a given center distance must be maintained and no standard diametral pitch can be used, gears should be designed with reference to the gear set center distance procedure discussed in *Gears for Given Center Distance and Ratio* starting on page 2155.

**Table 1. Formulas for Dimensions of Standard Spur Gears**

Outside Diameter	$D_O = (N + 2) \div P$	$D_O = 0.3183 \times (N + 2)p$
Root Diameter (Preferred)	$D_R = (N - 2.5) \div P$	$D_R = 0.3183 \times (N - 2.5)p$
(Shaved or Ground Teeth)	$D_R = (N - 2.7) \div P$	$D_R = 0.3183 \times (N - 2.7)p$
Circular Thickness—Basic	$t = 1.5708 \div P$	$t = p \div 2$

<sup>a</sup> When gears are preshaved cut on a gear shaper the dedendum will usually need to be increased to  $1.40/P$  to allow for the higher fillet trochoid produced by the shaper cutter. This is of particular importance on gears of few teeth or if the gear blank configuration requires the use of a small diameter shaper cutter, in which case the dedendum may need to be increased to as much as  $1.45/P$ . This should be avoided on highly loaded gears where the consequently reduced  $J$  factor will increase gear tooth stress excessively.

<sup>b</sup> A minimum clearance of  $0.157/P$  may be used for the basic 20-degree and 25-degree pressure angle rack in the case of shallow root sections and use of existing hobs or cutters. However, whenever less than standard clearance is used, the location of the TIF diameter should be determined by the method shown in *True Involute Form Diameter* starting on page 2173. The TIF diameter must be less than the Contact Diameter determined by the method shown on page 2171.

<sup>c</sup> The fillet radius of the basic rack should not exceed  $0.235/P$  for a 20-degree pressure angle rack or  $0.270/P$  for a 25-degree pressure angle rack for a clearance of  $0.157/P$ . The basic rack fillet radius must be reduced for teeth with a 25-degree pressure angle having a clearance in excess of  $0.250/P$ .

**American National Standard Coarse Pitch Spur Gear Tooth Forms.**— The American National Standard (ANSI B6.1-1968, R1974) provides tooth proportion information on two involute spur gear forms. These two forms are identical except that one has a pressure angle of 20 degrees and a minimum allowable tooth number of 18 while the other has a pressure angle of 25 degrees and a minimum allowable tooth number of 12. (For pinions with fewer teeth, see tooth proportions for long addendum pinions and their mating short addendum gears in Tables 7 through 9d starting on page 2162.) A gear tooth standard is established by specifying the tooth proportions of the basic rack. Gears made to this standard will thus be conjugate with the specified rack and with each other. The basic rack forms for the 20-degree and 25-degree standard are shown on the following page; basic formulas for these proportions as a function of the gear diametral pitch and also of the circular pitch are given in Table 2. Tooth parts data are given in Table 3.

In recent years the established standard of almost universal use is the ANSI 20-degree standard spur gear form. It provides a gear with good strength and without fillet undercut in pinions of as few as eighteen teeth. Some more recent applications have required a tooth form of even greater strength and fewer teeth than eighteen. This requirement has stimulated the establishment of the ANSI 25-degree standard. This 25-degree form will give greater tooth strength than the 20-degree standard, will provide pinions of as few as twelve teeth without fillet undercut and will provide a lower contact compressive stress for greater gear set surface durability.

**American National Standard and Former American Standard Gear Tooth Forms**

<sup>a</sup>When using equal addendums on pinion and gear the minimum number of teeth on the pinion is 18 and the minimum total number of teeth in the pair is 36 for 20-degree full depth involute tooth form and 12 and 24, respectively, for 25-degree full depth tooth form.

<sup>b</sup>The dedendum in this column is used when the gear tooth is shaved. It allows for the higher fillet cut by a protuberance hob.

The working depth is equal to twice the addendum.

The whole depth is equal to the addendum plus the dedendum.

**Table 4. Tooth Proportions for Fine-Pitch Involute Spur and Helical Gears of 14½-, 20-, and 25-Degree Pressure Angle ANSI B6.7-1977**

Item	Spur	Helical
Addendum, $a$	$\frac{1.000}{P}$	$\frac{1.000}{P_n}$
Dedendum, $b$	$\frac{1.200}{P} + 0.002$ (min.)	$\frac{1.200}{P_n} + 0.002$ (min.)
Working Depth, $h_k$	$\frac{2.000}{P}$	$\frac{2.000}{P_n}$
Whole Depth, $h_t$	$\frac{2.200}{P} + 0.002$ (min.)	$\frac{2.200}{P_n} + 0.002$ (min.)
Clearance, $c$ (Standard)	$\frac{0.200}{P} + 0.002$ (min.)	$\frac{0.200}{P_n} + 0.002$ (min.)
(Shaved or Ground Teeth)	$\frac{0.350}{P} + 0.002$ (min.)	$\frac{0.350}{P_n} + 0.002$ (min.)
Tooth Thickness, $t$ At Pitch Diameter	$t = \frac{1.5708}{P}$	$t_n = \frac{1.5708}{P_n}$
Circular Pitch, $p$	$p = \frac{\pi D}{N}$ or $\frac{\pi d}{n}$ or $\frac{\pi}{P}$	$p_n = \frac{\pi}{P_n}$
Pitch Diameter Pinion, $d$	$\frac{n}{P}$	$\frac{n}{P_n \cos \psi}$
Gear, $D$	$\frac{N}{P}$	$\frac{N}{P_n \cos \psi}$
Outside Diameter Pinion, $d_o$	$\frac{n+2}{P}$	$\frac{1}{P_n} \left( \frac{n}{\cos \psi} + 2 \right)$
Gear, $D_o$	$\frac{N+2}{P}$	$\frac{1}{P_n} \left( \frac{N}{\cos \psi} + 2 \right)$
Center Distance, $C$	$\frac{N+n}{2P}$	$\frac{N+n}{2P_n \cos \psi}$
All dimensions are in inches. $P$ = Transverse Diametral Pitch $P_n$ = Normal Diametral Pitch $t_n$ = Normal Tooth Thickness at Pitch Diameter $p_n$ = Normal Circular Pitch		$\psi$ = Helix Angle $n$ = Number of pinion teeth $N$ = Number of gear teeth

**American National Standard Tooth Proportions for Fine-Pitch Involute Spur and Helical Gears.**— The proportions of spur gears in this Standard (ANSI B6.7-1977) follow closely ANSI B6.1-1968, R1974, “Tooth Proportions for Coarse-Pitch Involute Spur Gears.” The main difference between fine-pitch and coarse-pitch gears is the greater clearance specified for fine-pitch gears. The increased clearance provides for any foreign material that may tend to accumulate at the bottoms of the teeth and also the relatively larger fillet radius resulting from proportionately greater wear on the tips of fine-pitch cutting tools.

**Pressure Angle:** The standard pressure angle for fine-pitch gears is 20 degrees and is recommended for most applications. For helical gears this pressure angle applies in the *normal* plane. In certain cases, notably sintered or molded gears, or in gearing where greatest strength and wear resistance are desired, a 25-degree pressure angle may be required.

However, pressure angles greater than 20 degrees tend to require use of generating tools having very narrow point widths, and higher pressure angles require closer control of center distance when backlash requirements are critical.

In those cases where consideration of angular position or backlash is critical and both pinion and gear contain relatively large numbers of teeth, a  $14\frac{1}{2}$ -degree pressure angle may be desirable. In general, pressure angles less than 20 degrees require greater amounts of tooth modification to avoid undercutting problems and are limited to larger total numbers of teeth in pinion and gear when operating at a standard center distance. Information Sheet B in the Standard provides tooth proportions for both  $14\frac{1}{2}$ - and 25-degree pressure angle fine-pitch gears. **Table 4** provides tooth proportions for fine-pitch spur and helical gears with  $14\frac{1}{2}$ -, 20-, and 25-degree pressure angles, and **Table 5** provides tooth parts.

*Diametral Pitches:* Diametral pitches preferred are: 20, 24, 32, 40, 48, 64, 72, 80, 96, and 120.

**Table 5. American National Standard Fine Pitch Standard Gear Tooth Parts— $14\frac{1}{2}$ -, 20-, and 25-Degree Pressure Angles**

Diametral Pitch	Circular Pitch	Circular Thickness	Standard Addend.	Standard Dedend.	Special Dedend. <sup>a</sup>
<i>P</i>	<i>p</i>	<i>t</i>	<i>a</i>	<i>b</i>	<i>b</i>
20	0.1571	0.0785	0.0500	0.0620	0.0695
24	0.1309	0.0654	0.0417	0.0520	0.0582
32	0.0982	0.0491	0.0313	0.0395	0.0442
40	0.0785	0.0393	0.0250	0.0320	0.0358
48	0.0654	0.0327	0.0208	0.0270	0.0301
64	0.0491	0.0245	0.0156	0.0208	0.0231
72	0.0436	0.0218	0.0139	0.0187	0.0208
80	0.0393	0.0196	0.0125	0.0170	0.0189
96	0.0327	0.0164	0.0104	0.0145	0.0161
120	0.0262	0.0131	0.0083	0.0120	0.0132

<sup>a</sup>Based upon clearance for shaved or ground teeth.

The working depth is equal to twice the addendum. The whole depth is equal to the addendum plus the dedendum. For minimum number of teeth see page 2170.

**Other American Spur Gear Standards.**— An appended information sheet in the American National Standard ANSI B6.1-1968, R1974 provides tooth proportion information for three spur gear forms with the notice that they are “not recommended for new designs.” These forms are therefore considered to be obsolescent but the information is given on their proportions because they have been used widely in the past. These forms are the  $14\frac{1}{2}$ -degree full depth form, the 20-degree stub involute form and the  $14\frac{1}{2}$ -degree composite form which were covered in the former American Standard (ASA B6.1-1932). The basic rack for the  $14\frac{1}{2}$ -degree full depth form is shown on page 2148; basic formulas for these proportions are given in **Table 6**.

**Table 6. Formulas for Tooth Parts—Former American Standard Spur Gear Tooth Forms ASA B6.1-1932**

To Find	Diametral Pitch, $P$ Known	Circular Pitch, $p$ Known
14½-Degree Involute Full-depth Teeth		
Addendum	$a = 1.000 \div P$	$a = 0.3183 \times p$
Minimum Dedendum	$b = 1.157 \div P$	$b = 0.3683 \times p$
Working Depth	$h_k = 2.000 \div P$	$h_k = 0.6366 \times p$
Minimum Whole Depth	$h_t = 2.157 \div P$	$h_t = 0.6866 \times p$
Basic Tooth Thickness on Pitch Line	$t = 1.5708 \div P$	$t = 0.500 \times p$
Minimum Clearance	$c = 0.157 \div P$	$c = 0.050 \times p$
20-Degree Involute Stub Teeth		
Addendum	$a = 0.800 \div P$	$a = 0.2546 \times p$
Minimum Dedendum	$b = 1.000 \div P$	$b = 0.3183 \times p$
Working Depth	$h_k = 1.600 \div P$	$h_k = 0.5092 \times p$
Minimum Whole Depth	$h_t = 1.800 \div P$	$h_t = 0.5729 \times p$
Basic Tooth Thickness on Pitch Line	$t = 1.5708 \div P$	$t = 0.500 \times p$
Minimum Clearance	$c = 0.200 \div P$	$c = 0.0637 \times p$

*Note:* Radius of fillet equals  $1\frac{1}{3} \times$  clearance for 14½-degree full-depth teeth and  $1\frac{1}{2} \times$  clearance for 20-degree full-depth teeth.

*Note:* A suitable working tolerance should be considered in connection with all minimum recommendations.

**Fellows Stub Tooth.**—The system of stub gear teeth introduced by the Fellows Gear Shaper Co. is based upon the use of two diametral pitches. One diametral pitch, say, 8, is used as the basis for obtaining the dimensions for the addendum and dedendum, while another diametral pitch, say, 6, is used for obtaining the dimensions of the thickness of the tooth, the number of teeth, and the pitch diameter. Teeth made according to this system are designated as  $\frac{6}{8}$  pitch,  $\frac{12}{14}$  pitch, etc., the numerator in this fraction indicating the pitch determining the thickness of the tooth and the number of teeth, and the denominator, the pitch determining the depth of the tooth. The clearance is made greater than in the ordinary gear-tooth system and equals  $0.25 \div$  denominator of the diametral pitch. The pressure angle is 20 degrees.

This type of stub gear tooth is now used infrequently. For information as to the tooth part dimensions see 18th and earlier editions of *Machinery's Handbook*.

**Basic Gear Dimensions.**—The basic dimensions for all involute spur gears may be obtained using the formulas shown in **Table 1**. This table is used in conjunction with **Table 3** to obtain dimensions for coarse pitch gears and **Table 5** to obtain dimensions for fine pitch standard spur gears. To obtain the dimensions of gears that are specified at a standard circular pitch, the equivalent diametral pitch is first calculated by using the formula in **Table 1**. If the required number of teeth in the pinion ( $N_p$ ) is less than the minimum specified in either **Table 3** or **Table 5**, whichever is applicable, the gears must be proportioned by the long and short addendum method shown on page 2164.

### Formulas for Outside and Root Diameters of Spur Gears that Are Finish-hobbed, Shaped, or Pre-shaved

Notation	
$D$ = Pitch Diameter	$a$ = Standard Addendum
$D_O$ = Outside Diameter	$b$ = Standard Minimum Dedendum
$D_R$ = Root Diameter	$b_s$ = Standard Dedendum
$P$ = Diametral Pitch	$b_{ps}$ = Dedendum for Pre-shaving
14½-, 20-, And 25-degree Involute Full-depth Teeth (19 <i>P</i> and coarser) <sup>a</sup>	
$D_O = D + 2a = \frac{N}{P} + \left(2 \times \frac{1}{P}\right)$	
$D_R = D - 2b = \frac{N}{P} - \left(2 \times \frac{1.157}{P}\right)$	(Hobbed) <sup>b</sup>
$D_R = D - 2b_s = \frac{N}{P} - \left(2 \times \frac{1.25}{P}\right)$	(Shaped) <sup>c</sup>
$D_R = D - 2b_{ps} = \frac{N}{P} - \left(2 \times \frac{1.35}{P}\right)$	(Pre-shaved) <sup>d</sup>
$D_R = D - 2b_{ps} = \frac{N}{P} - \left(2 \times \frac{1.40}{P}\right)$	(Pre-shaved) <sup>e</sup>
20-degree Involute Fine-pitch Full-depth Teeth (20 <i>P</i> and finer)	
$D_O = D + 2a = \frac{N}{P} + \left(2 \times \frac{1}{P}\right)$	
$D_R = D - 2b = \frac{N}{P} - 2\left(\frac{1.2}{P} + 0.002\right)$	(Hobbed or Shaped) <sup>f</sup>
$D_R = D - 2b_{ps} = \frac{N}{P} - 2\left(\frac{1.35}{P} + 0.002\right)$	(Pre-shaved) <sup>g</sup>
20-degree Involute Stub Teeth <sup>a</sup>	
$D_O = D + 2a = \frac{N}{P} + \left(2 \times \frac{0.8}{P}\right)$	
$D_R = D - 2b = \frac{N}{P} - \left(2 \times \frac{1}{P}\right)$	(Hobbed)
$D_R = D - 2b_{ps} = \frac{N}{P} - \left(2 \times \frac{1.35}{P}\right)$	(Pre-shaved)

<sup>a</sup> 14½-degree full-depth and 20-degree stub teeth are not recommended for new designs.

<sup>b</sup> According to ANSI B6.1-1968 a minimum clearance of  $0.157/P$  may be used for the basic 20-degree and 25-degree pressure angle rack in the case of shallow root sections and the use of existing hobs and cutters.

<sup>c</sup> According to ANSI B6.1-1968 the preferred clearance is  $0.250/P$ .

<sup>d</sup> According to ANSI B6.1-1968 the clearance for teeth which are shaved or ground is  $0.350/P$ .

<sup>e</sup> When gears are preshaved cut on a gear shaper the dedendum will usually need to be increased to  $1.40/P$  to allow for the higher fillet trochoid produced by the shaper cutter; this is of particular importance on gears of few teeth or if the gear blank configuration requires the use of a small diameter shaper cutter, in which case the dedendum may need to be increased to as much as  $1.45/P$ . This should be avoided on highly loaded gears where the consequently reduced  $J$  factor will increase gear tooth stress excessively.

<sup>f</sup> According to ANSI B6.7-1967 the standard clearance is  $0.200/P + 0.002$  (min.).

<sup>g</sup> According to ANSI B6.7-1967 the clearance for shaved or ground teeth is  $0.350/P + 0.002$  (min.).

**Gears for Given Center Distance and Ratio.**— When it is necessary to use a pair of gears of given ratio at a specified center distance  $C_1$ , it may be found that no gears of standard diametral pitch will satisfy the center distance requirement. Gears of standard diametral pitch  $P$  may need to be redesigned to operate at other than their standard pitch diameter  $D$  and standard pressure angle  $\phi$ . The diametral pitch  $P_1$  at which these gears will operate is

$$P_1 = \frac{N_P + N_G}{2C_1} \quad (1)$$

where  $N_P$  = number of teeth in pinion

$N_G$  = number of teeth in gear

and their operating pressure angle  $\phi_1$  is

$$\phi_1 = \arccos\left(\frac{P_1}{P} \cos \phi\right) \quad (2)$$

Thus although the pair of gears are cut to a diametral pitch  $P$  and a pressure angle  $\phi$ , they operate as standard gears of diametral pitch  $P_1$  and pressure angle  $\phi_1$ . The pitch  $P$  and pressure angle  $\phi$  should be chosen so that  $\phi_1$  lies between about 18 and 25 degrees.

The operating pitch diameters of the pinion  $D_{p1}$  and of the gear  $D_{G1}$  are

$$D_{P1} = \frac{N_P}{P_1} \quad (3a) \quad \text{and} \quad D_{G1} = \frac{N_G}{P_1} \quad (3b)$$

The base diameters of the pinion  $D_{PB1}$  and of the gear  $D_{GB1}$  are

$$D_{PB1} = D_{P1} \cos \phi_1 \quad (4a) \quad \text{and} \quad D_{GB1} = D_{G1} \cos \phi_1 \quad (4b)$$

The basic tooth thickness,  $t_1$ , at the operating pitch diameter for both pinion and gear is

$$t_1 = \frac{1.5708}{P_1} \quad (5)$$

The root diameters of the pinion  $D_{PR1}$  and gear  $D_{GR1}$  and the corresponding outside diameters  $D_{PO1}$  and  $D_{GO1}$  are not standard because each gear is to be cut with a cutter that is not standard for the operating pitch diameters  $D_{P1}$  and  $D_{G1}$ .

The root diameters are

$$D_{PR1} = \frac{N_P}{P} - 2b_{P1} \quad (6a) \quad \text{and} \quad D_{GR1} = \frac{N_G}{P} - 2b_{G1} \quad (6b)$$

$$\text{where} \quad b_{P1} = b_c - \left( \frac{t_{P2} - 1.5708/P}{2 \tan \phi} \right) \quad (7a)$$

$$\text{and} \quad b_{G1} = b_c - \frac{t_{G2} - 1.5708/P}{2 \tan \phi} \quad (7b)$$

where  $b_c$  is the hob or cutter addendum for the pinion and gear.

The tooth thicknesses of the pinion  $t_{P2}$  and the gear  $t_{G2}$  are

$$t_{P2} = \frac{N_P}{P} \left( \frac{1.5708}{N_P} + \text{inv } \phi_1 - \text{inv } \phi \right) \quad (8a)$$

$$t_{G2} = \frac{N_G}{P} \left( \frac{1.5708}{N_G} + \text{inv}\phi_1 - \text{inv}\phi \right) \quad (8b)$$

The outside diameter of the pinion  $D_{PO}$  and the gear  $D_{GO}$  are

$$D_{PO} = 2 \times C_1 - D_{GR1} - 2(b_c - 1/P) \quad (9a)$$

and 
$$D_{GO} = 2 \times C_1 - D_{PR1} - 2(b_c - 1/P) \quad (9b)$$

*Example:* Design gears of 8 diametral pitch, 20-degree pressure angle, and 28 and 88 teeth to operate at 7.50-inch center distance. The gears are to be cut with a hob of 0.169-inch addendum.

$$P_1 = \frac{28 + 88}{2 \times 7.50} = 7.7333 \quad (1)$$

$$\phi_1 = \arccos\left(\frac{7.7333}{8} \times 0.93969\right) = 24.719^\circ \quad (2)$$

$$D_{P1} = \frac{28}{7.7333} = 3.6207 \text{ in.} \quad (3a)$$

and 
$$D_{G1} = \frac{88}{7.7333} = 11.3794 \text{ in.} \quad (3b)$$

$$D_{PB1} = 3.6207 \times 0.90837 = 3.2889 \text{ in.} \quad (4a)$$

and 
$$D_{GB1} = 11.3794 \times 0.90837 = 10.3367 \text{ in.} \quad (4b)$$

$$t_1 = \frac{1.5708}{7.7333} = 0.20312 \text{ in.} \quad (5)$$

$$D_{PR1} = \frac{28}{8} - 2 \times 0.1016 = 3.2968 \text{ in.} \quad (6a)$$

and 
$$D_{GR1} = \frac{88}{8} - 2 \times (-0.0428) = 11.0856 \text{ in.} \quad (6b)$$

$$b_{P1} = 0.169 - \left(\frac{0.2454 - 1.5708/8}{2 \times 0.36397}\right) = 0.1016 \text{ in.} \quad (7a)$$

$$b_{G1} = 0.169 - \left(\frac{0.3505 - 1.5708/8}{2 \times 0.36397}\right) = -0.0428 \text{ in.} \quad (7b)$$

$$t_{P2} = \frac{28}{8} \left( \frac{1.5708}{28} + 0.028922 - 0.014904 \right) = 0.2454 \text{ in.} \quad (8a)$$

$$t_{G2} = \frac{88}{8} \left( \frac{1.5708}{88} + 0.028922 - 0.014904 \right) - 0.3505 \text{ in.} \quad (8b)$$

$$D_{PO1} = 2 \times 7.50 - 11.0856 - 2(0.169 - 1/8) = 3.8264 \text{ in.} \quad (9a)$$

$$D_{GO1} = 2 \times 7.50 - 3.2968 - 2(0.169 - 1/8) = 11.6152 \text{ in.} \quad (9b)$$

**Tooth Thickness Allowance for Shaving.**— Proper stock allowance is important for good results in shaving operations. If too much stock is left for shaving, the life of the shaving tool is reduced and, in addition, shaving time is increased. The following figures represent the amount of stock to be left on the teeth for removal by shaving under average conditions: For diametral pitches of 2 to 4, a thickness of 0.003 to 0.004 inch (0.0762–0.1016 mm)— one-half on each side of the tooth; for 5 to 6 diametral pitch, 0.0025 to 0.0035 inch (0.0635–0.0889 mm); for 7 to 10 diametral pitch, 0.002 to 0.003 inch (0.0508–0.0762 mm); for 11 to 14 diametral pitch, 0.0015 to 0.0020 inch (0.0381–0.0508 mm); for 16 to 18 diametral pitch, 0.001 to 0.002 inch (0.0254–0.0508 mm); for 20 to 48 diametral pitch, 0.0005 to 0.0015 inch (0.0127–0.0381 mm); and for 52 to 72 diametral pitch, 0.0003 to 0.0007 inch (0.00762–0.01778 mm).

The thickness of the gear teeth may be measured in several ways to determine the amount of stock left on the sides of the teeth to be removed by shaving. If it is necessary to measure the tooth thickness during the preshaving operation while the gear is in the gear shaper or hobbing machine, a gear tooth caliper or pins would be employed. Caliper methods of measuring gear teeth are explained in detail on page 2163 for measurements over single teeth, and on page 2252 for measurements over two or more teeth.

When the preshaved gear can be removed from the machine for checking, the center distance method may be employed. In this method, the preshaved gear is meshed without backlash with a gear of standard tooth thickness and the increase in center distance over standard is noted. The amount of total tooth thickness over standard on the preshaved gear can then be determined by the formula:  $t_2 = 2 \tan \phi \times d$ , where  $t_2$  = amount that the total thickness of the tooth exceeds the standard thickness,  $\phi$  = pressure angle, and  $d$  = amount that the center distance between the two gears exceeds the standard center distance.

**Circular Pitch for Given Center Distance and Ratio.**— When it is necessary to use a pair of gears of given ratio at a specified center distance, it may be found that no gears of standard diametral pitch will satisfy the center distance requirement. Hence, circular pitch gears may be selected. To find the required circular pitch  $p$ , when the center distance  $C$  and total number of teeth  $N$  in both gears are known, use the following formula:

$$p = \frac{C \times 6.2832}{N}$$

*Example:* A pair of gears having a ratio of 3 is to be used at a center distance of 10.230 inches. If one gear has 60 teeth and the other 20, what must be their circular pitch?

$$p = \frac{10.230 \times 6.2832}{60 + 20} = 0.8035 \text{ inch}$$

**Circular Thickness of Tooth when Outside Diameter is Standard.**— For a full-depth or stub tooth gear of standard outside diameter, the tooth thickness on the pitch circle (circular thickness or arc thickness) is found by the following formula:

$$t = \frac{1.5708}{P}$$

where  $t$  = circular thickness and  $P$  = diametral pitch. In Fellows stub tooth gears the diametral pitch used is the numerator of the pitch fraction (for example, 6 if the pitch is 6/8).

*Example 1:* Find the tooth thickness on the pitch circle of a 14½-degree full-depth tooth of 12 diametral pitch.

$$t = 1.5708 / 12 = 0.1309 \text{ inch}$$

*Example 2:* Find the tooth thickness on the tooth circle of a 20-degree full-depth involute tooth having a diametral pitch of 5.

$$t = \frac{1.5708}{5} = 0.31416, \text{ say } 0.3142 \text{ inch}$$

The tooth thickness on the pitch circle can be determined very accurately by means of measurement over wires which are located in tooth spaces that are diametrically opposite or as nearly diametrically opposite as possible. Where measurement over wires is not feasible, the circular or arc tooth thickness can be used in determining the chordal thickness which is the dimension measured with a gear tooth caliper.

**Circular Thickness of Tooth when Outside Diameter has been Enlarged.**— When the outside diameter of a small pinion is not standard but is enlarged to avoid undercut and to improve tooth action, the teeth are located farther out radially relative to the standard pitch diameter and consequently the circular tooth thickness at the standard pitch diameter is increased. To find this increased arc thickness the following formula is used, where  $t$  = tooth thickness;  $e$  = amount outside diameter is increased over standard;  $\phi$  = pressure angle; and  $p$  = circular pitch at the standard pitch diameter.

$$t = \frac{p}{2} + e \tan \phi$$

*Example:* The outside diameter of a pinion having 10 teeth of 5 diametral pitch and a pressure angle of  $14\frac{1}{2}$  degrees is to be increased by 0.2746 inch. The circular pitch equivalent to 5 diametral pitch is 0.6283 inch. Find the arc tooth thickness at the standard pitch diameter.

$$t = \frac{0.6283}{2} + (0.2746 \times \tan 14\frac{1}{2}^\circ)$$

$$t = 0.3142 + (0.2746 \times 0.25862) = 0.3852 \text{ inch}$$

**Circular Thickness of Tooth when Outside Diameter has been Reduced.**— If the outside diameter of a gear is reduced, as is frequently done to maintain the standard center distance when the outside diameter of the mating pinion is increased, the circular thickness of the gear teeth at the standard pitch diameter will be reduced. This decreased circular thickness can be found by the following formula where  $t$  = circular thickness at the standard pitch diameter;  $e$  = amount outside diameter is reduced under standard;  $\phi$  = pressure angle; and  $p$  = circular pitch.

$$t = \frac{p}{2} - e \tan \phi$$

*Example:* The outside diameter of a gear having a pressure angle of  $14\frac{1}{2}$  degrees is to be reduced by 0.2746 inch or an amount equal to the increase in diameter of its mating pinion. The circular pitch is 0.6283 inch. Determine the circular tooth thickness at the standard pitch diameter.

$$t = \frac{0.6283}{2} - (0.2746 \times \tan 14\frac{1}{2}^\circ)$$

$$t = 0.3142 - (0.2746 \times 0.25862) = 0.2432 \text{ inch}$$

**Chordal Thickness of Tooth when Outside Diameter is Standard.**— To find the chordal or straight line thickness of a gear tooth the following formula can be used where  $t_c$  = chordal thickness;  $D$  = pitch diameter; and  $N$  = number of teeth.

$$t_c = D \sin\left(\frac{90^\circ}{N}\right)$$

*Example:* A pinion has 15 teeth of 3 diametral pitch; the pitch diameter is equal to  $15 \div 3$  or 5 inches. Find the chordal thickness at the standard pitch diameter.

$$t_c = 5 \sin\left(\frac{90^\circ}{15}\right) = 5 \sin 6^\circ = 5 \times 0.10453 = 0.5226 \text{ inch}$$

### Chordal Thicknesses and Chordal Addenda of Milled, Full-depth Gear Teeth and of Gear Milling Cutters

$T$  = chordal thickness of gear tooth and cutter tooth at pitch line;  
 $H$  = chordal addendum for full-depth gear tooth;  
 $A$  = chordal addendum of cutter =  $(2.157 \div \text{diametral pitch}) - H$   
 $= (0.6866 \times \text{circular pitch}) - H$ .

**Chordal Thickness of Tooth when Outside Diameter is Special.**— When the outside diameter is larger or smaller than standard the chordal thickness at the standard pitch diameter is found by the following formula where  $t_c$  = chordal thickness at the standard pitch diameter  $D$ ;  $t$  = circular thickness at the standard pitch diameter of the enlarged pinion or reduced gear being measured.

$$t_c = t - \frac{t^3}{6 \times D^2}$$

*Example 1:* The outside diameter of a pinion having 10 teeth of 5 diametral pitch has been enlarged by 0.2746 inch. This enlargement has increased the circular tooth thickness at the standard pitch diameter (as determined by the formula previously given) to 0.3852 inch. Find the equivalent chordal thickness.

$$t_c = 0.3852 - \frac{0.3852^3}{6 \times 2^2} = 0.3852 - 0.0024 = 0.3828 \text{ inch}$$

(The error introduced by rounding the circular thickness to three significant figures before cubing it only affects the fifth decimal place in the result.)

*Example 2:* A gear having 30 teeth is to mesh with the pinion in **Example 1** and is *reduced* so that the circular tooth thickness at the standard pitch diameter is 0.2432 inch. Find the equivalent chordal thickness.

$$t_c = 0.2432 - \frac{0.2432^3}{6 \times 6^2} = 0.2432 - 0.00007 = 0.2431 \text{ inch}$$

**Chordal Addendum.**— In measuring the chordal thickness, the vertical scale of a gear tooth caliper is set to the chordal or “corrected” addendum to locate the caliper jaws at the pitch line (see *Method of setting a gear tooth caliper* on page 2164). The simplified formula which follows may be used in determining the chordal addendum either when the addendum is standard for full-depth or stub teeth or when the addendum is either longer or shorter than standard as in case of an enlarged pinion or a gear which is to mesh with an enlarged pinion and has a reduced addendum to maintain the standard center distance. If  $a_c$  = chordal addendum;  $a$  = addendum; and  $t$  = circular thickness of tooth at pitch diameter  $D$ ; then,

$$a_c = a + \frac{t^2}{4D}$$

*Example 1:* The outside diameter of an 8 diametral pitch 14-tooth pinion with 20-degree full-depth teeth is to be increased by using an enlarged addendum of  $1.234 \div 8 = 0.1542$  inch (see **Table 7** on page 2162). The basic tooth thickness of the enlarged pinion is  $1.741 \div 8 = 0.2176$  inch. What is the chordal addendum?

$$\text{Chordal addendum} = 0.1542 + \frac{0.2176^2}{4 \times (14 \div 8)} = 0.1610 \text{ inch}$$

*Example 2:* The outside diameter of a  $14\frac{1}{2}$ -degree pinion having 12 teeth of 2 diametral pitch is to be enlarged 0.624 inch to avoid undercut (see **Table 8** on page 2162), thus increasing the addendum from 0.5000 to 0.8120 inch and the arc thickness at the pitch line from 0.7854 to 0.9467 inch. Then,

$$\text{Chordal addendum of pinion} = 0.8120 + \frac{0.9467^2}{4 \times (12 \div 2)} = 0.8493 \text{ inch}$$

**Table 7. Addendums and Tooth Thicknesses for Coarse-Pitch Long-Addendum Pinions and their Mating Short-Addendum Gears—20- and 25-degree Pressure Angles ANSI B6.1-1968 (R1974)**

Number of Teeth in Pinion	Addendum		Basic Tooth Thickness		Number of Teeth in Gear
	Pinion	Gear	Pinion	Gear	
$N_P$	$a_P$	$a_G$	$t_P$	$t_G$	$N_G$ (min)
20-Degree Involute Full Depth Tooth Form (Less than 20 Diametral Pitch)					
10	1.468	.532	1.912	1.230	25
11	1.409	.591	1.868	1.273	24
12	1.351	.649	1.826	1.315	23
13	1.292	.708	1.783	1.358	22
14	1.234	.766	1.741	1.400	21
15	1.175	.825	1.698	1.443	20
16	1.117	.883	1.656	1.486	19
17	1.058	.942	1.613	1.529	18
25-Degree Involute Full Depth Tooth Form (Less than 20 Diametral Pitch)					
10	1.184	.816	1.742	1.399	15
11	1.095	.905	1.659	1.482	14

All values are for 1 diametral pitch. For any other sizes of teeth all linear dimensions should be divided by the diametral pitch. Basic tooth thicknesses do not include an allowance for backlash.

**Table 8. Enlarged Pinion and Reduced Gear Dimensions to Avoid Interference Coarse Pitch 14½-degree Involute Full Depth Teeth**

Number of Pinion Teeth	Changes in Pinion and Gear Diameters	Circular Tooth Thickness		Min. No. of Teeth in Mating Gear

29	0.1820	1.6179	1.5237	35	25
30	0.1193	1.6017	1.5399	34	24
31	0.0566	1.5854	1.5562	33	24

All dimensions are given in inches and are for 1 diametral pitch. For other pitches divide tabular values by desired diametral pitch.

Add to the standard outside diameter of the pinion the amount given in the second column of the table divided by the desired diametral pitch, and (to maintain standard center distance) subtract the same amount from the outside diameter of the mating gear. Long addendum pinions will mesh with standard gears, but the center distance will be greater than standard.

*Example 3:* The outside diameter of the mating gear for the pinion in **Example 3** is to be reduced 0.624 inch. The gear has 60 teeth and the addendum is reduced from 0.5000 to 0.1881 inch (to maintain the standard center distance), thus reducing the arc thickness to 0.6240 inch. Then,

$$\text{Chordal addendum of gear} = 0.1881 + \frac{0.6240^2}{4 \times (60 \div 2)} = 0.1913 \text{ inch}$$

When a gear addendum is reduced as much as the mating pinion addendum is enlarged, the minimum number of gear teeth required to prevent undercutting depends upon the enlargement of the mating pinion. To illustrate, if a  $14\frac{1}{2}$ -degree pinion with 13 teeth is enlarged 1.185 inches, then the reduced mating gear should have a minimum of 51 teeth to avoid undercut (see **Table 8** on page 2162).

**Tables for Chordal Thicknesses and Chordal Addenda of Milled, Full-depth Teeth.**— Two convenient tables for checking gears with milled, full-depth teeth are given on pages 2159 and 2160. The first shows chordal thicknesses and chordal addenda for the lowest number of teeth cut by gear cutters Nos. 1 through 8, and for the commonly used diametral pitches. The second gives similar data for commonly used circular pitches. In each case the data shown are accurate for the number of gear teeth indicated, but are approximate for other numbers of teeth within the range of the cutter under which they appear in the table. For the higher diametral pitches and lower circular pitches, the error introduced by using the data for any tooth number within the range of the cutter under which it appears is comparatively small. The chordal thicknesses and chordal addenda for gear cutters Nos. 1 through 8 of the more commonly used diametral and circular pitches can be obtained from the table and formulas on pages 2159 and 2160.

**Caliper Measurement of Gear Tooth.**— In cutting gear teeth, the general practice is to adjust the cutter or hob until it grazes the outside diameter of the blank; the cutter is then sunk to the total depth of the tooth space plus whatever slight additional amount may be required to provide the necessary play or backlash between the teeth. (For recommendations concerning backlash and excess depth of cut required, see *Backlash* starting on page 2179.) If the outside diameter of the gear blank is correct, the tooth thickness should also be correct after the cutter has been sunk to the depth required for a given pitch and backlash. However, it is advisable to check the tooth thickness by measuring it, and the vernier gear-tooth caliper (see following illustration) is commonly used in measuring the thickness.

The vertical scale of this caliper is set so that when it rests upon the top of the tooth as shown, the lower ends of the caliper jaws will be at the height of the pitch circle; the horizontal scale then shows the chordal thickness of the tooth at this point. If the gear is being cut on a milling machine or with the type of gear-cutting machine employing a formed milling cutter, the tooth thickness is checked by first taking a trial cut for a short distance at one side of the blank; then the gear blank is indexed for the next space and another cut is taken far enough to mill the full outline of the tooth. The tooth thickness is then measured.

Before the gear-tooth caliper can be used, it is necessary to determine the correct chordal thickness and also the chordal addendum (or “corrected addendum” as it is sometimes called). The vertical scale is set to the chordal addendum, thus locating the ends of the jaws at the height of the pitch circle. The rules or formulas to use in determining the chordal thickness and chordal addendum will depend upon the outside diameter of the gear; for example, if the outside diameter of a small pinion is enlarged to avoid undercut and improve the tooth action, this must be taken into account in figuring the chordal thickness and chordal addendum as shown by the accompanying rules. The detail of a gear tooth included with the gear-tooth caliper illustration represents the chordal thickness  $T$ , the addendum  $S$ , and the chordal addendum  $H$ . For the caliper measurements over two or more teeth see *Checking Spur Gear Size by Chordal Measurement Over Two or More Teeth* starting on page 2252.

Method of setting a gear tooth caliper

### Selection of Involute Gear Milling Cutter for a Given Diametral Pitch and Number of Teeth.

When gear teeth are cut by using formed milling cutters, the cutter must be selected to suit both the pitch and the number of teeth, because the shapes of the tooth spaces vary according to the number of teeth. For instance, the tooth spaces of a small pinion are not of the same shape as the spaces of a large gear of equal pitch. Theoretically, there should be a different formed cutter for every tooth number, but such refinement is unnecessary in practice. The involute formed cutters commonly used are made in series of eight cutters for each diametral pitch (see *Series of Involute, Finishing Gear Milling Cutters for Each Pitch*). The shape of each cutter in this series is correct for a certain number of teeth only, but it can be used for other numbers within the limits given. For instance, a No. 6 cutter may be used for gears having from 17 to 20 teeth, but the tooth outline is correct only for 17 teeth or the lowest number in the range, which is also true of the other cutters listed. When this cutter is used for a gear having, say, 19 teeth, too much material is removed from the upper surfaces of the teeth, although the gear meets ordinary requirements. When greater accuracy of tooth shape is desired to ensure smoother or quieter operation, an intermediate series of cutters having half-numbers may be used provided the number of gear teeth is between the number listed for the regular cutters (see *Series of Involute, Finishing Gear Milling Cutters for Each Pitch*).

Involute gear milling cutters are designed to cut a composite tooth form, the center portion being a true involute while the top and bottom portions are cycloidal. This composite form is necessary to prevent tooth interference when milled mating gears are meshed with each other. Because of their composite form, milled gears will not mate satisfactorily enough for high grade work with those of generated, full-involute form. Composite form hobs are available, however, which will produce generated gears that mesh with those cut by gear milling cutters.

*Metric Module Gear Cutters:* The accompanying table for selecting the cutter number to be used to cut a given number of teeth may be used also to select metric module gear cutters except that the numbers are designated in reverse order. For example, cutter No. 1, in the metric module system, is used for 12-13 teeth, cutter No. 2 for 14-16 teeth, etc.

**Increasing Pinion Diameter to Avoid Undercut or Interference.**— On coarse-pitch pinions with small numbers of teeth (10 to 17 for 20-degree and 10 and 11 for 25-degree pressure angle involute tooth forms) undercutting of the tooth profile or fillet interference

**Circular Pitch in Gears—Pitch Diameters, Outside Diameters, and Root Diameters**

For any particular circular pitch and number of teeth, use the table as shown in the example to find the pitch diameter, outside diameter, and root diameter. *Example:* Pitch diameter for 57 teeth of 6-inch circular pitch = 10 × pitch diameter given under factor for 5 teeth plus pitch diameter given under factor for 7 teeth. (10 × 9.5493) + 13.3690 = 108.862 inches.

Outside diameter of gear equals pitch diameter plus outside diameter factor from next-to-last column in table = 108.862 + 3.8197 = 112.682 inches.

Root diameter of gear equals pitch diameter minus root diameter factor from last column in table = 108.862 – 4.4194 = 104.443 inches.

Circular Pitch in Inches	Factor for Number of Teeth									Outside Dia. Factor	Root Diameter Factor

1/16	0.0199	0.0398	0.0597	0.0796	0.0995	0.1194	0.1393	0.1592	0.1790	0.0398	0.0460

with the tip of the mating gear can be avoided by making certain changes from the standard tooth proportions that are specified in **Table 3** on page 2150. These changes consist essentially in increasing the addendum and hence the outside diameter of the pinion and decreasing the addendum and hence the outside diameter of the mating gear. These changes in outside diameters of pinion and gear do not change the velocity ratio or the procedures in cutting the teeth on a hobbing machine or generating type of shaper or planer.

Data in **Table 7** on page 2162 are taken from ANSI Standard B6.1-1968, reaffirmed 1974, and show for 20-degree and 25-degree full-depth standard tooth forms, respectively,

the addendums and tooth thicknesses for long addendum pinions and their mating short addendum gears when the number of teeth in the pinion is as given. Similar data for former standard  $14\frac{1}{2}$ -degree full-depth teeth (20 diametral pitch and coarser) are given in [Table 8](#) on page [2162](#).

*Example:* A 14-tooth, 20-degree pressure angle pinion of 6 diametral pitch is to be enlarged. What will be the outside diameters of the pinion and a 60-tooth mating gear? If the mating gear is to have the minimum number of teeth to avoid undercut, what will be its outside diameter?

$$D_o(\text{ pinion}) = \frac{N_P}{P} + 2a = \frac{14}{6} + 2\left(\frac{1.234}{6}\right) = 2.745 \text{ inches}$$

$$D_o(\text{ gear}) = \frac{N_G}{P} + 2a = \frac{60}{6} + 2\left(\frac{0.766}{6}\right) = 10.255 \text{ inches}$$

For a mating gear with minimum number of teeth to avoid undercut:

$$D_o(\text{ gear}) = \frac{N_G}{P} + 2a = \frac{21}{6} + 2\left(\frac{0.766}{6}\right) = 3.755 \text{ inches}$$

### Series of Involute, Finishing Gear Milling Cutters for Each Pitch

Number of Cutter	Will cut Gears from	Number of Cutter	Will cut Gears from
1	135 teeth to a rack	5	21 to 25 teeth
2	55 to 134 teeth	6	17 to 20 teeth
3	35 to 54 teeth	7	14 to 16 teeth
4	26 to 34 teeth	8	12 to 13 teeth
The regular cutters listed above are used ordinarily.			
The cutters listed below (an intermediate series having half numbers) may be used when greater accuracy of tooth shape is essential in cases where the number of teeth is between the numbers for which the regular cutters are intended.			
Number of Cutter	Will cut Gears from	Number of Cutter	Will cut Gears from
$1\frac{1}{2}$	80 to 134 teeth	$5\frac{1}{2}$	19 to 20 teeth
$2\frac{1}{2}$	42 to 54 teeth	$6\frac{1}{2}$	15 to 16 teeth
$3\frac{1}{2}$	30 to 34 teeth	$7\frac{1}{2}$	13 teeth
$4\frac{1}{2}$	23 to 25 teeth	...	...

Roughing cutters are made with No. 1 form only. Dimensions of roughing and finishing cutters are given on page [865](#). Dimensions of cutters for bevel gears are given on page [866](#).

*Enlarged Fine-Pitch Pinions:* American Standard ANSI B6.7-1977, Information Sheet A provides a different system for 20-degree pressure angle pinion enlargement than is used for coarse-pitch gears. Pinions with 11 through 23 teeth (9 through 14 teeth for 25-degree pressure angle) are enlarged so that a standard tooth thickness rack with addendum  $1.05/P$  will start contact  $5^\circ$  of roll above the base circle radius. The use of  $1.05/P$  for the addendum allows for center distance variation and eccentricity of the mating gear outside diameter; the  $5^\circ$  roll angle avoids the fabrication of the involute in the troublesome area near the base circle.

Pinions with less than 11 teeth (9 teeth for 25-degree pressure angle) are enlarged to the extent that the highest point of undercut coincides with the start of contact with the standard rack described previously. The height of undercut considered is that produced by a sharp-cornered 120 pitch hob. Pinions with less than 13 teeth (11 teeth for 25-degree pressure angle) are truncated to provide a top land of  $0.275/P$ . Data for enlarged pinions may be found in [Tables 9a, 9b, 9c, and 9d](#).

**Table 9a. Increase in Dedendum,  $\Delta$  for 20 -, and 25 -Degree Pressure Angle Fine-Pitch Enlarged Pinions and Reduced Gears ANSI B6.7-1977**

Diametral Pitch, $P$	$\Delta$	Diametral Pitch, $P$	$\Delta$	Diametral Pitch, $P$	$\Delta$	Diametral Pitch, $P$	$\Delta$	Diametral Pitch, $P$	$\Delta$
20	0.0000	32	0.0007	48	0.0012	72	0.0015	96	0.0016
24	0.0004	40	0.0010	64	0.0015	80	0.0015	120	0.0017

$\Delta$  = increase in standard dedendum to provide increased clearance. See footnote to Table 9d.

<sup>a</sup> If enlarged mating pinions are of unequal size, the center distance is increased by an amount equal to one-half the sum of their increase over standard outside diameters. Data in this column are not given in the standard.

<sup>b</sup> To maintain standard center distance when using an enlarged pinion, the mating gear diameter must be decreased by the amount of the pinion enlargement.

All dimensions are given in inches and are for 1 diametral pitch. For other pitches divide tabulated dimensions by the diametral pitch.

<sup>a</sup>Caution should be exercised in the use of pinions above the horizontal lines. They should be checked for suitability, particularly in the areas of contact ratio (less than 1.2 is not recommended), center distance, clearance, and tooth strength.

<sup>b</sup>The actual dedendum is calculated by dividing the values in this column by the desired diametral pitch and then adding to the result an amount  $\Delta$  found in Table 9a. As an example, a 20-degree pressure angle 7-tooth pinion meshing with a 42-tooth gear would have, for 24 diametral pitch, a dedendum of  $0.4565 \div 24 + 0.0004 = 0.0194$ . The 42-tooth gear would have a dedendum of  $2.0235 \div 24 + 0.004 = 0.0847$  inch.

All dimensions are given in inches.

<sup>a</sup> Caution should be exercised in the use of pinions above the horizontal lines. They should be checked for suitability, particularly in the areas of contact ratio (less than 1.2 is not recommended), center distance, clearance, and tooth strength.

<sup>b</sup> The actual dedendum is calculated by dividing the values in this column by the desired diametral pitch and then adding to the result an amount  $\Delta$  found in Table 9a. As an example, a 20-degree pressure angle 7-tooth pinion meshing with a 42-tooth gear would have, for 24 diametral pitch, a dedendum of  $0.4565 \div 24 + 0.0004 = 0.0194$ . The 42-tooth gear would have a dedendum of  $2.0235 \div 24 + 0.004 = 0.0847$  inch.

All dimensions are given in inches.

All values are for 1 diametral pitch. For any other sizes of teeth, all linear dimensions should be divided by the diametral pitch.

*Note:* The tables in the ANSI B6.7-1977 standard also specify Form Diameter, Roll Angle to Form Diameter, and Top Land. These are not shown here. The top land is in no case less than  $0.275/P$ . The form diameters and the roll angles to form diameter shown in the Standard are the values which should be met with a standard hob when generating the tooth thicknesses shown in the tables. These form diameters provides more than enough length of involute profile for any mating gear smaller than a rack. However, since these form diameters are based on gear tooth generation using standard hobs, they should impose little or no hardship on manufacture except in cases of the most critical quality levels. In such cases, form diameter specifications and master gear design should be based upon actual mating conditions.

**Minimum Number of Teeth to Avoid Undercutting by Hob.**—The data in the above tables give tooth proportions for low numbers of teeth to avoid interference between the gear tooth tip and the pinion tooth flank. Consideration must also be given to possible undercutting of the pinion tooth flank by the hob used to cut the pinion. The minimum number of teeth  $N_{\min}$  of standard proportion that may be cut without undercut is:

$N_{\min} = 2P \csc^2 \phi [a_H - r_t (1 - \sin \phi)]$  where:  $a_H$  = cutter addendum;  $r_t$  = radius at cutter tip or corners;  $\phi$  = cutter pressure angle; and  $P$  = diametral pitch.

**Gear to Mesh with Enlarged Pinion.**—Data in the fifth column of **Table 8** show minimum number of teeth in a mating gear which can be cut with hob or rack type cutter without undercut, when outside diameter of gear has been reduced an amount equal to the pinion enlargement to retain the standard center distance. To calculate  $N$  for the gear, insert addendum  $a$  of enlarged mating pinion in the formula  $N = 2a \times \csc^2 \phi$ .

*Example:* A gear is to mesh with a 24-tooth pinion of 1 diametral pitch which has been enlarged 0.4954 inch, as shown by the table. The pressure angle is  $14\frac{1}{2}$  degrees. Find minimum number of teeth  $N$  for reduced gear.

$$\text{Pinion addendum} = 1 + (0.4954 \div 2) = 1.2477$$

$$\text{Hence, } N = 2 \times 1.2477 \times 15.95 = 39.8 \text{ (use 40)}$$

In the case of fine pitch gears with reduced outside diameters, the recommended minimum numbers of teeth given in **Tables 9b, 9c, and 9d** are somewhat more than the minimum numbers required to prevent undercutting and are based upon studies made by the *American Gear Manufacturers Association*.

**Standard Center-distance System for Enlarged Pinions.**—In this system, sometimes referred to as “long and short addendums,” the center distance is made standard for the numbers of teeth in pinion and gear. The outside diameter of the gear is decreased by the same amount that the outside of the pinion is enlarged.

The advantages of this system are: 1) No change in center distance or ratio is required; 2) The operating pressure angle remains standard; and 3) A slightly greater contact ratio is obtained than when the center distance is increased.

The disadvantages are 1) The gears as well as the pinion must be changed from standard dimensions; 2) Pinions having fewer than the minimum number of teeth to avoid undercut cannot be satisfactorily meshed together; and 3) In most cases where gear trains include idler gears, the standard center-distance system cannot be used.

**Enlarged Center-distance System for Enlarged Pinions.**—If an enlarged pinion is meshed with another enlarged pinion or with a gear of standard outside diameter, the center distance must be increased. For fine-pitch gears, it is usually satisfactory to increase the center distance by an amount equal to one-half of the enlargements (see eighth column of **Table 9b**). This is an approximation as theoretically there is a slight increase in backlash.

The advantages of this system are: 1) Only the pinions need be changed from the standard dimensions; 2) Pinions having fewer than 18 teeth may engage other pinions in this range; 3) The pinion tooth, which is the weaker member, is made stronger by the enlargement; and 4) The tooth contact stress, which controls gear durability, is lowered by being moved away from the pinion base circle.

The disadvantages are: 1) Center distances must be enlarged over the standard; 2) The operating pressure angle increases slightly with different combinations of pinions and gears, which is usually not important; and 3) The contact ratio is slightly smaller than that obtained with the standard center-distance system.

This consideration is of minor importance as in the worst case the loss is approximately only 6 percent.

*Enlarged Pinions Meshing without Backlash:* When two enlarged pinions are to mesh without backlash, their center distance will be greater than the standard and less than that

for the enlarged center-distance system. This center distance may be calculated by the formulas given in the following section.

**Center Distance at Which Modified Mating Spur Gears Will Mesh with No Backlash.**— When the tooth thickness of one or both of a pair of mating spur gears has been increased or decreased from the standard value ( $\pi + 2P$ ), the center distance at which they will mesh tightly (without backlash) may be calculated from the following formulas:

$$\text{inv}\phi_1 = \text{inv}\phi + \frac{P(t+T) - \pi}{n+N} \quad C = \frac{n+N}{2P} \quad C_1 = \frac{\cos\phi}{\cos\phi_1} \times C$$

In these formulas,  $P$  = diametral pitch;  $n$  = number of teeth in pinion;  $N$  = number of teeth in gear;  $t$  and  $T$  are the actual tooth thicknesses of the pinion and gear, respectively, on their standard pitch circles;  $\text{inv}\phi$  = involute function of standard pressure angle of gears;  $C$  = standard center distance for the gears;  $C_1$  = center distance at which the gears mesh without backlash; and  $\text{inv}\phi_1$  = involute function of operating pressure angle when gears are meshed tightly at center distance  $C_1$ .

*Example:* Calculate the center distance for no backlash when an enlarged 10-tooth pinion of 100 diametral pitch and 20-degree pressure angle is meshed with a standard 30-tooth gear, the circular tooth thickness of the pinion and gear, respectively, being 0.01873 and 0.015708 inch. From the table of involute functions, page 106,  $\text{inv} 20\text{-degrees} = 0.014904$ . Therefore,

$$\text{inv}\phi_1 = \text{inv} 20^\circ + \frac{100(0.01873 + 0.015708) - \pi}{(10 + 30)} = 0.014904 + \frac{0.34438 - 0.31416}{4}$$

$$\text{inv}\phi_1 = 0.022459 \quad \text{then, from the involute table} \quad \phi_1 = 22^\circ 49'$$

$$C = \frac{n+N}{2P} = \frac{10+30}{2 \times 100} = 0.2000 \text{ inch}$$

$$C_1 = \frac{\cos 20^\circ}{\cos 22^\circ 49'} \times 0.2000 = \frac{0.93969}{0.92175} \times 0.2000 = 0.2039 \text{ inch}$$

**Contact Diameter.**— For two meshing gears it is important to know the contact diameter of each. A first gear with number of teeth,  $n$ , and outside diameter,  $d_0$ , meshes at a standard center distance with a second gear with number of teeth,  $N$ , and outside diameter,  $D_0$ ; both gears have a diametral pitch,  $P$ , and pressure angle,  $\phi$ ,  $A$ ,  $B$ , and  $B$  are unnamed angles used only in the calculations. The contact diameter,  $d_c$ , is found by a three-step calculation that can be done by hand using a trigonometric table and a logarithmic table or a desk calculator. Slide rule calculation is not recommended because it is not accurate enough to give good results. The three-step formulas to find the contact diameter,  $d_c$ , of the first gear are:

$$\cos A = \frac{N \cos \phi}{D_0 \times P} \quad (1)$$

$$\tan b = \tan \phi - \frac{N}{n} (\tan A - \tan \phi) \quad (2)$$

$$d_c = \frac{n \cos \phi}{P \cos b} \quad (3)$$

Similarly the three-step formulas to find the contact diameter,  $D_c$ , of the second gear are:

$$\cos a = \frac{n \cos \phi}{d_0 \times P} \quad (4)$$

$$\tan B = \tan \phi - \frac{n}{N}(\tan a - \tan \phi) \quad (5)$$

$$D_c = \frac{N \cos \phi}{P \cos B} \quad (6)$$

**Contact Ratio.**— The contact ratio of a pair of mating spur gears must be well over 1.0 to assure a smooth transfer of load from one pair of teeth to the next pair as the two gears rotate under load. Because of a reduction in contact ratio due to such factors as tooth deflection, tooth spacing errors, tooth tip breakage, and outside diameter and center distance tolerances, the contact ratio of gears for power transmission as a general rule should not be less than about 1.4. A contact ratio of as low as 1.15 may be used in extreme cases, provided the tolerance effects mentioned above are accounted for in the calculation. The formula for determining the contact ratio,  $m_f$ , using the nomenclature in the previous section is:

$$m_f = \frac{N}{6.28318}(\tan A - \tan B) \quad (7a)$$

or

$$m_f = \frac{N}{6.28318}(\tan a - \tan b) \quad (7b)$$

or

$$m_f = \frac{\sqrt{R_0^2 - R_B^2} + \sqrt{r_0^2 - r_B^2} - C \sin \theta}{P \cos \theta} \quad (7c)$$

where  $R_0$  = outside radius of first gear;  $R_B$  = base radius of first gear;  $r_0$  = outside radius of second gear;  $r_B$  = base radius of second gear;  $C$  = center distance;  $I$  = pressure angle; and,  $p$  = circular pitch.

Both formulas, Equations (7a) and (7b), should give the same answer. It is good practice to use both formulas as a check on the previous calculations.

**Lowest Point of Single Tooth Contact.**— This diameter on the pinion (sometimes referred to as LPSTC) is used to find the maximum contact compressive stress (sometimes called the Hertz Stress) of a pair of mating spur gears. The two-step formulas for determining this pinion diameter,  $d_L$ , using the same nomenclature as in the previous sections with  $c$  and  $C$  as unnamed angles used only in the calculations are:

$$\tan c = \tan a - \frac{6.28318}{n} \quad (8)$$

$$d_L = \frac{n \cos \phi}{P \cos c} \quad (9)$$

In some cases it is necessary to have a plot of the compressive stress over the whole cycle of contact; in this case the LPSTC for the gear is required also. The similar two-step formulas for this gear diameter are:

$$\tan C = \tan A - \frac{6.28318}{N} \quad (10)$$

$$D_L = \frac{N \cos \phi}{P \cos C} \quad (11)$$

**Maximum Hob Tip Radius.**— The standard gear tooth proportions given by the formulas in Table 2 on page 2147 provide a specified size for the rack fillet radius in the general form of (a constant)  $\times$  (pitch). For any given standard this constant may vary up to a maximum

which it is geometrically impossible to exceed; this maximum constant,  $r_c$  (max), is found by the formula:

$$r_c \text{ (max)} = \frac{0.785398 \cos \phi - b \sin \phi}{1 - \sin \phi} \quad (12)$$

where  $b$  is the similar constant in the specified formula for the gear dedendum. The hob tip radius of any standard hob to finish cut any standard gear may vary from zero up to this limiting value.

**Undercut Limit for Hobbed Involute Gears.**— It is well to avoid designing and specifying gears that will have a hobbled trochoidal fillet that undercuts the involute gear tooth profile. This should be avoided because it may cause the involute profile to be cut away up to a point above the required contact diameter with the mating gear so that involute action is lost and the contact ratio reduced to a level that may be too low for proper conjugate action. An undercut fillet will also weaken the beam strength and thus raise the fillet tensile stress of the gear tooth. To assure that the hobbled gear tooth will not have an undercut fillet, the following formula must be satisfied:

$$\frac{b - r_c}{\sin \phi} + r_c \leq 0.5n \sin \phi \quad (13)$$

where  $b$  is the dedendum constant;  $r_c$  is the hob or rack tip radius constant;  $n$  is the number of teeth in the gear; and  $\phi$  is the gear and hob pressure angle. If the gear is not standard or the hob does not roll at the gear pitch diameter, this formula can not be applied and the determination of the expected existence of undercut becomes a considerably more complicated procedure.

**Highest Point of Single Tooth Contact.**— This diameter is used to place the maximum operating load for the determination of the gear tooth fillet stress. The two-step formulas for determining this diameter,  $d_H$ , of the pinion using the same nomenclature as in the previous sections with  $d$  and  $D$  as unnamed angles used only in the calculations are:

$$\tan d = \tan b + \frac{6.28318}{n} \quad (14)$$

$$d_H = \frac{n \cos \phi}{P \cos d} \quad (15)$$

Similarly for the gear:

$$\tan D = \tan B + \frac{6.28318}{N} \quad (16)$$

$$D_H = \frac{N \cos \phi}{P \cos D} \quad (17)$$

**True Involute Form Diameter.**— The point on the gear tooth at which the fillet and the involute profile are tangent to each other should be determined to assure that it lies at a smaller diameter than the required contact diameter with the mating gear. If the TIF diameter is larger than the contact diameter, then fillet interference will occur with severe damage to the gear tooth profile and rough action of the gear set. This two-step calculation is made by using the following two formulas with  $e$  and  $E$  as unnamed angles used only in the calculations:

$$\tan e = \tan \phi - \frac{4}{n} \left( \frac{b - r_c}{\sin 2\phi} + \frac{r_c}{2 \cos \phi} \right) \quad (18)$$

$$d_{TIF} = \frac{n \cos \phi}{P \cos e} \quad (19)$$

As in the previous sections,  $\phi$  is the pressure angle of the gear;  $n$  is the number of teeth in the pinion;  $b$  is the dedendum constant;  $r_c$  is the rack or hob tip radius constant;  $P$  is the gear diametral pitch and  $d_{TIF}$  is the true involute form diameter.

Similarly, for the mating gear:

$$\tan E = \tan \phi - \frac{4}{N} \left( \frac{b - r_c}{\sin 2\phi} + \frac{r_c}{2 \cos \phi} \right) \quad (20)$$

$$D_{TIF} = \frac{N \cos \phi}{P \cos E} \quad (21)$$

where  $N$  is number of teeth in this mating gear and  $D_{TIF}$  is the true involute form diameter.

**Profile Checker Settings.**—The actual tooth profile tolerance will need to be determined on high performance gears that operate either at high unit loads or at high pitch-line velocity. This is done on an involute checker, a machine which requires two settings, the gear base radius and the roll angle in degrees to significant points on the involute. From the smallest diameter outward these significant points are: TIF, Contact Diameter, LPSTC, Pitch Diameter, HPSTC, and Outside Diameter.

The base radius is:

$$R_b = \frac{N \cos \phi}{2P} \quad (22)$$

The roll angle, in degrees, at any point is equal to the tangent of the pressure angle at that point multiplied by 57.2958. The following table shows the tangents to be used at each significant diameter.

Significant Point on Tooth Profile	Pinion	Gear	For Computation
TIF	$\tan e$	$\tan E$	(See Formulas (18) & (20))
Contact Dia.	$\tan b$	$\tan B$	(See Formulas (2) & (5))
LPSTC	$\tan c$	$\tan C$	(See Formulas (8) & (10))
Pitch Dia.	$\tan \phi$	$\tan \phi$	( $\phi$ = Pressure angle)
HPSTC	$\tan d$	$\tan D$	(See Formulas (14) & (16))
Outside Dia.	$\tan a$	$\tan A$	(See Formulas (4) & (1))

*Example:* Find the significant diameters, contact ratio and hob tip radius for a 10-diametral pitch, 23-tooth, 20-degree pressure angle pinion of 2.5-inch outside diameter if it is to mesh with a 31-tooth gear of 3.3-inch outside diameter.

Thus:  $n = 23$

$$d_o = 2.5$$

$$P = 10$$

$$N = 31$$

$$D_o = 3.3$$

$$\phi = 20^\circ$$

1) Pinion contact diameter,  $d_c$ 

$$\cos A = \frac{31 \times 0.93969}{3.3 \times 10} \quad (1)$$

$$= 0.88274 \quad A = 28^\circ 1' 30''$$

$$\tan b = 0.36397 - \frac{31}{23}(0.53227 - 0.36397) \quad (2)$$

$$= 0.13713 \quad b = 7^\circ 48' 26''$$

$$d_c = \frac{23 \times 0.93969}{10 \times 0.99073} \quad (3)$$

$$= 2.1815 \text{ inches}$$

2) Gear contact diameter,  $D_c$ 

$$\cos a = \frac{23 \times 0.93963}{2.5 \times 10} \quad (4)$$

$$= 0.86452 \quad a = 30^\circ 10' 20''$$

$$\tan B = 0.36397 - \frac{23}{31}(0.58136 - 0.36937) \quad (5)$$

$$= 0.20267 \quad B = 11^\circ 27' 26''$$

$$D_c = \frac{31 \times 0.93969}{10 \times 0.98000} \quad (6)$$

$$= 2.9725 \text{ inches}$$

3) Contact ratio,  $m_f$ 

$$m_f = \frac{31}{6.28318}(0.53227 - 0.20267) \quad (7a)$$

$$= 1.626$$

$$m_f = \frac{23}{6.28318}(0.58136 - 0.13713) \quad (7b)$$

$$= 1.626$$

4) Pinion LPSTC,  $d_L$ 

$$\tan c = 0.58136 - \frac{6.28318}{23} \quad (8)$$

$$= 0.30818 \quad c = 17^\circ 7' 41''$$

$$d_L = \frac{23 \times 0.93969}{10 \times 0.95565} \quad (9)$$

$$= 2.2616 \text{ inches}$$

5) Gear LPSTC,  $D_L$ 

$$\tan C = 0.53227 - \frac{6.28318}{31} \quad (10)$$

$$= 0.32959 \quad C = 18^\circ 14' 30''$$

$$D_L = \frac{31 \times 0.93969}{10 \times 0.94974} \quad (11)$$

$$= 3.0672 \text{ inches}$$

6) Maximum permissible hob tip radius,  $r_c$  (max). The dedendum factor is 1.25.

$$r_c \text{ (max)} = \frac{0.785398 \times 0.93969 - 1.25 \times 0.34202}{1 - 0.34202} \quad (12)$$

$$= 0.4719 \text{ inch}$$

7) If the hob tip radius  $r_c$  is 0.30, determine if the pinion involute is undercut.

$$\frac{1.25 - 0.30}{0.34202} + 0.30 \leq 0.5 \times 23 \times 0.34202 \quad (13)$$

$$3.0776 < 3.9332$$

8) Therefore there is no involute undercut.

9) Pinion HPSTC,  $d_H$

$$\tan d = 0.13713 + \frac{6.28318}{23} \quad (14)$$

$$= 0.41031 \quad d = 22^\circ 18' 32''$$

$$d_H = \frac{23 \times 0.93969}{10 \times 0.92515} \quad (15)$$

$$= 2.3362 \text{ inches}$$

10) Gear HPSTC,  $D_H$

$$\tan D = 0.20267 + \frac{6.28318}{31} \quad (16)$$

$$= 0.40535 \quad D = 22^\circ 3' 55''$$

$$D_H = \frac{31 \times 0.93969}{10 \times 0.92676} \quad (17)$$

$$= 3.1433 \text{ inches}$$

11) Pinion TIF diameter,  $d_{TIF}$

$$\tan e = 0.36397 - \frac{4}{23} \left( \frac{1.25 - 0.30}{0.64279} + \frac{0.30}{2 \times 0.93969} \right) \quad (18)$$

$$= 0.07917 \quad e = 4^\circ 31' 36''$$

$$d_{TIF} = \frac{23 \times 0.93969}{10 \times 0.99688} \quad (19)$$

$$= 2.1681 \text{ inches}$$

12) Gear TIF diameter,  $D_{TIF}$

$$\tan E = 0.36397 - \frac{4}{31} \left( \frac{1.25 - 0.30}{0.64279} + \frac{0.30}{2 \times 0.93969} \right) \quad (20)$$

$$= 0.15267 \quad E = 8^\circ 40' 50''$$

$$D_{TIF} = \frac{31 \times 0.93969}{10 \times 0.98855} = 2.9468 \text{ inches} \quad (21)$$

**Gear Blanks for Fine-pitch Gears.**— The accuracy to which gears can be produced is considerably affected by the design of the gear blank and the accuracy to which the various surfaces of the blank are machined. The following recommendations should not be regarded as inflexible rules, but rather as minimum average requirements for gear-blank quality compatible with the expected quality class of the finished gear.

*Design of Gear Blanks:* The accuracy to which gears can be produced is affected by the design of the blank, so the following points of design should be noted: 1) Gears designed with a hole should have the hole large enough that the blank can be adequately supported during machining of the teeth and yet not so large as to cause distortion; 2) Face widths should be wide enough, in proportion to outside diameters, to avoid springing and to permit obtaining flatness in important surfaces; 3) Short bore lengths should be avoided wherever possible. It is feasible, however, to machine relatively thin blanks in stacks, provided the surfaces are flat and parallel to each other; 4) Where gear blanks with hubs are to be designed, attention should be given to the wall sections of the hubs. Too thin a section will not permit proper clamping of the blank during machining operations and may also affect proper mounting of the gear; and 5) Where pinions or gears integral with their shafts are to be designed, deflection of the shaft can be minimized by having the shaft length and shaft diameter well proportioned to the gear or pinion diameter. The foregoing general principles may also be useful when applied to blanks for coarser pitch gears.

**Specifying Spur and Helical Gear Data on Drawings.**— The data that may be shown on drawings of spur and helical gears fall into three groups: The first group consists of data basic to the design of the gear; the second group consists of data used in manufacturing and inspection; and the third group consists of engineering reference data. The accompanying table may be used as a checklist for the various data which may be placed on gear drawings and the sequence in which they should appear.

*Explanation of Terms Used in Gear Specifications:* 1) Number of teeth is the number of teeth in 360 deg of gear circumference. In a sector gear, both the actual number of teeth in the sector and the theoretical number of teeth in 360 deg should be given.

2) Diametral pitch is the ratio of the number of teeth in the gear to the number of inches in the standard pitch diameter. It is used in this standard as a nominal specification of tooth size.

a) Normal diametral pitch is the diametral pitch in the normal plane.

b) Transverse diametral pitch is the diametral pitch in the transverse plane.

c) Module is the ratio of the number of teeth in the gear to the number of mm in the standard pitch diameter.

d) Normal module is the module measured in the normal plane.

e) Transverse module is the module measured in the transverse plane.

3) Pressure angle is the angle between the gear tooth profile and a radial line at the pitch point. It is used in this standard to specify the pressure angle of the basic rack used in defining the gear tooth profile.

a) Normal pressure angle is the pressure angle in the normal plane.

b) Transverse pressure angle is the pressure angle in the transverse plane.

4) Helix angle is the angle between the pitch helix and an element of the pitch cylinder, unless otherwise specified.

a) Hand of helix is the direction in which the teeth twist as they recede from an observer along the axis. A right hand helix twists clockwise and a left hand helix twists counterclockwise.

5) Standard pitch diameter is the diameter of the pitch circle. It equals the number of teeth divided by the transverse diametral pitch.

6) Tooth form may be specified as standard addendum, long addendum, short addendum, modified involute or special. If a modified involute or special tooth form is required, a detailed view should be shown on the drawing. If a special tooth form is specified, roll angles must be supplied (see page 2174).

7) Addendum is the radial distance between the standard pitch circle and the outside circle. The actual value depends on the specification of outside diameter.

8) Whole depth is the total radial depth of the tooth space. The actual value is dependent on the specification of outside diameter and root diameter.

9) Maximum calculated circular thickness on the standard pitch circle is the tooth thickness which will provide the desired minimum backlash when the gear is assembled in mesh with its mate on minimum center distance. Control may best be exerted by testing in tight mesh with a master which integrates all errors in the several teeth in mesh through the arc of action as explained on page 2185. This value is independent of the effect of runout.

a) Maximum calculated *normal* circular thickness is the circular tooth thickness in the normal plane which satisfies requirements explained in (9).

10) Gear testing radius is the distance from its axis of rotation to the standard pitch line of a standard master when in intimate contact under recommended pressure on a variable-center-distance running gage. Maximum testing radius should be calculated to provide the maximum circular tooth thickness specified in (9) when checked as explained on page 2185. This value is affected by the runout of the gear. Tolerance on testing radius must be equal to or greater than the total composite error permitted by the quality class specified in (11).

11) Quality class is specified for convenience when talking or writing about the accuracy of the gear.

12) Maximum total composite error, and 13) Maximum tooth-to-tooth composite error. Actual tolerance values (12 and 13) permitted by the quality class (11) are specified in inches to provide machine operator or inspector with tolerances required to inspect the gear.

14) Testing pressure recommendations are given on page 2185. Incorrect testing pressure will result in incorrect measurement of testing radius.

15) Master specifications by tool or code number may be required to call for the use of a special master gear when tooth thickness deviates excessively from standard.

16) Measurement over two 0.xxxx diameter pins may be specified to assist the manufacturing department in determining size at machine for setup only.

17) Outside diameter is usually shown on the drawing of the gear together with other blank dimensions so that it will not be necessary for machine operators to search gear tooth data for this dimension. Since outside diameter is also frequently used in the manufacture and inspection of the teeth, it may be included in the data block with other tooth specifications if preferred. To permit use of topping hobs for cutting gears on which the tooth thickness has been modified from standard, the outside diameter should be related to the specified gear testing radius (10).

18) Maximum root diameter is specified to assure adequate clearance for the outside diameter of the mating gear. This dimension is usually considered acceptable if the gear is checked with a master and meets specifications (10) through (13).

19) Active profile diameter of a gear is the smallest diameter at which the mating gear tooth profile can make contact. Because of difficulties involved in checking, this specification is not recommended for gears finer than 48 pitch.

20) Surface roughness on active profile surfaces may be specified in microinches to be checked by instrument up to about 32 pitch, or by visual comparison in the finer pitch ranges. It is difficult to determine accurately the surface roughness of fine pitch gears. For many commercial applications surface roughness may be considered acceptable on gears which meet the maximum tooth-to-tooth-error specification (13).

21) Mating gear part number may be shown as a convenient reference. If the gear is used in several applications, all mating gears may be listed but usual practice is to record this information in a reference file.

22) Number of teeth in mating gear, and 23) Minimum operating center distance. This information is often specified to eliminate the necessity of getting prints of the mating gear and assemblies for checking the design specifications, interference, backlash, determination of master gear specification, and acceptance or rejection of gears made out of tolerance.

## Data for Spur and Helical Gear Drawings

Type of Data	Min. Spur Gear Data	Min. Helical Gear-Data	Add'l Optional Data	Item Number <sup>a</sup>	Data <sup>a</sup>
Basic Specifications	•	•		1	Number of teeth
	•			2	Diametral pitch or module
		•		2a	Normal diametral pitch or module
			•	2b	Transverse diametral pitch or module
	•			3	Pressure angle
		•		3a	Normal pressure angle
			•	3b	Transverse pressure angle
		•		4	Helix angle
	•	•		4a	Hand of helix
	•	•		5	Standard pitch diameter
	•	•		6	Tooth form
			•	7	Addendum
		•	8	Whole depth	
	•		9	Max. calc. circular thickness on std. pitch circle	
	•		9a	Max. calc. normal circular thickness on std. pitch circle	
Manufacturing and Inspection			•	10	Roll angles
	•	•		11	A.G.M.A. quality class
	•	•		12	Max. total composite error
	•	•		13	Max. tooth-to-tooth composite error
			•	14	Testing pressure (Ounces)
	•	•		15	Master specification
	•	•	•	16	Meas. over two .xxxx dia. pins (For setup only)
			•	17	Outside diameter (Preferably shown on drawing of gear)
			•	18	Max. root diameter
		•	19	Active profile diameter	
		•	20	Surface roughness of active profile	
Engineering Reference			•	21	Mating gear part number
			•	22	Number of teeth in mating gear
			•	23	Minimum operating center distance

<sup>a</sup> An item-by-item explanation of the terms used in this table is given beginning on page 2177.

### Backlash

In general, backlash in gears is play between mating teeth. For purposes of measurement and calculation, backlash is defined as the amount by which a tooth space exceeds the thickness of an engaging tooth. It does not include the effect of center-distance changes of the mountings and variations in bearings. When not otherwise specified, numerical values of backlash are understood to be given on the pitch circles. The general purpose of backlash is to prevent gears from jamming together and making contact on both sides of their teeth simultaneously. Lack of backlash may cause noise, overloading, overheating of the gears and bearings, and even seizing and failure.

Excessive backlash is objectionable, particularly if the drive is frequently reversing, or if there is an overrunning load as in cam drives. On the other hand, specification of an unnecessarily small amount of backlash allowance will increase the cost of gears, because errors in runout, pitch, profile, and mounting must be held correspondingly smaller. Backlash does not affect involute action and usually is not detrimental to proper gear action.

**Determining Proper Amount of Backlash.**— In specifying proper backlash and tolerances for a pair of gears, the most important factor is probably the maximum permissible amount of runout in both gear and pinion (or worm). Next are the allowable errors in profile, pitch, tooth thickness, and helix angle. Backlash between a pair of gears will vary as successive teeth make contact because of the effect of composite tooth errors, particularly runout, and errors in the gear center distances and bearings.

Other important considerations are speed and space for lubricant film. Slow-moving gears, in general, require the least backlash. Fast-moving fine-pitch gears are usually lubri-

cated with relatively light oil, but if there is insufficient clearance for an oil film, and particularly if oil trapped at the root of the teeth cannot escape, heat and excessive tooth loading will occur.

Heat is a factor because gears may operate warmer, and, therefore, expand more, than the housings. The heat may result from oil churning or from frictional losses between the teeth, at bearings or oil seals, or from external causes. Moreover, for the same temperature rise, the material of the gears—for example, bronze and aluminum—may expand more than the material of the housings, usually steel or cast iron.

The higher the helix angle or spiral angle, the more transverse backlash is required for a given normal backlash. The transverse backlash is equal to the normal backlash divided by the cosine of the helix angle.

In designs employing normal pressure angles higher than 20 degrees, special consideration must be given to backlash, because more backlash is required on the pitch circles to obtain a given amount of backlash in a direction normal to the tooth profiles.

Errors in boring the gear housings, both in center distance and alignment, are of extreme importance in determining allowance to obtain the backlash desired. The same is true in the mounting of the gears, which is affected by the type and adjustment of bearings, and similar factors. Other influences in backlash specification are heat treatment subsequent to cutting the teeth, lapping operations, need for recutting, and reduction of tooth thickness through normal wear.

Minimum backlash is necessary for timing, indexing, gun-sighting, and certain instrument gear trains. If the operating speed is very low and the necessary precautions are taken in the manufacture of such gear trains, the backlash may be held to extremely small limits. However, the specification of “zero backlash,” so commonly stipulated for gears of this nature, usually involves special and expensive techniques, and is difficult to obtain.

**Table 1. AGMA Recommended Backlash Range for Coarse-Pitch Spur, Helical, and Herringbone Gearing**

Center Distance (Inches)	Normal Diametral Pitches				
	0.5-1.99	2-3.49	3.5-5.99	6-9.99	10-19.99

<sup>a</sup> Suggested backlash, on nominal centers, measured after rotating to the point of closest engagement. For helical and herringbone gears, divide above values by the cosine of the helix angle to obtain the transverse backlash.

The above backlash tolerances contain allowance for gear expansion due to differential in the operating temperature of the gearing and their supporting structure. The values may be used where the operating temperatures are up to 70 deg F higher than the ambient temperature.

For most gearing applications the recommended backlash ranges will provide proper running clearance between engaging teeth of mating gears. Deviation below the minimum or above the maximum values shown, which do not affect operational use of the gearing, should not be cause for rejection.

Definite backlash tolerances on coarse-pitch gearing are to be considered binding on the gear manufacturer only when agreed upon in writing.

Some applications may require less backlash than shown in the above table. In such cases the amount and tolerance should be by agreement between manufacturer and purchaser.

**Recommended Backlash:** In the following tables American Gear Manufacturers Association recommendations for backlash ranges for various kinds of gears are given.\* For purposes of measurement and calculation, backlash is defined as the amount by which a tooth space exceeds the thickness of an engaging tooth. When not otherwise specified, numerical values of backlash are understood to be measured at the tightest point of mesh on the pitch circle in a direction normal to the tooth surface when the gears are mounted in their specified position.

**Coarse-Pitch Gears::** Table 1 gives the recommended backlash range for coarse-pitch spur, helical and herringbone gearing. Because backlash for helical and herringbone gears is more conveniently measured in the normal plane, Table 1 has been prepared to show backlash in the normal plane for coarse-pitch helical and herringbone gearing and in the transverse plane for spur gears. To obtain backlash in the transverse plane for helical and herringbone gears, divide the normal plane backlash in Table 1 by the cosine of the helix angle.

**Table 2. AGMA Recommended Backlash Range for Bevel and Hypoid Gears**

Diametral Pitch	Normal Backlash, Inch		Diametral Pitch	Normal Backlash, Inch	
	Quality Numbers 7 through 13	Quality Numbers 3 through 6		Quality Numbers 7 through 13	Quality Numbers 3 through 6
1.00 to 1.25	0.020-0.030	0.045-0.065	5.00 to 6.00	0.005-0.007	0.006-0.013

Measured at tightest point of mesh

The backlash tolerances given in this table contain allowances for gear expansion due to a differential in the operating temperature of the gearing and their supporting structure. The values may be used where the operating temperature is up to 70 °F higher (39 °C higher) than the ambient temperature. These backlash values will provide proper running clearances for most gear applications.

The following important factors must be considered in establishing backlash tolerances:

- a) Center distance tolerance; b) Parallelism of gear axes; c) Side runout or wobble;
- d) Tooth thickness tolerance; e) Pitch line runout tolerance; f) Profile tolerance; g) Pitch tolerance; h) Lead tolerance; i) Types of bearings and subsequent wear; j) Deflection under load; k) Gear tooth wear; l) Pitch line velocity; m) Lubrication requirements; and
- n) Thermal expansion of gears and housing.

A tight mesh may result in objectionable gear sound, increased power losses, overheating, rupture of the lubricant film, overloaded bearings and premature gear failure. However, it is recognized that there are some gearing applications where a tight mesh (zero backlash) may be required.

Specifying unnecessarily close backlash tolerances will increase the cost of the gearing. It is obvious from the above summary that the desired amount of backlash is difficult to evaluate. It is, therefore, recommended that when a designer, user or purchaser includes a reference to backlash in a gearing specification and drawing, consultation be arranged with the manufacturer.

\* Extracted from Gear Classification Manual, AGMA 390.03 with permission of the publisher, the American Gear Manufacturers Association, 1500 King St., Alexandria, VA 22314.

*Bevel and Hypoid Gears:* Table 2 gives similar backlash range values for bevel and hypoid gears. These are values based upon average conditions for general purpose gearing, but may require modification to meet specific needs.

Backlash on bevel and hypoid gears can be controlled to some extent by axial adjustment of the gears during assembly. However, due to the fact that actual adjustment of a bevel or hypoid gear in its mounting will alter the amount of backlash, it is imperative that the amount of backlash cut into the gears during manufacture is not excessive. Bevel and hypoid gears must always be capable of operation without interference when adjusted for zero backlash. This requirement is imposed by the fact that a failure of the axial thrust bearing might permit the gears to operate under this condition. Therefore, bevel and hypoid gears should never be designed to operate with normal backlash in excess of  $0.080/P$  where  $P$  is diametral pitch.

*Fine-Pitch Gears:* Table 3 gives similar backlash range values for fine-pitch spur, helical and herringbone gearing.

**Providing Backlash.**— In order to obtain the amount of backlash desired, it is necessary to decrease tooth thicknesses. However, because of manufacturing and assembling inaccuracies not only in the gears but also in other parts, the allowances made on tooth thickness almost always must exceed the desired amount of backlash. Since the amounts of these allowances depend on the closeness of control exercised on all manufacturing operations, no general recommendations for them can be given.

It is customary to make half the allowance for backlash on the tooth thickness of each gear of a pair, although there are exceptions. For example, on pinions having very low numbers of teeth it is desirable to provide all the allowance on the mating gear, so as not to weaken the pinion teeth. In worm gearing, ordinary practice is to provide all of the allowance on the worm which is usually made of a material stronger than that of the worm gear.

In some instances the backlash allowance is provided in the cutter, and the cutter is then operated at the standard tooth depth. In still other cases, backlash is obtained by setting the distance between two tools for cutting the two sides of the teeth, as in straight bevel gears, or by taking side cuts, or by changing the center distance between the gears in their mountings. In spur and helical gearing, backlash allowance is usually obtained by sinking the cutter deeper into the blank than the standard depth. The accompanying table gives the excess depth of cut for various pressure angles.

**Excess Depth of Cut  $E$  to Provide Backlash Allowance**

Distribution of Backlash	Pressure Angle $\phi$ , Degrees				
	14½	17½	20	25	30
Excess Depth of Cut $E$ to Obtain Circular Backlash $B^a$					
All on One Gear	1.93 $B$	1.59 $B$	1.37 $B$	1.07 $B$	0.87 $B$
One-half on Each Gear	0.97 $B$	0.79 $B$	0.69 $B$	0.54 $B$	0.43 $B$
Excess Depth of Cut $E$ to Obtain Backlash $B_b$ Normal to Tooth Profile <sup>b</sup>					
All on One Gear	2.00 $B_b$	1.66 $B_b$	1.46 $B_b$	1.18 $B_b$	1.99 $B_b$
One-half on Each Gear	1.00 $B_b$	0.83 $B_b$	0.73 $B_b$	0.59 $B_b$	0.50 $B_b$

<sup>a</sup>Circular backlash is the amount by which the width of a tooth space is greater than the thickness of the engaging tooth on the pitch circles. As described in pages 2179 and 2183 this is what is meant by backlash unless otherwise specified.

<sup>b</sup>Backlash measured normal to the tooth profile by inserting a feeler gage between meshing teeth; to convert to circular backlash,  $B = B_b \div \cos \phi$ .

**Control of Backlash Allowances in Production.**— Measurement of the tooth thickness of gears is perhaps the simplest way of controlling backlash allowances in production.

There are several ways in which this may be done including: 1) chordal thickness measurements as described on page 2161; 2) caliper measurements over two or more teeth as described on page 2252; and 3) measurements over wires.

In this last method, first the theoretical measurement over wires when the backlash allowance is zero is determined by the method described on page 2237; then the amount this measurement must be reduced to obtain a desired backlash allowance is taken from the table on page 2251.

It should be understood, as explained in the section *Measurement of Backlash*, that merely making tooth thickness allowances will not guarantee the amount of backlash in the ready-to-run assembly of two or more gears. Manufacturing limitations will introduce such gear errors as runout, pitch error, profile error, and lead error, and gear-housing errors in both center distance and alignment. All of these make the backlash of the assembled gears different from that indicated by tooth thickness measurements on the individual gears.

**Measurement of Backlash.**— Backlash is commonly measured by holding one gear of a pair stationary and rocking the other back and forth. The movement is registered by a dial indicator having its pointer or finger in a plane of rotation at or near the pitch diameter and in a direction parallel to a tangent to the pitch circle of the moving gear. If the direction of measurement is normal to the teeth, or other than as specified above, it is recommended that readings be converted to the plane of rotation and in a tangent direction at or near the pitch diameter, for purposes of standardization and comparison.

In spur gears, parallel helical gears, and bevel gears, it is immaterial whether the pinion or gear is held stationary for the test. In crossed helical and hypoid gears, readings may vary according to which member is stationary; hence, it is customary to hold the pinion stationary and measure on the gear.

In some instances, backlash is measured by thickness gages or feelers. A similar method utilizes a soft lead wire inserted between the teeth as they pass through mesh. In both methods, it is likewise recommended that readings be converted to the plane of rotation and in a tangent direction at or near the pitch diameter, taking into account the normal pressure angle, and the helix angle or spiral angle of the teeth.

Sometimes backlash in parallel helical or herringbone gears is checked by holding the gear stationary, and moving the pinion axially back and forth, readings being taken on the face or shaft of the pinion, and converted to the plane of rotation by calculation. Another method consists of meshing a pair of gears tightly together on centers and observing the variation from the specified center distance. Such readings should also be converted to the plane of rotation and in a tangent direction at or near the pitch diameter for the reasons previously given.

Measurements of backlash may vary in the same pair of gears, depending on accuracy of manufacturing and assembling. Incorrect tooth profiles will cause a change of backlash at different phases of the tooth action. Eccentricity may cause a substantial difference between maximum and minimum backlash at different positions around the gears. In stating amounts of backlash, it should always be remembered that merely making allowances on tooth thickness does not guarantee the minimum amount of backlash that will exist in assembled gears.

*Fine-Pitch Gears:* The measurement of backlash of fine-pitch gears, when assembled, cannot be made in the same manner and by the same techniques employed for gears of coarser pitches. In the very fine pitches, it is virtually impossible to use indicating devices for measuring backlash. Sometimes a toolmaker's microscope is used for this purpose to good advantage on very small mechanisms.

Another means of measuring backlash in fine-pitch gears is to attach a beam to one of the shafts and measure the angular displacement in inches when one member is held stationary. The ratio of the length of the beam to the nominal pitch radius of the gear or pinion to which the beam is attached gives the approximate ratio of indicator reading to circular backlash. Because of the limited means of measuring backlash between a pair of fine-pitch gears, gear centers and tooth thickness of the gears when cut must be held to very close lim-

its. Tooth thickness of fine-pitch spur and helical gears can best be checked on a variable-center-distance fixture using a master gear. When checked in this manner, tooth thickness change =  $2 \times$  center distance change  $\times$  tangent of transverse pressure angle, approximately.

**Control of Backlash in Assemblies.**— Provision is often made for adjusting one gear relative to the other, thereby affording complete control over backlash at initial assembly and throughout the life of the gears. Such practice is most common in bevel gearing. It is fairly common in spur and helical gearing when the application permits slight changes between shaft centers. It is practical in worm gearing only for single thread worms with low lead angles. Otherwise faulty contact results.

Another method of controlling backlash quite common in bevel gears and less common in spur and helical gears is to match the high and low spots of the runout gears of one to one ratio and mark the engaging teeth at the point where the runout of one gear cancels the runout of the mating gear.

**Table 3. AGMA Backlash Allowance and Tolerance for Fine-Pitch Spur, Helical and Herringbone Gearing**

Backlash Designation	Normal Diametral Pitch Range	Tooth Thinning to Obtain Backlash <sup>a</sup>		Resulting Approximate Backlash (per Mesh) Normal Plane <sup>b</sup> Inch
		Allowance, per Gear, Inch	Tolerance, per Gear, Inch	
A	20 thru 45	.002	0 to .002	.004 to .008
	46 thru 70	.0015	0 to .002	.003 to .007
	71 thru 90	.001	0 to .00175	.002 to .0055
	91 thru 200	.00075	0 to .00075	.0015 to .003

	61 thru 120	.0002	0 to .0002	.0004 to .0008
	121 thru 200	.0001	0 to .0001	.0002 to .0004
E	20 thru 60	Zero <sup>c</sup>	0 to .00025	0 to .0005
	61 thru 120		0 to .0002	0 to .0004
	121 thru 200		0 to .0001	0 to .0002

<sup>a</sup>These dimensions are shown primarily for the benefit of the gear manufacturer and represent the amount that the thickness of teeth should be reduced in the pinion and gear below the standard calculated value, to provide for backlash in the mesh. In some cases, particularly with pinions involving small numbers of teeth, it may be desirable to provide for total backlash by thinning the teeth in the gear member only by twice the allowance value shown in column (3). In this case both members will have the tolerance shown in column (4). In some cases, particularly in meshes with a small number of teeth, backlash may be achieved by an increase in basic center at distance. In such cases, neither member is reduced by the allowance shown in column (3).

<sup>b</sup>These dimensions indicate the approximate backlash that will occur in a mesh in which each of the mating pairs of gears have the teeth thinned by the amount referred to in Note 1, and are meshed on theoretical centers.

<sup>c</sup>Backlash in gear sets can also be achieved by increasing the center distance above nominal and using the teeth at standard tooth thickness. Class E backlash designation infers gear sets operating under these conditions.

*Backlash* in gears is the play between mating tooth surfaces. For purposes of measurement and calculation, backlash is defined as the amount by which a tooth space exceeds the thickness of an engaging tooth. When not otherwise specified, numerical values of backlash are understood to be measured at the tightest point of mesh on the pitch circle in a direction normal to the tooth surface when the gears are mounted in their specified position.

*Allowance* is the basic amount that a tooth is thinned from basic calculated circular tooth thickness to obtain the required backlash class.

*Tolerance* is the total permissible variation in the circular thickness of the teeth.

**Angular Backlash in Gears.**— When the backlash on the pitch circles of a meshing pair of gears is known, the angular backlash or angular play corresponding to this backlash may be computed from the following formulas.

$$\theta_D = \frac{6875B}{D} \text{ minutes} \quad \theta_d = \frac{6875B}{d} \text{ minutes}$$

In these formulas,  $B$  = backlash between gears, in inches;  $D$  = pitch diameter of larger gear, in inches;  $d$  = pitch diameter of smaller gear, in inches;  $\theta_D$  = angular backlash or angular movement of larger gear in minutes when smaller gear is held fixed and larger gear rocked back and forth; and  $\theta_d$  = angular backlash or angular movement of smaller gear, in minutes, when the larger gear is held fixed and the smaller gear rocked back and forth.

**Inspection of Gears.**— Perhaps the most widely used method of determining relative accuracy in a gear is to rotate the gear through at least one complete revolution in intimate contact with a master gear of known accuracy. The gear to be tested and the master gear are mounted on a variable-center-distance fixture and the resulting radial displacements or changes in center distance during rotation of the gear are measured by a suitable device. Except for the effect of backlash, this so-called “composite check” approximates the action of the gear under operating conditions and gives the combined effect of the following errors: runout; pitch error; tooth-thickness variation; profile error; and lateral runout (sometimes called wobble).

*Tooth-to-Tooth Composite Error*, illustrated below, is the error that shows up as flicker on the indicator of a variable-center-distance fixture as the gear being tested is rotated from tooth to tooth in intimate contact with the master gear. Such flicker shows the combined or composite effect of circular pitch error, tooth-thickness variation, and profile error.

Diagram Showing Nature of Composite Errors

*Total Composite Error*, shown above, is made up of runout, wobble, and the tooth-to-tooth composite error; it is the total center-distance displacement read on the indicating device of the testing fixture, as shown in the accompanying diagram.

**Pressure for Composite Checking of Fine-Pitch Gears.**— In using a variable-center-distance fixture, excessive pressure on fine-pitch gears of narrow face width will result in incorrect readings due to deflection of the teeth. Based on tests, the following checking pressures are recommended for gears of 0.100-inch face width: 20 to 29 diametral pitch, 28 ounces; 30 to 39 pitch, 24 ounces; 40 to 49 pitch, 20 ounces; 50 to 59 pitch, 16 ounces; 60 to 79 pitch, 12 ounces; 80 to 99 pitch, 8 ounces; 100 to 149 pitch, 4 ounces; and 150 and finer pitches, 2 ounces, minimum. These recommended checking pressures are based on the use of antifricition mountings for the movable head of the checking fixture and include the pressure of the indicating device. For face widths less than 0.100 inch, the recommended pressures should be reduced proportionately; for larger widths, no increase is necessary although the force may be increased safely in the proper proportion.

### Internal Gearing

**Internal Spur Gears.**— An internal gear may be proportioned like a standard spur gear turned “outside in” or with addendum and dedendum in reverse positions; however, to avoid interference or improve the tooth form and action, the internal diameter of the gear should be increased and the outside diameter of the mating pinion is also made larger than the size based upon standard or conventional tooth proportions. The extent of these enlargements will be illustrated by means of examples given in the following table, *Rules for Internal Gears – 20-degree Full-Depth Teeth*. The 20-degree involute full-depth tooth form is recommended for internal gears; the 20-degree stub tooth and the 14½-degree full-depth tooth are also used.

**Methods of Cutting Internal Gears.**— Internal spur gears are cut by methods similar in principle to those employed for external spur gears.

They may be cut by one of the following methods: 1) By a generating process, as when using a Fellows gear shaper; 2) by using a formed cutter and milling the teeth; 3) by planing, using a machine of the template or form-copying type (especially applicable to gears of large pitch); and 4) by using a formed tool that reproduces its shape and is given a planing action either on a slotting or a planing type of machine.

Internal gears frequently have a web at one side that limits the amount of clearance space at the ends of the teeth. Such gears may be cut readily on a gear shaper. The most practical method of cutting very large internal gears is on a planer of the form-copying type. A regular spur gear planer is equipped with a special tool holder for locating the tool in the position required for cutting internal teeth.

**Formed Cutters for Internal Gears.**— When formed cutters are used, a special cutter usually is desirable, because the tooth spaces of an internal gear are not the same shape as the tooth spaces of external gearing having the same pitch and number of teeth. This difference is because an internal gear is a spur gear “turned outside in.” According to one rule, the standard No. 1 cutter for external gearing may be used for internal gears of 4 diametral pitch and finer, when there are 60 or more teeth. This No. 1 cutter, as applied to external gearing, is intended for all gears having from 135 teeth to a rack. The finer the pitch and the larger the number of teeth, the better the results obtained with a No. 1 cutter. The standard No. 1 cutter is considered satisfactory for jobbing work, and usually when the number of gears to be cut does not warrant obtaining a special cutter, although the use of the No. 1 cutter is not practicable when the number of teeth in the pinion is large in proportion to the number of teeth in the internal gear.

**Arc Thickness of Internal Gear Tooth.**— *Rule:* If internal diameter of an internal gear is enlarged as determined by Rules 1 and 2 for Internal Diameters (see *Rules for Internal Gears – 20-degree Full-Depth Teeth*), the arc tooth thickness at the pitch circle equals 1.3888 divided by the diametral pitch, assuming a pressure angle of 20 degrees.

**Arc Thickness of Pinion Tooth.**— *Rule:* If the pinion for an internal gear is larger than conventional size (see Outside Diameter of Pinion for Internal Gear, under *Rules for Internal Gears – 20-degree Full-Depth Teeth*), then the arc tooth thickness on the pitch circle equals 1.7528 divided by the diametral pitch, assuming a pressure angle of 20 degrees.

*Note:* For chordal thickness and chordal addendum, see rules and formulas for spur gears.

**Relative Sizes of Internal Gear and Pinion.**— If a pinion is too large or too near the size of its mating internal gear, serious interference or modification of the tooth shape may occur.

*Rule:* For internal gears having a 20-degree pressure angle and full-depth teeth, the difference between the numbers of teeth in gear and pinion should not be less than 12. For teeth of stub form, the smallest difference should be 7 or 8 teeth. For a pressure angle of 14½ degrees, the difference in tooth numbers should not be less than 15.

**Rules for Internal Gears – 20-degree Full-Depth Teeth**

To Find	Rule
Pitch Diameter	<i>Rule:</i> To find the pitch diameter of an internal gear, divide the number of internal gear teeth by the diametral pitch. The pitch diameter of the mating pinion also equals the number of pinion teeth divided by the diametral pitch, the same as for external spur gears.
Internal Diameter (Enlarged to Avoid Interference)	<p><i>Rule 1:</i> For internal gears to mesh with pinions having 16 teeth or more, subtract 1.2 from the number of teeth and divide the remainder by the diametral pitch.</p> <p><i>Example:</i> An internal gear has 72 teeth of 6 diametral pitch and the mating pinion has 18 teeth; then</p> $\text{Internal diameter} = \frac{72 - 1.2}{6} = 11.8 \text{ inches}$ <p><i>Rule 2:</i> If circular pitch is used, subtract 1.2 from the number of internal gear teeth, multiply the remainder by the circular pitch, and divide the product by 3.1416.</p>
Internal Diameter (Based upon Spur Gear Reversed)	<p><i>Rule:</i> If the internal gear is to be designed to conform to a spur gear turned outside in, subtract 2 from the number of teeth and divide the remainder by the diametral pitch to find the internal diameter.</p> <p><i>Example:</i> (Same as Example above.)</p> $\text{Internal diameter} = \frac{72 - 2}{6} = 11.666 \text{ inches}$
Outside Diameter of Pinion for Internal Gear	<p><i>Note:</i> If the internal gearing is to be proportioned like standard spur gearing, use the rule or formula previously given for spur gears in determining the outside diameter. The rule and formula following apply to a pinion that is enlarged and intended to mesh with an internal gear enlarged as determined by the preceding Rules 1 and 2 above.</p> <p><i>Rule:</i> For pinions having 16 teeth or more, add 2.5 to the number of pinion teeth and divide by the diametral pitch.</p> <p><i>Example 1:</i> A pinion for driving an internal gear is to have 18 teeth (full depth) of 6 diametral pitch; then</p> $\text{Outside diameter} = \frac{18 + 2.5}{6} = 3.416 \text{ inches}$ <p>By using the rule for external spur gears, the outside diameter = 3.333 inches.</p>
Center Distance	<i>Rule:</i> Subtract the number of pinion teeth from the number of internal gear teeth and divide the remainder by two times the diametral pitch.
Tooth Thickness	See paragraphs, <i>Arc Thickness of Internal Gear Tooth</i> and <i>Effect of Diameter of Cutting on Profile and Pressure Angle of Worms</i> , on previous page.

### British Standard for Spur and Helical Gears

**British Standard For Spur And Helical Gears.**—BS 436: Part 1: 1967: Spur and Helical Gears, Basic Rack Form, Pitches and Accuracy for Diametral Pitch Series, now has sections concerned with basic requirements for general tooth form, standard pitches, accuracy and accuracy testing procedures, and the showing of this information on engineering drawings to make sure that the gear manufacturer receives the required data. The latest form of the standard complies with ISO agreements. The standard pitches are in accordance with ISO R54, and the basic rack form and its modifications are in accordance with the ISO R53 “Basic Rack of Cylindrical Gears for General Engineering and for Heavy Engineering Standard”.

Five grades of gear accuracy in previous versions are replaced by grades 3 to 12 of the draft ISO Standard. Grades 1 and 2 cover master gears that are not dealt with here. BS 436: Part 1: 1967 is a companion to the following British Standards:

BS 235 “Gears for Traction”

BS 545 “Bevel Gears (Machine Cut)”

BS 721 “Worm Gearing”

BS 821 “Iron Castings for Gears and Gear Blanks (Ordinary, Medium and High Grade)”

BS 978 “Fine Pitch Gears” Part 1, “Involute, Spur and Helical Gears”; Part 2, “Cycloidal Gears” (with addendum 1, PD 3376: “Double Circular Arc Type Gears”; Part 3, “Bevel Gears”

BS 1807 “Gears for Turbines and Similar Drives” Part 1, “Accuracy” Part 2, “Tooth Form and Pitches”

BS 2519 “Glossary of Terms for Toothed Gearing”

BS 3027 “Dimensions for Worm Gear Units”

BS 3696 “Master Gears”

Part 1 of BS 436 applies to external and internal involute spur and helical gears on parallel shafts and having normal diametral pitch of 20 or coarser. The basic rack and tooth form are specified, also first and second preference standard pitches and fundamental tolerances that determine the grades of gear accuracy, and requirements for terminology and notation.

These requirements include: center distance  $a$ ; reference circle diameter  $d$ , for pinion  $d_1$  and wheel  $d_2$ ; tip diameter  $d_a$  for pinion  $d_{a1}$  and wheel  $d_{a2}$ ; center distance modification coefficient  $\gamma$ ; face width  $b$  for pinion  $b_1$  and wheel  $b_2$ ; addendum modification coefficient  $x$ , for pinion  $x_1$  and wheel  $x_2$ ; length of arc  $l$ ; diametral pitch  $P_n$ ; normal diametral pitch  $p_n$ ; transverse pitch  $p_t$ ; number of teeth  $z$ , for pinion  $z_1$  and wheel  $z_2$ ; helix angle at reference cylinder  $\beta$ ; pressure angle at reference cylinder  $\alpha$ ; normal pressure angle at reference cylinder  $\alpha_n$ ; transverse pressure angle at reference cylinder  $\alpha_t$ ; and transverse pressure angle, working,  $\alpha_{tw}$ .

The basic rack tooth profile has a pressure angle of 20. The Standard permits the total tooth depth to be varied within 2.25 to 2.40, so that the root clearance can be increased within the limits of 0.25 to 0.040 to allow for variations in manufacturing processes; and the root radius can be varied within the limits of 0.25 to 0.39. Tip relief can be varied within the limits shown at the right in the illustration.

*Standard normal diametral pitches  $P_n$* , BS 436 Part 1:1967, are in accordance with ISO R54. The preferred series, rather than the second choice, should be used where possible. Preferred normal diametral pitches for spur and helical gears (second choices in parentheses) are: 20 (18), 16 (14), 12 (11), 10 (9), 8 (7), 6 (5.5), 5 (4.5), 4 (3.5), 3 (2.75), 2.5 (2.25), 2 (1.75), 1.5, 1.25, and 1.

*Information to be Given on Drawings:* British Standard BS 308, “Engineering Drawing Practice”, specifies data to be included on drawings of spur and helical gears. For all gears the data should include: number of teeth, normal diametral pitch, basic rack tooth form, axial pitch, tooth profile modifications, blank diameter, reference circle diameter, and helix angle at reference cylinder (0 for straight spur gears), tooth thickness at reference cyl-

inder, grade of gear, drawing number of mating gear, working center distance, and backlash.

For single helical gears, the above data should be supplemented with hand and lead of the tooth helix; and for double helical gears, with the hand in relation to a specific part of the face width and the lead of tooth helix.

Inspection instructions should be included, care being taken to avoid conflicting requirements for accuracy of individual elements, and single- and dual-flank testing. Supplementary data covering specific design, manufacturing and inspection requirements or limitations may be needed, together with other dimensions and tolerances, material, heat treatment, hardness, case depth, surface texture, protective finishes, and drawing scale.

**Addendum Modification to Involute Spur and Helical Gears.**— The British Standards Institute guide PD 6457:1970 contains certain design recommendations aimed at making it possible to use standard cutting tools for some sizes of gears. Essentially, the guide covers addendum modification and includes formulas for both English and metric units.

*Addendum Modification* is an enlargement or reduction of gear tooth dimensions that results from displacement of the reference plane of the generating rack from its normal position. The displacement is represented by the coefficient  $X$ ,  $X1$ , or  $X2$ , where  $X$  is the equivalent dimension for gears of unit module or diametral pitch. The addendum modification establishes a datum tooth thickness at the reference circle of the gear but does not necessarily establish the height of either the reference addendum or the working addendum. In any pair of gears, the datum tooth thicknesses are those that always give zero backlash at the meshing center distance. Normal practice requires allowances for backlash for all unmodified gears.

Taking full advantage of the adaptability of the involute system allows various tooth design features to be obtained. Addendum modification has the following applications: avoiding undercut tooth profiles; achieving optimum tooth proportions and control of the proportion of receding to approaching contact; adapting a gear pair to a predetermined center distance without recourse to non-standard pitches; and permitting use of a range of working pressure angles using standard geometry tools.

**BS 436, Part 3:1986 “Spur and Helical Gears”.**— This part provides methods for calculating contact and root bending stresses for metal involute gears, and is somewhat similar to the ANSI/AGMA Standard for calculating stresses in pairs of involute spur or helical gears. Stress factors covered in the British Standard include the following:

*Tangential Force* is the nominal force for contact and bending stresses.

*Zone Factor* accounts for the influence of tooth flank curvature at the pitch point on Hertzian stress.

*Contact Ratio Factor* takes account of the load-sharing influence of the transverse contact ratio and the overlap ratio on the specific loading.

*Elasticity Factor* takes into account the influence of the modulus of elasticity of the material and of Poisson's ratio on the Hertzian stress.

*Basic Endurance Limit* for contact makes allowance for the surface hardness.

*Material Quality* covers the quality of the material used.

*Lubricant Influence, Roughness, and Speed* The lubricant viscosity, surface roughness and pitch line speed affect the lubricant film thickness, which in turn, affects the Hertzian stresses.

*Work Hardening Factor* accounts for the increase in surface durability due to the meshing action.

*Size Factor* covers the possible influences of size on the material quality and its response to manufacturing processes.

*Life Factor* accounts for the increase in permissible stresses when the number of stress cycles is less than the endurance life.

*Application Factor* allows for load fluctuations from the mean load or loads in the load histogram caused by sources external to the gearing.

*Dynamic Factor* allows for load fluctuations arising from contact conditions at the gear mesh.

*Load Distribution* accounts for the increase in local load due to maldistribution of load across the face of the gear tooth caused by deflections, alignment tolerances and helix modifications.

*Minimum Demanded and Actual Safety Factor* The minimum demanded safety factor is agreed between the supplier and the purchaser. The actual safety factor is calculated.

*Geometry Factors* allow for the influence of the tooth form, the effect of the fillet and the helix angle on the nominal bending stress for the application of load at the highest point of single pair tooth contact.

*Sensitivity Factor* allows for the sensitivity of the gear material to the presence of notches such as the root fillet.

*Surface Condition Factor* accounts for reduction of the endurance limit due to flaws in the material and the surface roughness of the tooth root fillets.

**ISO TC/600.**— The ISO TC/600 Standard is similar to BS 436, Part 3:1986, but is far more comprehensive. For general gear design, the ISO Standard provides a complicated method of arriving at a conclusion similar to that reached by the less complex British Standard. Factors additional to the above that are included in the ISO Standard include the following:

*Application Factor* accounts for dynamic overloads from sources external to the gearing.

*Dynamic Factor* allows for internally generated dynamic loads caused by vibrations of the pinion and wheel against each other.

*Load Distribution* makes allowance for the effects of non-uniform distribution of load across the face width, depending on the mesh alignment error of the loaded gear pair and the mesh stiffness.

*Transverse Load Distribution Factor* takes into account the effect of the load distribution on gear tooth contact stresses.

*Gear Tooth Stiffness Constants* are defined as the load needed to deform one or several meshing gear teeth having 1 mm face width, by an amount of 1  $\mu\text{m}$  (0.00004 in).

*Allowable Contact Stress* is the permissible Hertzian pressure on the gear tooth face.

*Minimum Demanded and Calculated Safety Factors* The minimum demanded safety factor is agreed between the supplier and the customer. The calculated safety factor is the actual safety factor of the gear pair.

*Zone Factor* accounts for the influence on the Hertzian pressure of the tooth flank curvature at the pitch point.

*Elasticity Factor* takes account of the influence of the material properties such as the modulus of elasticity and Poisson's ratio.

*Contact Ratio Factor* accounts for the influence of the transverse contact ratio and the overlap ratio on the specific surface load of the gears.

*Helix Angle Factor* makes allowance for influence of helix angle on surface durability.

*Endurance Limit* is the limit of repeated Hertzian stresses that can be permanently endured by a given material.

*Life Factor* takes account of a higher permissible Hertzian stress if only limited durability is demanded.

*Lubrication Film Factor* The film of lubricant between the tooth flanks influences the surface load capacity. Factors include the oil viscosity, pitch line velocity and roughness of the tooth flanks.

*Work Hardening Factor* takes account of the increase in surface durability due to meshing a steel wheel with a hardened pinion having smooth tooth surfaces.

*Coefficient of Friction* The mean value of the local coefficient of friction depends on the lubricant, surface roughness, the lay of surface irregularities, material properties of the tooth flanks, and the force and size of tangential velocities.

*Bulk Temperature Thermal Flash Factor* is dependent on moduli of elasticity and thermal contact coefficients of pinion and wheel materials and geometry of the line of action.

*Welding Factor* accounts for different tooth materials and heat treatments.

*Geometrical Factor* is defined as a function of the gear ratio and the dimensionless parameter on the line of action.

*Integral Temperature Criterion* The integral temperature of the gears depends on the lubricant viscosity and tendency toward cuffing and scoring of the gear materials.

Examination of the above factors shows the similarity in the approach of the British and the ISO Standards to that of the ANSI/AGMA Standards. Slight variations in the methods used to calculate the factors will result in different allowable stress figures. Experimental work using some of the stressing formulas has shown wide variations and designers must continue to rely on experience to arrive at satisfactory results.

### Standards Nomenclature

All standards are referenced and identified throughout this book by an alphanumeric prefix which designates the organization that administered the development work on the standard, and followed by a standards number.

All standards are reviewed by the relevant committees at regular time intervals, as specified by the overseeing standards organization, to determine whether the standard should be confirmed (reissued without changes other than correction of typographical errors), updated, or removed from service.

The following is for example use only. ANSI B18.8.2-1984, R1994 is a standard for Taper, Dowel, Straight, Grooved, and Spring Pins. ANSI refers to the American National Standards Institute that is responsible for overseeing the development or approval of the standard, and B18.8.2 is the number of the standard. The first date, 1984, indicates the year in which the standard was issued, and the sequence R1994 indicates that this standard was reviewed and reaffirmed in 1994. The current designation of the standard, ANSI/ASME B18.8.2-1995, indicates that it was revised in 1995; it is ANSI approved; and ASME (American Society of Mechanical Engineers) was the standards body responsible for development of the standard. This standard is sometimes also designated ASME B18.8.2-1995.

ISO (International Organization for Standardization) standards use a slightly different format, for example, ISO 5127-1:1983. The entire ISO reference number consists of a prefix ISO, a serial number, and the year of publication.

Aside from content, ISO standards differ from American National standards in that they are often smaller focused documents, which in turn reference other standards or other parts of the same standard. Unlike the numbering scheme used by ANSI, ISO standards related to a particular topic often do not carry sequential numbers nor are they in consecutive series.

British Standards Institute standards use the following format: BS 1361: 1971 (1986). The first part is the organization prefix BS, followed by the reference number and the date of issue. The number in parenthesis is the date that the standard was most recently reconfirmed. British Standards may also be designated *withdrawn* (no longer to be used) and *obsolescent* (going out of use, but may be used for servicing older equipment).

## HYPOID AND BEVEL GEARING

### Hypoid Gears

Hypoid gears are offset and, in effect, are spiral gears whose axes do not intersect but are staggered by an amount decided by the application. Due to the offset, contact between the teeth of the two gears does not occur along a surface line of the cones as it does with spiral bevels having intersecting axes, but along a curve in space inclined to the surface line. The basic solids of the hypoid gear members are not cones, as in spiral bevels, but are hyperboloids of revolution which cannot be projected into the common plane of ordinary flat gears, thus the name hypoid. The visualization of hypoid gears is based on an imaginary flat gear which is a substitute for the theoretically correct helical surface. If certain rules are observed during the calculations to fix the gear dimensions, the errors that result from the use of an imaginary flat gear as an approximation are negligible.

The staggered axes result in meshing conditions that are beneficial to the strength and running properties of the gear teeth. A uniform sliding action takes place between the teeth, not only in the direction of the tooth profile but also longitudinally, producing ideal conditions for movement of lubricants. With spiral gears, great differences in sliding motion arise over various portions of the tooth surface, creating vibration and noise. Hypoid gears are almost free from the problems of differences in these sliding motions and the teeth also have larger curvature radii in the direction of the profile. Surface pressures are thus reduced so that there is less wear and quieter operation.

The teeth of hypoid gears are 1.5 to 2 times stronger than those of spiral bevel gears of the same dimensions, made from the same material. Certain limits must be imposed on the dimensions of hypoid gear teeth so that their proportions can be calculated in the same way as they are for spiral bevel gears. The offset must not be larger than 1/7th of the ring gear outer diameter, and the tooth ratio must not be much less than 4 to 1. Within these limits, the tooth proportions can be calculated in the same way as for spiral bevel gears and the radius of lengthwise curvature can be assumed in such a way that the normal module is a maximum at the center of the tooth face width to produce stabilized tooth bearings.

If the offset is larger or the ratio is smaller than specified above, a tooth form must be selected that is better adapted to the modified meshing conditions. In particular, the curvature of the tooth length curve must be determined with other points in view. The limits are only guidelines since it is impossible to account for all other factors involved, including the pitch line speed of the gears, lubrication, loads, design of shafts and bearings, and the general conditions of operation.

Of the three different designs of hypoid bevel gears now available, the most widely used, especially in the automobile industry, is the Gleason system. Two other hypoid gear systems have been introduced by Oerlikon (Swiss) and Klingelberg (German). All three methods use the involute gear form, but they have teeth with differing curvatures, produced by the cutting method. Teeth in the Gleason system are arc shaped and their depth tapers. Both the European systems are designed to combine rolling with the sideways motion of the teeth and use a constant tooth depth. Oerlikon uses an epicycloidal tooth form and Klingelberg uses a true involute form.

With their circular accurate tooth face curves, Gleason hypoid gears are produced with multi-bladed face milling cutters. The gear blank is rolled relative to the rotating cutter to make one inter-tooth groove; then the cutter is withdrawn and returned to its starting position while the blank is indexed into the position for cutting the next tooth. Both roughing and finishing cutters are kept parallel to the tooth root lines, which are at an angle to the gear pitch line. Depending on this angularity, plus the spiral angle, a correction factor must be calculated for both the leading and trailing faces of the gear tooth.

In operation, the convex faces of the teeth on one gear always bear on the concave faces of the teeth on the mating gear. For correct meshing between the pinion and gear wheel, the

spiral angles should not vary over the full face width. The tooth form generated is a logarithmic spiral and, as a compromise, the cutter radius is made equal to the mean radius of a corresponding logarithmic spiral.

The involute tooth face curves of the Klingelnberg system gears have constant-pitch teeth cut by (usually) a single-start taper hob. The machine is set up to rotate both the cutter and the gear blank at the correct relative speeds. The surface of the hob is set tangential to a circle radius, which is the gear base circle, from which all the parallel involute curves are struck. To keep the hob size within reasonable dimensions, the cone must lie a minimum distance within the teeth and this requirement governs the size of the module.

Both the module and the tooth depth are constant over the full face width and the spiral angle varies. The cutting speed variations, especially with regard to crown wheels, over the cone surface of the hob, make it difficult to produce a uniform surface finish on the teeth, so a finishing cut is usually made with a truncated hob which is tilted to produce the required amount of crowning automatically, for correct tooth marking and finishing. The dependence of the module, spiral angle and other features on the base circle radius, and the need for suitable hob proportions restrict the gear dimensions and the system cannot be used for gears with a low or zero angle. However, gears can be cut with a large root radius giving teeth of high strength. The favorable geometry of the tooth form gives quieter running and tolerance of inaccuracies in assembly.

Teeth of gears made by the Oerlikon system have elongated epicycloidal form, produced with a face-type rotating cutter. Both the cutter and the gear blank rotate continuously, with no indexing. The cutter head has separate groups of cutters for roughing, outside cutting and inside cutting so that tooth roots and flanks are cut simultaneously, but the feed is divided into two stages. As stresses are released during cutting, there is some distortion of the blank and this distortion will usually be worse for a hollow crown wheel than for a solid pinion.

All the heavy cuts are taken during the first stages of machining with the Oerlikon system and the second stage is used to finish the tooth profile accurately, so distortion effects are minimized. As with the Klingelnberg process, the Oerlikon system produces a variation in spiral angle and module over the width of the face, but unlike the Klingelnberg method, the tooth length curve is cycloidal. It is claimed that, under load, the tilting force in an Oerlikon gear set acts at a point 0.4 times the distance from the small diameter end of the gear and not in the mid-tooth position as in other gear systems, so that the radius is obviously smaller and the tilting moment is reduced, resulting in lower loading of the bearings.

Gears cut by the Oerlikon system have tooth markings of different shape than gears cut by other systems, showing that more of the face width of the Oerlikon tooth is involved in the load-bearing pattern. Thus, the surface loading is spread over a greater area and becomes lighter at the points of contact.

### Bevel Gearing

**Types of Bevel Gears.**— Bevel gears are conical gears, that is, gears in the shape of cones, and are used to connect shafts having intersecting axes. Hypoid gears are similar in general form to bevel gears, but operate on axes that are offset. With few exceptions, most bevel gears may be classified as being either of the straight-tooth type or of the curved-tooth type. The latter type includes spiral bevels, Zerol bevels, and hypoid gears. The following is a brief description of the distinguishing characteristics of the different types of bevel gears.

*Straight Bevel Gears:* The teeth of this most commonly used type of bevel gear are straight but their sides are tapered so that they would intersect the axis at a common point called the pitch cone apex if extended inward. The face cone elements of most straight bevel gears, however, are now made parallel to the root cone elements of the mating gear to obtain uniform clearance along the length of the teeth. The face cone elements of such

gears, therefore, would intersect the axis at a point inside the pitch cone. Straight bevel gears are the easiest to calculate and are economical to produce.

Straight bevel gear teeth may be generated for full-length contact or for localized contact. The latter are slightly convex in a lengthwise direction so that some adjustment of the gears during assembly is possible and small displacements due to load deflections can occur without undesirable load concentration on the ends of the teeth. This slight lengthwise rounding of the tooth sides need not be computed in the design but is taken care of automatically in the cutting operation on the newer types of bevel gear generators.

*Zerol Bevel Gears:* The teeth of Zerol bevel gears are curved but lie in the same general direction as the teeth of straight bevel gears. They may be thought of as spiral bevel gears of zero spiral angle and are manufactured on the same machines as spiral bevel gears. The face cone elements of Zerol bevel gears do not pass through the pitch cone apex but instead are approximately parallel to the root cone elements of the mating gear to provide uniform tooth clearance. The root cone elements also do not pass through the pitch cone apex because of the manner in which these gears are cut. Zerol bevel gears are used in place of straight bevel gears when generating equipment of the spiral type but not the straight type is available, and may be used when hardened bevel gears of high accuracy (produced by grinding) are required.

*Spiral Bevel Gears:* Spiral bevel gears have curved oblique teeth on which contact begins gradually and continues smoothly from end to end. They mesh with a rolling contact similar to straight bevel gears. As a result of their overlapping tooth action, however, spiral bevel gears will transmit motion more smoothly than straight bevel or Zerol bevel gears, reducing noise and vibration that become especially noticeable at high speeds.

One of the advantages associated with spiral bevel gears is the complete control of the localized tooth contact. By making a slight change in the radii of curvature of the mating tooth surfaces, the amount of surface over which tooth contact takes place can be changed to suit the specific requirements of each job. Localized tooth contact promotes smooth, quiet running spiral bevel gears, and permits some mounting deflections without concentrating the load dangerously near either end of the tooth. Permissible deflections established by experience are given under the heading *Mountings for Bevel Gears*.

Because their tooth surfaces can be ground, spiral bevel gears have a definite advantage in applications requiring hardened gears of high accuracy. The bottoms of the tooth spaces and the tooth profiles may be ground simultaneously, resulting in a smooth blending of the tooth profile, the tooth fillet, and the bottom of the tooth space. This feature is important from a strength standpoint because it eliminates cutter marks and other surface interruptions that frequently result in stress concentrations.

*Hypoid Gears:* In general appearance, hypoid gears resemble spiral bevel gears, except that the axis of the pinion is offset relative to the gear axis. If there is sufficient offset, the shafts may pass one another thus permitting the use of a compact straddle mounting on the gear and pinion. Whereas a spiral bevel pinion has equal pressure angles and symmetrical profile curvatures on both sides of the teeth, a hypoid pinion properly conjugate to a mating gear having equal pressure angles on both sides of the teeth must have nonsymmetrical profile curvatures for proper tooth action. In addition, to obtain equal arcs of motion for both sides of the teeth, it is necessary to use unequal pressure angles on hypoid pinions. Hypoid gears are usually designed so that the pinion has a larger spiral angle than the gear. The advantage of such a design is that the pinion diameter is increased and is stronger than a corresponding spiral bevel pinion. This diameter increment permits the use of comparatively high ratios without the pinion becoming too small to allow a bore or shank of adequate size. The sliding action along the lengthwise direction of their teeth in hypoid gears is a function of the difference in the spiral angles on the gear and pinion. This sliding effect makes such gears even smoother running than spiral bevel gears. Grinding of hypoid gears can be accomplished on the same machines used for grinding spiral bevel and Zerol bevel gears.

**Applications of Bevel and Hypoid Gears.**— Bevel and hypoid gears may be used to transmit power between shafts at practically any angle and speed. The particular type of gearing best suited for a specific job, however, depends on the mountings and the operating conditions.

*Straight and Zerol Bevel Gears:* For peripheral speeds up to 1000 feet per minute (305 m/min), where maximum smoothness and quietness are not the primary consideration, straight and Zerol bevel gears are recommended. For such applications, plain bearings may be used for radial and axial loads, although the use of antifriction bearings is always preferable. Plain bearings permit a more compact and less expensive design, which is one reason why straight and Zerol bevel gears are much used in differentials. This type of bevel gearing is the simplest to calculate and set up for cutting, and is ideal for small lots where fixed charges must be kept to a minimum.

Zerol bevel gears are recommended in place of straight bevel gears where hardened gears of high accuracy are required, because Zerol gears may be ground; and when only spiral-type equipment is available for cutting bevel gears.

*Spiral Bevel and Hypoid Gears:* Spiral bevel and hypoid gears are recommended for applications where peripheral speeds exceed 1000 feet per minute (305 m/min) or 1000 revolutions per minute. In many instances, they may be used to advantage at lower speeds, particularly where extreme smoothness and quietness are desired. For peripheral speeds above 8000 feet per minute (2438 m/min), ground gears should be used.

For large reduction ratios the use of spiral and hypoid gears will reduce the overall size of the installation because the continuous pitch line contact of these gears makes it practical to obtain smooth performance with a smaller number of teeth in the pinion than is possible with straight or Zerol bevel gears.

Hypoid gears are recommended for industrial applications: when maximum smoothness of operation is desired; for high reduction ratios where compactness of design, smoothness of operation, and maximum pinion strength are important; and for nonintersecting shafts.

Bevel and hypoid gears may be used for both speed-reducing and speed-increasing drives. In speed-increasing drives, however, the ratio should be kept as low as possible and the pinion mounted on antifriction bearings; otherwise bearing friction will cause the drive to lock.

**Notes on the Design of Bevel Gear Blanks.**— The quality of any finished gear is dependent, to a large degree, on the design and accuracy of the gear blank. A number of factors that affect manufacturing economy as well as performance must be considered.

A gear blank should be designed to avoid localized stresses and serious deflections within itself. Sufficient thickness of metal should be provided under the roots of gear teeth to give them proper support. As a general rule, the amount of metal under the root should equal the whole depth of the tooth; this metal depth should be maintained under the small ends of the teeth as well as under the middle. On webless-type ring gears, the minimum stock between the root line and the bottom of tap drill holes should be one-third the tooth depth. For heavily loaded gears, a preliminary analysis of the direction and magnitude of the forces is helpful in the design of both the gear and its mounting. Rigidity is also necessary for proper chucking when cutting the teeth. For this reason, bores, hubs, and other locating surfaces must be in proper proportion to the diameter and pitch of the gear. Small bores, thin webs, or any condition that necessitates excessive overhang in cutting should be avoided.

Other factors to be considered are the ease of machining and, in gears that are to be hardened, proper design to ensure the best hardening conditions. It is desirable to provide a locating surface of generous size on the backs of gears. This surface should be machined or ground square with the bore and is used both for locating the gear axially in assembly and for holding it when the teeth are cut. The front clamping surface must, of course, be flat and parallel to the back surface. In connection with cutting the teeth on Zerol bevel, spiral

bevel, and hypoid gears, clearance must be provided for face-mill type cutters; front and rear hubs should not intersect the extended root line of the gear or they will interfere with the path of the cutter. In addition, there must be enough room in the front of the gear for the clamp nut that holds the gear on the arbor, or in the chuck, while cutting the teeth. The same considerations must be given to straight bevel gears that are to be generated using a circular-type cutter instead of reciprocating tools.

**Mountings for Bevel Gears.**— Rigid mountings should be provided for bevel gears to keep the displacements of the gears under operating loads within recommended limits. To align gears properly, care should be taken to ensure accurately machined mountings, properly fitted keys, and couplings that run true and square.

As a result of deflection tests on gears and their mountings, and having observed these same units in service, the *Gleason Works* recommends that the following allowable deflections be used for gears from 6 to 15 inches (15.24–38.10 cm) in diameter: neither the pinion nor the gear should lift or depress more than 0.003 inch (0.076 mm) at the center of the face width; the pinion should not yield axially more than 0.003 inch (0.076 mm) in either direction; and the gear should not yield axially more than 0.003 inch (0.076 mm) in either direction on 1 to 1 ratio gears (miter gears), or near miters, or more than 0.010 inch (0.25 mm) away from the pinion on higher ratios.

When deflections exceed these limits, additional problems are involved in obtaining satisfactory gears. It becomes necessary to narrow and shorten the tooth contacts to suit the more flexible mounting. These changes decrease the bearing area, raise the unit tooth pressure, and reduce the number of teeth in contact, resulting in increased noise and the danger of surface failure as well as tooth breakage.

Spiral bevel and hypoid gears in general should be mounted on antifriction bearings in an oil-tight case. Designs for a given set of conditions may use plain bearings for radial and thrust loads; maintaining gears in satisfactory alignment is usually more easily accomplished with ball or roller bearings.

*Bearing Spacing and Shaft Stiffness:* Bearing spacing and shaft stiffness are extremely important if gear deflections are to be minimized. For both straddle mounted and overhung mounted gears the spread between bearings should never be less than 70 percent of the pitch diameter of the gear. On overhung mounted gears the spread should be at least  $2\frac{1}{2}$  times the overhang and, in addition, the shaft diameter should be equal to or preferably greater than the overhang to provide sufficient shaft stiffness. When two spiral bevel or hypoid gears are mounted on the same shaft, the axial thrust should be taken at one place only and near the gear where the greater thrust is developed. Provision should be made for adjusting both the gear and pinion axially in assembly. Details on how this may be accomplished are given in the *Gleason Works* booklet, "Assembling Bevel Gears."

**Cutting Bevel Gear Teeth.**— A correctly formed bevel gear tooth has the same sectional shape throughout its length, but on a uniformly diminishing scale from the large to the small end. The only way to obtain this correct form is by using a generating type of bevel gear cutting machine. This accounts, in part, for the extensive use of generating type gear cutting equipment in the production of bevel gears.

Bevel gears too large to be cut by generating equipment — 100 inches (254 cm) or over in diameter — may be produced by a form-copying type of gear planer. A template or former is used to mechanically guide a single cutting tool in the proper path to cut the profile of the teeth. Since the tooth profile produced by this method is dependent on the contour of the template used, it is possible to produce tooth profiles to suit a variety of requirements.

Although generating methods are to be preferred, there are still some cases where straight bevel gears are produced by milling. Milled gears cannot be produced with the accuracy of generated gears and generally are not suitable for use in high-speed applications or where angular motion must be transmitted with a high degree of accuracy. Milled gears are used chiefly as replacement gears in certain applications, and gears which are

subsequently to be finished on generating type equipment are sometimes roughed out by milling. Formulas and methods used for the cutting of bevel gears are given in the latter part of this section.

In producing gears by generating methods, the tooth curvature is generated from a straight-sided cutter or tool having an angle equal to the required pressure angle. This tool represents the side of a crown gear tooth. The teeth of a true involute crown gear, however, have sides which are very slightly curved. If the curvature of the cutting tool conforms to that of the involute crown gear, an involute form of bevel gear tooth will be obtained. The use of a straight-sided tool is more practical and results in a very slight change of tooth shape to what is known as the "octoid" form. Both the octoid and involute forms of bevel gear tooth give theoretically correct action.

Bevel gear teeth, like those for spur gears, differ as to pressure angle and tooth proportions. The whole depth and the addendum at the large end of the tooth may be the same as for a spur gear of equal pitch. Most bevel gears, however, both of the straight tooth and spiral-bevel types, have lengthened pinion addendums and shortened gear addendums as in the case of some spur gears, the amount of departure from equal addendums varying with the ratio of gearing. Long addendums on the pinion are used principally to avoid undercut and to increase tooth strength. In addition, where long and short addendums are used, the tooth thickness of the gear is decreased and that of the pinion increased to provide a better balance of strength. See the Gleason Works System for straight and spiral bevel gears and also the British Standard.

**Nomenclature for Bevel Gears.**—The accompanying diagram, *Fig. 1a, Bevel Gear Nomenclature*, illustrates various angles and dimensions referred to in describing bevel gears. In connection with the face angles shown in the diagram, it should be noted that the face cones are made parallel to the root cones of the mating gears to provide uniform clearance along the length of the teeth. See also *Fig. 1b*, page 2199.

**American Standard for Bevel Gears.**—American Standard ANSI/AGMA 2005-B88, Design Manual for Bevel Gears, replaces AGMA Standards 202.03, 208.03, 209.04, and 330.01, and provides standards for design of straight, zero, and spiral bevel gears and hypoid gears with information on fabrication, inspection, and mounting. The information covers preliminary design, drawing formats, materials, rating, strength, inspection, lubrication, mountings, and assembly. Blanks for standard taper, uniform depth, duplex taper, and tilted root designs are included so that the material applies to users of Gleason, Klingelnberg, and Oerlikon gear cutting machines.

**Formulas for Dimensions of Milled Bevel Gears.**—As explained earlier, most bevel gears are produced by generating methods. Even so, there are applications for which it may be desired to cut a pair of mating bevel gears by using rotary formed milling cutters. Examples of such applications include replacement gears for certain types of equipment and gears for use in experimental developments.

The tooth proportions of milled bevel gears differ in some respects from those of generated gears, the principal difference being that for milled bevel gears the tooth thicknesses of pinion and gear are made equal, and the addendum and dedendum of the pinion are respectively the same as those of the gear. The rules and formulas in the accompanying table may be used to calculate the dimensions of milled bevel gears with shafts at a right angle, an acute angle, and an obtuse angle.

In the accompanying diagrams, *Figs. 1a* and *1b*, and list of notations, the various terms and symbols applied to milled bevel gears are as indicated.

$N$  = number of teeth

$P$  = diametral pitch

$p$  = circular pitch

$\alpha$  = pitch cone angle and edge angle

$\Sigma$  = angle between shafts

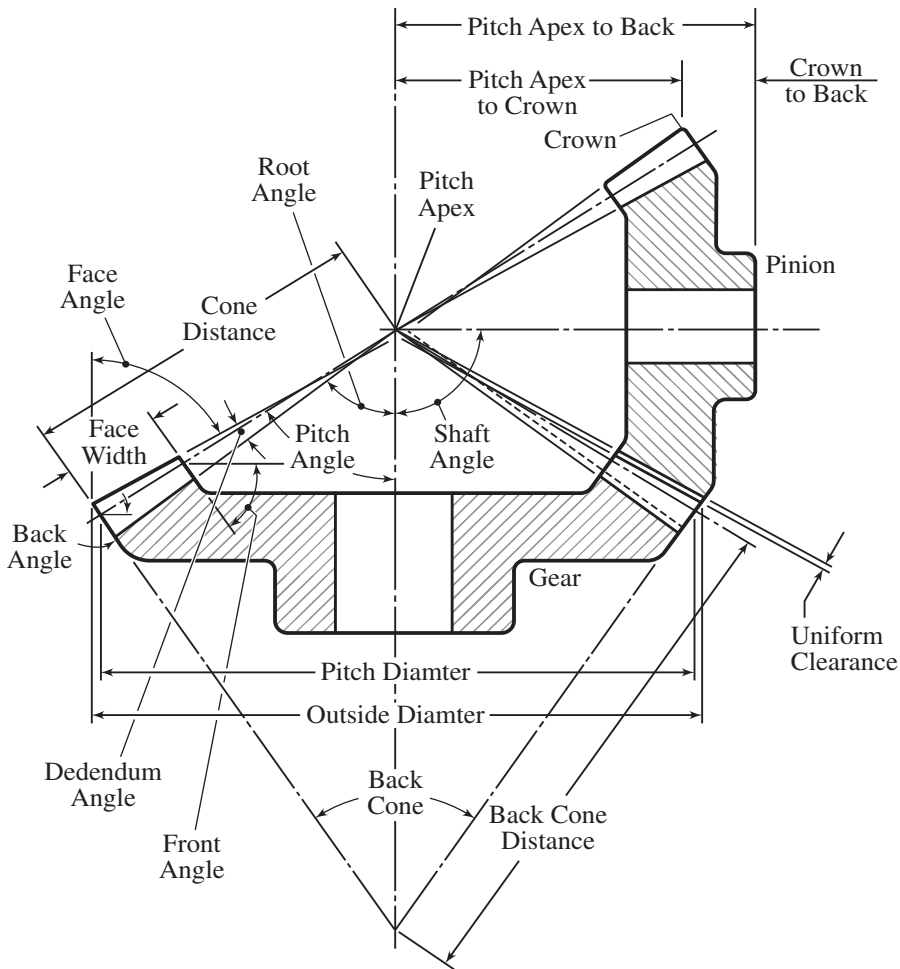

Fig. 1a. Bevel Gear Nomenclature

- $D$  = pitch diameter  
 $S$  = addendum  
 $S + A$  = dedendum ( $A$  = clearance)  
 $W$  = whole depth of tooth  
 $T$  = thickness of tooth at pitch line  
 $C$  = pitch cone radius  
 $F$  = width of face  
 $s$  = addendum at small end of tooth  
 $t$  = thickness of tooth at pitch line at small end  
 $\theta$  = addendum angle  
 $\phi$  = dedendum angle  
 $\gamma$  = face angle = pitch cone angle + addendum angle  
 $\delta$  = angle of compound rest  
 $\zeta$  = cutting angle  
 $K$  = angular addendum  
 $O$  = outside diameter  
 $J$  = vertex distance  
 $j$  = vertex distance at small end  
 $N'$  = number of teeth for which to select cutter

Fig. 1b. Bevel Gear Nomenclature

The formulas for milled bevel gears should be modified to make the clearance at the bottom of the teeth uniform instead of tapering toward the vertex. If this recommendation is followed, then the cutting angle (root angle) should be determined by subtracting the *addendum* angle from the pitch cone angle instead of subtracting the dedendum angle as in the formula given in the table.

**Rules and Formulas for Calculating Dimensions of Milled Bevel Gears**

To Find	Rule	Formula
Pitch Cone Angle of Pinion	Divide the sine of the shaft angle by the sum of the cosine of the shaft angle and the quotient obtained by dividing the number of teeth in the gear by the number of teeth in the pinion; this gives the tangent. <i>Note:</i> For shaft angles greater than 90° the cosine is negative.	$\tan \alpha_p = \frac{\sin \Sigma}{\frac{N_G}{N_P} + \cos \Sigma}$ For 90° shaft angle, $\tan \alpha_p = \frac{N_P}{N_G}$
Pitch Cone Angle of Gear	Subtract the pitch cone angle of the pinion from the shaft angle.	$\alpha_G = \Sigma - \alpha_p$
Pitch Diameter	Divide the number of teeth by the diametral pitch.	$D = N \div P$

**Rules and Formulas for Calculating Dimensions of Milled Bevel Gears(Continued)**

To Find	Rule	Formula	
These dimensions are the same for both gear and pinion.	Addendum	Divide 1 by the diametral pitch.	$S = 1 \div P$
	Dedendum	Divide 1.157 by the diametral pitch.	$S + A = 1.157 \div P$
	Whole Depth of Tooth	Divide 2.157 by the diametral pitch.	$W = 2.157 \div P$
	Thickness of Tooth at Pitch Line	Divide 1.571 by the diametral pitch.	$T = 1.571 \div P$
	Pitch Cone Radius	Divide the pitch diameter by twice the sine of the pitch cone angle.	$C = \frac{D}{2 \times \sin \alpha}$
	Addendum of Small End of Tooth	Subtract the width of face from the pitch cone radius, divide the remainder by the pitch cone radius and multiply by the addendum.	$s = S \times \frac{C-F}{C}$
	Thickness of Tooth at Pitch Line at Small End	Subtract the width of face from the pitch cone radius, divide the remainder by the pitch cone radius and multiply by the thickness of the tooth at pitch line.	$t = T \times \frac{C-F}{C}$
	Addendum Angle	Divide the addendum by the pitch cone radius to get the tangent.	$\tan \theta = \frac{S}{C}$
	Dedendum Angle	Divide the dedendum by the pitch cone radius to get the tangent.	$\tan \phi = \frac{S+A}{C}$
	Face Width (Max.)	Divide the pitch cone radius by 3 or divide 8 by the diametral pitch, whichever gives the smaller value.	$F = \frac{C}{3}$ or $F = \frac{8}{P}$
	Circular Pitch	Divide 3.1416 by the diametral pitch.	$p = 3.1416 \div P$
Face Angle	Add the addendum angle to the pitch cone angle	$\gamma = \alpha + \theta$	
Compound Rest Angle for Turning Blank	Subtract both the pitch cone angle and the addendum angle from 90 degrees.	$\delta = 90^\circ - \alpha - \theta$	
Cutting Angle	Subtract the dedendum angle from the pitch cone angle.	$\zeta = \alpha - \phi$	
Angular Addendum	Multiply the addendum by the cosine of the pitch cone angle.	$K = S \times \cos \alpha$	
Outside Diameter	Add twice the angular addendum to the pitch diameter.	$O = D + 2K$	
Vertex or Apex Distance	Multiply one-half the outside diameter by the cotangent of the face angle.	$J = \frac{O}{2} \times \cot \gamma$	
Vertex Distance at Small End of Tooth	Subtract the width of face from the pitch cone radius; divide the remainder by the pitch cone radius and multiply by the apex distance.	$j = J \times \frac{C-F}{C}$	
Number of Teeth for which to Select Cutter	Divide the number of teeth by the cosine of the pitch cone angle.	$N' = \frac{N}{\cos \alpha}$

Number of cutter for gear given first, followed by number for pinion. See text, page 2203

**Selecting Formed Cutters for Milling Bevel Gears.**— For milling  $14\frac{1}{2}$ -degree pressure angle bevel gears, the standard cutter series furnished by manufacturers of formed milling cutters is commonly used. There are 8 cutters in the series for each diametral pitch to cover the full range from a 12-tooth pinion to a crown gear. The difference between formed cutters used for milling spur gears and those used for bevel gears is that bevel gear cutters are thinner because they must pass through the narrow tooth space at the small end of the bevel gear; otherwise the shape of the cutter and, hence, the cutter number are the same.

To select the proper number of cutter to be used when a bevel gear is to be milled, it is necessary, first, to compute what is called the “Number of Teeth,  $N'$  for which to Select Cutter.” This number of teeth can then be used to select the proper number of bevel gear cutter from the spur gear milling cutter table on page 2166. The value of  $N'$  may be computed using the last formula in the table on page 2199.

*Example 1:* What numbers of cutters are required for a pair of bevel gears of 4 diametral pitch and 70 degree shaft angle if the gear has 50 teeth and the pinion 20 teeth?

The pitch cone angle of the pinion is determined by using the first formula in the table on page 2199:

$$\tan \alpha_P = \frac{\sin \Sigma}{\frac{N_G}{N_P} + \cos \Sigma} = \frac{\sin 70^\circ}{\frac{50}{20} + \cos 70^\circ} = 0.33064; \alpha_P = 18^\circ 18'$$

The pitch cone angle of the gear is determined from the second formula in the table on page 2199:

$$\alpha_G = \Sigma - \alpha_P = 70^\circ - 18^\circ 18' = 51^\circ 42'$$

The numbers of teeth  $N'$  for which to select the cutters for the gear and pinion may now be determined from the last formula in the table on page 2199:

$$N' \text{ for the pinion} = \frac{N_P}{\cos \alpha_P} = \frac{20}{\cos 18^\circ 18'} = 21.1 \approx 21 \text{ teeth}$$

$$N' \text{ for the gear} = \frac{N_G}{\cos \alpha_G} = \frac{50}{\cos 51^\circ 42'} = 80.7 \approx 81 \text{ teeth}$$

From the table on page 2166 the numbers of the cutters for pinion and gear are found to be, respectively, 5 and 2.

*Example 2:* The cutters for a pair of bevel gears are required where the gear has 24 teeth and the pinion 12 teeth. The shaft angle is 90 degrees. As in the first example, the formulas given in the table on page 2199 will be used.

$$\tan \alpha_P = N_P \div N_G = 12 \div 24 = 0.5000 \text{ and } \alpha_P = 26^\circ 34'$$

$$\alpha_G = \Sigma - \alpha_P = 90^\circ - 26^\circ 34' = 63^\circ 26'$$

$$N' \text{ for pinion} = 12 \div \cos 26^\circ 34' = 13.4 \approx 13 \text{ teeth}$$

$$N' \text{ for gear} = 24 \div \cos 63^\circ 26' = 53.6 \approx 54 \text{ teeth}$$

And from the table on page 2166 the cutters for pinion and gear are found to be, respectively, 8 and 3.

**Use of Table for Selecting Formed Cutters for Milling Bevel Gears.**— The table beginning on page 2201 gives the numbers of cutters to use for milling various numbers of teeth in the gear and pinion. The table applies only to bevel gears with axes at right angles. Thus, in *Example 2* given above, the numbers of the cutters could have been obtained directly by entering the table with the actual numbers of teeth in the gear, 24, and the pinion, 12.

**Offset of Cutter for Milling Bevel Gears.**— When milling bevel gears with a rotary formed cutter, it is necessary to take two cuts through each tooth space with the gear blank slightly off center, first on one side and then on the other, to obtain a tooth of approximately the correct form. The gear blank is also rotated proportionately to obtain the proper tooth thickness at the large and small ends. The amount that the gear blank or cutter should be offset from the central position can be determined quite accurately by the use of the table *Factors for Obtaining Offset for Milling Bevel Gears* in conjunction with the following rule: Find the factor in the table corresponding to the number of cutter used and to the ratio of the pitch cone radius to the face width; then divide this factor by the diametral pitch and subtract the result from half the thickness of the cutter at the pitch line.

**Factors for Obtaining Offset for Milling Bevel Gears**

No. of Cutter	Ratio of Pitch Cone Radius to Width of Face $\left(\frac{C}{F}\right)$												
	$\frac{3}{1}$	$\frac{3\frac{1}{4}}{1}$	$\frac{3\frac{1}{2}}{1}$	$\frac{3\frac{3}{4}}{1}$	$\frac{4}{1}$	$\frac{4\frac{1}{4}}{1}$	$\frac{4\frac{1}{2}}{1}$	$\frac{4\frac{3}{4}}{1}$	$\frac{5}{1}$	$\frac{5\frac{1}{2}}{1}$	$\frac{6}{1}$	$\frac{7}{1}$	$\frac{8}{1}$
1	0.254	0.254	0.255	0.256	0.257	0.257	0.257	0.258	0.258	0.259	0.260	0.262	0.264
2	0.266	0.268	0.271	0.272	0.273	0.274	0.274	0.275	0.277	0.279	0.280	0.283	0.284
3	0.266	0.268	0.271	0.273	0.275	0.278	0.280	0.282	0.283	0.286	0.287	0.290	0.292

5	0.280	0.285	0.290	0.293	0.295	0.296	0.298	0.300	0.302	0.307	0.309	0.313	0.315
6	0.311	0.318	0.323	0.328	0.330	0.334	0.337	0.340	0.343	0.348	0.352	0.356	0.362
7	0.289	0.298	0.308	0.316	0.324	0.329	0.334	0.338	0.343	0.350	0.360	0.370	0.376
8	0.275	0.286	0.296	0.309	0.319	0.331	0.338	0.344	0.352	0.361	0.368	0.380	0.386

Note.— For obtaining offset by above table, use formula:

$$\text{Offset} = \frac{T}{2} - \frac{\text{factor from table}}{P}$$

$P$  = diametral pitch of gear to be cut

$T$  = thickness of cutter used, measured at pitch line

To illustrate, what would be the amount of offset for a bevel gear having 24 teeth, 6 diametral pitch, 30-degree pitch cone angle and  $1\frac{1}{4}$ -inch face or tooth length? In order to obtain a factor from the table, the ratio of the pitch cone radius to the face width must be determined. The pitch cone radius equals the pitch diameter divided by twice the sine of the pitch cone angle =  $4 \div (2 \times 0.5) = 4$  inches. As the face width is 1.25, the ratio is  $4 \div 1.25$  or about  $3\frac{1}{4}$  to 1. The factor in the table for this ratio is 0.280 with a No. 4 cutter, which would be the cutter number for this particular gear. The thickness of the cutter at the pitch line is measured by using a vernier gear tooth caliper. The depth  $S + A$  (see Fig. 2;  $S$  = addendum;  $A$  = clearance) at which to take the measurement equals  $1.157$  divided by the diametral pitch; thus,  $1.157 \div 6 = 0.1928$  inch. The cutter thickness at this depth will vary with different cutters and even with the same cutter as it is ground away, because formed bevel gear cutters are commonly provided with side relief. Assuming that the thickness is 0.1745 inch, and substituting the values in the formula given, we have:

$$\text{Offset} = \frac{0.1745}{2} - \frac{0.280}{6} = 0.0406 \text{ inch}$$

**Adjusting the Gear Blank for Milling.**— After the offset is determined, the blank is adjusted laterally by this amount, and the tooth spaces are milled around the blank. After having milled one side of each tooth to the proper dimensions, the blank is set over in the

**Typical Steels Used for Bevel Gear Applications**

Carburizing Steels					
SAE or AISI No.	Type of Steel	Purchase Specifications			Remarks
		Preliminary Heat Treatment	Brinell Hard- ness Number	ASTM Grain Size	
1024	Manganese	Normalize			Low Alloy — oil quench limited to thin sections
2512	Nickel Alloy	Normalize — Anneal	163-228	5-8	Aircraft quality
3310 3312X	Nickel-Chromium	Normalize, then heat to 1450°F, cool in furnace. Reheat to 1170°F — cool in air	163-228	5-8	Used for maximum resistance to wear and fatigue
4028	Molybdenum	Normalize	163-217		Low Alloy
4615 4620	Nickel-Molybdenum	Normalize — 1700°F-1750°F	163-217	5-8	Good machining qualities. Well adapted to direct quench — gives tough core with minimum distortion
4815 4820	Nickel-Molybdenum	Normalize	163-241	5-8	For aircraft and heavily loaded service
5120	Chromium	Normalize	163-217	5-8	
8615 8620 8715 8720	Chromium-Nickel- Molybdenum	Normalize — cool at hammer	163-217	5-8	Used as an alternate for 4620
Oil Hardening and Flame Hardening Steels					
1141	Sulfurized free-cutting carbon steel	Normalize Heat-treated	179-228 255-269	5 or Coarser	Free-cutting steel used for unhardened gears, oil-treated gears, and for gears to be surface hardened where stresses are low
4140 4640	Chromium- Molybdenum Nickel- Molybdenum	For oil hardening, Normalize — Anneal For surface hardening, Normalize, reheat, quench, and draw	179-212 235-269 269-302 302-341		Used for heat-treated, oil-hardened, and surface-hardened gears. Machine qualities of 4640 are superior to 4140, and it is the preferred steel for flame hardening
6145	Chromium- Vanadium	Normalize— reheat, quench, and draw	235-269 269-302 302-341		Fair machining qualities. Used for surface hardened gears when 4640 is not available
8640 8739	Chromium-Nickel- Molybdenum	Same as for 4640			Used as an alternate for 4640
Nitriding Steels					
Nitral- loy H & G	Special Alloy	Anneal	163-192		Normal hardness range for cutting is 20-28 Rockwell C

Other steels with qualities equivalent to those listed in the table may also be used.

## WORM GEARING

**Worm Gearing.**— Worm gearing may be divided into two general classes, fine-pitch worm gearing, and coarse-pitch worm gearing. Fine-pitch worm gearing is segregated from coarse-pitch worm gearing for the following reasons:

1) Fine-pitch worms and wormgears are used largely to transmit motion rather than power. Tooth strength except at the coarser end of the fine-pitch range is seldom an important factor; durability and accuracy, as they affect the transmission of uniform angular motion, are of greater importance.

2) Housing constructions and lubricating methods are, in general, quite different for fine-pitch worm gearing.

3) Because fine-pitch worms and wormgears are so small, profile deviations and tooth bearings cannot be measured with the same accuracy as can those of coarse pitches.

4) Equipment generally available for cutting fine-pitch wormgears has restrictions which limit the diameter, the lead range, the degree of accuracy attainable, and the kind of tooth bearing obtainable.

5) Special consideration must be given to top lands in fine-pitch hardened worms and wormgear-cutting tools.

6) Interchangeability and high production are important factors in fine-pitch worm gearing; individual matching of the worm to the gear, as often practiced with coarse-pitch precision worms, is impractical in the case of fine-pitch worm drives.

**American Standard Design for Fine-pitch Worm Gearing (ANSI B6.9-1977).**— This standard is intended as a design procedure for fine-pitch worms and wormgears having axes at right angles. It covers cylindrical worms with helical threads, and wormgears hobbled for fully conjugate tooth surfaces. It does not cover helical gears used as wormgears.

*Hobs:* The hob for producing the gear is a duplicate of the mating worm with regard to tooth profile, number of threads, and lead. The hob differs from the worm principally in that the outside diameter of the hob is larger to allow for resharpening and to provide bottom clearance in the wormgear.

*Pitches:* Eight standard axial pitches have been established to provide adequate coverage of the pitch range normally required: 0.030, 0.040, 0.050, 0.065, 0.080, 0.100, 0.130, and 0.160 inch.

Axial pitch is used as a basis for this design standard because: 1) Axial pitch establishes lead which is a basic dimension in the production and inspection of worms; 2) the axial pitch of the worm is equal to the circular pitch of the gear in the central plane; and 3) only one set of change gears or one master lead cam is required for a given lead, regardless of lead angle, on commonly-used worm-producing equipment.

*Lead Angles:* Fifteen standard lead angles have been established to provide adequate coverage: 0.5, 1, 1.5, 2, 3, 4, 5, 7, 9, 11, 14, 17, 21, 25, and 30 degrees.

This series of lead angles has been standardized to: 1) Minimize tooling; 2) permit obtaining geometric similarity between worms of different axial pitch by keeping the same lead angle; and 3) take into account the production distribution found in fine-pitch worm gearing applications.

For example, most fine-pitch worms have either one or two threads. This requires smaller increments at the low end of the lead angle series. For the less frequently used thread numbers, proportionately greater increments at the high end of the lead angle series are sufficient.

*Pressure Angle of Worm:* A pressure angle of 20 degrees has been selected as standard for cutters and grinding wheels used to produce worms within the scope of this Standard because it avoids objectionable undercutting regardless of lead angle.

**Table 1. Formulas for Proportions of American Standard Fine-pitch Worms and Wormgears ANSI B6.9-1977**

<p>LETTER SYMBOLS</p> <p><math>P</math> = Circular pitch of wormgear  <math>P</math> = Axial pitch of the worm, <math>P_x</math>, in the central plane  <math>P_x</math> = Axial pitch of worm  <math>P_n</math> = Normal circular pitch of worm and wormgear  <math>= P_x \cos \lambda = P \cos \psi</math>  <math>\lambda</math> = Lead angle of worm  <math>\psi</math> = Helix angle of wormgear  <math>n</math> = Number of threads in worm  <math>N</math> = Number of teeth in wormgear  <math>N = nm_G</math>  <math>m_G</math> = Ratio of gearing = <math>N \div n</math></p>

Item	Formula	Item	Formula
WORM DIMENSIONS		WORMGEAR DIMENSIONS <sup>a</sup>	
Lead	$l = nP_x$	Pitch Diameter	$D = NP \div \pi = NP_x \div \pi$
Pitch Diameter	$d = l \div (\pi \tan \lambda)$	Outside Diameter	$D_o = 2C - d + 2a$
Outside Diameter	$d_o = d + 2a$	Face Width	$F_{Gmin} = 1.125 \times \sqrt{(d_o + 2c)^2 - (d_o - 4a)^2}$
Safe Minimum Length of Threaded Portion of Worm <sup>b</sup>	$F_W = \sqrt{D_o^2 - D^2}$		
DIMENSIONS FOR BOTH WORM AND WORMGEAR			
Addendum	$a = 0.3183P_n$	Tooth thickness	$t_n = 0.5P_n$
Whole Depth	$h_t = 0.7003P_n + 0.002$	Approximate normal pressure angle <sup>c</sup>	$\phi_n = 20$ degrees
Working Depth	$h_k = 0.6366P_n$		
Clearance	$c = h_t - h_k$	Center distance	$C = 0.5(d + D)$

All dimensions in inches unless otherwise indicated.

<sup>a</sup> Current practice for fine-pitch worm gearing does not require the use of throated blanks. This results in the much simpler blank shown in the diagram which is quite similar to that for a spur or helical gear. The slight loss in contact resulting from the use of non-throated blanks has little effect on the load-carrying capacity of fine-pitch worm gears. It is sometimes desirable to use topping hobs for producing wormgears in which the size relation between the outside and pitch diameters must be closely controlled. In such cases the blank is made slightly larger than  $D_o$  by an amount (usually from 0.010 to 0.020) depending on the pitch. Topped wormgears will appear to have a small throat which is the result of the hobbing operation. For all intents and purposes, the throating is negligible and a blank so made is not to be considered as being a throated blank.

<sup>b</sup> This formula allows a sufficient length for fine-pitch worms.

<sup>c</sup> As stated in the text on page 2207, the actual pressure angle will be slightly greater due to the manufacturing process.

Although the pressure angle of the cutter or grinding wheel used to produce the worm is 20 degrees, the normal pressure angle produced in the worm will actually be slightly greater, and will vary with the worm diameter, lead angle, and diameter of cutter or grinding wheel. A method for calculating the pressure angle change is given under the heading *Effect of Production Method on Worm Profile and Pressure Angle*.

*Pitch Diameter Range of Worms:* The minimum recommended worm pitch diameter is 0.250 inch and the maximum is 2.000 inches.

**Tooth Form of Worm and Wormgear:** The shape of the worm thread in the normal plane is defined as that which is produced by a symmetrical double-conical cutter or grinding wheel having straight elements and an included angle of 40 degrees.

Because worms and wormgears are closely related to their method of manufacture, it is impossible to specify clearly the tooth form of the wormgear without referring to the mating worm. For this reason, worm specifications should include the method of manufacture and the diameter of cutter or grinding wheel used. Similarly, for determining the shape of the generating tool, information about the method of producing the worm threads must be given to the manufacturer if the tools are to be designed correctly.

The worm profile will be a curve that departs from a straight line by varying amounts, depending on the worm diameter, lead angle, and the cutter or grinding wheel diameter. A method for calculating this deviation is given in the Standard. The tooth form of the wormgear is understood to be made fully conjugate to the mating worm thread.

### Effect of Diameter of Cutting on Profile and Pressure Angle of Worms

**Effect of Production Method on Worm Profile and Pressure Angle.**— In worm gearing, tooth bearing is usually used as the means of judging tooth profile accuracy since direct profile measurements on fine-pitch worms or wormgears is not practical. According to AGMA 370.01, Design Manual for Fine-Pitch Gearing, a minimum of 50 percent initial area of contact is suitable for most fine-pitch worm gearing, although in some cases, such as when the load fluctuates widely, a more restricted initial area of contact may be desirable.

Except where single-pointed lathe tools, end mills, or cutters of special shape are used in the manufacture of worms, the pressure angle and profile produced by the cutter are different from those of the cutter itself. The amounts of these differences depend on several factors, namely, diameter and lead angle of the worm, thickness and depth of the worm thread, and diameter of the cutter or grinding wheel. The accompanying diagram shows the curvature and pressure angle effects produced in the worm by cutters and grinding wheels, and how the amount of variation in worm profile and pressure angle is influenced by the diameter of the cutting tool used.

**Materials for Worm Gearing.**— Worm gearing, especially for power transmission, should have steel worms and phosphor bronze wormgears. This combination is used extensively. The worms should be hardened and ground to obtain accuracy and a smooth finish.

The phosphor bronze wormgears should contain from 10 to 12 percent of tin. The S.A.E. phosphor gear bronze (No. 65) contains 88-90% copper, 10-12% tin, 0.50% lead, 0.50% zinc (but with a maximum total lead, zinc and nickel content of 1.0 percent), phosphorous

0.10-0.30%, aluminum 0.005%. The S.A.E. nickel phosphor gear bronze (No. 65 + Ni) contains 87% copper, 11% tin, 2% nickel and 0.2% phosphorous.

**Single-thread Worm Gears.**— The ratio of the worm speed to the wormgear speed may range from 1.5 or even less up to 100 or more. Worm gearing having high ratios are not very efficient as transmitters of power; nevertheless high as well as low ratios often are required. Since the ratio equals the number of wormgear teeth divided by the number of threads or “starts” on the worm, single-thread worms are used to obtain a high ratio. As a general rule, a ratio of 50 is about the maximum recommended for a single worm and wormgear combination, although ratios up to 100 or higher are possible. When a high ratio is required, it may be preferable to use, in combination, two sets of worm gearing of the multi-thread type in preference to one set of the single-thread type in order to obtain the same total reduction and a higher combined efficiency.

Single-thread worms are comparatively inefficient because of the effect of the low lead angle; consequently, single-thread worms are not used when the primary purpose is to transmit power as efficiently as possible but they may be employed either when a large speed reduction with one set of gearing is necessary, or possibly as a means of adjustment, especially if “mechanical advantage” or self-locking are important factors.

**Multi-thread Worm Gears.**— When worm gearing is designed primarily for transmitting power efficiently, the lead angle of the worm should be as high as is consistent with other requirements and preferably between, say, 25 or 30 and 45 degrees. This means that the worm must be multi-threaded. To obtain a given ratio, some number of wormgear teeth divided by some number of worm threads must equal the ratio. Thus, if the ratio is 6, combinations such as the following might be used:

$$\frac{24}{4}, \frac{30}{5}, \frac{36}{6}, \frac{42}{7}$$

The numerators represent numbers of wormgear teeth and the denominators, the number of worm threads or “starts.” The number of wormgear teeth may not be an exact multiple of the number of threads on a multi-thread worm in order to obtain a “hunting tooth” action.

*Number of Threads or “Starts” on Worm:* The number of threads on the worm ordinarily varies from one to six or eight, depending upon the ratio of the gearing. As the ratio is increased, the number of worm threads is reduced, as a general rule. In some cases, however, the higher of two ratios may also have a larger number of threads. For example, a ratio of  $6\frac{1}{2}$  would have 5 threads whereas a ratio of  $6\frac{2}{3}$  would have 6 threads. Whenever the ratio is fractional, the number of threads on the worm equals the denominator of the fractional part of the ratio.

**Worm-Gear Cutting.**— The machines used for cutting worm-gears include ordinary milling machines, gear-hobbing machines of the type adapted to cutting either spur, spiral, or worm gearing, and special machines designed expressly for cutting worm-gears. The general methods employed are (1) cutting by using a straight hob and a radial feeding movement between hob and gear blank; (2) cutting by feeding a fly cutter tangentially with relation to the worm gear blank; and (3) cutting by feeding a tapering hob tangentially. The fly-cutter method is slow as compared with hobbing but it has two decided advantages: First, a very simple and inexpensive cutter may be used instead of an expensive hob. This is of great importance when the number of worm-gears is not large enough to warrant making a hob. Second, with the fly-cutter method, it is possible to produce worm-gears having more accurate teeth than are obtainable by the use of a straight hob. Taper hobs are especially adapted for cutting worm-gears that are to mesh with worms having large helix angles; they are also preferable for worm-gears having large face widths in proportion to the worm diameter. Worm-gear teeth are generated more accurately with a taper hob than with a straight hob that is given a radial feeding movement.

## HELICAL GEARING

**Basic Rules and Formulas for Helical Gear Calculations.**— The rules and formulas in the following table and elsewhere in this article are basic to helical gear calculations. The notation used in the formulas is:  $P_n$  = normal diametral pitch of cutter;  $D$  = pitch diameter;  $N$  = number of teeth;  $\alpha$  = helix angle;  $\gamma$  = center angle or angle between shafts;  $C$  = center distance;  $N'$  = number of teeth for which to select a formed cutter for milled teeth;  $L$  = lead of tooth helix;  $S$  = addendum;  $W$  = whole depth;  $T_n$  = normal tooth thickness at pitch line; and  $O$  = outside diameter.

## Rules and Formulas for Helical Gear Calculations

No.	To Find	Rule	Formula
1	Pitch Diameter	Divide the number of teeth by the product of the normal diametral pitch and the cosine of the helix angle.	$D = \frac{N}{P_n \cos \alpha}$
2	Center Distance	Add together the two pitch diameters and divide by 2.	$C = \frac{D_a + D_b}{2}$
3	Lead of Tooth Helix	Multiply the pitch diameter by 3.1416 by the cotangent of the helix angle.	$L = \pi D \cot \alpha$
4	Addendum	Divide 1 by the normal diametral pitch.	$S = \frac{1}{P_n}$
5	Whole Depth of tooth	Divide 2.157 by the normal diametral pitch.	$W = \frac{2.157}{P_n}$
6	Normal Tooth Thickness at Pitch Line	Divide 1.5708 by the normal diametral pitch.	$T_n = \frac{1.5708}{P_n}$
7	Outside Diameter	Add twice the addendum to the pitch diameter.	$O = D + 2S$

**Determining Direction of Thrust.**— The first step in helical gear design is to determine the desired direction of the thrust. When the direction of the thrust has been determined and the relative positions of the driver and driven gears are known, then the direction of helix (right- or left-hand) may be found from the accompanying thrust diagrams, *Directions of Rotation and Resulting Thrust for Parallel Shaft and 90 Degree Shaft Angle Helical Gears*. The diagrams show the directions of rotation and the resulting thrust for parallel-

shaft and 90-degree shaft angle helical gears. The thrust bearings are located so as to take the thrust caused by the tooth loads. The direction of the thrust depends on the direction of the helix, the relative positions of driver and driven gears, and the direction of rotation. The thrust may be changed to the opposite direction by changing any one of the three conditions, namely, by changing the hand of the helix, by reversing the direction of rotation, or by exchanging of driver and driven gear positions.

Directions of Rotation and Resulting Thrust for Parallel Shaft and 90 Degree Shaft Angle Helical Gears

**Determining Helix Angles.**— The following rules should be observed for helical gears with shafts at any given angle. If each helix angle is less than the shaft angle, then the sum of the helix angles of the two gears will equal the angle between the shafts, and the helix angle is of the same hand for both gears; if the helix angle of one of the gears is larger than the shaft angle, then the difference between the helix angles of the two gears will be equal to the shaft angle, and the gears will be of opposite hand.

**Pitch of Cutter to be Used.**— The thickness of the cutter at the pitchline for cutting helical gears should equal one-half the *normal* circular pitch. The normal pitch varies with the helix angle, hence, the helix angle must be considered when selecting a cutter. The cutter should be of the same pitch as the *normal* diametral pitch of the gear. This normal pitch is found by dividing the transverse diametral pitch of the gear by the cosine of the helix angle. To illustrate, if the pitch diameter of a helical gear is 6.718 and there are 38 teeth having a helix angle of 45 degrees, the transverse diametral pitch equals 38 divided by 6.718 = 5.656; then the normal diametral pitch equals 5.656 divided by 0.707 = 8. A cutter, then, of 8 diametral pitch is the one to use for this particular gear.

Helical gears should preferably be cut on a generating-type gear cutting machine such as a hobber or shaper. Milling machines are used in some shops when hobbers or shapers are not available or when single, replacement gears are being made. In such instances, the pitch of the formed cutter used in milling a helical gear must not only conform to the normal diametral pitch of the gear, but the cutter number must also be determined. See *Selecting Cutter for Milling Helical Gears* starting on page 2220.

**1. Shafts Parallel, Center Distance Approximate.**— Given or assumed:

1) Position of gear having right- or left-hand helix, depending upon rotation and direction in which thrust is to be received

2)  $C_a$  = approximate center distance

3)  $P_n$  = normal diametral pitch

4)  $N$  = number of teeth in large gear

5)  $n$  = number of teeth in small gear

6)  $\alpha$  = angle of helix

To find:

$$1) D = \text{pitch diameter of large gear} = \frac{N}{P_n \cos \alpha}$$

$$2) d = \text{pitch diameter of small gear} = \frac{n}{P_n \cos \alpha}$$

$$3) O = \text{outside diameter of large gear} = D + \frac{2}{P_n}$$

$$4) o = \text{outside diameter of small gear} = d + \frac{2}{P_n}$$

$$5) T = \text{number of teeth marked on formed milling cutter (large gear)} = \frac{N}{\cos^3 \alpha}$$

$$6) t = \text{number of teeth marked on formed milling cutter (small gear)} = \frac{n}{\cos^3 \alpha}$$

$$7) L = \text{lead of helix on large gear} = \pi D \cot \alpha$$

$$8) l = \text{lead of helix on small gear} = \pi d \cot \alpha$$

$$9) C = \text{center distance (if not right, vary } \alpha) = \frac{1}{2}(D + d)$$

*Example:* Given or assumed: 1) See illustration; 2)  $C_a = 17$  inches; 3)  $P_n = 2$ ; 4)  $N = 48$ ; 5)  $n = 20$ ; and 6)  $\alpha = 20$ .

To find:

$$1) D = \frac{N}{P_n \cos \alpha} = \frac{48}{2 \times 0.9397} = 25.541 \text{ inches}$$

$$2) d = \frac{n}{P_n \cos \alpha} = \frac{20}{2 \times 0.9397} = 10.642 \text{ inches}$$

$$3) O = \frac{2}{P_n} = 25.541 + \frac{2}{2} = 26.541 \text{ inches}$$

$$4) o = d + \frac{2}{P_n} = 10.642 + \frac{2}{2} = 11.642 \text{ inches}$$

$$5) T = \frac{N}{\cos^3 \alpha} = \frac{48}{(0.9397)^3} = 57.8, \text{ say } 58 \text{ teeth}$$

$$6) t = \frac{n}{\cos^3 \alpha} = \frac{20}{(0.9397)^3} = 24.1, \text{ say } 24 \text{ teeth}$$

$$7) L = \pi D \cot \alpha = 3.1416 \times 25.541 \times 2.747 = 220.42 \text{ inches}$$

$$8) l = \pi d \cot \alpha = 3.1416 \times 10.642 \times 2.747 = 91.84 \text{ inches}$$

$$9) C = \frac{1}{2}(D + d) = \frac{1}{2}(25.541 + 10.642) = 18.091 \text{ inches}$$

**2. Shafts Parallel, Center Distance Exact.**— Given or assumed:

- 1) Position of gear having right- or left-hand helix, depending upon rotation and direction in which thrust is to be received
- 2)  $C$  = exact center distance
- 3)  $P_n$  = normal diametral pitch (pitch of cutter)
- 4)  $N$  = number of teeth in large gear
- 5)  $n$  = number of teeth in small gear

To find:

$$1) \cos \alpha = \frac{N + n}{2P_n C}$$

$$2) D = \text{pitch diameter of large gear} = \frac{N}{P_n \cos \alpha}$$

$$3) d = \text{pitch diameter of small gear} = \frac{n}{P_n \cos \alpha}$$

$$4) O = \text{outside diameter of large gear} = D + \frac{2}{P_n}$$

$$5) o = \text{outside diameter of small gear} = d + \frac{2}{P_n}$$

$$6) T = \text{number of teeth marked on formed milling cutter (large gear)} = \frac{N}{\cos^3 \alpha}$$

$$7) t = \text{number of teeth marked on formed milling cutter (small gear)} = \frac{n}{\cos^3 \alpha}$$

$$8) L = \text{lead of helix (large gear)} = \pi D \cot \alpha$$

$$9) l = \text{lead of helix (small gear)} = \pi d \cot \alpha$$

*Example:* Given or assumed: 1) See illustration; 2)  $C = 18.75$  inches; 3)  $P_n = 4$ ; 4)  $N = 96$ ; and 5)  $n = 48$ .

$$1) \cos \alpha = \frac{N + n}{2P_n C} = \frac{96 + 48}{2 \times 4 \times 18.75} = 0.96, \text{ or } \alpha = 16^\circ 16'$$

$$2) D = \frac{N}{P_n \cos \alpha} = \frac{96}{4 \times 0.96} = 25 \text{ inches}$$

$$3) d = \frac{n}{P_n \cos \alpha} = \frac{48}{4 \times 0.96} = 12.5 \text{ inches}$$

$$4) O = D + \frac{2}{P_n} = 25 + \frac{2}{4} = 25.5 \text{ inches}$$

$$5) o = d + \frac{2}{P_n} = 12.5 + \frac{2}{4} = 13 \text{ inches}$$

$$6) T = \frac{N}{\cos^3 \alpha} = \frac{96}{(0.96)^3} = 108 \text{ teeth}$$

$$7) t = \frac{n}{\cos^3 \alpha} = \frac{48}{(0.96)^3} = 54 \text{ teeth}$$

$$8) L = \pi D \cot \alpha = 3.1416 \times 25 \times 3.427 = 269.15 \text{ inches}$$

$$9) l = \pi d \cot \alpha = 3.1416 \times 12.5 \times 3.427 = 134.57 \text{ inches}$$

**3. Shafts at Right Angles, Center Distance Approximate.**— Sum of helix angles of gear and pinion must equal 90 degrees.

Given or assumed:

- 1) Position of gear having right- or left-hand helix, depending on rotation and direction in which thrust is to be received
- 2)  $C_a$  = approximate center distance
- 3)  $P_n$  = normal diametral pitch (pitch of cutter)
- 4)  $R$  = ratio of gear to pinion size

$$5) n = \text{number of teeth in pinion} = \frac{1.41 C_a P_n}{R + 1} \text{ for 45 degrees;}$$

$$\text{and } \frac{2 C_a P_n \cos \alpha \cos \beta}{R \cos \beta + \cos \alpha} \text{ for any angle}$$

$$6) N = \text{number of teeth in gear} = Rn$$

$$7) \alpha = \text{angle of helix of gear}$$

$$8) \beta = \text{angle of helix of pinion}$$

To find:

a) When helix angles are 45 degrees,

$$1) D = \text{pitch diameter of gear} = \frac{N}{0.70711 P_n}$$

$$2) d = \text{pitch diameter of pinion} = \frac{n}{0.70711 P_n}$$

$$3) O = \text{outside diameter of gear} = D + \frac{2}{P_n}$$

$$4) o = \text{outside diameter of pinion} = d + \frac{2}{P_n}$$

$$5) T = \text{number of formed cutter (gear)} = \frac{N}{0.353}$$

$$6) t = \text{number of formed cutter (pinion)} = \frac{n}{0.353}$$

$$7) L = \text{lead of helix of gear} = \pi D$$

$$8) l = \text{lead of helix of pinion} = \pi d$$

$$9) C = \text{center distance (exact)} = \frac{D + d}{2}$$

b) When helix angles are other than 45 degrees

$$1) D = \frac{N}{P_n \cos \alpha} \quad 2) d = \frac{n}{P_n \cos \beta} \quad 3) T = \frac{N}{\cos^3 \alpha}$$

$$4) t = \frac{n}{\cos^3 \beta} \quad 5) L = \pi D \cot \alpha \quad 6) l = \pi d \cot \beta$$

*Example:* Given or assumed: 1) See illustration; 2)  $C_a = 3.2$  inches; 3)  $P_n = 10$ ; and 4)  $R = 1.5$ .

$$5) n = \frac{1.41 C_a P_n}{R + 1} = \frac{1.41 \times 3.2 \times 10}{1.5 + 1} = \text{say 18 teeth.}$$

6)  $N = nR = 18 \times 1.5 = 27$  teeth; 7)  $\alpha = 45$  degrees; and 8)  $\beta = 45$  degrees.

To find:

$$1) D = \frac{N}{0.70711 P_n} = \frac{27}{0.70711 \times 10} = 3.818 \text{ inches}$$

$$2) d = \frac{n}{0.70711 P_n} = \frac{18}{0.70711 \times 10} = 2.545 \text{ inches}$$

$$3) O = D + \frac{2}{P_n} = 3.818 + \frac{2}{10} = 4.018 \text{ inches}$$

$$4) o = d + \frac{2}{P_n} = 2.545 + \frac{2}{10} = 2.745 \text{ inches}$$

$$5) T = \frac{N}{0.353} = \frac{27}{0.353} = 76.5, \text{ say } 76 \text{ teeth}$$

$$6) t = \frac{n}{0.353} = \frac{18}{0.353} = 51 \text{ teeth}$$

$$7) L = \pi D = 3.1416 \times 3.818 = 12 \text{ inches}$$

$$8) l = \pi d = 3.1416 \times 2.545 = 8 \text{ inches}$$

$$9) C = \frac{D + d}{2} = \frac{3.818 + 2.545}{2} = 3.182 \text{ inches}$$

**4A. Shafts at Right Angles, Center Distance Exact.**—Gears have same direction of helix. Sum of the helix angles will equal 90 degrees.

Given or assumed:

- 1) Position of gear having right- or left-hand helix depending on rotation and direction in which thrust is to be received
- 2)  $P_n$  = normal diametral pitch (pitch of cutter)
- 3)  $R$  = ratio of number of teeth in large gear to number of teeth in small gear
- 4)  $\alpha_a$  = approximate helix angle of large gear
- 5)  $C$  = exact center distance

To find:

$$1) n = \text{number of teeth in small gear nearest} = 2 CP_n \sin \alpha_a \div 1 + R \tan \alpha_a$$

$$2) N = \text{number of teeth in large gear} = Rn$$

$$3) \alpha = \text{exact helix angle of large gear, found by trial from } R \sec \alpha + \operatorname{cosec} \alpha = 2 CP_n \div n$$

$$4) \beta = \text{exact helix angle of small gear} = 90^\circ - \alpha$$

$$5) D = \text{pitch diameter of large gear} = \frac{N}{P_n \cos \alpha}$$

$$6) d = \text{pitch diameter of small gear} = \frac{n}{P_n \cos \beta}$$

$$7) O = \text{outside diameter of large gear} = D + \frac{2}{P_n}$$

$$8) o = \text{outside diameter of small gear} = d + \frac{2}{P_n}$$

9)  $N'$  and  $n'$  = numbers of teeth marked on cutters for large and small gears (see page 2220)

$$10) L = \text{lead of helix on large gear} = \pi D \cot \alpha$$

$$11) l = \text{lead of helix on small gear} = \pi d \cot \beta$$

*Example:* Given or assumed: 1) See illustration; 2)  $P_n = 8$ ; 3)  $R = 3$ ; 4)  $\alpha_a = 45$  degrees; and 5)  $C = 10$  in.

To find:

$$1) n = \frac{2CP_n \sin \alpha_a}{1 + R \tan \alpha_a} = \frac{2 \times 10 \times 8 \times 0.70711}{1 + 3} = 28.25, \text{ say } 28 \text{ teeth}$$

$$2) N = Rn = 3 \times 28 = 84 \text{ teeth}$$

$$3) R \sec \alpha + \operatorname{cosec} \alpha = \frac{2CP_n}{n} = \frac{2 \times 10 \times 8}{28} = 5.714, \text{ or } \alpha = 46^\circ 6'$$

$$4) \beta = 90^\circ - \alpha = 90^\circ - 46^\circ 6' = 43^\circ 54'$$

$$5) D = \frac{N}{P_n \cos \alpha} = \frac{84}{8 \times 0.6934} = 15.143 \text{ inches}$$

$$6) d = \frac{n}{P_n \cos \beta} = \frac{28}{8 \times 0.72055} = 4.857 \text{ inches}$$

$$7) O = D + \frac{2}{P_n} = 15.143 + 0.25 = 15.393 \text{ inches}$$

$$8) o = d + \frac{2}{P_n} = 4.857 + 0.25 = 5.107 \text{ inches}$$

$$9) N' = 275; n' = 94 \text{ (see page 2220)}$$

$$10) L = \pi D \cot \alpha = 3.1416 \times 15.143 \times 0.96232 = 45.78 \text{ inches}$$

$$11) l = \pi d \cot \beta = 3.1416 \times 4.857 \times 1.0392 = 15.857 \text{ inches}$$

#### 4B. Shafts at Right Angles, Any Ratio, Helix Angle for Minimum Center Distance.—

Diagram similar to 4A. Gears have same direction of helix. The sum of the helix angles will equal 90 degrees.

For any given ratio of gearing  $R$  there is a helix angle  $\alpha$  for the larger gear and a helix angle  $\beta = 90^\circ - \alpha$  for the smaller gear that will make the center distance  $C$  a minimum. Helix angle  $\alpha$  is found from the formula  $\cot \alpha = R^{1/3}$ . As an example, using the data found in Case 4A, helix angles  $\alpha$  and  $\beta$  for minimum center distance would be:  $\cot \alpha = R^{1/3} = 1.4422$ ;  $\alpha = 34^\circ 44'$  and  $\beta = 90^\circ - 34^\circ 44' = 55^\circ 16'$ . Using these helix angles,  $D = 12.777$ ;  $d = 6.143$ ; and  $C = 9.460$  from the formulas for  $D$  and  $d$  given under Case 4A.

**5. Shafts at Any Angle, Center Distance Approximate.—**

The sum of the helix angles of the two gears equals the shaft angle, and the gears are of the same hand, if each angle is less than the shaft angle. The difference between the helix angles equals the shaft angle, and the gears are of opposite hand, if either angle is greater than the shaft angle.

Given or assumed:

- 1) Hand of helix, depending on rotation and direction in which thrust is to be received
- 2)  $C_a$  = center distance

3)  $P_n$  = normal diametral pitch (pitch of cutter)

4)  $R$  = ratio of gear to pinion =  $\frac{N}{n}$

5)  $\alpha$  = angle of helix, gear

6)  $\beta$  = angle of helix, pinion

7)  $n$  = number of teeth in pinion nearest  $\frac{2C_a P_n \cos \alpha \cos \beta}{R \cos \beta + \cos \alpha}$  for any angle

and  $\frac{2C_a P_n \cos \alpha}{R + 1}$  when both angles are equal

8)  $N$  = number of teeth in gear =  $Rn$

To find:

1)  $D$  = pitch diameter of gear =  $\frac{N}{P_n \cos \alpha}$

2)  $d$  = pitch diameter of pinion =  $\frac{n}{P_n \cos \beta}$

3)  $O$  = outside diameter of gear =  $D + \frac{2}{P_n}$

4)  $o$  = outside diameter of pinion =  $d + \frac{2}{P_n}$

5)  $T$  = number of teeth marked on cutter for gear =  $\frac{N}{\cos^3 \alpha}$

6)  $t$  = number of teeth marked on cutter for pinion =  $\frac{n}{\cos^3 \beta}$

7)  $L$  = lead of helix on gear =  $\pi D \cot \alpha$

8)  $l$  = lead of helix on pinion =  $\pi d \cot \beta$

9)  $C$  = actual center distance =  $\frac{D + d}{2}$

*Example:* Given or assumed (angle of shafts, 60 degrees):

1) See illustration 2)  $C_a$  = 12 inches 3)  $P_n$  = 8

4)  $R$  = 4 5)  $\alpha$  = 30 degrees 6)  $\beta$  = 30 degrees

7)  $n$  =  $\frac{2C_a P_n \cos \alpha}{R + 1} = \frac{2 \times 12 \times 8 \times 0.86603}{4 + 1} = 33$  teeth

8)  $N$  =  $4 \times 33 = 132$  teeth

To find:

$$1) D = \frac{N}{P_n \cos \alpha} = \frac{132}{8 \times 0.86603} = 19.052 \text{ inches}$$

$$2) d = \frac{n}{P_n \cos \beta} = \frac{33}{8 \times 0.86603} = 4.763 \text{ inches}$$

$$3) O = D + \frac{2}{P_n} = 19.052 + \frac{2}{8} = 19.302 \text{ inches}$$

$$4) o = d + \frac{2}{P_n} = 4.763 + \frac{2}{8} = 5.013 \text{ inches}$$

$$5) T = \frac{N}{\cos^3 \alpha} = \frac{132}{0.65} = 203 \text{ teeth}$$

$$6) t = \frac{n}{\cos^3 \beta} = \frac{33}{0.65} = 51 \text{ teeth}$$

$$7) L = \pi D \cot \alpha = \pi \times 19.052 \times 1.732 = 103.66 \text{ inches}$$

$$8) l = \pi d \cot \beta = \pi \times 4.763 \times 1.732 = 25.92 \text{ inches}$$

$$9) C = \frac{D + d}{2} = \frac{19.052 + 4.763}{2} = 11.9075 \text{ inches}$$

**6. Shafts at Any Angle, Center Distance Exact.**— The sum of the helix angles of the two

gears equals the shaft angle, and the gears are of the same hand, if each angle is less than the shaft angle. The difference between the helix angles equals the shaft angle, and the gears are of opposite hand, if either angle is greater than the shaft angle.

Given or assumed:

1) Hand of helix, depending on rotation and direction in which thrust is to be received

2)  $C$  = center distance

3)  $P_n$  = normal diametral pitch (pitch of cutter)

4)  $\alpha_a$  = approximate helix angle of gear

5)  $\beta_a$  = approximate helix angle of pinion

6)  $R$  = ratio of gear to pinion size =  $\frac{N}{n}$

7)  $n$  = number of pinion teeth nearest  $\frac{2CP_n \cos \alpha_a \cos \beta_a}{R \cos \beta_a + \cos \alpha_a}$

8)  $N$  = number of gear teeth =  $Rn$

To find:

1)  $\alpha$  and  $\beta$ , exact helix angles, found by trial from  $R \sec \alpha + \sec \beta = \frac{2CP_n}{n}$

$$2) D = \text{pitch diameter of gear} = \frac{N}{P_n \cos \alpha}$$

$$3) d = \text{pitch diameter of pinion} = \frac{n}{P_n \cos \beta}$$

$$4) O = \text{outside diameter of gear} = D + \frac{2}{P_n}$$

$$5) o = \text{outside diameter of pinion} = d + \frac{2}{P_n}$$

6)  $N'$  = number of teeth marked on formed cutter for gear (see below)

7)  $n'$  = number of teeth marked on formed cutter for pinion (see below)

8)  $L$  = lead of helix on gear =  $\pi D \cot \alpha$

9)  $l$  = lead of helix on pinion =  $\pi d \cot \beta$

**Selecting Cutter for Milling Helical Gears.**— The proper milling cutter to use for *spur* gears depends on the pitch of the teeth and also upon the number of teeth as explained on page 2164 but a cutter for milling helical gears is not selected with reference to the actual number of teeth in the gear, as in spur gearing, but rather with reference to a calculated number  $N'$  that takes into account the effect on the tooth profile of lead angle, normal diametral pitch, and cutter diameter.

In the helical gearing examples starting on page 2213 the number of teeth  $N'$  on which to base the selection of the cutter has been determined using the approximate formula  $N' = N \div \cos^3 \alpha$  or  $N' = N \sec^3 \alpha$ , where  $N$  = the actual number of teeth in the helical gear and  $\alpha$  = the helix angle. However, the use of this formula may, where a combination of high helix angle and low tooth number is involved, result in the selection of a higher number of cutter than should actually be used for greatest accuracy. This condition is most likely to occur when the aforementioned formula is used to calculate  $N'$  for gears of high helix angle and low number of teeth.

To avoid the possibility of error in choice of cutter number, the following formula, which gives theoretically correct results for all combinations of helix angle and tooth numbers, is to be preferred:

$$N' = N \sec^3 \alpha + P_n D_c \tan^2 \alpha \quad (1)$$

where:  $N'$  = number of teeth on which to base selection of cutter number from table on page 2166;  $N$  = actual number of teeth in helical gear;  $\alpha$  = helix angle;  $P_n$  = normal diametral pitch of gear and cutter; and  $D_c$  = pitch diameter of cutter.

To simplify calculations, Formula (1) may be written as follows:

$$N' = NK + QK' \quad (2)$$

In this formula,  $K$ ,  $K'$  and  $Q$  are constants obtained from the tables on page 2221.

*Example:* Helix angle = 30 degrees; number of teeth in helical gear = 15; and normal diametral pitch = 20. From the tables on page 2221  $K$ ,  $K'$ , and  $Q$  are, respectively, 1.540, 0.333, and 37.80.

$$\begin{aligned} N' &= (15 \times 1.540) + (37.80 \times 0.333) = 23.10 + 12.60 \\ &= 35.70, \text{ say, } 36 \end{aligned}$$

Hence, from page 2166 select a number 3 cutter. Had the approximate formula been used, then a number 5 cutter would have been selected on the basis of  $N' = 23$ .

## Factors for Selecting Cutters for Milling Helical Gears

Pitch diameters shown in the table are computed from the formula:  $D_c = D_o - 2(1.57 \div P_n)$ . This same formula may be used to compute the pitch diameter of a non-standard outside diameter cutter when the normal diametral pitch  $P_n$  and the outside diameter  $D_o$  are known.

**Milling the Helical Teeth.**—The teeth of a helical gear are proportioned from the normal pitch and not the circular pitch. The whole depth of the tooth can be found by dividing 2.157 by the normal diametral pitch of the gear, which corresponds to the pitch of the cut-

ter. The thickness of the tooth at the pitch line equals 1.571 divided by the normal diametral pitch. After a tooth space has been milled, the cutter should be prevented from dragging through it when being returned for another cut. This can be done by lowering the blank slightly, or by stopping the machine and turning the cutter to such a position that the teeth will not touch the work. If the gear has teeth coarser than 10 or 12 diametral pitch, it is well to take a roughing and a finishing cut. When pressing a helical gear blank on the arbor, it should be remembered that it is more likely to slip when being milled than a spur gear, because the pressure of the cut, being at an angle, tends to rotate the blank on the arbor.

*Angular Position of Table:* When cutting a helical gear on a milling machine, the table is set to the helix angle of the gear. If the lead of the helical gear is known, but not the helix angle, the helix angle is determined by multiplying the pitch diameter of the gear by 3.1416 and dividing this product by the lead; the result is the tangent of the lead angle which may be obtained from trigonometric tables or a calculator.

**American National Standard Fine-Pitch Teeth for Helical Gears.**— This Standard, ANSI B6.7-1977, provides a 20-degree tooth form for both spur and helical gears of 20 diametral pitch and finer. Formulas for tooth parts are given on page 2151.

*Enlargement of Helical Pinions, 20-Degree Normal Pressure Angle:* Formula (4) and the accompanying graph are based on the use of hobs having sharp corners at their top lands. Pinions cut by shaper cutters may not require as much modification as indicated by (4) or the graph. The number 2.1 appearing in (4) results from the use of a standard tooth thickness rack having an addendum of  $1.05/P_n$  which will start contact at a roll angle 5 degrees above the base radius. The roll angle of 5 degrees is also reflected in Formula (4).

To avoid undercutting of the teeth and to provide more favorable contact conditions near the base of the tooth, it is recommended that helical pinions with less than 24 teeth be enlarged in accordance with the following graph and formulas. As with enlarged spur pinions, when an enlarged helical pinion is used it is necessary either to reduce the diameter of the mating gear or to increase the center distance. In the formulas that follow,  $\phi_n$  = normal pressure angle;  $\phi_t$  = transverse pressure angle;  $\psi$  = helix angle of pinion;  $P_n$  = normal diametral pitch;  $P_t$  = transverse diametral pitch;  $d$  = pitch diameter of pinion;  $d_o$  = outside diameter of enlarged pinion;  $K_h$  = enlargement for full depth pinions of 1 normal diametral pitch; and  $n$  = number of teeth in pinion.

To eliminate the need for making the calculations indicated in **Formulas (3) and (4)**, the accompanying graph may be used to obtain the value of  $K_h$  directly for full-depth pinions of 20-degree normal pressure angle.

$$P_t = P_n \cos \psi \quad (1)$$

$$d = n \div P_t \quad (2)$$

$$\tan \psi_t = \tan \phi_n \div \cos \psi \quad (3)$$

$$K_h = 2.1 - \frac{n}{\cos \psi} (\sin \phi_t - \cos \phi_t \tan 5^\circ) \sin \phi_t \quad (4)$$

$$d_o = d + \frac{2 + K_h}{P_n} \quad (5)$$

*Example:* Find the outside diameter of a helical pinion having 12 teeth, 32 normal diametral pitch, 20-degree pressure angle, and 18-degree helix angle.

$$P_t = P_n \cos \psi = 32 \cos 18^\circ = 32 \times 0.95106 = 30.4339$$

$$d = n \div P_t = 12 \div 30.4339 = 0.3943 \text{ inch}$$

$$K_h = 0.851 \text{ (from graph)}$$

$$d_o = 0.3943 + \frac{2 + 0.851}{32} = 0.4834$$

#### Center Distance at which Modified Mating Helical Gears Mesh Without Backlash.—

If the helical pinion in the previous example on page 2223 had been made to standard dimensions, that is, not enlarged, and was in tight mesh with a standard 24-tooth mating gear, the center distance for tight mesh could be calculated from the formula on page 2151:

$$C = \frac{n + N}{2P_n \cos \psi} = \frac{12 + 24}{2 \times 32 \times \cos 18^\circ} = 0.5914 \text{ inch} \quad (1)$$

However, if the pinion is enlarged as in the example and meshed with the same standard 24-tooth gear, then the center distance for tight mesh will be increased. To calculate the new center distance, the following formulas and calculations are required:

First, calculate the transverse pressure angle  $\phi_t$  using **Formula (2)**:

$$\tan \phi_t = \tan \phi_n \div \cos \psi = \tan 20^\circ \div \cos 18^\circ = 0.38270 \quad (2)$$

and from a calculator the angle  $\phi_t$  is found to be  $20^\circ 56' 30''$ . In the table on page 106,  $\text{inv } \phi_t$  is found to be 0.017196, and the cosine from a calculator as 0.93394.

Using **Formula (3)**, calculate the pressure angle  $\phi$  at which the gears are in tight mesh:

$$\text{inv } \phi = \text{inv } \phi_t + \frac{(t_{nP} + t_{nG}) - \pi}{n + N} \quad (3)$$

In this formula, the value for  $t_{nP}$  for 1 diametral pitch is that found in **Table 9c** on page 2168, for a 12-tooth pinion, in the fourth column: 1.94703. The value of  $t_{nG}$  for 1 diametral pitch for a standard gear is always 1.5708.

$$\text{inv } \phi = 0.017196 + \frac{(1.94703 + 1.5708) - \pi}{12 + 24} = 0.027647$$

From the table on page 107, or a calculator, 0.027647 is the involute of  $24^\circ 22' 7''$  and the cosine corresponding to this angle is 0.91091.

Finally, using **Formula (4)**, the center distance for tight mesh,  $C'$  is found:

$$C' = \frac{C \cos \phi_t}{\cos \phi} = \frac{0.5914 \times 0.93394}{0.91091} = 0.606 \text{ inch} \quad (4)$$

**Change-gears for Helical Gear Hobbing.**— If a gear-hobbing machine is not equipped with a differential, there is a fixed relation between the index and feed gears and it is necessary to compensate for even slight errors in the index gear ratio, to avoid excessive lead errors. This may be done readily (as shown by the example to follow) by modifying the ratio of the feed gears slightly, thus offsetting the index gear error and making very accurate leads possible.

*Machine Without Differential:* The formulas which follow may be applied in computing the index gear ratio.

- $R$  = index-gear ratio  
 $L$  = lead of gear, inches  
 $F$  = feed per gear revolution, inch  
 $K$  = machine constant  
 $T$  = number of threads on hob  
 $N$  = number of teeth on gear  
 $P_n$  = normal diametral pitch  
 $P_{nc}$  = normal circular pitch  
 $A$  = helix angle, relative to axis  
 $M$  = feed gear constant

$$R = \frac{L \div F}{(L \div F) \pm 1} \times \frac{KT}{N} = \frac{L}{L \pm F} \times \frac{KT}{N} = \frac{\text{Driving gear sizes}}{\text{Driven gear sizes}} \quad (1)$$

Use minus (–) sign in **Formulas (1) and (2)** when gear and hob are the same “hand” and plus (+) sign when they are of opposite hand; when *climb* hobbing is to be used, reverse this rule.

$$R = \frac{KT}{N \pm \frac{P_n \times \sin A \times F}{\pi}} = \frac{KT}{N \pm \frac{\sin A \times F}{P_{nc}}} \quad (2)$$

$$\text{Ratio of feed gears} = \frac{F}{M} \quad F = \frac{L(NR - KT)}{NR} \quad (3)$$

$$L = \frac{FNR}{(NR - KT)} = \text{lead obtained with available index and feed gears} \quad (4)$$

*Note:* If gear and hob are of opposite hand, then in **Formulas (3) and (4)** change  $(NR - KT)$  to  $(KT - NR)$ . This change is also made if gear and hob are of same hand but *climb* hobbing is used.

*Example:* A right-hand helical gear with 48 teeth of 10 normal diametral pitch, has a lead of 44.0894 inches. The feed is to be 0.035 inch, with whatever slight adjustment may be necessary to compensate for the error in available index gears.  $K = 30$  and  $M = 0.075$ . A single-thread right-hand hob is to be used.

$$R = \frac{44.0894}{44.0894 - 0.035} \times \frac{30 \times 1}{48} = 0.62549654$$

Using the method of *Conjugate Fractions* starting on page 3111 in the *ADDITIONAL* material on *Machinery's Handbook 30 CD*, several suitable ratios close to 0.62549654 were found. One of these,  $(34 \times 53)/(43 \times 67) = 0.625477264839$ , will be used as the index ratio. Other usable ratios and their decimal values were found to be as follows:

$$\begin{aligned} \frac{32 \times 38}{27 \times 72} &= 0.6255144 & \frac{27 \times 42}{42 \times 37} &= 0.62548263 \\ \frac{44 \times 29}{34 \times 60} &= 0.6254902 & \frac{26 \times 97}{96 \times 42} &= 0.62549603 \\ \frac{20 \times 41}{23 \times 57} &= 0.62547674 \end{aligned}$$

Index ratio error =  $0.62549654 - 0.62547726 = 0.00001928$ .

Now use **Formula (3)** to find slight change required in rate of feed. This change compensates sufficiently for the error in available index gears.

*Change in Feed Rate:* Insert in **Formula (3)** obtainable index ratio.

$$F = \frac{44.0894 \times (48 \times 0.62547726 - 30)}{48 \times 0.62547726} = 0.0336417$$

$$\text{Modified feed gear ratio} = \frac{F}{M} = \frac{0.0336417}{0.075} = 0.448556$$

$$\log 0.448556 = \bar{1}.651817 \quad \log \text{ of reciprocal} = 0.348183$$

To find close approximation to modified feed gear ratio, proceed as in finding suitable gears for index ratio, thus obtaining  $\frac{106}{71} \times \frac{112}{75}$ . Inverting, modified feed gear ratio =

$$\frac{71}{106} \times \frac{75}{112} = 0.448534.$$

Modified feed  $F$  = obtainable modified feed ratio  $\times M = 0.448534 \times 0.075 = 0.03364$  inch. If the feed rate is not modified, even a small error in the index gear ratio may result in an excessive lead error.

*Checking Accuracy of Lead:* The modified feed and obtainable index ratio are inserted in **Formula (4)**. Desired lead = 44.0894 inches. Lead obtained = 44.087196 inches; hence the computed error =  $44.0894 - 44.087196 = 0.002204$  inch or about 0.00005 inch per inch of lead.

*Machine with Differential:* If a machine is equipped with a differential, the *lead gears* are computed in order to obtain the required helix angle and lead. The instructions of the hobbing machine manufacturer should be followed in computing the lead gears, because the ratio formula is affected by the location of the differential gears. If these gears are *ahead* of the index gears, the lead gear ratio is not affected by a change in the number of teeth to be cut (see **Formula (5)**); hence, the same lead gears are used when, for example, a gear and pinion are cut on the same machine. In the formulas which follow, the notation is the same as previously given, with these exceptions:  $R_d$  = lead gear ratio for machine with differential;  $P_a$  = axial or linear pitch of helical gear = distance from center of one tooth to center of next tooth measured parallel to gear axis = total lead  $L \div$  number of teeth  $N$ .

$$R_d = \frac{P_a \times T}{K} = \frac{L \times T}{N \times K} = \frac{\pi \times \operatorname{cosec} A \times T}{P_n \times K} = \frac{\text{Driven gear sizes}}{\text{Driving gear sizes}} \quad (5)$$

The number of hob threads  $T$  is included in the formula because double-thread hobs are used sometimes, especially for roughing in order to reduce the hobbing time. Lead gears having a ratio sufficiently close to the required ratio may be determined by using the table of gear ratio logarithms as previously described in connection with the non-differential type of machine. When using a machine equipped with a differential, the effect of a lead-gear ratio error upon the lead of the gear is small in comparison with the effect of an index gear error when using a non-differential type of machine. The lead obtained with a given or

obtainable lead gear ratio may be determined by the following formula:  $L = (R_d NK) \div T$ . In this formula,  $R_d$  represents the ratio obtained with available gears. If the given lead is 44.0894 inches, as in the preceding example, then the desired ratio as obtained with **Formula (5)** would be 0.9185292 if  $K = 1$ . Assume that the lead gears selected by using logs of ratios have a ratio of 0.9184704; then this ratio error of 0.0000588 would result in a computed lead error of only 0.000065 inch per inch.

**Formula (5)**, as mentioned, applies to machines having the differential located *ahead* of the index gears. If the differential is located after the index gears, it is necessary to change lead gears whenever the index gears are changed for hobbing a different number of teeth, as indicated by the following formula which gives the lead gear ratio. In this formula,  $D =$  pitch diameter.

$$R_d = \frac{L \times T}{K} = \frac{D \times \pi \times T}{K \times \tan A} = \frac{\text{Driven gear sizes}}{\text{Driving gear sizes}} \quad (6)$$

**General Remarks on Helical Gear Hobbing.**— In cutting teeth having large angles, it is desirable to have the direction of helix of the hob the same as the direction of helix of the gear, or in other words, the gear and the hob of the same “hand.” Then the direction of the cut will come against the movement of the blank. At ordinary angles, however, one hob will cut both right- and left-hand gears. In setting up the hobbing machine for helical gears, care should be taken to see that the vertical feed does not trip until the machine has been stopped or the hob has fed down past the finished gear.

### Herringbone Gears

Double helical or herringbone gears are commonly used in parallel-shaft transmissions, especially when a smooth, continuous action (due to the gradual overlapping engagement of the teeth) is essential, as in high-speed drives where the pitch-line velocity may range from about 1000 to 3000 feet per minute (305–914 m/min) in commercial gearing and up to 12,000 feet per minute (3658 m/min) or higher in more specialized installations. These relatively high speeds are encountered in marine reduction gears, in certain speed-reducing and speed-increasing units, and in various other transmissions, particularly in connection with steam turbine and electric motor drives.

**General Classes of Helical Gear Problems.**— There are two general classes of problems. In one, the problem is to design gears capable of transmitting a given amount of power at a given speed, safely and without excessive wear; hence, the required proportions must be determined. In the second, the proportions and speed are known and the power-transmitting capacity is required. The first is the more difficult and common problem.

**Causes of Herringbone Gear Failures.**— Where failure occurs in a herringbone gear transmission, it is rarely due to tooth breakage but usually to excessive wear or sub-surface failures, such as pitting and spalling; hence, it is common practice to base the design of such gears upon durability, or upon tooth pressures which are within the allowable limits for wear. In this connection, it seems to have been well established by tests of both spur gears and herringbone gears, that there is a critical surface pressure value for teeth having given physical properties and coefficient of friction. According to these tests, pressures above the critical value result in rapid wear and a short gear life, whereas when pressures are below the critical, wear is negligible. The yield point or endurance limit of the material marks the critical loading point, and in practical designing a reasonable factor of safety would, of course, be employed.

## OTHER GEAR TYPES

### Elliptic Gears

Gears of this type provide simple means of obtaining a quick-return motion but they present a rather cumbersome manufacturing problem and, as a general rule, it is preferable to obtain quick-return motions by some other type of mechanism. When elliptic gears are used, the two gears that mesh with each other must be equal in size, and each gear must revolve about one of the foci of the ellipse forming the pitch line, as indicated by the diagram, in Fig. 1. By the use of elliptic gears so mounted, it is possible to obtain a variable motion of the driven shaft, because the gear on the driving shaft, while revolving one half of a revolution, will engage with only a small portion of the circumference of the driven gear, while during the other half of its revolution, the driving gear will engage with a great deal more than one-half of the total number of teeth in the driven gear; hence, the cutting stroke of a machine tool, for example, may be made to have a slow motion, while the return stroke is at a rapid rate. The ellipse has two points, each of which is called a *focus*, located as indicated at *A* and *B*. The sum of the distance between the foci and the elliptic curve is constant at all points and is equal to the longer or major axis of the ellipse. On account of this peculiarity of the ellipse, two equal ellipses can be made to mesh with each other during a complete revolution about their axes, if one is mounted on a shaft at its focus *A* and the other at its focus *B*. (See also *Elliptic Gears* on the CD).

Fig. 1. General Arrangement of Elliptic Gears.

### Planetary Gearing

Planetary or epicyclic gearing provides means of obtaining a compact design of transmission, with driving and driven shafts in line, and a large speed reduction when required. Typical arrangements of planetary gearing are shown by the following diagrams which are accompanied by speed ratio formulas. When planetary gears are arranged as shown by Figs. 5, 6, 9 and 12, the speed of the follower relative to the driver is increased, whereas Figs. 7, 8, 10, and 11 illustrate speed-reducing mechanisms.

**Direction of Rotation.**— In using the following formulas, if the final result is preceded by a minus sign (negative), this indicates that the driver and follower will rotate in opposite directions; otherwise, both will rotate in the same direction.

**Compound Drive.**— The formulas accompanying Figs. 19 through 22 are for obtaining the speed ratios when there are *two* driving members rotating at different speeds. For example, in Fig. 19, the central shaft with its attached link is one driver. The internal gear  $z$ , instead of being fixed, is also rotated. In Fig. 22, if  $z = 24$ ,  $B = 60$  and  $S = 3\frac{1}{2}$ , with both drivers rotating in the same direction, then  $F = 0$ , thus indicating, in this case, the point where a larger value of  $S$  will reverse follower rotation.

**Planetary Bevel Gears.**— Two forms of planetary gears of the bevel type are shown in Figs. 23 and 24. The planet gear in Fig. 23 rotates about a fixed bevel gear at the center of which is the driven shaft. Fig. 24 illustrates the Humpage reduction gear. This is sometimes referred to as cone-pulley back-gearing because of its use within the cone pulleys of certain types of machine tools.

## Ratios of Planetary or Epicyclic Gearing

$D$  = rotation of *driver* per revolution of follower or driven member

$F$  = rotation of *follower* or driven member per revolution of driver. (In Figs. 1 through 4,  $F$  = rotation of planet type follower about its axis.)

$A$  = size of driving gear (use either number of teeth or pitch diameter). Note: When follower derives its motion both from  $A$  and from a secondary driving member,  $A$  = size of *initial* driving gear, and formula gives speed relationship between  $A$  and follower.

$B$  = size of *driven gear or follower* (use either pitch diameter or number of teeth)

$C$  = size of *fixed gear* (use either pitch diameter or number of teeth)

$x$  = size of *planet gear* as shown by diagram (use either pitch diameter or number of teeth)

$y$  = size of *planet gear* as shown by diagram (use either pitch diameter or number of teeth)

$z$  = size of secondary or *auxiliary driving gear*, when follower derives its motion from two driving members

$S$  = rotation of *secondary driver*, per revolution of *initial driver*.  $S$  is negative when secondary and initial drivers rotate in opposite directions. (Formulas in which  $S$  is used give speed relationship between follower and the initial driver.)

Note: In all cases, if  $D$  is known,  $F = 1 \div D$ , or, if  $F$  is known,  $D = 1 \div F$ .

### Ratchet Gearing

Ratchet gearing may be used to transmit intermittent motion, or its only function may be to prevent the ratchet wheel from rotating backward. Ratchet gearing of this latter form is commonly used in connection with hoisting mechanisms of various kinds, to prevent the hoisting drum or shaft from rotating in a reverse direction under the action of the load.

#### Types of Ratchet Gearing

Ratchet gearing in its simplest form consists of a toothed ratchet wheel *a* (see Fig. a), and a pawl or detent *b*, and it may be used to transmit intermittent motion or to prevent relative motion between two parts except in one direction. The pawl *b* is pivoted to lever *c* which, when given an oscillating movement, imparts an intermittent rotary movement to ratchet wheel *a*. Fig. b illustrates another application of the ordinary ratchet and pawl mechanism. In this instance, the pawl is pivoted to a stationary member and its only function is to prevent the ratchet wheel from rotating backward. With the stationary design, illustrated at

Fig. c, the pawl prevents the ratchet wheel from rotating in either direction, so long as it is in engagement with the wheel.

The principle of *multiple-pawl ratchet gearing* is illustrated at Fig. d, which shows the use of two pawls. One of these pawls is longer than the other, by an amount equal to one-half the pitch of the ratchet-wheel teeth, so that the practical effect is that of reducing the pitch one-half. By placing a number of driving pawls side by side and proportioning their lengths according to the pitch of the teeth, a very fine feed can be obtained with a ratchet wheel of comparatively coarse pitch.

This method of obtaining a fine feed from relatively coarse-pitch ratchets may be preferable to the use of single ratchets of fine pitch which, although providing the feed required, may have considerably weaker teeth.

The type of ratchet gearing shown at Fig. e is sometimes employed to impart a rotary movement to the ratchet wheel for both the forward and backward motions of the lever to which the two pawls are attached.

A simple form of *reversing ratchet* is illustrated at Fig. f. The teeth of the wheel are so shaped that either side may be used for driving by simply changing the position of the double-ended pawl, as indicated by the full and dotted lines.

Another form of reversible ratchet gearing for shapers is illustrated at Fig. g. The pawl, in this case, instead of being a pivoted latch, is in the form of a plunger which is free to move in the direction of its axis, but is normally held into engagement with the ratchet wheel by a small spring. When the pawl is lifted and turned one-half revolution, the driving face then engages the opposite sides of the teeth and the ratchet wheel is given an intermittent rotary motion in the opposite direction.

The *frictional type* of ratchet gearing differs from the designs previously referred to, in that there is no positive engagement between the driving and driven members of the ratchet mechanism, the motion being transmitted by frictional resistance. One type of frictional ratchet gearing is illustrated at Fig. h. Rollers or balls are placed between the ratchet wheel and an outer ring which, when turned in one direction, causes the rollers or balls to wedge between the wheel and ring as they move up the inclined edges of the teeth.

Fig. i illustrates one method of utilizing ratchet gearing for moving the driven member in a straight line, as in the case of a lifting jack. The pawl *g* is pivoted to the operating lever of the jack and does the lifting, whereas the pawl *h* holds the load while the lifting pawl *g* is being returned preparatory to another lifting movement.

**Shape of Ratchet Wheel Teeth.**— When designing ratchet gearing, it is important to so shape the teeth that the pawl will remain in engagement when a load is applied. The faces of the teeth which engage the end of the pawl should be in such relation with the center of the pawl pivot that a line perpendicular to the face of the engaging tooth will pass somewhere between the center of the ratchet wheel and the center of the pivot about which the pawl swings. This is true if the pawl *pushes* the ratchet wheel, or if the ratchet wheel *pushes* the pawl. However, if the pawl *pulls* the ratchet wheel or if the ratchet wheel *pulls* the pawl, the perpendicular from the face of the ratchet teeth should fall outside the pawl pivot center. Ratchet teeth may be either cut by a milling cutter having the correct angle, or hobbled in a gear-hobbing machine by the use of a special hob.

**Pitch of Ratchet Wheel Teeth.**— The pitch of ratchet wheels used for holding suspended loads may be calculated by the following formula, in which  $P$  = circular pitch, in inches (mm), measured at the outside circumference;  $M$  = turning moment acting upon the ratchet wheel shaft, in inch-pounds (N-mm);  $L$  = length of tooth face (thickness of ratchet gear), in inches (millimeters);  $S$  = safe stress (for steel, 2500 pounds per square inch or 17 MPa when subjected to shock, and 4000 pounds per square inch or 28 MPa when not subjected to shock);  $N$  = number of teeth in ratchet wheel;  $F$  = a factor the value of which is 50 for ratchet gears with 12 teeth or less, 35 for gears having from 12 to 20 teeth, and 20 for gears having over 20 teeth:

$$P = \frac{\sqrt{FM}}{\sqrt{LSN}}$$

This formula has been used in the calculation of ratchet gears for crane design.

**Gear Design Based upon Module System.**— The *module* of a gear is equal to the pitch diameter divided by the number of teeth, whereas *diametral pitch* is equal to the number of teeth divided by the pitch diameter. The module system (see accompanying table and diagram) is in general use in countries that have adopted the metric system; hence, the term module is usually understood to mean the pitch diameter *in millimeters* divided by the number of teeth. The module system, however, may also be based on inch measurements and then it is known as the English module to avoid confusion with the metric module. Module is an actual dimension, whereas diametral pitch is only a ratio. Thus, if the pitch diameter of a gear is 50 millimeters and the number of teeth 25, the module is 2, which means that there are 2 millimeters of pitch diameter for each tooth. The table *Tooth Dimensions Based Upon Module System* shows the relation among module, diametral pitch, and circular pitch.

### German Standard Tooth Form for Spur and Bevel Gears *DIN 867*

The flanks or sides are straight (involute system) and the pressure angle is 20 degrees. The shape of the root clearance space and the amount of clearance depend upon the method of cutting and special requirements. The amount of clearance may vary from  $0.1 \times$  module to  $0.3 \times$  module.

To Find	Module Known	Circular Pitch Known
Addendum	Equals module	$0.31823 \times$ Circular pitch
Dedendum	$1.157 \times$ module* $1.167 \times$ module**	$0.3683 \times$ Circular pitch* $0.3714 \times$ Circular pitch**
Working Depth	$2 \times$ module	$0.6366 \times$ Circular pitch
Total Depth	$2.157 \times$ module* $2.167 \times$ module**	$0.6866 \times$ Circular pitch* $0.6898 \times$ Circular pitch**
Tooth Thickness on Pitch Line	$1.5708 \times$ module	$0.5 \times$ Circular pitch

Formulas for dedendum and total depth, marked (\*) are used when clearance equals  $0.157 \times$  module. Formulas marked (\*\*) are used when clearance equals one-sixth module. It is common practice among American cutter manufacturers to make the clearance of metric or module cutters equal to  $0.157 \times$  module.

<sup>a</sup> Dedendum and total depth when clearance =  $0.1666 \times$  module, or one-sixth module.<sup>b</sup> Total depth equivalent to American standard full-depth teeth. (Clearance =  $0.157 \times$  module.)

**Rules for Module System of Gearing**

To Find	Rule
Metric Module	<p><i>Rule 1:</i> To find the metric module, divide the pitch diameter in millimeters by the number of teeth.</p> <p><i>Example 1:</i> The pitch diameter of a gear is 200 millimeters and the number of teeth, 40; then</p> $\text{Module} = \frac{200}{40} = 5$ <p><i>Rule 2:</i> Multiply circular pitch in millimeters by 0.3183.</p> <p><i>Example 2:</i> (Same as Example 1. Circular pitch of this gear equals 15.708 millimeters.)</p> $\text{Module} = 15.708 \times 0.3183 = 5$ <p><i>Rule 3:</i> Divide outside diameter in millimeters by the number of teeth plus 2.</p>
English Module	<p><i>Note:</i> The module system is usually applied when gear dimensions are expressed in millimeters, but module may also be based on inch measurements.</p> <p><i>Rule:</i> To find the English module, divide pitch diameter in inches by the number of teeth.</p> <p><i>Example:</i> A gear has 48 teeth and a pitch diameter of 12 inches.</p> $\text{Module} = \frac{12}{48} = \frac{1}{4} \text{ module or 4 diametral pitch}$
Metric Module Equivalent to Diametral Pitch	<p><i>Rule:</i> To find the metric module equivalent to a given diametral pitch, divide 25.4 by the diametral pitch.</p> <p><i>Example:</i> Determine metric module equivalent to 10 diametral pitch.</p> $\text{Equivalent module} = \frac{25.4}{10} = 2.54$ <p><i>Note:</i> The nearest standard module is 2.5.</p>
Diametral Pitch Equivalent to Metric Module	<p><i>Rule:</i> To find the diametral pitch equivalent to a given module, divide 25.4 by the module. (25.4 = number of millimeters per inch.)</p> <p><i>Example:</i> The module is 12; determine equivalent diametral pitch.</p> $\text{Equivalent diametral pitch} = \frac{25.4}{12} = 2.117$ <p><i>Note:</i> A diametral pitch of 2 is the nearest <i>standard</i> equivalent.</p>
Pitch Diameter	<p><i>Rule:</i> Multiply number of teeth by module.</p> <p><i>Example:</i> The metric module is 8 and the gear has 40 teeth; then</p> $D = 40 \times 8 = 320 \text{ millimeters} = 12.598 \text{ inches}$
Outside Diameter	<p><i>Rule:</i> Add 2 to the number of teeth and multiply sum by the module.</p> <p><i>Example:</i> A gear has 40 teeth and module is 6. Find outside or blank diameter.</p> $\text{Outside diameter} = (40 + 2) \times 6 = 252 \text{ millimeters}$

For tooth dimensions, see table *Tooth Dimensions Based Upon Module System*; also formulas in *German Standard Tooth Form for Spur and Bevel Gears DIN 867*.

The module of a gear is the pitch diameter divided by the number of teeth. The module may be expressed in any units; but when no units are stated, it is understood to be in millimeters. The metric module, therefore, equals the pitch diameter in millimeters divided by the number of teeth. To find the metric module equivalent to a given diametral pitch, divide 25.4 by the diametral pitch. To find the diametral pitch equivalent to a given module, divide 25.4 by the module. (25.4 = number of millimeters per inch.)

## CHECKING GEAR SIZES

## Checking Gear Size by Measurement Over Wires or Pins

The wire or pin method of checking gear sizes is accurate, easily applied, and especially useful in shops with limited inspection equipment. Two cylindrical wires or pins of predetermined diameter are placed in diametrically opposite tooth spaces (see diagram). If the gear has an odd number of teeth, the wires are located as nearly opposite as possible, as shown by the diagram at the right. The overall measurement  $M$  is checked by using any sufficiently accurate method of measurement. The value of measurement  $M$  when the pitch diameter is correct can be determined easily and quickly by means of the calculated values in the accompanying tables.

**Measurements for Checking External Spur Gears when Wire Diameter Equals 1.728 Divided by Diametral Pitch.**—Tables 1 and 2 give measurements  $M$ , in inches, for checking the pitch diameters of external spur gears of 1 diametral pitch. For any other diametral pitch, divide the measurement given in the table by whatever diametral pitch is required. The result shows what measurement  $M$  should be when the pitch diameter is correct and there is no allowance for backlash. The procedure for obtaining a given amount of backlash will be explained later. Tables 1 through 4 inclusive are based on wire sizes conforming to the Van Keuren standard. For external spur gears, the wire size equals 1.728 divided by the diametral pitch. The wire diameters for various diametral pitches will be found in the left-hand section of Table 5.

**Even Number of Teeth:** Table 1 is for even numbers of teeth. To illustrate the use of the table, assume that a spur gear has 32 teeth of 4 diametral pitch and a pressure angle of 20 degrees. Table 1 shows that the measurement for 1 diametral pitch is 34.4130; hence, for 4 diametral pitch, the measurement equals  $34.4130 \div 4 = 8.6032$  inches. This dimension is the measurement over the wires when the pitch diameter is correct, provided there is no allowance for backlash. The wire diameter here equals  $1.728 \div 4 = 0.432$  inch (Table 5).

Measurement for even numbers of teeth above 170 and not in Table 1 may be determined as shown by the following example: Assume that number of teeth = 240 and pressure angle =  $14\frac{1}{2}$  degrees; then, for 1 diametral pitch, figure at left of decimal point = given No. of teeth + 2 =  $240 + 2 = 242$ . Figure at right of decimal point lies between decimal values given in table for 200 teeth and 300 teeth and is obtained by interpolation. Thus,  $240 - 200 = 40$  (change to 0.40);  $0.5395 - 0.5321 = 0.0074$  = difference between decimal values for 300 and 200 teeth; hence, decimal required =  $0.5321 + (0.40 \times 0.0074) = 0.53506$ . Total dimension = 242.53506 divided by the diametral pitch required.

**Odd Number of Teeth:** Table 2 is for odd numbers of teeth. Measurement for odd numbers above 171 and not in Table 2 may be determined as shown by the following example: Assume that number of teeth = 335 and pressure angle = 20 degrees; then, for 1 diametral

pitch, figure at left of decimal point = given No. of teeth + 2 = 335 + 2 = 337. Figure at right of decimal point lies between decimal values given in table for 301 and 401 teeth. Thus, 335 - 301 = 34 (change to 0.34); 0.4565 - 0.4538 = 0.0027; hence, decimal required = 0.4538 + (0.34 × 0.0027) = 0.4547. Total dimension = 337.4547.

**Measurements for Checking Internal Gears when Wire Diameter Equals 1.44 Divided by Diametral Pitch.**— Tables 3 and 4 give measurements between wires for checking internal gears of 1 diametral pitch. For any other diametral pitch, divide the measurement given in the table by the diametral pitch required. These measurements are based upon the Van Keuren standard wire size, which, for internal spur gears, equals 1.44 divided by the diametral pitch (see Table 5).

*Even Number of Teeth:* For an even number of teeth above 170 and not in Table 3, proceed as shown by the following example: Assume that the number of teeth = 380 and pressure angle is  $14\frac{1}{2}$  degrees; then, for 1 diametral pitch, figure at left of decimal point = given number of teeth  $- 2 = 380 - 2 = 378$ . Figure at right of decimal point lies between decimal values given in table for 300 and 400 teeth and is obtained by interpolation. Thus,  $380 - 300 = 80$  (change to 0.80);  $0.8803 - 0.8795 = 0.0008$ ; hence, decimal required =  $0.8795 + (0.80 \times 0.0008) 0.88014$ . Total dimension = 378.88014.

*Odd Number of Teeth:* Table 4 is for internal gears having odd numbers of teeth. For tooth numbers above 171 and not in the table, proceed as shown by the following example: Assume that number of teeth = 337 and pressure angle is  $14\frac{1}{2}$  degrees; then, for 1 diametral pitch, figure at left of decimal point = given No. of teeth  $- 2 = 337 - 2 = 335$ . Figure at right of decimal point lies between decimal values given in table for 301 and 401 teeth and is obtained by interpolation. Thus,  $337 - 301 = 36$  (change to 0.36);  $0.8776 - 0.8759 = 0.0017$ ; hence, decimal required =  $0.8759 + (0.36 \times 0.0017) = 0.8765$ . Total dimension = 335.8765.

**Measurements for Checking External Spur Gears when Wire Diameter Equals 1.68 Divided by Diametral Pitch.**— Tables 7 and 8 give measurements  $M$ , in inches, for checking the pitch diameters of external spur gears of 1 diametral pitch. For any other diametral pitch, divide the measurement given in the table by whatever diametral pitch is required. The result shows what measurement  $M$  should be when the pitch diameter is correct and there is no allowance for backlash. The procedure for checking for a given amount of backlash when the diameter of the measuring wires equals 1.68 divided by the diametral pitch is explained under a subsequent heading. Tables 7 and 8 are based upon wire sizes equal to 1.68 divided by the diametral pitch. The corresponding wire diameters for various diametral pitches are given in Table 6.

**Table 6. Wire Diameters for Spur and Helical Gears Based upon 1.68 Constant**

Diametral or Normal Diametral Pitch	Wire Diameter	Diametral or Normal Diametral Pitch	Wire Diameter	Diametral or Normal Diametral Pitch	Wire Diameter	Diametral or Normal Diametral Pitch	Wire Diameter
2	0.840	8	0.210	18	0.09333	40	0.042
$2\frac{1}{2}$	0.672	9	0.18666	20	0.084	48	0.035
3	0.560	10	0.168	22	0.07636	64	0.02625
4	0.420	11	0.15273	24	0.070	72	0.02333
5	0.336	12	0.140	28	0.060	80	0.021
6	0.280	14	0.120	32	0.0525	...	...
7	0.240	16	0.105	36	0.04667	...	...

Pin diameter =  $1.68 \div$  diametral pitch for spur gears and  $1.68 \div$  normal diametral pitch for helical gears.

To find measurement  $M$  of an external spur gear using wire sizes equal to 1.68 inches divided by the diametral pitch, the same method is followed in using Tables 7 and 8 as that outlined for Tables 1 and 2.

**Table 7. Checking External Spur Gear Sizes  
by Measurement Over Wires**

EVEN NUMBERS OF TEETH					
Dimensions in table are for 1 diametral pitch and 1.68-inch series wire sizes (a Van Keuren standard). For any other diametral pitch, divide dimension in table by given pitch.					
Wire or pin diameter = $\frac{1.68}{\text{Diametral Pitch}}$

*Allowance for Backlash:* Tables 1, 2, 7, and 8 give measurements over wires when the pitch diameters are correct and there is no allowance for backlash or play between meshing teeth. Backlash is obtained by cutting the teeth somewhat deeper than standard, thus reducing the thickness. Usually, the teeth of both mating gears are reduced in thickness an amount equal to one-half of the total backlash desired. However, if the pinion is small, it is common practice to reduce the gear teeth the full amount of backlash and the pinion is made to standard size. The changes in measurements  $M$  over wires, for obtaining backlash in external spur gears, are listed in Table 9.

**Table 8. Checking External Spur Gear Sizes  
by Measurement Over Wires**

ODD NUMBERS OF TEETH					
Dimensions in table are for 1 diametral pitch and 1.68-inch series wire sizes (a Van Keuren standard). For any other diametral pitch, divide dimension in table by given pitch.					
Wire or pin diameter = $\frac{1.68}{\text{Diametral Pitch}}$					
No. of Teeth	Pressure Angle

*External Gears:* For each 0.001 inch reduction in pitch-line tooth thickness, *reduce* measurement over wires obtained from **Tables 1, 2, 7, or 8** by the amount shown below.

*Internal Gears:* For each 0.001 inch reduction in pitch-line tooth thickness, *increase* measurement between wires obtained from **Tables 3 or 4** by the amounts shown below.

Backlash on pitch line equals double tooth thickness reduction when teeth of *both* mating gears are reduced. If teeth of *one* gear only are reduced, backlash on pitch line equals amount of reduction.

*Example:* For a 30-tooth, 10-diametral pitch, 20-degree pressure angle external gear, the measurement over wires from **Table 1** is  $32.4102 \div 10$ . For a backlash of 0.002, this measurement must be reduced by  $2 \times 0.0024$  to 3.2362 or  $(3.2410 - 0.0048)$ .

**Measurements for Checking Helical Gears Using Wires or Balls.**— Helical gears may be checked for size by using one wire, or ball; two wires, or balls; and three wires, depending on the case at hand. Three wires may be used for measurement of either even or odd tooth numbers provided that the face width and helix angle of the gear permit the arrangement of two wires in adjacent tooth spaces on one side of the gear and a third wire on the opposite side. The wires should be held between flat, parallel plates. The measurement between these plates, and perpendicular to the gear axis, will be the same for both even and odd numbers of teeth because the axial displacement of the wires with the odd numbers of teeth does not affect the perpendicular measurement between the plates. The calculation of measurements over three wires is the same as described for measurements over two wires for even numbers of teeth.

*Measurements over One Wire or One Ball for Even or Odd Numbers of Teeth:* This measurement is calculated by the method for measurement over two wires for even numbers of teeth and the result divided by two to obtain the measurement from over the wire or ball to the center of the gear mounted on an arbor.

*Measurement over Two Wires or Two Balls for Even Numbers of Teeth:* The measurement over two wires (or two balls kept in the same plane by holding them against a surface parallel to the face of the gear) is calculated as follows: First, calculate the pitch diameter of the helical gear from the formula  $D = \text{Number of teeth} \div \text{product of the normal diametral pitch and the cosine of the helix angle}$ ,  $D = N \div (P_n \times \cos \psi)$ . Next, calculate the number of teeth,  $N_e$ , there would be in a spur gear for it to have the same tooth curvature as the helical gear has in the normal plane:  $N_e = N / \cos^3 \psi$ . Next, refer to **Table 7** for spur gears with even tooth numbers and find, by interpolation, the *decimal* value of the constant for this number of teeth under the given *normal* pressure angle. Finally, add 2 to this decimal value and divide the sum by the normal diametral pitch  $P_n$ . The result of this calculation, added to the pitch diameter  $D$ , is the measurement over two wires or balls.

*Example:* A helical gear has 32 teeth of 6 normal diametral pitch, 20 degree pressure angle, and 23 degree helix angle. Determine the measurement over two wires,  $M$ , without allowance for backlash.

$D = 32 \div 6 \times \cos 23^\circ = 5.7939$ ;  $N_e = 32 \div \cos^3 23^\circ = 41.027$ ; and in **Table 7**, fourth column, the decimal part of the measurement for 40 teeth is .2473 and that for 42 teeth is 0.2485.

The decimal part for 41.027 teeth is, by interpolation,  $\frac{(41.027 - 40)}{(42 - 40)} \times (0.2485 - 0.2473) + 0.2473 = 0.2479$ ;  $(0.2479 + 2) \div 6 = 0.3747$ ; and  $M = 0.3747 + 5.7939 = 6.1686$ .

This measurement over wires or balls is based upon the use of  $1.68/P_n$  wires or balls. If measurements over  $1.728/P_n$  diameter wires or balls are preferred, use **Table 1** to find the decimal part described above instead of **Table 7**.

*Measurement Over Two Wires or Two Balls for Odd Numbers of Teeth:* The procedure is similar to that for two wire or two ball measurement for even tooth numbers except that a correction is made in the final  $M$  value to account for the wires or balls not being diametrically opposite by one-half tooth interval. In addition, care must be taken to ensure that the balls or wires are kept in a plane of the gear's rotation as described previously.

*Example:* A helical gear has 13 teeth of 8 normal diametral pitch,  $14\frac{1}{2}$  degree pressure angle, and 45 degree helix angle. Determine measurement  $M$  without allowance for backlash based upon the use of  $1.728/P_n$  balls or wires.

As before,  $D = 13/8 \times \cos 45^\circ = 2.2981$ ;  $N_e = 13/\cos^3 45^\circ = 36.770$ ; and in the second column of **Table 1** the decimal part of the measurement for 36 teeth is 0.4565 and that for 38 teeth is 0.4603. The decimal part for 36.770 teeth is, by interpolation,  $\frac{(36.770 - 36)}{(38 - 36)} \times (0.4603 - 0.4565) + 0.4565 = 0.4580$ ;  $(0.4580 + 2)/8 = 0.3073$ ; and  $M = 0.3073 + 2.2981 = 2.6054$ . This measurement is correct for three-wire measurements but, for two balls or wires held in the plane of rotation of the gear,  $M$  must be corrected as follows:

$$\begin{aligned} M \text{ corrected} &= (M - \text{Ball Diam.}) \times \cos(90^\circ/N) + \text{Ball Diam.} \\ &= (2.6054 - 1.728/8) \times \cos(90^\circ/13) + 1.728/8 = 2.5880 \end{aligned}$$

### Checking Spur Gear Size by Chordal Measurement Over Two or More Teeth.—

Another method of checking gear sizes, that is generally available, is illustrated by the diagram accompanying **Table 10**. A vernier caliper is used to measure the distance  $M$  over two or more teeth. The diagram illustrates the measurement over two teeth (or with one intervening tooth space), but three or more teeth might be included, depending upon the pitch. The jaws of the caliper are merely held in contact with the sides or profiles of the teeth and perpendicular to the axis of the gear. Measurement  $M$  for involute teeth of the correct size is determined as follows.

*General Formula for Checking External and Internal Spur Gears by Measurement Over Wires:* The following formulas may be used for pressure angles or wire sizes not covered by the tables. In these formulas,  $M$  = measurement over wires for external gears or measurement between wires for internal gears;  $D$  = pitch diameter;  $T$  = arc tooth thickness on pitch circle;  $W$  = wire diameter;  $N$  = number of gear teeth;  $A$  = pressure angle of gear;  $a$  = angle, the cosine of which is required in **Formulas (2)** and **(3)**.

First determine the involute function of angle  $a$  ( $\text{inv } a$ ); then the corresponding angle  $a$  is found by referring to the tables of involute functions beginning on page 106,

$$\text{inv } a = \text{inv } A \pm \frac{T}{D} \pm \frac{W}{D \cos A} \mp \frac{\pi}{N} \quad (1)$$

$$\text{For even numbers of teeth, } M = \frac{D \cos A}{\cos a} \pm W \quad (2)$$

$$\text{For odd numbers of teeth, } M = \left( \frac{D \cos A}{\cos a} \right) \left( \cos \frac{90^\circ}{N} \right) \pm W \quad (3)$$

*Note:* In **Formulas (1)**, **(2)**, and **(3)**, use the upper sign for *external* and the lower sign for *internal* gears wherever a  $\pm$  or  $\mp$  appears in the formulas.

**Table 10. Chordal Measurements over Spur Gear Teeth of 1 Diametral Pitch**

Find value of  $M$  under pressure angle and opposite number of teeth; divide  $M$  by diametral pitch of gear to be measured and then subtract one-half total backlash to obtain a measurement  $M$  equivalent to given pitch and backlash. The number of teeth to gage or measure over is shown by Table 11.

Number of Gear Teeth	$M$ in Inches for 1 D.P.	Number of Gear Teeth	$M$ in Inches for 1 D.P.	Number of Gear Teeth	$M$ in Inches for 1 D.P.	Number of Gear Teeth	$M$ in Inches for 1 D.P.

*Table for Determining the Chordal Dimension:* **Table 10** gives the chordal dimensions for one diametral pitch when measuring over the number of teeth indicated in **Table 11**. To obtain any chordal dimension, it is simply necessary to divide chord  $M$  in the table (opposite the given number of teeth) by the diametral pitch of the gear to be measured and then subtract from the quotient one-half the total backlash between the mating pair of gears. In cases where a small pinion is used with a large gear and all of the backlash is to be obtained by reducing the gear teeth, the total amount of backlash is subtracted from the chordal dimension of the gear and nothing from the chordal dimension of the pinion. The application of the tables will be illustrated by an example.

**Table 11. Number of Teeth Included in Chordal Measurement**

Tooth Range for 14½° Pressure Angle	Tooth Range for 20° Pressure Angle	Number of Teeth to Gage Over	Tooth Range for 14½° Pressure Angle	Tooth Range for 20° Pressure Angle	Number of Teeth to Gage Over
12 to 18	12 to 18	2	63 to 75	46 to 54	6
19 to 37	19 to 27	3	76 to 87	55 to 63	7
38 to 50	28 to 36	4	88 to 100	64 to 72	8
51 to 62	37 to 45	5	101 to 110	73 to 81	9

This table shows the number of teeth to be included between the jaws of the vernier caliper in measuring dimension  $M$  as explained in connection with **Table 10**.

*Example:* Determine the chordal dimension for checking the size of a gear having 30 teeth of 5 diametral pitch and a pressure angle of 20 degrees. A total backlash of 0.008 inch is to be obtained by reducing equally the teeth of both mating gears.

**Table 10** shows that chordal distance for 30 teeth of one diametral pitch and a pressure angle of 20 degrees is 10.7526 inches; one-half of the backlash equals 0.004 inch; hence,

$$\text{Chordal dimension} = \frac{10.7526}{5} - 0.004 = 2.1465 \text{ inches}$$

**Table 11** shows that this is the chordal dimension when the vernier caliper spans four teeth, this being the number of teeth to gage over whenever gears of 20-degree pressure angle have any number of teeth from 28 to 36, inclusive.

If it is considered necessary to leave enough stock on the gear teeth for a shaving or finishing cut, this allowance is simply added to the chordal dimension of the finished teeth to obtain the required measurement over the teeth for the roughing operation. It may be advisable to place this chordal dimension for rough machining on the detail drawing.

**Formula for Chordal Dimension  $M$ .**— The required measurement  $M$  over spur gear teeth may be obtained by the following formula in which  $R$  = pitch radius of gear,  $A$  = pressure angle,  $T$  = tooth thickness along pitch circle,  $N$  = number of gear teeth,  $S$  = number of tooth spaces between caliper jaws,  $F$  = a factor depending on the pressure angle = 0.01109 for 14½°; = 0.01973 for 17½°; = 0.0298 for 20°; = 0.04303 for 22½°; = 0.05995 for 25°. This factor  $F$  equals twice the involute function of the pressure angle.

$$M = R \times \cos A \times \left( \frac{T}{R} + \frac{6.2832 \times S}{N} + F \right)$$

*Example:* A spur gear has 30 teeth of 6 diametral pitch and a pressure angle of 14½ degrees. Determine measurement  $M$  over three teeth, there being two intervening tooth spaces.

The pitch radius = 2½ inches, the arc tooth thickness equivalent to 6 diametral pitch is 0.2618 inch (if no allowance is made for backlash) and factor  $F$  for 14½ degrees = 0.01109 inch.

$$M = 2.5 \times 0.96815 \times \left( \frac{0.2618}{2.5} + \frac{6.2832 \times 2}{30} + 0.01109 \right) = 1.2941 \text{ inches}$$

**Checking Enlarged Pinions by Measuring Over Pins or Wires.**— When the teeth of small spur gears or pinions would be undercut if generated by an unmodified straight-sided rack cutter or hob, it is common practice to make the outside diameter larger than standard. The amount of increase in outside diameter varies with the pressure angle and number of teeth, as shown by **Table 7** on page 2162. The teeth are always cut to standard depth on a generating type of machine such as a gear hobber or gear shaper; and because the number of teeth and pitch are not changed, the pitch diameter also remains unchanged. The tooth thickness on the pitch circle, however, is increased and wire sizes suitable for standard gears are not large enough to extend above the tops of these enlarged gears or pinions; hence, the Van Keuren wire size recommended for these enlarged pinions equals  $1.92 \div$  diametral pitch. **Table 12** gives measurements over wires of this size, for checking full-depth involute gears of 1 diametral pitch. For any other pitch, merely divide the measurement given in the table by the diametral pitch. **Table 12** applies to pinions that have been enlarged by the same amounts as given in tables 7 and 8, starting on page 2162. These enlarged pinions will mesh with standard gears; but if the standard center distance is to be maintained, reduce the gear diameter below the standard size by as much as the pinion diameter is increased.

**Table 12. Checking Enlarged Spur Pinions by Measurement Over Wires**

Measurements over wires are given in table for 1 diametral pitch. For any other diametral pitch, divide measurement in table by given pitch. Wire size equals $1.92 \div$ diametral pitch.							
Number of Teeth	Outside or Major Diameter (Note 1)	Circular Tooth Thickness (Note 2)	Measurement Over Wires	Number of Teeth	Outside or Major Diameter (Note 1)	Circular Tooth Thickness (Note 2)	Measurement Over Wires
14½-degree full-depth involute teeth:				20-degree full-depth involute teeth:

29	31.1820	1.6179	32.2558				
30	32.1193	1.6017	33.2661				
31	33.0566	1.5854	34.1889				

*Note 1:* These enlargements, which are to improve the tooth form and avoid undercut, conform to those given in **Tables 7** and **8**, starting on page 2162 where data will be found on the minimum number of teeth in the mating gear.

*Note 2:* The circular or arc thickness is at the standard pitch diameter. The corresponding chordal thickness may be found as follows: Multiply arc thickness by 90 and then divide product by  $3.1416 \times$  pitch radius; find sine of angle thus obtained and multiply it by pitch diameter.

## GEAR MATERIALS

**Classification of Gear Steels.**— Gear steels may be divided into two general classes — the plain carbon and the alloy steels. Alloy steels are used to some extent in the industrial field, but heat-treated plain carbon steels are far more common. The use of untreated alloy steels for gears is seldom, if ever, justified, and then, only when heat-treating facilities are lacking. The points to be considered in determining whether to use heat-treated plain carbon steels or heat-treated alloy steels are: Does the service condition or design require the superior characteristics of the alloy steels, or, if alloy steels are not required, will the advantages to be derived offset the additional cost? For most applications, plain carbon steels, heat-treated to obtain the best of their qualities for the service intended, are satisfactory and quite economical. The advantages obtained from using heat-treated alloy steels in place of heat-treated plain carbon steels are as follows:

- 1) Increased surface hardness and depth of hardness penetration for the same carbon content and quench.
- 2) Ability to obtain the same surface hardness with a less drastic quench and, in the case of some of the alloys, a lower quenching temperature, thus giving less distortion.
- 3) Increased toughness, as indicated by the higher values of yield point, elongation, and reduction of area.
- 4) Finer grain size, with the resulting higher impact toughness and increased wear resistance.
- 5) In the case of some of the alloys, better machining qualities or the possibility of machining at higher hardnesses.

**Use of Casehardening Steels.**— Each of the two general classes of gear steels may be further subdivided as follows: 1) Casehardening steels; 2) full-hardening steels; and 3) steels that are heat-treated and drawn to a hardness that will permit machining.

The first two — casehardening and full-hardening steels — are interchangeable for some kinds of service, and the choice is often a matter of personal opinion. Casehardening steels with their extremely hard, fine-grained (when properly treated) case and comparatively soft and ductile core are generally used when resistance to wear is desired. Casehardening alloy steels have a fairly tough core, but not as tough as that of the full-hardening steels. In order to realize the greatest benefits from the core properties, casehardened steels should be double-quenched. This is particularly true of the alloy steels, because the benefits derived from their use seldom justify the additional expense, unless the core is refined and toughened by a second quench. The penalty that must be paid for the additional refinement is increased distortion, which may be excessive if the shape or design does not lend itself to the casehardening process.

**Use of “Thru-Hardening” Steels.**— Thru-hardening steels are used when great strength, high endurance limit, toughness, and resistance to shock are required. These qualities are governed by the kind of steel and treatment used. Fairly high surface hardnesses are obtainable in this group, though not so high as those of the casehardening steels. For that reason, the resistance to wear is not so great as might be obtained, but when wear resistance combined with great strength and toughness is required, this type of steel is superior to the others. Thru-hardening steels become distorted to some extent when hardened, the amount depending upon the steel and quenching medium used. For that reason, thru-hardening steels are not suitable for high-speed gearing where noise is a factor, or for gearing where accuracy is of paramount importance, except, of course, in cases where grinding of the teeth is practicable. The medium and high-carbon percentages require an oil quench, but a water quench may be necessary for the lower carbon contents, in order to obtain the highest physical properties and hardness. The distortion, however, will be greater with the water quench.

**Heat-Treatment that Permits Machining.**— When the grinding of gear teeth is not practicable and a high degree of accuracy is required, hardened steels may be drawn or tem-

pered to a hardness that will permit the cutting of the teeth. This treatment gives a highly refined structure, great toughness, and, in spite of the low hardness, excellent wearing qualities. The lower strength is somewhat compensated for by the elimination of the increment loads due to the impacts which are caused by inaccuracies. When steels that have a low degree of hardness penetration from surface to core are treated in this manner, the design cannot be based on the physical properties corresponding to the hardness at the surface. Since the physical properties are determined by the hardness, the drop in hardness from surface to core will give lower physical properties at the root of the tooth, where the stress is greatest. The quenching medium may be either oil, water, or brine, depending on the steel used and hardness penetration desired. The amount of distortion, of course, is immaterial, because the machining is done after heat-treating.

**Making Pinion Harder than Gear to Equalize Wear.**— Beneficial results from a wear standpoint are obtained by making the pinion harder than the gear. The pinion, having a lesser number of teeth than the gear, naturally does more work per tooth, and the differential in hardness between the pinion and the gear (the amount being dependent on the ratio) serves to equalize the rate of wear. The harder pinion teeth correct the errors in the gear teeth to some extent by the initial wear and then seem to burnish the teeth of the gear and increase its ability to withstand wear by the greater hardness due to the cold-working of the surface. In applications where the gear ratio is high and there are no severe shock loads, a casehardened pinion running with an oil-treated gear, treated to a Brinell hardness at which the teeth may be cut after treating, is an excellent combination. The pinion, being relatively small, is distorted but little, and distortion in the gear is circumvented by cutting the teeth after treatment.

**Forged and Rolled Carbon Steels for Gears.**— These compositions cover steel for gears in three groups, according to heat treatment, as follows:

- a) case-hardened gears
- b) unhardened gears, not heat treated after machining
- c) hardened and tempered gears

Forged and rolled carbon gear steels are purchased on the basis of the requirements as to chemical composition specified in [Table 1](#). Class N steel will normally be ordered in ten point carbon ranges within these limits. Requirements as to physical properties have been omitted, but when they are called for the requirements as to carbon shall be omitted. The steels may be made by either or both the open hearth and electric furnace processes.

**Table 1. Compositions of Forged and Rolled Carbon Steels for Gears**

Heat Treatment	Class	Carbon	Manganese	Phosphorus	Sulfur
Case-hardened	C	0.15-0.25	0.40-0.70	0.045 max	0.055 max
Untreated	N	0.25-0.50	0.50-0.80	0.045 max	0.055 max
Hardened (or untreated)	H	0.40-0.50	0.40-0.70	0.045 max	0.055 max

**Forged and Rolled Alloy Steels for Gears.**— These compositions cover alloy steel for gears, in two classes according to heat treatment, as follows:

- a) case-hardened gears
- b) hardened and tempered gears

Forged and rolled alloy gear steels are purchased on the basis of the requirements as to chemical composition specified in [Table 2](#). Requirements as to physical properties have been omitted. The steel shall be made by either or both the open hearth and electric furnace process.

**Table 2. Compositions of Forged and Rolled Alloy Steels for Gears**

Steel Specification	Chemical Composition <sup>a</sup>

<sup>a</sup>C = carbon; Mn = manganese; Si = silicon; Ni = nickel; Cr = chromium, and Mo = molybdenum.

<sup>b</sup>Both Nitralloy alloys contain aluminum 0.85–1.2%

**Steel Castings for Gears.**— It is recommended that steel castings for cut gears be purchased on the basis of chemical analysis and that only two types of analysis be used, one for case-hardened gears and the other for both untreated gears and those which are to be hardened and tempered. The steel is to be made by the open hearth, crucible, or electric furnace processes. The converter process is not recognized. Sufficient risers must be provided to secure soundness and freedom from undue segregation. Risers should not be broken off the unannealed castings by force. Where risers are cut off with a torch, the cut should be at least one-half inch above the surface of the castings, and the remaining metal removed by chipping, grinding, or other noninjurious method.

Steel for use in gears should conform to the requirements for chemical composition indicated in [Table 3](#). All steel castings for gears must be thoroughly normalized or annealed, using such temperature and time as will entirely eliminate the characteristic structure of unannealed castings.

**Table 3. Compositions of Cast Steels for Gears**

Steel Specification	Chemical Composition <sup>a</sup>			
	C	Mn	Si	
SAE-0022	0.12-0.22	0.50-0.90	0.60 Max.	May be carburized
SAE-0050	0.40-0.50	0.50-0.90	0.80 Max.	Hardenable 210-250

<sup>a</sup>C = carbon; Mn = manganese; and Si = silicon.

**Effect of Alloying Metals on Gear Steels.**— The effect of the various alloying elements on steel are here summarized to assist in deciding on the particular kind of alloy steel to use for specific purposes. The characteristics outlined apply only to heat-treated steels. When the effect of the addition of an alloying element is stated, it is understood that reference is made to alloy steels of a given carbon content, compared with a plain carbon steel of the same carbon content.

*Nickel:* The addition of nickel tends to increase the hardness and strength, with but little sacrifice of ductility. The hardness penetration is somewhat greater than that of plain carbon steels. Use of nickel as an alloying element lowers the critical points and produces less distortion, due to the lower quenching temperature. The nickel steels of the case-hardening group carburize more slowly, but the grain growth is less.

*Chromium:* Chromium increases the hardness and strength over that obtained by the use of nickel, though the loss of ductility is greater. Chromium refines the grain and imparts a

greater depth of hardness. Chromium steels have a high degree of wear resistance and are easily machined in spite of the fine grain.

*Manganese:* When present in sufficient amounts to warrant the use of the term alloy, the addition of manganese is very effective. It gives greater strength than nickel and a higher degree of toughness than chromium. Owing to its susceptibility to cold-working, it is likely to flow under severe unit pressures. Up to the present time, it has never been used to any great extent for heat-treated gears, but is now receiving an increasing amount of attention.

*Vanadium:* Vanadium has a similar effect to that of manganese—increasing the hardness, strength, and toughness. The loss of ductility is somewhat more than that due to manganese, but the hardness penetration is greater than for any of the other alloying elements. Owing to the extremely fine-grained structure, the impact strength is high; but vanadium tends to make machining difficult.

*Molybdenum:* Molybdenum has the property of increasing the strength without affecting the ductility. For the same hardness, steels containing molybdenum are more ductile than any other alloy steels, and having nearly the same strength, are tougher; in spite of the increased toughness, the presence of molybdenum does not make machining more difficult. In fact, such steels can be machined at a higher hardness than any of the other alloy steels. The impact strength is nearly as great as that of the vanadium steels.

*Chrome-Nickel Steels:* The combination of the two alloying elements chromium and nickel adds the beneficial qualities of both. The high degree of ductility present in nickel steels is complemented by the high strength, finer grain size, deep hardening, and wear-resistant properties imparted by the addition of chromium. The increased toughness makes these steels more difficult to machine than the plain carbon steels, and they are more difficult to heat treat. The distortion increases with the amount of chromium and nickel.

*Chrome-Vanadium Steels:* Chrome-vanadium steels have practically the same tensile properties as the chrome-nickel steels, but the hardening power, impact strength, and wear resistance are increased by the finer grain size. They are difficult to machine and become distorted more easily than the other alloy steels.

*Chrome-Molybdenum Steels:* This group has the same qualities as the straight molybdenum steels, but the hardening depth and wear resistance are increased by the addition of chromium. This steel is very easily heat treated and machined.

*Nickel-Molybdenum Steels:* Nickel-molybdenum steels have qualities similar to chrome-molybdenum steel. The toughness is said to be greater, but the steel is somewhat more difficult to machine.

**Sintered Materials.**— For high production of low and moderately loaded gears, significant production cost savings may be effected by the use of a sintered metal powder. With this material, the gear is formed in a die under high pressure and then sintered in a furnace. The primary cost saving comes from the great reduction in labor cost of machining the gear teeth and other gear blank surfaces. The volume of production must be high enough to amortize the cost of the die and the gear blank must be of such a configuration that it may be formed and readily ejected from the die.

**Bronze and Brass Gear Castings.**— These specifications cover nonferrous metals for spur, bevel, and worm gears, bushings and flanges for composition gears. This material shall be purchased on the basis of chemical composition. The alloys may be made by any approved method.

*Spur and Bevel Gears:* For spur and bevel gears, hard cast bronze is recommended (ASTM B-10-18; SAE No. 62; and the well-known 88-10-2 mixture) with the following limits as to composition: Copper, 86 to 89; tin, 9 to 11; zinc, 1 to 3; lead (max), 0.20; iron (max), 0.06 percent. Good castings made from this bronze should have the following minimum physical characteristics: Ultimate strength, 30,000 pounds per square inch; yield point, 15,000 pounds per square inch; elongation in 2 inches, 14 percent.

**Steels for Industrial Gearing**

Material Specification	Hardness		Typical Heat Treatment, Characteristics, and Uses
	Case Rc	Core Bhn	
Case-Hardening Steels			
AISI 1020 AISI 1116	55-60	160-230	Carburize, harden, temper at 350°F. For gears that must be wear-resistant. Normalized material is easily machined. Core is ductile but has little strength.
AISI 4130 AISI 4140	50-55	270-370	Harden, temper at 900°F, Nitride. For parts requiring greater wear resistance than that of through-hardened steels but unable to tolerate the distortion of carburizing. Case is shallow, core is tough.
AISI 4615 AISI 4620	} 55-60	170-260	Carburize, harden, temper at 350°F. For gears requiring high fatigue resistance and strength. The 86xx series has better machinability. The 20 point steels are used for coarser teeth.
AISI 8615 AISI 8620	} 55-60	200-300	
AISI 9310	58-63	250-350	Carburize, harden, temper at 300°F. Primarily for aerospace gears that are highly loaded and operate at high pitch line velocity and for other gears requiring high reliability under extreme operating conditions. This material is not used at high temperatures.
Nitalloy N and Type 135 Mod. (15-N)	90-94	300-370	Harden, temper at 1200°F, Nitride. For gears requiring high strength and wear resistance that cannot tolerate the distortion of the carburizing process or that operate at high temperatures. Gear teeth are usually finished before nitriding. Care must be exercised in running nitrided gears together to avoid crazing of case-hardened surfaces.
Through-Hardening Steels			
AISI 1045 AISI 1140	24-40	...	Harden and temper to required hardness. Oil quench for lower hardness and water quench for higher hardness. For gears of medium and large size requiring moderate strength and wear resistance. Gears that must have consistent, solid sections to withstand quenching.
AISI 4140AISI 4340	24-40	...	Harden (oil quench), temper to required hardness. For gears requiring high strength and wear resistance, and high shock loading resistance. Use 41xx series for moderate sections and 43xx series for heavy sections. Gears must have consistent, solid sections to withstand quenching.

*Worm Gears:* For bronze worm gears, two alternative analyses of phosphor bronze are recommended, SAE No. 65 and No. 63.

SAE No. 65 (called phosphor gear bronze) has the following composition: Copper, 88 to 90; tin, 10 to 12; phosphorus, 0.1 to 0.3; lead, zinc, and impurities (max) 0.5 percent.

Good castings made of this alloy should have the following minimum physical characteristics: Ultimate strength, 35,000 pounds per square inch; yield point, 20,000 pounds per square inch; elongation in 2 inches, 10 percent.

The composition of SAE No. 63 (called leaded gun metal) follows: copper, 86 to 89; tin, 9 to 11; lead, 1 to 2.5; phosphorus (max), 0.25; zinc and impurities (max), 0.50 percent.

Good castings made of this alloy should have the following minimum physical characteristics: Ultimate strength, 30,000 pounds per square inch; yield point, 12,000 pounds per square inch; elongation in 2 inches, 10 percent.

These alloys, especially No. 65, are adapted to chilling for hardness and refinement of grain. No. 65 is to be preferred for use with worms of great hardness and fine accuracy. No. 63 is to be preferred for use with unhardened worms.

*Gear Bushings:* For bronze bushings for gears, SAE No. 64 is recommended of the following analysis: copper, 78.5 to 81.5; tin, 9 to 11; lead, 9 to 11; phosphorus, 0.05 to 0.25; zinc (max), 0.75; other impurities (max), 0.25 percent. Good castings of this alloy should have the following minimum physical characteristics: Ultimate strength, 25,000 pounds per square inch; yield point, 12,000 pounds per square inch; elongation in 2 inches, 8 percent.

*Flanges for Composition Pinions:* For brass flanges for composition pinions ASTM B-30-32T, and SAE No. 40 are recommended. This is a good cast red brass of sufficient strength and hardness to take its share of load and wear when the design is such that the flanges mesh with the mating gear. The composition is as follows: copper, 83 to 86; tin, 4.5 to 5.5; lead, 4.5 to 5.5; zinc, 4.5 to 5.5; iron (max) 0.35; antimony (max), 0.25 percent; aluminum, none. Good castings made from this alloy should have the following minimum physical characteristics: ultimate strength, 27,000 pounds per square inch; yield point, 12,000 pounds per square inch; elongation in 2 inches, 16 percent.

**Materials for Worm Gearing.**—The Hamilton Gear & Machine Co. conducted an extensive series of tests on a variety of materials that might be used for worm gears, to ascertain which material is the most suitable. According to these tests chill-cast nickel-phosphor-bronze ranks first in resistance to wear and deformation. This bronze is composed of approximately 87.5 percent copper, 11 percent tin, 1.5 percent nickel, with from 0.1 to 0.2 percent phosphorus. The worms used in these tests were made from SAE-2315, 3½ percent nickel steel, case-hardened, ground, and polished. The Shore scleroscope hardness of the worms was between 80 and 90. This nickel alloy steel was adopted after numerous tests of a variety of steels, because it provided the necessary strength, together with the degree of hardness required.

The material that showed up second best in these tests was a No. 65 SAE bronze. Navy bronze (88-10-2) containing 2 percent zinc, with no phosphorus, and not chilled, performed satisfactorily at speeds of 600 revolutions per minute, but was not sufficiently strong at lower speeds. Red brass (85-5-5) proved slightly better at from 1500 to 1800 revolutions per minute, but would bend at lower speeds, before it would show actual wear.

**Non-metallic Gearing.**—Non-metallic or composition gearing is used primarily where quietness of operation at high speed is the first consideration. Non-metallic materials are also applied very generally to timing gears and numerous other classes of gearing. Rawhide was used originally for non-metallic gears, but other materials have been introduced that have important advantages. These later materials are sold by different firms under various trade names, such as Micarta, Textolite, Formica, Dilecto, Spauldite, Phenolite, Fibroc, Fabroil, Synthane, Celoron, etc. Most of these gear materials consist of layers of canvas or other material that is impregnated with plastics and forced together under hydraulic pressure, which, in conjunction with the application of heat, forms a dense rigid mass.

Although phenol resin gears in general are resilient, they are self-supporting and require no side plates or shrouds unless subjected to a heavy starting torque. The phenol resinoid element protects these gears from vermin and rodents.

The non-metallic gear materials referred to are generally assumed to have the power-transmitting capacity of cast iron. Although the tensile strength may be considerably less than that of cast iron, the resiliency of these materials enables them to withstand impact and

abrasion to a degree that might result in excessive wear of cast-iron teeth. Thus, composition gearing of impregnated canvas has often proved to be more durable than cast iron.

**Application of Non-metallic Gears.**— The most effective field of use for these non-metallic materials is for high-speed duty. At low speeds, when the starting torque may be high, or when the load may fluctuate widely, or when high shock loads may be encountered, these non-metallic materials do not always prove satisfactory. In general, non-metallic materials should not be used for pitch-line velocities below 600 feet per minute (3.05 m/s).

**Tooth Form:** The best tooth form for non-metallic materials is the 20-degree stub-tooth system. When only a single pair of gears is involved and the center distance can be varied, the best results will be obtained by making the non-metallic driving pinion of all-addendum form, and the driven metal gear with standard tooth proportions. Such a drive will carry from 50 to 75 percent greater loads than one of standard tooth proportions.

**Material for Mating Gear:** For durability under load, the use of hardened steel (over 400 Brinell) for the mating metal gear appears to give the best results. A good second choice for the material of the mating member is cast iron. The use of brass, bronze, or soft steel (under 400 Brinell) as a material for the mating member of phenolic laminated gears leads to excessive abrasive wear.

**Power-Transmitting Capacity of Non-metallic Gears.**— The characteristics of gears made of phenolic laminated materials are so different from those of metal gears that they should be considered in a class by themselves. Because of the low modulus of elasticity, most of the effects of small errors in tooth form and spacing are absorbed at the tooth surfaces by the elastic deformation, and have but little effect on the strength of the gears.

If  $S$  = safe working stress for a given velocity lb/in<sup>2</sup> (MPa)

$S_s$  = allowable static stress lb/in<sup>2</sup> (MPa)

$V$  = pitch-line velocity in feet per minute (meter/s)

then, the recommended practice of the American Gear Manufacturers' Association,

$$S = S_s \times \left( \frac{150}{200 + V} + 0.25 \right) \text{ US Units} \quad S = S_s \times \left( \frac{0.76}{1.016 + V} + 0.25 \right) \text{ SI Units}$$

The value of  $S_s$  for phenolic laminated materials is given as 6000 lb/in<sup>2</sup> (41.36 MPa). The accompanying table gives the safe working stresses  $S$  for different pitch-line velocities. When the value of  $S$  is known, the horsepower capacity is determined by substituting the value of  $S$  for  $S_s$  in the appropriate equations in the section on power-transmitting capacity of plastics gears starting on page 592.

**Safe Working Stresses for Non-metallic Gears**

Pitch-Line Velocity, $V$		Safe Working Stress, $S$		Pitch-Line Velocity, $V$		Safe Working Stress, $S$		Pitch-Line Velocity, $V$		Safe Working Stress, $S$	
fpm	m/s	lb/in <sup>2</sup>	MPa	fpm	m/s	lb/in <sup>2</sup>	MPa	fpm	m/s	lb/in <sup>2</sup>	MPa
600	3.05	2625	18.10	1800	9.14	1950	13.44	4000	20.32	1714	11.82
700	3.56	2500	17.24	2000	10.16	1909	13.16	4500	22.86	1691	11.66
800	4.06	2400	16.54	2200	11.18	1875	12.93	5000	25.40	1673	11.53
900	4.57	2318	15.98	2400	12.19	1846	12.73	5500	27.94	1653	11.40
1000	5.08	2250	15.51	2600	13.20	1821	12.56	6000	30.48	1645	11.34
1200	6.10	2143	14.78	2800	14.22	1800	12.41	6500	33.02	1634	11.27
1400	7.11	2063	14.22	3000	15.24	1781	12.28	7000	35.56	1622	11.18
1600	8.13	2000	13.79	3500	17.78	1743	12.02	7500	38.10	1617	11.15

The tensile strength of the phenolic laminated materials used for gears is slightly less than that of cast iron. These materials are far softer than any metal, and the modulus of elas-

ticity is about one-thirtieth that of steel. In other words, if the tooth load on a steel gear that causes a deformation of 0.001 inch (0.025 mm) were applied to the tooth of a similar gear made of phenolic laminated material, the tooth of the non-metallic gear would be deformed about  $\frac{1}{32}$  inch (0.794 mm). Under these conditions, several things will happen. With all gears, regardless of the theoretical duration of contact, one tooth only will carry the load until the load is sufficient to deform the tooth the amount of the error that may be present. On metal gears, when the tooth has been deformed the amount of the error, the stresses set up in the materials may approach or exceed the elastic limit of the material. Hence, for standard tooth forms and those generated from standard basic racks, it is dangerous to calculate their strength as very much greater than that which can safely be carried on a single tooth. On gears made of phenolic laminated materials, on the other hand, the teeth will be deformed the amount of this normal error without setting up any appreciable stresses in the material, so that the load is actually supported by several teeth.

All materials have their own peculiar and distinct characteristics, so that under certain specific conditions, each material has a field of its own where it is superior to any other. Such fields may overlap to some extent, and only in such overlapping fields are different materials directly competitive. For example, steel is more or less ductile, has a high tensile strength, and a high modulus of elasticity. Cast iron, on the other hand, is not ductile, has a low tensile strength, but a high compressive strength, and a low modulus of elasticity. Hence, when stiffness and high tensile strength are essential, steel is far superior to cast iron. On the other hand, when these two characteristics are unimportant, but high compressive strength and a moderate amount of elasticity are essential, cast iron is superior to steel.

**Preferred Pitch for Non-metallic Gears.**— The pitch of the gear or pinion should bear a reasonable relation either to the power or speed or to the applied torque, as shown by the accompanying table. The upper half of this table is based upon horsepower (kw) transmitted at a given pitch-line velocity. The lower half gives the torque in pounds-feet (N-m) or the torque at a 1-foot (meter) radius. This torque  $T$  for any given horsepower (kw) and speed can be obtained from the following formulas:

$$T = \frac{5252 \times hp}{rpm} \text{ pound-feet} \quad T = \frac{9550 \times kw}{rpm} \text{ N-m}$$

**Bore Sizes for Non-metallic Gears.**— For plain phenolic laminated pinions, that is, pinions without metal end plates, a drive fit of 0.001 inch per inch (or mm/mm) of shaft diameter should be used. For shafts above 2.5 inches (63.5 mm) in diameter, the fit should be constant at 0.0025 to 0.003 inch (0.064–0.076 mm). When metal reinforcing end plates are used, the drive fit should conform to the same standards as used for metal.

The root diameter of a pinion of phenolic laminated type should be such that the minimum distance from the edge of the keyway to the root diameter will be at least equal to the depth of tooth.

**Keyway Stresses for Non-metallic Gears.**— The keyway stress should not exceed 3000 psi (20.68 MPa) on a plain phenolic laminated gear or pinion. The keyway stress is calculated by the formulas:

$$S = \frac{33,000 \times hp}{V \times A} \text{ psi} \quad S = \frac{1,000 \times kw}{V \times A} \text{ MPa}$$

where  $S$  = unit stress in pounds per square inch (newton per square meter)

$hp$  = horsepower transmitted

$kw$  = kilowatt power transmitted

$V$  = peripheral speed of shaft in feet per minute (meter/sec)

$A$  = square inch (square meter) area of keyway in pinion (length  $\times$  height)

If the keyway stress formula is expressed in terms of shaft radius  $r$  (inch or meter) and revolutions per minute, it will read:

**Preferred Pitches for Non-metallic Gears**

Applicable both to rawhide and the phenolic laminated types of materials

<b>Diametral Pitch for Given Horsepower and Pitch Line Velocities</b>			
Horsepower Transmitted	Pitch Line Velocity up to 1000 Feet per Minute	Pitch Line Velocity from 1000 to 2000 Feet per Minute	Pitch Line Velocity over 2000 Feet per Minute
¼-1	8-10	10-12	12-16
1-2	7-8	8-10	10-12
2-3	6-7	7-8	8-10
3-7½	5-6	6-7	7-8
7½-10	4-5	5-6	6-7
10-15	3-4	4-5	5-6
15-25	2½-3	3-4	4-5
25-60	2-2½	2½-3	3-4
60-100	1¾-2	2-2½	2½-3
100-150	1½-1¾	1¾-2	2-2½

<b>Torque in Pounds-feet for Given Diametral Pitch</b>					
Diametral Pitch	Torque in Pounds-feet		Diametral Pitch	Torque in Pounds-feet	
	Minimum	Maximum		Minimum	Maximum
16	1	2	4	50	100
12	2	4	3	100	200
10	4	8	2½	200	450
8	8	15	2	450	900
6	15	30	1½	900	1800
5	30	50	1	1800	3500

$$S = \frac{63,000 \times \text{hp}}{\text{rpm} \times r \times A} \text{ psi} \quad S = \frac{9550 \times \text{kw}}{\text{rpm} \times r \times A} \text{ N-m}$$

When the design is such that the keyway stresses exceed 3000 psi (20.68 MPa), metal reinforcing end plates may be used. Such end plates should not extend beyond the root diameter of the teeth. The distance from the outer edge of the retaining bolt to the root diameter of the teeth shall not be less than a full tooth depth. The use of drive keys should be avoided, but if required, metal end plates should be used on the pinion to take the wedging action of the key.

For phenolic laminated pinions, the face of the mating gear should be the same or slightly greater than the pinion face.

**Invention of Gear Teeth.**—The invention of gear teeth represents a gradual evolution from gearing of primitive form. The earliest evidence we have of an investigation of the problem of *uniform motion* from toothed gearing and the successful solution of that problem dates from the time of Olaf Roemer, the celebrated Danish astronomer, who, in the year 1674, proposed the epicycloidal form to obtain uniform motion. Evidently Robert Willis, professor at the University of Cambridge, was the first to make a practical application of the epicycloidal curve so as to provide for an interchangeable series of gears. Willis gives credit to Charles Étienne Louis Camus for conceiving the idea of interchangeable gears, but claims for himself its first application. The involute tooth was suggested as a theory by early scientists and mathematicians, but it remained for Willis to present it in a practical form. Perhaps the earliest conception of the application of this form of teeth to gears was by Philippe de Lahire, a Frenchman, who considered it, in theory, equally suitable

with the epicycloidal for tooth outlines. This was about 1695 and not long after Roemer had first demonstrated the epicycloidal form. The applicability of the involute had been further elucidated by Leonard Euler, a Swiss mathematician, born at Basel, 1707, who is credited by Willis with being the first to suggest it. Willis devised the Willis odontograph for laying out involute teeth.

A pressure angle of  $14\frac{1}{2}$  degrees was selected for three different reasons. First, because the sine of  $14\frac{1}{2}$  degrees is nearly  $\frac{1}{4}$ , making it convenient in calculation; second, because this angle coincided closely with the pressure angle resulting from the usual construction of epicycloidal gear teeth; third, because the angle of the straight-sided involute rack is the same as the 29-degree worm thread.

**Calculating Replacement-Gear Dimensions from Simple Measurements.**—The following Tables 1a, 1b, and 1c provide formulas with which to calculate the dimensions needed to produce replacement spur, bevel, and helical gears when only the number of teeth, the outside diameter, and the tooth depth of the gear to be replaced are known.

For helical gears, exact helix angles can be obtained by the following procedure.

- 1) Using a common protractor, measure the approximate helix angle  $A$  at the approximate pitch line.
- 2) Place sample or its mating gear on the arbor of a gear hobbing machine.
- 3) Calculate the index and lead gears differentially for the angle obtained by the measurements, and set up the machine as though a gear is to be cut.
- 4) Attach a dial indicator on an adjustable arm to the vertical swivel head, with the indicator plunger in a plane perpendicular to the gear axis and in contact with the tooth face. Contact may be anywhere between the top and the root of the tooth.
- 5) With the power shut off, engage the starting lever and traverse the indicator plunger axially by means of the handwheel.
- 6) If angle  $A$  is correct, the indicator plunger will not move as it traverses the face width of the gear. If it does move from 0, note the amount. Divide the amount of movement by the width of the gear to obtain the tangent of the angle by which to correct angle  $A$ , plus or minus, depending on the direction of indicator movement.

**Table 1a. Formulas for Calculating Spur Gear Dimensions**

Tooth Form and Pressure Angle	Diametral Pitch $P$	Pitch Diameter $D$	Circular Pitch $P_c$	Outside Diameter $O$	Addendum $J$	Dedendum $K$	Whole Tooth Depth $W$	Clearance $K - J$	Tooth Thickness on Pitch Circle
American Standard $14\frac{1}{2}$ - and 20-degree full depth	$\frac{N+2}{O}$	$\frac{N}{P}$	$\frac{3.1416}{P}$	$\frac{N+2}{P}$	$\frac{1}{P}$	$\frac{1.157}{P}$	$\frac{2.157}{P}$	$\frac{0.157}{P}$	$\frac{1.5708}{P}$
American Standard 20-degree stub	$\frac{N+1.6}{O}$	$\frac{N}{P}$	$\frac{3.1416}{P}$	$\frac{N+1.6}{P}$	$\frac{0.8}{P}$	$\frac{1}{P}$	$\frac{1.8}{P}$	$\frac{0.2}{P}$	$\frac{1.5708}{P}$
Fellows 20-degree stub	See Note <sup>a</sup>	$\frac{N}{P_N}$	$\frac{3.1416}{P_N}$	$\frac{N}{P_N} + \frac{2}{P_D}$	$\frac{1}{P_D}$	$\frac{1.25}{P_D}$	$\frac{2.25}{P_D}$	$\frac{0.25}{P_D}$	$\frac{1.5708}{P_N}$

<sup>a</sup> In the Fellows stub-tooth system,  $P_N$  = diametral pitch in numerator of stub-tooth designation and is used to determine circular pitch and number of teeth, and  $P_D$  = diametral pitch in the denominator of stub-tooth designation and is used to determine tooth depth.

$N$  = number of teeth.

**Table 1b. Formulas for Calculating Dimensions of Milled Bevel Gears — 90 degree Shafts<sup>a</sup>**

Tooth Form and Pressure Angle	Tangent of Pitch Cone Angle of Gear, $\tan A$	Tangent of Pitch Cone Angle of Pinion, $\tan a$	Diametral Pitch <sup>b</sup> of Both Gear and Pinion, $P$	Outside Diameter of Gear, $O$ , or Pinion, $o$	Pitch-Cone Radius <sup>b</sup> or Cone Distance, $E$	Tangent of Addendum Angle <sup>b</sup>	Tangent of Dedendum Angle <sup>b</sup>	Cosine of Pitch-Cone Angle <sup>c</sup> of Gear, $\cos A$
American Standard 14½- and 20-degree full depth	$\frac{N_G}{N_P}$	$\frac{N_P}{N_G}$	$\frac{N_G + 2 \cos A}{O}$ or $\frac{N_P + 2 \cos a}{o}$	$\frac{N_G + 2 \cos A}{P}$ or $\frac{N_P + 2 \cos a}{P}$	$\frac{D}{2 \sin A}$ or $\frac{d}{2 \sin a}$	$\frac{2 \sin A}{N_a}$ or $\frac{2 \sin a}{N_p}$	$\frac{2.314 \sin A}{N_G}$ or $\frac{2.314 \sin a}{N_P}$	$\frac{(P \times O) - N_G}{2}$
American Standard 20-degree stub	$\frac{N_G}{N_P}$	$\frac{N_P}{N_G}$	$\frac{N_G + 1.6 \cos A}{O}$ or $\frac{N_P + 1.6 \cos a}{o}$	$\frac{N_G + 1.6 \cos A}{P}$ or $\frac{N_P + 1.6 \cos a}{P}$	$\frac{D}{2 \sin A}$ or $\frac{d}{2 \sin a}$	$\frac{1.6 \sin A}{N_G}$ or $\frac{1.6 \sin a}{N_P}$	$\frac{2 \sin A}{N_G}$ or $\frac{2 \sin a}{N_P}$	$\frac{(P \times O) - N_G}{1.6}$
Fellows 20-degree stub	$\frac{N_G}{N_P}$	$\frac{N_P}{N_G}$	...	$\frac{N_G}{P_N} + \frac{2 \cos A}{P_D}$ or $\frac{N_P}{P_N} + \frac{2 \cos a}{P_D}$	$\frac{D}{2 \sin A}$ or $\frac{d}{2 \sin a}$	$\frac{2 P_N \sin A}{N_G \times P_D}$ or $\frac{2 P_N \sin a}{N_P \times P_D}$	$\frac{2.5 P_N \sin A}{N_G \times P_D}$ or $\frac{2.5 P_N \sin a}{N_P \times P_D}$	$\frac{P_D [(O \times P_N) - N_G]}{2 P_N}$

<sup>a</sup>These formulas do not apply to Gleason System Gearing.

<sup>b</sup>These values are the same for both gear and pinion.

<sup>c</sup>The same formulas apply to the pinion, substituting  $N_P$  for  $N_G$  and  $o$  for  $O$ .

$N_G$  = number of teeth in gear;  $N_P$  = number of teeth in pinion;  $O$  = outside diameter of gear;  $o$  = outside diameter of pinion;  $D$  = pitch diameter of gear =  $N_G + P$ ;  $d$  = pitch diameter of pinion =  $N_P + P$ ;  $P_c$  = circular pitch;  $J$  = addendum;  $K$  = dedendum;  $W$  = whole depth.

See footnote in Table 1a for meaning of  $P_N$  and  $P_D$ . The tooth thickness on the pitch circle is found by means of the formulas in the last column under spur gears.

**Table 1c. Formulas for Calculating Dimensions of Helical Gears**

Tooth Form and Pressure Angle	Normal Diametral Pitch, $P_N$	Diametral Pitch, $P$	Outside Diameter of Blank, $O$	Pitch Diameter, $D$	Cosine of Helix Angle, $A$	Addendum	Dedendum	Whole Depth
American Standard 14½- and 20-degree full depth	$\frac{N + 2 \cos A}{O \times \cos A}$ or $\frac{P}{\cos A}$	$P_N \cos A$ or $\frac{N + 2 \cos A}{O}$	$\frac{N + 2 \cos A}{P_N \cos A}$ or $\frac{N + 2 \cos A}{P}$	$\frac{N}{P_N \cos A}$ or $\frac{N}{P}$	$\frac{P}{P_N}$ or $\frac{N}{O \times P_N - 2}$	$\frac{1}{P_N}$ or $\frac{\cos A}{P}$	$\frac{1.157}{P_N}$ or $\frac{1.157 \cos A}{P}$	$\frac{2.157}{P_N}$ or $\frac{2.157 \cos A}{P}$
American Standard 20-degree stub	$\frac{N + 1.6 \cos A}{O \times \cos A}$ or $\frac{P}{\cos A}$	$P_n \cos A$ or $\frac{N + 1.6 \cos A}{O}$	$\frac{N + 1.6 \cos A}{P_N \cos A}$ or $\frac{N + 1.6 \cos A}{P}$	$\frac{N}{P_N \cos A}$ or $\frac{N}{P}$	$\frac{P}{P_N}$ or $\frac{N}{O \times P_N - 1.6}$	$\frac{0.8}{P_N}$ or $\frac{0.8 \cos A}{P}$	$\frac{1}{P_N}$ or $\frac{\cos A}{P}$	$\frac{1.8}{P_N}$ or $\frac{1.8 \cos A}{P}$
Fellows 20-degree stub	...	...	$\frac{N}{(P_N)_N \cos A} + \frac{2}{(P_N)_D}$	$\frac{N}{(P_N)_N \cos A}$	$\frac{N}{(P_N)_N \left( O - \frac{2}{(P_N)_D} \right)}$	$\frac{1}{(P_N)_D}$	$\frac{1.25}{(P_N)_D}$	$\frac{2.25}{(P_N)_D}$

$P_N$  = normal diametral pitch = normal diametral pitch of cutter or hob used to cut teeth

$P$  = diametral pitch

$O$  = outside diameter of blank

$D$  = pitch diameter

$A$  = helix angle

$N$  = number of teeth

$(P_N)_N$  = normal diametral pitch in numerator of stub-tooth designation, which determines thickness of tooth and number of teeth

$(P_N)_D$  = normal diametral pitch in denominator of stub-tooth designation, which determines the addendum, dedendum, and whole depth

## SPLINES AND SERRATIONS

A splined shaft is one having a series of parallel keys formed integrally with the shaft and mating with corresponding grooves cut in a hub or fitting; this arrangement is in contrast to a shaft having a series of keys or feathers fitted into slots cut into the shaft. The latter construction weakens the shaft to a considerable degree because of the slots cut into it and consequently, reduces its torque-transmitting capacity.

Splined shafts are most generally used in three types of applications: 1) for coupling shafts when relatively heavy torques are to be transmitted without slippage; 2) for transmitting power to slidably-mounted or permanently-fixed gears, pulleys, and other rotating members; and 3) for attaching parts that may require removal for indexing or change in angular position.

Splines having straight-sided teeth have been used in many applications (see SAE Parallel Side Splines for Soft Broached Holes in Fittings); however, the use of splines with teeth of involute profile has steadily increased since 1) involute spline couplings have greater torque-transmitting capacity than any other type; 2) they can be produced by the same techniques and equipment as is used to cut gears; and 3) they have a self-centering action under load even when there is backlash between mating members.

### Involute Splines

**American National Standard Involute Splines\*.**— These splines or multiple keys are similar in form to internal and external involute gears. The general practice is to form the external splines either by hobbing, rolling, or on a gear shaper, and internal splines either by broaching or on a gear shaper. The internal spline is held to basic dimensions and the external spline is varied to control the fit. Involute splines have maximum strength at the base, can be accurately spaced and are self-centering, thus equalizing the bearing and stresses, and they can be measured and fitted accurately.

In American National Standard ANSI B92.1-1970 (R 1993), many features of the 1960 standard are retained, plus the addition of three tolerance classes, for a total of four. The term “involute serration,” formerly applied to involute splines with 45-degree pressure angle, has been deleted and the standard now includes involute splines with 30-, 37.5-, and 45-degree pressure angles. Tables for these splines have been rearranged accordingly. The term “serration” will no longer apply to splines covered by this Standard.

The Standard has only one fit class for all side fit splines: the former Class 2 fit. Class 1 fit has been deleted because of its infrequent use. The major diameter of the flat root side fit spline has been changed and a tolerance applied to include the range of the 1950 and the 1960 standards. The interchangeability limitations with splines made to previous standards are given later in the section entitled “Interchangeability.”

There have been no tolerance nor fit changes to the major diameter fit section.

The Standard recognizes the fact that proper assembly between mating splines is dependent only on the spline being within effective specifications from the tip of the tooth to the form diameter. Therefore, on side fit splines, the internal spline major diameter now is shown as a maximum dimension and the external spline minor diameter is shown as a minimum dimension. The minimum internal major diameter and the maximum external minor diameter must clear the specified form diameter and thus do not need any additional control.

The spline specification tables now include a greater number of tolerance level selections. These tolerance classes were added for greater selection to suit end product needs. The selections differ only in the tolerance as applied to space width and tooth thickness.

\* See American National Standard ANSI B92.2M-1980 (R1989), Metric Module Involute Splines; also see page 2288.

The tolerance class used in ASA B5.15-1960 is the basis and is now designated as tolerance Class 5. The newer tolerance classes are based on the following formulas:

$$\text{Tolerance Class 4} = \text{Tolerance Class 5} \times 0.71$$

$$\text{Tolerance Class 6} = \text{Tolerance Class 5} \times 1.40$$

$$\text{Tolerance Class 7} = \text{Tolerance Class 5} \times 2.00$$

All dimensions listed in this standard are for the finished part. Therefore, any compensation that must be made for operations that take place during processing, such as heat treatment, must be taken into account when selecting the tolerance level for manufacturing.

The standard has the same internal minimum effective space width and external maximum effective tooth thickness for all tolerance classes and has two types of fit. For tooth side fits, the minimum effective space width and the maximum effective tooth thickness are of equal value. This basic concept makes it possible to have interchangeable assembly between mating splines where they are made to this standard regardless of the tolerance class of the individual members. A tolerance class "mix" of mating members is thus allowed, which often is an advantage where one member is considerably less difficult to produce than its mate, and the "average" tolerance applied to the two units is such that it satisfies the design need. For instance, assigning a Class 5 tolerance to one member and Class 7 to its mate will provide an assembly tolerance in the Class 6 range. The maximum effective tooth thickness is less than the minimum effective space width for major diameter fits to allow for eccentricity variations.

In the event the fit as provided in this standard does not satisfy a particular design need and a specific amount of effective clearance or press fit is desired, the change should be made only to the external spline by a reduction or an increase in effective tooth thickness and a like change in actual tooth thickness. The minimum effective space width, in this standard, is always basic. The basic minimum effective space width should always be retained when special designs are derived from the concept of this standard.

**Terms Applied to Involute Splines.**—The following definitions of involute spline terms, here listed in alphabetical order, are given in the American National Standard. Some of these terms are illustrated in the diagram in [Table 6](#).

*Active Spline Length ( $L_a$ )* is the length of spline that contacts the mating spline. On sliding splines, it exceeds the length of engagement.

*Actual Space Width ( $s$ )* is the circular width on the pitch circle of any single space considering an infinitely thin increment of axial spline length.

*Actual Tooth Thickness ( $t$ )* is the circular thickness on the pitch circle of any single tooth considering an infinitely thin increment of axial spline length.

*Alignment Variation* is the variation of the effective spline axis with respect to the reference axis (see [Fig. 1c](#)).

*Base Circle* is the circle from which involute spline tooth profiles are constructed.

*Base Diameter ( $D_b$ )* is the diameter of the base circle.

*Basic Space Width* is the basic space width for 30-degree pressure angle splines, half the circular pitch. The basic space width for 37.5- and 45-degree pressure angle splines, however, is greater than half the circular pitch. The teeth are proportioned so that the external tooth, at its base, has about the same thickness as the internal tooth at the form diameter. This proportioning results in greater minor diameters than those of comparable involute splines of 30-degree pressure angle.

*Circular Pitch ( $p$ )* is the distance along the pitch circle between corresponding points of adjacent spline teeth.

*Depth of Engagement* is the radial distance from the minor circle of the internal spline to the major circle of the external spline, minus corner clearance and/or chamfer depth.

*Diametral Pitch ( $P$ )* is the number of spline teeth per inch of pitch diameter. The diametral pitch determines the circular pitch and the basic space width or tooth thickness. In conjunction with the number of teeth, it also determines the pitch diameter. (See also Pitch.)

*Effective Clearance ( $c_v$ )* is the effective space width of the internal spline minus the effective tooth thickness of the mating external spline.

*Effective Space Width ( $S_v$ )* of an internal spline is equal to the circular tooth thickness on the pitch circle of an imaginary perfect external spline that would fit the internal spline without looseness or interference considering engagement of the entire axial length of the spline. The minimum effective space width of the internal spline is always basic, as shown in Table 3. Fit variations may be obtained by adjusting the tooth thickness of the external spline.

### Three Types of Involute Spline Variations

Fig. 1a. Lead Variation

Fig. 1b. Parallelism Variation

Fig. 1c. Alignment Variation

*Effective Tooth Thickness ( $t_v$ )* of an external spline is equal to the circular space width on the pitch circle of an imaginary perfect internal spline that would fit the external spline without looseness or interference, considering engagement of the entire axial length of the spline.

*Effective Variation* is the accumulated effect of the spline variations on the fit with the mating part.

*External Spline* is a spline formed on the outer surface of a cylinder.

*Fillet* is the concave portion of the tooth profile that joins the sides to the bottom of the space.

*Fillet Root Splines* are those in which a single fillet in the general form of an arc joins the sides of adjacent teeth.

*Flat Root Splines* are those in which fillets join the arcs of major or minor circles to the tooth sides.

*Form Circle* is the circle which defines the deepest points of involute form control of the tooth profile. This circle along with the tooth tip circle (or start of chamfer circle) determines the limits of tooth profile requiring control. It is located near the major circle on the internal spline and near the minor circle on the external spline.

*Form Clearance* ( $c_F$ ) is the radial depth of involute profile beyond the depth of engagement with the mating part. It allows for looseness between mating splines and for eccentricities between the minor circle (internal), the major circle (external), and their respective pitch circles.

*Form Diameter* ( $D_{Fe}, D_{Fi}$ ) is the diameter of the form circle.

*Internal Spline* is a spline formed on the inner surface of a cylinder.

*Involute Spline* is one having teeth with involute profiles.

*Lead Variation* is the variation of the direction of the spline tooth from its intended direction parallel to the reference axis, also including parallelism and alignment variations (see Fig. 1a). *Note:* Straight (nonhelical) splines have an infinite lead.

*Length of Engagement* ( $L_q$ ) is the axial length of contact between mating splines.

*Machining Tolerance* ( $m$ ) is the permissible variation in actual space width or actual tooth thickness.

*Major Circle* is the circle formed by the outermost surface of the spline. It is the outside circle (tooth tip circle) of the external spline or the root circle of the internal spline.

*Major Diameter* ( $D_o, D_{ri}$ ) is the diameter of the major circle.

*Minor Circle* is the circle formed by the innermost surface of the spline. It is the root circle of the external spline or the inside circle (tooth tip circle) of the internal spline.

*Minor Diameter* ( $D_{re}, D_i$ ) is the diameter of the minor circle.

*Nominal Clearance* is the actual space width of an internal spline minus the actual tooth thickness of the mating external spline. It does not define the fit between mating members, because of the effect of variations.

*Out of Roundness* is the variation of the spline from a true circular configuration.

*Parallelism Variation* is the variation of parallelism of a single spline tooth with respect to any other single spline tooth (see Fig. 1b).

*Pitch* ( $P/P_s$ ) is a combination number of a one-to-two ratio indicating the spline proportions; the upper or first number is the diametral pitch, the lower or second number is the stub pitch and denotes, as that fractional part of an inch, the basic radial length of engagement, both above and below the pitch circle.

*Pitch Circle* is the reference circle from which all transverse spline tooth dimensions are constructed.

*Pitch Diameter* ( $D$ ) is the diameter of the pitch circle.

*Pitch Point* is the intersection of the spline tooth profile with the pitch circle.

*Pressure Angle* ( $\phi$ ) is the angle between a line tangent to an involute and a radial line through the point of tangency. Unless otherwise specified, it is the standard pressure angle.

*Profile Variation* is any variation from the specified tooth profile normal to the flank.

*Spline* is a machine element consisting of integral keys (spline teeth) or keyways (spaces) equally spaced around a circle or portion thereof.

*Standard (Main) Pressure Angle* ( $\phi_D$ ) is the pressure angle at the specified pitch diameter.

*Stub Pitch* ( $P_s$ ) is a number used to denote the radial distance from the pitch circle to the major circle of the external spline and from the pitch circle to the minor circle of the internal spline. The stub pitch for splines in this standard is twice the diametral pitch.

*Total Index Variation* is the greatest difference in any two teeth (adjacent or otherwise) between the actual and the perfect spacing of the tooth profiles.

*Total Tolerance* ( $m + \lambda$ ) is the machining tolerance plus the variation allowance.

*Variation Allowance* ( $\lambda$ ) is the permissible effective variation.

**Tooth Proportions.**— There are 17 pitches: 2.5/5, 3/6, 4/8, 5/10, 6/12, 8/16, 10/20, 12/24, 16/32, 20/40, 24/48, 32/64, 40/80, 48/96, 64/128, 80/160, and 128/256. The numerator in this fractional designation is known as the diametral pitch and controls the pitch diameter; the denominator, which is always double the numerator, is known as the stub pitch and controls the tooth depth. For convenience in calculation, only the numerator is used in the formulas given and is designated as  $P$ . Diametral pitch, as in gears, means the number of teeth per inch of pitch diameter.

**Table 1** shows the symbols and **Table 2** the formulas for basic tooth dimensions of involute spline teeth of various pitches. Basic dimensions are given in **Table 3**.

**Table 1. American National Standard Involute Spline Symbols  
ANSI B92.1-1970, R1993**

$c_v$	effective clearance	$M_i$	measurement between pins, internal spline
$c_F$	form clearance	$N$	number of teeth
$D$	pitch diameter	$P$	diametral pitch
$D_b$	base diameter	$P_s$	stub pitch
$D_{ci}$	pin contact diameter, internal spline	$p$	circular pitch
$D_{ce}$	pin contact diameter, external spline	$r_f$	fillet radius
$D_{Fe}$	form diameter, external spline	$s$	actual space width, circular
$D_{Fi}$	form diameter, internal spline	$s_v$	effective space width, circular
$D_i$	minor diameter, internal spline	$s_c$	allowable compressive stress, psi
$D_o$	major diameter, external spline	$s_s$	allowable shear stress, psi
$D_{re}$	minor diameter, external spline (root)	$t$	actual tooth thickness, circular
$D_{ri}$	major diameter, internal spline (root)	$t_v$	effective tooth thickness, circular
$d_e$	diameter of measuring pin for external spline	$\lambda$	variation allowance
$d_i$	diameter of measuring pin for internal spline	$\epsilon$	involute roll angle
$K_e$	change factor for external spline	$\phi$	pressure angle
$K_i$	change factor for internal spline	$\phi_D$	standard pressure angle
$L$	spline length	$\phi_{ci}$	pressure angle at pin contact diameter, internal spline
$L_a$	active spline length	$\phi_{ce}$	pressure angle at pin contact diameter, external spline
$L_g$	length of engagement	$\phi_i$	pressure angle at pin center, internal spline
$m$	machining tolerance	$\phi_e$	pressure angle at pin center, external spline
$M_e$	measurement over pins, external spline	$\phi_F$	pressure angle at form diameter

**Tooth Numbers.**— The American National Standard covers involute splines having tooth numbers ranging from 6 to 60 with a 30- or 37.5-degree pressure angle and from 6 to 100 with a 45-degree pressure angle. In selecting the number of teeth for a given spline application, it is well to keep in mind that there are no advantages to be gained by using odd numbers of teeth and that the diameters of splines with odd tooth numbers, particularly internal splines, are troublesome to measure with pins since no two tooth spaces are diametrically opposite each other.

**Types and Classes of Involute Spline Fits.**— Two types of fits are covered by the American National Standard for involute splines: the side fit and the major diameter fit. Dimensional data for flat root side fit, flat root major diameter fit, and fillet root side fit splines are tabulated in this standard for 30-degree pressure angle splines, but for only the fillet root side fit for 37.5- and 45-degree pressure angle splines.

*Side Fit:* In the side fit, the mating members contact only on the sides of the teeth; major and minor diameters are clearance dimensions. The tooth sides act as drivers and centralize the mating splines.

*Major Diameter Fit:* Mating parts for this fit contact at the major diameter for centralizing. The sides of the teeth act as drivers. The minor diameters are clearance dimensions.

The major diameter fit provides a minimum effective clearance that will allow for contact and location at the major diameter with a minimum amount of location or centralizing effect by the sides of the teeth. The major diameter fit has only one space width and tooth thickness tolerance which is the same as side fit Class 5.

A fillet root may be specified for an external spline, even though it is otherwise designed to the flat root side fit or major diameter fit standard. An internal spline with a fillet root can be used only for the side fit.

**Classes of Tolerances.**— This standard includes four classes of tolerances on space width and tooth thickness. This has been done to provide a range of tolerances for selection to suit a design need. The classes are variations of the former single tolerance which is now Class 5 and are based on the formulas shown in the footnote of Table 4. All tolerance classes have the same minimum effective space width and maximum effective tooth thickness limits so that a mix of classes between mating parts is possible.

**Table 4. Maximum Tolerances for Space Width and Tooth Thickness of Tolerance Class 5 Splines ANSI B92.1-1970, R1993 (Values shown in ten thousandths; 20 = 0.0020)**

No. of Teeth	Pitch, $P/P_s$

Variation	2	3	4	5	6	7	8	9	10	11	12	13

For other tolerance classes: Class 4 =  $0.71 \times$  Tabulated value

Class 5 = As tabulated in table

Class 6 =  $1.40 \times$  Tabulated value

Class 7 =  $2.00 \times$  Tabulated value

**Fillets and Chamfers.**— Spline teeth may have either a flat root or a rounded fillet root.

*Flat Root Splines:* are suitable for most applications. The fillet that joins the sides to the bottom of the tooth space, if generated, has a varying radius of curvature. Specification of this fillet is usually not required. It is controlled by the form diameter, which is the diameter at the deepest point of the desired true involute form (sometimes designated as TIF).

When flat root splines are used for heavily loaded couplings that are not suitable for fillet root spline application, it may be desirable to minimize the stress concentration in the flat root type by specifying an approximate radius for the fillet.

Because internal splines are stronger than external splines due to their broad bases and high pressure angles at the major diameter, broaches for flat root internal splines are normally made with the involute profile extending to the major diameter.

*Fillet Root Splines:* are recommended for heavy loads because the larger fillets provided reduce the stress concentrations. The curvature along any generated fillet varies and cannot be specified by a radius of any given value.

External splines may be produced by generating with a pinion-type shaper cutter or with a hob, or by cutting with no generating motion using a tool formed to the contour of a tooth space. External splines are also made by cold forming and are usually of the fillet root design. Internal splines are usually produced by broaching, by form cutting, or by generating with a shaper cutter. Even when full-tip radius tools are used, each of these cutting methods produces a fillet contour with individual characteristics. Generated spline fillets are curves related to the prolate epicycloid for external splines and the prolate hypocycloid for internal splines. These fillets have a minimum radius of curvature at the point where the fillet is tangent to the external spline minor diameter circle or the internal spline major diameter circle and a rapidly increasing radius of curvature up to the point where the fillet comes tangent to the involute profile.

*Chamfers and Corner Clearance:* In major diameter fits, it is always necessary to provide corner clearance at the major diameter of the spline coupling. This clearance is usually effected by providing a chamfer on the top corners of the external member. This method may not be possible or feasible because of the following:

- a) If the external member is roll formed by plastic deformation, a chamfer cannot be provided by the process.
- b) A semitopping cutter may not be available.
- c) When cutting external splines with small numbers of teeth, a semitopping cutter may reduce the width of the top land to a prohibitive point.

In such conditions, the corner clearance can be provided on the internal spline, as shown in Fig. 2.

When this option is used, the form diameter may fall in the protuberance area.

Fig. 2. Internal corner clearance

**Spline Variations.**— The maximum allowable variations for involute splines are listed in Table 4.

*Profile Variation:* The reference profile, from which variations occur, passes through the point used to determine the actual space width or tooth thickness. This is either the pitch point or the contact point of the standard measuring pins.

Profile variation is positive in the direction of the space and negative in the direction of the tooth. Profile variations may occur at any point on the profile for establishing effective fits and are shown in Table 4.

*Lead Variations:* The lead tolerance for the total spline length applies also to any portion thereof unless otherwise specified.

*Out of Roundness:* This condition may appear merely as a result of index and profile variations given in Table 4 and requires no further allowance. However, heat treatment and deflection of thin sections may cause out of roundness, which increases index and profile variations. Tolerances for such conditions depend on many variables and are therefore not tabulated. Additional tooth and/or space width tolerance must allow for such conditions.

*Eccentricity:* Eccentricity of major and minor diameters in relation to the effective diameter of side fit splines should not cause contact beyond the form diameters of the mating splines, even under conditions of maximum effective clearance. This standard does not establish specific tolerances.

Eccentricity of major diameters in relation to the effective diameters of major diameter fit splines should be absorbed within the maximum material limits established by the tolerances on major diameter and effective space width or effective tooth thickness.

If the alignment of mating splines is affected by eccentricity of locating surfaces relative to each other and/or the splines, it may be necessary to decrease the effective and actual tooth thickness of the external splines in order to maintain the desired fit condition. This standard does not include allowances for eccentric location.

**Effect of Spline Variations.**— Spline variations can be classified as index variations, profile variations, or lead variations.

*Index Variations:* These variations cause the clearance to vary from one set of mating tooth sides to another. Because the fit depends on the areas with minimum clearance, index variations reduce the effective clearance.

*Profile Variations:* Positive profile variations affect the fit by reducing effective clearance. Negative profile variations do not affect the fit but reduce the contact area.

*Lead Variations:* These variations will cause clearance variations and therefore reduce the effective clearance.

*Variation Allowance:* The effect of individual spline variations on the fit (effective variation) is less than their total, because areas of more than minimum clearance can be altered without changing the fit. The variation allowance is 60 percent of the sum of twice the positive profile variation, the total index variation and the lead variation for the length of engagement. The variation allowances in Table 4 are based on a lead variation for an assumed length of engagement equal to one-half the pitch diameter. Adjustment may be required for a greater length of engagement.

**Effective and Actual Dimensions.**— Although each space of an internal spline may have the same width as each tooth of a perfect mating external spline, the two may not fit because of variations of index and profile in the internal spline. To allow the perfect external spline to fit in any position, all spaces of the internal spline must then be widened by the amount of interference. The resulting width of these tooth spaces is the *actual* space width of the internal spline. The *effective* space width is the tooth thickness of the perfect mating external spline. The same reasoning applied to an external spline that has variations of index and profile when mated with a perfect internal spline leads to the concept of effective

tooth thickness, which exceeds the actual tooth thickness by the amount of the effective variation.

The effective space width of the internal spline minus the effective tooth thickness of the external spline is the effective clearance and defines the fit of the mating parts. (This statement is strictly true only if high points of mating parts come into contact.) Positive effective clearance represents looseness or backlash. Negative effective clearance represents tightness or interference.

**Space Width and Tooth Thickness Limits.**— The variation of actual space width and actual tooth thickness within the machining tolerance causes corresponding variations of effective dimensions, so that there are four limit dimensions for each component part.

These variations are shown diagrammatically in [Table 5](#).

**Table 5. Specification Guide for Space Width and Tooth Thickness**  
*ANSI B92.1-1970, R1993*

Dimensions of Variations, Clearances, and Tolerances on Part			Dimensioning Method		
Dimension	Effective	Actual	Standard	Alternatives	
				A	B
Space Width of Internal Spine		Max	Required	Required	Ref.
		Min	Ref.	Ref.	Ref.
			Ref.	Required	Required
			Required	Required	Required
(Basic)	$\frac{\pi}{2P}$		Required	Required	Required
Tooth Thickness of External Spine		Max	Ref.	Required	Required
		Min	Ref.	Ref.	Ref.
			Required	Required	Ref.
			Required	Required	Ref.

The minimum effective space width is always basic. The maximum effective tooth thickness is the same as the minimum effective space width except for the major diameter fit. The major diameter fit maximum effective tooth thickness is less than the minimum effective space width by an amount that allows for eccentricity between the effective spline and the major diameter. The permissible variation of the effective clearance is divided between the internal and external splines to arrive at the maximum effective space width and the minimum effective tooth thickness. Limits for the actual space width and actual tooth thickness are constructed from suitable variation allowances.

**Use of Effective and Actual Dimensions.**— Each of the four dimensions for space width and tooth thickness shown in [Table 5](#) has a definite function.

*Minimum Effective Space Width and Maximum Effective Tooth Thickness:* These dimensions control the minimum effective clearance, and must always be specified.

*Minimum Actual Space Width and Maximum Actual Tooth Thickness:* These dimensions cannot be used for acceptance or rejection of parts. If the actual space width is less than the minimum without causing the effective space width to be undersized, or if the actual tooth thickness is more than the maximum without causing the effective tooth thickness to be oversized, the effective variation is less than anticipated; such parts are desirable and not defective. The specification of these dimensions as processing reference dimensions is optional. They are also used to analyze undersize effective space width or oversize effective tooth thickness conditions to determine whether or not these conditions are caused by excessive effective variation.

*Maximum Actual Space Width and Minimum Actual Tooth Thickness:* These dimensions control machining tolerance and limit the effective variation. The spread between

these dimensions, reduced by the effective variation of the internal and external spline, is the maximum effective clearance. Where the effective variation obtained in machining is appreciably less than the variation allowance, these dimensions must be adjusted in order to maintain the desired fit.

*Maximum Effective Space Width and Minimum Effective Tooth Thickness:* These dimensions define the maximum effective clearance but they do not limit the effective variation. They may be used, in addition to the maximum actual space width and minimum actual tooth thickness, to prevent the increase of maximum effective clearance due to reduction of effective variations. The notation “inspection optional” may be added where maximum effective clearance is an assembly requirement, but does not need absolute control. It will indicate, without necessarily adding inspection time and equipment, that the actual space width of the internal spline must be held below the maximum, or the actual tooth thickness of the external spline above the minimum, if machining methods result in less than the allowable variations. Where effective variation needs no control or is controlled by laboratory inspection, these limits may be substituted for maximum actual space width and minimum actual tooth thickness.

**Combinations of Involute Spline Types.**— Flat root side fit internal splines may be used with fillet root external splines where the larger radius is desired on the external spline for control of stress concentrations. This combination of fits may also be permitted as a design option by specifying, for the minimum root diameter of the external, the value of the minimum root diameter of the fillet root external spline and noting this as “optional root.”

A design option may also be permitted to provide either flat root internal or fillet root internal by specifying, for the maximum major diameter, the value of the maximum major diameter of the fillet root internal spline and noting this as “optional root.”

**Interchangeability.**— Splines made to this standard may interchange with splines made to older standards. Exceptions are listed below.

*External Splines:* These external splines will mate with older internal splines as follows:

Year	Major Dia. Fit	Flat Root Side Fit	Fillet Root Side Fit
1946	Yes	No (A) <sup>a</sup>	No (A)
1950 <sup>b</sup>	Yes (B)	Yes (B)	Yes (C)
1950 <sup>c</sup>	Yes (B)	No (A)	Yes (C)
1957 SAE	Yes	No (A)	Yes (C)
1960	Yes	No (A)	Yes (C)

<sup>a</sup> For exceptions A, B, C, see the paragraph on *Exceptions* that follows.

<sup>b</sup> Full dedendum.

<sup>c</sup> Short dedendum.

*Internal Splines:* These will mate with older external splines as follows:

Year	Major Dia. Fit	Flat Root Side Fit	Fillet Root Side Fit
1946	No (D) <sup>a</sup>	No (E)	No (D)
1950	Yes (F)	Yes	Yes (C)
1957 SAE	Yes (G)	Yes	Yes
1960	Yes (G)	Yes	Yes

<sup>a</sup> For exceptions C, D, E, F, G, see the paragraph on *Exceptions* that follows.

**Table 6. Spline Terms, Symbols, and Drawing Data, 30-Degree Pressure Angle, Flat Root Side Fit ANSI B92.1-1970, R1993**

The fit shown is used in restricted areas (as with tubular parts with wall thickness too small to permit use of fillet roots, and to allow hobbing closer to shoulders, etc.) and for economy (when hobbing, shaping, etc., and using shorter broaches for the internal member).

Press fits are not tabulated because their design depends on the degree of tightness desired and must allow for such factors as the shape of the blank, wall thickness, material, hardness, thermal expansion, etc. Close tolerances or selective size grouping may be required to limit fit variations.

#### Drawing Data

Internal Involute Spline Data		External Involute Spline Data	
Flat Root Side Fit		Flat Root Side Fit	
Number of Teeth	xx	Number of Teeth	xx
Pitch	xx/xx	Pitch	xx/xx
Pressure Angle	30°	Pressure Angle	30°
Base Diameter	x.xxxxx Ref	Base Diameter	x.xxxxx Ref
Pitch Diameter	x.xxxxx Ref	Pitch Diameter	x.xxxxx Ref
Major Diameter	x.xxx max	Major Diameter	x.xxx/x.xxx
Form Diameter	x.xxx	Form Diameter	x.xxx
Minor Diameter	x.xxx/x.xxx	Minor Diameter	x.xxx min
Circular Space Width		Circular Tooth Thickness	
Max Actual	x.xxxx	Max Effective	x.xxxx
Min Effective	x.xxxx	Min Actual	x.xxxx
The following information may be added as required:		The following information may be added as required:	
Max Measurement Between Pins	x.xxx Ref	Min Measurement Over Pins	x.xxxx Ref
Pin Diameter	x.xxxx	Pin Diameter	x.xxxx

The above drawing data are required for the spline specifications. The standard system is shown; for alternate systems, see Table 5. Number of x's indicates number of decimal places normally used.

*Exceptions:*

a) The external major diameter, unless chamfered or reduced, may interfere with the internal form diameter on flat root side fit splines. Internal splines made to the 1957 and 1960 standards had the same dimensions as shown for the major diameter fit splines in this standard.

b) For 15 teeth or less, the minor diameter of the internal spline, unless chamfered, will interfere with the form diameter of the external spline.

c) For 9 teeth or less, the minor diameter of the internal spline, unless chamfered, will interfere with form diameter of the external spline.

d) The internal minor diameter, unless chamfered, will interfere with the external form diameter.

e) The internal minor diameter, unless chamfered, will interfere with the external form diameter.

f) For 10 teeth or less, the minimum chamfer on the major diameter of the external spline may not clear the internal form diameter.

g) Depending upon the pitch of the spline, the minimum chamfer on the major diameter may not clear the internal form diameter.

**Drawing Data.**— It is important that uniform specifications be used to show complete information on detail drawings of splines. Much misunderstanding will be avoided by following the suggested arrangement of dimensions and data as given in [Table 6](#). The number of x's indicates the number of decimal places normally used. With this tabulated type of spline specifications, it is usually not necessary to show a graphic illustration of the spline teeth.

**Spline Data and Reference Dimensions.**— Spline data are used for engineering and manufacturing purposes. Pitch and pressure angle are not subject to individual inspection.

As used in this standard, *reference* is an added notation or modifier to a dimension, specification, or note when that dimension, specification, or note is:

- 1) Repeated for drawing clarification.
- 2) Needed to define a nonfeature datum or basis from which a form or feature is generated.
- 3) Needed to define a nonfeature dimension from which other specifications or dimensions are developed.
- 4) Needed to define a nonfeature dimension at which toleranced sizes of a feature are specified.
- 5) Needed to define a nonfeature dimension from which control tolerances or sizes are developed or added as useful information.

Any dimension, specification, or note that is noted "REF" should not be used as a criterion for part acceptance or rejection.

**Estimating Key and Spline Sizes and Lengths.**— [Fig. 3](#) may be used to estimate the size of American Standard involute splines required to transmit a given torque. It also may be used to find the outside diameter of shafts used with single keys. After the size of the shaft is found, the proportions of the key can be determined from [Table 1](#) on page 2488.

Curve A is for flexible splines with teeth hardened to Rockwell C 55-65. For these splines, lengths are generally made equal to or somewhat greater than the pitch diameter for diameters below  $1\frac{1}{4}$  inches; on larger diameters, the length is generally one-third to two-thirds the pitch diameter. Curve A also applies for a single key used as a fixed coupling, the length of the key being one to one and one-quarter times the shaft diameter. The stress in the shaft, neglecting stress concentration at the keyway, is about 7500 pounds per square inch. See also *Effect of Keyways on Shaft Strength* starting on page 293.

Curve B represents high-capacity single keys used as fixed couplings for stresses of 9500 pounds per square inch, neglecting stress concentration. Key-length is one to one and one-quarter times shaft diameter and both shaft and key are of moderately hard heat-treated

Fig. 3. Chart for Estimating Involute Spline Size Based on Diameter-Torque Relationships steel. This type of connection is commonly used to key commercial flexible couplings to motor or generator shafts.

Curve C is for multiple-key fixed splines with lengths of three-quarters to one and one-quarter times pitch diameter and shaft hardness of 200-300 BHN.

Curve D is for high-capacity splines with lengths one-half to one times the pitch diameter. Hardnesses up to Rockwell C 58 are common and in aircraft applications the shaft is generally hollow to reduce weight.

Curve E represents a solid shaft with 65,000 pounds per square inch shear stress. For hollow shafts with inside diameter equal to three-quarters of the outside diameter the shear stress would be 95,000 pounds per square inch.

*Length of Splines:* Fixed splines with lengths of one-third the pitch diameter will have the same shear strength as the shaft, assuming uniform loading of the teeth; however, errors in spacing of teeth result in only half the teeth being fully loaded. Therefore, for balanced strength of teeth and shaft the length should be two-thirds the pitch diameter. If weight is not important, however, this may be increased to equal the pitch diameter. In the case of flexible splines, long lengths do not contribute to load carrying capacity when there is misalignment to be accommodated. Maximum effective length for flexible splines may be approximated from Fig. 4.

**Formulas for Torque Capacity of Involute Splines.**— The formulas for torque capacity of 30-degree involute splines given in the following paragraphs are derived largely from an article “When Splines Need Stress Control” by D. W. Dudley, *Product Engineering*, Dec. 23, 1957.

In the formulas that follow the symbols used are as defined on page 2272 with the following additions:  $D_h$  = inside diameter of hollow shaft, inches;  $K_a$  = application factor from Table 7;  $K_m$  = load distribution factor from Table 8;  $K_f$  = fatigue life factor from Table 9;  $K_w$

Fig. 4. Maximum Effective Length for Fixed and Flexible Splines = wear life factor from Table 10;  $L_e$  = maximum effective length from Fig. 4, to be used in stress formulas even though the actual length may be greater;  $T$  = transmitted torque, pound-inches. For fixed splines without helix modification, the effective length  $L_e$  should never exceed  $5000 D^{3.5} \div T$ .

Table 7. Spline Application Factors,  $K_a$

Power Source	Type of Load			
	Uniform (Generator, Fan)	Light Shock (Oscillating Pumps, etc.)	Intermittent Shock (Actuating Pumps, etc.)	Heavy Shock (Punches, Shears, etc.)
	Application Factor, $K_a$			
Uniform (Turbine, Motor)	1.0	1.2	1.5	1.8
Light Shock (Hydraulic Motor)	1.2	1.3	1.8	2.1
Medium Shock (Internal Combustion Engine)	2.0	2.2	2.4	2.8

Table 8. Load Distribution Factors,  $K_m$ , for Misalignment of Flexible Splines

Misalignment, inches per inch	Load Distribution Factor, $K_m^a$			
	½-in. Face Width	1-in. Face Width	2-in. Face Width	4-in. Face Width
0.001	1	1	1	1½
0.002	1	1	1½	2
0.004	1	1½	2	2½
0.008	1½	2	2½	3

<sup>a</sup> For fixed splines,  $K_m=1$ .

**Table 9. Fatigue-Life Factors,  $K_f$ , for Splines**

No. of Torque Cycles <sup>a</sup>	Fatigue-Life Factor, $K_f$	
	Unidirectional	Fully-reversed
1,000	1.8	1.8
10,000	1.0	1.0
100,000	0.5	0.4
1,000,000	0.4	0.3
10,000,000	0.3	0.2

<sup>a</sup> A torque cycle consists of one start and one stop, not the number of revolutions.

**Table 10. Wear Life Factors,  $K_w$ , for Flexible Splines**

Number of Revolutions of Spline	Life Factor, $K_w$	Number of Revolutions of Spline	Life Factor, $K_w$
10,000	4.0	100,000,000	1.0
100,000	2.8	1,000,000,000	0.7
1,000,000	2.0	10,000,000,000	0.5
10,000,000	1.4	...	...

Wear life factors, unlike fatigue life factors given in Table 9, are based on the total number of revolutions of the spline, since each revolution of a flexible spline results in a complete cycle of rocking motion which contributes to spline wear.

*Definitions:* A *fixed* spline is one which is either shrink fitted or loosely fitted but piloted with rings at each end to prevent rocking of the spline which results in small axial movements that cause wear. A *flexible* spline permits some rocking motion such as occurs when the shafts are not perfectly aligned. This flexing or rocking motion causes axial movement and consequently wear of the teeth. Straight-toothed flexible splines can accommodate only small angular misalignments (less than 1 deg.) before wear becomes a serious problem. For greater amounts of misalignment (up to about 5 deg.), crowned splines are preferable to reduce wear and end-loading of the teeth.

*Shear Stress Under Roots of External Teeth:* For a transmitted torque  $T$ , the torsional shear stress induced in the shaft under the root diameter of an external spline is:

$$S_s = \frac{16TK_a}{\pi D_{re}^3 K_f} \quad \text{for a solid shaft} \quad (1)$$

$$S_s = \frac{16TD_{re}K_a}{\pi(D_{re}^4 - D_h^4)K_f} \quad \text{for a hollow shaft} \quad (2)$$

The computed stress should not exceed the values in Table 11.

**Table 11. Allowable Shear, Compressive, and Tensile Stresses for Splines**

Material	Hardness		Max. Allowable Stress			
			Shear Stress, psi	Compressive Stress, psi		Tensile Stress, psi
	Brinell	Rockwell C		Straight	Crowned	
Steel	160-200	—	20,000	1,500	6,000	22,000
	230-260	—	30,000	2,000	8,000	32,000
	302-351	33-38	40,000	3,000	12,000	45,000
Surface-hardened Steel	—	48-53	40,000	4,000	16,000	45,000
Case-hardened Steel	—	58-63	50,000	5,000	20,000	55,000
Through-hardened Steel (Aircraft Quality)	—	42-46	45,000	—	—	50,000

*Shear Stress at the Pitch Diameter of Teeth:* The shear stress at the pitch line of the teeth for a transmitted torque  $T$  is:

$$S_s = \frac{4TK_aK_m}{DNL_e t K_f} \quad (3)$$

The factor of 4 in (3) assumes that only half the teeth will carry the load because of spacing errors. For poor manufacturing accuracies, change the factor to 6.

The computed stress should not exceed the values in **Table 11**.

*Compressive Stresses on Sides of Spline Teeth:* Allowable compressive stresses on splines are very much lower than for gear teeth since non-uniform load distribution and misalignment result in unequal load sharing and end loading of the teeth.

$$\text{For flexible splines, } S_c = \frac{2TK_mK_a}{DNL_e h K_w} \quad (4)$$

$$\text{For fixed splines, } S_c = \frac{2TK_mK_a}{9DNL_e h K_f} \quad (5)$$

In these formulas,  $h$  is the depth of engagement of the teeth, which for flat root splines is  $0.9/P$  and for fillet root splines is  $1/P$ , approximately.

The stresses computed from **Formulas (4) and (5)** should not exceed the values in **Table 11**.

*Bursting Stresses on Splines:* Internal splines may burst due to three kinds of tensile stress: 1) tensile stress due to the radial component of the transmitted load; 2) centrifugal tensile stress; and 3) tensile stress due to the tangential force at the pitch line causing bending of the teeth.

$$\text{Radial load tensile stress, } S_1 = \frac{T \tan \phi}{\pi D t_w L} \quad (6)$$

where  $t_w$  = wall thickness of internal spline = outside diameter of spline sleeve minus spline major diameter, all divided by 2.  $L$  = full length of spline.

$$\text{Centrifugal tensile stress, } S_2 = \frac{1.656 \times (\text{rpm})^2 (D_{oi}^2 + 0.212 D_{ri}^2)}{1,000,000} \quad (7)$$

where  $D_{oi}$  = outside diameter of spline sleeve.

$$\text{Beam loading tensile stress, } S_3 = \frac{4T}{D^2 L_e Y} \quad (8)$$

In **Equation (8)**,  $Y$  is the Lewis form factor obtained from a tooth layout. For internal splines of 30-deg. pressure angle a value of  $Y = 1.5$  is a satisfactory estimate. The factor 4 in (8) assumes that only half the teeth are carrying the load.

The total tensile stress tending to burst the rim of the external member is:

$$S_r = [K_a K_m (S_1 + S_3) + S_2] / K_f; \text{ and should be less than those in } \mathbf{Table 11}.$$

**Crowned Splines for Large Misalignments.**— As mentioned on page 2284, crowned splines can accommodate misalignments of up to about 5 degrees. Crowned splines have considerably less capacity than straight splines of the same size if both are operating with precise alignment. However, when large misalignments exist, the crowned spline has greater capacity.

American Standard tooth forms may be used for crowned external members so that they may be mated with straight internal members of Standard form.

The accompanying diagram of a crowned spline shows the radius of the crown  $r_1$ ; the radius of curvature of the crowned tooth,  $r_2$ ; the pitch diameter of the spline,  $D$ ; the face width,  $F$ ; and the relief or crown height  $A$  at the ends of the teeth. The crown height  $A$  should always be made somewhat greater than one-half the face width multiplied by the tangent of the misalignment angle. For a crown height  $A$ , the approximate radius of curvature  $r_2$  is  $F^2 \div 8A$ , and  $r_1 = r_2 \tan \phi$ , where  $\phi$  is the pressure angle of the spline.

For a torque  $T$ , the compressive stress on the teeth is:

$$S_c = 2290 \sqrt{2T \div DNhr_2}$$

and should be less than the value in **Table 11**.

**Fretting Damage to Splines and Other Machine Elements.**— Fretting is wear that occurs when cyclic loading, such as vibration, causes two surfaces in intimate contact to undergo small oscillatory motions with respect to each other. During fretting, high points or asperities of the mating surfaces adhere to each other and small particles are pulled out, leaving minute, shallow pits and a powdery debris. In steel parts exposed to air, the metallic debris oxidizes rapidly and forms a red, rustlike powder or sludge; hence, the coined designation “fretting corrosion.”

Fretting is mechanical in origin and has been observed in most materials, including those that do not oxidize, such as gold, platinum, and nonmetallics; hence, the corrosion accompanying fretting of steel parts is a secondary factor.

Fretting can occur in the operation of machinery subject to motion or vibration or both. It can destroy close fits; the debris may clog moving parts; and fatigue failure may be accelerated because stress levels to initiate fatigue in fretted parts are much lower than for undamaged material. Sites for fretting damage include interference fits; splined, bolted, keyed, pinned, and riveted joints; between wires in wire rope; flexible shafts and tubes; between leaves in leaf springs; friction clamps; small amplitude-of-oscillation bearings; and electrical contacts.

Vibration or cyclic loadings are the main causes of fretting. If these factors cannot be eliminated, greater clamping force may reduce movement but, if not effective, may actually worsen the damage. Lubrication may delay the onset of damage; hard plating or surface hardening methods may be effective, not by reducing fretting, but by increasing the fatigue strength of the material. Plating soft materials having inherent lubricity onto contacting surfaces is effective until the plating wears through.

**Involute Spline Inspection Methods.**— Spline gages are used for routine inspection of production parts.

Analytical inspection, which is the measurement of individual dimensions and variations, may be required:

- a) To supplement inspection by gages, for example, where NOT GO composite gages are used in place of NOT GO sector gages and variations must be controlled.
- b) To evaluate parts rejected by gages.
- c) For prototype parts or short runs where spline gages are not used.

d) To supplement inspection by gages where each individual variation must be restrained from assuming too great a portion of the tolerance between the minimum material actual and the maximum material effective dimensions.

**Inspection with Gages.**— A variety of gages is used in the inspection of involute splines.

*Types of Gages:* A composite spline gage has a full complement of teeth. A sector spline gage has two diametrically opposite groups of teeth. A sector plug gage with only two teeth per sector is also known as a “paddle gage.” A sector ring gage with only two teeth per sector is also known as a “snap ring gage.” A progressive gage is a gage consisting of two or more adjacent sections with different inspection functions. Progressive GO gages are physical combinations of GO gage members that check consecutively first one feature or one group of features, then their relationship to other features. GO and NOT GO gages may also be combined physically to form a progressive gage.

Fig. 5. Space width and tooth-thickness inspection

*GO and NOT GO Gages:* GO gages are used to inspect maximum material conditions (maximum external, minimum internal dimensions). They may be used to inspect an individual dimension or the relationship between two or more functional dimensions. They control the minimum looseness or maximum interference.

NOT GO gages are used to inspect minimum material conditions (minimum external, maximum internal dimensions), thereby controlling the maximum looseness or minimum interference. Unless otherwise agreed upon, a product is acceptable only if the NOT GO gage does not enter or go on the part. A NOT GO gage can be used to inspect only one dimension. An attempt at simultaneous NOT GO inspection of more than one dimension could result in failure of such a gage to enter or go on (acceptance of part), even though all but one of the dimensions were outside product limits. In the event all dimensions are outside the limits, their relationship could be such as to allow acceptance.

*Effective and Actual Dimensions:* The effective space width and tooth thickness are inspected by means of an accurate mating member in the form of a composite spline gage.

The actual space width and tooth thickness are inspected with sector plug and ring gages, or by measurements with pins.

**Measurements with Pins.**— The actual space width of internal splines, and the actual tooth thickness of external splines, may be measured with pins. These measurements do not determine the fit between mating parts, but may be used as part of the analytic inspection of splines to evaluate the effective space width or effective tooth thickness by approximation.

*Formulas for 2-Pin Measurement Between Pins:* For measurement *between* pins of internal splines using the symbols given on page 2272:

1) Find involute of pressure angle at pin center:

$$\text{inv } \phi_i = \frac{s}{D} + \text{inv } \phi_d - \frac{d_i}{D_b}$$

2) Find the value of  $\phi_i$  in degrees, in the involute function tables beginning on page 106. Find  $\sec \phi_i = 1/\cosine \phi_i$  in the trig tables, pages 102 through 104, using interpolation to obtain higher accuracy.

3) Compute measurement,  $M_i$ , between pins:

For even numbers of teeth:  $M_i = D_b \sec \phi_i - d_i$

For odd numbers of teeth:  $M_i = (D_b \cos 90^\circ/N) \sec \phi_i - d_i$

where  $d_i = 1.7280/P$  for  $30^\circ$  and  $37.5^\circ$  standard pressure angle ( $\phi_D$ ) splines

$d_i = 1.9200/P$  for  $45^\circ$  pressure angle splines

*Example:* Find the measurement between pins for *maximum* actual space width of an internal spline of  $30^\circ$  pressure angle, tolerance class 4,  $\frac{3}{6}$  diametral pitch, and 20 teeth.

*Solution:* The maximum actual space width to be substituted for  $s$  in Step 1 above is obtained as follows: In Table 5, page 2278, the maximum actual space width is the sum of the minimum effective space width (second column) and  $\lambda + m$  (third column). The minimum effective space width  $s_v$  from Table 2, page 2273, is  $\pi/2P = \pi/(2 \times 3)$ . The values of  $\lambda$  and  $m$  from Table 4, page 2275, are, for a class 4 fit,  $\frac{3}{6}$  diametral pitch, 20-tooth spline:  $\lambda = 0.0027 \times 0.71 = 0.00192$ ; and  $m = 0.00176 \times 0.71 = 0.00125$ , so that  $s = 0.52360 + 0.00192 + 0.00125 = 0.52677$ .

Other values required for Step 1 are:

$$D = N \div P = 20 \div 3 = 6.66666$$

$$\text{inv } \phi_D = \text{inv } 30^\circ = 0.053751 \text{ from a calculator}$$

$$d_i = 1.7280/3 = 0.57600$$

$$D_b = D \cos \phi_D = 6.66666 \times 0.86603 = 5.77353$$

The computation is made as follows:

$$1) \text{inv } \phi_i = 0.52677/6.66666 + 0.053751 - 0.57600/5.77353 = 0.03300$$

$$2) \text{ From a calculator, } \phi_i = 25^\circ 46.18' \text{ and } \sec \phi_i = 1.11044$$

$$3) M_i = 5.77353 \times 1.11044 - 0.57600 = 5.8352 \text{ inches}$$

*Formulas for 2-Pin Measurement Over Pins:* For measurement *over* pins of external splines:

1) Find involute of pressure angle at pin center:

$$\text{inv } \phi_e = \frac{t}{D} + \text{inv } \phi_D + \frac{d_e}{D_b} - \frac{\pi}{N}$$

2) Find the value of  $\phi_e$  and  $\sec \phi_e$  from the involute function tables beginning on page 106.

3) Compute measurement,  $M_e$ , over pins:

For even numbers of teeth:  $M_e = D_b \sec \phi_e + d_e$

For odd numbers of teeth:  $M_e = (D_b \cos 90^\circ/N) \sec \phi_e + d_e$

where  $d_e = 1.9200/P$  for all external splines

**American National Standard Metric Module Splines.**— ANSI B92.2M-1980 (R1989) is the American National Standards Institute version of the International Standards Organization involute spline standard. It is not a “soft metric” conversion of any previous, inch-based, standard,\* and splines made to this hard metric version are not intended for use with components made to the B92.1 or other, previous standards. The ISO 4156 Standard from

\* A “soft” conversion is one in which dimensions in inches, when multiplied by 25.4 will, after being appropriately rounded off, provide equivalent dimensions in millimeters. In a “hard” system the tools of production, such as hobs, do not bear a usable relation to the tools in another system; i.e., a 10 diametral pitch hob calculates to be equal to a 2.54 module hob in the metric module system, a hob that does not exist in the metric standard.

which this one is derived is the result of a cooperative effort between the ANSI B92 committee and other members of the ISO/TC 14-2 involute spline committee.

Many of the features of the previous standard, ANSI B92.1-1970 (R1993), have been retained such as: 30-, 37.5-, and 45-degree pressure angles; flat root and fillet root side fits; the four tolerance classes 4, 5, 6, and 7; tables for a single class of fit; and the effective fit concept.

Among the major differences are: use of modules of from 0.25 through 10 mm in place of diametral pitch; dimensions in millimeters instead of inches; the “basic rack”; removal of the major diameter fit; and use of ISO symbols in place of those used previously. Also, provision is made for calculating three defined clearance fits.

The Standard recognizes that proper assembly between mating splines is dependent only on the spline being within effective specifications from the tip of the tooth to the form diameter. Therefore, the internal spline major diameter is shown as a maximum dimension and the external spline minor diameter is shown as a minimum dimension. The minimum internal major diameter and the maximum external minor diameter must clear the specified form diameter and thus require no additional control. All dimensions are for the finished part; any compensation that must be made for operations that take place during processing, such as heat treatment, must be considered when selecting the tolerance level for manufacturing.

The Standard provides the same internal minimum effective space width and external maximum effective tooth thickness for all tolerance classes. This basic concept makes possible interchangeable assembly between mating splines regardless of the tolerance class of the individual members, and permits a tolerance class “mix” of mating members. This arrangement is often an advantage when one member is considerably less difficult to produce than its mate, and the “average” tolerance applied to the two units is such that it satisfies the design need. For example, by specifying Class 5 tolerance for one member and Class 7 for its mate, an assembly tolerance in the Class 6 range is provided.

If a fit given in this Standard does not satisfy a particular design need, and a specific clearance or press fit is desired, the change shall be made only to the external spline by a reduction of, or an increase in, the effective tooth thickness and a like change in the actual tooth thickness. The minimum effective space width is always basic and this basic width should always be retained when special designs are derived from the concept of this Standard.

*Spline Terms and Definitions:* The spline terms and definitions given for American National Standard ANSI B92.1-1970 (R1993) described in the preceding section may be used in regard to ANSI B92.2M-1980 (R1989). The 1980 Standard utilizes ISO symbols in place of those used in the 1970 Standard; these differences are shown in [Table 12](#).

*Dimensions and Tolerances:* Dimensions and tolerances of splines made to the 1980 Standard may be calculated using the formulas given in [Table 13](#). These formulas are for metric module splines in the range of from 0.25 to 10 mm metric module of side-fit design and having pressure angles of 30-, 37.5-, and 45-degrees. The standard modules in the system are: 0.25; 0.5; 0.75; 1; 1.25; 1.5; 1.75; 2; 2.5; 3; 4; 5; 6; 8; and 10. The range of from 0.5 to 10 module applies to all splines except 45-degree fillet root splines; for these, the range of from 0.25 to 2.5 module applies.

*Fit Classes:* Four classes of side fit splines are provided: spline fit class H/h having a minimum effective clearance,  $c_v = es = 0$ ; classes H/f, H/e, and H/d having tooth thickness modifications,  $es$ , of  $f$ ,  $e$ , and  $d$ , respectively, to provide progressively greater effective clearance  $c_v$ . The tooth thickness modifications  $h$ ,  $f$ ,  $e$ , and  $d$  in [Table 14](#) are fundamental deviations selected from ISO R286, “ISO System of Limits and Fits.” They are applied to the external spline by shifting the tooth thickness total tolerance below the basic tooth thickness by the amount of the tooth thickness modification to provide a prescribed minimum effective clearance  $c_v$ .

**Table 12. Comparison of Symbols Used in ANSI B92.2M-1980 (R1989) and Those in ANSI B92.1-1970, R1993**

<sup>a</sup> Internal splines are fit class H and have space width modification from basic space width equal to zero; thus, an H/h fit class has effective clearance  $c_v = 0$ .

*Note:* The values listed in this table are taken from ISO R286 and have been computed on the basis of the geometrical mean of the size ranges shown. Values in **boldface** type do not comply with any documented rule for rounding but are those used by ISO R286; they are used in this table to comply with established international practice.

*Basic Rack Profiles:* The basic rack profile for the standard pressure angle splines are shown in Figs. 6a, 6b, 6c, and 6d. The dimensions shown are for maximum material condition and for fit class H/h.

**Spline Machining Tolerances and Variations.**— The total tolerance ( $T + \lambda$ ), Table 15, is the sum of Effective Variation,  $\lambda$ , and a Machining Tolerance,  $T$ .

**Table 15. Space Width and Tooth Thickness Total Tolerance, ( $T + \lambda$ ), in Millimeters**

Spline Tolerance Class	Formula for Total Tolerance, ( $T + \lambda$ )	Spline Tolerance Class	Formula for Total Tolerance, ( $T + \lambda$ )	In these formulas, $i^*$ and $i^{**}$ are tolerance units based upon pitch diameter and tooth thickness, respectively: $i^* = 0.001(0.45^3\sqrt{D} + 0.001D)$ for $D \leq 500$ mm $= 0.001(0.004D + 2.1)$ for $D > 500$ mm $i^{**} = 0.001(0.45^3\sqrt{S_{\text{bsc}}} + 0.001S_{\text{bsc}})$
4	$10i^* + 40i^{**}$	6	$25i^* + 100i^{**}$	
5	$16i^* + 64i^{**}$	7	$40i^* + 160i^{**}$	

*Effective Variation:* The effective variation,  $\lambda$ , is the combined effect that total index variation, positive profile variation, and tooth alignment variation has on the effective fit of mating involute splines. The effect of the individual variations is less than the sum of the allowable variations because areas of more than minimum clearance can have profile, tooth alignment, or index variations without changing the fit. It is also unlikely that these variations would occur in their maximum amounts simultaneously on the same spline. For this reason, total index variation, total profile variation, and tooth alignment variation are used to calculate the combined effect by the following formula:

$$\lambda = 0.6 \sqrt{(F_p)^2 + (f_f)^2 + (F_\beta)^2} \text{ millimeters}$$

The above variation is based upon a length of engagement equal to one-half the pitch diameter of the spline; adjustment of  $\lambda$  may be required for a greater length of engagement. Formulas for values of  $F_p$ ,  $f_f$ , and  $F_\beta$  used in the above formula are given in Table 16.

**Table 16. Formulas for  $F_p$ ,  $f_f$ , and  $F_\beta$  used to calculate  $\lambda$**

Spline Tolerance Class	Total Index Variation, in mm, $F_p$	Total Profile Variation, in mm, $f_f$	Total Lead Variation, in mm, $F_\beta$
4	$0.001(2.5\sqrt{mZ\pi/2} + 6.3)$	$0.001[1.6m(1 + 0.0125Z) + 10]$	$0.001(0.8\sqrt{g} + 4)$
5	$0.001(3.55\sqrt{mZ\pi/2} + 9)$	$0.001[2.5m(1 + 0.0125Z) + 16]$	$0.001(1.0\sqrt{g} + 5)$
6	$0.001(5\sqrt{mZ\pi/2} + 12.5)$	$0.001[4m(1 + 0.0125Z) + 25]$	$0.001(1.25\sqrt{g} + 6.3)$
7	$0.001(7.1\sqrt{mZ\pi/2} + 18)$	$0.001[6.3m(1 + 0.0125Z) + 40]$	$0.001(2\sqrt{g} + 10)$

$g$  = length of spline in millimeters.

These values are used with the applicable formulas in Table 13.

**Machining Tolerance:** A value for machining tolerance may be obtained by subtracting the effective variation,  $\lambda$ , from the total tolerance ( $T + \lambda$ ). Design requirements or specific processes used in spline manufacture may require a different amount of machining tolerance in relation to the total tolerance.

**British Standard Straight Splines.**— British Standard BS 2059:1953, "Straight-sided Splines and Serrations", was introduced because of the widespread development and use of splines, and because of the increasing use of involute splines it was necessary to provide a separate standard for straight-sided splines. BS 2059 was prepared on the hole basis, the hole being the constant member, and provided for different fits to be obtained by varying the size of the splined or serrated shaft. Part 1 of the standard deals with 6 splines only, irrespective of the shaft diameter, with two depths termed shallow and deep. The splines are bottom fitting with top clearance.

The standard contains three different grades of fit, based on the principle of variations in the diameter of the shaft at the root of the splines, in conjunction with variations in the widths of the splines themselves. Fit 1 represents the condition of closest fit and is designed for minimum backlash. Fit 2 has a positive allowance and is designed for ease of assembly, and Fit 3 has a larger positive allowance for applications that can accept such clearances. All these splines allow for clearance on the sides of the splines (the widths), but in Fit 1, the minor diameters of the hole and the shaft may be of identical size.

Assembly of a splined shaft and hole requires consideration of the designed profile of each member, and this consideration should concentrate on the maximum diameter of the shafts and the widths of external splines, in association with the minimum diameter of the hole and the widths of the internal splineways. In other words, both internal and external splines are in the maximum metal condition. The accuracy of spacing of the splines will affect the quality of the resultant fit. If angular positioning is inaccurate, or the splines are not parallel with the axis, there will be interference between the hole and the shaft.

Part 2 of the Standard deals with straight-sided 90 serrations having nominal diameters from 0.25 to 6.0 inches. Provision is again made for three grades of fits, the basic constant being the serrated hole size. Variations in the fits of these serrations is obtained by varying the sizes of the serrations on the shaft, and the fits are related to flank bearing, the depth of engagement being constant for each size and allowing positive clearance at crest and root.

Fit 1 is an interference fit intended for permanent or semi-permanent assemblies. Heating to expand the internally-serrated member is needed for assembly. Fit 2 is a transition fit intended for assemblies that require accurate location of the serrated members, but must allow disassembly. In maximum metal conditions, heating of the outside member may be needed for assembly. Fit. 3 is a clearance or sliding fit, intended for general applications.

Maximum and minimum dimensions for the various features are shown in the Standard for each class of fit. Maximum metal conditions presupposes that there are no errors of form such as spacing, alignment, or roundness of hole or shaft. Any compensation needed for such errors may require reduction of a shaft diameter or enlargement of a serrated bore, but the measured effective size must fall within the specified limits.

British Standard BS 3550:1963, "Involute Splines", is complementary to BS 2059, and the basic dimensions of all the sizes of splines are the same as those in the ANSI/ASME B5.15-1960, for major diameter fit and side fit. The British Standard uses the same terms and symbols and provides data and guidance for design of straight involute splines of 30 pressure angle, with tables of limiting dimensions. The standard also deals with manufacturing errors and their effect on the fit between mating spline elements. The range of splines covered is:

Side fit, flat root, 2.5/5.0 to 32/64 pitch, 6 to 60 splines.

Major diameter, flat root, 3.0/6.0 to 16/32 pitch, 6 to 60 splines.

Side fit, fillet root, 2.5/5.0 to 48/96 pitch, 6 to 60 splines.

British Standard BS 6186, Part 1:1981, "Involute Splines, Metric Module, Side Fit" is identical with sections 1 and 2 of ISO 4156 and with ANSI B92.2M-1980 (R1989) "Straight Cylindrical Involute Splines, Metric Module, Side Fit – Generalities, Dimensions and Inspection".

**S.A.E. Standard Spline Fittings.**—The S.A.E. spline fittings (Tables 18 through 21 inclusive) have become an established standard for many applications in the agricultural, automotive, machine tool, and other industries. The dimensions given, in inches, apply only to soft broached holes. Dimensions are illustrated in Figs. 7a, 7b, and 7c. The tolerances given may be readily maintained by usual broaching methods. The tolerances selected for the large and small diameters may depend upon whether the fit between the mating part, as finally made, is on the large or the small diameter. The other diameter, which is designed for clearance, may have a larger manufactured tolerance. If the final fit between the parts is on the sides of the spline only, larger tolerances are permissible for both the large and small diameters. The spline should not be more than 0.006 inch per foot out of parallel with respect to the shaft axis. No allowance is made for corner radii to obtain clearance. Radii at the corners of the spline should not exceed 0.015 inch.

<sup>a</sup> *Torque Capacity of Spline Fittings*: The torque capacities of the different spline fittings are given in the columns headed "T." The torque capacity, per inch of bearing length at 1000 pounds pressure per square inch on the sides of the spline, may be determined by the following formula, in which  $T$  = torque capacity in inch-pounds per inch of length,  $N$  = number of splines,  $R$  = mean radius or radial distance from center of hole to center of spline,  $h$  = depth of spline:  $T = 1000NRh$

**Table 22. Formulas for Determining Dimensions of S.A.E. Standard Splines**

Sixteen	0.098D	0.045D	0.910D	0.070D	0.860D	0.095D	0.810D

<sup>a</sup> Four splines for fits A and B only.

The formulas in the table above give the maximum dimensions for  $W$ ,  $h$ , and  $d$ , as listed in Tables 18 through 21 inclusive.

**Polygon-Type Shaft Connections.**— Involute-form and straight-sided splines are used for both fixed and sliding connections between machine members such as shafts and gears. Polygon-type connections, so called because they resemble regular polygons but with curved sides, may be used similarly. German DIN Standards 32711 and 32712 include data for three- and four-sided metric polygon connections. Data for 11 of the sizes shown in those Standards, but converted to inch dimensions by Stoffel Polygon Systems, are given in the accompanying table.

Dimensions  $Q$  and  $R$  shown on the diagrams are approximate and used only for drafting purposes:  $Q \approx 7.5e$ ;  $R \approx D_I/2 + 16e$ .

Dimension  $D_M = D_I + 2e$ . Pressure angle  $B_{\max}$  is approximately  $344e/D_M$  degrees for three sides, and  $299e/D_M$  degrees for four sides.

Tolerances: ISO H7 tolerances apply to bore dimensions. For shafts, g6 tolerances apply for sliding fits; k7 tolerances for tight fits.

**Choosing Between Three- and Four-Sided Designs:** Three-sided designs are best for applications in which no relative movement between mating components is allowed while torque is transmitted. If a hub is to slide on a shaft while under torque, four-sided designs, which have larger pressure angles  $B_{\max}$  than those of three-sided designs, are better suited to sliding even though the axial force needed to move the sliding member is approximately 50 percent greater than for comparable involute spline connections.

*Strength of Polygon Connections:* In the formulas that follow,

$H_w$  = hub width, inches     $H_t$  = hub wall thickness, inches

$M_b$  = bending moment, lb-inch

$M_t$  = torque, lb-inch

$Z$  = section modulus, bending, in<sup>3</sup>

=  $0.098D_M^4/D_A$  for three sides    =  $0.15D_I^3$  for four sides

$Z_p$  = polar section modulus, torsion, in<sup>3</sup>

=  $0.196D_M^4/D_A$  for three sides    =  $0.196D_I^3$  for four sides

$D_A$  and  $D_M$ . See table footnotes.

$S_b$  = bending stress, allowable, lb/in<sup>2</sup>

$S_s$  = shearing stress, allowable, lb/in<sup>2</sup>

$S_t$  = tensile stress, allowable, lb/in<sup>2</sup>

For shafts,         $M_t$  (maximum) =  $S_s Z_p$

$M_b$  (maximum) =  $S_b Z$

For bores,

$$H_t \text{ (minimum)} = K \sqrt{\frac{M_t}{S_t H_w}}$$

in which  $K = 1.44$  for three sides except that if  $D_M$  is greater than 1.375 inches, then  $K = 1.2$ ;  $K = 0.7$  for four sides.

Failure may occur in the hub of a polygon connection if the hoop stresses in the hub exceed the allowable tensile stress for the material used. The radial force tending to expand the rim and cause tensile stresses is calculated from

$$\text{Radial Force, lb} = \frac{2M_t}{D_I n \tan(B_{max} + 11.3)}$$

This radial force acting at  $n$  points may be used to calculate the tensile stress in the hub wall using formulas from strength of materials.

*Manufacturing:* Polygon shaft profiles may be produced using conventional machining processes such as hobbing, shaping, contour milling, copy turning, and numerically controlled milling and grinding. Bores are produced using broaches, spark erosion, gear shapers with generating cutters of appropriate form, and, in some instances, internal grinders of special design. Regardless of the production methods used, points on both of the mating profiles may be calculated from the following equations:

$$X = \left(\frac{D_I}{2} + e\right) \cos \alpha - e \cos(n\alpha) \cos \alpha - ne \sin(n\alpha) \sin \alpha$$

$$Y = \left(\frac{D_I}{2} + e\right) \sin \alpha - e \cos(n\alpha) \sin \alpha + ne \sin(n\alpha) \cos \alpha$$

In these equations,  $\alpha$  is the angle of rotation of the workpiece from any selected reference position;  $n$  is the number of polygon sides, either 3 or 4;  $D_I$  is the diameter of the inscribed circle shown on the diagram in the table; and  $e$  is the dimension shown on the diagram in the table and may be used as a setting on special polygon grinding machines. The value of  $e$  determines the shape of the profile. A value of 0, for example, results in a circular shaft having a diameter of  $D_I$ . The values of  $e$  in the table were selected arbitrarily to provide suitable proportions for the sizes shown.

## CAMS AND CAM DESIGN

**Classes of Cams.**—Cams may, in general, be divided into two classes: uniform motion cams and accelerated motion cams. The uniform motion cam moves the follower at the same rate of speed from the beginning to the end of the stroke; but as the movement is started from zero to the full speed of the uniform motion and stops in the same abrupt way, there is a distinct shock at the beginning and end of the stroke, if the movement is at all rapid. In machinery working at a high rate of speed, therefore, it is important that cams are so constructed that sudden shocks are avoided when starting the motion or when reversing the direction of motion of the follower.

The uniformly accelerated motion cam is suitable for moderate speeds, but it has the disadvantage of sudden changes in acceleration at the beginning, middle and end of the stroke. A cycloidal motion curve cam produces no abrupt changes in acceleration and is often used in high-speed machinery because it results in low noise, vibration and wear. The cycloidal motion displacement curve is so called because it can be generated from a cycloid which is the locus of a point of a circle rolling on a straight line.\*

**Cam Follower Systems.**—The three most used cam and follower systems are radial and offset translating roller follower, **Figs. 1a** and **1b**; and the swinging roller follower, **Fig. 1c**. When the cam rotates, it imparts a translating motion to the roller followers in **Figs. 1a** and **1b** and a swinging motion to the roller follower in **Fig. 1c**. The motion of the follower is, of course, dependent on the shape of the cam; and the following section on displacement diagrams explains how a favorable motion is obtained so that the cam can rotate at high speed without shock.

Fig. 1a. Radial Translating Roller Follower

Fig. 1b. Offset Translating Roller Follower

Fig. 1c. Swinging Roller Follower

Fig. 2a. Closed-Track Cam

Fig. 2b. Closed-Track Cam With Two Rollers

The arrangements in **Figs. 1a**, **1b**, and **1c** show open-track cams. In **Figs. 2a** and **2b** the roller is forced to move in a closed track. Open-track cams build smaller than closed-track

\* Jensen, P. W., *Cam Design and Manufacture*, Industrial Press Inc.

cams but, in general, springs are necessary to keep the roller in contact with the cam at all times. Closed-track cams do not require a spring and have the advantage of positive drive throughout the rise and return cycle. The positive drive is sometimes required as in the case where a broken spring would cause serious damage to a machine.

**Displacement Diagrams.**— Design of a cam begins with the displacement diagram. A simple displacement diagram is shown in Fig. 3. One cycle means one whole revolution of the cam; i.e., one cycle represents  $360^\circ$ . The horizontal distances  $T_1, T_2, T_3, T_4$  are expressed in units of time (seconds); or radians or degrees. The vertical distance,  $h$ , represents the maximum “rise” or stroke of the follower.

Fig. 3. A Simple Displacement Diagram

The displacement diagram of Fig. 3 is not a very favorable one because the motion from rest (the horizontal lines) to constant velocity takes place instantaneously and this means that accelerations become infinitely large at these transition points.

*Types of Cam Displacement Curves:* A variety of cam curves are available for moving the follower. In the following sections only the rise portions of the total time-displacement diagram are studied. The return portions can be analyzed in a similar manner. Complex cams are frequently employed which may involve a number of rise-dwell-return intervals in which the rise and return aspects are quite different. To analyze the action of a cam it is necessary to study its time-displacement and associated velocity and acceleration curves. The latter are based on the first and second time-derivatives of the equation describing the time-displacement curve:

$$y = \text{displacement} = f(t) \quad \text{or} \quad y = f(\phi)$$

$$v = \frac{dy}{dt} = \text{velocity} = \omega \frac{dy}{d\phi}$$

$$a = \frac{d^2y}{dt^2} = \text{acceleration} = \omega^2 \frac{d^2y}{d\phi^2}$$

#### Meaning of Symbols and Equivalent Relations

$y$  = displacement of follower, inch (m)

$h$  = maximum displacement of follower, inch (m)

$t$  = time for cam to rotate through angle  $\phi$ , sec, =  $\phi/\omega$ , sec

$T$  = time for cam to rotate through angle  $\beta$ , sec, =  $\beta/\omega$ , or  $\beta/6N$ , sec

$\phi$  = cam angle rotation for follower displacement  $y$ , degrees

$\beta$  = cam angle rotation for total rise  $h$ , degrees

$v$  = velocity of follower, in/sec (m/s)

$a$  = follower acceleration, in/sec<sup>2</sup> (m/s<sup>2</sup>)

$t/T = \phi/\beta$

$N$  = cam speed, rpm

$\omega$  = angular velocity of cam, degrees/sec =  $\beta/T = \phi/t = d\phi/dt = 6N$

$\omega_R$  = angular velocity of cam, radians/sec =  $\pi\omega/180$

- $W$  = effective weight, lbs (kg)  
 $g$  = gravitational constant = 386 in/sec<sup>2</sup> (9.81 m/s<sup>2</sup>)  
 $f(t)$  = means a function of  $t$   
 $f(\phi)$  = means a function of  $\phi$   
 $R_{min}$  = minimum radius to the cam pitch curve, inch (m)  
 $R_{max}$  = maximum radius to the cam pitch curve, inch (m)  
 $r_f$  = radius of cam follower roller, inch (m)  
 $\rho$  = radius of curvature of cam pitch curve (path of center of roller follower), inch (m)  
 $R_c$  = radius of curvature of actual cam surface, in., (m) =  $\rho - r_f$  for convex surface;  
 =  $\rho + r_f$  for concave surface.

Fig. 4. Cam Displacement, Velocity, and Acceleration Curves for Constant Velocity Motion  
 Four displacement curves are of the greatest utility in cam design.

1. *Constant-Velocity Motion:* (Fig. 4)

$$y = h \frac{t}{T} \quad \text{or} \quad y = \frac{h\phi}{\beta} \quad (1a)$$

$$v = \frac{dy}{dt} = \frac{h}{T} \quad \text{or} \quad v = \frac{h\omega}{\beta} \quad (1b) \quad \left. \vphantom{\frac{dy}{dt}} \right\} 0 < t < T$$

$$a = \frac{d^2y}{dt^2} = 0^* \quad (1c)$$

\* Except at  $t=0$  and  $t=T$  where the acceleration is theoretically infinite.

This motion and its disadvantages were mentioned previously. While in the unaltered form shown it is rarely used except in very crude devices, nevertheless, the advantage of uniform velocity is an important one and by modifying the start and finish of the follower stroke this form of cam motion can be utilized. Such modification is explained in the section *Displacement Diagram Synthesis* on page 2304.

2. *Parabolic Motion:* (Fig. 5)

**For  $0 \leq t \leq T/2$  and  $0 \leq \phi \leq \beta/2$**

$$y = 2h(t/T)^2 = 2h(\phi/\beta)^2 \quad (2a)$$

$$v = 4ht/T^2 = 4h\omega\phi/\beta^2 \quad (2b)$$

$$a = 4h/T^2 = 4h(\omega/\beta)^2 \quad (2c)$$

**For  $T/2 \leq t \leq T$  and  $\beta/2 \leq \phi \leq \beta$**

$$y = h[1 - 2(1 - t/T)^2] = h[1 - 2(1 - \phi/\beta)^2] \quad (2d)$$

$$v = 4h/T(1 - t/T) = (4h\omega/\beta)(1 - \phi/\beta) \quad (2e)$$

$$a = -4h/T^2 = -4h(\omega/\beta)^2 \quad (2f)$$

Examination of the above formulas shows that the velocity is zero when  $t=0$  and  $y=0$ ; and when  $t=T$  and  $y=h$ .

Fig. 5. Cam Displacement, Velocity, and Acceleration Curves for Parabolic Motion

The most important advantage of this curve is that for a given angle of rotation and rise it produces the smallest possible acceleration. However, because of the sudden changes in acceleration at the beginning, middle, and end of the stroke, shocks are produced. If the follower system were perfectly rigid with no backlash or flexibility, this would be of little significance. But such systems are mechanically impossible to build and a certain amount of impact is caused at each of these changeover points.

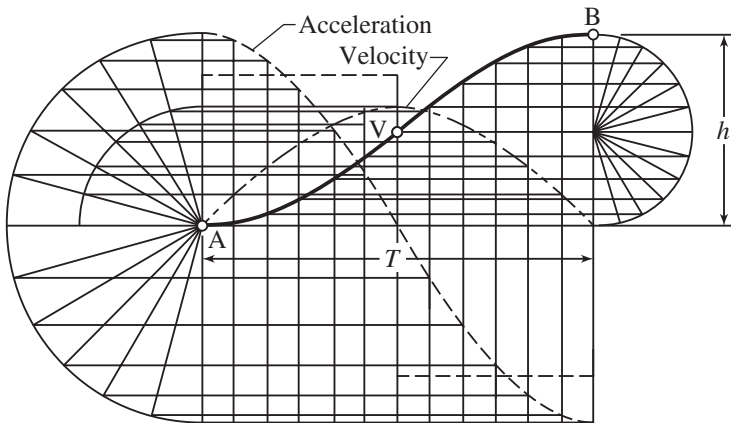

Fig. 6. Cam Displacement, Velocity, and Acceleration Curves for Simple Harmonic Motion

### 3. Simple Harmonic Motion: (Fig. 6)

$$y = \frac{h}{2} \left[ 1 - \cos\left(\frac{180^\circ t}{T}\right) \right] \quad \text{or} \quad y = \frac{h}{2} \left[ 1 - \cos\left(\frac{180^\circ \phi}{\beta}\right) \right] \quad (3a)$$

$$v = \frac{h}{2} \cdot \frac{\pi}{T} \sin\left(\frac{180^\circ t}{T}\right) \quad \text{or} \quad v = \frac{h}{2} \cdot \frac{\pi \omega}{\beta} \sin\left(\frac{180^\circ \phi}{\beta}\right) \quad (3b) \quad \left. \vphantom{\frac{h}{2} \cdot \frac{\pi \omega}{\beta}} \right\} 0 \leq t \leq T$$

$$a = \frac{h}{2} \cdot \frac{\pi^2}{T^2} \cos\left(\frac{180^\circ t}{T}\right) \quad \text{or} \quad a = \frac{h}{2} \cdot \left(\frac{\pi \omega}{\beta}\right)^2 \cos\left(\frac{180^\circ \phi}{\beta}\right) \quad (3c)$$

Smoothness in velocity and acceleration during the stroke is the advantage inherent in this curve. However, the instantaneous changes in acceleration at the beginning and end of the stroke tend to cause vibration, noise, and wear. As can be seen from Fig. 6, the maximum acceleration values occur at the ends of the stroke. Thus, if inertia loads are to be overcome by the follower, the resulting forces cause stresses in the members. These forces are in many cases much larger than the externally applied loads.

## 4. Cycloidal Motion: (Fig. 7)

$$y = h \left[ \frac{t}{T} - \frac{1}{2\pi} \sin \left( \frac{360^\circ t}{T} \right) \right] \quad \text{or} \quad y = h \left[ \frac{\phi}{\beta} - \frac{1}{2\pi} \sin \left( \frac{360^\circ \phi}{\beta} \right) \right] \quad (4a)$$

$$v = \frac{h}{T} \left[ 1 - \cos \left( \frac{360^\circ t}{T} \right) \right] \quad \text{or} \quad v = \frac{h\omega}{\beta} \left[ 1 - \cos \left( \frac{360^\circ \phi}{\beta} \right) \right] \quad (4b) \quad \left. \vphantom{\frac{h}{T}} \right\} 0 \leq t \leq T$$

$$a = \frac{2\pi h}{T^2} \sin \left( \frac{360^\circ t}{T} \right) \quad \text{or} \quad a = \frac{2\pi h\omega^2}{\beta^2} \sin \left( \frac{360^\circ \phi}{\beta} \right) \quad (4c)$$

Fig. 7. Cam Displacement, Velocity, and Acceleration Curves for Cycloidal Motion

This time-displacement curve has excellent acceleration characteristics; there are no abrupt changes in its associated acceleration curve. The maximum value of the acceleration of the follower for a given rise and time is somewhat higher than that of the simple harmonic motion curve. In spite of this, the cycloidal curve is used often as a basis for designing cams for high-speed machinery because it results in low levels of noise, vibration, and wear.

**Displacement Diagram Synthesis.**—The straight-line graph shown in Fig. 3 has the important advantage of uniform velocity. This is so desirable that many cams based on this graph are used. To avoid impact at the beginning and end of the stroke, a modification is introduced at these points. There are many different types of modifications possible, ranging from a simple circular arc to much more complicated curves. One of the better curves used for this purpose is the parabolic curve given by Equation (2a). As seen from the derived time graphs, this curve causes the follower to begin a stroke with zero velocity but having a finite and constant acceleration. We must accept the necessity of acceleration, but effort should be made to hold it to a minimum.

**Matching of Constant Velocity and Parabolic Motion Curves:** By matching a parabolic cam curve to the beginning and end of a straight-line cam displacement diagram it is possible to reduce the acceleration from infinity to a finite constant value to avoid impact loads. As illustrated in Fig. 8, it can be shown that for any parabola the vertex of which is at  $O$ , the tangent to the curve at the point  $P$  intersects the line  $OQ$  at its midpoint. This means that the tangent at  $P$  represents the velocity of the follower at time  $X_0$  as shown in Fig. 8. Since the tangent also represents the velocity of the follower over the constant velocity portion of the stroke, the transition from rest to the maximum velocity is accomplished with smoothness.

Fig. 8. The Tangent at  $P$  Bisects  $OQ$  When Curve is a Parabola

*Example:* A cam follower is to rise  $\frac{1}{4}$  in. with constant acceleration;  $1\frac{1}{4}$  in. with constant velocity, over an angle of  $50^\circ$ ; and then  $\frac{1}{2}$  in. with constant deceleration.

In Fig. 9 the three rise distances are laid out,  $y_1 = \frac{1}{4}$  in.,  $y_2 = 1\frac{1}{4}$  in.,  $y_3 = \frac{1}{2}$  in., and horizontals drawn. Next, an arbitrary horizontal distance  $\phi_2$  proportional to  $50^\circ$  is measured off and points  $A$  and  $B$  are located. The line  $AB$  is extended to  $M_1$  and  $M_2$ . By remembering that a tangent to a parabola, Fig. 8, will cut the abscissa axis at point  $(X_0/2, 0)$  where  $X_0$  is the abscissa of the point of tangency, the two values  $\phi_1 = 20^\circ$  and  $\phi_3 = 40^\circ$  will be found. Analytically,

$$\frac{M_1E}{\phi_2} = \frac{y_1}{y_2} \quad \frac{\frac{1}{2}\phi_1}{50^\circ} = \frac{0.25}{1.25} \quad \therefore \phi_1 = 20^\circ$$

$$\frac{FM_2}{\phi_2} = \frac{y_3}{y_2} \quad \frac{\frac{1}{2}\phi_3}{50^\circ} = \frac{0.50}{1.25} \quad \therefore \phi_3 = 40^\circ$$

In Fig. 9, the portions of the parabola have been drawn in; the details of this operation are as follows:

Assume that accuracy to the nearest thousandth of one inch is desired, and it is decided to plot values for every  $5^\circ$  of cam rotation.

The formula for the acceleration portion of the parabolic curve is:

$$y = \frac{2h}{T^2}t^2 = 2h\left(\frac{\phi}{\beta}\right)^2 \quad (5)$$

Two different parabolas are involved in this example; one for accelerating the follower during a cam rotation of  $20^\circ$ , the other for decelerating it in  $40^\circ$ , these two being tangent, to opposite ends of the same line  $AB$ .

In Fig. 9 only the first half of a complete acceleration-deceleration parabolic curve is used to blend with the left end of the straight line  $AB$ . Therefore, in using the Formula (5) substitute  $2y_1$  for  $h$  and  $2\phi_1$  for  $\beta$  so that

$$y = \frac{2h\phi^2}{\beta^2} = \frac{(2)(2y_1)}{(2\phi_1)^2}\phi^2$$

For the right end of the straight line  $AB$ , the calculations are similar but, in using **Formula (5)**, calculated  $y$  values are *subtracted* from the *total rise* of the cam ( $y_1 + y_2 + y_3$ ) to obtain the follower displacement.

Fig. 9. Matching a Parabola at Each End of Straight Line Displacement Curve  $AB$  to Provide More Acceptable Acceleration and Deceleration

**Table 1** shows the computations and resulting values for the cam displacement diagram described. The calculations are shown in detail so that if equations are programmed for a digital computer, the results can be verified easily. Obviously, the intermediate points are not needed to draw the straight line, but when the cam profile is later to be drawn or cut, these values will be needed since they are to be measured on radial lines.

The matching procedure when using cycloidal motion is exactly the same as for parabolic motion, because parabolic and cycloidal motion have the same maximum velocity for equal rise (or return) and lift angle (or return angle).

**Cam Profile Determination.**— In the cam constructions that follow an artificial device called an *inversion* is used. This represents a mental concept which is very helpful in performing the graphical work. The construction of a cam profile requires the drawing of many positions of the cam with the follower in each case in its related location. However, instead of revolving the cam, it is assumed that the follower rotates around the *fixed* cam. It requires the drawing of many follower positions, but since this is done more or less diagrammatically, it is relatively simple.

As part of the inversion process, the direction of rotation is important. In order to preserve the correct sequence of events, the artificial rotation of the follower must be the reverse of the cam's prescribed rotation. Thus, in **Fig. 10** the cam rotation is counterclockwise, whereas the artificial rotation of the follower is clockwise.

**Radial Translating Roller Follower:** The time-displacement diagram for a cam with a radial translating roller follower is shown in **Fig. 10(a)**. This diagram is read from left to right as follows: For 100 degrees of cam shaft rotation the follower rises  $h$  inches ( $AB$ ), dwells in its upper position for 20 degrees ( $BC$ ), returns over 180 degrees ( $CD$ ), and finally dwells in its lowest position for 60 degrees ( $DE$ ). Then the entire cycle is repeated.

**Fig. 10(b)** shows the cam construction layout with the cam pitch curve as a dot and dash line. To locate a point on this curve, take a point on the displacement curve, as  $6'$  at the 60-degree position, and project this horizontally to point  $6''$  on the 0-degree position of the cam construction diagram. Using the center of cam rotation, an arc is struck from point  $6''$  to intercept the 60-degree position radial line which gives point  $6'''$  on the cam pitch curve. It will be seen that the smaller circle in the cam construction layout has a radius  $R_{\min}$  equal to the smallest distance from the center of cam rotation to the pitch curve and, similarly, the

**Table 1. Development of Modified Constant Velocity Cam with Parabolic Matching**

Rise Angle	$\phi$ Degrees	Computation	Follower Displacement $y$	Explanation

<sup>a</sup> Since the deceleration portion of a parabolic cam is the same shape as the acceleration portion, but inverted, **Formula (5)** may be used to calculate the  $y$  values by substituting  $2y_3$  for  $h$  and for  $\beta$  and the result subtracted from the total rise ( $y_1 + y_2 + y_3$ ) to obtain the follower displacement.

larger circle has a radius  $R_{\max}$  equal to the largest distance to the pitch curve. Thus, the difference in radii of these two circles is equal to the maximum rise  $h$  of the follower.

The cam pitch curve is also the actual profile or working surface when a knife-edged follower is used. To get the profile or working surface for a cam with a roller follower, a series of arcs with centers on the pitch curve and radii equal to the radius of the roller are drawn and the inner envelope drawn tangent to these arcs is the cam working surface or profile shown as a solid line in **Fig. 10(b)**.

**Cam Grinding:** The cams used on gas and gasoline motors, for operating the inlet and exhaust valves, are finished to the correct form by grinding. This grinding may be done in a regular cylindrical grinding machine by using a suitable cam grinding attachment. The general method of grinding cams is by so mounting the cam or camshaft that, while rotating, it will be moved toward and from the grinding wheel by a master cam, the movement causing the cam to be ground to the required form or contour. The master cam is in engagement with a roller which transmits motion to the work-holding fixture. It is evident that cam grinding first involves the generation of master cams, since these must be made to suit each different form of cam that is ground. In modern CNC cam grinding machines, downloaded master cam data replaces the "hard" master cam required on older manual machines.

Fig. 13. Displacement Diagram

**Determination of Cam Size for a Radial or an Offset Translating Follower.**—Fig. 13 shows a time-displacement diagram. The maximum displacement is preferably made to scale, but the length of the abscissa,  $L$ , can be chosen arbitrarily. The distance  $L$  from 0 to 360 degrees is measured and is set equal to  $2\pi k$  from which

$$k = \frac{L}{2\pi}$$

$k$  is calculated and laid out as length  $E$  to  $M$  in Fig. 14.

In Fig. 13 the two points  $P_1$  and  $P_2$  having the maximum angles of slope,  $\tau_1$ , and  $\tau_2$ , are located by inspection. In this example,  $y_1$  and  $y_2$  are of equal length.

Angles  $\tau_1$  and  $\tau_2$  are laid out as shown in Fig. 14, and the points of intersection with a perpendicular to  $EM$  at  $M$  determine  $Q_1$  and  $Q_2$ . The measured distances

$$MQ_1 = k \tan \tau_1 \quad \text{and} \quad MQ_2 = k \tan \tau_2$$

are laid out in Fig. 15, which is constructed as follows:

Draw a vertical line  $R_u R_o$  of length  $h$  equal to the stroke of the roller follower,  $R_u$  being the lowest position and  $R_o$  the highest position of the center of the roller follower. From  $R_u$  lay out  $R_u R_{y1} = y_1$  and  $R_u R_{y2} = y_2$ ; these are equal lengths in this example. Next, if the rotation of the cam is counterclockwise, lay out  $k \tan \tau_1$ , to the left,  $k \tan \tau_2$  to the right from points  $R_{y1}$  and  $R_{y2}$ , respectively,  $R_{y1}$  and  $R_{y2}$  being the same point in this case.

Fig. 14. Construction to Find  $k \tan \tau_1$  and  $k \tan \tau_2$ 

The specified maximum pressure angle  $\alpha_1$  is laid out at  $E_1$  as shown, and a ray (line)  $E_1 F_1$  is determined. Any point on this ray chosen as the cam shaft center will proportion the cam so that the pressure angle at a point on the cam profile corresponding to point  $P_1$ , of the displacement diagram will be exactly  $\alpha_1$ .

Fig. 15. Finding Proportions of Cam; Offset Translating Follower

The angle  $\alpha_2$  is laid out at  $E_2$  as shown, and another ray  $E_2F_2$  is determined. Similarly, any point on this ray chosen as the cam shaft center will proportion the cam so that the pressure angle at a point on the cam profile corresponding to point  $P_2$  of the displacement diagram will be exactly  $\alpha_2$ .

Any point chosen within the cross-hatched area A as the cam center will yield a cam whose pressure angles at points corresponding to  $P_1$  and  $P_2$  will not exceed the specified values  $\alpha_1$  and  $\alpha_2$  respectively. If  $O_1$  is chosen as the cam shaft center, the pressure angles on the cam profile corresponding to points  $P_1$  and  $P_2$  are exactly  $\alpha_1$  and  $\alpha_2$ , respectively. Selection of point  $O_1$  also yields the smallest possible cam for the given requirements and requires an offset follower in which  $e$  is the offset distance.

If  $O_2$  is chosen as the cam shaft center, a radial translating follower is obtained (zero offset). In that case, the pressure angle  $\alpha_1$  for the rise is unchanged, whereas the pressure angle for the return is changed from  $\alpha_2$  to  $\alpha'_2$ . That is, the pressure angle on the return stroke is reduced at the point  $P_2$ . If point  $O_3$  had been selected, then  $\alpha_2$  would remain unchanged but  $\alpha_1$  would be decreased and the offset  $e$  increased.

Fig. 16. Construction of Cam Contour; Offset Translating Follower

Fig. 16 shows the shape of the cam when  $O_1$  from Fig. 15 is chosen as the cam shaft center, and it is seen that the pressure angle at a point on the cam profile corresponding to point  $P_1$  is  $\alpha_1$  and at a point corresponding to point  $P_2$  is  $\alpha_2$ .

In the foregoing, a cam mechanism has been so proportioned that the pressure angles  $\alpha_1$  and  $\alpha_2$  at points on the cam corresponding to points  $P_1$  and  $P_2$  were obtained. Even though  $P_1$  and  $P_2$  are the points of greatest slope on the displacement diagram, the pressure angles produced at some other points on the actual cam may be slightly greater.

However, if the pressure angles  $\alpha_1$  and  $\alpha_2$  are not to be exceeded at any point — i.e., they are to be maximum pressure angles — then  $P_1$  and  $P_2$  must be selected to be at the locations where these maximum pressure angles occur. If these locations are not known, then the graphical procedure described must be repeated, letting  $P_1$  take various positions on the curve for rise ( $AB$ ) and  $P_2$  various positions on the return curve ( $CD$ ) and then setting  $R_{\min}$  equal to the largest of the values determined from the various positions.

Fig. 17. Displacement Diagram

**Determination of Cam Size for Swinging Roller Follower.**—The proportioning of a cam with swinging roller follower having specific pressure angles at selected points follows the same procedure as that for a translating follower.

*Example:* Given the diagram for the roller displacement along its circular arc, Fig. 17 with  $h = 1.95$  in., the periods of rise and fall, respectively,  $\beta_1 = 160^\circ$  and  $\beta_2 = 120^\circ$ , the length of the swinging follower arm  $L_f = 3.52$  in., rotation of the cam away from pivot point  $M$ , and pressure angles  $\alpha_1 = \alpha_2 = 45^\circ$  (corresponding to the points  $P_1$  and  $P_2$  in the displacement diagram). Find the cam proportions.

*Solution:* Distances  $k \tan \tau_1$  and  $k \tan \tau_2$  are determined as in the previous example, Fig. 14. In Fig. 18,  $R_{y_1}$  is determined by making the distance  $R_u R_{y_1} = y_1$  along the arc  $R_u R_o$  and  $R_{y_2}$  by making  $R_u R_{y_2} = y_2$ . The arc  $R_u R_o = h$  and  $R_u$  indicates the lowest position of the center of the swinging roller follower and  $R_o$  the highest position.

Because the cam (i.e., the surface of the cam as it passes under the follower roller) rotates away from pivot point  $M$ ,  $k \tan \tau_1$  is laid out away from  $M$ , that is, from  $R_{y_1}$  to  $E_1$  and  $k \tan \tau_2$  is laid out toward  $M$  from  $R_{y_2}$  to  $E_2$ . Angle  $\alpha_1$  at  $E_1$  determines one ray and  $\alpha_2$  at  $E_2$  another ray, which together subtend an area  $A$  having the property that if the cam shaft center is chosen inside this area, the pressure angles at the points of the cam corresponding to  $P_1$  and  $P_2$  in the displacement diagram will not exceed the given values  $\alpha_1$  and  $\alpha_2$ , respectively. If the cam shaft center is chosen on the ray drawn from  $E_1$  at an angle  $\alpha_1 = 45^\circ$ , the pressure angle  $\alpha_1$  on the cam profile corresponding to point  $P_1$  will be exactly  $45^\circ$ , and if chosen on the ray from  $E_2$ , the pressure angle  $\alpha_2$  corresponding to  $P_2$  will be exactly  $45^\circ$ . If another point,  $O_2$  for example, is chosen as the cam shaft center, the pressure angle corresponding to  $P_1$  will be  $\alpha'_1$  and that corresponding to  $P_2$  will be  $\alpha_2$ .

tical solution. However, for some of the standard cam profiles utilizing *radial* translating roller followers, the following formulas may be used to determine key cam dimensions before laying out the cam. These formulas enable the designer to specify the maximum pressure angle (usually 30° or less) and, using the specified value, to calculate the minimum cam size that will satisfy the requirement.

The following symbols are in addition to those starting on page 2301.

- $\alpha_{\max}$  = specified maximum pressure angle, degrees
- $R_{\alpha_{\max}}$  = radius from cam center to point on pitch curve where  $\alpha_{\max}$  is located, inches (m)
- $\phi_p$  = rise angle, in degrees, corresponding to  $\alpha_{\max}$  and  $R_{\alpha_{\max}}$
- $\alpha$  = pressure angle at any selected point, degrees
- $R_\alpha$  = radius from cam center to pitch curve at  $\alpha$ , inches (m)
- $\phi$  = rise angle, in degrees, corresponding to  $\alpha$  and  $R_\alpha$

*For Uniform Velocity Motion*

$$\alpha = \arctan \left[ \frac{180^\circ h}{\pi \beta R_\alpha} \right] \text{ at radius } R_\alpha \text{ to the pitch curve} \quad (6a)$$

$$\alpha_{\max} = \arctan \left[ \frac{180^\circ h}{\pi \beta R_{\min}} \right] \text{ at radius } R_{\min} \text{ of the pitch curve } (\phi = 0^\circ). \quad (6b)$$

If  $\alpha_{\max}$  is specified, the minimum radius to the lowest point on the pitch curve,  $R_{\min}$ , is:

$$R_{\min} = \frac{180^\circ h}{\pi \beta \tan \alpha_{\max}} \text{ which corresponds to } \phi = 0^\circ. \quad (6c)$$

*For Parabolic Motion*

$$\alpha = \arctan \left[ \frac{720^\circ h \phi}{\pi \beta^2 R_\alpha} \right] \text{ at radius } R_\alpha \text{ to the pitch curve at angle } \phi, \text{ where } 0 \leq \phi \leq \beta/2 \quad (7a)$$

and  $\alpha = \arctan \left[ \frac{720^\circ h (1 - \phi/\beta)}{\pi \beta R_\alpha} \right]$  at radius  $R_\alpha$  to pitch curve at angle  $\phi$ , where  $\beta/2 \leq \phi \leq \beta$ .

$$\alpha_{\max} = \arctan \left[ \frac{360^\circ h}{\pi \beta R_\alpha} \right] \text{ which occurs at } \phi = \beta/2 \text{ and } R_\alpha = R_{\min} + h/2 \quad (7b)$$

If  $\alpha_{\max}$  is specified, then the minimum radius to the lowest point of the pitch curve is:

$$R_{\min} = \left[ \frac{360^\circ h}{\pi \beta \tan \alpha_{\max}} - \frac{h}{2} \right] \text{ which corresponds to } \phi = 0^\circ. \quad (7c)$$

*For Simple Harmonic Motion*

$$\alpha = \arctan \left[ \frac{90^\circ h}{\beta R_\alpha} \sin \left( \frac{180^\circ \phi}{\beta} \right) \right] \text{ at radius } R_\alpha \text{ to the pitch curve at angle } \phi \quad (8a)$$

$$\phi_p = \left( \frac{\beta}{180^\circ} \right) \left[ \operatorname{arccot} \left( \frac{\beta}{180^\circ} \tan \alpha_{\max} \right) \right] = \phi \text{ where pressure angle } \alpha_{\max} \text{ occurs} \quad (8b)$$

$$R_{\alpha_{\max}} = \frac{h [\sin(180^\circ \phi_p / \beta)]^2}{2 \cos(180^\circ \phi_p / \beta)} \text{ at point where } \alpha = \alpha_{\max} \text{ and } \phi = \phi_{\max} \quad (8c)$$

$$R_{\min} = R_{\alpha_{\max}} - \frac{h}{2} \left[ 1 - \cos \left( \frac{180^\circ \phi_p}{\beta} \right) \right] \quad (8d)$$

For Cycloidal Motion:

$$\alpha = \arctan \left[ \frac{180^\circ}{\pi \beta R_\alpha} \left( 1 - \cos \frac{360^\circ \phi}{\beta} \right) \right] \text{ at radius } R_\alpha \text{ to the pitch curve at angle } \phi \quad (9a)$$

$$\phi_p = \frac{\beta}{180^\circ} \left[ \operatorname{arccot} \left( \frac{\beta \tan \alpha_{\max}}{360^\circ} \right) \right] = \text{value of } \phi \text{ where pressure angle } \alpha_{\max} \text{ occurs} \quad (9b)$$

$$R_{\alpha_{\max}} = \frac{h}{2\pi} \frac{[1 - \cos(360^\circ \phi_p / \beta)]^2}{\sin(360^\circ \phi_p / \beta)} \text{ at point where } \alpha = \alpha_{\max} \text{ and } \phi = \phi_p \quad (9c)$$

$$R_{\min} = R_{\alpha_{\max}} - h \left[ \frac{\phi_p}{\beta} - \frac{1}{2\pi} \sin \left( \frac{360^\circ \phi_p}{\beta} \right) \right] \quad (9d)$$

**Radius of Curvature.**— The minimum radius of curvature of a cam should be kept as large as possible (1) to prevent undercutting of the convex portion of the cam and (2) to prevent too high surface stresses. Figs. 20(a), (b) and (c) illustrate how undercutting occurs.

Fig. 20. (a) No Undercutting. (b) Sharp Corner on Cam. (c) Undercutting

In Fig. 20(a) the radius of curvature of the path of the follower is  $\rho_{\min}$  and the cam will at that point have a radius of curvature  $R_c = \rho_{\min} - r_f$ .

In Fig. 20(b)  $\rho_{\min} = r_f$  and  $R_c = 0$ . Therefore, the actual cam will have a sharp corner which in most cases will result in too high surface stresses.

In Fig. 20(c) is shown the case where  $\rho_{\min} < r_f$ . This case is not possible because undercutting will occur and the actual motion of the roller follower will deviate from the desired one as shown.

Undercutting cannot occur at the *concave* portion of the cam profile (working surface), but caution should be exerted in not making the radius of curvature equal to the radius of the roller follower. This condition would occur if there is a cusp on the displacement diagram which, of course, should always be avoided. To enable milling or grinding of *concave* portions of a cam profile, the radius of curvature of concave portions of the cam,  $R_c = \rho_{\min} + r_f$ , must be larger than the radius of the cutter to be used.

The radius of curvature is used in calculating surface stresses (see following section), and may be determined by measurement on the cam layout or, in the case of radial translating followers, may be calculated using the formulas that follow. Although these formulas are exact for radial followers, they may be used for offset and swinging followers to obtain an approximation.

Based upon polar coordinates, the radius of curvature is:

$$\rho = \frac{\left[ r^2 + \left( \frac{dr}{d\phi} \right)^2 \right]^{3/2}}{r^2 + 2 \left( \frac{dr}{d\phi} \right)^2 - r \left( \frac{d^2r}{d\phi^2} \right)} \quad (10)$$

\*Positive values (+) indicate convex curve; negative values (-), concave.

In Equation (10),  $r = (R_{\min} + y)$ , where  $R_{\min}$  is the smallest radius to the pitch curve (see Fig. 12) and  $y$  is the displacement of the follower from its lowest position given in terms of  $\phi$ , the angle of cam rotation. The following formulas for  $r$ ,  $dr/d\phi$ , and  $d^2r/d\phi^2$  may be substituted into Equation (10) to calculate the radius of curvature at any point of the cam pitch curve; however, to determine the possibility of undercutting of the convex portion of the cam, it is the minimum radius of curvature on the convex portion,  $\rho_{\min}$ , that is needed. The minimum radius of curvature occurs, generally, at the point of maximum *negative* acceleration.

*Parabolic motion:*

$$r = R_{\min} + h - 2h \left( 1 - \frac{\phi}{\beta} \right)^2 \quad (11a)$$

$$\frac{dr}{d\phi} = \frac{720^\circ h}{\pi \beta} \left( 1 - \frac{\phi}{\beta} \right) \quad (11b) \quad \left. \vphantom{\frac{dr}{d\phi}} \right\} \frac{\beta}{2} \leq \phi \leq \beta$$

$$\frac{d^2r}{d\phi^2} = \frac{-4(180^\circ)^2 h}{\pi^2 \beta^2} \quad (11c)$$

These equations are for the deceleration portion of the curve as explained in the footnote to Table 1.

The minimum radius of curvature can occur at either  $\phi = \beta/2$  or at  $\phi = \beta$ , depending on the magnitudes of  $h$ ,  $R_{\min}$ , and  $\beta$ . Therefore, to determine which is the case, make two calculations using Formula (10), one for  $\phi = \beta/2$ , and the other for  $\phi = \beta$ .

*Simple harmonic motion:*

$$r = R_{\min} + \frac{h}{2} \left[ 1 - \cos \left( \frac{180^\circ \phi}{\beta} \right) \right] \quad (12a)$$

$$\frac{dr}{d\phi} = \frac{180^\circ h}{2\beta} \sin \left( \frac{180^\circ \phi}{\beta} \right) \quad (12b) \quad \left. \vphantom{\frac{dr}{d\phi}} \right\} 0 \leq \phi \leq \beta$$

$$\frac{d^2r}{d\phi^2} = \frac{(180^\circ)^2 h}{2\beta^2} \cos \left( \frac{180^\circ \phi}{\beta} \right) \quad (12c)$$

The minimum radius of curvature can occur at either  $\phi = \beta/2$  or at  $\phi = \beta$ , depending on the magnitudes of  $h$ ,  $R_{\min}$ , and  $\beta$ . Therefore, to determine which is the case, make two calculations using Formula (10), one for  $\phi = \beta/2$ , and the other for  $\phi = \beta$ .

*Cycloidal motion:*

$$r = R_{\min} + h \left[ \frac{\phi}{\beta} - \frac{1}{2\pi} \sin \left( \frac{360^\circ \phi}{\beta} \right) \right] \quad (13a)$$

$$\frac{dr}{d\phi} = \frac{180^\circ h}{\pi \beta} \left[ 1 - \cos \left( \frac{360^\circ \phi}{\beta} \right) \right] \quad (13b) \quad \left. \vphantom{\frac{dr}{d\phi}} \right\} 0 \leq \phi \leq \beta$$

$$\frac{d^2r}{d\phi^2} = \frac{2(180^\circ)^2 h}{\pi\beta^2} \sin\left(\frac{360^\circ\phi}{\beta}\right) \quad (13c) \quad 0 \leq \phi \leq \beta$$

$$\rho_{\min} = \frac{[(R_{\min} + 0.91h)^2 + (180^\circ h/\pi\beta)^2]^{3/2}}{(R_{\min} + 0.91h)^2 + 2(180^\circ h/\pi\beta)^2 + (R_{\min} + 0.91h)[2(180^\circ)^2 h/\pi\beta^2]} \quad (13d)$$

( $\rho_{\min}$  occurs near  $\phi = 0.75\beta$ )

*Example:* Given  $h = 1$  inch(m),  $R_{\min} = 2.9$  inch(m), and  $\beta = 60^\circ$ . Find  $\rho_{\min}$  for parabolic motion, simple harmonic motion, and cycloidal motion.

*Solution:*  $\rho_{\min} = 2.02$  inch(m) for parabolic motion, from Equation (10)

$\rho_{\min} = 1.8$  inch(m) for simple harmonic motion, from Equation (10)

$\rho_{\min} = 1.6$  inch(m) for cycloidal motion, from Equation (13d)

The value of  $\rho_{\min}$  on any cam may also be obtained by measurement on the layout of the cam using a compass.

**Cam Forces, Contact Stresses, and Materials.**— After a cam and follower configuration has been determined, the forces acting on the cam may be calculated or otherwise determined. Next, the stresses at the cam surface are calculated and suitable materials to withstand the stress are selected. If the calculated maximum stress is too great, it will be necessary to change the cam design.

Such changes may include: 1) increasing the cam size to decrease pressure angle and increase the radius of curvature; 2) changing to an offset or swinging follower to reduce the pressure angle; 3) reducing the cam rotation speed to reduce inertia forces; 4) increasing the cam rise angle,  $\beta$ , during which the rise,  $h$ , occurs; 5) increasing the thickness of the cam, provided that deflections of the follower are small enough to maintain uniform loading across the width of the cam; and 6) using a more suitable cam curve or modifying the cam curve at critical points.

Although parabolic motion seems to be the best with respect to minimizing the calculated maximum acceleration and, therefore, also the maximum acceleration forces, nevertheless, in the case of high speed cams, cycloidal motion yields the lower maximum acceleration forces. Thus, it can be shown that owing to the sudden change in acceleration (called *jerk* or *pulse*) in the case of parabolic motion, the actual forces acting on the cam are doubled and sometimes even tripled at high speed, whereas with cycloidal motion, owing to the gradually changing acceleration, the actual dynamic forces are only slightly higher than the theoretical. Therefore, the calculated force due to acceleration should be multiplied by at least a factor of 2 for parabolic and 1.05 for cycloidal motion to provide an allowance for the load-increasing effects of elasticity and backlash.

The main factors influencing cam forces are: 1) displacement and cam speed (forces due to acceleration); 2) dynamic forces due to backlash and flexibility; 3) linkage dimensions which affect weight and weight distribution; 4) pressure angle and friction forces; and 5) spring forces.

The main factors influencing stresses in cams are: 1) radius of curvature for cam and roller; and 2) materials.

*Acceleration Forces:* The formula for the force acting on a translating body given an acceleration  $a$  is:

$$R = \frac{Wa}{g} = \frac{Wa}{386} \quad (14)$$

In this formula,  $g = 386$  inches/second squared,  $a =$  acceleration of  $W$  in inches/second squared;  $R =$  resultant of all the external forces (except friction) acting on the weight  $W$ . For cam analysis purposes,  $W$ , in pounds, consists of the weight of the follower, a portion of the

weight of the return spring ( $\frac{1}{3}$ ), and the weight of the members of the external mechanism against which the follower pushes, for example, the weight of a piston:

$$W = W_f + \frac{1}{3}W_s + W_e \quad (15)$$

where  $W$  = equivalent single weight;  $W_f$  = follower weight;  $W_s$  = spring weight; and  $W_e$  = external weight, all in pounds.

**Spring Forces:** The return spring,  $K_s$ , shown in Fig. 21a must be strong enough to hold the follower against the cam at all times. At high cam speeds the main force attempting to separate the follower from the cam surface is the acceleration force  $R$  at the point of maximum *negative* acceleration. Thus, at that point the spring must exert a force  $F_s$ ,

$$F_s = R - W_f - F_e - F_f \quad (16)$$

where  $F_e$  = external force resisting motion of follower, and  $F_f$  = friction force from follower guide bushings and other sources.

When the follower is at its lowest position ( $R_{\min}$  in Fig. 21a), it is usual practice to have the spring provide some estimated preload to account for "set" that takes place in a spring after repeated use and to prevent roller sliding at the start of movement.

The required spring constant  $K_s$ , in pounds per inch of spring deflection, is:

$$K_s = \frac{F_s - \text{preload}}{y_a} \quad (17)$$

where  $y_a$  = rise of cam from  $R_{\min}$  to height at which maximum negative acceleration takes place.

The force,  $F_y$ , that the spring exerts at any height  $y$  above  $R_{\min}$  is:

$$F_y = yK_s + \text{preload} \quad (18)$$

Fig. 21. (a) Radial Translating Follower and Cam System (b) Force Acting on a Translating Follower

**Pressure Angle and Friction Forces:** As shown in Fig. 21b, the pressure angle of the cam causes a sideways component  $F_n \sin \alpha$  which produces friction forces  $\mu F_1$  and  $\mu F_2$  in the guide bushing. If the follower rod is too flexible, bending of the follower will increase

these friction forces. The effect of the friction forces and the pressure angle are taken into account in the formula,

$$F_n = \frac{P}{\cos \alpha - \frac{\mu \sin \alpha}{l_2} (2l_1 + l_2 - \mu d)} \quad (19a)$$

where  $\mu$  = coefficient of friction in bushing;  $l_1, l_2$ , and  $d$  are as shown in Fig. 21; and  $P$  = the sum of all the forces acting down against the upward motion of the follower (acceleration force + spring force + follower weight + external force)

$$P = \frac{W \times a}{386} + (yK_s + \text{preload}) + W_f + F_e \quad (19b)$$

*Cam Torque:* The follower pressing against the cam causes resisting torques during the rise period and assisting torques during the return period. The maximum value of the resisting torque determines the cam drive requirements. Instantaneous torque values may be calculated from

$$T_o = \frac{30vF_n \cos \alpha}{\pi N} = (R_{\min} + y)F_n \sin \alpha \quad (20)$$

in which  $T_o$  = instantaneous torque in pound-inches.

*Example of Force Analysis:* A radial translating follower system is shown in Fig. 21a. The follower is moved with cycloidal motion over a distance of 1 in. and an angle of lift  $\beta = 100^\circ$ . Cam speed  $N = 900$  rpm. The weight of the follower mass,  $W_f$ , is 2 pounds. Both the spring weight  $W_s$  and the external weight  $W_e$  are negligible. The follower stem diameter is 0.75 in.,  $l_1 = 1.5$  in.,  $l_2 = 4$  in., coefficient of friction  $\mu = 0.05$ , external force  $F_e = 10$  lbs, and the pressure angle is not to exceed  $30^\circ$ .

(a) What is the smallest radius  $R_{\min}$  to the pitch curve?

From Formula (9b) the rise angle  $\phi_p$  to where the maximum pressure angle  $\alpha_{\max}$  exists is:

$$\begin{aligned} \phi_p &= \frac{\beta}{180^\circ} \left[ \operatorname{arccot} \left( \frac{\beta \tan \alpha_{\max}}{360^\circ} \right) \right] = \frac{100^\circ}{180^\circ} \left[ \operatorname{arccot} \left( \frac{100^\circ \times \tan 30^\circ}{360^\circ} \right) \right] \\ &= 44.94^\circ = 45^\circ \end{aligned}$$

From Formula (9c) the radius,  $R_{\alpha_{\max}}$ , at which the angle of rise is  $\phi_p$  is:

$$R_{\alpha_{\max}} = \frac{h [1 - \cos(360^\circ \phi_p / \beta)]^2}{2\pi \sin(360^\circ \phi_p / \beta)} = \frac{1 [1 - \cos(360^\circ \times 45^\circ / 100^\circ)]^2}{2\pi \sin[360^\circ \times 45^\circ / 100^\circ]} = 1.96 \text{ in.}$$

From Formula (9d),  $R_{\min}$  is given by

$$\begin{aligned} R_{\min} &= R_{\alpha_{\max}} - h \left[ \frac{\phi_p}{\beta} - \frac{1}{2\pi} \sin \left( \frac{360^\circ \phi_p}{\beta} \right) \right] \\ &= 1.96 - 1 \times \left[ \frac{45^\circ}{100^\circ} - \frac{1}{2\pi} \sin \left( \frac{360^\circ \times 45^\circ}{100^\circ} \right) \right] = 1.560 \text{ in.} \end{aligned}$$

The same results could have been obtained graphically. If this  $R_{\min}$  is too small, i.e., if the cam bore and hub require a larger cam, then  $R_{\min}$  can be increased, in which case the maximum pressure angle will be less than  $30^\circ$ .

(b) If the return spring  $K_s$  is specified to provide a preload of 36 lbs when the follower is at  $R_{\min}$ , what is the spring constant required to hold the follower on the cam throughout the cycle?

The follower tends to leave the cam at the point of maximum *negative* acceleration. Fig. 7 shows this to be at  $\phi = \frac{3}{4}\beta = 75^\circ$ .

From Formula (4c),

$$a = \frac{2\pi h \omega^2}{\beta^2} \sin\left(\frac{360^\circ \phi}{\beta}\right) = \frac{2\pi \times 1 \times (6 \times 900)^2}{(100^\circ)^2} \sin\left(\frac{360^\circ \times 75^\circ}{100^\circ}\right) = -18,300 \text{ in./sec}^2$$

From Formulas (14) and (15),

$$R = \frac{Wa}{386} = \frac{(W_f + \frac{1}{3}W_s + W_e)a}{386} = \frac{(2 + 0 + 0)(-18,300)}{386} = 95 \text{ lbs (upward)}$$

Using Formula (16) to determine the spring force  $F_s$  to hold the follower on the cam,

$$F_s = R - W_f - F_e - F_f$$

as stated on page 2317, the value of  $R$  in the above formula should be multiplied by 1.05 for cycloidal motion to provide a factor of safety for dynamic pulses. Thus,

$$F_s = 1.05R - W_f - F_e - F_f = 1.05 \times 95 - 2 - 10 - 0 = 88 \text{ lbs (downward)}$$

The spring constant from Formula (17) is:

$$K_s = \frac{F_s - \text{preload}}{y_a} = \frac{88 - 36}{y_a}$$

and, from Formula (4a),  $y_a$  is:

$$y_a = h \left[ \frac{\phi}{\beta} - \frac{1}{2\pi} \sin\left(\frac{360^\circ \phi}{\beta}\right) \right] = 1 \times \left[ \frac{75^\circ}{100^\circ} - \frac{1}{2\pi} \sin\left(\frac{360^\circ \times 75^\circ}{100^\circ}\right) \right] = 0.909 \text{ in.}$$

so that  $K_s = (88 - 36)/0.909 = 57 \text{ lb/in.}$

(c) At the point where the pressure angle  $\alpha_{\max}$  is  $30^\circ$  ( $\phi = 45^\circ$ ) the rise of the follower is  $1.96 - 1.56 = 0.40 \text{ in.}$  What is the normal force,  $F_n$ , on the cam? From Formulas (19a) and (19b)

$$F_n = \frac{Wa/386 + yK_s + \text{preload} + W_f + F_e}{\cos \alpha - \frac{\mu \sin \alpha}{l_2} (2l_1 + l_2 - \mu d)}$$

using  $\phi = 45^\circ$ ,  $h = 1 \text{ in.}$ ,  $\beta = 100^\circ$ , and  $\omega = 6 \times 900 \text{ in Formula (4c)}$  gives  $a = 5660 \text{ in/sec}^2$ . So that, with  $W = 2 \text{ lbs}$ ,  $y = 0.4$ ,  $K_s = 57$ , preload = 36 lbs,  $W_f = 2 \text{ lbs}$ ,  $F_e = 10 \text{ lbs}$ ,  $\alpha = 30^\circ$ ,  $\mu = 0.05$ ,  $l_1 = 1.5$ ,  $l_2 = 4$ , and  $d = 0.75$ ,

$$F_n = \frac{(2 \times 5660)/386 + 0.4 \times 57 + 36 + 2}{\cos 30^\circ - \frac{0.05 \times \sin 30^\circ}{4} (2 \times 1.5 + 4 - 0.05 \times 0.75)} = 110 \text{ lbs}$$

*Note:* If the coefficient of friction had been assumed to be 0, then  $F_n = 104$ ; on the other hand, if the follower is too flexible, so that sidewise bending occurs causing jamming in the bushing, the coefficient of friction may increase to, say, 0.5, in which case the calculated  $F_n = 200 \text{ lbs}$ .

(d) Assume that in the manufacture of this cam an error or "bump" resulting from a chattermark or as a result of poor blending occurred, and that this "bump" rose to a height of 0.001 in. in a  $1^\circ$  rise of the cam in the vicinity of  $\phi = 45^\circ$ . What effect would this bump have on the acceleration force  $R$ ?

One formula that may be used to calculate the change in acceleration caused by such a cam error is:

$$\Delta a = \pm 2e \left( \frac{6N}{\Delta\phi} \right)^2 \quad (21)$$

where  $\Delta a$  = change in acceleration,

$e$  = error in inches,

$\Delta\phi$  = width of error in degrees. The plus (+) sign is used for a "bump" and the minus (-) sign for a dent or hollow in the surface

For  $e = 0.001$ ,  $\Delta\phi = 1^\circ$ , and  $N = 900$  rpm,

$$\Delta a = +2 \times 0.001 \left( \frac{6 \times 900}{1^\circ} \right)^2 = 58,320 \text{ in./sec}^2$$

which is 10 times the acceleration calculated for a perfect cam and would cause sufficient force  $F_n$  to damage the cam surface. On high speed cams, therefore, accuracy is of considerable importance.

(e) What is the cam torque at  $\phi = 45^\circ$ ?

From **Formula (20)**,

$$\begin{aligned} T_o &= (R_{\min} + y)F_n \sin \alpha \\ &= (1.56 + 0.4) \times 110 \times \sin 30^\circ = 108 \text{ in.-lbs} \end{aligned}$$

(f) What is the radius of curvature at  $\phi = 45^\circ$ ?

From **Formula (10)**,

$$\begin{aligned} \rho &= \frac{\left[ r^2 + \left( \frac{dr}{d\phi} \right)^2 \right]^{3/2}}{r^2 + 2 \left( \frac{dr}{d\phi} \right)^2 - r \left( \frac{d^2r}{d\phi^2} \right)} \\ r &= R_{\min} + y = 1.56 + 0.4 = 1.96 \end{aligned}$$

From **Formula (13b)**,

$$\begin{aligned} \frac{dr}{d\phi} &= \frac{180^\circ h}{\pi \beta} \left[ 1 - \cos \left( \frac{360^\circ \phi}{\beta} \right) \right] = \frac{180^\circ \times 1}{\pi \times 100^\circ} \left[ 1 - \cos \left( \frac{360^\circ \times 45^\circ}{100^\circ} \right) \right] \\ &= 1.12 \end{aligned}$$

From **Formula (13c)**,

$$\begin{aligned} \frac{d^2r}{d\phi^2} &= \frac{2(180^\circ)^2 h}{\pi \beta^2} \sin \left( \frac{360^\circ \phi}{\beta} \right) = \frac{2 \times (180^\circ)^2 \times 1}{\pi \times (100^\circ)^2} \sin \left( \frac{360^\circ \times 45^\circ}{100^\circ} \right) \\ &= 0.64 \\ \rho &= \frac{[(1.96)^2 + (1.12)^2]^{3/2}}{(1.96)^2 + 2(1.12)^2 - 1.96 \times 0.64} = 2.26 \text{ in.} \end{aligned}$$

**Calculation of Contact Stresses.**— When a roller follower is loaded against a cam, the compressive stress developed at the surface of contact may be calculated from

$$S_c = 2290 \sqrt{\frac{F_n}{b} \left( \frac{1}{r_f} \pm \frac{1}{R_c} \right)} \quad (22)$$

for a steel roller against a steel cam. For a steel roller on a cast iron cam, use 1850 instead of 2290 in Equation (22).

$S_c$  = maximum calculated compressive stress, psi

$F_n$  = normal load, lb

$b$  = width of cam, inch

$R_c$  = radius of curvature of cam surface, inch

$r_f$  = radius of roller follower, inch

The plus sign in (21) is used in calculating the maximum compressive stress when the roller is in contact with the convex portion of the cam profile and the minus sign is used when the roller is in contact with the concave portion. When the roller is in contact with the straight (flat) portion of the cam profile,  $R_c = \infty$  and  $1/R_c = 0$ . In practice, the greatest compressive stress is most apt to occur when the roller is in contact with that part of the cam profile which is convex and has the smallest radius of curvature.

*Example:* Given the previous cam example, the radius of the roller  $r_f = 0.25$  in., the convex radius of the cam  $R_c = (2.26 - 0.25)$  in., the width of contact  $b = 0.3$  in., and the normal load  $F_n = 110$  lbs. Find the maximum surface compressive stress. From (21),

$$S_c = 2290 \sqrt{\frac{110}{0.3} \left( \frac{1}{0.25} + \frac{1}{2.01} \right)} = 93,000 \text{ psi}$$

This calculated stress should be less than the allowable stress for the material selected from Table 2.

*Cam Materials:* In considering materials for cams it is difficult to select any single material as being the best for every application. Often the choice is based on custom or the machinability of the material rather than its strength. However, the failure of a cam or roller is commonly due to fatigue, so that an important factor to be considered is the limiting wear load, which depends on the surface endurance limits of the materials used and the relative hardnesses of the mating surfaces.

**Table 2. Cam Materials**

Cam Materials for Use with Roller of Hardened Steel	Maximum Allowable Compressive Stress, psi
Gray-iron casting, ASTM A 48-48, Class 20, 160-190 Bhn, phosphate-coated	58,000
Gray-iron casting, ASTM A 339-51T, Grade 20, 140-160 Bhn	51,000
Nodular-iron casting, ASTM A 339-51T, Grade 80-60-03, 207-241 Bhn	72,000
Gray-iron casting, ASTM A 48-48, Class 30, 200-220 Bhn	65,000
Gray-iron casting, ASTM A 48-48, Class 35, 225-225 Bhn	78,000
Gray-iron casting, ASTM A 48-48, Class 30, heat treated (Austempered), 225-300 Bhn	90,000
SAE 1020 steel, 130-150 Bhn	82,000
SAE 4150 steel, heat treated to 270-300 Bhn, phosphate-coated	20,000
SAE 4150 steel, heat treated to 270-300 Bhn	188,000
SAE 1020 steel, carburized to 0.045 in. depth of case, 50-58 Rc	226,000
SAE 1340 steel, induction hardened to 45-55 Rc	198,000
SAE 4340 steel, induction hardened to 50-55 Rc	226,000

Based on United Shoe Machinery Corp. data by Guy J. Talbourdet.

In Table 2 are given maximum permissible compressive stresses (surface endurance limits) for various cam materials when in contact with a roller of hardened steel. The stress values shown are based on 100,000,000 cycles or repetitions of stress for pure rolling. Where the repetitions of stress are considerably greater than 100,000,000, where there is appreciable misalignment, or where there is sliding, more conservative stress figures must be used.

**Layout of Cylinder Cams.**— In Fig. 22 is shown the development of a uniformly accelerated motion cam curve laid out on the surface of a cylindrical cam. This development is necessary for finding the projection on the cylindrical surface, as shown at *KL*. To construct the developed curve, first divide the base circle of the cylinder into, say, twelve equal parts. Set off these parts along line *ag*. Only one-half of the layout has been shown, as the other half is constructed in the same manner, except that the curve is here falling instead of rising. Divide line *aH* into the same number of divisions as the half circle, the divisions being in the proportion 1 : 3 : 5 : 5 : 3 : 1. Draw horizontal lines from these division points and vertical lines from *a, b, c, etc.* The intersections between the two sets of lines are points on the developed cam curve. These points are transferred to the cylindrical surface at the left by projection in the usual manner.

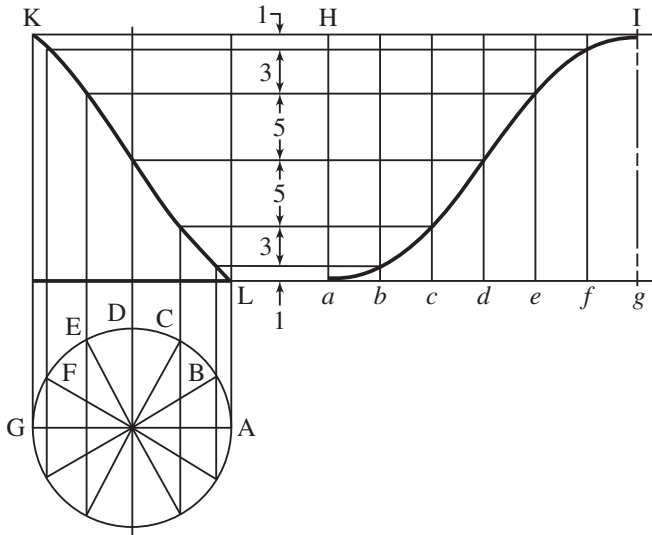

Fig. 22. Development of Cylindrical Cam

**Shape of Rolls for Cylinder Cams.**— The rolls for cylindrical cams working in a groove in the cam should be conical rather than cylindrical in shape, in order that they may rotate freely and without excessive friction. Fig. 23(a) shows a straight roll and groove, the action of which is faulty because of the varying surface speed at the top and bottom of the groove. Fig. 23(b) shows a roll with curved surface. For heavy work, however, the small bearing area is quickly worn down and the roll presses a groove into the side of the cam as well, thus destroying the accuracy of the movement and creating backlash. Fig. 23(c) shows the conical shape which permits a true rolling action in the groove. The amount of taper depends on the angle of spiral of the cam groove. As this angle, as a rule, is not constant for the whole movement, the roll and groove should be designed to meet the requirements on that section of the cam where the heaviest duty is performed. Frequently the cam groove is of a nearly even spiral angle for a considerable length. The method for determining the angle of the roll and groove to work correctly during the important part of the cycle is as follows:

In Fig. 23(d), *b* is the circumferential distance on the surface of the cam that includes the section of the groove for which correct rolling action is required. The throw of the cam for this circumferential movement is *a*. Line *OU* is the development of the movement of the cam roll during the given part of the cycle, and *c* is the movement corresponding to *b*, but

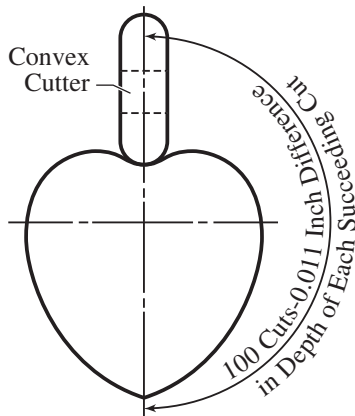

$$\sin \alpha = \frac{360^\circ \times 0.125}{300^\circ \times 0.670} = 0.2239$$

which is the sine of  $12^\circ 56'$ . Therefore, to secure a rise of 0.125 inch with the machine geared for 0.670 inch lead, the spiral head is elevated to an angle of  $12^\circ 56'$  and the vertical milling attachment is also swiveled around to locate the cutter in line with the spiral-head spindle, so that the edge of the finished cam will be parallel to its axis of rotation. In the example given, the lead used was 0.670. A larger lead, say 0.930, could have been selected from the table on page 2122. In that case,  $\alpha = 9^\circ 17'$ .

When there are several lobes on a cam, having different leads, the machine can be geared for a lead somewhat in excess of the greatest lead on the cam, and then all the lobes can be milled without changing the spiral head gearing, by simply varying the angle of the spiral head and cutter to suit the different cam leads. Whenever possible, it is advisable to mill on the under side of the cam, as there is less interference from chips; moreover, it is easier to see any lines that may be laid out on the cam face. To set the cam for a new cut, it is first turned back by operating the handle of the table feed screw, after which the index crank is disengaged from the plate and turned the required amount.

**Simple Method for Cutting Uniform Motion Cams.**—Some cams are laid out with dividers, machined and filed to the line; but for a cam that must advance a certain number of thousandths per revolution of spindle this method is not accurate. Cams are easily and accurately cut in the following manner.

Let it be required to make the heart cam shown in the illustration. The throw of this cam is 1.1 inch. Now, by setting the index on the milling machine to cut 200 teeth and also dividing 1.1 inch by 100, we find that we have 0.011 inch to recede from or advance towards the cam center for each cut across the cam. Placing the cam securely on an arbor, and the latter between the centers of the milling machine, and using a convex cutter set the proper distance from the center of the arbor, make the first cut across the cam. Then, by lowering the milling machine knee 0.011 inch and turning the index pin the proper number of holes on the index plate, take the next cut and so on.

## PLAIN BEARINGS

### Introduction

On the following pages are given data and procedures for designing full-film or hydrodynamically lubricated bearings of the journal and thrust types. However, before proceeding to these design methods, it is useful to first review those bearing aspects concerning the types of bearings available; lubricants and lubrication methods; hardness and surface finish; machining methods; seals; retainers; and typical length-to-diameter ratios for various applications.

The following paragraphs preceding the design sections provide guidance in these matters and suggest modifications in allowable loads when other than full-film operating conditions exist in a bearing.

**Classes of Plain Bearings.**— Bearings that provide sliding contact between mating surfaces fall into three general classes: *radial bearings* that support rotating shafts or journals; *thrust bearings* that support axial loads on rotating members; and *guide or slipper bearings* that guide moving parts in a straight line. Radial sliding bearings, more commonly called sleeve bearings, may be of several types, the most usual being the plain full journal bearing, which has 360-degree contact with its mating journal, and the partial journal bearing, which has less than 180-degree contact. This latter type is used when the load direction is constant and has the advantages of simplicity, ease of lubrication, and reduced frictional loss.

The relative motions between the parts of plain bearings may take place: 1) as pure sliding without the benefit of a liquid or gaseous lubricating medium between the moving surfaces such as with the dry operation of nylon or Teflon; 2) with hydrodynamic lubrication in which a wedge or film buildup of lubricating medium is produced, with either whole or partial separation of the bearing surfaces; 3) with hydrostatic lubrication in which a lubricating medium is introduced under pressure between the mating surfaces causing a force opposite to the applied load and a lifting or separation of these surfaces; and 4) with a hybrid form or combination of hydrodynamic and hydrostatic lubrication.

Listed below are some of the advantages and disadvantages of sliding contact (plain) bearings as compared with rolling contact (antifriction) bearings.

*Advantages:* 1) require less space; 2) are quieter in operation; 3) are lower in cost, particularly in high-volume production; 4) have greater rigidity; and 5) their life is generally not limited by fatigue.

*Disadvantages:* 1) have higher frictional properties resulting in higher power consumption; 2) are more susceptible to damage from foreign material in lubrication system; 3) have more stringent lubrication requirements; and 4) are more susceptible to damage from interrupted lubrication supply.

**Types of Journal Bearings.**— Many types of journal bearing configurations have been developed; some of these are shown in Fig. 1.

*Circumferential-groove bearings*, Fig. 1(a), have an oil groove extending circumferentially around the bearing. The oil is maintained under pressure in the groove. The groove divides the bearing into two shorter bearings that tend to run at a slightly greater eccentricity. However, the advantage in terms of stability is slight, and this design is most commonly used in reciprocating-load main and connecting-rod bearings because of the uniformity of oil distribution.

Short cylindrical bearings are a better solution than the circumferential-groove bearing for high-speed, low-load service. Often the bearing can be shortened enough to increase the unit loading to a substantial value, causing the shaft to ride at a position of substantial eccentricity in the bearing. Experience has shown that instability rarely results when the shaft eccentricity is greater than 0.6. Very short bearings are not often used for this type of

Fig. 1. Typical shapes of several types of pressure-fed bearings.

application, because they do not provide a high temporary rotating-load capacity in the event some unbalance should be created in the rotor during service.

*Cylindrical-overshot bearings*, Fig. 1(b), are used where surface speeds of 10,000 fpm or more exist, and where additional oil flow is desired to maintain a reasonable bearing temperature. This bearing has a wide circumferential groove extending from one axial oil groove to the other over the upper half of the bearing. Oil is usually admitted to the trailing-edge oil groove. An inlet orifice is used to control the oil flow. Cooler operation results from the elimination of shearing action over a large section of the upper half of the bearing and, to a great extent, from the additional flow of cool oil over the top half of the bearing.

*Pressure bearings*, Fig. 1(c), employ a groove over the top half of the bearing. The groove terminates at a sharp dam about 45 degrees beyond the vertical in the direction of shaft rotation. Oil is pumped into this groove by shear action from the rotation of the shaft and is then stopped by the dam. In high-speed operation, this situation creates a high oil pressure over the upper half of the bearing. The pressure created in the oil groove and surrounding upper half of the bearing increases the load on the lower half of the bearing. This self-generated load increases the shaft eccentricity. If the eccentricity is increased to 0.6 or greater, stable operation under high-speed, low-load conditions can result. The central oil groove can be extended around the lower half of the bearing, further increasing the effective loading. This design has one primary disadvantage: Dirt in the oil will tend to abrade the sharp edge of the dam and impair ability to create high pressures.

*Multiple-groove bearings*, Fig. 1(d), are sometimes used to provide increased oil flow. The interruptions in the oil film also appear to give this bearing some merit as a stable design.

*Elliptical bearings*, Fig. 1(e), are not truly elliptical, but are formed from two sections of a cylinder. This two-piece bearing has a large clearance in the direction of the split and a smaller clearance in the load direction at right angles to the split. At light loads, the shaft runs eccentric to both halves of the bearing, and hence, the elliptical bearing has a higher oil flow than the corresponding cylindrical bearing. Thus, the elliptical bearing will run cooler and will be more stable than a cylindrical bearing.

*Elliptical-overshot bearings* (not shown) are elliptical bearings in which the upper half is relieved by a wide oil groove connecting the axial oil grooves. They are analogous to cylindrical-overshot bearings.

*Displaced elliptical bearings*, Fig. 1(f), shift the centers of the two bearing arcs in both a horizontal and a vertical direction. This design has greater stiffness than a cylindrical bearing, in both horizontal and vertical directions, with substantially higher oil flow. It has not been extensively used, but offers the prospect of high stability and cool operation.

*Three-lobe bearings*, Fig. 1(g), are made up in cross section of three circular arcs. They are most effective as antioil whip bearings when the centers of curvature of each of the three lobes lie well outside the clearance circle that the shaft center can describe within the bearing. Three axial oil-feed grooves are used. It is a more difficult design to manufacture, because it is almost necessary to make it in three parts instead of two. The bore is machined with shims between each of the three parts. The shims are removed after machining is completed.

*Pivoted-shoe bearings*, Fig. 1(h), are one of the most stable bearings. The bearing surface is divided into three or more segments, each of which is pivoted at the center. In operation, each shoe tilts to form a wedge-shaped oil film, thus creating a force tending to push the shaft toward the center of the bearing. For single-direction rotation, the shoes are sometimes pivoted near one end and forced toward the shaft by springs.

*Nutcracker bearings*, Fig. 1(i), consist of two cylindrical half-bearings. The upper half-bearing is free to move in a vertical direction and is forced toward the shaft by a hydraulic cylinder. External oil pressure may be used to create load on the upper half of the bearing through the hydraulic cylinder. Or the high-pressure oil may be obtained from the lower half of the bearing by tapping a hole into the high-pressure oil film, thus creating a self-loading bearing. Either type can increase bearing eccentricity to the point where stable operation can be achieved.

**Hydrostatic Bearings.**—Hydrostatic bearings are used when operating conditions require full film lubrication that cannot be developed hydrodynamically. The hydrostatically lubricated bearing, either thrust or radial, is supplied with lubricant under pressure from an external source. Some advantages of the hydrostatic bearing over bearings of other types are: low friction; high load capacity; high reliability; high stiffness; and long life.

Hydrostatic bearings are used successfully in many applications including machine tools, rolling mills, and other heavily loaded slow-moving machinery. However, specialized techniques, including a thorough understanding of hydraulic components external to the bearing package is required. The designer is cautioned against use of this type of bearing without a full knowledge of all aspects of the problem. Determination of the operating performance of hydrostatic bearings is a specialized area of the lubrication field and is described in specialized reference books.

**Guide Bearings.**—This type of bearing is generally used as a positioning device or as a guide to linear motion such as in machine tools. Fig. 2 shows several examples of guide-way bearing designs. It is normal for this type of bearing to operate in the boundary lubrication region with either dry, dry film such as molybdenum disulfide ( $\text{MoS}_2$ ) or tetrafluorethylene (TFE), grease, oil, or gaseous lubrication. Hydrostatic lubrication is often used to improve performance, reduce wear, and increase stability. This type of design uses pumps to supply air or gas under pressure to pockets designed to produce a bearing film and maintain complete separation of the sliding surfaces.

Fig. 2. Types of Guide Bearings

**Design.**—The design of a sliding bearing is generally accomplished in one of two ways:

1) a bearing operating under similar conditions is used as a model or basis from which the new bearing is designed; and 2) in the absence of any previous experience with similar bearings in similar environments, certain assumptions concerning operating conditions and requirements are made and a tentative design prepared based on general design parameters or rules of thumb. Detailed lubrication analysis is then performed to establish design and operating details and requirements.

**Modes of Bearing Operation.**—The load-carrying ability of a sliding bearing depends upon the kind of fluid film that is formed between its moving surfaces. The formation of this film is dependent, in part, on the design of the bearing and, in part, on the speed of rotation. The bearing has three modes or regions of operation designated as *full-film*, *mixed-film*, and *boundary* lubrication with effects on bearing friction, as shown in Fig. 3.

In terms of physical bearing operation these three modes may be further described as follows:

Fig. 3. Three modes of bearing operation.

1) Full-film, or hydrodynamic, lubrication produces a complete physical separation of the sliding surfaces resulting in low friction and long wear-free service life.

To promote full-film lubrication in hydrodynamic operation, the following parameters should be satisfied: a) Lubricant selected has the correct viscosity for the proposed operation; b) proper lubricant flow rates are maintained; c) proper design methods and considerations have been utilized; and d) surface velocity in excess of 25 fpm (7.62 m/min) is maintained.

When full-film lubrication is achieved, a coefficient of friction between 0.001 and 0.005 can be expected.

2) Mixed-film lubrication is a mode of operation between the full-film and boundary modes. With this mode, there is a partial separation of the sliding surfaces by the lubricant film; however, as in boundary lubrication, limitations on surface speed and wear will result. With this type of lubrication, a surface velocity in excess of 10 fpm (3.05 m/min) is required with resulting coefficients of friction of 0.02 to 0.08.

3) Boundary lubrication takes place when the sliding surfaces are rubbing together with only an extremely thin film of lubricant present. This type of operation is acceptable only in applications with oscillating or slow rotary motion. In complete boundary lubrication, the oscillatory or rotary motion is usually less than 10 feet per minute with resulting coefficients of friction of 0.08 to 0.14. These bearings are usually grease lubricated or periodically oil lubricated.

In starting up and accelerating to its operating point, a journal bearing passes through all three modes of operation. At rest, the journal and bearing are in contact, and thus when starting, the operation is in the boundary lubrication region. As the shaft begins to rotate more rapidly and the hydrodynamic film starts to build up, bearing operation enters the

region of mixed-film lubrication. When design speeds and loads are reached, the hydrodynamic action in a properly designed bearing will promote full-film lubrication.

**Methods of Retaining Bearings.**— Several methods are available to ensure that a bearing remains in place within a housing. Which method to use depends upon the particular application but requires first that the unit lends itself to convenient assembly and disassembly; additionally, the bearing wall should be of uniform thickness to avoid introduction of weak points in the construction that may lead to elastic or thermal distortion.

*Press or Shrink Fit:* One common and satisfactory technique for retaining the bearing is to press or shrink the bearing in the housing with an interference fit. This method permits the use of bearings having uniform wall thickness over the entire bearing length.

Standard bushings with finished inside and outside diameters are available in sizes up to approximately 5 inches (127 mm) inside diameter. Stock bushings are commonly provided 0.002 to 0.003 inch (50.8–76.2 mm) over nominal on outside diameter sizes of 3 inches (76.2 mm) or less. For diameters greater than 3 inches, outside diameters are 0.003 to 0.005 inch (76.2–127 mm) over nominal. Because these tolerances are built into standard bushings, the amount of press fit is controlled by the housing-bore size.

As a result of a press or shrink fit, the bore of the bearing material “closes in” by some amount. In general, this diameter decrease is approximately 70 to 100 percent of the amount of the interference fit. Any attempt to accurately predict the amount of reduction, in an effort to avoid final clearance machining, should be avoided.

Shrink fits may be accomplished by chilling the bearing in a mixture of dry ice and alcohol, or in liquid air. These methods are easier than heating the housing and are preferred. Dry ice in alcohol has a temperature of  $-110^{\circ}\text{F}$  ( $-79^{\circ}\text{C}$ ) and liquid air boils at  $-310^{\circ}\text{F}$  ( $-190^{\circ}\text{C}$ ).

When a bearing is pressed into the housing, the driving force should be uniformly applied to the end of the bearing to avoid upsetting or peening of the bearing. Of equal importance, the mating surfaces must be clean, smoothly finished, and free of machining imperfections.

*Keying Methods:* A variety of methods can be used to fix the position of the bearing with respect to its housing by “keying” the two together. Possible keying methods are shown in Figs. 4a through 4f including: a) set screws; b) Woodruff keys; c) bolted bearing flanges; d) threaded bearings; e) dowel pins; and f) housing caps.

Factors to be considered when selecting one of these methods are as follows:

- 1) Maintaining uniform wall thickness of the bearing material, if possible, especially in the load-carrying region of the bearing.
- 2) Providing as much contact area as possible between bearing and housing. Mating surfaces should be clean, smooth, and free from imperfections to facilitate heat transfer.
- 3) Preventing any local deformation of the bearing that might result from the keying method. Machining after keying is recommended.
- 4) Considering the possibility of bearing distortion resulting from the effect of temperature changes on the particular keying method.

**Methods of Sealing.**— In applications where lubricants or process fluids are utilized in operation, provision must be made normally to prevent leakage to other areas. This provision is made by the use of static and dynamic type sealing devices. In general, three terms are used to describe the devices used for sealing:

*Seal:* A means of preventing migration of fluids, gases, or particles across a joint or opening in a container.

*Packing:* A dynamic seal, used where some form of relative motion occurs between rigid members of an assembly.

*Gaskets:* A static seal, used where there is no relative motion between joined parts.

## Methods of Bearing Retention

Fig. 4a. Set Screws

Fig. 4b. Woodruff Key

Fig. 4c. Bolts through Flange

Fig. 4d. Bearing Screwed into Housing

Fig. 4e. Dowel Pin

Fig. 4f. Housing Cap

Two major functions must be achieved by all sealing applications: prevent escape of fluid; and prevent migration of foreign matter from the outside.

The first determination in selecting the proper seal is whether the application is static or dynamic. To meet the requirements of a static application there must be no relative motion between the joining parts or between the seal and the mating part. If there is any relative motion, the application must be considered dynamic, and the seal selected accordingly.

Dynamic sealing requires control of fluids leaking between parts with relative motion. Two primary methods are used to this end: positive contact or rubbing seals; and controlled clearance noncontact seals.

*Positive Contact or Rubbing Seals:* These seals are used where positive containment of liquids or gases is required, or where the seal area is continuously flooded. If properly selected and applied, contact seals can provide zero leakage for most fluids. However, because they are sensitive to temperature, pressure, and speed, improper application can result in early failure. These seals are applicable to rotating and reciprocating shafts. In many assemblies, positive-contact seals are available as off-the-shelf items. In other instances, they are custom-designed to the special demands of a particular application. Custom design is offered by many seal manufacturers and, for extreme cases, probably offers the best solution to the sealing problem.

*Controlled Clearance Noncontact Seals:* Representative of the controlled-clearance seals, which includes all seals in which there is no rubbing contact between the rotating and

stationary members, are throttling bushings and labyrinths. Both types operate by fluid-throttling action in narrow annular or radial passages.

Clearance seals are frictionless and very insensitive to temperature and speed. They are chiefly effective as devices for limiting leakage rather than stopping it completely. Although they are employed as primary seals in many applications, the clearance seal also finds use as auxiliary protection in contact-seal applications. These seals are usually designed into the equipment by the designer himself, and they can take on many different forms.

Advantages of this seal are that friction is kept to an absolute minimum and there is no wear or distortion during the life of the equipment. However, there are two significant disadvantages: The seal has limited use when leakage rates are critical; and it becomes quite costly as the configuration becomes elaborate.

*Static Seals:* Static seals such as gaskets, “O” rings, and molded packings cover very broad ranges of both design and materials.

Some of the typical types are as follows: 1) Molded packings: a) lip type, and b) squeeze-molded; 2) simple compression packings; 3) diaphragm seals; 4) nonmetallic gaskets; 5) “O” rings; and 6) metallic gaskets and “O” rings.

Data on “O” rings are found starting on page 2603.

Detailed design information for specific products should be obtained directly from manufacturers.

**Hardness and Surface Finish.**— Even in well-lubricated full-film sleeve bearings, momentary contact between journal and bearing may occur under such conditions as starting, stopping, or overloading. In mixed-film and boundary-film lubricated sleeve bearings, continuous metal-to-metal contact occurs. Hence, to allow for any necessary wearing-in, the journal is usually made harder than the bearing material. This arrangement allows the effects of scoring or wearing to take place on the bearing, which is more easily replaced, rather than on the more expensive shaft. As a general rule, recommended Brinell\* hardness (HB) of the journal is at least 100 points harder than the bearing material.

The softer cast bronzes used for bearings are those with high lead content and very little tin. Such bronzes give adequate service in boundary- and mixed-film applications where full advantage is taken of their excellent “bearing” characteristics.

High-tin, low-lead content cast bronzes are the harder bronzes and these have high ultimate load-carrying capacity: higher journal hardnesses are required with these bearing bronzes. Aluminum bronze, for example, requires a journal hardness in the range of 550 to 600 HB.

In general, harder bearing materials require better alignment and more reliable lubrication to minimize local heat generation if and when the journal touches the shaft. Also, abrasives that find their way into the bearing are a problem for the harder bearing materials and greater care should be taken to exclude them.

*Surface Finish:* Whether bearing operation is complete boundary, mixed film, or fluid film, surface finishes of the journal and bearing must receive careful attention. In applications where operation is hydrodynamic or full-film, peak surface variations should be less than the expected minimum film thickness; otherwise, peaks on the journal surface will contact peaks on the bearing surface, with resulting high friction and temperature rise. Ranges of surface roughness obtained by various finishing methods are: boring, broaching, and reaming, 32 to 64  $\mu\text{in}$  (0.813–1.626  $\mu\text{m}$ ), rms; grinding, 16 to 64  $\mu\text{in}$  (0.406–1.626  $\mu\text{m}$ ), rms; and fine grinding, 4 to 16  $\mu\text{in}$  (0.102–0.406  $\mu\text{m}$ ), rms.

In general, the better surface finishes are required for full-film bearings operating at high eccentricity ratios because full-film lubrication must be maintained with small clearances,

\* Brinell hardness, formerly abbreviated BHN, is now generically abbreviated HB, HBS for hardness measured with a steel indenter, and HBW for hardness measured with a carbide indenter.

and metal-to-metal contact must be avoided. Also, the harder the material, the better the surface finish required. For boundary- and mixed-film applications, surface finish requirements may be somewhat relaxed because bearing wear-in will in time smooth the surfaces.

Fig. 5 is a general guide to the ranges required for bearing and journal surface finishes. Selecting a particular surface finish in each range can be simplified by observing the general rule that smoother finishes are required for the harder materials, for high loads, and for high speeds.

Fig. 5. Recommended ranges of surface finish for the three types of sleeve bearing operations.

**Machining Bores.**—The methods most commonly used in finishing journal bearing bores are boring, broaching, reaming, and burnishing.

Broaching is a rapid finishing method providing good size and alignment control when adequate piloting is possible. Soft babbitt materials are particularly compatible with the broaching method. A third finishing method, reaming, facilitates good size and alignment control when piloting is utilized. Reaming can be accomplished both manually or by machine, the machine method being preferred. Burnishing is a fast sizing operation that gives good alignment control, but does not give as good size control as the cutting methods. It is not recommended for soft materials such as babbitt. Burnishing has an ironing effect that gives added seating of the bushing outside diameter in the housing bore; consequently, it is often used for this purpose, especially on a  $\frac{1}{32}$ -inch (0.794 mm) wall bushing, even if a further sizing operation is to be used subsequently.

Boring of journal bearings provides the best concentricity, alignment, and size control and is the finishing method of choice when close tolerances and clearances are desirable.

**Methods of Lubrication.**—There are numerous ways to supply lubricant to bearings. The more common of these are described in the following.

*Pressure lubrication*, in which an abundance of oil is fed to the bearing from a central groove, single or multiple holes, or axial grooves, is effective and efficient. The moving oil assists in flushing dirt from the bearing and helps keep the bearing cool. In fact, it removes heat faster than other lubricating methods and, therefore, permits thinner oil films and unimpaired load capacities. The oil-supply pressure needed for bushings carrying the basic load is directly proportional to the shaft speed, but for most installations, 50 psi (345 kPa) will be adequate.

*Splash fed* applies to a variety of intermittently lubricated bushings. It includes everything from bearings spattered with oil from the action of other moving parts to bearings regularly dipped in oil. Like oil bath lubrication, splash feeding is practical when the housing can be made oiltight and when the moving parts do not churn the oil. The fluctuating nature of the load and the intermittent oil supply in splash fed applications requires the designer to use experience and judgment when determining the probable load capacity of bearings lubricated in this way.

*Oil bath lubrication*, in which the bushing is submerged in oil, is the most reliable of all methods except pressure lubrication. It is practical if the housing can be made oil tight, and if the shaft speed is not so great as to cause excessive churning of the oil.

*Oil ring lubrication*, in which oil is supplied to the bearing by a ring in contact with the shaft, will, within reasonable limits, bring enough oil to the bearing to maintain hydrodynamic lubrication. If the shaft speed is too low, little oil will follow the ring to the bearing; and, if the speed is too high, the ring speed will not keep pace with the shaft. Also, a ring revolving at high speed will lose oil by centrifugal force. For best results, the peripheral speed of the shaft should be between 200 and 2000 fpm (61 and 610 m/min). Safe load to achieve hydrodynamic lubrication should be one-half of that for pressure fed bearings. Unless the load is light, hydrodynamic lubrication is doubtful. The safe load, then, to achieve hydrodynamic lubrication, should be one-quarter of that of pressure fed bearings.

*Wick or waste pack lubrication* delivers oil to a bushing by the capillary action of a wick or waste pack; the amount delivered is proportional to the size of the wick or pack.

*Lubricants:* The value of an oil as a lubricant depends mainly on its film-forming capacity, that is, its capability to maintain a film of oil between the bearing surfaces. The film-forming capacity depends to a large extent on the viscosity of the oil, but this should not be understood to mean that oil of the highest viscosity is always the most suitable lubricant. For practical reasons, an oil of the lowest viscosity that will retain an unbroken oil film between the bearing surfaces is the most suitable for purposes of lubrication. A higher viscosity than that necessary to maintain the oil film results in a waste of power due to the expenditure of energy necessary to overcome the internal friction of the oil itself.

Fig. 6 provides representative values of viscosity in centipoises for SAE mineral oils. Table 56a on page 2791 is provided as a means of converting viscosities of other units to centipoises.

Grease packed in a cavity surrounding the bushing is less adequate than an oil system, but it has the advantage of being more or less permanent. Although hydrodynamic lubrication is possible under certain very favorable circumstances, boundary lubrication is the usual state.

**Lubricant Selection.**— In selecting lubricants for journal bearing operation, several factors must be considered: 1) type of operation (full, mixed, or boundary film) anticipated; 2) surface speed; and 3) bearing loading.

Fig. 7 combines these factors and facilitates general selection of the proper lubricant viscosity range.

As an example of using these curves, consider a lightly loaded bearing operating at 2000 rpm. At the bottom of the figure, locate 2000 rpm and move vertically to intersect the light-load full-film lubrication curve, which indicates an SAE 5 oil.

As a general rule-of-thumb, heavier oils are recommended for high loads and lighter oils for high speeds.

In addition, other than using conventional lubrication oils, journal bearings may be lubricated with greases or solid lubricants. Some of the reasons for use of these lubricants are to:

- 1) Lengthen the period between relubrication:
- 2) Avoid contaminating surrounding equipment or material with “leaking” lubricating oil;

Fig. 6. Viscosity vs. Temperature—SAE oils.

- 3) Provide effective lubrication under extreme temperature ranges;
- 4) Provide effective lubrication in the presence of contaminating atmospheres; and
- 5) Prevent intimate metal-to-metal contact under conditions of high unit pressure which might destroy boundary lubricating films.

**Greases:** Where full-film lubrication is not possible or is impractical for slow-speed fairly high-load applications, greases are widely used as bearing lubricants. Although full-film lubrication with grease is possible, it is not normally considered since an elaborate pumping system is required to continuously supply a prescribed amount of grease to the bearing. Bearings supplied with grease are usually lubricated periodically. Grease lubrication, therefore, implies that the bearing will operate under conditions of complete boundary lubrication and should be designed accordingly.

Lubricating greases are essentially a combination of a mineral lubricating oil and a thickening agent, which is usually a metallic soap. When suitably mixed, they make excellent

Fig. 7. Lubricant Selection Guide

bearing lubricants. There are many different types of greases which, in general, may be classified according to the soap base used. Information on commonly used greases is shown in [Table 1](#).

**Table 1. Commonly Used Greases and Solid Lubricants**

Type	Operating Temperature		Load	Comments
	°F	°C		
Greases				
Calcium or lime soap	160	71	Moderate	...
Sodium soap	300	149	Wide	For wide speed range
Aluminum soap	180	82	Moderate	...
Lithium soap	300	149	Moderate	Good low temperature
Barium soap	350	177	Wide	...
Solid Lubricants				
Graphite	1000	538	Wide	...
Molybdenum disulfide	-100 to 750	-73 to 399	Wide	...

Synthetic greases are composed of normal types of soaps but use synthetic hydrocarbons instead of normal mineral oils. They are available in a range of consistencies in both water-soluble and insoluble types. Synthetic greases can accommodate a wide range of variation in operating temperature; however, recommendations on special-purpose greases should be obtained from the lubricant manufacturer.

Application of grease is accomplished by one of several techniques depending upon grease consistency. These classifications are shown in [Table 2](#) along with typical methods of application. Grooves for grease are generally greater in width, up to 1.5 times, than for oil.

Coefficients of friction for grease-lubricated bearings range from 0.08 to 0.16, depending upon consistency of the grease, frequency of lubrication, and type of grease. An average value of 0.12 may be used for design purposes.

**Table 2. NLGI Consistency Numbers**

NLGI <sup>a</sup> Consistency No.	Consistency of Grease	Typical Method of Application
0	Semifluid	Brush or gun
1	Very soft	Pin-type cup or gun
2	Soft	Pressure gun or centralized pressure system
3	Light cup grease	Pressure gun or centralized pressure system
4	Medium cup grease	Pressure gun or centralized pressure system
5	Heavy cup grease	Pressure gun or hand
6	Block grease	Hand, cut to fit

<sup>a</sup>NLGI is National Lubricating Grease Institute

**Solid Lubricants:** The need for effective high-temperature lubricants led to the development of several solid lubricants. Essentially, solid lubricants may be described as low-shear-strength solid materials. Their function within a bronze bearing is to act as an intermediary material between sliding surfaces. Since these solids have very low shear strength, they shear more readily than the bearing material and thereby allow relative motion. So long as solid lubricant remains between the moving surfaces, effective lubrication is provided and friction and wear are reduced to acceptable levels.

Solid lubricants provide the most effective boundary films in terms of reduced friction, wear, and transfer of metal from one sliding component to the other. However, there is a significant deterioration in these desirable properties as the operating temperature of the boundary film approaches the melting point of the solid film. At this temperature the friction may increase by a factor of 5 to 10 and the rate of metal transfer may increase by as much as 1000. What occurs is that the molecules of the lubricant lose their orientation to the surface that exists when the lubricant is solid. As the temperature further increases, additional deterioration sets in with the friction increasing by some additional small amount but the transfer of metal accelerates by an additional factor of 20 or more. The final effect of too high temperature is the same as metal-to-metal contact without benefit of lubricant. These changes, which are due to the physical state of the lubricant, are reversed when cooling takes place.

The effects just described also partially explain why fatty acid lubricants are superior to paraffin base lubricants. The fatty acid lubricants react chemically with the metallic surfaces to form a metallic soap that has a higher melting point than the lubricant itself, the result being that the breakdown temperature of the film, now in the form of a metallic soap is raised so that it acts more like a solid film lubricant than a fluid film lubricant.

### Journal or Sleeve Bearings

Although this type of bearing may take many shapes and forms, there are always three basic components: journal or shaft, bushing or bearing, and lubricant. Fig. 1 shows these components with the nomenclature generally used to describe a journal bearing:  $W$  = applied load,  $N$  = revolution,  $e$  = eccentricity of journal center to bearing center,  $\theta$  = attitude angle, which is the angle between the applied load and the point of minimum film thickness,  $d$  = diameter of the shaft,  $c_d$  = bearing clearance,  $d + c_d$  = diameter of the bearing and  $h_o$  = minimum film thickness.

**Grooving and Oil Feeding.**— Grooving in a journal bearing has two purposes:

- 1) to establish and maintain an efficient film of lubricant between the bearing moving surfaces and
- 2) to provide adequate bearing cooling

The obvious and only practical location for introducing lubricant to the bearing is in a region of low pressure. A typical pressure profile of a bearing is shown by Fig. 2. The

Fig. 1. Basic components of a journal bearing. arrow  $W$  shows the applied load. Typical grooving configurations used for journal bearings are shown in Figs. 3a through 3e.

Fig. 2. Typical pressure profile of journal bearing.

### Types of Journal Bearing Oil Grooving

Fig. 3a. Single inlet hole

Fig. 3b. Circular groove

Fig. 3c. Straight axial groove

Fig. 3d. Straight axial groove with feeder groove

Fig. 3e. Straight axial groove in shaft

**Heat Radiating Capacity.**— In a self-contained lubrication system for a journal bearing, the heat generated by bearing friction must be removed to prevent continued temperature rise to an unsatisfactory level. The heat-radiating capacity  $H_R$  of the bearing in foot-pounds per minute may be calculated from the formula  $H_R = Ld Ct_R$  in which  $C$  is a constant determined by O. Lasche, and  $t_R$  is temperature rise in degrees Fahrenheit.

Values for the product  $Ct_R$  may be found from the curves in Fig. 4 for various values of bearing temperature rise  $t_R$  and for three operating conditions. In this equation,  $L$  = total length of the bearing in inches and  $d$  = bearing diameter in inches.

Fig. 4. Heat-radiating capacity factor,  $C_{tR}$ , vs. bearing temperature rise,  $t_R$ —journal bearings.

**Journal Bearing Design Notation.**— The symbols used in the following step-by-step procedure for lubrication analysis and design of a plain sleeve or journal bearing are as follows:

- $c$  = specific heat of lubricant, Btu/lb/degree F
- $c_d$  = diametral clearance, inches
- $C_n$  = bearing capacity number
- $d$  = journal diameter, inches
- $e$  = eccentricity, inches
- $h_o$  = minimum film thickness, inch
- $K$  = constants
- $l$  = bearing length as defined in Fig. 5, inches
- $L$  = actual length of bearing, inches
- $m$  = clearance modulus
- $N$  = rpm
- $p_b$  = unit load, psi
- $p_s$  = oil supply pressure, psi
- $P_f$  = friction horsepower
- $P'$  = bearing pressure parameter
- $q$  = flow factor
- $Q_1$  = hydrodynamic flow, gpm
- $Q_2$  = pressure flow, gpm
- $Q$  = total flow, gpm
- $Q_{new}$  = new total flow, gpm
- $Q_R$  = total flow required, gpm

- $r$  = journal radius, inches  
 $\Delta t$  = actual temperature rise of oil in bearing, °F  
 $\Delta t_a$  = assumed temperature rise of oil in bearing, °F  
 $\Delta t_{new}$  = new assumed temperature rise of oil in bearing, °F  
 $t_b$  = bearing operating temperature, °F  
 $t_{in}$  = oil inlet temperature, °F  
 $T_f$  = friction torque, inch-pounds/inch  
 $T'$  = torque parameter  
 $W$  = load, pounds  
 $X$  = factor  
 $Z$  = viscosity, centipoises  
 $\epsilon$  = eccentricity ratio — ratio of eccentricity to radial clearance  
 $\alpha$  = oil density, lbs/inch<sup>3</sup>

Fig. 5. Length,  $l$ , of bearing for circular groove type (left) and single inlet hole type (right).

**Journal Bearing Lubrication Analysis.**— The following procedure leads to a complete lubrication analysis which forms the basis for the bearing design.

1) *Diameter of bearing  $d$* : This is usually determined by considering strength and/or deflection requirements for the shaft using principles of strength of materials.

2) *Length of bearing  $L$* : This is determined by an assumed  $l/d$  ratio in which  $l$  may or may not be equal to the overall length,  $L$  (see Step 6). Bearing pressure and the possibility of edge loading due to shaft deflection and misalignment are factors to be considered. In general, shaft misalignment resulting from location tolerances and/or shaft deflections should be maintained below 0.0003 inch per inch of length.

3) *Bearing pressure  $p_b$* : The unit load in pound per square inch is calculated from the formula:

$$p_b = \frac{W}{Kld}$$

where  $K = 1$  for single oil hole

$K = 2$  for central groove

$W$  = load, pounds

$l$  = bearing length as defined in Fig. 5, inches

$d$  = journal diameter, inches

Typical unit loads in service are shown in Table 3. These pressures can be used as a safe guide in selection. However, if space limitations impose a higher limit of loading, the complete lubrication analysis and evaluation of material properties will determine acceptability.

**Table 3. Allowable Sleeve Bearing Pressures for Various Classes of Bearings**

Types of Bearing or Kind of Service	Pressure <sup>a</sup> psi(MPa)	Types of Bearing or Kind of Service	Pressure <sup>a</sup> psi(MPa)
Electric Motor & Generator Bearings (General)	100–200 (0.69–1.38)	Diesel Engine Rod	1000–2000 (6.89–13.79)
Turbine & Reduction Gears	100–250 (0.69–1.72)	Wrist Pins	1800–2000 (12.41–13.79)
Heavy Line Shafting	100–150 (0.69–1.03)	Automotive, Main Bearings	500–700 (3.45–4.83)
Locomotive Axles	300–350 (2.07–2.41)	Automotive, Rod Bearings	1500–2500 (10.34–17.24)
Light Line Shafting	15–35 (0.103–0.241)	Centrifugal Pumps	80–100 (0.55–0.689)
Diesel Engine, Main	800–1500 (5.52–10.34)	Aircraft Rod Bearings	700–3000 (4.83–20.68)

<sup>a</sup>These pressures in psi(MPa) of area equal to length times diameter are intended as a general guide only. The allowable unit pressure depends upon operating conditions, especially in regard to lubrication, design of bearings, workmanship, velocity, and nature of load.

4) *Diametral clearance  $c_d$* : This is selected on a trial basis from Fig. 6 which shows suggested diametral clearance ranges for various shaft sizes and for two speed ranges. These are *hot* or *operating* clearances so that thermal expansion of journal and bearing to these temperatures must be taken into consideration in establishing machining dimensions. The optimum operating clearance should be determined on the basis of a complete lubrication analysis (see paragraph following Step 23).

5) *Clearance modulus  $m$* : This is calculated from the formula:  $m = \frac{c_d}{d}$

6) *Length to diameter ratio  $l/d$* : This is usually between 1 and 2; however, with the modern trend toward higher speeds and more compact units, lower ratios down to 0.3 are used. In shorter bearings there is a consequent reduction in load carrying capacity due to excessive end or side leakage of lubricant. In longer bearings there may be a tendency towards edge loading. Length  $l$  for a single oil feed hole is taken as the total length of the bearing as shown in Fig. 5. For a central oil groove length,  $l$  is taken as one-half the total length.

Typical  $l/d$  ratio's use for various types of applications are given in Table 4.

7) *Assumed operating temperature  $t_b$* : A temperature rise of the lubricant as it passes through the bearing is assumed and the consequent operating temperature in degrees F is calculated from the formula:

$$t_b = t_{in} + \Delta t_a$$

where  $t_{in}$  = inlet temperature of oil in °F

$\Delta t_a$  = assumed temperature rise of oil in bearing in °F. An initial assumption of 20°F is usually made.

8) *Viscosity of lubricant  $Z$* : The viscosity in centipoises at the assumed bearing operating temperature is found from the curve in Fig. 6 which shows the viscosity of SAE grade oils versus temperature.

9) *Bearing pressure parameter  $P'$* : This value is required to find the eccentricity ratio and is calculated from the formula:

Fig. 6. Operating diametral clearance  $C_d$  vs. journal diameter  $d$ .

**Table 4. Representative  $l/d$  Ratios**

Type of Service	$l/d$	Type of Service	$l/d$
Gasoline and diesel engine		Light shafting	2.5 to 3.5
main bearings and crankpins	0.3 to 1.0	Heavy shafting	2.0 to 3.0
Generators and motors	1.2 to 2.5	Steam engine	
Turbogenerators	0.8 to 1.5	Main bearings	1.5 to 2.5
Machine tools	2.0 to 3.0	Crank and wrist pins	1.0 to 1.3

$$P' = \frac{6.9(1000m)^2 p_b}{ZN}$$

where  $N = \text{rpm}$

10) *Eccentricity ratio*  $\epsilon$ : Using  $P'$  and  $l/d$ , the value of  $1/(1 - \epsilon)$  is determined from Fig. 7 and from this,  $\epsilon$  can be determined.

Fig. 7. Bearing parameter,  $P'$ , vs. eccentricity ratio,  $1/(1-\epsilon)$  — journal bearings.

11) *Torque parameter  $T'$* : This value is obtained from Fig. 8 or Fig. 9 using  $1/(1-\epsilon)$  and  $l/d$ .

12) *Friction torque  $T$* : This value is calculated from the formula:

$$T = \frac{T' r^2 Z N}{6900(1000m)}$$

where  $r$  = journal radius, inches

13) *Friction horsepower  $P_f$* : This value is calculated from the formula:

$$P_f = \frac{KTNI}{63,000}$$

where  $K = 1$  for single oil hole, 2 for central groove.

14) *Factor  $X$* : This factor is used in the calculation of the lubricant flow and can either be obtained from Table 5 or calculated from the formula:

$$X = 0.1837/\alpha c$$

where  $\alpha$  = oil density in pounds per cubic inch

$c$  = specific heat of lubricant in Btu/lb/°F

15) *Total flow of lubricant required  $Q_R$* : This is calculated from the formula:

$$Q_R = \frac{X(P_f)}{\Delta t_a}$$

16) *Bearing capacity number  $C_n$* : This value is needed to obtain the flow factor and is calculated from the formula:

Fig. 8. Torque parameter,  $T'$ , vs eccentricity ratio,  $1/(1-\epsilon)$  — journal bearings.

Fig. 9. Torque parameter,  $T'$ , vs eccentricity ratio,  $1/(1-\epsilon)$  — journal bearings.

**Table 5. X Factor vs. Temperature of Mineral Oils**

Temperature	X Factor
100	12.9
150	12.4
200	12.1
250	11.8
300	11.5

$$C_n = \left(\frac{l}{d}\right)^2 / 60P'$$

17) *Flow factor*  $q$ : This value is obtained from the curve in Fig. 10.

Fig. 10. Flow factor,  $q$ , vs. bearing capacity number,  $C_n$ —journal bearings.

18) *Hydrodynamic flow of lubricant*  $Q_1$ : This flow in gallons per minute is calculated from the formula:

$$Q_1 = \frac{Nl c_d q d}{294}$$

19) *Pressure flow of lubricant*  $Q_2$ : This flow in gallons per minute is calculated from the formula:

$$Q_2 = \frac{K p_s c_d^3 d (1 + 1.5 \epsilon^2)}{Zl}$$

where  $K = 1.64 \times 10^5$  for single oil hole

$K = 2.35 \times 10^5$  for central groove

$p_s$  = oil supply pressure

20) *Total flow of lubricant  $Q$* : This value is obtained by adding the hydrodynamic flow and the pressure flow.

$$Q = Q_1 + Q_2$$

21) *Bearing temperature rise  $\Delta t$* : This temperature rise in degrees F is obtained from the formula:

$$\Delta t = \frac{X(P_f)}{Q}$$

22) *Comparison of actual and assumed temperature rises*: At this point if  $\Delta t_a$  and  $\Delta t$  differ by more than 5 °F, Steps 7 through 22 are repeated using a  $\Delta t_{new}$  halfway between the former  $\Delta t_a$  and  $\Delta t$ .

23) *Minimum film thickness  $h_o$* : When Step 22 has been satisfied, the minimum film thickness in inches is calculated from the formula:  $h_o = \frac{1}{2}C_d(1 - \epsilon)$ .

A new diametral clearance  $c_d$  is now assumed and Steps 5 through 23 are repeated. When this repetition has been done for a sufficient number of values for  $c_d$ , the full lubrication study is plotted as shown in Fig. 11. From this chart a working range of diametral clearance can be determined that optimizes film thickness, differential temperature, friction horsepower and oil flow.

Fig. 11. Example of lubrication analysis curves for journal bearing.

**Use of Lubrication Analysis.**— Once the lubrication analysis has been completed and plotted as shown in Fig. 11, the following steps lead to the optimum bearing design, taking into consideration both basic operating requirements and requirements peculiar to the application.

1) Examine the curve (Fig. 11) for minimum film thickness and determine the acceptable range of diametral clearance,  $c_d$ , based on

- a) a minimum of  $200 \times 10^{-6}$  inches for small bearings under 1 inch diameter
- b) a minimum of  $500 \times 10^{-6}$  inches for bearings from 1 to 4 inches diameter

c) a minimum of  $750 \times 10^{-6}$  inches for larger bearings.

More conservative designs would increase these requirements

2) Determine the minimum acceptable  $c_d$  based on a maximum  $\Delta t$  of  $40^\circ\text{F}$  from the oil temperature rise curve (Fig. 11).

3) If there are no requirements for maintaining low friction horsepower and oil flow, the possible limits of diametral clearance are now defined.

4) The required manufacturing tolerances can now be placed within this band to optimize  $h_o$  as shown by Fig. 11.

5) If oil flow and power loss are a consideration, the manufacturing tolerances may then be shifted within the range permitted by the requirements for  $h_o$  and  $\Delta t$ .

Fig. 12. Full journal bearing example design.

✧ *Example:* A full journal bearing, Fig. 12, 2.3 inches in diameter and 1.9 inches long, is to carry a load of 6000 pounds at 4800 rpm, using SAE 30 oil supplied at  $200^\circ\text{F}$  through a single oil hole at 30 psi. Determine the operating characteristics of this bearing as a function of diametral clearance.

1) *Diameter of bearing*, given as 2.3 inches.

2) *Length of bearing*, given as 1.9 inches.

3) *Bearing pressure:*

$$p_b = \frac{6000}{1 \times 1.9 \times 2.3} = 1372 \text{ lbs. per sq. in.}$$

4) *Diametral clearance:* Assume  $c_d$  is equal to 0.003 inch from Fig. 6 on page 2347 for first calculation.

5) *Clearance modulus:*  $m = \frac{0.003}{2.3} = 0.0013$  inch

6) *Length-to-diameter ratio:*

$$\frac{l}{d} = \frac{1.9}{2.3} = 0.83$$

7) *Assumed operating temperature:* If the temperature rise  $\Delta t_a$  is assumed to be  $20^\circ\text{F}$ ,

$$t_b = 200 + 20 = 220^\circ\text{F}$$

8) *Viscosity of lubricant:* From Fig. 6 on page 2340,  $Z = 7.7$  centipoises

9) *Bearing-pressure parameter:*

$$P' = \frac{6.9 \times 1.3^2 \times 1372}{7.7 \times 4800} = 0.43$$

10) *Eccentricity ratio:* From Fig. 7,  $\frac{1}{1 - \epsilon} = 6.8$  and  $\epsilon = 0.85$

11) *Torque parameter*: From Fig. 8,  $T' = 1.46$

12) *Friction torque*:

$$T_f = \frac{1.46 \times 1.15^2 \times 7.7 \times 4800}{6900 \times 1.3} = 7.96 \text{ inch-pounds per inch}$$

13) *Friction horsepower*:

$$P_f = \frac{1 \times 7.96 \times 4800 \times 1.9}{63,000} = 1.15 \text{ horsepower}$$

14) *Factor X*: From Table 5,  $X = 12$ , approximately

15) *Total flow of lubricant required*:

$$Q_R = \frac{12 \times 1.15}{20} = 0.69 \text{ gallon per minute}$$

16) *Bearing-capacity number*:

$$C_n = \frac{0.83^2}{60 \times 0.43} = 0.027$$

17) *Flow factor*: From Fig. 10,  $q = 1.43$

18) *Actual hydrodynamic flow of lubricant*:

$$Q_1 = \frac{4800 \times 1.9 \times 0.003 \times 1.43 \times 2.3}{294} = 0.306 \text{ gallon per minute}$$

19) *Actual pressure flow of lubricant*:

$$Q_2 = \frac{1.64 \times 10^5 \times 30 \times 0.003^3 \times 2.3 \times (1 + 1.5 \times 0.85^2)}{7.7 \times 1.9} = 0.044 \text{ gallon per min}$$

20) *Actual total flow of lubricant*:

$$Q = 0.306 + 0.044 = 0.350 \text{ gallon per minute}$$

21) *Actual bearing-temperature rise*:

$$\Delta t = \frac{12 \times 1.15}{0.350} = 39.4^\circ\text{F}$$

22) *Comparison of actual and assumed temperature rises*: Because  $\Delta t_a$  and  $\Delta t$  differ by more than  $5^\circ\text{F}$ , a new  $\Delta t_a$ , midway between these two, of  $30^\circ\text{F}$  is assumed and Steps 7 through 22 are repeated.

7a) *Assumed operating temperature*:

$$t_b = 200 + 30 = 230^\circ\text{F}$$

8a) *Viscosity of lubricant*: From Fig. 6,  $Z = 6.8$  centipoises

9a) *Bearing-pressure parameter*:

$$P' = \frac{6.9 \times 1.3^2 \times 1372}{6.8 \times 4800} = 0.49$$

10a) *Eccentricity ratio*: From Fig. 7,

$$\frac{1}{1 - \epsilon} = 7.4$$

and  $\epsilon = 0.86$

11a) *Torque parameter*: From Fig. 8,  $T' = 1.53$

12a) *Friction torque*:

$$T_f = \frac{1.53 \times 1.15^2 \times 6.8 \times 4800}{6900 \times 1.3} = 7.36 \text{ inch-pounds per inch}$$

13a) *Friction horsepower*:

$$P_f = \frac{1 \times 7.36 \times 4800 \times 1.9}{63,000} = 1.07 \text{ horsepower}$$

14a) *Factor X*: From **Table 5**,  $X = 11.9$  approximately

15a) *Total flow of lubricant required*:

$$Q_R = \frac{11.9 \times 1.07}{30} = 0.42 \text{ gallon per minute}$$

16a) *Bearing-capacity number*:

$$C_n = \frac{0.83^2}{60 \times 0.49} = 0.023$$

17a) *Flow factor*: From **Fig. 10**,  $q = 1.48$

18a) *Actual hydrodynamic flow of lubricant*:

$$Q_1 = \frac{4800 \times 1.9 \times 0.003 \times 1.48 \times 2.3}{294} = 0.317 \text{ gallon per minute}$$

19a) *Pressure flow*:

$$Q_2 = \frac{1.64 \times 10^5 \times 30 \times 0.003^3 \times 2.3 \times (1 + 1.5 \times 0.86^2)}{6.8 \times 1.9} = 0.050 \text{ gallon per minute}$$

20a) *Actual flow of lubricant*:

$$Q_{\text{new}} = 0.317 + 0.050 = 0.367 \text{ gallon per minute}$$

21a) *Actual bearing-temperature rise*:

$$\Delta t = \frac{11.9 \times 1.06}{0.367} = 34.4^\circ\text{F}$$

22a) *Comparison of actual and assumed temperature rises*: Now  $\Delta t$  and  $\Delta t_a$  are within 5 °F.

23) *Minimum film thickness*:

$$h_o = \frac{0.003}{2}(1 - 0.86) = 0.00021 \text{ inch}$$

This analysis may now be repeated for other values of  $c_d$  determined from **Fig. 6** and a complete lubrication analysis performed and plotted as shown in **Fig. 11**. An operating range for  $c_d$  can then be determined to optimize minimum clearance, friction horsepower loss, lubricant flow, and temperature rise.

### Thrust Bearings

As the name implies, thrust bearings are used either to absorb axial shaft loads or to position shafts axially. Brief descriptions of the normal designs for these bearings follow with approximate design methods for each. The generally accepted load ranges for these types of bearings are given in **Table 1** and the schematic configurations are shown in **Fig. 1**.

*The parallel or flat plate thrust bearing* is probably the most frequently used type. It is the simplest and lowest in cost of those considered; however, it is also the least capable of absorbing load, as can be seen from **Table 1**. It is most generally used as a positioning device where loads are either light or occasional.

*The step bearing*, like the parallel plate, is also a relatively simple design. This type of bearing will accept the normal range of thrust loads and lends itself to low-cost, high-volume production. However, this type of bearing becomes sensitive to alignment as its size increases.

*The tapered land thrust bearing*, as shown in **Table 1**, is capable of high load capacity. Where the step bearing is generally used for small sizes, the tapered land type can be used in larger sizes. However, it is more costly to manufacture and does require good alignment as size is increased.

*The tilting pad or Kingsbury thrust bearing* (as it is commonly referred to) is also capable of high thrust capacity. Because of its construction it is more costly, but it has the inherent advantage of being able to absorb significant amounts of misalignment.

Fig. 1. Types of thrust bearings.

**Table 1. Thrust Bearing Loads\***

Type	Normal Unit Loads, lb/in <sup>2</sup>	Maximum Unit Loads, lb/in <sup>2</sup>
Parallel surface	<75	<150
Step	200	500
Tapered land	200	500
Tilting pad	200	500

**Thrust Bearing Design Notation.**— The symbols used in the design procedures that follow for flat plate, step, tapered land, and tilting pad thrust bearings are as follows:

$a$  = radial width of pad, inches

$b$  = circumferential length of pad at pitch line, inches

$b_2$  = pad step length

$B$  = circumference of pitch circle, inches

$c$  = specific heat of oil, Btu/gal/°F

$D$  = diameter, inches

$e$  = depth of step, inch

$f$  = coefficient of friction

$g$  = depth of 45° chamfer, inches

$h$  = film thickness, inch

$i$  = number of pads

$J$  = power loss coefficient

$K$  = film thickness factor

$K_g$  = fraction of circumference occupied by the pads; usually 0.8

$l$  = length of chamfer, inches

$M$  = horsepower per square inch

$N$  = revolutions per minute

$O$  = operating number

$p$  = bearing unit load, psi

$p_s$  = oil-supply pressure, psi

$P_f$  = friction horsepower

$Q$  = total flow, gpm

\* Reproduced with permission from Wilcock and Booser, *Bearing Design and Applications*, McGraw-Hill Book Co., Copyright © 1957.

$Q_c$  = required flow per chamfer, gpm

$Q_c^o$  = uncorrected required flow per chamfer, gpm

$Q_F$  = film flow, gpm

$s$  = oil-groove width

$\Delta t$  = temperature rise, °F

$U$  = velocity, feet per minute

$V$  = effective width-to-length ratio for one pad

$W$  = applied load, pounds

$Y_G$  = oil-flow factor

$Y_L$  = leakage factor

$Y_S$  = shape factor

$Z$  = viscosity, centipoises

$\alpha$  = dimensionless film-thickness factor

$\delta$  = taper

$\xi$  = kinetic energy correction factor

*Note:* In the following, subscript 1 denotes inside diameter and subscript 2 denotes outside diameter. Subscript  $i$  denotes inlet and subscript  $o$  denotes outlet.

**Flat Plate Thrust Bearing Design.**— The following steps define the performance of a flat plate thrust bearing, one section of which is shown in Fig. 2. Although each bearing section is wedge shaped, as shown below right, for the purposes of design calculation, it is considered to be a rectangle with a length  $b$  equal to the circumferential length along the pitch line of the section being considered, and a width  $a$  equal to the difference in the external and internal radii.

*General Parameters:* a) From Table 1, the maximum unit load is between 75 and 100 pounds per square inch; and b) the outside diameter is usually between 1.5 and 2.5 times the inside diameter.

Fig. 2. Basic elements of flat plate thrust bearing.\*

1) *Inside diameter*,  $D_1$ . Determined by shaft size and clearance.

2) *Outside diameter*,  $D_2$ . Calculated by the formula

$$D_2 = \left( \frac{4W}{\pi K_g p} + D_1^2 \right)^{1/2}$$

where  $W$  = applied load, pounds

$K_g$  = fraction of circumference occupied by pads; usually 0.8

$p$  = bearing unit load, psi

\* See footnote on page 2355.

3) *Radial pad width, a*. Equal to one-half the difference between the inside and outside diameters.

$$a = \frac{D_2 - D_1}{2}$$

4) *Pitch line circumference, B*. Found from the pitch diameter.

$$B = \pi(D_2 - a)$$

5) *Number of pads, i*. Assume an oil groove width, *s*. If the length of pad is assumed to be optimum, i.e., equal to its width,

$$i_{\text{app}} = \frac{B}{a + s}$$

Take *i* as nearest even number.

6) *Length of pad, b*. If number of pads and oil groove width are known,

$$b = \frac{B - (i \times s)}{i}$$

7) *Actual unit load, p*. Calculated in pounds per square inch based on pad dimensions.

$$p = \frac{W}{iab}$$

8) *Pitch line velocity, U*. Found in feet per minute from

$$U = \frac{BN}{12}$$

where  $N = \text{rpm}$

9) *Friction power loss, P<sub>f</sub>*. Friction power loss is difficult to calculate for this type of bearing because there is no theoretical method of determining the operating film thickness. However, a good approximation can be made using Fig. 3. From this curve, the value of *M*, horsepower loss per square inch of bearing surface, can be obtained. The total power loss, *P<sub>f</sub>*, is then calculated from

$$P_f = iabM$$

10) *Oil flow required, Q*. May be estimated in gallons per minute for a given temperature rise from

$$Q = \frac{42.4P_f}{c\Delta t}$$

where  $c = \text{specific heat of oil in Btu/gal/}^\circ\text{F}$

$\Delta t = \text{temperature rise of the oil in } ^\circ\text{F}$

*Note:* A  $\Delta t$  of 50°F is an acceptable maximum.

Because there is no theoretical method of predicting the minimum film thickness in this type of bearing, only an approximation, based on experience, of the film flow can be made. For this reason and based on practical experience, it is desirable to have a minimum of one-half of the desired oil flow pass through the chamfer.

11) *Film flow, Q<sub>F</sub>*. Calculated in gallons per minute from

$$Q_F = \frac{(1.5)(10^5)ih^3p_s}{Z_2}$$

where  $V = \text{effective width-to-length ratio for one pad, } a/b$

$Z_2 = \text{oil viscosity at outlet temperature}$

$h = \text{film thickness}$

*Note:* Because  $h$  cannot be calculated, use  $h = 0.002$  inch.

Fig. 3. Friction power loss,  $M$ , vs. peripheral speed,  $U$  — thrust bearings.<sup>a</sup>

<sup>a</sup> See footnote on page 2355.

12) *Required flow per chamfer,  $Q_c$ .* Readily found from the formula

$$Q_c = \frac{Q}{i}$$

13) *Kinetic energy correction factor,  $\xi$ .* Found by assuming a chamfer length  $l$  and entering Fig. 4 with a value  $Z_2 l$  and  $Q_c$ .

14) *Uncorrected required flow per chamfer,  $Q_c^0$ .* Found from the formula

$$Q_c^0 = \frac{Q_c}{\xi}$$

15) *Depth of chamfer,  $g$ .* Found from the formula

$$g = \sqrt[4]{\frac{Q_c^0 l Z_2}{4.74 \times 10^4 p_s}}$$

Fig. 4. Kinetic energy correction factor,  $\xi$ —thrust bearings.<sup>a</sup>

<sup>a</sup> See footnote on page 2355.

*Example:* Design a flat plate thrust bearing to carry 900 pounds load at 4000 rpm using an SAE 10 oil with a specific heat of 3.5 Btu/gal/°F at 120°F and 30-psi inlet conditions. The shaft is  $2\frac{3}{4}$  inches in diameter and the temperature rise is not to exceed 40°F. Fig. 5 shows the final design of this bearing.

1) *Inside diameter.* Assumed to be 3 inches to clear shaft.

2) *Outside diameter.* Assuming a unit bearing load of 75 psi from Table 1,

$$D_2 = \sqrt{\frac{4 \times 900}{\pi \times 0.8 \times 75} + 3^2} = 5.30 \text{ inches}$$

Use  $5\frac{1}{2}$  inches.

3) *Radial pad width.*

$$a = \frac{5.5 - 3}{2} = 1.25 \text{ inches}$$

4) *Pitch-line circumference.*

$$B = \pi \times 4.25 = 13.35 \text{ inches}$$

5) *Number of pads.* Assume an oil groove width of  $\frac{3}{16}$  inch. If length of pad is assumed to be equal to width of pad, then

$$i_{\text{app}} = \frac{13.3}{1.25 + 0.1875} = 9+$$

If the number of pads,  $i$ , is taken as 10, then

$$6) \text{ Length of pad. } b = \frac{13.35 - (10 \times 0.1875)}{10} = 1.14 \text{ inches}$$

7) *Actual unit load.*

$$p = \frac{900}{10 \times 1.25 \times 1.14} = 63 \text{ psi}$$

8) *Pitch-line velocity.*

$$U = \frac{13.35 \times 4000}{12} = 4,430 \text{ ft per min.}$$

9) *Friction power loss.* From Fig. 3,  $M = 0.19$

$$P_f = 10 \times 1.25 \times 1.14 \times 0.19 = 2.7 \text{ horsepower}$$

10) *Oil flow required.*

$$Q = \frac{42.4 \times 2.7}{3.5 \times 40} = 0.82 \text{ gallon per minute}$$

(Assuming a temperature rise of 40°F—the maximum allowable according to the given condition—then the assumed operating temperature will be 120°F + 40°F = 160°F and the oil viscosity  $Z_2$  is found from Fig. 6 to be 9.6 centipoises.)

11) *Film flow.*

$$Q_F = \frac{1.5 \times 10^5 \times 10 \times 1 \times 0.002^3 \times 30}{9.6} = 0.038 \text{ gpm}$$

Because 0.038 gpm is a very small part of the required flow of 0.82 gpm, the bulk of the flow must be carried through the chamfers.

12) *Required flow per chamfer.* Assume that all the oil flow is to be carried through the chamfers.

$$Q_c = \frac{0.82}{10} = 0.082 \text{ gpm}$$

13) *Kinetic energy correction factor.* If  $l$ , the length of chamfer is made  $\frac{1}{8}$  inch, then  $Z_2 l = 9.6 \times \frac{1}{8} = 1.2$ . Entering Fig. 4 with this value and  $Q_c = 0.082$ ,

$$\xi = 0.44$$

14) *Uncorrected required oil flow per chamfer.*

$$Q_c^0 = \frac{0.082}{0.44} = 0.186 \text{ gpm}$$

15) *Depth of chamfer.*

$$g = 4 \sqrt[4]{\frac{0.186 \times 0.125 \times 9.6}{4.74 \times 10^4 \times 30}}$$

$$g = 0.02 \text{ inch}$$

A schematic drawing of this bearing is shown in Fig. 5.

Fig. 5. Flat plate thrust bearing example design.\*

**Step Thrust Bearing Design.**—The following steps define the performance of a step thrust bearing, one section of which is shown in Fig. 6.

Fig. 6. Basic elements of step thrust bearing.\*

Although each bearing section is wedge shaped, as shown at the right in Fig. 6, for the purposes of design calculation it is considered to be a rectangle with a length  $b$  equal to the circumferential length along the pitch line of the section being considered, and a width  $a$  equal to the difference in the external and internal radii.

*General Parameters:* For optimum proportions,  $a = b$ ,  $b_2 = 1.2b_1$ , and  $e = 0.7h$ .

1) *Internal diameter,  $D_1$ .* An internal diameter is assumed that is sufficient to clear the shaft.

2) *External diameter,  $D_2$ .* A unit bearing pressure is assumed from Table 1 and the external diameter is then found from the formula

$$D_2 = \sqrt{\frac{4W}{\pi K_g p} + D_1^2}$$

3) *Radial pad width,  $a$ .* Equal to the difference between the external and internal radii.

$$a = \frac{D_2 - D_1}{2}$$

\* See footnote on page 2355.

4) *Pitch-line circumference, B.* Found from the formula

$$B = \frac{\pi(D_1 + D_2)}{2}$$

5) *Number of pads, i.* Assume an oil groove width,  $s$  (0.062 inch may be taken as a minimum), and find the approximate number of pads, assuming the pad length is equal to  $a$ . Note that if a chamfer is found necessary to increase the oil flow (see Step 13), the oil groove width should be greater than the chamfer width.

$$i_{\text{app}} = \frac{B}{a + s}$$

Then  $i$  is taken as the nearest even number.

6) *Length of pad, b.* Readily determined from the number of pads and groove width.

$$b = \frac{B}{i} - s$$

7) *Pitch-line velocity, U.* Found in feet per minute from the formula  $U = \frac{BN}{12}$

8) *Film thickness, h.* Found in inches from the formula

$$h = \sqrt{\frac{2.09 \times 10^{-9} ia^3 UZ}{W}}$$

9) *Depth of step, e.* According to the general parameter

$$e = 0.7h$$

10) *Friction power loss, P<sub>f</sub>.* Found from the formula

$$P_f = \frac{7.35 \times 10^{-13} ia^2 U^2 Z}{h}$$

11) *Pad step length, b<sub>2</sub>.* This distance, on the pitch line, from the leading edge of the pad to the step in inches is determined by the general parameters

$$b_2 = \frac{1.2b}{2.2}$$

12) *Hydrodynamic oil flow, Q.* Found in gallons per minute from the formula

$$Q = 6.65 \times 10^{-4} ia h U$$

13) *Temperature rise, Δt.* Found in degrees F from the formula

$$\Delta t = \frac{42.4 P_f}{c Q}$$

If the flow is insufficient, as indicated by too high a temperature rise, chamfers can be added to provide adequate flow as in Steps 12-15 of the flat plate thrust bearing design.

*Example:* Design a step thrust bearing for positioning a  $\frac{7}{8}$ -inch diameter shaft operating with a 25-pound thrust load and a speed of 5000 rpm. The lubricating oil has a viscosity of 25 centipoises at the operating temperature of 160 °F and has a specific heat of 3.4 Btu per gal per °F.

1) *Internal diameter.* Assumed to be 1 inch to clear the shaft.

2) *External diameter.* Because the example is a positioning bearing with low total load, unit load will be negligible and the external diameter is not established by using the formula given in Step 2 of the procedure, but a convenient size is taken to give the desired overall bearing proportions.

$$D_2 = 3 \text{ inches}$$

3) *Radial pad width.*

$$a = \frac{3-1}{2} = 1 \text{ inch}$$

4) *Pitch-line circumference.*

$$B = \frac{\pi(3+1)}{2} = 6.28 \text{ inches}$$

5) *Number of pads.* Assuming a minimum groove width of 0.062 inch,

$$i_{\text{app}} = \frac{6.28}{1+0.062} = 5.9$$

Take  $i = 6$ .

6) *Length of pad.*

$$b = \frac{6.28}{6} - 0.062 = 0.985$$

7) *Pitch-line velocity.*

$$U = \frac{6.28 \times 5000}{12} = 2620 \text{ fpm}$$

8) *Film thickness.*

$$h = \sqrt{\frac{2.09 \times 10^{-9} \times 6 \times 1^3 \times 2620 \times 25}{25}} = 0.0057 \text{ inch}$$

9) *Depth of step.*

$$e = 0.7 \times 0.0057 = 0.004 \text{ inch}$$

10) *Power loss.*

$$P_f = \frac{7.35 \times 10^{-13} \times 6 \times 1^2 \times 2620^2 \times 25}{0.0057} = 0.133 \text{ hp}$$

11) *Pad step length.*

$$b_2 = \frac{1.2 \times 0.985}{2.2} = 0.537 \text{ inch}$$

12) *Total hydrodynamic oil flow.*

$$Q = 6.65 \times 10^{-4} \times 6 \times 1 \times 0.0057 \times 2620 = 0.060 \text{ gpm}$$

13) *Temperature rise.*

$$\Delta t = \frac{42.4 \times 0.133}{3.4 \times 0.060} = 28 \text{ }^\circ\text{F}$$

**Tapered Land Thrust Bearing Design.**— The following steps define the performance of a tapered land thrust bearing, one section of which is shown in Fig. 7. Although each bearing section is wedge shaped, as shown in Fig. 7, right, for the purposes of design calculation, it is considered to be a rectangle with a length  $b$  equal to the circumferential length along the pitch line of the section being considered and a width  $a$  equal to the difference in the external and internal radii.

*General Parameters:* Usually, the taper extends to only 80 percent of the pad length with the remainder being flat, thus:  $b_2 = 0.8b$  and  $b_1 = 0.2b$ .

## THRUST BEARINGS

Fig. 7. Basic elements of tapered land thrust bearing.\*

1) *Inside diameter,  $D_1$* . Determined by shaft size and clearance.

2) *Outside diameter,  $D_2$* . Calculated by the formula

$$D_2 = \left( \frac{4W}{\pi K_g P_a} + D_1^2 \right)^{1/2}$$

where  $K_g = 0.8$  or  $0.9$  and  $W =$  applied load, pounds

$P_a =$  assumed unit load from Table 1, page 2355

3) *Radial pad width,  $a$* . Equal to one-half the difference between the inside and outside diameters.

$$a = \frac{D_2 - D_1}{2}$$

4) *Pitch-line circumference,  $B$* . Found from the mean diameter:

$$B = \frac{\pi(D_1 + D_2)}{2}$$

5) *Number of pads,  $i$* . Assume an oil groove width,  $s$ , and find the approximate number of pads, assuming the pad length is equal to  $a$ .

$$i_{\text{app}} = \frac{B}{a + s}$$

Then  $i$  is taken as the nearest even number.

6) *Length of pad,  $b$* . Readily determined because the number of pads and groove width are known.

$$b = \frac{B - is}{i}$$

7) *Taper values,  $\delta_1$  and  $\delta_2$* . Can be taken from Table 2.

8) *Actual bearing unit load,  $p$* . Calculated in pounds per square inch from the formula

$$p = \frac{W}{iab}$$

9) *Pitch-line velocity,  $U$* . Found in feet per minute at the pitch circle from the formula

$$U = \frac{BN}{12}$$

where  $N =$  rpm

10) *Oil leakage factor,  $Y_L$* . Found either from Fig. 8 which shows curves for  $Y_L$  as functions of the pad width  $a$  and length of land  $b$  or from the formula

$$Y_L = \frac{b}{1 + (\pi^2 b^2 / 12 a^2)}$$

11) *Film thickness factor,  $K$* . Calculated using the formula

$$K = \frac{5.75 \times 10^6 p}{UY_L Z}$$

\* See footnote on page 2355.

12) *Minimum film thickness,  $h$ .* Using the value of  $K$  just determined and the selected taper values  $\delta_1$  and  $\delta_2$ ,  $h$  is found from Fig. 9. In general,  $h$  should be 0.001 inch for small bearings and 0.002 inch for larger and high-speed bearings.

13) *Friction power loss,  $P_f$ .* Using the film thickness  $h$ , the coefficient  $J$  can be obtained from Fig. 10. The friction loss in horsepower is then calculated from the formula

$$P_f = 8.79 \times 10^{-13} i a b J U^2 Z$$

14) *Required oil flow,  $Q$ .* May be estimated in gallons per minute for a given temperature rise  $\Delta t$  from the formula

$$Q = \frac{42.4 P_f}{c \Delta t}$$

where  $c$  = specific heat of the oil in Btu/gal/°F

Note: A  $\Delta t$  of 50°F is an acceptable maximum.

15) *Shape factor,  $Y_s$ .* Needed to compute the actual oil flow and calculated from

$$Y_s = \frac{8ab}{D_2^2 - D_1^2}$$

16) *Oil flow factor,  $Y_G$ .* Found from Fig. 11 using  $Y_s$  and  $D_1/D_2$ .

17) *Actual oil film flow,  $Q_F$ .* The amount of oil in gallons per minute that the bearing film will pass is calculated from the formula

$$Q_F = \frac{8.9 \times 10^{-4} i \delta_2 D_2^3 N Y_G Y_s^2}{D_2 - D_1}$$

18) If the flow is insufficient, the tapers can be increased or chamfers calculated to provide adequate flow, as in Steps 12-15 of the flat plate thrust bearing design procedure.

*Example:* Design a tapered land thrust bearing for 70,000 pounds at 3600 rpm. The shaft diameter is 6.5 inches. The oil inlet temperature is 110°F at 20 psi. 

Fig. 8. Leakage factor,  $Y_L$ , vs. pad dimensions  $a$  and  $b$ —tapered land thrust bearings.\*

\* See footnote on page 2355.

Fig. 9. Thickness,  $h$ , vs. factor  $K$ —tapered land thrust bearings.\*Fig. 10. Power-loss coefficient,  $J$ , vs. film thickness,  $h$ —tapered land thrust bearings.\*

A maximum temperature rise of  $50^{\circ}\text{F}$  is acceptable and results in a viscosity of 18 centipoises. Use values of  $K_g = 0.9$  and  $c = 3.5$  Btu/gal/ $^{\circ}\text{F}$ .

\* See footnote on page 2355.

1) *Internal diameter.* Assume  $D_1 = 7$  inches to clear shaft.

2) *External diameter.* Assume a unit bearing load  $p_a$  of 400 pounds per square inch from **Table 1**, then

$$D_2 = \sqrt{\frac{4 \times 70,000}{3.14 \times 0.9 \times 400} + 7^2} = 17.2 \text{ inches}$$

Round off to 17 inches.

3) *Radial pad width.*

$$a = \frac{17 - 7}{2} = 5 \text{ inches}$$

4) *Pitch-line circumference.*

$$B = \frac{3.14(17 + 7)}{2} = 37.7 \text{ inches}$$

5) *Number of pads.* Assume groove width of 0.5 inch, then

$$i_{\text{app}} = \frac{37.7}{5 + 0.5} = 6.85$$

Take  $i = 6$ .

6) *Length of pad.*

$$b = \frac{37.7 - 6 \times 0.5}{6} = 5.78 \text{ inches}$$

Fig. 11. Oil-flow factor,  $Y_G$ , vs. diameter ratio  $D_1/D_2$ —tapered land bearings.\*

7) *Taper values.* Interpolate in **Table 2** to obtain

$$\delta_1 = 0.008 \text{ inch} \quad \text{and} \quad \delta_2 = 0.005 \text{ inch}$$

8) *Actual bearing unit load.*

$$p = \frac{70,000}{6 \times 5 \times 5.78} = 404 \text{ psi}$$

\* See footnote on page 2355.

9) *Pitch-line velocity.*

$$U = \frac{37.7 \times 3600}{12} = 11,300 \text{ ft per min}$$

10) *Oil leakage factor.*

$$\text{From Fig. 8, } Y_L = 2.75$$

11) *Film-thickness factor.*

$$K = \frac{5.75 \times 10^6 \times 404}{11,300 \times 2.75 \times 18} = 4150$$

12) *Minimum film thickness.*

$$\text{From Fig. 9, } h = 2.2 \text{ mils}$$

13) *Friction power loss.* From Fig. 10,  $J = 260$ , then

$$P_f = 8.79 \times 10^{-13} \times 6 \times 5 \times 5.78 \times 260 \times 11,300^2 \times 18 = 91 \text{ hp}$$

14) *Required oil flow.*

$$Q = \frac{42.4 \times 91}{3.5 \times 50} = 22.0 \text{ gpm}$$

See footnote on page 2355.

15) *Shape factor.*

$$Y_S = \frac{8 \times 5 \times 5.78}{17^2 - 7^2} = 0.963$$

16) *Oil-flow factor.*

$$\text{From Fig. 11, } Y_G = 0.61$$

where  $D_1/D_2 = 0.41$

17) *Actual oil film flow.*

$$Q_F = \frac{8.9 \times 10^{-4} \times 6 \times 0.005 \times 17^3 \times 3600 \times 0.61 \times 0.963^2}{17 - 7} = 26.7 \text{ gpm}$$

Because calculated film flow exceeds required oil flow, chamfers are not necessary. However, if film flow were less than required, suitable chamfers would be needed.

**Table 2. Taper Values for Tapered Land Thrust Bearings**

Pad Dimensions, Inches	Taper, Inch	
	$\delta_1 = h_2 - h_1$ (at ID)	$\delta_2 = h_2 - h_1$ (at OD)
$\frac{1}{2} \times \frac{1}{2}$	0.0025	0.0015
$1 \times 1$	0.005	0.003
$3 \times 3$	0.007	0.004
$7 \times 7$	0.009	0.006

**Tilting Pad Thrust Bearing Design.**— The following steps define the performance of a tilting pad thrust bearing, one section of which is shown in Fig. 12. Although each bearing section is wedge shaped, as shown at the right below, for the purposes of design calculation, it is considered to be a rectangle with a length  $b$  equal to the circumferential length along the pitch line of the section being considered and a width  $a$  equal to the difference in the external and internal radii, as shown at left in Fig. 12. The location of the pivot shown in Fig. 12 is optimum. If shaft rotation in both directions is required, however, the pivot must be at the midpoint, which results in little or no detrimental effect on the performance.

Fig. 12. Basic elements of tilting pad thrust bearing.\*

1) *Inside diameter,  $D_1$* . Determined by shaft size and clearance.

2) *Outside diameter,  $D_2$* . Calculated from the formula

$$D_2 = \left( \frac{4W}{\pi K_g p} + D_1^2 \right)^{1/2}$$

where  $W$  = applied load, pounds

$$K_g = 0.8$$

$p$  = unit load from **Table 1**

3) *Radial pad width,  $a$* . Equal to one-half the difference between the inside and outside diameters:

$$a = \frac{D_2 - D_1}{2}$$

4) *Pitch-line circumference,  $B$* . Found from the mean diameter:

$$B = \pi \left( \frac{D_1 + D_2}{2} \right)$$

5) *Number of pads,  $i$* . The number of pads may be estimated from the formula

$$i = \frac{BK_g}{a}$$

Select the nearest even number.

6) *Length of pad,  $b$* . Found from the formula

$$b \cong \frac{BK_g}{i}$$

7) *Pitch-line velocity,  $U$* . Calculated in feet per minute from the formula

$$U = \frac{BN}{12}$$

8) *Bearing unit load,  $p$* . Calculated from the formula

$$p = \frac{W}{iab}$$

9) *Operating number,  $O$* . Calculated from the formula

$$O = \frac{1.45 \times 10^{-7} Z_2 U}{5pb}$$

where  $Z_2$  = viscosity of oil at outlet temperature (inlet temperature plus assumed temperature rise through the bearing).

\* See footnote on page 2355.

10) *Minimum film thickness,  $h_{\min}$* . By using the operating number, the value of  $\alpha$  = dimensionless film thickness is found from Fig. 13. Then the actual minimum film thickness is calculated from the formula:

$$h_{\min} = \alpha b$$

In general, this value should be 0.001 inch for small bearings and 0.002 inch for larger and high-speed bearings.

11) *Coefficient of friction,  $f$* . Found from Fig. 14.

12) *Friction power loss,  $P_f$* . This horsepower loss now is calculated by the formula

$$P_f = \frac{fWU}{33,000}$$

13) *Actual oil flow,  $Q$* . This flow over the pad in gallons per minute is calculated from the formula

$$Q = 0.0591 \alpha i a b U$$

14) *Temperature rise,  $\Delta t$* . Found from the formula

$$\Delta t = 0.0217 \frac{f p}{\alpha c}$$

where  $c$  = specific heat of oil in Btu/gal/°F

If the flow is insufficient, as indicated by too high a temperature rise, chamfers can be added to provide adequate flow, as in Steps 12-15 of the flat plate thrust bearing design.

 *Example:* Design a tilting pad thrust bearing for 70,000 pounds thrust at 3600 rpm. The shaft diameter is 6.5 inches and a maximum OD of 15 inches is available. The oil inlet temperature is 110°F and the supply pressure is 20 pounds per square inch. A maximum temperature rise of 50°F is acceptable and results in a viscosity of 18 centipoises. Use a value of 3.5 Btu/gal/°F for  $c$ .

1) *Inside diameter*. Assume  $D_1 = 7$  inches to clear shaft.

2) *Outside diameter*. Given maximum  $D_2 = 15$  inches.

3) *Radial pad width*.

$$a = \frac{15 - 7}{2} = 4 \text{ inches}$$

4) *Pitch-line circumference*.

$$B = \pi \left( \frac{7 + 15}{2} \right) = 34.6 \text{ inches}$$

5) *Number of pads*.

$$i = \frac{34.6 \times 0.8}{4} = 6.9$$

Select 6 pads:  $i = 6$ .

6) *Length of pad*.

$$b = \frac{34.6 \times 0.8}{6} = 4.61 \text{ inches}$$

Make  $b = 4.75$  inches.

7) *Pitch-line velocity*.

$$U = \frac{34.6 \times 3600}{12} = 10,400 \text{ ft/min}$$

8) *Bearing unit load*.

$$p = \frac{70,000}{6 \times 4 \times 4.75} = 614 \text{ psi}$$

Fig. 13. Dimensionless minimum film thickness,  $\alpha$ , vs. operating number,  $O$ —tilting pad thrust bearings.\*

Fig. 14. Coefficient of friction  $f$  vs. dimensionless film thickness  $\alpha$  for tilting pad thrust bearings with optimum pivot location.\*

\* See footnote on page 2355.

9) *Operating number.*

$$O = \frac{1.45 \times 10^{-7} \times 18 \times 10,400}{5 \times 614 \times 4.75} = 1.86 \times 10^{-6}$$

10) *Minimum film thickness.* From Fig. 13,  $\alpha = 0.30 \times 10^{-3}$ .

$$h_{\min} = 0.00030 \times 4.75 = 0.0014 \text{ inch}$$

11) *Coefficient of friction.* From Fig. 14,  $f = 0.0036$ .

12) *Friction power loss.*

$$P_f = \frac{0.0036 \times 70,000 \times 10,400}{33,000} = 79.4 \text{ hp}$$

13) *Oil flow.*

$$Q = 0.0591 \times 6 \times 0.30 \times 10^{-3} \times 4 \times 4.75 \times 10,400 = 21.02 \text{ gpm}$$

14) *Temperature rise.*

$$\Delta t = \frac{0.0217 \times 0.0036 \times 614}{0.30 \times 10^{-3} \times 3.5} = 45.7^\circ \text{F}$$

Because this temperature is less than the  $50^\circ\text{F}$ , which is considered as the acceptable maximum, the design is satisfactory.

### Plain Bearing Materials

Materials used for sliding bearings cover a wide range of metals and nonmetals. To make the optimum selection requires a complete analysis of the specific application. The important general categories are: Babbitts, alkali-hardened lead, cadmium alloys, copper lead, aluminum bronze, silver, sintered metals, plastics, wood, rubber, and carbon graphite.

**Properties of Bearing Materials.**— For a material to be used as a plain bearing, it must possess certain physical and chemical properties that permit it to operate properly. If a material does not possess all of these characteristics to some degree, it will not function long as a bearing. It should be noted, however, that few, if any, materials are outstanding in all these characteristics. Therefore, the selection of the optimum bearing material for a given application is at best a compromise to secure the most desirable combination of properties required for that particular usage.

The seven properties generally acknowledged to be the most significant are: 1) Fatigue resistance; 2) embeddability; 3) compatibility; 4) conformability; 5) thermal conductivity; 6) corrosion resistance; and 7) load capacity.

These properties are described as follows:

1) *Fatigue resistance* is the ability of the bearing lining material to withstand repeated applications of stress and strain without cracking, flaking, or being destroyed by some other means.

2) *Embeddability* is the ability of the bearing lining material to absorb or embed within itself any of the larger of the small dirt particles present in a lubrication system. Poor embeddability permits particles circulating around the bearing to score both the bearing surface and the journal or shaft. Good embeddability will permit these particles to be trapped and forced into the bearing surface and out of the way where they can do no harm.

3) *Compatibility or antiscoring tendencies* permit the shaft and bearing to “get along” with each other. It is the ability to resist galling or seizing under conditions of metal-to-metal contact such as at startup. This characteristic is most truly a bearing property, because contact between the bearing and shaft in good designs occurs only at startup.

4) *Conformability* is defined as malleability or as the ability of the bearing material to creep or flow slightly under load, as in the initial stages of running, to permit the shaft and bearing contours to conform with each other or to compensate for nonuniform loading caused by misalignment.

**Table 1. Bearing and Bushing Alloys—Composition, Forms, Characteristics, and Applications** *SAE General Information*

SAE No. and Alloy Grouping		Nominal Composition, Percent	Form of Use (1), Characteristics (2), and Applications (3)
Sn-Base Alloys	11	Sn, 87.5; Sb, 6.75; Cu, 5.75	(1) Cast on steel, bronze, or brass backs, or directly in the bearing housing. (2) Soft, corrosion-resistant with moderate fatigue resistance. (3) Main and connecting-rod bearings; motor bushings. Operates with either hard or soft journal.
	12	Sn, 89; Sb, 7.5; Cu, 3.5	
Pb-Base Alloys	13	Pb, 84; Sb, 10; Sn, 6	(1) SAE 13 and 14 are cast on steel, bronze, or brass, or in the bearing housing; SAE 15 is cast on steel; and SAE 16 is cast into and on a porous sintered matrix, usually copper-nickel bonded to steel. (2) Soft, moderately fatigue-resistant, corrosion-resistant. (3) Main and connecting-rod bearings. Operates with hard or soft journal with good finish.
	14	Pb, 75; Sb, 15; Sn, 10	
	15	Pb, 83; Sb, 15; Sn, 14; As, 1	
Pb-Sn Overlays	16	Pb, 92; Sb, 3.5; Sn, 4.5	(1) Electrodeposited as a thin layer on copper-lead or silver bearings faces. (2) Soft, corrosion-resistant. Bearings so coated run satisfactorily against soft shafts throughout the life of the coating. (3) Heavy-duty, high-speed main and connecting-rod bearings.
	190	Pb, 93; Sn, 7	
Cu-Pb Alloys	49	Cu, 76; Pb, 24	(1) Cast or sintered on steel back with the exception of SAE 481, which is cast on steel back only. (2) Moderately hard. Somewhat subject to oil corrosion. Some oils minimize this; protection with overlay may be desirable. Fatigue resistance good to fairly good. Listed in order of decreasing hardness and fatigue resistance. (3) Main and connecting-rod bearings. The higher lead alloys can be used unplated against a soft shaft, although an overlay is helpful. The lower lead alloys may be used against a hard shaft, or with an overlay against a soft one.
	48	Cu, 70; Pb, 30	
	480	Cu, 65; Pb, 35	
	481	Cu, 60; Pb, 40	
Cu-Pb-Sn Alloys	482	Cu, 67; Pb, 28; Sn, 5	(1) Steel-backed and lined with a structure combining sintered copper alloy matrix with corrosion-resistant lead alloy. (2) Moderately hard. Corrosion resistance improved over copper-leads of equal lead content without tin. Fatigue resistance fairly good. Listed in order of decreasing hardness and fatigue resistance. (3) Main and connecting-rod bearings. Generally used without overlay. SAE 484 and 485 may be used with hard or soft shaft, and a hardened or cast shaft is recommended for SAE 482.
	484	Cu, 55; Pb, 42; Sn, 3	
	485	Cu, 46; Pb, 51; Sn, 3	
Al-Base Alloys	770	Al, 91.75; Sn, 6.25; Cu, 1; Ni, 1	(1) SAE 770 cast in permanent molds; work-hardened to improve physical properties. SAE 780 and 782 usually bonded to steel back but is procurable in strip form without steel backing. SAE 781 usually bonded to steel back but can be produced as castings or wrought strip without steel back. (2) Hard, extremely fatigue-resistant, resistant to oil corrosion. (3) Main and connecting-rod bearings. Generally used with suitable overlay. SAE 781 and 782 also used for bushings and thrust bearings with or without overlay.
	780	Al, 91; Sn, 6; Si, 1.5; Cu, 1; Ni, 0.5	
	781	Al, 95; Si, 4; Cd, 1	
	782	Al, 95; Cu, 1; Ni, 1; Cd, 3	
Other Cu-Base Alloys	795	Cu, 90; Zn, 9.5; Sn, 0.5	(1) Wrought solid bronze, (2) Hard, strong, good fatigue resistance, (3) Intermediate-load oscillating motion such as tie-rods and brake shafts.
	791	Cu, 88; Zn, 4; Sn, 4; Pb, 4	
	793	Cu, 84; Pb, 8; Sn, 4; Zn, 4	
	798	Cu, 84; Pb, 8; Sn, 4; Zn, 4	
Other Cu-Base Alloys	792	Cu, 80; Sn, 10; Pb, 10	(1) SAE 792, cast on steel back, SAE 797, sintered on steel back. (2) Has maximum shock and load-carrying capacity of conventional cast bearing alloys; hard, both fatigue- and corrosion-resistant. Hard shaft desirable. (3) Heavy loads with oscillating or rotating motion. Used for piston pins, steering knuckles, differential axles, thrust washers, and wear plates.
	797	Cu, 80; Sn, 10; Pb, 10	
	794	Cu, 73.5; Pb, 23; Sn, 3.5	(1) SAE 794, cast on steel back; SAE 799, sintered on steel back. (2) Higher lead content gives improved surface action for higher speeds but results in somewhat less corrosion resistance. (3) Intermediate load application for both oscillating and rotating shafts, that is, rocker-arm bushings, transmissions, and farm implements.
	799	Cu, 73.5; Pb, 23; Sn, 3.5	

5) *High thermal conductivity* is required to absorb and carry away the heat generated in the bearing. This conductivity is most important, not in removing frictional heat generated in the oil film, but in preventing seizures due to hot spots caused by local asperity breakthroughs or foreign particles.

6) *Corrosion resistance* is required to resist attack by organic acids that are sometimes formed in oils at operating conditions.

7) *Load capacity or strength* is the ability of the material to withstand the hydrodynamic pressures exerted upon it during operation.

**Babbitt or White Metal Alloys.**— Many different bearing metal compositions are referred to as babbitt metals. The exact composition of the original babbitt metal is not known; however, the ingredients were probably tin, copper, and antimony in approximately the following percentages: 89.3, 3.6, and 7.1. Tin and lead-base babbitts are probably the best known of all bearing materials. With their excellent embeddability and compatibility characteristics under boundary lubrication, babbitt bearings are used in a wide range of applications including household appliances, automobile and diesel engines, railroad cars, electric motors, generators, steam and gas turbines, and industrial and marine gear units.

**Table 2. White Metal Bearing Alloys—Composition and Properties**

<sup>a</sup>Data for ASTM alloys 1, 2, 3, 7, 8, and 15 appear in the Appendix of ASTM B23-83; the data for alloys 4, 5, 6, 10, 11, 12, 16, and 19 are given in ASTM B23-49. All values are for reference purposes only.

<sup>b</sup>The values for yield point were taken from stress-strain curves at the deformation of 0.125 percent reduction of gage.

<sup>c</sup>The ultimate strength values were taken as the unit load necessary to produce a deformation of 25 percent of the length of the specimen.

<sup>d</sup>These values are the average Brinell number of three impressions on each alloy using a 10-mm ball and a 500-kg load applied for 30 seconds.

<sup>e</sup>Also nominal arsenic, 0.45 percent.

<sup>f</sup>Also nominal arsenic, 1 percent.

The compression test specimens were cylinders 1.5 inches in length and 0.5 inch in diameter, machined from chill castings 2 inches in length and 0.75 inch in diameter. The Brinell tests were made on the bottom face of parallel machined specimens cast in a 2-inch diameter by 0.625-inch deep steel mold at room temperature.

Both the Society of Automotive Engineers and American Society for Testing and Materials have classified white metal bearing alloys. **Tables 1 and 2** give compositions and properties or characteristics for the two classifications.

In small bushings for fractional-horsepower motors and in automotive engine bearings, babbitt is generally used as a thin coating over a flat steel strip. After forming oil distribution grooves and drilling required holes, the strip is cut to size, rolled, and shaped into finished bearing. These bearings are available for shaft diameters from 0.5 to 5 inches (12.7–127 mm). Strip bearings are turned out by the millions yearly in highly automated factories and offer an excellent combination of low cost with good bearing properties.

For larger bearings in heavy-duty equipment, a thicker babbitt is cast on a rigid backing of steel or cast iron. Chemical and electrolytic cleaning of the bearing shell, thorough rinsing, tinning, and then centrifugal casting of the babbitt are desirable for sound bonding of the babbitt to the bearing shell. After machining, the babbitt layer is usually  $\frac{1}{2}$  to  $\frac{1}{4}$  inch (12.7–6.35 mm) thick.

Compared to other bearing materials, babbitts generally have lower load-carrying capacity and fatigue strength, are a little higher in cost, and require a more complicated design. Also, their strength decreases rapidly with increasing temperature. These shortcomings can be avoided by using an intermediate layer of high-strength, fatigue-resistant material that is placed between a steel backing and a thin babbitt surface layer. Such composite bearings frequently eliminate any need for using alternate materials having poorer bearing characteristics.

Tin babbitt is composed of 80 to 90 percent tin to which is added about 3 to 8 percent copper and 4 to 14 percent antimony. An increase in copper or antimony produces increased hardness and tensile strength and decreased ductility. However, if the percentages of these alloys are increased above those shown in [Table 2](#), the resulting alloy will have decreased fatigue resistance. These alloys have very little tendency to cause wear to their journals because of their ability to embed dirt. They resist the corrosive effects of acids, are not prone to oil-film failure, and are easily bonded and cast. Two drawbacks are encountered from use of these alloys because they have low fatigue resistance and their hardness and strength drop appreciably at low temperatures.

Lead babbitt compositions generally range from 10 to 15 percent antimony and up to 10 percent tin in combination with the lead. Like tin-base babbitts, these alloys have little tendency to cause wear to their journals, embed dirt well, resist the corrosive effects of acids, are not prone to oil-film failure and are easily bonded and cast. Their chief disadvantages when compared with tin-base alloys are a rather lower strength and a susceptibility to corrosion.

**Cadmium Base.**— Cadmium alloy bearings have a greater resistance to fatigue than babbitt bearings, but their use is very limited due to their poor corrosion resistance. These alloys contain 1 to 15 percent nickel, or 0.4 to 0.75 percent copper, and 0.5 to 2.0 percent silver. Their prime attribute is their high-temperature capability. The load-carrying capacity and relative basic bearing properties are shown in [Table 3](#).

**Copper-Lead.**— Copper-lead bearings are a binary mixture of copper and lead containing from 20 to 40 percent lead. Lead is practically insoluble in copper, so a cast microstructure consists of lead pockets in a copper matrix. A steel backing is commonly used with this material and high volume is achieved either by continuous casting or by powder metallurgy techniques. This material is very often used with an overplate such as lead-tin and lead-tin-copper to increase basic bearing properties. [Table 3](#) provides comparisons of material properties.

The combination of good fatigue strength, high-load capacity, and high-temperature performance has resulted in extensive use of this material for heavy-duty main and connecting-rod bearings as well as moderate-load and speed applications in turbines and electric motors.

**Leaded Bronze and Tin-Bronze.**— Leaded and tin-bronzes contain up to 25 percent lead or approximately 10 percent tin, respectively. Cast leaded bronze bearings offer good compatibility, excellent casting, and easy machining characteristics, low cost, good struc-

**Table 3. Properties of Bearing Alloys and Bearing Characteristics Ratings**

Material	Recommended Shaft Hardness, Brinell	Load-Carrying Capacity, psi <sup>a</sup>	Maximum Operating Temp., °F <sup>b</sup>	Compatibility <sup>c</sup>	Conformability and Embeddability <sup>c</sup>	Corrosion Resistance <sup>c</sup>	Fatigue Strength <sup>c</sup>
Tin-Base Babbitt	150 or less	800 – 1500	300	1	1	1	5
Lead-Base Babbitt	150 or less	800 – 1200	300	1	1	3	5
Cadmium Base	200 – 250	1200 – 2000	500	1	2	5	4
Copper-Lead	300	1500 – 2500	350	2	2	5	3
Tin-Bronze	300 – 400	4000+	500+	3	5	2	1
Lead-Bronze	300	3000 – 4500	450 – 500	3	4	4	2
Aluminum	300	4000+	225 – 300	5	3	1	2
Silver-Overplate	300	4000+	500	2	3	1	1
Trimetal-Overplate	230 or less	2000 – 4000+	225 – 300	1	2	2	3

<sup>a</sup> 1 psi = 6.8947 kPa.

<sup>b</sup> Temp. in °C = (°F – 32)/1.8.

<sup>c</sup> Note: 1 is best; 5 is worst.

tural properties and high-load capacity, usefulness as a single material that requires neither a separate overlay nor a steel backing. Bronzes are available in standard bar stock, sand or permanent molds, investment, centrifugal or continuous casting. Leaded bronzes have better compatibility than tin-bronzes because the spheroids of lead smear over the bearing surface under conditions of inadequate lubrication. These alloys are generally a first choice at intermediate loads and speeds. **Table 3** provides comparisons of basic bearing properties of these materials.

**Aluminum.**— Aluminum bearings are either cast solid aluminum, aluminum with a steel backing, or aluminum with a suitable overlay. The aluminum is usually alloyed with small amounts of tin, silicon, cadmium, nickel, or copper, as shown in **Table 1**. An aluminum bearing alloy with 20 to 30 percent tin alloy and up to 3 percent copper has shown promise as a substitute for bronzes in some industrial applications.

These bearings are best suited for operation with hard journals. Owing to the high thermal expansion of the metal (resulting in diametral contraction when it is confined as a bearing in a rigid housing), large clearances are required, which tend to make the bearing noisy, especially on starting. Overlays of lead-tin, lead, or lead-tin-copper may be applied to aluminum bearings to facilitate their use with soft shafts.

Aluminum alloys are available with properties specifically designed for bearing applications, such as high load-carrying capacity, fatigue strength, and thermal conductivity, in addition to excellent corrosion resistance and low cost.

**Silver.**— Silver bearings were developed for and have an excellent record in heavy-duty applications such as aircraft master rod and diesel engine main bearings. Silver has a higher fatigue rating than any of the other bearing materials; the steel backing used with this material may show evidence of fatigue before the silver. The advent of overlays, or more commonly called overplates, made it possible for silver to be used as a bearing material. Silver by itself does not possess any of the desirable bearing qualities except high fatigue resistance and high thermal conductivity. The overlays such as lead, lead-tin, or lead-indium improve the embeddability and antiscoring properties of silver. The relative basic properties of this material, when used as an overplate, are shown in **Table 3**.

**Cast Iron.**— Cast iron is an inexpensive bearing material capable of operation at light loads and low speeds, i.e., up to 130 ft/min (40 m/min) and 150 lb/in<sup>2</sup> (1.03 MPa). These bearings must be well lubricated and have a rather large clearance so as to avoid scoring from particles torn from the cast iron that ride between bearing and journal. A journal hardness of between 150 – 250 Brinell has been found to be best when using cast-iron bearings.

**Porous Metals.**—Porous metal self-lubricating bearings are usually made by sintering metals such as plain or leaded bronze, iron, and stainless steel. The sintering produces a spongelike structure capable of absorbing fairly large quantities of oil, usually 10–35 percent of the total volume. These bearings are used where lubrication supply is difficult, inadequate, or infrequent. This type of bearing should be flooded from time to time to resaturate the material. Another use of these porous materials is to meter a small quantity of oil to the bearings such as in drip feed systems. The general design operating characteristics of this class of materials are shown in [Table 4](#).

**Table 4. Application Limits — Sintered Metal and Nonmetallic Bearings**

Bearing Material	Load Capacity		Maximum Temperature		Surface Speed, $V_{max}$ (max. fpm)	$PV$ Limit $P = \text{psi load}$ $V = \text{surface ft/min}$

Maple & Lignum Vitae	2000	13790	150	66	2000	15,000

1 fpm = 0.3048 m/min; 1 psi = 6.8947 kPa

[Tables 5a](#), [5b](#), and [5c](#) give the chemical compositions, permissible loads, interference fits, and running clearances of bronze-base and iron-base metal-powder sintered bearings that are specified in the ASTM specifications for oil-impregnated metal-powder sintered bearings (B438-83a and B439-83).

**Plastics Bearings.**—Plastics are finding increased use as bearing materials because of their resistance to corrosion, quiet operation, ability to be molded into many configurations, and their excellent compatibility, which minimizes or eliminates the need for lubrication. Many plastics are capable of operating as bearings, especially phenolic, tetrafluoroethylene (TFE), and polyamide (nylon) resins. The general application limits for these materials are shown in [Table 4](#).

*Laminated Phenolics:* These composite materials consist of cotton fabric, asbestos, or other fillers bonded with phenolic resin. They have excellent compatibility with various fluids as well as strength and shock resistance. However, precautions must be taken to maintain adequate bearing cooling because the thermal conductivity of these materials is low.

*Nylon:* This material has the widest use for small, lightly loaded applications. It has low frictional properties and requires no lubrication.

*Teflon:* This material, with its exceptional low coefficient of friction, self-lubricating characteristics, resistance to attack by almost any chemicals, and its wide temperature range, is one of the most interesting of the plastics for bearing use. High cost combined

with low load capacity cause Teflon to be selected mostly in modified form, where other less expensive materials have proved inadequate for design requirements.

Bearings made of laminated phenolics, nylon, or Teflon are all unaffected by acids and alkalis except if highly concentrated and therefore can be used with lubricants containing dilute acids or alkalis. Water is used to lubricate most phenolic laminate bearings but oil, grease, and emulsions of grease and water are also used. Water and oil are used as lubricants for nylon and Teflon bearings. Almost all types of plastic bearings absorb water and oil to some extent. In some the dimensional change caused by the absorption may be as much as three percent in one direction. This means that bearings have to be treated before use so that proper clearances will be kept. This may be done by boiling in water, for water lubricated bearings. Boiling in water makes bearings swell the maximum amount. Clearances for phenolic bearings are kept at about 0.001 inch per inch (or mm per mm) of diameter on treated bearings. Partially lubricated or dry nylon bearings are given a clearance of 0.004 to 0.006 inch (101.6–152.4 mm) for a one-inch (25.4 mm) diameter bearing.

**Rubber:** Rubber bearings give excellent performance on propeller shafts and rudders of ships, hydraulic turbines, pumps, sand and gravel washers, dredges and other industrial equipment that handle water or slurries. The resilience of rubber helps to isolate vibration and provide quiet operation, allows running with relatively large clearances and helps to compensate for misalignment. In these bearings a fluted rubber structure is supported by a metal shell. The flutes or scallops in the rubber form a series of grooves through which lubricant or, as generally used, water and foreign material such as sand may pass through the bearing.

**Wood.**— Bearings made from such woods as lignum vitae, rock maple, or oak offer self-lubricating properties, low cost, and clean operation. However, they have frequently been displaced in recent years by various plastics, rubber and sintered-metal bearings. General applications are shown in [Table 4](#).

**Carbon-Graphite.**— Bearings of molded and machined carbon-graphite are used where regular maintenance and lubrication cannot be given. They are dimensionally stable over a wide range of temperatures, may be lubricated if desired, and are not affected by chemicals. These bearings may be used up to temperatures of 700 to 750°F (371–399°C) in air or 1200°F (649°C) in a non-oxidizing atmosphere, and generally are operated at a maximum load of 20 pounds per square inch. In some instances a metal or metal alloy is added to the carbon-graphite composition to improve such properties as compressive strength and density. The temperature limitation depends upon the melting point of the metal or alloy and the maximum load is generally 350 psi (2.4 MPa) when used with no lubrication or 600 psi (4.2 MPa) when used with lubrication.

Normal running clearances for both types of carbon-graphite bearings used with steel shafts and operating at a temperature of less than 200°F (93°C) are as follows: 0.001 inch (0.0254 mm) for bearings of 0.187 to 0.500-inch (4.75–12.7 mm) inside diameter, 0.002 inch (0.0508 mm) for bearings of 0.501 to 1.000-inch (12.73–25.4 mm) inside diameter, 0.003 inch (0.0762 mm) for bearings of 1.001 to 1.250-inch (25.43–31.75 mm) inside diameter, 0.004 inch (0.1016 mm) for bearings of 1.251 to 1.500-inch (31.77–38.1 mm) diameter, and 0.005 inch (0.127 mm) for bearings of 1.501 to 2.000-inch (38.13–50.8 mm) inside diameter. Speeds depend upon too many variables to list specifically so it can only be stated here that high loads require a low number of rpm and low loads permit a high number of rpm. Smooth journals are necessary in these bearings as rough ones tend to abrade the bearings quickly. Cast iron and hard chromium-plate steel shafts of 400 Brinell and over, and phosphor-bronze shafts over 135 Brinell are recommended.

Others	0.5 max.	0.5 max.	1.0 max.	1.0 max.	3.0 max.	3.0 max.	3.0 max.	3.0 max.

<sup>a</sup> Abbreviations used for the alloying elements are as follows: Cu, copper; Fe, iron; Sn, tin; Pb, lead; Zn, zinc; Ni, nickel; Sb, antimony; Si, silicon; Al, aluminum; and C, carbon.

<sup>b</sup> Total of iron plus copper shall be 97 percent, minimum.

<sup>c</sup> Combined carbon (on basis of iron only) may be a metallographic estimate of the carbon in the iron.

Permissible Loads						
Copper-Base Bearings				Iron-Base Bearings		
Shaft Velocity, fpm	Grades 1 & 2			Shaft Velocity, fpm	Grades 1 & 2	Grades 3 & 4
	Type 1	Type 2	Types 3 & 4			
	Max. Load, psi				Max. Load, psi	
Slow and intermittent	3200	4000	4000	Slow and intermittent	3600	8000
25	2000	2000	2000	25	1800	3000
50 to 100	500	500	550	50 to 100	450	700
Over 100 to 150	365	325	365	Over 100 to 150	300	400
Over 150 to 200	280	250	280	Over 150 to 200	225	300
Over 200		a	a	a	Over 200	a

<sup>a</sup> For shaft velocities over 200 fpm, the permissible loads may be calculated as follows:  $P = 50,000/V$ ; where  $P$  = safe load, psi of projected area; and  $V$  = shaft velocity, fpm. With a shaft velocity of less than 50 fpm and a permissible load greater than 1,000 psi, an extreme pressure lubricant should be used; with heat dissipation and removal techniques, higher  $PV$  ratings can be obtained.

Diameter Range	Flange and Thrust Bearings, Diameter, and Thickness Tolerances <sup>a</sup>				Parallellism <sup>a</sup> on Faces, max.			
	Flange Diameter Tolerance		Flange Thickness Tolerance		Copper Base		Iron Base	
	Standard	Special	Standard	Special	Standard	Special	Standard	Special
0 to 1½	±0.005	±0.0025	±0.005	±0.0025	0.003	0.002	0.005	0.003
Over 1½ to 3	±0.010	±0.005	±0.010	±0.007	0.004	0.003	0.007	0.005
Over 3 to 6	±0.025	±0.010	±0.015	±0.010	0.005	0.004	0.010	0.007

<sup>a</sup> Standard and special tolerances are specified for diameters, thicknesses, and parallelism. Special tolerances should not be specified unless required because they require additional or secondary operations and, therefore, are costlier. Thrust bearings (¼ inch thickness, max.) have a standard thickness tolerance of ±0.005 inch and a special thickness tolerance of ±0.0025 inch for all diameters.

All dimensions in inches except where otherwise noted.

## BALL, ROLLER, AND NEEDLE BEARINGS

### Rolling Contact Bearings

Rolling contact bearings substitute a rolling element, ball or roller, for a hydrodynamic or hydrostatic fluid film to carry an impressed load without wear and with reduced friction. Because of their greatly reduced starting friction, when compared to the conventional journal bearing, they have acquired the common designation of “anti-friction” bearings. Although normally made with hardened rolling elements and races, and usually utilizing a separator to space the rolling elements and reduce friction, many variations are in use throughout the mechanical and electrical industries. The most common anti-friction bearing application is that of the deep-groove ball bearing with ribbon-type separator and sealed-grease lubrication used to support a shaft with radial and thrust loads in rotating equipment. This shielded or sealed bearing has become a standard and commonplace item ordered from a supplier's catalogue in much the same manner as nuts and bolts. Because of the simple design approach and the elimination of a separate lubrication system or device, this bearing is found in as many installations as the wick-fed or impregnated porous plain bushing.

Currently, a number of manufacturers produce a complete range of ball and roller bearings in a fully interchangeable series with standard dimensions, tolerances and fits as specified in Anti-Friction Bearing Manufacturers Association (AFBMA) Standards. Except for deep-groove ball bearings, performance standards are not so well defined and sizing and selection must be done in close conformance with the specific manufacturer's catalogue requirements. In general, desired functional features should be carefully gone over with the vendor's representatives.

Rolling contact bearings are made to high standards of accuracy and with close metallurgical control. Balls and rollers are normally held to diametral tolerances of .0001 inch (2.54 mm) or less within one bearing and are often used as “gage” blocks in routine toolroom operations. This accuracy is essential to the performance and durability of rolling-contact bearings and in limiting runout, providing proper radial and axial clearances, and ensuring smoothness of operation.

Because of their low friction, both starting and running, rolling-contact bearings are utilized to reduce the complexity of many systems that normally function with journal bearings. Aside from this advantage and that of precise radial and axial location of rotating elements, however, they also are desirable because of their reduced lubrication requirements and their ability to function during brief interruptions in normal lubrication.

In applying rolling-contact bearings it is well to appreciate that their life is limited by the fatigue life of the material from which they are made and is modified by the lubricant used. In rolling-contact fatigue, precise relationships among life, load, and design characteristics are not predictable, but a statistical function described as the “probability of survival” is used to relate them according to equations recommended by the AFBMA. Deviations from these formulas result when certain extremes in applications such as speed, deflection, temperature, lubrication, and internal geometry must be dealt with.

**Types of Anti-friction Bearings.**—The general types are usually determined by the shape of the rolling element, but many variations have been developed that apply conventional elements in unique ways. Thus it is well to know that special bearings can be procured with races adapted to specific applications, although this is not practical for other than high volume configurations or where the requirements cannot be met in a more economical manner. “Special” races are appreciably more expensive. Quite often, in such situations, races are made to incorporate other functions of the mechanism, or are “submerged” in the surrounding structure, with the rolling elements supported by a shaft or housing that has been hardened and finished in a suitable manner. Typical anti-friction bearing types are shown in [Tables 1a](#) through [1g](#).

<sup>a</sup> A line through the ball contact points forms an acute angle with a perpendicular to the bearing axis.

**Types of Ball Bearings.**— Most types of ball bearings originate from three basic designs: the single-row radial, the single-row angular contact, and the double-row angular contact.

*Single-row Radial, Non-filling Slot:* This is probably the most widely used ball bearing and is employed in many modified forms. It is also known as the “Conrad” type or “Deep-groove” type. It is a symmetrical unit capable of taking combined radial and thrust loads in which the thrust component is relatively high, but is not intended for pure thrust loads, however. Because this type is not self-aligning, accurate alignment between shaft and housing bore is required.

*Single-row Radial, Filling Slot:* This type is designed primarily to carry radial loads. Bearings of this type are assembled with as many balls as can be introduced by eccentric displacement of the rings, as in the non-filling slot type, and then several more balls are inserted through the loading slot, aided by a slight spreading of the rings and heat expansion of the outer ring, if necessary. This type of bearing will take a certain degree of thrust when in combination with a radial load but is not recommended where thrust loads exceed 60 percent of the radial load.

BALL BEARINGS, DOUBLE ROW, SELF-ALIGNING <sup>a</sup>			
	Symbol	Description	
	BS	Raceway of outer ring spherical 	

<sup>a</sup> A line through the ball contact points forms an acute angle with a perpendicular to the bearing axis.

**Single-row Angular-contact:** This type is designed for combined radial and thrust loads where the thrust component may be large and axial deflection must be confined within very close limits. A high shoulder on one side of the outer ring is provided to take the thrust, while the shoulder on the other side is only high enough to make the bearing non-separable. Except where used for a pure thrust load in one direction, this type is applied either in pairs (duplex) or one at each end of the shaft, opposed.

**Double-row Bearings:** These are, in effect, two single-row angular-contact bearings built as a unit with the internal fit between balls and raceway fixed at the time of bearing assembly. This fit is therefore not dependent upon mounting methods for internal rigidity. These bearings usually have a known amount of internal preload built in for maximum resistance to deflection under combined loads with thrust from either direction. Thus, with balls and races under compression before an external load is applied, due to this internal preload, the bearings are very effective for radial loads where bearing deflection must be minimized.

**Other Types:** Modifications of these basic types provide arrangements for self-sealing, location by snap ring, shielding, etc., but the fundamentals of mounting are not changed. A special type is the *self-aligning* ball bearing which can be used to compensate for an appreciable degree of misalignment between shaft and housing due to shaft deflections, mount-

ing inaccuracies, or other causes commonly encountered. With a single row of balls, alignment is provided by a spherical outer surface on the outer ring; with a double row of balls, alignment is provided by a spherical raceway on the outer ring. Bearings in the wide series have a considerable amount of thrust capacity.

RAA	Single-ribbed inner ring Single-ribbed outer ring Both rings separable		

**Types of Roller Bearings.**—Types of roller bearings are distinguished by the design of rollers and raceways to handle axial, combined axial and thrust, or thrust loads.

*Cylindrical Roller:* These bearings have solid or helically wound hollow cylindrical rollers. The free ring may have a restraining flange to provide some restraint to endwise movement in one direction or may be without a flange so that the bearing rings may be displaced axially with respect to each other. Either rolls or roller path on the races may be slightly crowned to prevent edge loading under slight shaft misalignment. Low friction makes this type suitable for relatively high speeds.

*Barrel Roller:* These bearings have rollers that are barrel-shaped and symmetrical. They are furnished in both single- and double-row mountings. As with cylindrical roller bearings, the single-row mounting type has a low thrust capacity, but angular mounting of rolls in the double-row type permits its use for combined axial and thrust loads.

*Spherical Roller:* These bearings are usually furnished in a double-row, self-aligning mounting. Both rows of rollers have a common spherical outer raceway. The rollers are

barrel-shaped with one end smaller than the other to provide a small thrust to keep the rollers in contact with the center guide flange. This type of roller bearing has a high radial and thrust load carrying capacity with the ability to maintain this capacity under some degree of misalignment of shaft and bearing housing.

*Tapered Roller:* In this type, straight tapered rollers are held in accurate alignment by means of a guide flange on the inner ring. The basic characteristic of these bearings is that the apexes of the tapered working surfaces of both rollers and races, if extended, would coincide on the bearing axis. These bearings are separable. They have a high radial and thrust carrying capacity.

**Types of Ball and Roller Thrust Bearings.**— Are designed to take thrust loads alone or in combination with radial loads.

*One-direction Ball Thrust:* These bearings consist of a shaft ring and a flat or spherical housing ring with a single row of balls between. They are capable of carrying pure thrust loads in one direction only. They cannot carry any radial load.

*Two-direction Ball Thrust:* These bearings consist of a shaft ring with a ball groove in either side, two sets of balls, and two housing rings so arranged that thrust loads in either direction can be supported. No radial loads can be carried.

<sup>a</sup>Inch dimensioned only.

**Spherical Roller Thrust:** This type is similar in design to the radial spherical roller bearing except that it has a much larger contact angle. The rollers are barrel shaped with one end smaller than the other. This type of bearing has a very high thrust load carrying capacity and can also carry radial loads.

**Tapered Roller Thrust:** In this type the rollers are tapered and several different arrangements of housing and shaft are used.

**Roller Thrust:** In this type the rollers are straight and several different arrangements of housing and shaft are used.

**Types of Needle Bearings.**— Needle bearings are characterized by their relatively small size rollers, usually not above  $\frac{1}{4}$  inch (6.35 mm) in diameter, and a relatively high ratio of length to diameter, usually ranging from about 3 to 1 and 10 to 1. Another feature that is

	TT	Thrust bearings	

characteristic of several types of needle bearings is the absence of a cage or separator for retaining the individual rollers. Needle bearings may be divided into three classes: loose-roller, outer race and retained roller, and non-separable units.

**Loose-roller:** This type of bearing has no integral races or retaining members, the needles being located directly between the shaft and the outer bearing bore. Usually both shaft and outer bore bearing surfaces are hardened and retaining members that have smooth unbroken surfaces are provided to prevent endwise movement. Compactness and high radial load capacity are features of this type.

**Outer Race and Retained Roller:** There are two types of outer race and retained roller bearings. In the *Drawn Shell* type, the needle rollers are enclosed by a hardened shell that acts as a retaining member and as a hardened outer race. The needles roll directly on the shaft, the bearing surface of which should be hardened. The capacity for given roller length and shaft diameter is about two-thirds that of the loose roller type. It is mounted in the housing with a press fit.

In the *Machined Race* type, the outer race consists of a heavy machined member. Various modifications of this type provide heavy ends or faces for end location of the needle rollers, or open end construction with end washers for roller retention, or a cage that maintains alignment of the rollers and is itself held in place by retaining rings. An auxiliary outer member with spherical seat that holds the outer race may be provided for self-alignment.

Of additional value are: 1) their resistance to indentation from shock loads or oscillation; and 2) their self-lubricating properties.

Usually these bearings are not available from stock, but must be designed and produced in accordance with the data made available by the plastics processor.

**Pillow Block and Flanged Housing Bearings.**— Of great interest in the shop man and particularly adaptable to “line-shafting” applications are a series of ball and roller bearings supplied with their own housings, adapters, and seals. Often called pre-mounted bearings, they come with a wide variety of flange mountings permitting location on faces parallel to or perpendicular to the shaft axis.

Inner races can be mounted directly on ground shafts, or can be adapter-mounted to “drill-rod” or to commercial shafting. For installations sensitive to imbalance and vibration, the use of accurately ground shaft seats is recommended.

Most pillow block designs incorporate self-aligning types of bearings so they do not require the precision mountings utilized with more normal bearing installations.

**Conventional Bearing Materials.**— Most rolling contact bearings are made with all load carrying members of full hard steel, either through- or case-hardened. For greater reliability this material is controlled and selected for cleanliness and alloying practices in conformity with rigid specifications in order to reduce anomalies and inclusions that could limit the useful fatigue life. Magnaflux inspection is employed to ensure that elements are free from both material defects and cracks. Likewise, a light etch is employed between rough and finish grinding to allow detection of burns due to heavy stock removal and associated decarburization in finished pieces.

**Cage Materials.**— Standard bearings are normally made with cages of free-machining brass or low carbon sulfurized steel. In high-speed applications or where lubrication may be intermittent or marginal, special materials may be employed. Iron-silicon-bronze, laminated phenolics, silver-plating, over-lays, solid-film baked-on coatings, carbon-graphite inserts, and, in extreme cases, sintered or even impregnated materials are used in separators.

Commercial bearings usually rely on stamped steel with or without a phosphate treatment; some low cost varieties are found with snap-in plastic or metallic cages.

So long as lubrication is adequate and speeds are both reasonable and steady, the materials and design of the cage are of secondary importance when compared with those of the rolling elements and their contacts with the races. In spite of this tolerance, a good portion of all rolling bearing failures encountered can be traced to cage failures resulting from inadequate lubrication. It can never be overemphasized that *no bearing can be designed to run continuously without lubrication!*

**Standard Method of Bearing Designation.**— The Anti-Friction Bearing Manufacturers Association has adopted a standard identification code that provides a specific designation for each different ball, roller, and needle bearing. Thus, for any given bearing, a uniform designation is provided for manufacturer and user alike, so that the confusion of different company designations can be avoided.

In this identification code there is a “basic number” for each bearing that consists of three elements: a one- to four-digit number to indicate the size of the bore in numbers of millimeters (metric series); a two- or three-letter symbol to indicate the type of bearing; and a two-digit number to identify the dimension series to which the bearing belongs.

In addition to this “basic number” other numbers and letters are added to designate type of tolerance, cage, lubrication, fit up, ring modification, addition of shields, seals, mounting accessories, etc. Thus, a complete designating symbol might be *50BC02JPXE0A10*, for example. The basic number is *50BC02* and the remainder is the supplementary number. For a radial bearing, this latter consists of up to four letters to indicate modification of design, one or two digits to indicate internal fit and tolerances, a letter to indicate lubricants and preservatives, and up to three digits to indicate special requirements.

For a thrust bearing the supplementary number would consist of two letters to indicate modifications of design, one digit to indicate tolerances, one letter to indicate lubricants and preservatives, and up to three digits to indicate special requirements.

For a needle bearing the supplementary number would consist of up to three letters indicating cage material or integral seal information or whether the outer ring has a crowned outside surface and one letter to indicate lubricants or preservatives.

*Dimension Series:* Annular ball, cylindrical roller, and self-aligning roller bearings are made in a series of different outside diameters for every given bore diameter and in a series of different widths for every given outside diameter. Thus, each of these bearings belongs to a dimension series that is designated by a two-digit number such as 02, 23, 93, etc. The first digit (8, 0, 1, 2, 3, 4, 5, 6 and 9) indicates the *width series* and the second digit (7, 8, 9, 0, 1, 2, 3, and 4) the *diameter series* to which the bearing belongs. Similar types of identification codes are used for ball and roller thrust bearings and needle roller bearings.

### Bearing Tolerances

**Ball and Roller Bearings.**— In order to provide standards of precision for proper application of ball or roller bearings in all types of equipment, five classes of tolerances have been established by the Anti-Friction Bearing Manufacturers Association for ball bearings, three for cylindrical roller bearings and one for spherical roller bearings. These tolerances are given in [Tables 2, 3, 4, 5, and 6](#). They are designated as ABEC-1, ABEC-3, ABEC-5, ABEC-7 and ABEC-9 for ball bearings, the ABEC-9 being the most precise, RBEC-1, RBEC-3, and RBEC-5 for roller bearings. In general, bearings to specifications closer than ABEC-1 or RBEC-1 are required because of the need for very precise fits on shaft or housing, to reduce eccentricity or runout of shaft or supported part, or to permit operation at very high speeds. All five classes include tolerances for bore, outside diameter, ring width, and radial runouts of inner and outer rings. ABEC-5, ABEC-7 and ABEC-9 provide added tolerances for parallelism of sides, side runout and groove parallelism with sides.

**Thrust Bearings.**— Anti-Friction Bearing Manufacturers Association and American National Standard tolerance limits for metric single direction thrust ball and roller bearings are given in [Table 8](#). Tolerance limits for single direction thrust ball bearings, inch dimensioned are given in [Table 7](#), and for cylindrical thrust roller bearings, inch dimensioned in [Table 9](#).

Only one class of tolerance limits is established for metric thrust bearings.

**Radial Needle Roller Bearings.**— Tolerance limits for needle roller bearings, drawn cup, without inner ring, inch types NIB, NIBM, NIY, NIYM, NIH, and NIHM are given in [Table 10](#) and for metric types NB, NBM, NY, NYM, NH and NHM in [Table 11](#). Standard tolerance limits for needle roller bearings, with cage, machined ring, without inner ring, inch type NIA are given in [Table 12](#) and for needle roller bearings inner rings, inch type NIR in [Table 13](#).

**Table 2. ABEC-1 and RBEC-1 Tolerance Limits for Metric Ball and Roller Bearings ANSI/ABMA 20-1987**

Basic Inner Ring Bore Diameter, $d$		$V_{dp}$ , <sup>a</sup> max			$\Delta_{dmp}$ <sup>b</sup>		$K_{ia}$ <sup>c</sup>

<sup>a</sup> Single plane mean bore diameter deviation of central shaft washer ( $\Delta d_{mp}$ ) and outside diameter ( $\Delta D_{mp}$ ) variation.

<sup>b</sup> Raceway parallelism with the face, housing-mounted ( $S_e$ ) and boremounted ( $S_r$ ) race or washer.

<sup>c</sup> Deviation of the actual bearing height.

All dimensions in micrometers, unless otherwise indicated. Tolerances are for normal tolerance class only. For sizes beyond the range of this table and for other tolerance class values, see Standard. All entries apply to type TA bearings; boldface entries also apply to type TS bearings.

For fitting and mounting practice, see [Table 21](#).

**Metric Radial Ball and Roller Bearing Shaft and Housing Fits.**— To select the proper fits, it is necessary to consider the type and extent of the load, bearing type, and certain other design and performance requirements.

The required shaft and housing fits are indicated in [Tables 14](#) and [15](#). The terms “Light,” “Normal,” and “Heavy” loads refer to radial loads that are generally within the following limits, with some overlap ( $C$  being the Basic Load Rating computed in accordance with AFBMA-ANSI Standards):

Bearing Type	Radial Load		
	Light	Normal	Heavy
Ball	Up to $0.075C$	From $0.075C$ to $0.15C$	Over $0.15C$
Cylindrical Roller	Up to $0.075C$	From $0.075C$ to $0.2C$	Over $0.15C$
Spherical Roller	Up to $0.075C$	From $0.070C$ to $0.25C$	Over $0.15C$

**Shaft Fits:** [Table 14](#) indicates the initial approach to shaft fit selection. Note that for most normal applications where the shaft rotates and the radial load direction is constant, an interference fit should be used. Also, the heavier the load, the greater is the required interference. For stationary shaft conditions and constant radial load direction, the inner ring may be moderately loose on the shaft.

For pure thrust (axial) loading, heavy interference fits are not necessary; only a moderately loose to tight fit is needed.

The upper part of [Table 16](#) shows how the shaft diameters for various ANSI shaft limit classifications deviate from the basic bore diameters.

[Table 17](#) gives metric values for the shaft diameter and housing bore tolerance limits given in [Table 16](#).

The lower parts of [Tables 16](#) and [17](#) show how housing bores for various ANSI hole limit classifications deviate from the basic shaft outside diameters.

**Table 14. Selection of Shaft Tolerance Classifications for Metric Radial Ball and Roller Bearings of ABEC-1 and RBEC-1 Tolerance Classes ANSI/ABMA 7-1995 (R2001)**

Operating Conditions			Ball Bearings		Cylindrical Roller Bearings		Spherical Roller Bearings		Tolerance Symbol <sup>a</sup>

								r7 <sup>b</sup>	
Pure Thrust Load			All diams.	All diams.	Consult Bearing Manufacturer				j6

<sup>a</sup> For solid steel shafts. For hollow or nonferrous shafts, tighter fits may be needed.

<sup>b</sup> When greater accuracy is required, use j5, k5, and m5 instead of j6, k6, and m6, respectively.

Numerical values are given in [Tables 16](#) and [17](#).

**Table 15. Selection of Housing Tolerance Classifications for Metric Radial Ball and Roller Bearings of ABEC-1 and RBEC-1 Tolerance Classes**

Design and Operating Conditions				Tolerance Classification <sup>a</sup>
Rotational Conditions	Loading	Outer Ring Axial Displacement Limitations	Other Conditions	
Outer ring stationary in relation to load direction	Light Normal and Heavy	Outer ring must be easily axially displaceable	Heat input through shaft	G7
			Housing split axially	H7 <sup>b</sup>
			Housing not split axially	H6 <sup>b</sup>
Load direction is indeterminate	Shock with temporary complete unloading	Transitional Range <sup>c</sup>		J6 <sup>b</sup>
			Light and normal	
			Normal and Heavy	
Outer ring rotating in relation to load direction	Light	Outer ring need not be axially displaceable	Split housing not recommended	K6 <sup>b</sup>
				Normal and Heavy
	Heavy			
			Thin wall housing not split	P6 <sup>b</sup>

<sup>a</sup> For cast iron or steel housings. For housings of nonferrous alloys tighter fits may be needed.

<sup>b</sup> Where wider tolerances are permissible, use tolerance classifications P7, N7, M7, K7, J7, and H7, in place of P6, N6, M6, K6, J6, and H6, respectively.

<sup>c</sup> The tolerance zones are such that the outer ring may be either tight or loose in the housing.

Based on ANSI B4.1-1967 (R2009) Preferred Limits and Fits for Cylindrical Parts. Symbols g6, h6, etc., are shaft and G7, H7, etc., hole limits designations. For larger diameters and metric values see AFBMA Standard 7.

**Design and Installation Considerations.**— Interference fitting will reduce bearing radial internal clearance, so it is recommended that prospective users consult bearing manufacturers to make certain that the required bearings are correctly specified to satisfy all mounting, environmental and other operating conditions and requirements. This check is particularly necessary where heat sources in associated parts may further diminish bearing clearances in operation.

Standard values of radial internal clearances of radial bearings are listed in AFBMA-ANSI Standard 20.

**Allowance for Axial Displacement.**— Consideration should be given to axial displacement of bearing components owing to thermal expansion or contraction of associated parts. Displacement may be accommodated either by the internal construction of the bearing or by allowing one of the bearing rings to be axially displaceable. For unusual applications consult bearing manufacturers.

**Needle Roller Bearing Fitting and Mounting Practice.**— The tolerance limits required for shaft and housing seat diameters for needle roller bearings with inner and outer rings as well as limits for raceway diameters where inner or outer rings or both are omitted and rollers operate directly upon these surfaces are given in Tables 18 through 21, inclusive. Unusual design and operating conditions may require a departure from these practices. In such cases, bearing manufacturers should be consulted.

*Needle Roller Bearings, Drawn Cup:* These bearings without inner ring, Types NIB, NB, NIBM, NBM, NIY, NY, NIYM, NYM, NIH, NH, NIHM, NHM, and Inner Rings, Type NIR depend on the housings into which they are pressed for their size and shape. Therefore, the housings must not only have the proper bore dimensions but also must have sufficient strength. Tables 18 and 19, show the bore tolerance limits for rigid housings such as those made from cast iron or steel of heavy radial section equal to or greater than the ring gage section given in AFBMA Standard 4, 1984. The bearing manufacturers should be consulted for recommendations if the housings must be of lower strength materials such as aluminum or even of steel of thin radial section. The shape of the housing bores should be such that when the mean bore diameter of a housing is measured in each of several radial planes, the maximum difference between these mean diameters should not exceed 0.0005 inch (0.013 mm) or one-half the housing bore tolerance limit, if smaller. Also, the radial deviation from circular form should not exceed 0.00025 inch (0.006 mm). The housing bore surface finish should not exceed 125 micro-inches (3.2 micrometers) arithmetical average.

<sup>a</sup> See text for additional requirements.

For inner ring tolerance limits, see [Table 13](#).

Most needle roller bearings do not use inner rings, but operate directly on the surfaces of shafts. When shafts are used as inner raceways, they should be made of bearing quality steel hardened to Rockwell C 58 minimum. [Tables 15](#) and [19](#) show the shaft raceway tolerance limits and [Table 21](#) shows the shaft seat tolerance limits when inner rings are used. However, whether the shaft surfaces are used as inner raceways or as seats for inner rings, the mean outside diameter of the shaft surface in each of several radial planes should be determined. The difference between these mean diameters should not exceed 0.0003 inch (0.008 mm) or one-half the diameter tolerance limit, if smaller. The radial deviation from circular form should not exceed 0.0001 inch (0.0025 mm), for diameters up to and including 1 in. (25.4 mm). Above one inch the allowable deviation is 0.0001 times the shaft diameter. The surface finish should not exceed 16 micro-inches (0.4 micrometer) arithmetical average. The housing bore and shaft diameter tolerance limits depend upon whether the load rotates relative to the shaft or the housing.

*Needle Roller Bearing With Cage, Machined Ring, Without Inner Ring:* The following covers needle roller bearings Type NIA and inner rings Type NIR. The shape of the housing bores should be such that when the mean bore diameter of a housing is measured in each of several radial planes, the maximum difference between these mean diameters does not exceed 0.0005 inch (0.013 mm) or one-half the housing bore tolerance limit, if smaller. Also, the radial deviation from circular form should not exceed 0.00025 inch (0.006 mm). The housing bore surface finish should not exceed 125 micro-inches (3.2 micrometers) arithmetical average. [Table 21](#) shows the housing bore tolerance limits.

When shafts are used as inner raceways their requirements are the same as those given above for Needle Roller Bearings, Drawn Cup. [Table 20](#) shows the shaft raceway tolerance limits and [Table 21](#) shows the shaft seat tolerance limits when inner rings are used.

*Needle Roller and Cage Assemblies, Types NIM and NM:* For information concerning boundary dimensions, tolerance limits, and fitting and mounting practice, reference should be made to ANSI/ABMA 18.1-1982 (R1999) and ANSI/ABMA 18.2-1982 (R1999).

### Bearing Mounting Practice

Because of their inherent design and material rigidity, rolling contact bearings must be mounted with careful control of their alignment and runout. Medium-speed or slower (400,000  $DN$  values or less where  $D$  is the bearing bore in millimeters and  $N$  is the bearing speed in revolutions per minute), and medium to light load ( $C/P$  values of 7 or greater where  $C$  is the bearing specific dynamic capacity in pounds and  $P$  is the average bearing load in pounds) applications can endure misalignments equivalent to those acceptable for high-capacity, precision journal bearings utilizing hard bearing materials such as silver, copper-lead, or aluminum. In no case, however, should the maximum shaft deflection exceed .001 inch per inch (or mm per mm) for well-crowned roller bearings, and .003 inch per inch (or mm per mm) for deep-groove ball-bearings. Except for self-aligning ball-bearings and spherical or barrel roller bearings, all other types require shaft alignments with deflections no greater than .0002 inch per inch (or mm per mm). With preloaded ball bearings, this same limit is recommended as a maximum. Close-clearance tapered bearings or thrust bearings of most types require the same shaft alignment also.

Of major importance for all bearings requiring good reliability is the location of the races on the shaft and in the housing.

Assembly methods must insure: 1) that the faces are square before the cavity is closed; 2) that the cover face is square to the shoulder and pulled in evenly; and 3) that it will be located by a face parallel to it when finally seated against the housing.

These requirements are shown in the accompanying **Table 22**. In applications not controlled by automatic tooling with closely controlled fixtures and bolt torquing mechanisms, races should be checked for squareness by sweeping with a dial indicator mounted as shown below. For commercial applications with moderate life and reliability requirements, outer race runouts should be held to .0005 inch per inch (or mm per mm) of radius and inner race runout to .0004 inch per inch (or mm per mm) of radius. In preloaded and precision applications, these tolerances must be cut in half. In regard to the question of alignment, it must be recognized that rolling-contact bearings, being made of fully-hardened steel, do not wear in as may certain journal bearings when carefully applied and initially operated. Likewise, rolling contact bearings absorb relatively little deflection when loaded to  $C/P$  values of 6 or less. At such stress levels the rolling element-race deformation is generally not over .0002 inch (5.08  $\mu\text{m}$ ). Consequently, proper mounting and control of shaft deflections are imperative for reliable bearing performance. Aside from inadequate lubrication, these factors are the most frequent causes of premature bearing failures.

**Mountings for Precision and Quiet-running Applications.**— In applications of rolling-element bearings where vibration or smoothness of operation is critical, special precautions must be taken to eliminate those conditions which can serve to initiate radial and axial motions. These exciting forces can result in shaft excursions which are in resonance with shaft or housing components over a range of frequencies from well below shaft speed to as much as 100 times above it. The more sensitive the configuration, the greater is the need for precision bearings and mountings to be used.

Precision bearings are normally made to much closer tolerances than standard and therefore benefit from better finishing techniques. Special inspection operations are required, however, to provide races and rolling elements with smoothness and runouts compatible with the needs of the application. Similarly, shafts and housings must be carefully controlled.

Among the important elements to be controlled are shaft, race, and housing roundness; squareness of faces, diameters, shoulders, and rolling paths. Though not readily appreciated, grinding chatter, lobular and compensating out-of-roundness, waviness, and flats of less than 0.0005 inch (0.013 mm) deviation from the average or mean diameter can cause significant roughness. To detect these and insure the selection of good pieces, three-point electronic indicator inspection must be made. For ultra-precise or quiet applications,

pieces are often checked on a "Talyrond" or a similar continuous recording instrument capable of measuring to within a few millionths of an inch. Though this may seem extreme, it has been found that shaft deformities will be reflected through inner races shrunk onto them. Similarly, tight-fit outer races pick up significant deviations in housings. In many instrument and in missile guidance applications, such deviations and deformities may have to be limited to less than 0.00002 inch (0.508  $\mu\text{m}$ ).

In most of these precision applications, bearings are used with rolling elements controlled to less than 5 millionths of an inch deviation from roundness and within the same range for diameter.

Special attention is required both in housing design and in assembly of the bearing to shaft and housing. Housing response to axial excursions forced by bearing wobble (which in itself is a result of out-of-square mounting) has been found to be a major source of small electric and other rotating equipment noise and howl. Stiffer, more massive housings and careful alignment of bearing races can make significant improvements in applications where noise or vibration has been found to be objectionable.

**Table 22. Commercial Application Alignment Tolerances**

Feature	Location	Tolerance
<b>Housing Face Runout</b>	1	Square to shaft center within .0004 inch/inch of radius full indicator reading.
<b>Outer Race Face Runout</b>	2	Square to shaft center within .0004 inch/inch of radius full indicator reading and complementary to the housing runout (not opposed).
<b>Inner Race Face Runout</b>	3	Square to shaft center within .0003 inch/inch of radius full indicator reading.
<b>Cover and Closure Mounting Face Parallelism</b>	4 and 5	Parallel within .001.
<b>Housing Mounting Face Parallelism</b>	6	Parallel within .001

**Squareness and Alignment.**— In addition to the limits for roundness and wall variation of the races and their supports, squareness of end faces and shoulders must be closely controlled. Tolerances of .0001 inch (2.54  $\mu\text{m}$ ) full indicator reading per inch of diameter are normally required for end faces and shoulders, with appropriately selected limits for fillet eccentricities. The latter must also fall within specified limits for radii tolerances to prevent interference and the resulting cocking of the race. Reference should be made to the bearing dimension tables which list corner radii for typical bearings. Shoulders must also be of a sufficient height to insure proper support for the races, since they are of hardened steel and are less capable of absorbing shock loads and abuse. The general subject of squareness and alignment is of primary importance to the life of rolling element bearings.

The following recommendations for shaft and housing design are given by the New Departure Division of General Motors Corporation:\*

“As a rule, there is little trouble experienced with inaccuracies in shafts. Bearings seats and locating shoulders are turned and ground to size with the shaft held on centers and, with ordinary care, there is small chance for serious out-of-roundness or taper. Shaft shoulders should present sufficient surface in contact with the bearing face to assure positive and accurate location.

“Where an undercut must be made for wheel runout in grinding a bearing seat, care should be exercised that no sharp corners are left, for it is at such points that fatigue is most likely to result in shaft breakage. It is best to undercut as little as possible and to have the undercut end in a fillet instead of a sharp corner.

“Where clamping nuts are to be used, it is important to cut the threads as true and square as possible in order to insure even pressure at all points on the bearing inner ring faces when the nuts are set up tight. It is also important not to cut threads so far into the bearing seat as to leave part of the inner ring unsupported or carried on the threads. Excessive deflection is usually the result of improperly designed or undersized machine parts. With a weak shaft, it is possible to seriously affect bearing operation through misalignment due to shaft deflection. Where shafts are comparatively long, the diameter between bearings must be great enough to properly resist bending. In general, the use of more than two bearings on a single shaft should be avoided, owing to the difficulty of securing accurate alignment. With bearings mounted close to each other, this can result in extremely heavy bearing loads.

“Design is as important as careful machining in construction of accurate bearing housings. There should be plenty of metal in the wall sections and large, thin areas should be avoided as much as possible, since they are likely to permit deflection of the boring tool when the housing is being finish-machined.

“Wherever possible, it is best to design a housing so that the radial load placed on the bearing is transmitted as directly as possible to the wall or rib supporting the housing. Diaphragm walls connecting an offset housing to the main wall or side of a machine are apt to deflect unless made thick and well braced.

“When two bearings are to be mounted opposed, but in separate housings, the housings should be so reinforced with fins or webs as to prevent deflection due to the axial load under which the bearings are opposed.

“Where housings are deep and considerable overhang of the boring tool is required, there is a tendency to produce out-of-roundness and taper, unless the tool is very rigid and light finishing cuts are taken. In a too roughly bored housing there is a possibility for the ridges of metal topeen down under load, thus eventually resulting in too loose a fit for the bearing outer ring.”

**Soft Metal and Resilient Housings.**— In applications relying on bearing housings made of soft materials (aluminum, magnesium, light sheet metal, etc.) or those which lose their fit because of differential thermal expansion, outer race mounting must be approached in a cautious manner. Of first importance is the determination of the possible consequences of race loosening and turning. In conjunction with this, the type of loading must be considered for it may serve to magnify the effect of race loosening. It must be remembered that generally, balancing processes do not insure zero unbalance at operating speeds, but rather an “acceptable” maximum. This force exerted by the rotating element on the outer race can initiate a precession which will aggravate the race loosening problem by causing further attrition through wear, pounding, and abrasion. Since this force is generally of an order greater than the friction forces in effect between the outer race, housing, and closures (retaining nuts also), no foolproof method can be recommended for securing outer races in housings which deform significantly under load or after appreciable service wear. Though

\* New Departure Handbook. Vol. II — 1951.

many such “fixes” are offered, the only sure solution is to press the race into a housing of sufficient stiffness with the heaviest fit consistent with the installed and operating clearances. In many cases, inserts, or liners of cast iron or steel, are provided to maintain the desired fit and increase useful life of both bearing and housing.

**Quiet or Vibration-free Mountings.**— In seeming contradiction is the approach to bearing mountings in which all shaft or rotating element excursions must be isolated from the frame, housing, or supporting structure. Here bearing outer races are often supported on elastomeric or metallic springs. Fundamentally, this is an isolation problem and must be approached with caution to insure solution of the primary bearing objective — location and restraint of the rotating body, as well as the reduction or elimination of the dynamic problem. Again, the danger of skidding rolling elements must be considered and reference to the resident engineers or sales engineers of the numerous bearing companies is recommended, as this problem generally develops requirements for special, or non-catalog-type bearings.

**General Mounting Precautions.**— Since the last operations involving the bearing application — mounting and closing — have such important effects on bearing performance, durability, and reliability, it must be cautioned that more bearings are abused or “killed” in this early stage of their life than wear out or “die” under conditions for which they were designed. Hammer and chisel “mechanics” invariably handle bearings as though no blow could be too hard, no dirt too abrasive, and no misalignment of any consequence. Proper tools, fixtures, and techniques are a must for rolling bearing application, and it is the responsibility of the design engineer to provide for this in his design, advisory notes, mounting instructions, and service manuals. Nicks, dents, scores, scratches, corrosion staining, and dirt must be avoided if reliability, long life, and smooth running are to be expected of rolling bearings. All manufacturers have pertinent service instructions available for the bearing user. These should be followed for best performance. In a later section, methods for inspecting bearings and descriptions of most common bearing deficiencies will be given.

**Seating Fits for Bearings.**— Anti-Friction Bearing Manufacturers Association (AFBMA) standard shaft and housing bearing seat tolerances are given in [Tables 13](#) through [18](#), inclusive.

**Clamping and Retaining Methods.**— Various methods of clamping bearings to prevent axial movement on the shaft are employed, one of the most common being a nut screwed on the end of the shaft and held in place by a tongued lock washer (see [Table 23](#)). The shaft thread for the clamping nut (see [Table 24](#)) should be cut in accurate relation to bearing seats and shoulders if bearing stresses are to be avoided. The threads used are of American National Form, Class 3; special diameters and data for these are given in [Tables 25](#) and [26](#). Where somewhat closer than average accuracy is required, the washers and locknut faces may be obtained ground for closer alignment with the threads. For a high degree of accuracy the shaft threads are ground and a more precise clamping means is employed. Where a bearing inner ring is to be clamped, it is important to provide a sufficiently high shoulder on the shaft to locate the bearing positively and accurately. If the difference between bearing bore and maximum shaft diameter gives a low shoulder which would enter the corner of the radius of the bearing, a shoulder ring that extends above the shoulder and well into the shaft corner is employed. A shoulder ring with snap wire fitting into a groove in the shaft is sometimes used where no locating shaft shoulder is present. A snap ring fitting into a groove is frequently employed to prevent endwise movement of the bearing away from the locating shoulder where tight clamping is not required. Such a retaining ring should not be used where a slot in the shaft surface might lead to fatigue failure. Snap rings are also used to locate the outer bearing ring in the housing. Dimensions of snap rings used for this latter purpose are given in AFBMA and ANSI standards.

<sup>a</sup>Threads are American National form Class 3.

All dimensions in inches. For dimensions in millimeters, multiply inch values, except thread diameters, by 25.4 and round results to two decimal places. These data apply to steel. When either the nut or the shaft is made of stainless steel, aluminum, or other material having a tendency to seize, it is recommended that the maximum thread diameter of the shaft, both major and pitch, be reduced by 20 percent of the pitch diameter tolerance listed in the Standard. For sizes larger than shown, see ANSI/ABMA 8.2-1991.

**Bearing Closures.**— Shields, seals, labyrinths, and slingers are employed to retain the lubricant in the bearing and to prevent the entry of dirt, moisture, or other harmful substances. The type selected for a given application depends upon the lubricant, shaft, speed, and the atmospheric conditions in which the unit is to operate. The shields or seals may be located in the bearing itself. Shields differ from seals in that they are attached to one bearing race but there is a definite clearance between the shield and the other, usually the inner, race. When a shielded bearing is placed in a housing in which the grease space has been filled, the bearing in running will tend to expel excess grease past the shields or to accept grease from the housing when the amount in the bearing itself is low.

Seals of leather, rubber, cork, felt, or plastic composition may be used. Since they must bear against the rotating member, excessive pressure should be avoided and some lubricant must be allowed to flow into the area of contact in order to prevent seizing and burning of the seal and scoring of the rotating member. Some seals are made up in the form of cartridges which can be pressed into the end of the bearing housing.

Leather seals may be used over a wide range of speeds. Although lubricant is best retained with a leather cupped inward toward the bearing, this arrangement is not suitable at high speeds due to danger of burning the leather. At high speeds where abrasive dust is present, the seal should be arranged with the leather cupped outward to lead some lubricant into the contact area. Only light pressure of leather against the shaft should be maintained.

**Bearing Fits.**— The slipping or creeping of a bearing ring on a rotating shaft or in a rotating housing occurs when the fit of the ring on the shaft or in the housing is loose. Such slipping or creeping action may cause rapid wear of both shaft and bearing ring when the surfaces are dry and highly loaded. To prevent this action the bearing is customarily mounted with the rotating ring a press fit and the stationary ring a push fit, the tightness or looseness depending upon the service intended. Thus, where shock or vibratory loads are to be encountered, fits should be made somewhat tighter than for ordinary service. The stationary ring, if correctly fitted, is allowed to creep very slowly so that prolonged stressing of one part of the raceway is avoided.

To facilitate the assembly of a bearing on a shaft it may become necessary to expand the inner ring by heating. This should be done in clean oil or in a temperature-controlled furnace at a temperature of between 200 and 250°F (93 to 121°C). The utmost care must be used to make sure that the temperature does not exceed 250°F as overheating will tend to reduce the hardness of the rings. Prelubricated bearings should not be mounted by this method.

### Design Considerations

**Friction Losses in Rolling Element Bearings.**— The static and kinematic torques of rolling element bearings are generally small and in many applications are not significant. Bearing torque is a measure of the frictional resistance of the bearing to rotation and is the sum of three components: the torque due to the applied load; the torque due to viscous forces in lubricated rolling element bearings; and the torque due to roller end motions, for example, thrust loads against flanges. The friction or torque data may be used to calculate power absorption or heat generation within the bearing and can be utilized in efficiency or system-cooling studies.

Empirical equations have been developed for each of the torque components. These equations are influenced by such factors as bearing load, lubrication environment, and bearing design parameters. These design parameters include sliding friction from contact between the rolling elements and separator surfaces or between adjacent rolling elements; rolling friction from material deformations during the passage of the rolling elements over the race path; skidding or sliding of the Hertzian contact; and windage friction as a function of speed.

Starting or breakaway torques are also of interest in some situations. Breakaway torques tend to be between 1.5 and 1.8 times the running or kinetic torques.

When evaluating the torque requirements of a system under design, it should be noted that other components of the bearing package, such as seals and closures, can increase the overall system torque significantly. Seal torques have been shown to vary from a fraction of the bearing torque to several times that torque. In addition, the torque values given can vary significantly when load, speed of rotation, temperature, or lubrication are outside normal ranges.

For small instrument bearings friction torque has implications more critical than for larger types of bearings. These bearings have three operating friction torques to consider: starting torque, normal running torque, and peak running torque. These torque levels may vary between manufacturers and among lots from a given manufacturer.

Instrument bearings are even more critically dependent on design features — radial play, retainer type, and race conformity — than larger bearings. Typical starting torque values for small bearings are given in the accompanying table, extracted from the New Departure General Catalog.

Finally, if accurate control of friction torque is critical to a particular application, tests of the selected bearings should be conducted to evaluate performance.

#### Starting Torque — ABEC7

Bearing Bore (in.)	Max. Starting Torque (g cm)	Thrust Load (g)	Minimum Radial Play Range (inches)	
			High Carbon Chrome Steel and All Miniatures	Stainless Steel Except Miniatures
0.125	0.10	75	0.0003–0.0005	—

	0.75	400	0.0003–0.0005	0.0004–0.0006
	0.95	400	0.0002–0.0004	0.0003–0.0005

**Selection of Ball and Roller Bearings.**— As compared with sleeve bearings, ball and roller bearings offer the following advantages: 1) Starting friction is low; 2) Less axial space is required; 3) relatively accurate shaft alignment can be maintained; 4) both radial and axial loads can be carried by certain types; 5) angle of load application is not restricted; 6) replacement is relatively easy; 7) comparatively heavy overloads can be carried momentarily; 8) lubrication is simple; and 9) design and application can be made with the assistance of bearing supplier engineers.

In selecting a ball or roller bearing for a specific application five choices must be made:

1) the bearing series; 2) the type of bearing; 3) the size of bearing; 4) the method of lubrication; and 5) the type of mounting.

Naturally these considerations are modified or affected by the anticipated operating conditions, expected life, cost, and overhaul philosophy.

It is well to review the possible history of the bearing and its function in the machine it will be applied to, thus: 1) Will it be expected to endure removal and reapplication?; 2) Must it be free from maintenance attention during its useful life?; 3) Can wear of the housing or shaft be tolerated during the overhaul period?; 4) Must it be adjustable to take up wear, or to change shaft location?; 5) How accurately can the load spectrum be estimated?; and 6) Will it be relatively free from abuse in operation?.

Though many cautions could be pointed out, it should always be remembered that inadequate design approaches limit the utilization of rolling element bearings, reduce customer satisfaction, and reduce reliability. Time spent in this stage of design is the most rewarding effort of the bearing engineer, who, here again, can depend on the bearing manufacturers' field organization for assistance.

*Type:* Where loads are low, ball bearings are usually less expensive than roller bearings in terms of unit-carrying capacity. Where loads are high, the reverse is usually true.

For a purely radial load, almost any type of radial bearing can be used, the actual choice being determined by other factors. To support a combination of thrust and radial loads, several types of bearings may be considered. If the thrust load component is large, it may be most economical to provide a separate thrust bearing. When a separate thrust bearing cannot be used due to high speed, lack of space, or other factors, the following types may be considered: angular contact ball bearing, deep groove ball bearing without filling slot, tapered roller bearing with steep contact angle, and self-aligning bearing of the wide type. If movement or deflection in an axial direction must be held to a minimum, then a separate thrust bearing or a preloaded bearing capable of taking considerable thrust load is required. To minimize deflection due to a moment in an axial plane, a rigid bearing such as a double row angular contact type with outwardly converging load lines is required. In such cases, the resulting stresses must be taken into consideration in determining the proper size of the bearing.

For shock loads or heavy loads of short duration, roller bearings are usually preferred.

Special bearing designs may be required where accelerations are usually high as in planetary or crank motions.

Where the problem of excessive shaft deflection or misalignment between shaft and housing is present, a self-aligning type of bearing may be a satisfactory solution.

It should be kept in mind that a great deal of difficulty can be avoided if standard types of bearings are used in preference to special designs, wherever possible.

*Size:* The size of bearing required for a given application is determined by the loads that are to be carried and, in some cases, by the amount of rigidity that is necessary to limit deflection to some specified amount.

The forces to which a bearing will be subjected can be calculated by the laws of engineering mechanics from the known loads, power, operating pressure, etc. Where loads are irregular, varying, or of unknown magnitude, it may be difficult to determine the actual forces. In such cases, empirical determination of such forces, based on extensive experience in bearing design, may be needed to attack the problem successfully. Where such experience is lacking, the bearing manufacturer should be consulted or the services of a bearing expert obtained.

If a ball or roller bearing is to be subjected to a combination of radial and thrust loads, an *equivalent radial load* is computed in the case of radial or angular type bearings and an *equivalent thrust load* is computed in the case of thrust bearings.

**Method of Lubrication.**— If speeds are high, relubrication difficult, the shaft angle other than horizontal, the application environment incompatible with normal lubrication, leakage cannot be tolerated; if other elements of the mechanism establish the lubrication requirements, bearing selection must be made with these criteria as controlling influences. Modern bearing types cover a wide selection of lubrication means. Though the most popular type is the “cartridge” type of sealed grease ball bearing, many applications have

requirements which dictate against them. Often, operating environments may subject bearings to temperatures too high for seals utilized in the more popular designs. If minute leakage or the accumulation of traces of dirt at seal lips cannot be tolerated by the application (as in baking industry machinery), then the selections of bearings must be made with other sealing and lubrication systems in mind.

High shaft speeds generally dictate bearing selection based on the need for cooling, the suppression of churning or aeration of conventional lubricants, and most important of all, the inherent speed limitations of certain bearing types. An example of the latter is the effect of cage design and of the roller-end thrust-flange contact on the lubrication requirements in commercial taper roller bearings, which limit the speed they can endure and the thrust load they can carry. Reference to the manufacturers' catalog and application-design manuals is recommended before making bearing selections.

See *Selecting a Suitable Lubricant* on page 2449 for more information on this topic.

**Type of Mounting.**— Many bearing installations are complicated because the best adapted type was not selected. Similarly, performance, reliability, and maintenance operations are restricted because the mounting was not thoroughly considered. There is no universally adaptable bearing for all needs. Careful reviews of the machine requirements should be made before designs are implemented. In many cases complicated machining, redundant shaft and housings, and use of an oversize bearing can be eliminated if the proper bearing in a well-thought-out mounting is chosen.

Advantage should be taken of the many race variations available in “standard” series of bearings. Puller grooves, tapered sleeves, ranged outer races, split races, fully demountable rolling-element and cage assemblies, flexible mountings, hydraulic removal features, relubrication holes and grooves, and many other innovations are available beyond the obvious advantages which are inherent in the basic bearing types.

**Radial and Axial Clearance.**— In designing the bearing mounting, a major consideration is to provide running clearances consistent with the requirements of the application. Race fits must be expected to absorb some of the original bearing clearance so that allowance should be made for approximately 80 percent of the actual interference showing up in the diameter of the race. This will increase for heavy, stiff housings or for extra light series races shrunk onto solid shafts, while light metal housings (aluminum, magnesium, or sheet metal) and tubular shafts with wall sections less than the race wall thickness will cause a lesser change in the race diameter.

Where the application will impose heat losses through housing or shaft, or where a temperature differential may be expected, allowances must be made in the proper direction to insure proper operating clearance. Some compromises are required in applications where the indicated modification cannot be fully accommodated without endangering the bearing performance at lower speeds, during starting, or under lower temperature conditions than anticipated. Some leeway can be relied on with ball bearings since they can run with moderate preloads (0.0005 inch or 12.7 mm, max.) without affecting bearing life or temperature rise. Roller bearings, however, have a lesser tolerance for preloading, and must be carefully controlled to avoid overheating and resulting self-destruction.

In all critical applications axial and radial clearances should be checked with feeler gages or dial indicators to insure mounted clearances within tolerances established by the design engineer. Since chips, scores, race misalignment, shaft or housing denting, housing distortion, end cover (closure) off-squareness, and mismatch of rotor and housing axial dimensions can rob the bearing of clearance, careful checks of running clearance is recommended.

For precision applications, taper-sleeve mountings, opposed ball or tapered-roller bearings with adjustable or shimmed closures are employed to provide careful control of radial and/or axial clearances. This practice requires skill and experience as well as the initial assistance of the bearing manufacturer's field engineer.

Tapered bore bearings are often used in applications such as these, again requiring careful and well worked-out assembly procedures. They can be assembled on either tapered shafts or on adapter sleeves. Advancement of the inner race over the tapered shaft can be done either by controlled heating (to expand the race as required) or by the use of a hydraulic jack. The adapter sleeve is supplied with a lock-nut which is used to advance the race on the tapered sleeve. With the heavier fits normally required to effect the clearance changes compatible with such mountings, hydraulic removal devices are normally recommended.

For the conventional application, with standard fits, clearances provided in the standard bearing are suitable for normal operation. To insure that the design conditions are "normal," a careful review of the application requirements, environments, operating speed range, anticipated abuses, and design parameters must be made.

**General Bearing Handling Precautions.**— To insure that rolling element bearings are capable of achieving their design life and that they perform without objectionable noise, temperature rise, or shaft excursions, the following precautions are recommended:

1) Use the best bearing available for the application, consistent with the value of the application. Remember, the cost of the best bearing is generally small compared to the replacement costs of the rotating components that can be destroyed if a bearing fails or malfunctions.

2) If questions arise in designing the bearing application, seek out the assistance of the bearing manufacturer's representative.

3) Handle bearings with care, keeping them in the sealed, original container until ready to use.

4) Follow the manufacturer's instructions in handling and assembling the bearings.

5) Work with clean tools, clean dry hands, and in clean surroundings.

6) Do not wash or wipe bearings prior to installation unless special instructions or requirements have been established to do so.

7) Place unwrapped bearings on clean paper and keep them similarly covered until applied, if they cannot be kept in the original container.

8) Don't use wooden mallets, brittle or chipped tools, or dirty fixtures and tools in mounting bearings.

9) Don't spin uncleaned bearings, nor spin *any* bearing with an air blast.

10) Use care not to scratch or nick bearings.

11) Don't strike or press on race flanges.

12) Use adapters for mounting which provide uniform steady pressure rather than hammering on a drift or sleeve.

13) Insure that races are started onto shafts and into housings evenly so as to prevent cocking.

14) Inspect shafts and housings before mounting bearing to insure that proper fits will be maintained.

15) When removing bearings, clean housings, covers, and shafts before exposing the bearings. All dirt can be considered an abrasive, dangerous to the reuse of any rolling bearing.

16) Treat used bearings, which may be reused, as new ones.

17) Protect dismantled bearings from dirt and moisture.

18) Use clean, lint-free rags if bearings are wiped.

19) Wrap bearings in clean, oil-proof paper when not in use.

20) Use clean filtered, water-free Stoddard's solvent or flushing oil to clean bearings.

21) In heating bearings for mounting onto shafts, follow manufacturer's instructions.

22) In assembling bearings onto shafts *never* strike the outer race, or press on it to force the inner race. Apply the pressure on the inner race only. In dismantling follow the same precautions.

23) Do not press, strike, or otherwise force the seal or shield on factory-sealed bearings.

**Bearing Failures, Deficiencies, and Their Origins.**— The general classifications of failures and deficiencies requiring bearing removal are:

1) Overheating due to a) Inadequate or insufficient lubrication; b) Excessive lubrication; c) Grease liquefaction or aeration; d) Oil foaming; e) Abrasive or corrosive action due to contaminants in bearing; f) Distortion of housing due to warping, or out-of-round; g) Seal rubbing or failure; h) Inadequate or blocked scavenge oil passages; i) Inadequate bearing-clearance or bearing-preload; j) Race turning; k) Cage wear; and l) Shaft expansion-loss of bearing or seal clearance.

2) Vibration due to a) Dirt or chips in bearing; b) Fatigued race or rolling elements; c) Race turning; d) Rotor unbalance; e) Out-of-round shaft; f) Race misalignment; g) Housing resonance; h) Cage wear; i) Flats on races or rolling elements; j) Excessive clearance; k) Corrosion; l) False-brinelling or indentation of races; m) Electrical discharge (similar to corrosion effects); n) Mixed rolling element diameters; and o) Out-of-square rolling paths in races.

3) Turning on shaft due to a) Growth of race due to overheating; b) Fretting wear; c) Improper initial fit; d) Excessive shaft deflection; e) Initially coarse shaft finish; and f) Seal rub on inner race.

4) Binding of the shaft due to a) Lubricant breakdown; b) Contamination by abrasive or corrosive matter; c) Housing distortion or out-of-round pinching bearing; d) Uneven shimming of housing with loss of clearance; e) Tight rubbing seals; f) Preloaded bearings; g) Cocked races; h) Loss of clearance due to excessive tightening of adapter; i) Thermal expansion of shaft or housing; and j) Cage failure.

5) Noisy bearing due to a) Lubrication breakdown, inadequate lubrication, stiff grease; b) Contamination; c) Pinched bearing; d) Seal rubbing; e) Loss of clearance and preload; f) Bearing slipping on shaft or in housing; g) Flatted roller or ball; h) Brinelling due to assembly abuse, handling, or shock loads; i) Variation in size of rolling elements; j) Out-of-round or lobular shaft; k) Housing bore waviness; and l) Chips or scores under bearing race seat.

6) Displaced shaft due to a) Bearing wear; b) Improper housing or closure assembly; c) Overheated and shifted bearing; d) Inadequate shaft or housing shoulder; e) Lubrication and cage failure permitting rolling elements to bunch; f) Loosened retainer nut or adapter; g) Excessive heat application in assembling inner race, causing growth and shifting on shaft; and h) Housing pounding out.

7) Lubricant leakage due to a) Overfilling of lubricant; b) Grease churning due to use of too soft a consistency; c) Grease deterioration due to excessive operating temperature; d) Operating life longer than grease life (grease breakdown, aeration, and purging); e) Seal wear; f) Wrong shaft attitude (bearing seals designed for horizontal mounting only); g) Seal failure; h) Clogged breather; i) Oil foaming due to churning or air flow through housing; j) Gasket (O-ring) failure or misapplication; k) Porous housing or closure; and l) Lubricator set at wrong flow rate.

### Load Ratings and Fatigue Life

**Ball and Roller Bearing Life.**— The performance of ball and roller bearings is a function of many variables. These include the bearing design, the characteristics of the material from which the bearings are made, the way in which they are manufactured, as well as many variables associated with their application. The only sure way to establish the satisfactory operation of a bearing selected for a specific application is by actual performance in the application. As this is often impractical, another basis is required to estimate the suitability of a particular bearing for a given application. Two factors are taken into consideration: the bearing fatigue life, and its ability to withstand static loading.

*Life Criterion:* Even if a ball or roller bearing is properly mounted, adequately lubricated, protected from foreign matter and not subjected to extreme operating conditions, it

can ultimately fatigue. Under ideal conditions, the repeated stresses developed in the contact areas between the balls or rollers and the raceways eventually can result in the fatigue of the material which manifests itself with the spalling of the load-carrying surfaces. In most applications the fatigue life is the maximum useful life of a bearing.

*Static Load Criterion:* A static load is a load acting on a non-rotating bearing. Permanent deformations appear in balls or rollers and raceways under a static load of moderate magnitude and increase gradually with increasing load. The permissible static load is, therefore, dependent upon the permissible magnitude of permanent deformation. It has been found that for ball and roller bearings suitably manufactured from hardened alloy steel, deformations occurring under maximum contact stress of 4,000 megapascals (580,000 pounds per square inch) acting at the center of contact (in the case of roller bearings, of a uniformly loaded roller) do not greatly impair smoothness or friction. Depending on requirements for smoothness of operation, friction, or sound level, higher or lower static load limits may be tolerated.

**Ball Bearing Types Covered.**— AFBMA and American National Standard ANSI/ABMA 9-1990 sets forth the method of determining ball bearing Rating Life and Static Load Rating and covers the following types:

1) *Radial, deep groove and angular contact ball bearings* whose inner ring raceways have a cross-sectional radius not larger than 52 percent of the ball diameter and whose outer ring raceways have a cross-sectional radius not larger than 53 percent of the ball diameter.

2) *Radial, self-aligning ball bearings* whose inner ring raceways have cross-sectional radii not larger than 53 percent of the ball diameter.

3) *Thrust ball bearings* whose washer raceways have cross-sectional radii not larger than 54 percent of the ball diameter.

4) *Double row, radial and angular contact ball bearings* and double direction thrust ball bearings are presumed to be symmetrical.

**Limitations for Ball Bearings.**— The following limitations apply:

1) *Truncated contact area.* This standard\* may not be safely applied to ball bearings subjected to loading which causes the contact area of the ball with the raceway to be truncated by the raceway shoulder. This limitation depends strongly on details of bearing design which are not standardized.

2) *Material.* This standard applies only to ball bearings fabricated from hardened good quality steel.

3) *Types.* The  $f_c$  factors specified in the basic load rating formulas are valid only for those ball bearing types specified above.

4) *Lubrication.* The Rating Life calculated according to this standard is based on the assumption that the bearing is adequately lubricated. The determination of adequate lubrication depends upon the bearing application.

5) *Ring support and alignment.* The Rating Life calculated according to this standard assumes that the bearing inner and outer rings are rigidly supported and the inner and outer ring axes are properly aligned.

6) *Internal clearance.* The radial ball bearing Rating Life calculated according to this standard is based on the assumption that only a nominal interior clearance occurs in the mounted bearing at operating speed, load and temperature.

7) *High speed effects.* The Rating Life calculated according to this standard does not account for high speed effects such as ball centrifugal forces and gyroscopic moments. These effects tend to diminish fatigue life. Analytical evaluation of these effects frequently requires the use of high speed digital computation devices and hence is not covered in the standard.

\* All references to "standard" are to AFBMA and American National Standard "Load Ratings and Fatigue Life for Ball Bearings" ANSI/ABMA 9-1990.

8) *Groove radii*. If groove radii are smaller than those specified in the bearing types covered, the ability of a bearing to resist fatigue is not improved; however, it is diminished by the use of larger radii.

**Ball Bearing Rating Life.**— According to the Anti-Friction Bearing Manufacturers Association standards the Rating Life  $L_{10}$  of a group of apparently identical ball bearings is the life in millions of revolutions that 90 percent of the group will complete or exceed. For a single bearing,  $L_{10}$  also refers to the life associated with 90 percent reliability.

*Radial and Angular Contact Ball Bearings:* The magnitude of the Rating Life  $L_{10}$  in millions of revolutions, for a radial or angular contact ball bearing application is given by the formula:

$$L_{10} = \left( \frac{C}{P} \right)^3 \quad (1)$$

where  $C$  = basic load rating, newtons (pounds). See Formulas (2), (3a) and (3b)

$P$  = equivalent radial load, newtons (pounds). See Formula (4)

<sup>a</sup> A. When calculating the basic load rating for a unit consisting of two similar, single row, radial contact ball bearings, in a duplex mounting, the pair is considered as one, double row, radial contact ball bearing.

B. When calculating the basic load rating for a unit consisting of two, similar, single row, angular contact ball bearings in a duplex mounting, "face-to-face" or "back-to-back," the pair is considered as one, double row, angular contact ball bearing.

C. When calculating the basic load rating for a unit consisting of two or more similar, single angular contact ball bearings mounted "in tandem," properly manufactured and mounted for equal load distribution, the rating of the combination is the number of bearings to the 0.7 power times the rating of a single row ball bearing. If the unit may be treated as a number of individually interchangeable single row bearings, this footnote "C" does not apply.

<sup>b</sup> Use to obtain  $C$  in newtons when  $D$  is given in mm.

<sup>c</sup> Use to obtain  $C$  in pounds when  $D$  is given in inches.

<sup>a</sup> Symbol definitions are given on the following page.

<sup>b</sup> For single row bearings when  $F_d/F_r \leq e$ , use  $X = 1, Y = 0$ . Two similar, single row, angular contact ball bearings mounted face-to-face or back-to-back are considered as one double row, angular contact bearing.

Values of X, Y, and e for a load or contact angle other than shown are obtained by linear interpolation. Values of X, Y, and e do not apply to filling slot bearings for applications in which ball-raceway

contact areas project substantially into the filling slot under load. *Symbol Definitions:*  $F_a$  is the applied axial load in newtons (pounds);  $C_o$  is the static load rating in newtons (pounds) of the bearing under consideration and is found by [Formula \(20\)](#);  $i$  is the number of rows of balls in the bearing;  $Z$  is the number of balls per row in a radial or angular contact bearing or the number of balls in a single row, single direction thrust bearing;  $D$  is the ball diameter in millimeters (inches); and  $F_r$  is the applied radial load in newtons (pounds).

For radial and angular contact ball bearings with balls not larger than 25.4 mm (1 inch) in diameter,  $C$  is found by the formula:

$$C = f_c (i \cos \alpha)^{0.7} Z^{2/3} D^{1.8} \quad (2)$$

and with balls larger than 25.4 mm (1 inch) in diameter  $C$  is found by the formula:

$$C = 3.647 f_c (i \cos \alpha)^{0.7} Z^{2/3} D^{1.4} \quad (\text{metric}) \quad (3a)$$

$$C = f_c (i \cos \alpha)^{0.7} Z^{2/3} D^{1.4} \quad (\text{inch}) \quad (3b)$$

where  $f_c$  = a factor which depends on the geometry of the bearing components, the accuracy to which the various bearing parts are made and the material. Values of  $f_c$ , are given in [Table 27](#)

$i$  = number of rows of balls in the bearing

$\alpha$  = nominal contact angle, degrees

$Z$  = number of balls per row in a radial or angular contact bearing

$D$  = ball diameter, mm (inches)

The magnitude of the equivalent radial load,  $P$ , in newtons (pounds) for radial and angular contact ball bearings, under combined constant radial and constant thrust loads is given by the formula:

$$P = XF_r + YF_a \quad (4)$$

where  $F_r$  = the applied radial load in newtons (pounds)

$F_a$  = the applied axial load in newtons (pounds)

$X$  = radial load factor as given in [Table 30](#)

$Y$  = axial load factor as given in [Table 30](#)

*Thrust Ball Bearings:* The magnitude of the Rating Life  $L_{10}$  in millions of revolutions for a thrust ball bearing application is given by the formula:

$$L_{10} = \left( \frac{C_a}{P_a} \right)^3 \quad (5)$$

where  $C_a$  = the basic load rating, newtons (pounds). See [Formulas \(6\) to \(10\)](#)

$P_a$  = equivalent thrust load, newtons (pounds). See [Formula \(11\)](#)

For single row, single and double direction, thrust ball bearing with balls not larger than 25.4 mm (1 inch) in diameter,  $C_a$  is found by the formulas:

$$\text{for } \alpha = 90 \text{ degrees, } C_a = f_c Z^{2/3} D^{1.8} \quad (6)$$

$$\text{for } \alpha \neq 90 \text{ degrees, } C_a = f_c (\cos \alpha)^{0.7} Z^{2/3} D^{1.8} \tan \alpha \quad (7)$$

and with balls larger than 25.4 mm (1 inch) in diameter,  $C_a$  is found by the formulas:

$$\text{for } \alpha = 90 \text{ degrees, } C_a = 3.647 f_c Z^{2/3} D^{1.4} \quad (\text{metric}) \quad (8a)$$

$$C_a = f_c Z^{2/3} D^{1.4} \quad (\text{inch}) \quad (8b)$$

$$\text{for } \alpha \neq 90 \text{ degrees, } C_a = 3.647 f_c (\cos \alpha)^{0.7} Z^{2/3} D^{1.4} \tan \alpha \quad (\text{metric}) \quad (9a)$$

$$C_a = f_c (\cos \alpha)^{0.7} Z^{2/3} D^{1.4} \tan \alpha \quad (\text{inch}) \quad (9b)$$

where  $f_c$  = a factor which depends on the geometry of the bearing components, the accuracy to which the various bearing parts are made, and the material. Values of  $f_c$  are given in **Table 29**

$Z$  = number of balls per row in a single row, single direction thrust ball bearing

$D$  = ball diameter, mm (inches)

$\alpha$  = nominal contact angle, degrees

**Table 29. Values of  $f_c$  for Thrust Ball Bearings**

<sup>a</sup> Use to obtain  $C_a$  in newtons when  $D$  is given in mm.

<sup>b</sup> Use to obtain  $C_a$  in pounds when  $D$  is given in inches.

For thrust ball bearings with two or more rows of similar balls carrying loads in the same direction, the basic load rating,  $C_a$ , in newtons (pounds) is found by the formula:

$$C_a = (Z_1 + Z_2 + \dots + Z_n) \left[ \left( \frac{Z_1}{C_{a1}} \right)^{10/3} + \left( \frac{Z_2}{C_{a2}} \right)^{10/3} + \dots + \left( \frac{Z_n}{C_{an}} \right)^{10/3} \right]^{-0.3} \quad (10)$$

where  $Z_1, Z_2, \dots, Z_n$  = number of balls in respective rows of a single-direction multi-row thrust ball bearing

$C_{a1}, C_{a2}, \dots, C_{an}$  = basic load rating per row of a single-direction, multi-row thrust ball bearing, each calculated as a single-row bearing with  $Z_1, Z_2, \dots, Z_n$  balls, respectively

The magnitude of the equivalent thrust load,  $P_a$ , in newtons (pounds) for thrust ball bearings with  $\alpha \neq 90$  degrees under combined constant thrust and constant radial loads is found by the formula:

$$P_a = XF_r + YF_a \quad (11)$$

where  $F_r$  = the applied radial load in newtons (pounds)

$F_a$  = the applied axial load in newtons (pounds)

$X$  = radial load factor as given in **Table 30**

$Y$  = axial load factor as given in **Table 30**

**Table 30. Values of X and Y for Computing Equivalent Thrust Load  $P_a$  for Thrust Ball Bearings**

Contact Angle $\alpha$	$e$	Single Direction Bearings		Double Direction Bearings			
		$\frac{F_a}{F_r} > e$		$\frac{F_a}{F_r} \leq e$		$\frac{F_a}{F_r} > e$	
		X	Y	X	Y	X	Y
45°	1.25	0.66	1	1.18	0.59	0.66	1
60°	2.17	0.92	1	1.90	0.54	0.92	1
75°	4.67	1.66	1	3.89	0.52	1.66	1

For  $\alpha = 90^\circ$ ,  $F_r = 0$  and  $Y = 1$ .

**Roller Bearing Types Covered.**— This standard\* applies to *cylindrical, tapered and self-aligning radial and thrust roller bearings* and to *needle roller bearings*. These bearings are presumed to be within the size ranges shown in the AFBMA dimensional standards, of good quality and produced in accordance with good manufacturing practice.

Roller bearings vary considerably in design and execution. Since small differences in relative shape of contacting surfaces may account for distinct differences in load-carrying ability, this standard does not attempt to cover all design variations, rather it applies to basic roller bearing designs.

The following limitations apply:

1) *Truncated contact area.* This standard may not be safely applied to roller bearings subjected to application conditions which cause the contact area of the roller with the raceway to be severely truncated by the edge of the raceway or roller.

2) *Stress concentrations.* A cylindrical, tapered or self-aligning roller bearing must be expected to have a basic load rating less than that obtained using a value of  $f_c$  taken from **Table 31** or **32** if, under load, a stress concentration is present in some part of the roller-raceway contact. Such stress concentrations occur in the center of nominal point contacts, at the contact extremities for line contacts and at inadequately blended junctions of a rolling surface profile. Stress concentrations can also occur if the rollers are not accurately guided such as in bearings without cages and bearings not having rigid integral flanges. Values of  $f_c$  given in **Tables 31** and **32** are based upon bearings manufactured to achieve optimized contact. For no bearing type or execution will the factor  $f_c$  be greater than that obtained in **Tables 31** and **32**.

3) *Material.* This standard applies only to roller bearings fabricated from hardened, good quality steel.

4) *Lubrication.* Rating Life calculated according to this standard is based on the assumption that the bearing is adequately lubricated. Determination of adequate lubrication depends upon the bearing application.

5) *Ring support and alignment.* Rating Life calculated according to this standard assumes that the bearing inner and outer rings are rigidly supported, and that the inner and outer ring axes are properly aligned.

6) *Internal clearance.* Radial roller bearing Rating Life calculated according to this standard is based on the assumption that only a nominal internal clearance occurs in the mounted bearing at operating speed, load, and temperature.

7) *High speed effects.* The Rating Life calculated according to this standard does not account for high speed effects such as roller centrifugal forces and gyroscopic moments: These effects tend to diminish fatigue life. Analytical evaluation of these effects frequently requires the use of high speed digital computation devices and hence, cannot be included.

\* All references to "standard" are to AFBMA and American National Standard "Load Ratings and Fatigue Life for Roller Bearings" ANSI/AFBMA Std 11-1990.

**Roller Bearing Rating Life.**— The Rating Life  $L_{10}$  of a group of apparently identical roller bearings is the life in millions of revolutions that 90 percent of the group will complete or exceed. For a single bearing,  $L_{10}$  also refers to the life associated with 90 percent reliability.

*Radial Roller Bearings:* The magnitude of the Rating Life,  $L_{10}$ , in millions of revolutions, for a radial roller bearing application is given by the formula:

$$L_{10} = \left(\frac{C}{P}\right)^{10/3} \quad (12)$$

where  $C$  = the basic load rating in newtons (pounds), see [Formula \(13\)](#); and,  $P$  = equivalent radial load in newtons (pounds), see [Formula \(14\)](#).

For radial roller bearings,  $C$  is found by the formula:

$$C = f_c(i l_{eff} \cos \alpha)^{7/9} Z^{3/4} D^{29/27} \quad (13)$$

where  $f_c$  = a factor which depends on the geometry of the bearing components, the accuracy to which the various bearing parts are made, and the material. Maximum values of  $f_c$  are given in [Table 31](#)

$i$  = number of rows of rollers in the bearing

$l_{eff}$  = effective length, mm (inches)     $\alpha$  = nominal contact angle, degrees

$Z$  = number of rollers per row in a radial roller bearing

$D$  = roller diameter, mm (inches) (mean diameter for a tapered roller, major diameter for a spherical roller)

When rollers are longer than  $2.5D$ , a reduction in the  $f_c$  value must be anticipated. In this case, the bearing manufacturer may be expected to establish load ratings accordingly.

In applications where rollers operate directly on a shaft surface or a housing surface, such a surface must be equivalent in all respects to the raceway it replaces to achieve the basic load rating of the bearing.

When calculating the basic load rating for a unit consisting of two or more similar single-row bearings mounted "in tandem," properly manufactured and mounted for equal load distribution, the rating of the combination is the number of bearings to the 7/9 power times the rating of a single-row bearing. If, for some technical reason, the unit may be treated as a number of individually interchangeable single-row bearings, this consideration does not apply.

The magnitude of the equivalent radial load,  $P$ , in newtons (pounds), for radial roller bearings, under combined constant radial and constant thrust loads is given by the formula:

$$P = XF_r + YF_a \quad (14)$$

where  $F_r$  = the applied radial load in newtons (pounds)

$F_a$  = the applied axial load in newtons (pounds)

$X$  = radial load factor as given in [Table 33](#)

$Y$  = axial load factor as given in [Table 33](#)

**Table 33. Values of  $X$  and  $Y$  for Computing Equivalent Radial Load  $P$  for Radial Roller Bearing**

Light trucks	1500–2500	Briquette presses	20000–30000
Heavy trucks	2000–2500	Grinding spindles	1000–2000
Buses	2000–5000	Machine tools	10000–30000
Electrical		Mining machinery	4000–15000
Household appliances	1000–2000	Paper machines	50000–80000
Motors $\leq \frac{1}{2}$ hp	1000–2000	Rolling mills	
Motors $\leq 3$ hp	8000–10000	Small cold mills	5000–6000
Motors, medium	10000–15000	Large multipurpose mills	8000–10000
Motors, large	20000–30000	Rail vehicle axle	
Elevator cables sheaves	40000–60000	Mining cars	5000
Mine ventilation fans	40000–50000	Motor rail cars	16000–20000
Propeller thrust bearings	15000–25000	Open-pit mining cars	20000–25000
Propeller shaft bearings	> 80000	Streetcars	20000–25000
Gear drives		Passenger cars	26000
Boat gearing units	3000–5000	Freight cars	35000
Gear drives	> 50000	Locomotive outer bearings	20000–25000
Ship gear drives	20000–30000	Locomotive inner bearings	30000–40000
Machinery for 8 hour service which are not always fully utilized	14000–20000	Machinery for short or intermittent operation where service interruption is of minor importance	4000–8000
Machinery for 8 hour service which are fully utilized	20000–30000	Machinery for intermittent service where reliable operation is of great importance	8000–14000
Machinery for continuous 24 hour service	50000–60000	Instruments and apparatus in frequent use	0–500

Roller bearings are generally designed to achieve optimized contact; however, they usually support loads other than the loading at which optimized contact is maintained. The 10/3 exponent in Rating Life Formulas (12) and (15) was selected to yield satisfactory Rating Life estimates for a broad spectrum from light to heavy loading. When loading exceeds that which develops optimized contact, e.g., loading greater than  $C/4$  to  $C/2$  or  $C_a/4$  to  $C_a/2$ , the user should consult the bearing manufacturer to establish the adequacy of the Rating Life formulas for the particular application.

*Thrust Roller Bearings:* The magnitude of the Rating Life,  $L_{10}$ , in millions of revolutions for a thrust roller bearing application is given by the formula:

$$L_{10} = \left( \frac{C_a}{P_a} \right)^{10/3} \quad (15)$$

where  $C_a$  = basic load rating, newtons (pounds). See Formulas (16) to (18)

$P_a$  = equivalent thrust load, newtons (pounds). See Formula (19)

For single row, single and double direction, thrust roller bearings, the magnitude of the basic load rating,  $C_a$ , in newtons (pounds), is found by the formulas:

$$\text{for } \alpha = 90^\circ, C_a = f_c l_{eff}^{7/9} Z^{3/4} D^{29/27} \quad (16)$$

$$\text{for } \alpha \neq 90^\circ, C_a = f_c (l_{eff} \cos \alpha)^{7/9} Z^{3/4} D^{29/27} \tan \alpha \quad (17)$$

where  $f_c$  = a factor which depends on the geometry of the bearing components, the accuracy to which the various parts are made, and the material. Values of  $f_c$  are given in [Table 32](#)

$l_{eff}$  = effective length, mm (inches)

$Z$  = number of rollers in a single row, single direction, thrust roller bearing

$D$  = roller diameter, mm (inches) (mean diameter for a tapered roller, major diameter for a spherical roller)

$\alpha$  = nominal contact angle, degrees

For thrust roller bearings with two or more rows of rollers carrying loads in the same direction the magnitude of  $C_a$  is found by the formula:

$$C_a = (Z_1 l_{eff1} + Z_2 l_{eff2} + \dots + Z_n l_{effn}) \left\{ \left[ \frac{Z_1 l_{eff1}}{C_{a1}} \right]^{9/2} + \left[ \frac{Z_2 l_{eff2}}{C_{a2}} \right]^{9/2} + \dots + \left[ \frac{Z_n l_{effn}}{C_{an}} \right]^{9/2} \right\}^{-2/9} \quad (18)$$

where  $Z_1, Z_2, \dots, Z_n$  = the number of rollers in respective rows of a single direction, multi-row bearing

$C_{a1}, C_{a2}, \dots, C_{an}$  = the basic load rating per row of a single direction, multi-row, thrust roller bearing, each calculated as a single row bearing with  $Z_1, Z_2, \dots, Z_n$  rollers respectively

$l_{eff1}, l_{eff2}, \dots, l_{effn}$  = effective length, mm (inches), or rollers in the respective rows

In applications where rollers operate directly on a surface supplied by the user, such a surface must be equivalent in all respects to the washer raceway it replaces to achieve the basic load rating of the bearing.

In case the bearing is so designed that several rollers are located on a common axis, these rollers are considered as one roller of a length equal to the total effective length of contact of the several rollers. Rollers as defined above, or portions thereof which contact the same washer-raceway area, belong to one row.

When the ratio of the individual roller effective length to the pitch diameter (at which this roller operates) is too large, a reduction of the  $f_c$  value must be anticipated due to excessive slip in the roller-raceway contact.

When calculating the basic load rating for a unit consisting of two or more similar single row bearings mounted "in tandem," properly manufactured and mounted for equal load distribution, the rating of the combination is defined by [Formula \(18\)](#). If, for some technical reason, the unit may be treated as a number of individually interchangeable single-row bearings, this consideration does not apply.

The magnitude of the equivalent thrust load,  $P_a$ , in pounds, for thrust roller bearings with  $\alpha$  not equal to 90 degrees under combined constant thrust and constant radial loads is given by the formula:

$$P_a = XF_r + YF_a \quad (19)$$

where  $F_r$  = applied radial load, newtons (pounds)

$F_a$  = applied axial load, newtons (pounds)

$X$  = radial load factor as given in [Table 34](#)

$Y$  = axial load factor as given in [Table 34](#)

**Table 34. Values of X and Y for Computing Equivalent Thrust Load  $P_a$  for Thrust Roller Bearings**

Bearing Type	Single Direction Bearings		Double Direction Bearings			
	$\frac{F_a}{F_r} > e$		$\frac{F_a}{F_r} \leq e$		$\frac{F_a}{F_r} > e$

<sup>a</sup>For  $\alpha = 90^\circ$ ,  $F_r = 0$  and  $Y = 1$ .

$$e = 1.5 \tan \alpha$$

**Life Adjustment Factors.**— In certain applications of ball or roller bearings it is desirable to specify life for a reliability other than 90 percent. In other cases the bearings may be fabricated from special bearing steels such as vacuum-degassed and vacuum-melted steels, and improved processing techniques. Finally, application conditions may indicate other than normal lubrication, load distribution, or temperature. For such conditions a series of life adjustment factors may be applied to the fatigue life formula. This is fully explained in AFBMA and American National Standard “Load Ratings and Fatigue Life for Ball Bearings” ANSI/AFBMA Std 9-1990 and AFBMA and American National Standard “Load Ratings and Fatigue Life for Roller Bearings” ANSI/AFBMA Std 11-1990. In addition to consulting these standards it may be advantageous to also obtain information from the bearing manufacturer.

*Life Adjustment Factor for Reliability:* For certain applications, it is desirable to specify life for a reliability greater than 90 percent which is the basis of the Rating Life.

To determine the bearing life of ball or roller bearings for reliability greater than 90 percent, the Rating Life must be adjusted by a factor  $a_1$  such that  $L_n = a_1 L_{10}$ . For a reliability of 95 percent, designated as  $L_5$ , the life adjustment factor  $a_1$  is 0.62; for 96 percent,  $L_4$ ,  $a_1$  is 0.53; for 97 percent,  $L_3$ ,  $a_1$  is 0.44; for 98 percent,  $L_2$ ,  $a_1$  is 0.33; and for 99 percent,  $L_1$ ,  $a_1$  is 0.21.

*Life Adjustment Factor for Material:* For certain types of ball or roller bearings which incorporate improved materials and processing, the Rating Life can be adjusted by a factor  $a_2$  such that  $L_{10}' = a_2 L_{10}$ . Factor  $a_2$  depends upon steel analysis, metallurgical processes, forming methods, heat treatment, and manufacturing methods in general. Ball and roller bearings fabricated from consumable vacuum remelted steels and certain other special analysis steels, have demonstrated extraordinarily long endurance. These steels are of exceptionally high quality, and bearings fabricated from these are usually considered special manufacture. Generally,  $a_2$  values for such steels can be obtained from the bearing manufacturer. However, all of the specified limitations and qualifications for the application of the Rating Life formulas still apply.

*Life Adjustment Factor for Application Condition:* Application conditions which affect ball or roller bearing life include: 1) lubrication; 2) load distribution (including effects of clearance, misalignment, housing and shaft stiffness, type of loading, and thermal gradients); and 3) temperature.

Items 2 and 3 require special analytical and experimental techniques, therefore the user should consult the bearing manufacturer for evaluations and recommendations.

Operating conditions where the factor  $a_3$  might be less than 1 include: a) exceptionally low values of  $Nd_m$  (rpm times pitch diameter, in mm); e.g.  $Nd_m < 10,000$ ; b) lubricant viscosity at less than 70 SSU for ball bearings and 100 SSU for roller bearings at operating temperature; and c) excessively high operating temperatures.

When  $a_3$  is less than 1 it may not be assumed that the deficiency in lubrication can be overcome by using an improved steel. When this factor is applied,  $L_{10}' = a_3 L_{10}$ .

In most ball and roller bearing applications, lubrication is required to separate the rolling surfaces, i.e., rollers and raceways, to reduce the retainer-roller and retainer-land friction and sometimes to act as a coolant to remove heat generated by the bearing.

*Factor Combinations:* A fatigue life formula embodying the foregoing life adjustment factors is  $L_{10}' = a_1 a_2 a_3 L_{10}$ . Indiscriminate application of the life adjustment factors in this formula may lead to serious overestimation of bearing endurance, since fatigue life is only one criterion for bearing selection. Care must be exercised to select bearings which are of sufficient size for the application.

**Ball Bearing Static Load Rating.**— For ball bearings suitably manufactured from hardened alloy steels, the static radial load rating is that uniformly distributed static radial bearing load which produces a maximum contact stress of 4,000 megapascals (580,000 pounds per square inch). In the case of a single row, angular contact ball bearing, the static radial load rating refers to the radial component of that load which causes a purely radial displacement of the bearing rings in relation to each other. The static axial load rating is that uniformly distributed static centric axial load which produces a maximum contact stress of 4,000 megapascals (580,000 pounds per square inch).

*Radial and Angular Contact Groove Ball Bearings:* The magnitude of the static load rating  $C_o$  in newtons (pounds) for radial ball bearings is found by the formula:

$$C_o = f_o i Z D^2 \cos \alpha \quad (20)$$

where  $f_o$  = a factor for different kinds of ball bearings given in **Table 35**

$i$  = number of rows of balls in bearing

$Z$  = number of balls per row

$D$  = ball diameter, mm (inches)

$\alpha$  = nominal contact angle, degrees

This formula applies to bearings with a cross sectional raceway groove radius not larger than  $0.52D$  in radial and angular contact groove ball bearing inner rings and  $0.53D$  in radial and angular contact groove ball bearing outer rings and self-aligning ball bearing inner rings.

The load-carrying ability of a ball bearing is not necessarily increased by the use of a smaller groove radius but is reduced by the use of a larger radius than those indicated above.

*Radial or Angular Contact Ball Bearing Combinations:* The basic static load rating for two similar single row radial or angular contact ball bearings mounted side by side on the same shaft such that they operate as a unit (duplex mounting) in “back-to-back” or “face-to-face” arrangement is two times the rating of one single row bearing.

The basic static radial load rating for two or more single row radial or angular contact ball bearings mounted side by side on the same shaft such that they operate as a unit (duplex or stack mounting) in “tandem” arrangement, properly manufactured and mounted for equal load distribution, is the number of bearings times the rating of one single row bearing.

*Thrust Ball Bearings:* The magnitude of the static load rating  $C_{oa}$  for thrust ball bearings is found by the formula:

$$C_{oa} = f_o Z D^2 \cos \alpha \quad (21)$$

where  $f_o$  = a factor given in **Table 35**

$Z$  = number of balls carrying the load in one direction

$D$  = ball diameter, mm (inches)

$\alpha$  = nominal contact angle, degrees

This formula applies to thrust ball bearings with a cross sectional raceway radius not larger than  $0.54D$ . The load-carrying ability of a bearing is not necessarily increased by use of a smaller radius, but is reduced by use of a larger radius.

**Roller Bearing Static Load Rating:** For roller bearings suitably manufactured from hardened alloy steels, the static radial load rating is that uniformly distributed static radial bearing load which produces a maximum contact stress of 4,000 megapascals (580,000 pounds per square inch) acting at the center of contact of the most heavily loaded rolling element. The static axial load rating is that uniformly distributed static centric axial load which produces a maximum contact stress of 4,000 megapascals (580,000 pounds per square inch) acting at the center of contact of each rolling element.

0.42	7.8	1130	2.6	377	25.7	3720
0.43	7.6	1100	2.6	383	25.1	3640
0.44	7.4	1080	2.7	388	24.6	3560
0.45	7.2	1050	2.7	393	24.0	3480

**Table 35.** (Continued)  $f_o$  for Calculating Static Load Rating for Ball Bearings

$\frac{D \cos \alpha}{d_m}$	Radial and Angular Contact Groove Type		Radial Self-Aligning		Thrust	
	Metric <sup>a</sup>	Inch <sup>b</sup>	Metric <sup>a</sup>	Inch <sup>b</sup>	Metric <sup>a</sup>	Inch <sup>b</sup>
0.46	7.1	1030	2.8	399	23.5	3400
0.47	6.9	1000	2.8	404	22.9	3320
0.48	6.7	977	2.8	410	22.4	3240
0.49	6.6	952	2.9	415	21.8	3160
0.50	6.4	927	2.9	421	21.2	3080

<sup>a</sup> Use to obtain  $C_o$  or  $C_{oa}$  in newtons when  $D$  is given in mm.

<sup>b</sup> Use to obtain  $C_o$  or  $C_{oa}$  in pounds when  $D$  is given in inches.

Note: Based on modulus of elasticity =  $2.07 \times 10^5$  megapascals ( $30 \times 10^6$  pounds per square inch) and Poisson's ratio = 0.3.

*Radial Roller Bearings:* The magnitude of the static load rating  $C_o$  in newtons (pounds) for radial roller bearings is found by the formulas:

$$C_o = 44 \left( 1 - \frac{D \cos \alpha}{d_m} \right) i Z l_{eff} D \cos \alpha \quad (\text{metric}) \quad (22a)$$

$$C_o = 6430 \left( 1 - \frac{D \cos \alpha}{d_m} \right) i Z l_{eff} D \cos \alpha \quad (\text{inch}) \quad (22b)$$

where  $D$  = roller diameter, mm (inches); mean diameter for a tapered roller and major diameter for a spherical roller

$d_m$  = mean pitch diameter of the roller complement, mm (inches)

$i$  = number of rows of rollers in bearing

$Z$  = number of rollers per row

$l_{eff}$  = effective length, mm (inches); overall roller length minus roller chamfers or minus grinding undercuts at the ring where contact is shortest

$\alpha$  = nominal contact angle, degrees

*Radial Roller Bearing Combinations:* The static load rating for two similar single row roller bearings mounted side by side on the same shaft such that they operate as a unit is two times the rating of one single row bearing.

The static radial load rating for two or more similar single row roller bearings mounted side by side on the same shaft such that they operate as a unit (duplex or stack mounting) in "tandem" arrangement, properly manufactured and mounted for equal load distribution, is the number of bearings times the rating of one single row bearing.

*Thrust Roller Bearings:* The magnitude of the static load rating  $C_{oa}$  in newtons (pounds) for thrust roller bearings is found by the formulas:

$$C_{oa} = 220 \left( 1 - \frac{D \cos \alpha}{d_m} \right) Z l_{eff} D \sin \alpha \quad (\text{metric}) \quad (23a)$$

$$C_{oa} = 32150 \left( 1 - \frac{D \cos \alpha}{d_m} \right) Z l_{eff} D \sin \alpha \quad (\text{inch}) \quad (23b)$$

where the symbol definitions are the same as for **Formulas (22a) and (22b)**.

*Thrust Roller Bearing Combination:* The static axial load rating for two or more similar single direction thrust roller bearings mounted side by side on the same shaft such that they operate as a unit (duplex or stack mounting) in "tandem" arrangement, properly manufactured and mounted for equal load distribution, is the number of bearings times the rating of one single direction bearing. The accuracy of this formula decreases in the case of single direction bearings when  $F_r > 0.44 F_a \cot \alpha$ , where  $F_r$  is the applied radial load in newtons (pounds) and  $F_a$  is the applied axial load in newtons (pounds).

**Ball Bearing Static Equivalent Load.**— For ball bearings the static equivalent radial load is that calculated static radial load which produces a maximum contact stress equal in magnitude to the maximum contact stress in the actual condition of loading. The static equivalent axial load is that calculated static centric axial load which produces a maximum contact stress equal in magnitude to the maximum contact stress in the actual condition of loading.

*Radial and Angular Contact Ball Bearings:* The magnitude of the static equivalent radial load  $P_o$  in newtons (pounds) for radial and angular contact ball bearings under combined thrust and radial loads is the greater of:

$$P_o = X_o F_r + Y_o F_a \quad (24)$$

$$P_o = F_r \quad (25)$$

where  $X_o$  = radial load factor given in **Table 36**

$Y_o$  = axial load factor given in **Table 36**

$F_r$  = applied radial load, newtons (pounds)

$F_a$  = applied axial load, newtons (pounds)

**Table 36. Values of  $X_o$  and  $Y_o$  for Computing Static Equivalent Radial Load  $P_o$  of Ball Bearings**

Contact Angle	Single Row Bearings <sup>a</sup>		Double Row Bearings	
	$X_o$	$Y_o$ <sup>b</sup>	$X_o$	$Y_o$ <sup>b</sup>
RADIAL CONTACT GROOVE BEARINGS <sup>c,a</sup>				
$\alpha = 0^\circ$	0.6	0.5	0.6	0.5
ANGULAR CONTACT GROOVE BEARINGS				
$\alpha = 15^\circ$	0.5	0.47	1	0.94
$\alpha = 20^\circ$	0.5	0.42	1	0.84
$\alpha = 25^\circ$	0.5	0.38	1	0.76
$\alpha = 30^\circ$	0.5	0.33	1	0.66
$\alpha = 35^\circ$	0.5	0.29	1	0.58
$\alpha = 40^\circ$	0.5	0.26	1	0.52
SELF-ALIGNING BEARINGS				
...	0.5	$0.22 \cot \alpha$	1	$0.44 \cot \alpha$

<sup>a</sup>  $P_o$  is always  $\geq F_r$ .

<sup>b</sup> Values of  $Y_o$  for intermediate contact angles are obtained by linear interpolation.

<sup>c</sup> Permissible maximum value of  $F_a/C_o$  (where  $F_a$  is applied axial load and  $C_o$  is static radial load rating) depends on the bearing design (groove depth and internal clearance).

*Thrust Ball Bearings:* The magnitude of the static equivalent axial load  $P_{oa}$  in newtons (pounds) for thrust ball bearings with contact angle  $\alpha \neq 90^\circ$  under combined radial and thrust loads is found by the formula:

$$P_{oa} = F_a + 2.3 F_r \tan \alpha \quad (26)$$

where the symbol definitions are the same as for **Formulas (24) and (25)**. This formula is valid for all load directions in the case of double direction ball bearings. For single direction ball bearings, it is valid where  $F_r/F_a \leq 0.44 \cot \alpha$  and gives a satisfactory but less conservative value of  $P_{oa}$  for  $F_r/F_a$  up to  $0.67 \cot \alpha$ .

Thrust ball bearings with  $\alpha = 90^\circ$  can support axial loads only. The static equivalent load for this type of bearing is  $P_{oa} = F_a$ .

**Roller Bearing Static Equivalent Load.**— The static equivalent radial load for roller bearings is that calculated, static radial load which produces a maximum contact stress acting at the center of contact of a uniformly loaded rolling element equal in magnitude to the maximum contact stress in the actual condition of loading. The static equivalent axial load is that calculated, static centric axial load which produces a maximum contact stress acting

at the center of contact of a uniformly loaded rolling element equal in magnitude to the maximum contact stress in the actual condition of loading.

*Radial Roller Bearings:* The magnitude of the static equivalent radial load  $P_o$  in newtons (pounds) for radial roller bearings under combined radial and thrust loads is the greater of:

$$P_o = X_o F_r + Y_o F_a \quad (27)$$

$$P_o = F_r \quad (28)$$

where  $X_o$  = radial factor given in **Table 37**

$Y_o$  = axial factor given in **Table 37**

$F_r$  = applied radial load, newtons (pounds)

$F_a$  = applied axial load, newtons (pounds)

**Table 37. Values of  $X_o$  and  $Y_o$  for Computing Static Equivalent Radial Load  $P_o$  for Self-Aligning and Tapered Roller Bearings**

Bearing Type	Single Row <sup>a</sup>		Double Row	
	$X_o$	$Y_o$	$X_o$	$Y_o$
Self-Aligning and Tapered $\alpha \neq 0$	0.5	$0.22 \cot \alpha$	1	$0.44 \cot \alpha$

<sup>a</sup>  $P_o$  is always  $\geq F_r$ .

The static equivalent radial load for radial roller bearings with  $\alpha = 0^\circ$  and subjected to radial load only is  $P_{or} = F_r$ .

Note: The ability of radial roller bearings with  $\alpha = 0^\circ$  to support axial loads varies considerably with bearing design and execution. The bearing user should therefore consult the bearing manufacturer for recommendations regarding the evaluation of equivalent load in cases where bearings with  $\alpha = 0^\circ$  are subjected to axial load.

*Radial Roller Bearing Combinations:* When calculating the static equivalent radial load for two similar single row angular contact roller bearings mounted side by side on the same shaft such that they operate as a unit (duplex mounting) in “back-to-back” or “face-to-face” arrangement, use the  $X_o$  and  $Y_o$  values for a double row bearing and the  $F_r$  and  $F_a$  values for the total loads on the arrangement.

When calculating the static equivalent radial load for two or more similar single row angular contact roller bearings mounted side by side on the same shaft such that they operate as a unit (duplex or stack mounting) in “tandem” arrangement, use the  $X_o$  and  $Y_o$  values for a single row bearing and the  $F_r$  and  $F_a$  values for the total loads on the arrangement.

*Thrust Roller Bearings:* The magnitude of the static equivalent axial load  $P_{oa}$  in newtons (pounds) for thrust roller bearings with contact angle  $\alpha \neq 90^\circ$ , under combined radial and thrust loads is found by the formula:

$$P_{oa} = F_a + 2.3 F_r \tan \alpha \quad (29)$$

where  $F_a$  = applied axial load, newtons (pounds)

$F_r$  = applied radial load, newtons (pounds)

$\alpha$  = nominal contact angle, degrees

The accuracy of this formula decreases for single direction thrust roller bearings when  $F_r > 0.44 F_a \cot \alpha$ .

*Thrust Roller Bearing Combinations:* When calculating the static equivalent axial load for two or more thrust roller bearings mounted side by side on the same shaft such that they operate as a unit (duplex or stack mounting) in “tandem” arrangement, use the  $F_r$  and  $F_a$  values for the total loads acting on the arrangement.

## LUBRICATION

### Lubrication Theory

Whenever a solid surface moves over another, it must overcome a resistive, opposing force known as *solid friction*. The first stage of solid friction, known as *static friction*, is the frictional resistance that must be overcome to initiate movement of a body at rest. The second stage of frictional resistance, known as *kinetic friction*, is the resistive force of a body in motion as it slides or rolls over another solid body. It is usually smaller in magnitude than static friction. Although friction varies according to applied load and solid surface roughness, it is unaffected by speed of motion and apparent contact surface area.

When viewed under a microscope a solid surface will appear rough with many *asperities* (peaks and valleys). When two solid surfaces interact without a lubricating medium, full metal-to-metal contact takes place in which the asperity peaks of one solid interfere with asperity peaks of the other solid. When any movement is initiated the asperities collide causing a rapid increase in heat and the metal peaks to adhere and weld to one another. If the force of motion is great enough the peaks will plow through each other's surface and the welded areas will shear causing surface degradation, or wear. In extreme cases, the resistance of the welded solid surfaces could be greater than the motive force causing mechanical seizure to take place.

Some mechanical systems designs, such as brakes, are designed to take advantage of friction. For other systems, such as bearings, this metal-to-metal contact state and level of wear is usually undesirable. To combat this level of solid friction, heat, wear, and consumed power, a suitable lubricating fluid or fluid film must be introduced as an intermediary between the two solid surfaces. Although lubricants themselves are not frictionless, the molecular resistive force of a gas or fluid in motion known as *fluid friction* is significantly less than *solid friction*. The level of fluid friction is dependent on the lubricant's *viscosity* (see page 2441.)

**Film Thickness Ratio,  $\lambda$ .**— For all bearings, the working lubricant film thickness has a direct relationship to bearing life. The “working” or specific film thickness ratio  $\lambda$  is defined by dividing the nominal film thickness by the surface roughness, as depicted in Fig. 1.

$$\lambda = \frac{T}{R} \quad (1)$$

where  $\lambda$  = specific film thickness  
 $T$  = nominal film thickness  
 $R$  = surface roughness

Fig. 1. Determining the Working Film Thickness Ratio Lambda

**The Lubrication Film.**— Whenever a plain journal style bearing operates with a fluid film, the coefficient of friction  $\mu$  or extent of friction reduction will depend on which one of three lubricant film conditions exists between the facing surfaces.

**Full Film Hydrodynamic Lubrication (HDL):** HDL is the desired lubrication condition for plain style bearings in which both surfaces are fully separated by a working or specific film thickness  $\lambda$ ,  $\lambda$  of more than 2 at the point of pressure distribution loading shown in Fig. 2. A fluid wedge is created in which the asperities will not collide. Both surfaces are said to be “metal-contact” free at all times.

Fig. 2. HDL Hydrodynamic Lubrication of a Journal Bearing

As the shaft speed accelerates, rotation of the journal acts as a pump, forcing lubricant into the pressure distribution area. Providing the lubricant is of a high enough viscosity, the wedge-shaped lubricant channel will create a load-carrying pressure sufficient to completely separate the two surfaces and support the moving journal. Full film thickness will vary between 5 and 200 microns depending on speed, load, and viscosity. As the speed increases so does the lubricating action and ability to carry heavier loads. Inversely, slow speeds do not allow the lubricant wedge to form, causing breakdown of the hydrodynamic action and an undesirable *Boundary Layer Lubrication* state to prevail.

**Boundary Layer Lubrication (BL):** When a journal shaft is at rest in the bearing, any full film lubricant wedge has collapsed leaving a residual film of lubricant in its place, insufficient to prevent metal-to-metal contact from occurring. Upon subsequent start up, the bearing surfaces partially collide and ride on the thin lubricant film (start up conditions promote heavy wear). When lubricant supply is inadequate, or heavy loads coupled with low shaft speeds is the only design possible, the boundary layer lubrication must rely heavily on the composition of the lubricant to provide specific anti-wear and extreme pressure sacrificial additives, designed to retard premature wear. These surface-active additives act to form a thin surface laminate that prevents metal adhesion. Boundary layer lubrication also occurs when a lubricant of too low a viscosity is chosen.

**Mixed Film Lubrication (MF):** Mixed film lubrication state is generally encountered under shock load conditions when a minimum thickness hydrodynamic film momentarily breaks down or “thins out” into a boundary layer condition under severe shock load. Mixed film condition is also encountered as a shaft accelerates toward full speed and the film thickness transforms from boundary to full hydrodynamic condition. Choosing too light a viscosity lubricant can lead to momentary or full time mixed film condition. Mixed film condition is encountered when the specific film thickness  $\lambda$  is between 1 and 2.

**Lubricating Film Transition:** Boundary layer condition is encountered when the specific film thickness  $\lambda$  ratio is less than 1, mixed-film when the  $\lambda$  ratio is between 1 and 2, and hydrodynamic when the  $\lambda$  ratio is more than 2. Once the  $\lambda$  ratio surpasses 4, relative bearing life is increased four-fold as depicted in Fig. 3.

Lambda $\lambda < 1$	$1 < \text{Lambda } \lambda < 2$	$2 < \text{Lambda } \lambda < 4$
Boundary Layer Film Lubrication	Mixed Film Lubrication	Hydrodynamic Lubrication

## LUBRICATING FILMS

Fig. 3. The Relationship between Film Thickness Ratio Lambda  $\lambda$  and Bearing Life

To achieve long life while supporting heavy loads, a plain bearing must successfully manage the relationship between load, speed, and lubricant viscosity. If the load and speed change, the lubricant viscosity must be able to compensate for the change. This relationship is shown in the Stribeck or ZNP curve illustrated in Fig. 4. Choosing the correct lubricant viscosity allows the bearing to run in the favored hydrodynamic range producing a low coefficient of friction ranging from 0.002 to 0.005.

Fig. 4. Stribeck (ZNP) Curve

Rolling element bearings (point contact) and the rolling section of mating gear teeth (line contact) also favor full hydrodynamic lubrication film. They differ from sliding elements in that rolling elements require considerably less lubrication than their sliding counterparts and that the load is concentrated over a much smaller footprint on a non-conforming surface—small diameter ball or roller “rolling” over or within a much larger diameter raceway. As the ball or roller “rolls” through the load zone, the point of contact experiences a rapid pressure rise causing momentary micro distortion of both the rolling element and race. This area of deformation is named the *Hertzian Contact Area* (Fig. 5) and is analogous to the contact patch of a properly inflated tire on a moving vehicle. As the loaded section of rolling element moves out of the Hertzian contact area the deformed surface elastically returns to its original shape. The lubricant trapped in the Hertzian contact area benefits greatly from a phenomenon in which a lubricant under pressure will experience a dramatic rise in viscosity and act as a solid lubricant, allowing small amounts of lubricant to provide full film separation under extreme loading conditions. Under these conditions the hydrodynamic film is termed *elastohydrodynamic lubrication* (EHD), and is unique to point/line contact situations typically found with rolling element bearings and mating gear teeth.

Fig. 5. Hertzian Contact Area Found in Rolling Element Bearing Surfaces

The wheels of industry run literally on a microfilm of lubricant; practical examples of typical oil film thicknesses expressed in machine dynamic clearance are stated in the following [Table 1](#).

**Table 1. Typical Oil Film Thicknesses Expressed as Machine Dynamic Clearances**

Machine Component	Typical Clearance in Microns
Plain Journal Bearings	0.5–100
Rolling Element Bearings	0.1–3
Gears	0.1–1
Hydraulic Spool To Sleeve	1–4
Engine Piston Ring to Cylinder	0.3–7
Engine Rod Bearing (Plain)	0.5–20
Engine Main Bearing (Plain)	0.5–80
Pump Piston to Bore	5–40

1 micron = 0.00003937 inch; 25.4 microns = 0.001 inch.

### Lubricants

A lubricant’s primary function is to reduce friction; in doing so it reduces wear and energy consumption. Secondary functions are to reduce temperature, impact shock, corrosion, and contamination.

A lubricant can be in liquid (oil), solid (grease), or gaseous (oil mist) form and can be formulated from animal, vegetable, hydrocarbon, or synthetic base oil stocks. Adding to each lubricant formulation numerous chemical thickeners, solids, and chemical additives, gives every single manufactured lubricant its own unique signature blend. Selection of lubricant style and type is arguably the most influential factor in assuring long bearing life.

In the 1970's, Dr. Ernest Rabinowicz of MIT performed a landmark study on the effects of lubrication on the Gross National Product (GNP) of the United States. The study concluded that at that time, US manufacturing companies spent over \$600 billion US annually to repair damage caused by friction-induced mechanical wear; more importantly, the study determined that over 70% of bearing loss of usefulness (failure) is directly attributable to surface degradation, a totally preventable condition. In his study, Rabinowicz determined there are four major contributors to surface degradation:

*Corrosive Wear:* All metallic-bearing surfaces will corrode if left unprotected from contact with water and corrosive acids. Water is introduced into lubricated environments from outside sources penetrating the sealed reservoir or bearing (washout, product contamination), or through condensation, causing ferrous metals to rust. Corrosive acids are produced when the lubricant becomes oxidized and suffers loss or breakdown of its corrosion inhibitor additive packages. Specifying and using a lubricant with rust inhibitors and corrosion-inhibitor additives, and replacing the lubricant in a timely manner when additives are depleted from the oil, will prevent corrosion.

*Mechanical Wear by Adhesion:* Adhesive wear occurs when a lubricant film separating two sliding surfaces fails to completely separate the two surfaces. Metal to metal contact occurs causing metal fragment transfer from one surface to the other. This transfer is commonly referred to as seizing, galling, scuffing, or scoring of surfaces. Correct lubricant viscosity and application frequency will significantly reduce or eliminate adhesive wear.

*Mechanical Wear by Abrasion:* Abrasive wear, sometimes referred to as *cutting wear*, is the result of hard particles (wear particles or introduced contaminant particles) bridging two moving surfaces, scraping and cutting either one surface (two body abrasion) or both bearing surfaces (three body abrasion). Controlling abrasive wear requires reduction of adhesive wear combined with contamination control of lubricant transfer, application, and filtration processes.

*Mechanical Wear by Fatigue:* Fatigue wear results when bridged wear particles cause small surface stress raisers (surface rippling) that eventually expand and break away from the parent metal as a spall (flake or splinter). Repeated cyclic stress at the damaged area accelerates the fatigue wear process. Correct lubricant viscosity choice and contamination control are essential to retard fatigue wear.

In all four types of wear, the primary solution for wear retardation lies in the correct choice of lubricant. Lubricants are categorized into two specific families—oil, and grease. The choice to use either oil or grease will depend upon temperature range, speed of rotation, environment, budget, machine design, bearing and seal design, which operating conditions.

**Lubricating Oil.**—For the majority of industrial applications requiring the separation of moving surfaces, the lubricant of choice continues to be petroleum based oil, also widely known as mineral oil. Although any liquid will provide a degree of lubrication, hydrocarbon-based petroleum oils provide excellent surface wetting capabilities, water resistance, thermal stability, and sufficient fluid viscosity or “stiffness” to provide full film protection under load - all at an inexpensive price. By adding chemicals, metals, solids, and fillers, mineral base oil stock can be formulated into an infinite number of tailored lubricating products, including grease. These modified mineral oils can be formulated for virtually any industrial application and widen the lubricant's specification and capabilities even further. The fundamental defining property for all lubricating oils is *viscosity*, and is the starting point for choosing one specific lubricant over another.

**Viscosity:** The viscosity of a fluid is measured as its resistance to flow and shear; resistance caused by fluid friction is set up along the molecular shear planes of the lubricant as depicted in Fig. 6. Thin or light lubricants, such as machine and spindle oils shear at a faster rate than thick lubricants such as gear oils, and are said to be less viscous. Although lower viscosity oil is desirable for reducing energy (less drag), it likely would not be “stiff” or viscous enough to withstand the demands of a heavily loaded gearbox.

Fig. 6. Viscosity Shear Planes

**Kinematic Viscosity:** Oil viscosity is measured by a variety of classifications. The two generally accepted industrial standards are: Saybolt Universal Seconds or SUS (imperial measure), and ISO VG-Centistokes-cSt (metric measure). These two standards rate oil by their *kinematic viscosity* values. The ratings, based on a fluid temperature of 100 °F (40 °C) and 212 °F (100 °C), relate the time taken for a fluid to flow through a viscosimeter capillary apparatus and directly measure oil's resistance to flow and shear by the forces of gravity. Other common viscosity classifications and comparison equivalents are shown in Table 2.

$$cSt = \frac{g/cc}{\eta(cP)} \text{ at } 60 \text{ } ^\circ\text{F} \quad (2)$$

where  $h$  = absolute or dynamic viscosity in centipoise

$g/cc$  = lubricant density (specific gravity)

$cSt$  = kinematic viscosity in centistokes

To convert cSt to SUS at 100 °F (40 °C), multiply by 4.632

To convert cSt to SUS at 210 °F (100 °C), multiply by 4.664

**Absolute Viscosity:** The *absolute* or *dynamic* viscosity is measured in poise (metric) or centipoise (cP) and reyn (imperial), where one reyn is equivalent to 68,950 poise. One-poise is equivalent to a one-dyne force required to move a plane surface (shear plane) of unit area a distance of one centimeter with unit speed (one centimeter per second) over a second plane at a unit distance (one centimeter) from it. *Absolute viscosity* is calculated by multiplying the kinematic viscosity value by the density of the lubricant measured at the test temperature, and is the measure of oil's resistance to flow and shear caused by internal friction. Absolute viscosity is the viscosity measured through oil analysis.

$$\eta(cP) = g/cc \text{ at } 60 \text{ } ^\circ\text{F} \times cSt \quad (3)$$

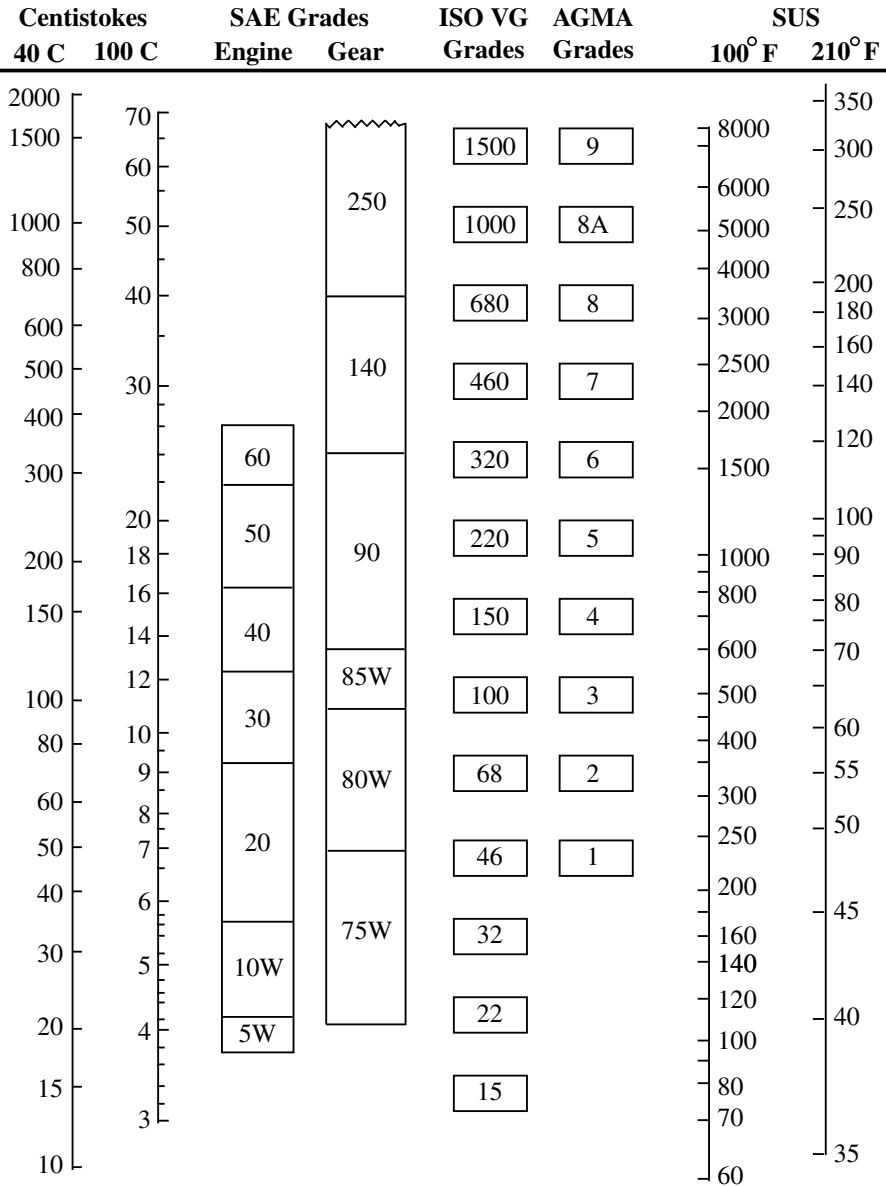

where  $h$  = absolute or dynamic viscosity in centipoise

$g/cc$  = lubricant density (specific gravity)

$cSt$  = kinematic viscosity in centistokes

VISCOSITY

Table 2. Viscosity Comparison Chart

Viscosities based on 95VI single grades relate horizontally. SAE - Society of Automotive Engineers (Automotive lubricants)  
 SAE grades specified at 100 °C. AGMA - American Gear Manufacturers Assn. (Gear lubricants)  
 SAE W grades are also specified at low temperatures. ISO - International Standards Organization  
 ISO and AGMA Grades specified at 40 °C. SUS - Saybolt Universal Seconds

**Viscosity Index (VI):** Viscosity is dependent on temperature. As oil heats up it becomes thinner or less viscous. Inversely, as oil cools down it becomes thicker or more viscous. This phenomenon dictates that all oils will change their physical properties once they have achieved their working environment temperature. Therefore, before a lubricant viscosity choice can be made, its expected working environment temperature must be known. To engineer for this phenomenon, oil is given a *Viscosity Index*, or *VI* rating, which defines the measure of a lubricant's viscosity change due to temperature change. Higher VI ratings are more desirable, reflecting narrower viscosity change over a standard temperature range.

To determine a specific oil's VI rating, its kinematic viscosity is measured at 100 °F (40 °C) and 212 °F (100 °C), then its results are compared with two or more series of oils. VI values once ranged between 0 and 100, but recent developments in lubricant technology and additives have allowed this index to raise its upper limit and include a Very High Viscosity Index (VHVI) group. Lubricants are generally classified in four basic VI groups depicted in [Table 3](#).

**Table 3. Viscosity Index Rating**

VI rating	Viscosity Index Group
< 35	Low (LVI)
35 - 80	Medium (MVI)
80 - 110	High (HVI)
> 110	Very High (VHVI)

**Composition of Oil.**— Oil is composed of either a mineral (hydrocarbon based) or synthetic oil base stock to which is added a variety of organic and inorganic compounds that are dissolved or suspended as solids in the formulated oil. Depending on the end use condition the oil formulation is designed for, the additive package can represent between 1% up to 30% of the formulated oil volume.

**Mineral Based Oil.**— Mineral oils are refined from crude oil stocks. Depending on where the crude stock is found in the world, the oil can be paraffinic or naphthenic based.

*Paraffinic* based stocks are generally found in the midcontinental United States, England's North Sea, and the Middle East. They contain a 60/30/10 mix of paraffin/naphthene/wax resulting in a very high VI rating up to 105. Because wax is present, they are known to have a *wax pour point* in which the oil's flow is severely constricted or stopped by wax crystallization at lower temperatures. This type of base oil stock is preferred when blending high quality crankcase oils, hydraulic fluids, turbine oils, gear oils, and bearing oils.

*Naphthenic* based oil stocks are generally found in South America and the coastal regions of the USA. They contain a 25/75/trace mix of paraffin/naphthene/wax, resulting in a less stable VI rating up to 70. Because only a trace of wax is present they are known as *viscosity pour point oils* in which oil flow is restricted by increases in the lubricant's viscosity at low temperatures. Naphthenic oils have lower pour points, higher flash points, and better additive solvency than paraffinic oils. This type of base stock is preferred when blending locomotive oils, refrigerant, and compressor oils.

**Oil Additives.**— When contact is likely between two bearing surfaces the lubricant should be designed to mitigate the friction through the addition of engineered additives to the base oil. Every manufactured lubricant on the market has its own unique formulation. In effect, it is an engineered liquid, custom built to perform a specific a job in a specific environment. All additives are sacrificial and therefore careful attention to additive package levels through the use of oil analysis will tell the user exactly when to change the oil to prevent damage to the bearing or contact parts. Typically oil additives as shown in [Table 4](#) are used to enhance the existing base oil, add additional properties to the oil, and suppress any undesirable properties the base oil may have.

**Table 4. Oil Additives**

Enhancement Additives	New Property Additives	Suppressant Additives
Anti-oxidant	EP	
Corrosion inhibitor	Anti-wear	Pour point depressant
Demulsifier	Detergent	Viscosity improver
Anti-foam	Dispersant	

The additive package formulation will depend on the end use. [Table 5](#) references what oil type generally carries what additive package in its formulation.

**Table 5. Additive Package by Oil Type Guide**

Additive	Bear- ing Oil	Gear Oil	Turbine Oil	Hydraulic Oil	Compres- sor Oil	Crankcase Oil	Grease
Anti-oxidant	●	●	●	●	●	●	●
Corrosion Inhibitor	●	●	●	●	●	●	●
Demulsifier	●	●	●	●	●		
Anti-foam	●	●	●	●	●	●	
Extreme Pressure EP		●					●
Anti-wear	●	●		●	●	●	●
Detergent					●	●	
Dispersant					●	●	
Pour Point		● some		● some	● some	● some	
Viscosity Improver						●	

*Anti-oxidants:* Oxygen attacks the base oil, especially at higher temperatures, leading to the formation of sludge, tars, varnish, and corrosive acids. Anti-oxidant additives can improve the oxidation stability of the oil by more than 10 times; lubricants designed for higher operating temperatures will contain higher levels of antioxidants.

*Corrosion Inhibitor or Antirust Agents :* Used to form a protective shield against water on ferrous metals, and copper, tin, and lead-based bearing metals. They also act to neutralize any corrosive acids that may attack the bearing materials.

*Demulsifying Agents:* Stop water from emulsifying with the oil.

*Antifoaming Agents:* When oil is moved quickly, these agents, usually silicon-based compounds, act to retard the formation of air bubbles at the lubricant's surface; air bubbles contain oxygen that will attack the base oil and cause cavitation in pumps.

*Extreme Pressure (EP) Additives:* Additives such as sulphur, phosphorous, and chlorine are employed to "soften" bearing surfaces, allowing them to break away as small asperities without adhesive "tearing" when metal-to-metal contact is unavoidable. These additives can be detrimental to yellow metal bearing material.

*Anti-wear Agents:* Solids such as molybdenum disulphide (moly), graphite, and PTFE, are employed to assist as additional sliding agents when metal-to-metal contact occurs under heavy loads. See [Table 6](#).

*Detergents* are organic metallic soaps of barium, calcium, and magnesium, acting as chemical cleaners to keep surfaces free from deposits and neutralize harmful combustion acids.

*Dispersants* work in conjunction with detergents to chemically suspend the dirt particles in the oil and allow them to be extracted by the lubrication system filters.

*Pour Point Depressants* prevent the formation of wax crystals in paraffinic-based mineral oil at low temperatures allowing it to be more fluid at colder temperatures.

*Viscosity Improvers :* Sometimes a base oil of inferior quality will require thickeners to assist in achieving the specified viscosity levels over a varied temperature range. Viscosity improvers are also used to prevent the oil from thinning at higher temperatures allowing the manufacturer to build multi-grade lubricants that operate over wider temperature ranges. Viscosity improvers use long chain organic molecules such as polymethacrylates and ethylene propylene copolymers to retard the viscosity shearing and improve an oil's viscosity performance.

**Table 6. Properties of Common Lubricant Solids Additives**

Solid Additive	Color	Load Capability	Thermal Stability	Average Particle Size	Moisture Sensitivity
Molybdenum Disulphide	Grey-Black	> 100,000 (psi)	< 750° F	< 1 - 6 micron	Detrimental
Graphite	Grey-Black	< 50,000 (psi)	< 1200° F	2 - 10 micron	Necessary
Polytetrafluoroethylene PTFE	White	< 6,000 (psi)	< 500° F	< 1 micron	No Effect

1 micron = 0.00003937 inch; 1 psi = 6.8947 kPa; Temp. in °C = (°F - 32)/1.8

Solids additives shown in **Table 6**, can be added to both mineral and synthetic base oil stocks. In certain high temperature and high-pressure conditions, solids can be mixed with a mineral spirits carrier and applied directly to the bearing surfaces as a dry solid lubricant. The volatile carrier flashes off with the heat and leaves a dry solid film on the bearing surface.

**Synthetic Based Oils.**— Originally developed to cope with extreme high temperature situations encountered in early jet engines, synthetic based oil differs from mineral based oil in that its base stock is man-made. Using a polymerization similar to that used in plastics manufacturing, synthetic based oils are scientifically designed with identifiable molecular structures, resulting in fluids with highly predictable properties.

Synthetic lubricants deliver many advantages; their stability under severe high and low temperature operating conditions enables equipment to operate in extreme conditions with a high degree of reliability. Although there are many different synthetic base stocks, industry is primarily served by the following five common synthetic lubricant types.

*Poly-Alph-Olefins (PAOs):* PAOs, **Table 7**, are often described as man-made mineral oils (synthesized hydrocarbons) and were amongst the first developed synthetic lubricants for popular use in automotive crankcase oils. They are formulated in a similar molecular structure to that of pure paraffin through the synthesis of ethylene gas molecules into a polymerized uniform structure. They have a wide range of uses that include crankcase oil, gear oil, compressor oil, and turbine oils.

**Table 7. Poly-Alph-Olefins (PAOs)**

Positive Features	Negative Features
Low pour point (down to -90 °F or -68 °C)	Cost (4-8 × mineral oil cost) Poor additive solubility Poor biodegradability
High viscosity index, VI > 140	
High viscosity range	
Good mineral oil compatibility	
Good seal compatibility	
Excellent corrosion stability	

*Poly-alkylene Glycols (PAGs):* PAGs, **Table 8**, are also known as organic chemical Ucon fluids that possess excellent lubricity and a unique property that causes decomposed or oxidized products to volatilize (clean burn) or become soluble, resulting in no sludge, varnish, or damaging particles to be formed at high temperatures. PAG's are polymers of alkylene oxides and are used for compressor oils, hydraulic oils (water glycols), and severe duty gear oils.

**Table 8. Polyalkylene Glycols (PAGs)**

Positive Features	Negative Features
Low pour point (to $-60^{\circ}\text{F}$ or $-51^{\circ}\text{C}$ ) High viscosity index, VI > 150 High viscosity range Fair seal compatibility Excellent biodegradability Do not produce sludge or varnish	Cost (4 - 8 $\times$ mineral oil cost) Poor mineral oil compatibility Poor PAO and synthetic ester based oil compatibility

*Di-Basic Acid Esters (Di-Esters):* Due to their high shear VI stability under extreme temperature, di-esters, **Table 9**, have become very popular in the aerospace industry. Formulated from the reaction between alcohol and acid-laden oxygen, di-esters originally saw primary use in jet engine oils, but are now used mainly in high temperature compressor oils.

**Table 9. Di-Basic Acid Esters (Di-esters)**

Positive Features	Negative Features
Low pour point (to $-80^{\circ}\text{F}$ or $-62^{\circ}\text{C}$ ) High viscosity index, VI > 150 High viscosity range Good mineral oil compatibility Good additive solvency	Cost (4 - 8 $\times$ mineral oil cost) Poor hydrolytic stability Poor seal compatibility Fair mineral oil compatibility Poor corrosion stability

*Polyol-Esters:* Due to their increased thermal stability over di-esters, polyol-esters, **Table 10**, have now taken over as the preferred oils for gas turbines, jet engines, and 2-cycle oil applications.

**Table 10. Polyol-Esters**

Positive Features	Negative Features
Low pour point (to $-95^{\circ}\text{F}$ or $-71^{\circ}\text{C}$ ) High viscosity index, VI > 160 High viscosity range Good oxidation stability Good mineral oil compatibility Good anti-wear properties Good additive solvency	Cost (10 - 15 $\times$ mineral oil cost) Poor hydrolytic stability Poor seal compatibility Fair mineral oil compatibility Poor corrosion stability

*Silicones:* Silicone lubricants, **Table 11**, are semi-inorganic compounds formulated to provide the stability of inorganic products, yet retain the versatility of organic products. Although they have poor lubricity, silicone lubricants find favor in lightly loaded instrument bearings and oils and situations requiring high temperature change and compatibility with plastics. Additives are added to the base stocks to enhance lubricant performance, just as with mineral oils.

**Table 11. Silicone**

Positive Features	Negative Features
Low pour point (to $-95^{\circ}\text{F}$ or $-71^{\circ}\text{C}$ ) High viscosity index, VI > 250 Very high Viscosity range Very high flash point Good seal compatibility	High Cost (30 - 100 $\times$ mineral oil cost) Poor lubricity Poor seal compatibility Poor mineral oil compatibility Poor biodegradability Poor additive solvency

**Temperature Effects on Oil .—** Changes in temperature effect an oil's viscosity and its ability to maintain a load carrying hydrodynamic film as depicted in **Fig. 7**. With the exception of silicone-based fluids, which unfortunately have poor lubricating qualities, most oils suffer a dramatic drop in viscosity once the temperature surpasses  $100^{\circ}\text{F}$  ( $38^{\circ}\text{C}$ ).

Fig. 7. Temperature Effect on Viscosity for Different Oils

Temperature affects not only the viscosity of the oil, it affects the condition and life expectancy of the oil as shown in Fig. 8. For every 17° F (10° C) increase in temperature, oxidation rates double and effective oil life is halved. Operating temperature is the leading indicator in determining oil change out frequencies

Fig. 8. Expected Oil Life at Varying Operating Temperatures.

*Oxidation* is the leading cause of lubricant failure. Fig. 9 shows typical upper and lower working limits for various lubricating oils.

**Lubricating Grease.**— In situations where the containment and continued application of lubricating oil is not practical, lubricating grease is widely used - most specifically in rolling element bearings requiring only periodic lubrication, and slow-speed, high-load boundary lubrication applications. Easier to retain than oil, grease offers lower lubricant losses and good sealing qualities. When utilized in an automatic delivery system, grease can provide full film lubrication.

Grease is a blended mix of the lubricating oil (mineral or synthetic—usually di-ester or silicone based), oil additive package, and fatty acids mixed with metallic alkaline soap to

Fig. 9. Temperature Limit Guidelines for Oil.

form the thickening agent. Varying the oil, additive package, and soap blend produces many unique types of grease formulated for a variety of operating conditions. Greases are classified according to their soap base as depicted in Table 12.

Grease works in a similar way to a sponge; as the temperature of the grease rises, the oil bleeds from the soap filler and performs the lubricating function to the balls, raceways, and sliding surfaces. Inversely, once the grease cools down, the oil is soaked back up into the soap filler, which essentially acts as a semi-fluid container for the lubricating oil. An important step in selecting the correct grease is determining if the base oil viscosity is suitable for the application. For example, grease designed for heavily loaded, high temperature applications will probably use a heavy viscosity oil base, whereas general-purpose grease is more likely to use a medium viscosity oil base.

Table 12. Grease Types and Their Properties

Type	Appearance	Pump-ability	Heat Resistance	Temperature Range	Water Resistance	Compatibility with other greases
Calcium (Lime Soap)	Buttery	Fair	Fair	230 °F (110 °C)	Excellent	Excellent
Sodium (Soda Soap)	Fibrous	Fair	Very Good	250 °F (120 °C)	Poor	Good
Calcium Complex	Stringy	Fair	Good	350 °F (175 °C)	Very Good	Fair
Lithium	Buttery	Excellent	Good	350 °F (175 °C)	Excellent	Excellent
Aluminum Complex	Stringy	Good	Excellent	350 °F (175 °C)	Excellent	Poor
Lithium Complex	Buttery	Excellent	Excellent	375 °F (190 °C)	Very Good	Excellent
Barium	Fibrous	Very Good	Excellent	380 °F (193 °C)	Excellent	Fair
Bentonite (non-soap)	Buttery	Good	Excellent	500 °F (260 °C)	Good	Poor
Urea	Buttery	Good	Excellent	> 500 °F (260 °C)	Excellent	Excellent

Grease properties may change according to the additive package used

At sustained high temperatures, grease will soften substantially and could leak or drop from the bearing unless rated specifically for high temperature applications. High temperatures rapidly oxidize the lubricant causing the soap to harden; higher temperatures require more frequent application of grease. Lower temperatures can be just as detrimental because the grease “stiffens” considerably as temperatures near  $-20^{\circ}\text{F}$  ( $-30^{\circ}\text{C}$ ). At this temperature the rolling elements no longer rotate and they drag across the raceway. Under heavier loads this effect causes “smearing” of the bearing surfaces leading to premature bearing failure. Grease temperature guidelines by type are shown in Fig. 10.

Fig. 10. Temperature Limit Guidelines for Grease

**Grease Classification:** The National Lubricating Grease Institute – NLGI, classifies grease according to a rating standard that measures the consistency of the grease. Using a penetrometer apparatus under laboratory conditions, a conical weight is dropped from a known height into the grease sample, and its depth of penetration is measured after a 5 second time period. The [Table 13](#) rating chart shows that stiffer greases are rated with a higher NLGI code than more fluid grease with higher levels of penetration. Grease consistency largely depends on the type and amount of soap thickener blended in the grease and the oil viscosity — **NOT** the base oil viscosity alone. Rolling element bearings will use grease in the NLGI 1 to 3 ranges. Centralized grease lubricating systems favor 0 to 2 NLGI rated grease.

**Table 13. NLGI Grease Consistency Rating Chart**

NLGI Rating	Description	Penetration Range (0.1mm@77° F)
6	Brick Hard	85–115
5	Very Stiff	130–160
4	Stiff	175–205
3	Medium	220–250
2	Medium Soft	265–295
1	Soft	310–340
0	Very Soft	355–385
00	Semi Fluid	400–430
000	Semi Fluid	445–475

**Grease Additives:** As with oil, grease will also contain solids additives such as graphite, molybdenum disulphide, and PTFE for use in extreme pressure and heavy wear conditions.

### Lubricant Application

**Selecting a Suitable Lubricant.**— Selecting a suitable lubricant will depend on a number of factors such as type of operation (full film, boundary layer), temperature, speed, load, working environment, and machine design. Machine maintenance requirements and maintenance schedules are not always taken into account in the equipment engineering design process of the lubrication system(s). Careful assessment of the conditions and consultation with a lubricant manufacturer/provider must take place to determine the optimal lubricant choice for each specific application. [Table 14](#) offers general guidelines for lubricant choice

when operating conditions are known, and Fig. 11 offers lubricant viscosity guideline choices based on bearing speed in rpm. Once the initial lubricant choice is made, its viscosity must be checked against the specific operating temperature to ensure that the lubricant is suitable for speed, load, and temperature conditions.

**Table 14. General Guidelines for Choosing a Preferred Lubricant Type**

Condition	Oil	Grease	Solid
Clearances Designed for Oil	●		●
Clearances Designed for Grease		●	●

Isolated Bearings		●	

<sup>a</sup> Automated delivery system.

Fig. 11. Lubricant Viscosity Selection Guide based on Bearing Speed in rpm

Lubricant additives deliver different working characteristics to the lubricant. Knowing and documenting a machine or system's lubricant application requirements will facilitate a consolidation of lubricant requirements and assist in determining the optimal lubricant additive package. Table 15 reviews typical lubricated components, and assigns priority guideline ratings against a number of important lubricant functional attributes. This information is a starting point when working with the lubricant manufacturer to enable consolidation of lubricant needs and choose lubricants with suitable additives.

**Table 15. Priority Guideline Ratings of Lubricant Functional Attributes for Different Lubricated Components**

Lubricant Attribute	Sliding Bearing	Rolling Bearing	Wire Rope, Chain, Open Gears	Closed Gears
Friction Reduction	1	2	1	2
Boundary Lubrication	1	2	2	3
Cooling Ability	2	2	0	3
Temperature Range	1	2	1	2
Corrosion Protection	1	2	2	1
Seal Out Contaminants	0	2	1	0

0 = Low Priority, 3 = High Priority

**Oil Application.**— Oil lubrication can be broken down into two major categories: terminating (total loss), and recirculating oil systems.

*Terminating Oil Systems:* Terminating oil systems are semi-automated and automated systems that dispense oil at a known rate to the bearing(s) and do not recover the oil. This system can be generally observed in use for lubricating plain bearings, gibs, and slide ways found in small to medium-sized machine tools. Reservoir oil is replenished with new oil on an “as used” basis.

*Recirculating Oil Systems:* Recirculating oil systems pump oil through the bearing(s) on a semi-continuous or continuous cycle, using the oil to cool the bearing as it lubricates. Depending on the system design the oil can be filtered prior to the pump suction inlet, on the pump discharge, and again on the gravity return to the oil storage reservoir.

Recirculating systems are used on every kind of small to very large equipment as long as the oil can be contained; reservoirs retain their original charge of oil, which is changed on a condition or time basis.

A simple method used by lubrication delivery system manufacturers for determining the bearing oil requirements under normal load and speed conditions uses a volumetric requirement over a specified time period (See Table 16), designated by:

$$V = A \times R \quad (4)$$

where  $V$  = oil volume in cubic centimeters, (cc)

$A$  = bearing contact surface area, (cm<sup>2</sup>)

$R$  = film thickness replenishment, (mm)

**Table 16. Lubrication Film Replenishment Rate Guidelines for Oil and Grease**

Lubricant Delivery Method	$R$ - Film Thickness	Time
Automatic Terminating Oil	0.025 mm (0.001 inch)	1 hour
Automatic Recirculating Oil	0.025 mm (0.001 inch)	1 minute

Other closed system oiling methods exist: Gearbox splash systems employ a simple recirculative pickup/transfer of oil by a submerged gear tooth from an oil reservoir bath. Constant level oilers maintain a constant level of oil in a specially designed oil bath bearing housing. Using air over oil technology, oil can be misted and “rifled” into the bearing allowing very high speeds of over 20,000 rpm at light loads.

When replenishing oil reservoirs always use new clean oil of the exact same specification, from the same manufacturer. Mixing different oils of similar specification can cause additive packages to react with one another causing detriment to the bearings. If changing to a new oil specification or manufacturer consult with the new manufacturer for the correct change out procedure.

**Grease Application.**— Because grease is easy to retain in a bearing housing over a long period of time and because it acts as a seal against contaminants, most rolling element bearings are grease lubricated. For most applications a NLGI 1 or 2 rating grease is used. The

method of grease lubrication will depend on the greased bearing design; bearings can be hand-packed, manually-lubricated with a terminating style grease gun, or automatically greased.

Open rolling bearings are received with a rust inhibiting compound from new and must be pre-packed on assembly — **DO NOT remove bearings from their packaging until ready to use**, and **DO NOT spin dry bearings as this will significantly degrade the life of the bearing**. Shielded or sealed bearings usually arrive pre-packed from the manufacturer - always specify your preferred grease to your bearing supplier when ordering. The initial amount of grease is determined by adjusting the volume according to the known speed and load. For operating temperatures above 180°F (80°C) the bearing is packed to 25% of the full pack volume. For temperatures below 180°F (80°C), the guideline for pack volume is shown in Table 17 and is based on the bearing surface speed in operation calculated as:

$$dn \text{ or } Dn = SD \times \text{RPM} \quad (5)$$

where  $dn$  = bearing surface speed factor, metric, mm

$Dn$  = bearing surface speed factor, US Customary, in.

$SD$  = shaft diameter of the bearing bore, mm or in.

$\text{RPM}$  = velocity, rotations per minute at full speed

**Table 17. Bearing Packing Guidelines**

$dn$ (mm)		$Dn$ (in.)		% Full Pack
From	To	From	To	
0	50,000	0	2,000	100
50,000	100,000	2,000	4,000	75
100,000	150,000	4,000	6,000	50
150,000	200,000	6,000	8,000	33
200,000+		8,000+		25

For vibration applications, do not fill more than 60% of full pack

When hand packing, work the grease with fingers around all the rolling elements; the bearing can be dismantled to make for this operation easier. The grease should fill the immediate bearing area. Before renewing grease in an existing bearing, the bearing must be removed and washed in kerosene or any suitable degreasing product. Once clean, the bearing is lightly coated in mineral oil, being careful not to spin the bearing at this point. Once filled with the appropriate amount of grease in the bearing area, the bearing can be hand spun to fling off grease excess, which is wiped away with a lint-free clean cloth. Free spacing in the housing should be filled from 30% to 50%. Overfilling bearings with grease is the leading cause of bearing lubrication-related failures. Over greasing causes the lubricant to “churn,” which in turn “spikes” the bearing internal temperature, significantly reducing the bearing life using considerably more energy to overcome fluid friction. Bearings designed to be lubricated by a grease handgun or automated delivery system will have a grease port built into the bearing housing and raceway. Grease lubrication intervals will depend on temperature and speed. Fig. 12 provides guidelines for renewing grease based on speed.

Bearings running at high temperature extremes will require more frequent application based on the temperature, load, speed, and type of grease used. When replenishing grease always use new clean grease of the exact same specification, from the same manufacturer. Mixing different greases can lead to compatibility problems causing detriment to the bearings. If changing to a new grease specification or manufacturer, consult with the new manufacturer for the correct change out procedure.

**Lubrication Delivery Methods and Systems .—**Numerous methods and systems are used to deliver oil and grease to bearing points. Automated centralized systems work on the premise of delivering a very small amount of lubrication on an almost continual basis,

Fig. 12. Grease Renewal Period based on Running Time and Speed providing optimal full film lubrication to the bearing. Although more expensive initially, automated centralized systems are credited with significant savings by extending bearing life up to three times longer than manually lubricated bearings. They also reduce downtime in changing out bearings, reduce lubricant consumption, and reduce energy consumption. Table 18 compares the different types of methods and delivery systems and some of their features, and can be used as a guide in determining a suitable lubrication delivery approach.

**Table 18. Lubrication Method and System Comparison Guide**

Feature	Hand Pack	Manual Gun	Single Point	Centralized Total Loss	Centralized Recirculating	Self Contained Splash/Bath	Gravity Fed
Oil		●	●	●	●	●	●
Grease	●	●	●	●			
Continuous Delivery			●		●	●	●
Cyclic Delivery		●		●			
Automatic Control			●	●	●		●
Manual Control	●	●		●			●
Positive Displacement		●	●	●	●		
Line Monitor Protection				●	●		
# Lube Points		Unlimited	Unlimited	20 Min.	200 Max.		20 Max.

Manual gun delivery systems are commonly known as grease guns and oil guns. These hand-dispensing devices are capable of delivering lubricant at pressures exceeding 15,000 psi (103 MPa), and must be used with extreme caution if the bearing seal is not to be compromised—especially when lubricating from a remote located grease nipple. Bearings manually lubricated with grease and oil guns are lubricated with significantly more lubricant and less frequent applications than automatic centralized lubricated bearings. Manual lubrication results in a high degree of bearing fluid friction and a significant lower life expectancy.

Single point lubricators are self-contained automatic dispensing units that house a lubricant reservoir and can dispense oil or grease to a single bearing or a small number of bearings through a manifold system. Earlier versions of the grease units employed a spring-loaded follower plate that dispensed against a bearing back pressure through a controllable bleed valve; while oil units used gravity (also known as gravity units) to allow oil to drip through a bleed valve at a controlled rate onto a brush or wick device touching the moving shaft or part. Both unit types are refillable and are still available. Modern day versions are mostly one-time-use units that employ programmable controlled battery operated positive displacement pumps, or electrochemical gas expandable bellows to move the lubricant to the bearing.

Centralized total loss systems employ a pump that can be automatically or manually activated to pump oil (solid or mist) or grease to a series of metering valves mounted at the lubrication point, or in a manifold device piped to the bearing point. These systems are capable of delivering a metered amount of lubricant on a cyclic basis to many hundreds of lubricant points simultaneously. Because the lubricant is not reclaimed at the bearing point, the pump reservoir must be filled with lubricant on a regular basis. This lubrication system is the most common type of found on industrial equipment.

Centralized oil recirculating systems are designed to continually pump a metered amount of oil through each bearing point. The oil is channeled back to the reservoir through a filter system and pumped out again through the distribution system.

Self contained bath and splash installations are “pick-up” type systems that employ oil in a reservoir filled to an engineered level that covers the lowest submersed gear teeth. As the gear moves it picks up the oil and transfers lubricant as each gear engages and disengages. Higher rpm speed causes the lubricant to be splashed high into the gearbox cavity so that it is distributed to all the internal devices.

### Contamination Control

Before an oil lubricant gets to perform its lubrication function at the bearing point, it must often go through a torturous handling process where the oil must be transferred multiple times before it eventually resides in the final application reservoir. The lubricant is shipped from the refinery to the blending station, to the manufacturer's bulk storage tank, to the supplier's storage tank, to the barrel or pail, to the user's storage facility, to the maintenance department, and finally to the machine's reservoir. If the transfer equipment and storage tanks/devices are not dedicated to this exact lubricant type and scrupulously clean, and the oil is not filtered at every transfer point, the virgin oil will be contaminated when placed in the equipment reservoir.

In a study performed by the National Research Council of Canada on bearing failure in primary industries it was found that 82% of wear-induced failure was particle-induced failure from dirty lubricants, with the greatest wear caused by particles whose size equaled the oil film thickness. Perhaps the greatest contamination enemy for bearings is the ever present silt and its abrasive properties. Fig. 13 shows the Macpherson curve, which depicts the contaminant effect on roller bearing life based on contaminant micron size.

Fig. 13. Macpherson Contamination Effect Curve

The graph in Fig. 13 clearly shows the relationship between bearing life extension and contaminant size. By focusing on controlling contaminants less than 10 microns in size with quality filtration methods, expected bearing life is more than tripled.

**ISO Cleanliness Code.**— When performing a solids lubricant analysis and cleanliness testing, the ISO Cleanliness Code ISO4406 (1999) is used as a guide. The number of 4-micron, 6-micron, and 14-micron diameter particles in a 1 ml lubricant sample are counted and compared to a particle concentration range, (see Table 19), then assigned a cleanliness code number for each particle count size.

Table 19. ISO Cleanliness Code 4406 (1999)

Particles per ml			Particles per ml		
More Than	Up to and Including	Range Number (R)	More Than	Up to and Including	Range Number (R)
80,000	160,000	24	20	40	12
40,000	80,000	23	10	20	11
20,000	40,000	22	5	10	10
10,000	20,000	21	2.5	5	9
5000	10,000	20	1.3	2.6	8
2500	5000	19	0.64	1,28	7
1300	2600	18	0.32	0.64	6
640	1280	17	0.16	0.32	5
320	640	16	0.08	0.16	4
160	320	15	0.04	0.08	3
80	160	14	0.02	0.04	2
40	80	13	0.01	0.02	1

*Example:* An ISO code of 21/19/17 would represent findings of between 10,000 to 20,000 4-micron sized particles per ml, between 2,500 and 5,000 6-micron sized particles per ml, and between 640 and 1,280 14-micron sized particles per ml; this sample would be considered very dirty.

Typical cleanliness targets for rolling element bearings would start at 16/14/12 or better, 17/15/12 or better for journal style bearings, 17/14/12 or better for industrial gearboxes, and 15/12 or better for hydraulic fluids.

A study conducted by the British Hydromechanics Research Association (BHRA) looked at the relationship between hydraulic fluid cleanliness and mean time between failure (MTBF) of over 100 hydraulic systems in a variety of industries over a three year period. The results are seen in Fig. 14 and show that systems that were successful in filtering out and excluding contaminants over 5 microns in size lasted tens of thousand of hours longer between system breakdowns.

Fig. 14. MTBF vs. Cleanliness Levels

Solid particle ingress into a closed lubrication/hydraulic system can come from a variety of sources that include new oil, service and manufacturing debris, improper seals, vents/breathers, filter breakdown, and internal wear generation. For the most part, ingress prevention is all about filtration. Introducing filtered clean new oil into a system will significantly retard the wear process and avoid clogging up breathers and in-line filter systems.

**Water Contamination .—** Water contamination is the other major lubricant contaminant that will significantly degrade the oil's life (Fig. 15). Lubrication fluid typically saturates at 0.04% or 400 ppm, whereas hydraulic fluid (excluding water glycol fluids) saturates at an even lower 0.03% or 300 ppm. Typical water sources are found in the fluid storage areas when lubricants are stored outdoors and subjected to the elements, or stored in continually changing temperatures causing condensation and rust that can be transferred into the equipment's lubrication system.

Fig. 15. Effect of Water in Oil on Bearing Life

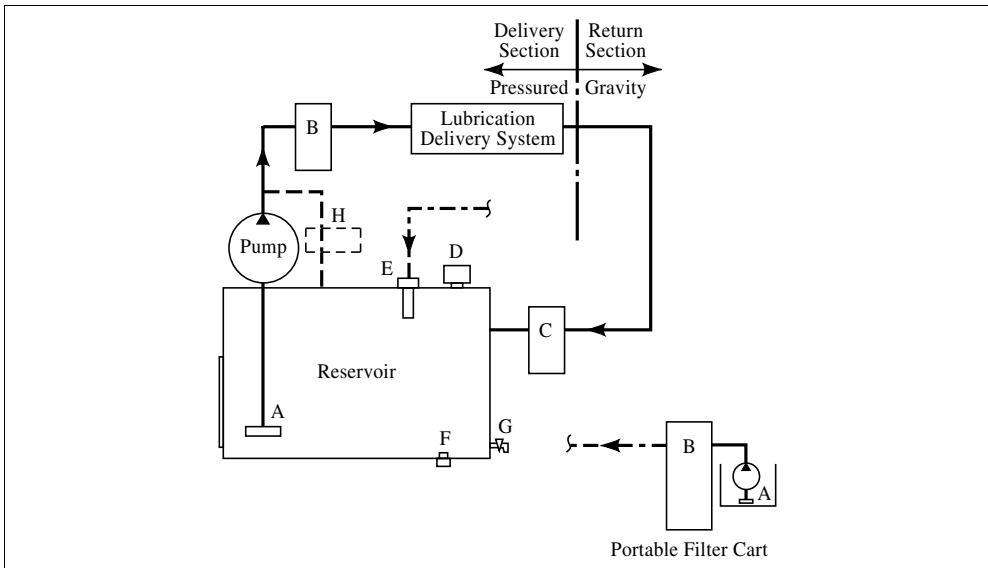

**Filtration Systems.**— Although contamination cannot be completely eliminated, with diligence and the use of effective filtration techniques and methods the effects of contamination can be seriously mitigated.

Working on the understanding that fluid cleanliness is the basis for contamination control, primary filtration commences on the virgin stock oils prior to the lubricant being placed in the working reservoir or lubrication / hydraulic system.

Once the lubricant is in a working system it will immediately begin to attract contaminants already in the system, from the air, outside sources, manufacturing materials, and wear materials that must be filtered out as the lubricant moves through the system. **Table 20** shows a typical pressure flow lubrication delivery, hydraulic system complete with a minimum filter media package. The function of these filters is to reduce operating costs and increase component life; therefore they must be properly sized for the system and be of the highest quality.

There are two basic types of filter design, surface filters and depth filters. Surface filters are the most common and use a screening material to trap debris. Depth filters are deep cleaning filtering devices that use multiple layers of dense materials to “polish” the lubricant. Depth filters are usually set up in parallel with the basic filter system and allow a small percentage of the lubricant flow to bypass the pump and be depth cleaned.

**Table 20. Typical Minimum Filtration Requirements for a Closed Loop Lubrication Hydraulic System**

	Location	Type	Degree	Material	Purpose
A	Pump Suction	Surface	Medium	Gauze, Paper	Pump Protection
B	Pump Delivery Header	Surface	Fine	Felt, Paper, Cellulose, Sintered Metal	Primary System Protection
C	Return Line	Surface	Medium	Felt, Paper, Cellulose	Wear Products Protection
D	Reservoir Vent	Surface	Course / Medium	Wire, Wool, Paper, Oil Bath Desiccant	Remove Airborne Contaminant and Condensation
E	Reservoir Fill Port	Surface	Course	Gauze, Paper	Prevent Course Solids Ingress
F	Drain Plug	Surface	Fine	Magnet	Capture Ferrite Wear Metals And Debris
G	Drain Valve	n/a	n/a	n/a	Water Removal
H	Delivery Bypass Filter	Depth	Very Fine	Carbon, Cellulose, Diamataceous Earth, Felt	Lubricant Deep Cleaning And Polishing

A diagram and tabulation of the filtration requirements of a closed loop hydraulic system are shown in **Table 20**. Fluid in the reservoir is sucked up by the pump through the suction filter (A) and pumped into the delivery header line under pressure. If a depth filter option is used, a small percentage, up to 15%, of the oil flow is diverted for deep cleaning through a depth filter (H) and sent back to the reservoir for recycling. The lubricant is then forced through the primary pressure filter and allowed to perform its work at the bearing point or hydraulic device before it eventually channels into the system return line under gravity to pass through a low pressure return line filter that takes out any wear materials gathered along the way. Once through the return filter the oil makes its way back into the reservoir. The reservoir is protected against airborne contaminants and condensation by the vent filter, and is protected against ingress of course solids by the fill neck screen filter. Because water is heavier than oil it will settle to the bottom of the tank where most of it can be drained off by opening the drain valve. Metallic debris also settle to the bottom and are captured by the magnetic drain plug at the bottom of the reservoir. As the lubricant oxidizes and breaks down, sludge will form on the bottom of the reservoir, which must be cleaned out periodically manually by removing the reservoir clean-out hatch.

*Filter Efficiency:* Most surface filters are sold in either one-time-use, or cleanable-reusable forms. Depth filters are all one-time-use filters. All filters are performance rated according to the media's particle removal efficiency, known as the filter's filtration ratio, or *Beta ratio*. Not all filters are made equal, and they are tested for dirt holding capacity, pressure differential capability, and filter efficiency, using an ISO 4572 Multipass Test Procedure in which fluid is circulated through a mock lube system in a controlled manner. Differential pressure across the test filter element is recorded as contamination is added into the lubricant upstream of the filter. Laser particle sensors determine contamination levels both upstream and downstream of the filter element and the beta ratio is determined using the following formula:

$$B_x = \frac{\# \text{ Upstream Particulate}}{\# \text{ Downstream Particulate}} \quad (6)$$

where  $B$  = filter filtration ratio

$x$  = a specific particle size

*Example:* If 100,000 particles, 10 microns and larger, are counted upstream of the test filter, and 1000 particles are counted after or downstream of the test filter element, the beta ratio would equal:

$$B_{10} = \frac{100,000}{1000}$$

Efficiency is determined using the following equation:

$$\begin{aligned} \text{Efficiency}_x &= \left(1 - \frac{1}{B_x}\right) \times 100 \\ \text{Efficiency}_{10} &= \left(1 - \frac{1}{100}\right) \times 100 = 99\% \end{aligned} \quad (7)$$

The higher the beta ratio, the better the capture efficiency of the filter, see **Table 21**.

**Table 21. Filter Efficiency**

Beta Ratio at a Specific Particle Size	Filter Efficiency at Same Specific Particle Size	Beta Ratio at a Specific Particle Size	Filter Efficiency at Same Specific Particle Size	Beta Ratio at a Specific Particle Size	Filter Efficiency at Same Specific Particle Size
1.01	1%	5	80%	100	99%
1.1	9%	10	90%	200	99.5%
1.5	33%	20	95%	1000	99.9%
2	50%	75	98.7%	...	...

## COUPLINGS, CLUTCHES, BRAKES

**Connecting Shafts.**—For couplings to transmit up to about 150 horsepower, simple flange-type couplings of appropriate size, as shown in the table, are commonly used. The design shown is known as a safety flange coupling because the bolt heads and nuts are shrouded by the flange, but such couplings today are normally shielded by a sheet metal or other cover.

### Safety Flange Couplings

For small sizes and low power applications, a setscrew may provide the connection between the hub and the shaft, but higher power usually requires a key and perhaps two setscrews, one of them above the key. A flat on the shaft and some means of locking the setscrew(s) in position are advisable. In the AGMA Class I and II fits, the shaft tolerances are  $-0.0005$  inch from  $\frac{1}{2}$  to  $1\frac{1}{2}$  inches diameter and  $-0.001$  inch on larger diameters up to 7 inches.

Class I coupling bore tolerances are  $+0.001$  inch up to  $1\frac{1}{2}$  inches diameter, then  $+0.0015$  inch to 7 inches diameter. Class II coupling bore tolerances are  $+0.002$  inch on sizes up to 3 inches diameter,  $+0.003$  inch on sizes from  $3\frac{1}{4}$  through  $3\frac{3}{4}$  inches diameter, and  $+0.004$  inch on larger diameters up to 7 inches.

**Interference Fits.**— Components of couplings transmitting over 150 horsepower often are made with an interference fit on the shafts, which may reduce fretting corrosion. These couplings may or may not use keys, depending on the degree of interference. Keys may range in size from  $\frac{1}{8}$  inch wide by  $\frac{1}{16}$  inch high for  $\frac{1}{2}$ -inch diameter shafts to  $1\frac{3}{4}$  inches wide by  $\frac{7}{8}$  inch high for 7-inch diameter shafts. Couplings transmitting high torque or operating at high speeds or both may use two keys. Keys must be a good fit in their keyways to ensure good transmission of torque and prevent failure. AGMA standards provide recommendations for square parallel, rectangular section, and plain tapered keys, for shafts of  $\frac{5}{16}$  through 7 inches diameter, in three classes designated commercial, precision, and fitted. These standards also cover keyway offset, lead, parallelism, finish and radii, and face keys and splines. (See also ANSI and other Standards in *KEYS AND KEYSEATS* starting on page 2476 of this Handbook.)

**Double-cone Clamping Couplings.**— As shown in the table, double-cone clamping couplings are made in a range of sizes for shafts from  $1\frac{1}{16}$  to 6 inches in diameter, and are easily assembled to shafts. These couplings provide an interference fit, but they usually cost more and have larger overall dimensions than regular flanged couplings.

**Double-cone Clamping Couplings**

**Flexible Couplings.**— Shafts that are out of alignment laterally or angularly can be connected by any of several designs of flexible couplings. Such couplings also permit some degree of axial movement in one or both shafts. Some couplings use disks or diaphragms to transmit the torque. Another simple form of flexible coupling consists of two flanges connected by links or endless belts made of leather or other strong, pliable material. Alternatively, the flanges may have projections that engage spacers of molded rubber or other flexible materials that accommodate uneven motion between the shafts. More highly developed flexible couplings use toothed flanges engaged by correspondingly toothed elements, permitting relative movement. These couplings require lubrication unless one or more of the elements is made of a self-lubricating material. Other couplings use diaphragms or bellows that can flex to accommodate relative movement between the shafts.

**The Universal Joint.**— This form of coupling, originally known as a Cardan or Hooke's coupling, is used for connecting two shafts the axes of which are not in line with each other, but which merely intersect at a point. There are many different designs of universal joints or couplings, which are based on the principle embodied in the original design. One well-known type is shown by the accompanying diagram.

As a rule, a universal joint does not work well if the angle  $\alpha$  (see illustration) is more than 45 degrees, and the angle should preferably be limited to about 20 degrees or 25 degrees, excepting when the speed of rotation is slow and little power is transmitted.

*Variation in Angular Velocity of Driven Shaft:* Owing to the angularity between two shafts connected by a universal joint, there is a variation in the angular velocity of one shaft during a single revolution, and because of this, the use of universal couplings is sometimes prohibited. Thus, the angular velocity of the driven shaft will not be the same at all points of the revolution as the angular velocity of the driving shaft. In other words, if the driving shaft moves with a uniform motion, then the driven shaft will have a variable motion and, therefore, the universal joint should not be used when absolute uniformity of motion is essential for the driven shaft.

*Determining Maximum and Minimum Velocities:* If shaft *A* (see diagram) runs at a constant speed, shaft *B* revolves at maximum speed when shaft *A* occupies the position shown in the illustration, and the minimum speed of shaft *B* occurs when the fork of the driving shaft *A* has turned 90 degrees from the position illustrated. The maximum speed of the driven shaft may be obtained by multiplying the speed of the driving shaft by the secant of angle  $\alpha$ . The minimum speed of the driven shaft equals the speed of the driver multiplied by cosine  $\alpha$ . Thus, if the driver rotates at a constant speed of 100 revolutions per minute and the shaft angle is 25 degrees, the maximum speed of the driven shaft is at a rate equal to  $1.1034 \times 100 = 110.34$  rpm. The minimum speed rate equals  $0.9063 \times 100 = 90.63$ ; hence, the extreme variation equals  $110.34 - 90.63 = 19.71$  rpm.

**Use of Intermediate Shaft between Two Universal Joints.**—The lack of uniformity in the speed of the driven shaft resulting from the use of a universal coupling, as previously explained, is objectionable for some forms of mechanisms. This variation may be avoided if the two shafts are connected with an intermediate shaft and two universal joints, provided the latter are properly arranged or located. Two conditions are necessary to obtain a constant speed ratio between the driving and driven shafts. First, the shafts must make the same angle with the intermediate shaft; second, the universal joint forks (assuming that the fork design is employed) on the intermediate shaft must be placed relatively so that when the plane of the fork at the left end coincides with the center lines of the intermediate shaft and the shaft attached to the left-hand coupling, the plane of the right-hand fork must also coincide with the center lines of the intermediate shaft and the shaft attached to the right-hand coupling; therefore the driving and the driven shafts may be placed in a variety of positions. One of the most common arrangements is with the driving and driven shafts parallel. The forks on the intermediate shafts should then be placed in the same plane.

This intermediate connecting shaft is frequently made telescoping, and then the driving and driven shafts can be moved independently of each other within certain limits in longitudinal and lateral directions. The telescoping intermediate shaft consists of a rod which enters a sleeve and is provided with a suitable spline, to prevent rotation between the rod and sleeve and permit a sliding movement. This arrangement is applied to various machine tools.

**Knuckle Joints.**—Movement at the joint between two rods may be provided by knuckle joints, for which typical proportions are seen in the table *Proportions of Knuckle Joints* on page 2463.

**Friction Clutches.**—Clutches which transmit motion from the driving to the driven member by the friction between the engaging surfaces are built in many different designs, although practically all of them can be classified under four general types, namely, conical clutches; radially expanding clutches; contracting-band clutches; and friction disk clutches in single and multiple types. There are many modifications of these general classes, some of which combine the features of different types. The proportions of various sizes of cone clutches are given in the table “Cast-iron Friction Clutches.”

The multicone friction clutch is a further development of the cone clutch. Instead of having a single cone-shaped surface, there is a series of concentric conical rings which engage annular grooves formed by corresponding rings on the opposite clutch member. The internal-expanding type is provided with shoes which are forced outward against an enclosing drum by the action of levers connecting with a collar free to slide along the shaft. The engaging shoes are commonly lined with wood or other material to increase the coefficient of friction. Disk clutches are based on the principle of multiple-plane friction, and use alternating plates or disks so arranged that one set engages with an outside cylindrical case and the other set with the shaft. When these plates are pressed together by spring pressure, or by other means, motion is transmitted from the driving to the driven members connected to the clutch. Some disk clutches have a few rather heavy or thick plates and others a relatively large number of thinner plates. Clutches of the latter type are common in automobile transmissions. One set of disks may be of soft steel and the other set of phosphor-bronze, or some other combination may be employed. For instance, disks are sometimes provided with cork inserts, or one set or series of disks may be faced with a special friction material such as asbestos-wire fabric, as in “dry plate” clutches, the disks of which are not lubricated like the disks of a clutch having, for example, the steel and phosphor-bronze combination. It is common practice to hold the driving and driven members of friction clutches in engagement by means of spring pressure, although pneumatic or hydraulic pressure may be employed.

**Power Transmitting Capacity of Friction Clutches.**— When selecting a clutch for a given class of service, it is advisable to consider any overloads that may be encountered and base the power transmitting capacity of the clutch upon such overloads. When the load varies or is subject to frequent release or engagement, the clutch capacity should be greater than the actual amount of power transmitted. If the power is derived from a gas or gasoline engine, the horsepower rating of the clutch should be 75 or 100 percent greater than that of the engine.

**Power Transmitted by Disk Clutches.**— The approximate amount of power that a disk clutch will transmit may be determined from the following formula, in which  $HP$  = horsepower transmitted by the clutch;  $\mu$  = coefficient of friction;  $r$  = mean radius of engaging surfaces;  $F$  = axial force in pounds (spring pressure) holding disks in contact;  $N$  = number of frictional surfaces;  $S$  = speed of shaft in revolutions per minute:

$$HP = \frac{\mu r F N S}{63,000}$$

## Cast-iron Friction Clutches

For sizes not given below:

$a = 2D$

$b = 4 \text{ to } 8D$

$c = 2\frac{1}{4}D$

$t = 1\frac{1}{2}D$

$e = \frac{3}{8}D$

$h = \frac{1}{2}D$

$s = \frac{5}{16}D, \text{ nearly}$

$k = \frac{1}{4}D$

Note: The angle  $\phi$  of the cone may be from 4 to 10 degrees

**Frictional Coefficients for Clutch Calculations.**— While the frictional coefficients used by designers of clutches differ somewhat and depend upon variable factors, the following values may be used in clutch calculations: For greasy leather on cast iron about 0.20 or 0.25, leather on metal that is quite oily 0.15; metal and cork on oily metal 0.32; the same on dry metal 0.35; metal on dry metal 0.15; disk clutches having lubricated surfaces 0.10.

**Formulas for Cone Clutches.**— In cone clutch design, different formulas have been developed for determining the horsepower transmitted. These formulas, at first sight, do not seem to agree, there being a variation due to the fact that in some of the formulas the friction clutch surfaces are assumed to engage without slip, whereas, in others, some allowance is made for slip. The following formulas include both of these conditions:

$HP$  = horsepower transmitted

$N$  = revolutions per minute

$r$  = mean radius of friction cone, in inches

$r_1$  = large radius of friction cone, in inches

$r_2$  = small radius of friction cone, in inches

$R_1$  = outside radius of leather band, in inches

$R_2$  = inside radius of leather band, in inches

$V$  = velocity of a point at distance  $r$  from the center, in feet per minute

$F$  = tangential force acting at radius  $r$ , in pounds

$P_n$  = total normal force between cone surfaces, in pounds

$P_s$  = spring force, in pounds

$\alpha$  = angle of clutch surface with axis of shaft = 7 to 13 degrees

$\beta$  = included angle of clutch leather, when developed, in degrees

$f$  = coefficient of friction = 0.20 to 0.25 for greasy leather on iron

$p$  = allowable pressure per square inch of leather band = 7 to 8 pounds

$W$  = width of clutch leather, in inches

$$R_1 = \frac{r_1}{\sin \alpha} \quad R_2 = \frac{r_2}{\sin \alpha}$$

$$\beta = \sin \alpha \times 360 \quad r = \frac{r_1 + r_2}{2}$$

$$V = \frac{2\pi r N}{12}$$

$$F = \frac{HP \times 33,000}{V} \quad W = \frac{P_n}{2\pi r p} \quad HP = \frac{P_n f r N}{63,025}$$

For engagement with some slip:

$$P_n = \frac{P_s}{\sin \alpha} \quad P_s = \frac{HP \times 63,025 \sin \alpha}{f r N}$$

For engagement without slip:

$$P_n = \frac{P_s}{\sin \alpha + f \cos \alpha} \quad P_s = \frac{HP \times 63,025 (\sin \alpha + f \cos \alpha)}{f r N}$$

**Angle of Cone.**— If the angle of the conical surface of the cone type of clutch is too small, it may be difficult to release the clutch on account of the wedging effect, whereas, if the angle is too large, excessive spring force will be required to prevent slipping. The minimum angle for a leather-faced cone is about 8 or 9 degrees and the maximum angle about

13 degrees. An angle of  $12\frac{1}{2}$  degrees appears to be the most common and is generally considered good practice. These angles are given with relation to the clutch axis and are one-half the included angle.

**Magnetic Clutches.**— Many disk and other clutches are operated electromagnetically with the magnetic force used only to move the friction disk(s) and the clutch disk(s) into or out of engagement against spring or other pressure. On the other hand, in a magnetic particle clutch, transmission of power is accomplished by magnetizing a quantity of metal particles enclosed between the driving and the driven components, forming a bond between them. Such clutches can be controlled to provide either a rigid coupling or uniform slip, useful in wire drawing and manufacture of cables.

Another type of magnetic clutch uses eddy currents induced in the input member which interact with the field in the output rotor. Torque transmitted is proportional to the coil current, so precise control of torque is provided. A third type of magnetic clutch relies on the hysteresis loss between magnetic fields generated by a coil in an input drum and a close-fitting cup on the output shaft, to transmit torque. Torque transmitted with this type of clutch also is proportional to coil current, so close control is possible.

Permanent-magnet types of clutches also are available, in which the engagement force is exerted by permanent magnets when the electrical supply to the disengagement coils is cut off. These types of clutches have capacities up to five times the torque-to-weight ratio of spring-operated clutches. In addition, if the controls are so arranged as to permit the coil polarity to be reversed instead of being cut off, the combined permanent magnet and electromagnetic forces can transmit even greater torque.

**Centrifugal and Free-wheeling Clutches.**— Centrifugal clutches have driving members that expand outward to engage a surrounding drum when speed is sufficient to generate centrifugal force. Free-wheeling clutches are made in many different designs and use balls, cams or sprags, ratchets, and fluids to transmit motion from one member to the other. These types of clutches are designed to transmit torque in only one direction and to take up the drive with various degrees of gradualness up to instantaneously.

**Slipping Clutch/Couplings.**— Where high shock loads are likely to be experienced, a slipping clutch or coupling or both should be used. The most common design uses a clutch plate that is clamped between the driving and driven plates by spring pressure that can be adjusted. When excessive load causes the driven member to slow, the clutch plate surfaces slip, allowing reduction of the torque transmitted. When the overload is removed, the drive is taken up automatically. Switches can be provided to cut off current supply to the driving motor when the driven shaft slows to a preset limit or to signal a warning or both. The slip or overload torque is calculated by taking 150 percent of the normal running torque.

**Wrapped-spring Clutches.**— For certain applications, a simple steel spring sized so that its internal diameter is a snug fit on both driving and driven shafts will transmit adequate torque in one direction. The tightness of grip of the spring on the shafts increases as the torque transmitted increases. Disengagement can be effected by slight rotation of the spring, through a projecting tang, using electrical or mechanical means, to wind up the spring to a larger internal diameter, allowing one of the shafts to run free within the spring.

Normal running torque  $T_r$  in lb-ft = (required horsepower  $\times$  5250)  $\div$  rpm. For heavy shock load applications, multiply by a 200 percent or greater overload factor. (See Motors, factors governing selection.)

The clutch starting torque  $T_c$ , in lb-ft, required to accelerate a given inertia in a specific time is calculated from the formula:

$$T_c = \frac{WR^2 \times \Delta N}{308t}$$

where  $WR^2$  = total inertia encountered by clutch in lb-ft<sup>2</sup> ( $W$  = weight and  $R$  = radius of gyration of rotating part)

$\Delta N = \text{final rpm} - \text{initial rpm}$

308 = constant (see *Factors Governing Motor Selection* on page 2589)

$t = \text{time to required speed in seconds}$

*Example 1:* If the inertia is 80 lb-ft<sup>2</sup>, and the speed of the driven shaft is to be increased from 0 to 1500 rpm in 3 seconds, the clutch starting torque in lb-ft is

$$T_c = \frac{80 \times 1500}{308 \times 3} = 130 \text{ lb-ft}$$

The heat  $E$ , in BTU, generated in one engagement of a clutch can be calculated from the formula:

$$E = \frac{T_c \times WR^2 \times (N_1^2 - N_2^2)}{(T_c - T_1) \times 4.7 \times 10^6}$$

where:  $WR^2 = \text{total inertia encountered by clutch in lb-ft}^2$

$N_1 = \text{final rpm}$      $N_2 = \text{initial rpm}$

$T_c = \text{clutch torque in lb-ft}$      $T_1 = \text{torque load in lb-ft}$

*Example 2:* Calculate the heat generated for each engagement under the conditions cited for **Example 1**.

$$E = \frac{130 \times 80 \times (1500)^2}{(130 - 10) \times 4.7 \times 10^6} = 41.5 \text{ BTU}$$

The preferred location for a clutch is on the high- rather than on the low-speed shaft because a smaller-capacity unit, of lower cost and with more rapid dissipation of heat, can be used. However, the heat generated may also be more because of the greater slippage at higher speeds, and the clutch may have a shorter life. For light-duty applications, such as to a machine tool, where cutting occurs after the spindle has reached operating speed, the calculated torque should be multiplied by a safety factor of 1.5 to arrive at the capacity of the clutch to be used. Heavy-duty applications such as frequent starting of a heavily loaded vibratory-finishing barrel require a safety factor of 3 or more.

**Positive Clutches.**— When the driving and driven members of a clutch are connected by the engagement of interlocking teeth or projecting lugs, the clutch is said to be “positive” to distinguish it from the type in which the power is transmitted by frictional contact. The positive clutch is employed when a sudden starting action is not objectionable and when the inertia of the driven parts is relatively small. The various forms of positive clutches differ merely in the angle or shape of the engaging surfaces. The least positive form is one having planes of engagement which incline backward, with respect to the direction of motion. The tendency of such a clutch is to disengage under load, in which case it must be held in position by axial pressure.

Fig. 1. Types of Clutch Teeth

This pressure may be regulated to perform normal duty, permitting the clutch to slip and disengage when over-loaded. Positive clutches, with the engaging planes parallel to the axis of rotation, are held together to obviate the tendency to jar out of engagement, but they provide no safety feature against over-load. So-called “under-cut” clutches engage more tightly the heavier the load, and are designed to be disengaged only when free from load.

The teeth of positive clutches are made in a variety of forms, a few of the more common styles being shown in Fig. 1. Clutch *A* is a straight-toothed type, and *B* has angular or saw-shaped teeth. The driving member of the former can be rotated in either direction; the latter is adapted to the transmission of motion in one direction only, but is more readily engaged. The angle  $\theta$  of the cutter for a saw-tooth clutch *B* is ordinarily 60 degrees. Clutch *C* is similar to *A*, except that the sides of the teeth are inclined to facilitate engagement and disengagement. Teeth of this shape are sometimes used when a clutch is required to run in either direction without backlash. Angle  $\theta$  is varied to suit requirements and should not exceed 16 or 18 degrees. The straight-tooth clutch *A* is also modified to make the teeth engage more readily, by rounding the corners of the teeth at the top and bottom. Clutch *D* (commonly called a "spiral-jaw" clutch) differs from *B* in that the surfaces *e* are helicoidal. The driving member of this clutch can transmit motion in only one direction.

Fig. 2. Diagrammatic View Showing Method of Cutting Clutch Teeth

Fig. 3.

Clutches of this type are known as right- and left-hand, the former driving when turning to the right, as indicated by the arrow in the illustration. Clutch *E* is the form used on the back-shaft of the Brown & Sharpe automatic screw machines. The faces of the teeth are radial and incline at an angle of 8 degrees with the axis, so that the clutch can readily be disengaged. This type of clutch is easily operated, with little jar or noise. The 2-inch (50.8 mm) diameter size has 10 teeth. Height of working face,  $\frac{1}{8}$  inch (3.175 mm).

**Cutting Clutch Teeth.**— A common method of cutting a straight-tooth clutch is indicated by the diagrams *A*, *B* and *C*, Fig. 2, which show the first, second and third cuts required for forming the three teeth. The work is held in the chuck of a dividing-head, the latter being set at right angles to the table. A plain milling cutter may be used (unless the corners of the teeth are rounded), the side of the cutter being set to exactly coincide with the center-line. When the number of teeth in the clutch is odd, the cut can be taken clear across the blank as shown, thus finishing the sides of two teeth with one passage of the cutter. When the number of teeth is even, as at *D*, it is necessary to mill all the teeth on one side and then set the cutter for finishing the opposite side. Therefore, clutches of this type commonly have an odd number of teeth. The maximum width of the cutter depends upon the width of the space at the narrow ends of the teeth. If the cutter must be quite narrow in order to pass the narrow ends, some stock may be left in the tooth spaces, which must be removed by a separate cut. If the tooth is of the modified form shown at *C*, Fig. 1, the cutter should be set as

indicated in Fig. 3; that is, so that a point *a* on the cutter at a radial distance *d* equal to one-half the depth of the clutch teeth lies in a radial plane. When it is important to eliminate all backlash, point *a* is sometimes located at a radial distance *d* equal to six-tenths of the depth of the tooth, in order to leave clearance spaces at the bottoms of the teeth; the two clutch members will then fit together tightly. Clutches of this type must be held in mesh.

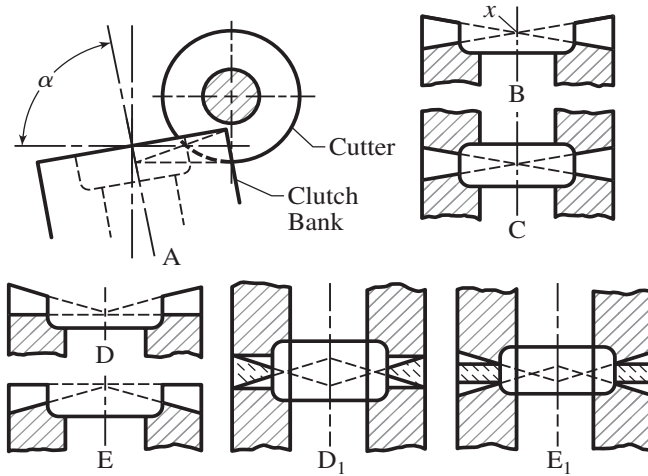

Fig. 4.

**Angle of Dividing-head for Milling V-shaped Teeth with Single-angle Cutter**

$$\cos \alpha = \frac{\tan(360^\circ/N) \times \cot \theta}{2}$$

$\alpha$  is the angle shown in Fig. 4 and is the angle shown by the graduations on the dividing head.  $\theta$  is the included angle of a single cutter, see Fig. 1.

No. of Teeth, <i>N</i>	Angle of Single-angle Cutter, $\theta$			No. of Teeth, <i>N</i>	Angle of Single-angle Cutter, $\theta$

**Cutting Saw-tooth Clutches:** When milling clutches having angular teeth as shown at *B*, Fig. 1, the axis of the clutch blank should be inclined a certain angle  $\alpha$  as shown at *A* in Fig. 4. If the teeth were milled with the blank vertical, the tops of the teeth would incline towards the center as at *D*, whereas, if the blank were set to such an angle that the tops of the teeth were square with the axis, the bottoms would incline upwards as at *E*. In either case,

the two clutch members would not mesh completely: the engagement of the teeth cut as shown at  $D$  and  $E$  would be as indicated at  $D_1$  and  $E_1$  respectively. As will be seen, when the outer points of the teeth at  $D_1$  are at the bottom of the grooves in the opposite member, the inner ends are not together, the contact area being represented by the dotted lines. At  $E_1$  the inner ends of the teeth strike first and spaces are left between the teeth around the outside of the clutch. To overcome this objectionable feature, the clutch teeth should be cut as indicated at  $B$ , or so that the bottoms and tops of the teeth have the same inclination, converging at a central point  $x$ . The teeth of both members will then engage across the entire width as shown at  $C$ . The angle  $\alpha$  required for cutting a clutch as at  $B$  can be determined by the following formula in which  $\alpha$  equals the required angle,  $N$  = number of teeth,  $\theta$  = cutter angle, and  $360^\circ/N$  = angle between teeth:

$$\cos \alpha = \frac{\tan(360^\circ/N) \times \cot \theta}{2}$$

The angles  $\alpha$  for various numbers of teeth and for 60-, 70- or 80-degree single-angle cutters are given in the table on page 2469. The following table is for double-angle cutters used to cut V-shaped teeth.

#### Angle of Dividing-head for Milling V-shaped Teeth with Double-angle Cutter

No. of Teeth, $N$	Included Angle of Cutter, $\theta$		No. of Teeth, $N$	Included Angle of Cutter, $\theta$	
	60°	90°		60°	90°

30	84 46.7	86 59.3	51	86 56.3	88 14

The angles given in the table above are applicable to the milling of V-shaped grooves in brackets, etc., which must have toothed surfaces to prevent the two members from turning relative to each other, except when unclamped for angular adjustment

## Friction Brakes

**Formulas for Band Brakes.**— In any band brake, such as shown in Fig. 1, in the tabulation of formulas, where the brake wheel rotates in a clockwise direction, the tension in that part of the band marked  $x$  equals  $P \frac{1}{e^{\mu\theta} - 1}$

The tension in that part marked  $y$  equals  $P \frac{e^{\mu\theta}}{e^{\mu\theta} - 1}$ .

$P$  = tangential force in pounds at rim of brake wheel

$e$  = base of natural logarithm = 2.71828

$\mu$  = coefficient of friction between the brake band and the brake wheel

$\theta$  = angle of contact of the brake band with the brake wheel expressed in radians

$$1 \text{ radian} = \frac{180 \text{ deg}}{\pi \text{ radians}} = 57.296 \frac{\text{deg}}{\text{radian}}$$

See also *Conversion Tables of Angular Measure* starting on page 98.

For simplicity in the formulas presented, the tensions at  $x$  and  $y$  (Fig. 1) are denoted by  $T_1$  and  $T_2$  respectively, for clockwise rotation. When the direction of the rotation is reversed, the tension in  $x$  equals  $T_2$ , and the tension in  $y$  equals  $T_1$ , which is the reverse of the tension in the clockwise direction.

The value of the expression  $e^{\mu\theta}$  in these formulas may be most easily found by using a hand-held calculator of the scientific type; that is, one capable of raising 2.71828 to the power  $\mu\theta$ . The following example outlines the steps in the calculations.

Table of Values of  $e^{\mu\theta}$ 

Proportion of Contact to Whole Circumference, $\frac{\theta}{2\pi}$	Steel Band on Cast Iron, $\mu = 0.18$	Leather Belt on			
		Wood	Cast Iron		
		Slightly Greasy; $\mu = 0.47$	Very Greasy; $\mu = 0.12$	Slightly Greasy; $\mu = 0.28$	Damp; $\mu = 0.38$
0.1	1.12	1.34	1.08	1.19	1.27
0.2	1.25	1.81	1.16	1.42	1.61
0.3	1.40	2.43	1.25	1.69	2.05
0.4	1.57	3.26	1.35	2.02	2.60
0.425	1.62	3.51	1.38	2.11	2.76

0.7	2.21	7.90	1.66	3.43	5.32
0.8	2.47	10.60	1.83	4.09	6.75
0.9	2.77	14.30	1.97	4.87	8.57
1.0	3.10	19.20	2.12	5.81	10.90

## Formulas for Simple and Differential Band Brakes

$F$  = force in pounds at end of brake handle;  $P$  = tangential force in pounds at rim of brake wheel;  $e$  = base of natural logarithm = 2.71828;  $\mu$  = coefficient of friction between the brake band and the brake wheel;  $\theta$  = angle of contact of the brake band with the brake wheel, expressed in radians (1 radian = 57.296 degrees).

$$T_1 = P \frac{1}{e^{\mu\theta} - 1} \quad T_2 = P \frac{e^{\mu\theta}}{e^{\mu\theta} - 1}$$

## Simple Band Brake

Fig. 1.

For clockwise rotation:

$$F = \frac{bT_2}{a} = \frac{Pb}{a} \left( \frac{e^{\mu\theta}}{e^{\mu\theta} - 1} \right)$$

For counter clockwise rotation:

$$F = \frac{bT_1}{a} = \frac{Pb}{a} \left( \frac{1}{e^{\mu\theta} - 1} \right)$$

Fig. 2.

For clockwise rotation:

$$F = \frac{bT_1}{a} = \frac{Pb}{a} \left( \frac{1}{e^{\mu\theta} - 1} \right)$$

For counter clockwise rotation:

$$F = \frac{bT_2}{a} = \frac{Pb}{a} \left( \frac{e^{\mu\theta}}{e^{\mu\theta} - 1} \right)$$

## Differential Band Brake

Fig. 3.

For clockwise rotation:

$$F = \frac{b_2T_2 - b_1T_1}{a} = \frac{P}{a} \left( \frac{b_2e^{\mu\theta} - b_1}{e^{\mu\theta} - 1} \right)$$

For counter clockwise rotation:

$$F = \frac{b_2T_1 - b_1T_2}{a} = \frac{P}{a} \left( \frac{b_2 - b_1e^{\mu\theta}}{e^{\mu\theta} - 1} \right)$$

In this case, if  $b_2$  is equal to, or less than,  $b_1e^{\mu\theta}$ , the force  $F$  will be 0 or negative and the band brake works automatically.

Fig. 4.

For clockwise rotation:

$$F = \frac{b_2T_2 + b_1T_1}{a} = \frac{P}{a} \left( \frac{b_2e^{\mu\theta} + b_1}{e^{\mu\theta} - 1} \right)$$

For counter clockwise rotation:

$$F = \frac{b_1T_2 + b_2T_1}{a} = \frac{P}{a} \left( \frac{b_1e^{\mu\theta} + b_2}{e^{\mu\theta} - 1} \right)$$

If  $b_2 = b_1$ , both of the above formulas reduce to  $F = \frac{Pb_1}{a} \left( \frac{e^{\mu\theta} + 1}{e^{\mu\theta} - 1} \right)$ .

In this case, the same force  $F$  is required for rotation in either direction.

*Example:* In a band brake of the type in Fig. 1, dimension  $a = 24$  inches, and  $b = 4$  inches; force  $P = 100$  pounds; coefficient  $\mu = 0.2$ , and angle of contact = 240 degrees, or

$$\theta = \frac{240}{180} \times \pi = 4.18$$

The rotation is clockwise. Find force  $F$  required.

$$\begin{aligned} F &= \frac{Pb}{a} \left( \frac{e^{\mu\theta}}{e^{\mu\theta} - 1} \right) \\ &= \frac{100 \times 4}{24} \left( \frac{2.71828^{0.2 \times 4.18}}{2.71828^{0.2 \times 4.18} - 1} \right) \\ &= \frac{400}{24} \times \frac{2.71828^{0.836}}{2.71828^{0.836} - 1} = 16.66 \times \frac{2.31}{2.31 - 1} = 29.4 \end{aligned}$$

If a hand-held calculator is not used, determining the value of  $e^{\mu\theta}$  is rather tedious, and the table on page 2471 will save calculations.

**Coefficient of Friction in Brakes.**— The coefficients of friction that may be assumed for friction brake calculations are as follows: Iron on iron, 0.25 to 0.3; leather on iron, 0.3; cork on iron, 0.35. Values somewhat lower than these should be assumed when the velocities exceed 400 feet per minute at the beginning of the braking operation.

For brakes where wooden brake blocks are used on iron drums, poplar has proved the best brake-block material. The best material for the brake drum is wrought iron. Poplar gives a high coefficient of friction, and is little affected by oil. The average coefficient of friction for poplar brake blocks and wrought-iron drums is 0.6; for poplar on cast iron, 0.35; for oak on wrought iron, 0.5; for oak on cast iron, 0.3; for beech on wrought iron, 0.5; for beech on cast iron, 0.3; for elm on wrought iron, 0.6; and for elm on cast iron, 0.35. The objection to elm is that the friction decreases rapidly if the friction surfaces are oily. The coefficient of friction for elm and wrought iron, if oily, is less than 0.4.

**Calculating Horsepower from Dynamometer Tests.**— When a dynamometer is arranged for measuring the horsepower transmitted by a shaft, as indicated by the diagrammatic view in Fig. 5, the horsepower may be obtained by the formula:

$$HP = \frac{2\pi LPN}{33000}$$

in which  $HP$  = horsepower transmitted;  $N$  = number of revolutions per minute;  $L$  = distance (as shown in illustration) from center of pulley to point of action of weight  $P$ , in feet;  $P$  = weight hung on brake arm or read on scale.

Fig. 5.

By adopting a length of brake arm equal to 5 feet 3 inches, the formula may be reduced to the simple form:

$$HP = \frac{NP}{1000}$$

If a length of brake arm equal to 2 feet 7½ inches is adopted as a standard, the formula takes the form:

$$HP = \frac{NP}{2000}$$

The *transmission* type of dynamometer measures the power by transmitting it through the mechanism of the dynamometer from the apparatus in which it is generated, or to the

apparatus in which it is to be utilized. Dynamometers known as *indicators* operate by simultaneously measuring the pressure and volume of a confined fluid. This type may be used for the measurement of the power generated by steam or gas engines or absorbed by refrigerating machinery, air compressors, or pumps. An electrical dynamometer is for measuring the power of an electric current, based on the mutual action of currents flowing in two coils. It consists principally of one fixed and one movable coil, which, in the normal position, are at right angles to each other. Both coils are connected in series, and, when a current traverses the coils, the fields produced are at right angles; hence, the coils tend to take up a parallel position. The movable coil with an attached pointer will be deflected, the deflection measuring directly the electric current.

### Formulas for Block Brakes

<p><math>F</math> = force in pounds at end of brake handle;  <math>P</math> = tangential force in pounds at rim of brake wheel;  <math>\mu</math> = coefficient of friction between the brake block and brake wheel.</p>	
 <p>Fig. 1.</p>	<p>Block brake.          For rotation in either direction:</p> $F = P \frac{b}{a+b} \times \frac{1}{\mu} = \frac{Pb}{a+b} \left( \frac{1}{\mu} \right)$
 <p>Fig. 2.</p>	<p>Block brake.          For clockwise rotation:</p> $F = \frac{\frac{Pb}{a+b} - Pc}{\mu} = \frac{Pb}{a+b} \left( \frac{1}{\mu} - \frac{c}{b} \right)$ <p>For counter clockwise rotation:</p> $F = \frac{\frac{Pb}{a+b} + Pc}{\mu} = \frac{Pb}{a+b} \left( \frac{1}{\mu} + \frac{c}{b} \right)$
 <p>Fig. 3.</p>	<p>Block brake.          For clockwise rotation:</p> $F = \frac{\frac{Pb}{a+b} + Pc}{\mu} = \frac{Pb}{a+b} \left( \frac{1}{\mu} + \frac{c}{b} \right)$ <p>For counter clockwise rotation:</p> $F = \frac{\frac{Pb}{a+b} - Pc}{\mu} = \frac{Pb}{a+b} \left( \frac{1}{\mu} - \frac{c}{b} \right)$
 <p>Fig. 4.</p>	<p>The brake wheel and friction block of the block brake are often grooved as shown in Fig. 4. In this case, substitute for <math>\mu</math> in the above equations the value <math>\frac{\mu}{\sin \alpha + \mu \cos \alpha}</math> where <math>\alpha</math> is one-half the angle included by the faces of the grooves.</p>

### Friction Wheels for Power Transmission

When a rotating member is driven intermittently and the rate of driving does not need to be positive, friction wheels are frequently used, especially when the amount of power to be transmitted is comparatively small. The driven wheels in a pair of friction disks should

always be made of a harder material than the driving wheels, so that if the driven wheel should be held stationary by the load, while the driving wheel revolves under its own pressure, a flat spot may not be rapidly worn on the driven wheel. The driven wheels, therefore, are usually made of iron, while the driving wheels are made of or covered with, rubber, paper, leather, wood or fiber. The safe working force per inch of face width of contact for various materials are as follows: Straw fiber, 150; leather fiber, 240; tarred fiber, 240; leather, 150; wood, 100 to 150; paper, 150. Coefficients of friction for different combinations of materials are given in the following table. Smaller values should be used for exceptionally high speeds, or when the transmission must be started while under load.

**Horsepower of Friction Wheels.**— Let  $D$  = diameter of friction wheel in inches;  $N$  = number of revolutions per minute;  $W$  = width of face in inches;  $f$  = coefficient of friction;  $P$  = force in pounds, per inch width of face. Then:

$$HP = \frac{3.1416 \times D \times N \times P \times W \times f}{33,000 \times 12}$$

Assume

$$\frac{3.1416 \times P \times f}{33,000 \times 12} = C$$

then,

$$\text{for } P = 100 \text{ and } f = 0.20, C = 0.00016$$

$$\text{for } P = 150 \text{ and } f = 0.20, C = 0.00024$$

$$\text{for } P = 200 \text{ and } f = 0.20, C = 0.00032$$

### Working Values of Coefficient of Friction

Materials	Coefficient of Friction	Materials	Coefficient of Friction
Straw fiber and cast iron	0.26	Tarred fiber and aluminum	0.18
Straw fiber and aluminum	0.27	Leather and cast iron	0.14
Leather fiber and cast iron	0.31	Leather and aluminum	0.22
Leather fiber and aluminum	0.30	Leather and type metal	0.25
Tarred fiber and cast iron	0.15	Wood and metal	0.25
Paper and cast iron	0.20		

The horsepower transmitted is then:

$$HP = D \times N \times W \times C$$

*Example:* Find the horsepower transmitted by a pair of friction wheels; the diameter of the driving wheel is 10 inches, and it revolves at 200 revolutions per minute. The width of the wheel is 2 inches. The force per inch width of face is 150 pounds, and the coefficient of friction 0.20.

$$HP = 10 \times 200 \times 2 \times 0.00024 = 0.96 \text{ horsepower}$$

### Horsepower Which May Be Transmitted by Means of a Clean Paper Friction Wheel of One-inch Face When Run Under a Force of 150 Pounds (Rockwood Mfg. Co.)

## KEYS AND KEYSEATS

### Metric Square and Rectangular Keys and Keyways

The ASME B18.25.1M standard covers requirements for square and rectangular parallel keys and keyways intended for both alignment of shafts and hubs, and transmitting torque between shafts and hubs. Keys covered by this standard have a relatively tight width tolerance. The deviations are less than the basic size. Keys with greater width tolerance and with deviations greater than the basic size are covered by ASME B18.25.3M. All dimensions in this standard are in millimeters (mm).

**Comparison with ISO R773-1969 and 2491-1974.**— This standard is based on ISO Standards R773-1969, *Rectangular or Square Parallel Keys* and their corresponding keyways, and 2491-1974, *Thin Parallel Keys* and their corresponding keyways (dimensions in millimeters). Product manufactured to this standard will meet the ISO standards. Because of tighter width tolerances in this standard, products manufactured to the ISO standard may not meet the requirements of this standard.

This standard differs from ISO in that it: a) does not restrict the corners of a key to be chamfered but allows either a chamfer or a radius on the key; and b) specifies a key material hardness rather than a tensile property.

**Tolerances.**— Many of the tolerances shown in [Tables 1 and 2](#) are from ANSI B4.2 (ISO 286-1 and ISO 286-2). As a result, in addition to plus-minus tolerances which are common in the U.S., some are expressed as plus-plus or minus-minus deviations from the basic size. For further interpretation of these tolerances refer to ANSI B4.2 or ISO 286.

**Designation.**— Keys conforming to this standard shall be designated by the following data, preferably in the sequence as follows: a) ASME document number; b) product name; c) nominal size, width ( $b$ )  $\times$  height ( $h$ )  $\times$  length; d) form; and e) hardness (if other than non-hardened).

*Examples:* ASME B18.25.1M square key  $3 \times 3 \times 15$  form B.

ASME B18.25.1 M rectangular key  $10 \times 6 \times 20$  form C hardened

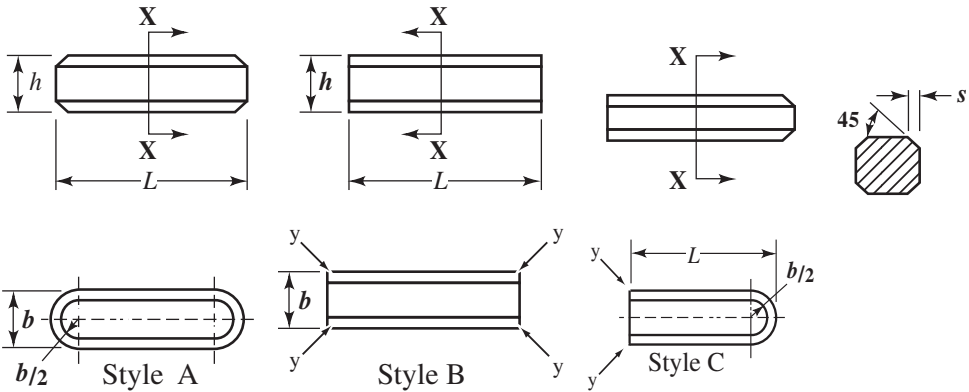

**Preferred Lengths and Tolerances.**— Preferred lengths and tolerances of square and rectangular keys are shown below. Tolerances are JS16. To minimize problems due to lack of straightness, key length should be less than 10 times the key width.

Length	$\pm$ Tolerances	Length	$\pm$ Tolerances
6	0.38	90, 100, 110	1.10
8, 10	0.45	125, 140, 150, 180	1.25
12, 14, 16, 18	0.56	200, 220, 250	1.45
20, 22, 25, 28	0.65	280	1.60
32, 36, 40, 45, 50	0.80	320, 360, 400	1.80
56, 63, 70, 80	0.95		

**Material Requirements.**— Standard steel keys shall have a hardness of 183 HV minimum. Hardened keys shall be alloy steel through hardened to a Vickers hardness of 390 to 510 HV. When other materials and properties are required, these shall be as agreed upon by the supplier and customer.

**Dimensions and Tolerances.**— Dimensions and tolerances for square and rectangular parallel keys are shown in [Table 1](#). Recommended dimensions and tolerances for keyways are shown in [Table 2](#).

<sup>a</sup> Some of the tolerances are expressed as plus-plus. See *Tolerances* on page 2476 for more information.

<sup>b</sup> Resulting fits: L indicates a clearance between the key and keyway; T indicates an interference between the key and keyway.

<sup>c</sup> This value differs from that given in ASME B18.25.1M, which is believed to be inaccurate.

**Metric Square and Rectangular Keys and Keyways:  
Width Tolerances and Deviations Greater than Basic Size**

This ASME B18.25.3M standard covers requirements for square and rectangular parallel keys and keyways intended for both alignment of shafts and hubs, and transmitting torque between shafts and hubs. Keys covered by this standard have a relatively loose width tolerance. All width tolerances are positive. Keys with minus width tolerances and a smaller tolerance range are covered by ASME B18.25.1M. Dimensions and tolerances for square and rectangular keys are shown in Table 3. Recommended dimensions and tolerances for keyways are shown in Table 4. All dimensions in this standard are in millimeters.

**Table 3. Dimensions and Tolerances for Metric Square and Rectangular Parallel Keys ASME B18.25.3M-1998**

<sup>a</sup> See *Preferred Lengths and Tolerances* on page 2482 for preferred maximum length of key except basic width of 2 mm.

**Comparison With ISO R773-1969 and 2491-1974.**— This standard has greater tolerances than ISO Standards R773-1969 and 2491-1974. Product manufactured to this standard is not interchangeable dimensionally with product manufactured to the ISO standards nor is product manufactured to the ISO standards dimensionally interchangeable with product manufactured to this standard. ISO standards do not include hardened keys.

**Preferred Lengths and Tolerances.**— Preferred lengths and tolerances of square and rectangular keys are shown below. Tolerances are JS 16 from ANSI B4.2. To minimize problems due to lack of straightness, key length should be less than 10 times the key width.

Length	±Tolerances	Length	±Tolerances
6	0.375	90, 100, 110	1.10
8, 10	0.45	125, 140, 160, 180	1.25
12, 14, 16, 18	0.55	200, 220, 250	1.45
20, 22, 25, 28	0.65	280	1.60
32, 36, 45, 50	0.80	320, 360, 400	1.80
56, 63, 70, 80	0.95

<sup>a</sup> In columns labeled "Fit," L indicates the maximum clearance between the key and keyway; the T indicates the maximum interference between the key and keyway.

<sup>b</sup> This value differs from that given in ASME B18.25.3M, which is believed to be inaccurate.

**Tolerances.**— Many of the tolerances shown in [Table 3](#) and [4](#) are from ANSI B4.2 (ISO 286-1 and ISO 286-2). As a result, in addition to plus-minus tolerances which are common in the U.S., some are expressed as plus-plus deviations from the basic size.

**Designation.**— Keys conforming to this standard shall be designed by the following data, preferably in the sequence shown: a) ASME document number; b) product name;

c) nominal size, width ( $b$ )  $\times$  height ( $h$ )  $\times$  length; d) style; and e) hardness (if other than non-hardened).

Optionally, a part identification number (PIN) per ASME B18.24.1 may be used.

**Material Requirements.**— Same as for ASME B18.25.1M. See page [2476](#).

### Metric Keyway Sizes According to Shaft Diameter

Based on BS 4235:Part 1:1972 (1986)

Nominal Shaft Diameter, $d$		Key Size, $b \times h$	Nominal Keyway Width, $b$	Nominal Shaft Diameter, $d$		Key Size, $b \times h$	Nominal Keyway Width, $b$
Over	Up to and Incl.			Over	Up to and Incl.		
Keyways for Square Parallel Keys				(Cont'd) Keyways for Rectangular Parallel Keys			
6	8	$2 \times 2$	2	85	95	$25 \times 14$	25
8	10	$3 \times 3$	3	95	110	$28 \times 16$	28
10	12	$4 \times 4$	4	110	130	$32 \times 18$	32
12	17	$5 \times 5$	5	130	150	$36 \times 20$	36
17	22	$6 \times 6$	6	150	170	$40 \times 22$	40
Keyways for Rectangular Parallel Keys				170	200	$45 \times 25$	45
22	30	$8 \times 7$	8	200	230	$50 \times 28$	50
30	38	$10 \times 8$	10	230	260	$56 \times 32$	56
38	44	$12 \times 8$	12	260	290	$63 \times 32$	63
44	50	$14 \times 9$	14	290	330	$70 \times 36$	70
50	58	$16 \times 10$	16	330	380	$80 \times 40$	80
58	65	$18 \times 11$	18	380	440	$90 \times 45$	90
65	75	$20 \times 12$	20	440	500	$100 \times 50$	100
75	85	$22 \times 14$	22	...	...	...	...

*Note:* This table is NOT part of ASME B18.25.1M or ASME B18.25.3M, and is included for reference only. The selection of the proper size and type of key must rest with the design authority.

### Metric Woodruff Keys and Keyways

This ASME B18.25.2M standard covers requirements for metric Woodruff keys and keyways intended for both alignment of shafts and hubs, and transmitting torque between shafts and hubs. All dimensions in this standard are in millimeters (mm). Dimensions and tolerances for Woodruff keys are shown in [Table 5](#). Recommended dimensions and tolerances for keyways are shown in [Table 6](#). For inch series Woodruff keys and keyseats, see *ANSI Standard Woodruff Keys and Keyseats* starting on page [2493](#).

**Comparison With ISO 3912-1977.**— This standard is based on ISO 3912-1977, *Woodruff Keys and Keyways*. However, to improve manufacturability, tolerances are decreased for the keyway width. The resulting fit is approximately the same. Keys manufactured to this standard are functionally interchangeable with keys manufactured to the ISO standard. Because of tighter width tolerances in this standard, products manufactured to the ISO standard may not meet the requirements of this standard.

ASME B18.25.2M also differs from ISO 3912 in that it: a) does not restrict the corners of a key to be chamfered but allows either a chamfer or a radius on the key; b) specifies a key material hardness rather than a tensile property; and c) specifies h12 rather than h11 for the tolerance of the height of the keys.

**Tolerances.**— Many of the tolerances shown in Tables 5 and 6 are from ANSI B4.2, Preferred Metric Limits and Fits (ISO 286-1 and ISO 286-2). As a result in addition to plus-minus tolerances which are common in the U.S. some are expressed as plus-plus deviations from the basic size.

**Table 5. Dimensions for Metric Woodruff Keys ASME B18.25.2M-1996**

Key Size $b \times h \times D$	Width		Height				Diameter, $D$		Chamfer or Radius, $s$	
	$b$	Tolerance	$h_1$	Tolerance h12	$h_2^a$	Tolerance h12	$D$	Tolerance h12	Min.	Max.
$1 \times 1.4 \times 4$	1		1.4	0	1.1		4	0 -0.120		
$1.5 \times 2.6 \times 7$	1.5		2.6	-0.10	2.1	0	7	0		
$2 \times 2.6 \times 7$	2		2.6		2.1	-0.10	7	0	0.16	0.25
$2 \times 3.7 \times 10$	2		3.7	0	3.0		10	-0.150		
$2.5 \times 3.7 \times 10$	2.5		3.7	-0.12	3.0		10	0		
$3 \times 5 \times 13$	3		5.0		4.0		13	0		
$3 \times 6.5 \times 16$	3		6.5		5.2		16	-0.180		
$4 \times 6.5 \times 16$	4		6.5		5.2		16	0		
$4 \times 7.5 \times 19$	4	0 -0.025	7.5		6.0	0 -0.12	19	0 -0.210		
$5 \times 6.5 \times 16$	5		6.5	0 -0.15	5.2		16	0 -0.180		
$5 \times 7.5 \times 19$	5		7.5		6.0		19	0	0.25	0.40
$5 \times 9 \times 22$	5		9.0		7.2		22	0		
$6 \times 9 \times 22$	6		9.0		7.2	0	22	-0.210		
$6 \times 10 \times 25$	6		10.0		8.0	-0.15	25	0		
$8 \times 11 \times 28$	8		11.0		8.8		28	0		
$10 \times 13 \times 32$	10		13.0	0 -0.18	10.4	0 -0.18	32	0 -0.250	0.40	0.60

<sup>a</sup>Height  $h_2$  is based on 0.80 times height  $h_1$ .

**Designation.**— Keys conforming to this standard shall be designated by the following data, preferably in the sequence as follows: a) ASME document number; b) product name; c) nominal size, width ( $b$ )  $\times$  height ( $h$ )  $\times$  length; d) form; and e) hardness (if other than non-hardened).

*Example:* ASME B18.25.2M, Woodruff Key  $6 \times 10 \times 25$  normal hardened;

ASME B18.25.2M, Woodruff Key  $3 \times 5 \times 13$  Whitney.

**Material Requirements.**— Same as for ASME B18.25.1M. See page 2476.

**Advantages of Woodruff Keys.**— In the Woodruff key system, half-circular disks of steel are used as keys, the half-circular side of the key being inserted into the keyseat. Part of the key projects and enters into a keyway in the part to be keyed to the shaft in the ordinary way. The advantage of this type of key is that the keyway is easily milled by simply sinking a milling cutter, of the same diameter as the diameter of the stock from which the keys are made, into the shaft. The keys are also very cheaply made, as they are simply cut off from round bar stock and milled apart in the center. Examples of Woodruff keyseat cutters are shown on page 869.

**Table 6. Keyway Dimensions for Metric Woodruff Keys ASME B18.25.2M-1996**

Key Size <sup>a</sup> $b \times h_1 \times D$	Width						Depth				Radius, $R$	
	Basic Size	Tolerance <sup>b</sup>					Shaft, $t_1$		Hub, $t_2$

<sup>a</sup>The nominal key diameter is the minimum keyway diameter.

<sup>b</sup>Some of the tolerances are expressed as plus-plus or minus-minus. See *Tolerances* on page 2486 for more information.

**ANSI Standard Inch Series Keys and Keyseats.**— American National Standard, B17.1 Keys and Keyseats, based on current industry practice, was approved in 1967, and reaffirmed in 2008. This standard establishes a uniform relationship between shaft sizes and key sizes for parallel and taper keys as shown in **Table 1**. Other data in this standard are given in **Tables 2 and 3** through **7**. The sizes and tolerances shown are for single key applications only.

The following definitions are given in the standard. *Note:* Inch dimensions converted to metric dimensions (enclosed in parentheses) are not included in the standard.

**Key:** A demountable machinery part which, when assembled into keyseats, provides a positive means for transmitting torque between the shaft and hub.

**Keyseat:** An axially located rectangular groove in a shaft or hub.

This standard recognizes that there are two classes of stock for parallel keys used by industry. One is a close, plus toleranced key stock and the other is a broad, negative toleranced bar stock. Based on the use of two types of stock, two classes of fit are shown:

**Class 1:** A clearance or metal-to-metal side fit obtained by using bar stock keys and keyseat tolerances as given in **Table 4**. This is a relatively free fit and applies only to parallel keys.

**Class 2:** A side fit, with possible interference or clearance, obtained by using key stock and keyseat tolerances as given in **Table 4**. This is a relatively tight fit.

**Class 3:** This is an interference side fit and is not tabulated in **Table 4** since the degree of interference has not been standardized. However, it is suggested that the top and bottom fit range given under Class 2 in **Table 4**, for parallel keys be used.

**Table 1. Key Size Versus Shaft Diameter ASME B17.1-1967 (R2013)**

Nominal Shaft Diameter		Nominal Key Size			Normal Keyseat Depth	
Over	To (Incl.)	Width, W	Height, H		H/2	
			Square	Rectangular	Square	Rectangular
$\frac{5}{16}$	$\frac{7}{16}$	$\frac{3}{32}$	$\frac{3}{32}$	...	$\frac{3}{64}$	...
$\frac{7}{16}$	$\frac{9}{16}$	$\frac{1}{8}$	$\frac{1}{8}$	$\frac{3}{32}$	$\frac{1}{16}$	$\frac{3}{64}$

$\frac{7}{8}$	$1\frac{1}{4}$	$\frac{1}{4}$	$\frac{1}{4}$	$\frac{3}{16}$	$\frac{1}{8}$	$\frac{3}{32}$
$1\frac{1}{4}$	$1\frac{3}{8}$	$\frac{5}{16}$	$\frac{5}{16}$	$\frac{1}{4}$	$\frac{5}{32}$	$\frac{1}{8}$
$1\frac{3}{8}$	$1\frac{3}{4}$	$\frac{3}{8}$	$\frac{3}{8}$	$\frac{1}{4}$	$\frac{3}{16}$	$\frac{1}{8}$
$1\frac{3}{4}$	$2\frac{1}{4}$	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{3}{8}$	$\frac{1}{4}$	$\frac{3}{16}$
$2\frac{1}{4}$	$2\frac{3}{4}$	$\frac{5}{8}$	$\frac{5}{8}$	$\frac{7}{16}$	$\frac{5}{16}$	$\frac{7}{32}$
$2\frac{3}{4}$	$3\frac{1}{4}$	$\frac{3}{4}$	$\frac{3}{4}$	$\frac{1}{2}$	$\frac{3}{8}$	$\frac{1}{4}$
$3\frac{1}{4}$	$3\frac{3}{4}$	$\frac{7}{8}$	$\frac{7}{8}$	$\frac{5}{8}$	$\frac{7}{16}$	$\frac{5}{16}$
$3\frac{3}{4}$	$4\frac{1}{2}$	1	1	$\frac{3}{4}$	$\frac{1}{2}$	$\frac{3}{8}$
$4\frac{1}{2}$	$5\frac{1}{2}$	$1\frac{1}{4}$	$1\frac{1}{4}$	$\frac{7}{8}$	$\frac{5}{8}$	$\frac{7}{16}$
$5\frac{1}{2}$	$6\frac{1}{2}$	$1\frac{1}{2}$	$1\frac{1}{2}$	1	$\frac{3}{4}$	$\frac{1}{2}$
Square Keys preferred for shaft diameters above this line; rectangular keys, below						
$6\frac{1}{2}$	$7\frac{1}{2}$	$1\frac{3}{4}$	$1\frac{3}{4}$	$1\frac{1}{2}$ <sup>a</sup>	$\frac{7}{8}$	$\frac{3}{4}$
$7\frac{1}{2}$	9	2	2	$1\frac{1}{2}$	1	$\frac{3}{4}$
9	11	$2\frac{1}{2}$	$2\frac{1}{2}$	$1\frac{3}{4}$	$1\frac{1}{4}$	$\frac{7}{8}$

<sup>a</sup> Some key standards show  $1\frac{1}{4}$  inches; preferred height is  $1\frac{1}{2}$  inches.

All dimensions are given in inches. For larger shaft sizes, see *ANSI Standard Woodruff Keys and Keyseats*.

**Key Size vs. Shaft Diameter:** Shaft diameters are listed in **Table 1** for identification of various key sizes and are not intended to establish shaft dimensions, tolerances or selections. For a stepped shaft, the size of a key is determined by the diameter of the shaft at the point of location of the key. Up through  $6\frac{1}{2}$ -inch (165.1 mm) diameter shafts square keys are preferred; rectangular keys are preferred for larger shafts.

If special considerations dictate the use of a keyseat in the hub shallower than the preferred nominal depth shown, it is recommended that the tabulated preferred nominal standard keyseat always be used in the shaft.

**Keyseat Alignment Tolerances:** A tolerance of 0.010 inch (0.254 mm), max is provided for offset (due to parallel displacement of keyseat centerline from centerline of shaft or bore) of keyseats in shaft and bore. The following tolerances for maximum lead (due to angular displacement of keyseat centerline from centerline of shaft or bore and measured at right angles to the shaft or bore centerline) of keyseats in shaft and bore are specified: 0.002 inch (0.0508 mm) for keyseat length up to and including 4 inches (101.6 mm); 0.0005 inch per inch of length (0.0127 mm per mm) for keyseat lengths above 4 inches to and including 10 inches (254 mm); and 0.005 inch (0.127 mm) for keyseat lengths above 10 inches. For the effect of keyways on shaft strength, see *Effect of Keyways on Shaft Strength* on page 293.

All dimensions are given in inches.

The key numbers indicate nominal key dimensions. The last two digits give the nominal diameter  $B$  in eighths of an inch and the digits preceding the last two give the nominal width  $W$  in thirty-seconds of an inch.

The key numbers with the -1 designation, while representing the nominal key size have a shorter length  $F$  and due to a greater distance below center  $E$  are less in height than the keys of the same number without the -1 designation.

<sup>a</sup> These Width *A* values were set with the maximum keyseat (shaft) width as that figure which will receive a key with the greatest amount of looseness consistent with assuring the key's sticking in the keyseat (shaft). Minimum keyseat width is that figure permitting the largest shaft distortion acceptable when assembling maximum key in minimum keyseat. Dimensions *A*, *B*, *C*, *D* are taken at side intersection.

All dimensions are given in inches.

The following definitions are given in this standard:

**Woodruff Key:** A demountable machinery part which, when assembled into key-seats, provides a positive means for transmitting torque between the shaft and hub.

**Woodruff Key Number:** An identification number by which the size of key may be readily determined.

**Woodruff Keyseat—Shaft:** The circular pocket in which the key is retained.

**Woodruff Keyseat—Hub:** An axially located rectangular groove in a hub. (This has been referred to as a keyway.)

**Woodruff Keyseat Milling Cutter:** An arbor type or shank type milling cutter normally used for milling Woodruff keyseats in shafts (see page 869).

**Chamfered Keys and Filleted Keyseats.**— In general practice, chamfered keys and filleted keyseats are not used. However, it is recognized that fillets in keyseats decrease stress concentration at corners. When used, fillet radii should be as large as possible without causing excessive bearing stresses due to reduced contact area between the key and its mating parts. Keys must be chamfered or rounded to clear fillet radii. Values in [Table 5](#) assume general conditions and should be used only as a guide when critical stresses are encountered.

✦ **Depths for Milling Keyseats.**— [Table 11](#) on page 2499 has been compiled to facilitate the accurate milling of keyseats. This table gives the distance  $M$  (see illustration accompanying table) between the top of the shaft and a line passing through the upper corners or edges of the keyseat. Dimension  $M$  is calculated by the formula:  $M = \frac{1}{2}(S - \sqrt{S^2 - E^2})$  where  $S$  is diameter of shaft, and  $E$  is width of keyseat. A simple approximate formula that gives  $M$  to within 0.001 inch is  $M = E^2 \div 4S$ .

**Keyseating Machines.**— The machines which are designed especially for cutting keyseats or keyways in the hubs of pulleys, gears, etc., are generally known as keyseaters. Machines of this class usually have a base or frame which contains the mechanism for imparting a reciprocating motion to a cutter bar, which moves vertically for cutting a keyseat in the work. There are several types of machines which are used for internal keyseating operations in addition to the machines designed especially for this work. Broaching machines as well as slotters are commonly used, and keyseating is also done to some extent in shapers and planers.

**Other Key Types.**— The *sunk key* is the most common type and is of rectangular section that engages a groove or slot formed both in the shaft and hub of the gear or pulley. The width of an ordinary sunk key ordinarily is equal to about one-fourth of the shaft diameter and the thickness, when a flat key is preferred to the square form, is usually about one-sixth of the shaft diameter; these proportions are varied somewhat by different manufacturers.

The *flat key* is a rectangular shape which bears upon a flat surface formed on one side of the shaft. The *draw* or *gib key* is a sunk key which has a head by means of which it can be removed. The *round tapered key* is simply a taper pin which is driven into a hole that is partly in the shaft and partly in the hub; this form is used for light work. The name *feather* or *spline* is applied to a key which is fixed to either a shaft or hub, as when a gear must be driven by a shaft, but at the same time be free to slide in a lengthwise direction.

The taper of American Standard square and flat keys is 1.8 inch per foot.

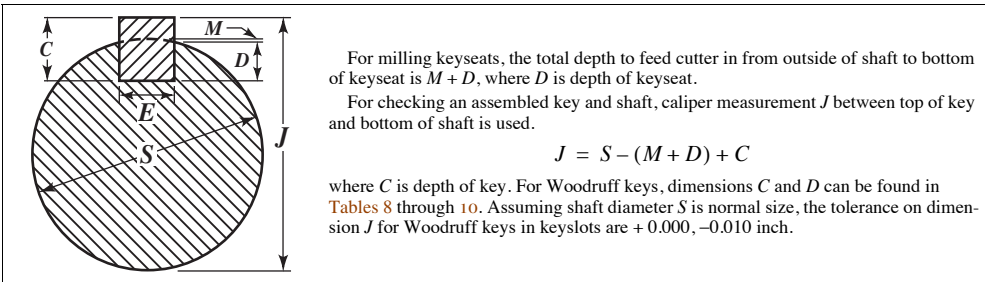

The *saddle key* does not enter a slot in the shaft. It has parallel sides and is curved on its under side to fit the shaft. It is slightly tapered on top so that, when it is driven tightly in place, the shaft is held by frictional resistance. This key should be fitted so that it bears lightly on the sides and heavily between the shaft and hub throughout its entire length. As the drive with this type of key is not positive, it is only used where there is little power to transmit. It is an inexpensive method of keying, as the shaft does not need to be machined.

**Effect of Keyways on Shaft Strength.**— See *SHAFTS* starting on page 287 and *Effect of Keyways on Shaft Strength* starting on page 293.

**British Standard Keys and Keyways.**— See *Keys and Keyways* in the *ADDITIONAL* material on *Machinery's Handbook 30 CD*.

**Cotters.**— A cotter is a form of key that is used to connect rods, etc., that are subjected either to tension or compression or both, the cotter being subjected to shearing stresses at two transverse cross-sections. When taper cotters are used for drawing and holding parts together, if the cotter is held in place by the friction between the bearing surfaces, the taper should not be too great. Ordinarily a taper varying from  $\frac{1}{4}$  to  $\frac{1}{2}$  inch per foot is used for plain cotters. When a set-screw or other device is used to prevent the cotter from backing out of its slot, the taper may vary from  $1\frac{1}{2}$  to 2 inches per foot.

## FLEXIBLE BELTS AND SHEAVES

Flexible belt drives are used in industrial power transmission applications, especially when the speeds of the driver and driven shafts must be different or when shafts must be widely separated. The trend toward higher speed prime movers and the need to achieve a slower, useful driven speed are additional factors favoring the use of belts. Belts have numerous advantages over other means of power transmission; these advantages include overall economy, cleanliness, no need for lubrication, lower maintenance costs, easy installation, dampening of shock loads, and the abilities to be used for clutching and variable speed power transmission between widely spaced shafts.

### Calculations for Belts and Pulleys

Belt speed plays an important role in the amount of load a friction drive system can transmit. Higher speeds will require higher preloads (increased belt tension) to compensate for the higher centrifugal force. In positive drive (toothed belt) systems, higher speeds generate dynamic forces caused by unavoidable tolerance errors that may result in increased tooth or pin stresses and shorter belt life.

**Pulley Diameters and Drive Ratios.**— Minimum pulley diameters determined by belt manufacturers are based on the minimum radius that a belt can wrap around a pulley without stressing the load-carrying members. For positive drive systems, minimum pulley diameters are also determined by the minimum number of teeth that must be engaged with the sprocket to guarantee the operating load.

Diameters of driving and driven pulleys determine the velocity ratio of the input relative to the output shaft and are derived from the following formulas: for all belt systems, velocity ratio  $V = D_{pi}/D_{po}$ , and for positive (toothed) drive systems, velocity ratio  $V = N_i/N_o$ , where  $D_{pi}$  is the pitch diameter of the driving pulley,  $D_{po}$  is the pitch diameter of the driven pulley,  $N_i$  is the number of teeth on the driving pulley, and  $N_o$  is the number of teeth on the driven pulley. For most drive systems, a velocity ratio of 8:1 is the largest that should be attempted with a single reduction drive, and 6:1 is a reasonable maximum.

**Wrap Angles and Center-to-Center Distances.**— The radial distance for which the belt is in contact with the pulley surface, or the number of teeth in engagement for positive drive belts, is called the wrap angle. Belt and sprocket combinations should be chosen to ensure a wrap angle of about  $120^\circ$  around the smaller pulley. The wrap angle should not be less than  $90^\circ$ , especially with positive drive belts, because if too few teeth are in engagement, the belt may jump a tooth or pin and timing or synchronization may be lost.

For flat belts, the minimum allowable center-to-center distance (CD) for any belt-and-sprocket combination should be chosen to ensure a minimum wrap angle around the smaller pulley. For high-velocity systems, a good rule of thumb is a minimum CD equal to the sum of the pitch diameter of the larger sprocket and one-half the pitch diameter of the smaller sprocket. This formula ensures a minimum wrap angle of approximately  $120^\circ$ , which is generally sufficient for friction drives and will ensure that positive drive belts do not jump teeth.

**Pulley Center Distances and Belt Lengths.**— Maximum center distances of pulleys should be about 15 to 20 times the pitch diameter of the smaller pulley. Greater spacing requires tight control of the belt tension because a small amount of stretch will cause a large drop in tension. Constant belt tension can be obtained by application of an adjustable tensioning pulley applied to the slack side of the belt. Friction drive systems using flat belts require much more tension than positive drive belt systems.

Belt length can be calculated from:  $L = 2C + \pi(D_2 + D_1)/2 + (D_2 - D_1)^2/4C$  for friction drives, and length  $L = 2C + \pi(D_2 + D_1)/2 + (D_2 + D_1)^2/4C$  for crossed belt friction belt drives, where  $C$  is the center distance,  $D_1$  is the pitch diameter of the small pulley, and  $D_2$  is

the pitch diameter of the large pulley. For serrated belt drives, the length determined by use of these equations should be divided by the serration pitch. The belt length must then be adjusted to provide a whole number of serrations.

**Pulley Diameters and Speeds.**— If  $D$  = diameter of driving pulley,  $d$  = diameter of driven pulley,  $S$  = speed of driving pulley, and  $s$  = speed of driven pulley:

$$D = \frac{d \times s}{S}, \quad d = \frac{D \times S}{s}, \quad S = \frac{d \times s}{D}, \quad \text{and} \quad s = \frac{D \times S}{d}$$

*Example 1:* If diameter of the driving pulley  $D$  is 24 inches, its speed is 100 rpm, and the driven pulley runs at 600 rpm, diameter of the driven pulley,  $d = 24 \times 100/600 = 4$  inches.

*Example 2:* If the diameter of the driving pulley  $D$  is 60 cm, its speed is 100 rpm, and the driven pulley is run at 600 rpm, the diameter of the driven pulley,  $d = 60 \times 100/600 = 10$  cm.

*Example 3:* If the diameter of the driven pulley  $d$  is 36 inches, its required speed is to be 150 rpm, and the speed of the driving pulley is to be 600 rpm, the diameter of the driving pulley  $D = 36 \times 150/600 = 9$  inches.

*Example 4:* If diameter of driven pulley  $d$  is 4 inches, its required speed is 800 rpm, and diameter of driving pulley  $D$  is 26 inches, speed of driving pulley =  $4 \times 800/26 = 123$  rpm. 

*Example 5:* If diameter of driven pulley  $d$  is 10 cm, its required speed is 800 rpm, and diameter of driving pulley  $D$  is 25 cm, speed of the driving pulley =  $10 \times 800/25 = 320$  rpm. 

*Example 6:* If the diameter of the driving pulley  $D$  is 15 inches and its speed is 180 rpm, and the diameter of the driven pulley  $d$  is 9 inches, then the speed of the driven pulley =  $15 \times 180/9 = 300$  rpm.

**Pulley Diameters in Compound Drive.**— If speeds of driving and driven pulleys,  $A$ ,  $B$ ,  $C$ , and  $D$  (see illustration) are known, the first step in finding their diameters is to form a fraction with the driving pulley speed as the numerator and the driven pulley speed as the denominator, and then reduce this fraction to its lowest terms. Resolve the numerator and the denominator into two pairs of factors (a pair being one factor in the numerator and one in the denominator) and, if necessary, multiply each pair by a trial number that will give pulleys of suitable diameters.

*Example 7:* If speed of pulley  $A$  is 260 rpm and the required speed of pulley  $D$  is 720 rpm, find the diameters of the four pulleys. Reduced to its lowest terms, the fraction  $260/720 = 13/36$ , which represents the required speed ratio. Resolve this ratio  $13/36$  into two factors: 

$$\frac{13}{36} = \frac{1 \times 13}{2 \times 18}$$

Multiply by trial numbers 12 and 1 to get:

$$\frac{(1 \times 12) \times (13 \times 1)}{(2 \times 12) \times (18 \times 1)} = \frac{12 \times 13}{24 \times 18}$$

Compound Drive with Four Pulleys.

The values 12 and 13 in the numerator represent the diameters of the *driven* pulleys,  $B$  and  $D$ , and the values 24 and 18 in the denominator represent the diameters of the *driving* pulleys,  $A$  and  $C$ , as shown in the illustration.

**Speed of Driven Pulley in Compound Drive.**— If diameters of pulleys  $A$ ,  $B$ ,  $C$ , and  $D$  (see illustration above), and speed of pulley  $A$  are known, the speed of the driven pulley  $D$  is found from:

$$\frac{\text{driving pulley diameter}}{\text{driven pulley diameter}} \times \frac{\text{driving pulley diameter}}{\text{driven pulley diameter}} \times \text{speed of first driving pulley}$$

**Example 8:** If the diameters of driving pulleys  $A$  and  $C$  are 18 and 24 inches, diameters of driven pulleys  $B$  and  $D$  are 12 and 13 inches, and the speed of driving pulley  $A$  is 260 rpm, speed of driven pulley

$$D = \frac{18 \times 24}{12 \times 13} \times 260 = 720 \text{ rpm}$$

**Length of Belt Traversing Three Pulleys.**— The length  $L$  of a belt traversing three pulleys, as shown in the diagram below, and touching them on one side only, can be found by the following formula.

Flat Belt Traversing Three Pulleys

Referring to the diagram,  $R_1$ ,  $R_2$ , and  $R_3$  are the radii of the three pulleys;  $C_{12}$ ,  $C_{13}$ , and  $C_{23}$  are the center distances; and  $\alpha_1$ ,  $\alpha_2$ , and  $\alpha_3$  are the angles, in radians, of the triangle formed by the center distances. Then:

$$L = C_{12} + C_{13} + C_{23} + \frac{1}{2} \left[ \frac{(R_2 - R_1)^2}{C_{12}} + \frac{(R_3 - R_1)^2}{C_{13}} + \frac{(R_3 - R_2)^2}{C_{23}} \right] + \pi(R_1 + R_2 + R_3) - (\alpha_1 R_1 + \alpha_2 R_2 + \alpha_3 R_3)$$

**Example 9:** Assume  $R_1 = 1$ ,  $R_2 = 2$ ,  $R_3 = 4$ ,  $C_{12} = 10$ ,  $C_{13} = 6$ ,  $C_{23} = 8$ ,  $\alpha_1 = 53.13$  degrees or 0.9273 radian,  $\alpha_2 = 36.87$  degrees or 0.6435 radian, and  $\alpha_3 = 90$  degrees or 1.5708 radians. Then:

$$\begin{aligned} L &= 10 + 6 + 8 + \frac{1}{2} \left[ \frac{(2-1)^2}{10} + \frac{(4-1)^2}{6} + \frac{(4-2)^2}{8} \right] \\ &\quad + \pi(1 + 2 + 4) + (0.9273 \times 1 + 0.6435 \times 2 + 1.5708 \times 4) \\ &= 24 + 1.05 + 21.9911 - 8.4975 = 38.5436 \end{aligned}$$

**Power Transmitted by Belts.**— With belt drives, the force that produces work acts on the rim of a pulley or sheave and causes it to rotate. Since a belt on a drive must be tight enough to prevent slip, there is a belt pull on both sides of a driven wheel. When a drive is stationary or operating with no power transmitted, the pulls on both sides of the driven wheel are equal. When the drive is transmitting power, however, the pulls are not the same. There is a tight side tension  $T_T$  and a slack side tension,  $T_S$ . The difference between these two pulls ( $T_T - T_S$ ) is called *effective pull* or *net pull*. This effective pull is applied at the rim of the pulley and is the force that produces work.

Net pull equals horsepower (HP)  $\times$  33,000  $\div$  belt speed (fpm). Belt speed in fpm can be set by changing the pulley, sprocket, or sheave diameter. The shaft speeds remain the same. Belt speed is directly related to pulley diameter. Double the diameter and the total belt pull is cut in half, reducing the load on the shafts and bearings.

A belt experiences three types of tension as it rotates around a pulley: working tension (tight side – slack side), bending tension, and centrifugal tension.

The *tension ratio* ( $R$ ) equals tight side divided by slack side tension (measured in pounds). The larger  $R$  is, the closer a V-belt is to slipping — the belt is too loose. (Synchronous belts do not slip, because they depend on the tooth grip principle.)

In addition to working tension (tight side – slack side), two other tensions are developed in a belt when it is operating on a drive. *Bending tension*  $T_B$  occurs when the belt bends around the pulley. One part of the belt is in tension and the other is in compression, so compressive stresses also occur. The amount of tension depends on the belt's construction and the pulley diameter. *Centrifugal tension* ( $T_C$ ) occurs as the belt rotates around the drive and is calculated by  $T_C = MV^2$ , where  $T_C$  is centrifugal tension in pounds,  $M$  is a constant dependent on the belt's weight, and  $V$  is the belt velocity in feet per minute. Neither the bending nor centrifugal tensions are imposed on the pulley, shaft, or bearing — only on the belt.

Combining these three types of tension results in *peak tension*, which is important in determining the degree of performance or belt life:  $T_{\text{peak}} = T_T + T_B + T_C$ .

**Measuring the Effective Length.**— The effective length of a V-belt is determined by placing the belt on a measuring device having two equal diameter sheaves with standard groove dimensions. The shaft of one of the sheaves is fixed. A specified measuring tension is applied to the housing for the shaft of the other sheave, moving it along a graduated scale. The belt is rotated around the sheaves at least two revolutions of the belt to seat it properly in the sheave grooves and to divide the total tension equally between the two strands of the belt.

The effective length of the belt is obtained by adding the effective (outside) circumference of one of the measuring sheaves to twice the center distance. Synchronous belts are measured in a similar manner.

The following sections cover common belts used in industrial applications for power transmission and specified in Rubber Manufacturers Association (RMA), Mechanical Power Transmission Association (MPTA), and The Rubber Association of Canada (RAC) standards. The information presented does not apply to automotive or agricultural drives, for which other standards exist. The belts covered in this section are Narrow, Classical, Double, and Light-Duty V-Belts, V-Ribbed Belts, Variable-Speed Belts, 60 deg V-Belts, and Synchronous (Timing) Belts.

### Flat Belting

Flat belting was originally made from leather because it was the most durable material available and could easily be cut and joined to make a driving belt suitable for use with cylindrical or domed pulleys. This type of belting was popular because it could be used to

transmit high torques over long distances and it was employed in factories to drive many small machines from a large common power source such as a steam engine. As electric motors became smaller, more efficient, and more powerful, and new types of belts and chains were made possible by modern materials and manufacturing processes, flat belts fell out of favor. Flat belts are still used for some drive purposes, but leather has been replaced by other natural and synthetic materials such as urethanes, which can be reinforced by high-strength polyamide or steel fabrics to provide properties such as resistance to stretching. The high modulus of elasticity in these flat belts eliminates the need for periodic retensioning that is usually necessary with V-belts.

Driving belts can be given a coating of an elastomer with a high coefficient of friction, to enable belts to grip pulleys without the degree of tension common with earlier materials. Urethanes are commonly used for driving belts where high resistance to abrasion is required, and also resist attack by chemical solvents of most kinds. Flat belts having good resistance to high temperatures are also available. Typical properties of polyurethane belts include tensile strength up to 40,000 psi (276 MPa), depending on reinforcement type and Shore hardness of 85 to 95. Most polyurethane belts are installed under tension. The amount of tension varies with the belt cross-section, being greater for belts of small section. Belt tension can be measured by marking lines 10 inches, or 100 mm, apart on an installed belt, then applying tension until the separation increases by the desired percentage. For 2 percent tension, lines on the tensioned belt would be 10.2 inches, or 102 mm, apart. Mechanical failure may result when belt tensioning is excessive, and 2 to 2.5 percent elongation should be regarded as the limit.

Flat belts offer high load capacities and are capable of transmitting power over long distances, maintaining relative rotational direction, can operate without lubricants, and are generally inexpensive to maintain or replace when worn. Flat belt systems will operate with little maintenance and only periodic adjustment. Because they transmit motion by friction, flat belts have the ability to slip under excessive loads, providing a fail-safe action to guard against malfunctions. This advantage is offset by the problem that friction drives can both slip and creep so that they do not offer exact, consistent velocity ratios nor precision timing between input and output shafts. Flat belts can be made to any desired length, being joined by reliable chemical bonding processes.

Increasing centrifugal force has less effect on the load-carrying capacity of flat belts at high speeds than it has on V-belts, for instance. The low thickness of a flat belt, compared with a V-belt, places its center of gravity near the pulley surface. Flat belts therefore may be run at surface speeds of up to 16,000 or even 20,000 ft/min (81.28 to 101.6 m/s), although ideal speeds are in the range of 3,000 to 10,000 ft/min (15.25 to 50.8 m/s). Elastomeric drive surfaces on flat belts have eliminated the need for belt dressings that were often needed to keep leather belts in place. These surface coatings can also contain antistatic materials. Belt pulley wear and noise are low with flat belts shock and vibration are damped, and efficiency is generally greater than 98% compared with 96% for V-belts.

Driving belt load capacities can be calculated from torque  $T = F(d/2)$  and horsepower  $HP = T \times rpm/396,000$ , where  $T$  is the torque in in-lb,  $F$  is the force transmitted in lb, and  $d$  is the pulley diameter in inches. Pulley width is usually about 10 percent larger than the belt, and for good tracking, pulleys are often crowned by 0.012–0.10 inch (0.305–2.54 mm) for diameters in the range of 1.5–80 inches (3.8–203 cm).

Before a belt specification is written, the system should be checked for excessive startup and shut-down loads, which sometimes are more than 10 percent above operating conditions. In overcoming such loads, the belt will transmit considerably more force than during normal operation. Large starting and stopping forces will also shorten belt life unless they are taken into account during the design stage.

**Flat Belt Pulleys.**— Flat belt pulleys are usually made of cast iron, fabricated steel, paper, fiber, or various kinds of wood. They may be solid or split and in either case the hub may be split for clamping to the shaft.

Pulley face widths are nominally the same as the widths of the belts they are to carry. The pulley face should be approximately one inch more than the belt width for belts under 12 inches (30.5 cm) wide, 2 inches (5.1 cm) more for belts from 12 to 24 inches (30.5–61 cm) wide, and 3 inches (7.6 cm) more for belts over 24 inches (61 cm) in width.

Belts may be made to center themselves by the use of crowned pulleys. The usual amount of crowning is  $\frac{1}{8}$  inch per foot (10.4 mm per meter) of pulley width. Thus, the difference in maximum and minimum radii of a crowned 6-inch (152.4 mm) wide pulley would be  $\frac{1}{16}$  inch (1.59 mm). Crowned pulleys have a rim section either with a convex curve or a flat V form. Flanges on the sides of flat belt pulleys are in general undesirable as the belt tends to crawl against them. Too much crown is undesirable because of the tendency to “break the belt's back.” This is particularly true for riding idlers close to driving pulleys where the curvature of the belt changes rapidly from one pulley to the other. Here, the idler should under no circumstances be crowned and the adjacent pulley should have very little crown. Pulleys carrying shifting belts are not crowned.

Open belt drives connecting pulleys on short centers with one pulley considerably larger than the other may be unsatisfactory due to the small angle of wrap on the smaller pulley. This angle may be increased by the use of idler pulleys on one or both sides of the belt.

### V-Belts

**Narrow V-Belts ANSI/RMA IP-22.**—Narrow V-belts serve the same applications as multiple, classical V-belts, but allow for a lighter, more compact drive. Three basic cross sections—3V and 3VX, 5V and 5VX, and 8V—are provided, as shown in Fig. 1. The 3VX and 5VX are molded, notched V-belts that have greater power capacity than conventional belts. Narrow V-belts are specified by cross section and effective length and have top widths ranging from  $\frac{3}{8}$  to 1 inch (9.525–25.4 mm).

Narrow V-belts usually provide substantial weight and space savings over classical belts. Some narrow belts can transmit up to three times the horsepower of conventional belts in the same drive space, or the same horsepower in one-third to one-half the space. These belts are designed to operate in multiples and are also available in the joined configuration.

*Belt Cross Sections:* Nominal dimensions of the three cross sections are given in Fig. 1.

*Belt Size Designation:* Narrow V-belt sizes are identified by a standard belt number. The first figure of this number followed by the letter V denotes the belt cross section. An X following the V indicates a notched cross section. The remaining figures show the effective belt length in tenths of an inch. For example, the number 5VX1400 designates a notched V-belt with a 5V cross section and an effective length of 140.0 in. Standard effective lengths of narrow V-belts are shown in Table 1.

Fig. 1. Nominal Narrow V-Belt Dimensions

*Sheave Dimensions:* Groove angles and dimensions for sheaves and face widths of sheaves for multiple belt drives are given in Tables 2a and 2b, along with various tolerance values. Standard sheave outside diameters are given in Table 3.

**Table 1. Narrow V-Belt Standard Effective Lengths ANSI/RMA IP-22 (1983)**

<sup>a</sup> Deep groove sheaves are intended for drives with belt offset such as quarter-turn or vertical shaft drives. They may also be necessary where oscillations in the center distance may occur. Joined belts will not operate in deep groove sheaves.

<sup>b</sup> Summation of the deviations from  $S_g$  for all grooves in any one sheave should not exceed  $\pm 0.031$  in. The variations in pitch diameter between the grooves in any one sheave must be within the following limits: Up through 19.9 in. outside diameter and up through 6 grooves—0.010 in. (add 0.0005 in. for each additional groove), 20.0 in. and over on outside diameter and up through 10 grooves—0.015 in. (add 0.0005 in. for each additional groove). This variation can be obtained by measuring the distance across two measuring balls or rods placed in the grooves diametrically opposite each other. Comparing this “diameter over balls or rods” measurement between grooves will give the variation in pitch diameter.

Other Sheave Tolerances		
Outside Diameter	Radial Runout <sup>a</sup>	Axial Runout <sup>a</sup>
Up through 8.0 in. outside diameter $\pm 0.020$ in. For each additional inch of outside diameter add $\pm 0.0025$ in.	Up through 10.0 in. outside diameter 0.010 in. For each additional inch of outside diameter add 0.0005 in.	Up through 5.0 in. outside diameter 0.005 in. For each additional inch of outside diameter add 0.001 in.

<sup>a</sup> Total indicator reading.  
All dimensions in inches.

All dimensions in inches. The nominal diameters were selected from R40 and R80 preferred numbers (see page 661).

**Minimum Sheave Size:** The recommended minimum sheave size depends on the rpm of the faster shaft. Minimum sheave diameters for each belt cross-section are listed in **Table 3**.

**Cross Section Selection:** The chart (**Fig. 2**, on page 2510) is a guide to the V-belt cross section to use for any combination of design horsepower and speed of the faster shaft. When the intersection of the design horsepower and speed of the faster shaft falls near a line between two areas on the chart, it is advisable to investigate the possibilities in both areas. Special circumstances (such as space limitations) may lead to a choice of belt cross section different from that indicated in the chart.

**Horsepower Ratings:** The horsepower ratings of narrow V-belts can be calculated using the following formula:

$$\text{HP} = d_p r [K_1 - K_2/d_p - K_3(d_p r)^2 - K_4 \log(d_p r)] + K_{SR} r$$

where  $d_p$  = the pitch diameter of the small sheave, in.;  $r$  = rpm of the faster shaft divided by 1000;  $K_{SR}$ , speed ratio correction factor (**Table 4**), and  $K_1$ ,  $K_2$ ,  $K_3$ , and  $K_4$ , cross section parameters, are listed in the accompanying **Table 5**. This formula gives the basic horsepower rating, corrected for the speed ratio. To obtain the horsepower per belt for an arc of contact other than  $180^\circ$  and for belts shorter or longer than average length, multiply the horsepower obtained from this formula by the length correction factor (**Table 7**) and the arc of contact correction factor (**Table 6**).

*Arc of Contact:* Arc of contact on the small sheave may be determined by the formulas.

*Exact formula:* Arc of Contact (deg) =  $2 \cos^{-1} \left( \frac{D_e - d_e}{2C} \right)$

*Approximate formula:* Arc of Contact (deg) =  $180 - \frac{(D_e - d_e)60}{C}$

where:  $D_e$  = effective diameter of large sheave, inch or mm

$d_e$  = effective diameter of small sheave, inch or mm

$C$  = center distance, inch or mm

*Number of Belts:* The number of belts required for an application is obtained by dividing the design horsepower by the corrected horsepower rating for one belt.

**Classical V-Belts ANSI/RMA IP-20.**— Classical V-belts are most commonly used in heavy-duty applications and include these standard cross sections: A, AX, B, BX, C, CX, D, and DX (Fig. 3, page 2515). Top widths range from  $\frac{1}{2}$  to  $1\frac{1}{4}$  in. and are specified by cross section and nominal length. Classical belts can be teamed in multiples of two or more. These multiple drives can transmit up to several hundred horsepower continuously and absorb reasonable shock loads.

*Belt Cross Sections:* Nominal dimensions of the four cross sections are given in Fig. 3.

*Belt Size Designation:* Classical V-belt sizes are identified by a standard belt number consisting of a letter-numeral combination. The letter identifies the cross section; the numeral identifies the length as shown in Table 8. For example, A60 indicates an A cross section and a standard length designation of 60. An X following the section letter designation indicates a molded notch cross section, for example, AX60.

*Sheave Dimensions:* Groove angles and dimensions for sheaves and the face widths of sheaves for multiple belt drives are given in **Table 9**, along with various tolerance values.

<sup>a</sup>The A/AX, B/BX combination groove should be used when deep grooves are required for A or AX belts.

<sup>b</sup>Summation of the deviations from  $S_g$  for all grooves in any one sheave should not exceed  $\pm 0.050$  in. The variation in datum diameter between the grooves in any one sheave must be within the following limits: Through 19.9 in. outside diameter and through 6 grooves: 0.010 in. (add 0.0005 in. for each additional groove). 20.0 in. and over on outside diameter and through 10 grooves: 0.015 in. (add 0.0005 in. for each additional groove). This variation can be obtained by measuring the distance across two measuring balls or rods placed diametrically opposite each other in a groove. Comparing this "diameter over balls or rods" measurement between grooves will give the variation in datum diameter.

<sup>c</sup>Diameters shown for combination grooves are outside diameters. A specific datum diameter does not exist for either A or B belts in combination grooves.

<sup>d</sup>The  $b_d$  value shown for combination grooves is the "constant width" point, but does not represent a datum width for either A or B belts ( $2h_d = 0.340$  ref).

<sup>e</sup> $2h_d$  values for combination grooves are calculated based on  $b_d$  for A and B grooves.

<sup>f</sup>Deep groove sheaves are intended for drives with belt offset such as quarter-turn or vertical shaft drives. Joined belts will not operate in deep groove sheaves. Also, A and AX joined belts will not operate in A/AX and B/BX combination grooves.

Other Sheave Tolerances		
Outside Diameter	Radial Runout <sup>a</sup>	Axial Runout <sup>a</sup>
Through 8.0 in. outside diameter $\pm 0.020$ in. For each additional inch of outside diameter add $\pm 0.005$ in.	Through 10.0 in. outside diameter 0.010 in. For each additional inch of outside diameter add 0.0005 in.	Through 5.0 in. outside diameter 0.005 in. For each additional inch of outside diameter add 0.001 in.

<sup>a</sup>Total indicator readings.

**A, AX & B, BX Combin.** All dimensions in inches.

**Minimum Sheave Size:** The recommended minimum sheave size depends on the rpm of the faster shaft. Minimum sheave diameters for each cross-section belt are listed in [Table 9](#).

**Cross Section Selection:** Use the chart ([Fig. 4](#)) as a guide to the Classical V-belt cross section for any combination of design horsepower and speed of the faster shaft. When the intersection of the design horsepower and speed of the faster shaft falls near a line between two areas on the chart, the possibilities in both areas should be investigated. Special circumstances (such as space limitations) may lead to a choice of belt cross section different from that indicated in the chart.

Fig. 3. Classical V-Belt Cross Sections

**Horsepower Ratings:** The horsepower rating formulas for classical V-belts are:

$$\begin{aligned} \mathbf{A:HP} = d_p r \left[ 1.004 - \frac{1.652}{d_p} - 1.547 \times 10^{-4} (d_p r)^2 - 0.2126 \log(d_p r) \right] \\ + 1.652 r \left( 1 - \frac{1}{K_{SR}} \right) \end{aligned}$$

$$\begin{aligned} \mathbf{AX:HP} = d_p r \left[ 1.462 - \frac{2.239}{d_p} - 2.198 \times 10^{-4} (d_p r)^2 - 0.4238 \log(d_p r) \right] \\ + 2.239 r \left( 1 - \frac{1}{K_{SR}} \right) \end{aligned}$$

$$\begin{aligned} \mathbf{B:HP} = d_p r \left[ 1.769 - \frac{4.372}{d_p} - 3.081 \times 10^{-4} (d_p r)^2 - 0.3658 \log(d_p r) \right] \\ + 4.372 r \left( 1 - \frac{1}{K_{SR}} \right) \end{aligned}$$

$$\text{BX:HP} = d_p r \left[ 2.051 - \frac{3.532}{d_p} - 3.097 \times 10^{-4} (d_p r)^2 - 0.5735 \log(d_p r) \right] \\ + 3.532 r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$\text{C:HP} = d_p r \left[ 3.325 - \frac{12.07}{d_p} - 5.828 \times 10^{-4} (d_p r)^2 - 0.6886 \log(d_p r) \right] \\ + 12.07 r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$\text{CX:HP} = d_p r \left[ 3.272 - \frac{6.655}{d_p} - 5.298 \times 10^{-4} (d_p r)^2 - 0.8637 \log(d_p r) \right] \\ + 6.655 r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$\text{D:HP} = d_p r \left[ 7.160 - \frac{43.21}{d_p} - 1.384 \times 10^{-3} (d_p r)^2 - 1.454 \log(d_p r) \right] \\ + 43.21 r \left( 1 - \frac{1}{K_{SR}} \right)$$

Fig. 4. Selection of Classic V-Belt Cross Sections

In these equations,  $d_p$  = pitch diameter of small sheave, in.;  $r$  = rpm of the faster shaft divided by 1000;  $K_{SR}$  = speed ratio factor given in the accompanying Table 10. These formulas give the basic horsepower rating, corrected for the speed ratio. To obtain the horsepower per belt for an arc of contact other than 180 degrees and for belts shorter or longer than average length, multiply the horsepower obtained from these formulas by the length correction factor (Table 11) and the arc of contact correction factor (Table 12).

**Table 10. Speed Ratio Correction Factors**

Speed Ratio <sup>a</sup> Range	$K_{SR}$	Speed Ratio <sup>a</sup> Range	$K_{SR}$
1.00–1.01	1.0000	1.15–1.20	1.0586
1.02–1.04	1.0112	1.21–1.27	1.0711

**Number of Belts:** The number of belts required for an application is obtained by dividing the design horsepower by the corrected horsepower rating for one belt.

**Arc of Contact:** Arc of contact on the small sheave may be determined by the formulas.

$$\text{Exact formula: Arc of Contact (deg)} = 2 \cos^{-1} \left( \frac{D_d - d_d}{2C} \right)$$

$$\text{Approximate formula: Arc of Contact (deg)} = 180 - \left( \frac{(D_d - d_d)60}{C} \right)$$

where  $D_d$  = datum diameter of large sheave or flat pulley, inch or mm;  $d_d$  = datum diameter of small sheave, inch or mm; and,  $C$  = Center distance, inch or mm.

**Table 12. Arc of Contact Correction Factors**

$\frac{D_d - d_d}{C}$	Arc of Contact, $\theta$ , Small Sheave (deg)	Correction Factor		$\frac{D_d - d_d}{C}$	Arc of Contact, $\theta$ Small Sheave (deg)	Correction Factor

<sup>a</sup> A V-flat drive is one using a small sheave and a large diameter flat pulley.

**Double V-Belts ANSI/RMA IP-21.**— Double V-belts or hexagonal belts are used when power input or takeoff is required on both sides of the belt. Designed for use on “serpentine” drives, which consist of sheaves rotating in opposite directions, the belts are available in AA, BB, CC, and DD cross sections and operate in standard classical sheaves. They are specified by cross section and nominal length.

*Belt Cross Sections:* Nominal dimensions of the four cross sections are given in Fig. 5.

*Belt Size Designation:* Double V-belt sizes are identified by a standard belt number, consisting of a letter-numeral combination. The letters identify the cross section; the numbers identify length as shown in Column 1 of Table 13. For example, AA51 indicates an AA cross section and a standard length designation of 51.

**Table 13. Double V-Belt Standard Effective Lengths ANSI/RMA IP-21, 1984**

Standard Length Designation <sup>a</sup>	Standard Effective Length				Permissible Deviation from Standard Effective Length	Matching Limits for One Set

360	...	...	362.2	362.7	±2.0	0.60

<sup>a</sup> To specify belt size use the Standard Length Designation prefixed by the letters indicating cross section; for example, BB90.

All dimensions in inches.

*Sheave Dimensions:* Groove angles and dimensions for sheaves and face widths of sheaves for multiple belt drives are given in Table 14, along with various tolerance values.

**Table 14. Double V-Belt Sheave and Groove Dimensions** *ANSI/RMA IP-21, 1984*

Face width of standard and deep groove sheaves =  $s_g(N_g - 1) + 2S_e$ , where  $N_g$  = number of grooves

Standard Groove Dimensions											Drive Design Factors

<sup>a</sup> Summation of the deviations from  $S_g$  for all grooves in any one sheave shall not exceed  $\pm 0.050$  in. The variation in pitch diameter between the grooves in any one sheave must be within the following limits: Up through 19.9 in. outside diameter and up through 6 grooves: 0.010 in. (add 0.005 in. for each additional groove). 20.0 in. and over on outside diameter and up through 10 grooves: 0.015 in. (add 0.0005 in. for each additional groove). This variation can be obtained easily by measuring the distance across two measuring balls or rods placed diametrically opposite each other in a groove. Comparing this "diameter over balls or rods" measurement between grooves will give the variation in pitch diameter.

<sup>b</sup> The  $a_p$  values shown for the A/B combination sheaves are the geometrically derived values. These values may be different from those shown in manufacturer's catalogs.

<sup>c</sup> Deep groove sheaves are intended for drives with belt offset such as quarter-turn or vertical shaft drives.

Up through 4.0 in. outside diameter $\pm 0.020$ in. For each additional inch of outside diameter add $\pm 0.005$ in.	Up through 10.0 in. outside diameter $\pm 0.010$ in. For each additional inch of outside diameter add 0.0005 in.	Up through 5.0 in. outside diameter 0.005 in. For each additional inch of outside diameter add 0.001 in.

<sup>a</sup> Total indicator reading.  
All dimensions in inches.

**Cross Section Selection:** Use the chart (Fig. 6) as a guide to the double V-belt cross section for any combination of design horsepower and speed of the faster shaft. When the intersection of the design horsepower and speed of the faster shaft falls near a line between two areas on the chart, it is best to investigate the possibilities in both areas. Special circumstances (such as space limitations) may lead to a choice of belt cross section different from that indicated in the chart.

Fig. 5. Double-V Belt Cross Section

Fig. 6. Selection of Double V-Belt Cross Section

**Effective Diameter Determination:** Fig. 6 shows the relationship of effective diameter, outside diameter, and nomenclature diameter. Nomenclature diameter is used when ordering sheaves for double V-belt drives. The effective diameter is determined as follows:

$$\text{Effective diameter} = \text{Nomenclature diameter} + 2h_d - 2a_p$$

The values of  $2h_d$  and  $2a_p$  are given in Table 14.

**Double V-belt Length Determination:** The effective belt length of a specific drive may be determined by making a scaled layout of the drive. Draw the sheaves in terms of their effective diameters and in the position when a new belt is applied and first brought to driv-

ing tension. Next, measure the tangents and calculate the effective arc length ( $AL_e$ ) of each sheave (see Table 15 for a glossary of terms):

$$AL_e = \frac{d_e \theta}{115}$$

The effective length of the belt will then be the sum of the tangents and the connecting arc lengths. Manufacturers may be consulted for mathematical calculation of effective belt length for specific drive applications.

**Table 15. Glossary of Terms for Double V-belt Calculations**

$AL_e$ = Length, arc, effective, in.	$R$ = Ratio, tight side to slack side tension
$2a_p$ = Diameter, differential, pitch to outside, in.	$R/(R - 1)$ = Factor, tension ratio
$d$ = Diameter, pitch, in. (same as effective diameter)	$r$ = Angular velocity, faster shaft, rpm/1000
$d_e$ = Diameter, effective, in.	$S$ = Speed, belt, fpm/1000
$2h_d$ = Diameter differential, nomenclature to outside, in.	$T_e$ = Tension, effective pull, lbf
$K_f$ = Factor, length - flex correction	$T_r$ = Tension, allowable tight side, lbf
$L_e$ = Length, effective, in.	$T_S$ = Tension, slack side, lbf
$n$ = Sheaves, number on drive	$T_T$ = Tension, tight side, lbf
$P_d$ = Power, design, horsepower (transmitted horsepower $\times$ service factor)	$\theta$ = Angle, arc of belt contact, deg

Fig. 7. Effective, Outside, and Nomenclature Sheave Diameters

**Number of Belts Determination:** The number of belts required may be determined on the basis of allowable tight side tension rating ( $T_r$ ) at the most severe sheave. The allowable tight side tensions per belt are given in Tables 16 through 19, and must be multiplied by the length-flex correction factors ( $K_f$ ) listed in Table 20. To select the allowable tight side tension from the tables for a given sheave, the belt speed and effective diameter of the sheave in question are required.

**Double V-Belt Drive Design Method:** The fourteen drive design steps are as follows:

- 1) Number the sheaves starting from the driver in the opposite direction to belt rotation; include the idlers.
- 2) Select the proper service factor for each loaded driven unit.
- 3) Multiply the horsepower requirement for each loaded driven sheave by the corresponding service factor. This is the design horsepower at each sheave.
- 4) Calculate driver design horsepower. This hp is equal to the sum of all the driven design horsepower.
- 5) Calculate belt speed ( $S$ ) in thousands of feet per minute:  $S = rd/3.820$ .
- 6) Calculate effective tension ( $T_e$ ) for each loaded sheave:  $T_e = 33P_d/S$ .
- 7) Determine minimum  $R/(R - 1)$  for each loaded sheave from Table 21 using the arc of contact determined from the drive layout.

8) In most drives, slippage will occur first at the driver sheave. Assume this to be true and calculate  $T_T$  and  $T_S$  for the driver:  $T_T = T_e [R/(R - 1)]$  and  $T_S = T_T - T_e$ . Use  $R/(R - 1)$  from Step 7 and  $T_e$  from Step 6 for the driver sheave.

9) Starting with the first driven sheave, determine  $T_T$  and  $T_S$  for each segment of the drive. The  $T_T$  for the driver becomes  $T_S$  for that sheave and is equal to  $T_T - T_e$ . Proceed around the drive in like manner.

10) Calculate actual  $R/(R - 1)$  for each sheave using:  $R/(R - 1) = T_T/T_e = T_T/(T_T - T_S)$ . The  $T_T$  and  $T_S$  values are for those determined in Step 9. If these values are equal to or greater than those determined in Step 7, the assumption that slippage will first occur at the driver is correct and the next two steps are not necessary. If the value is less, the assumption was not correct, so proceed with Step 11.

11) Take the sheave where the actual value  $R/(R - 1)$  (Step 10) is less than the minimum, as determined in Step 7, and calculate a new  $T_T$  and  $T_S$  for this sheave using the minimum  $R/(R - 1)$  as determined in Step 7:  $T_T = T_e [R/(R - 1)]$  and  $T_S = T_T - T_e$ .

12) Start with this sheave and recalculate the tension in each segment of the drive as in Step 9.

13) The length-flex factor ( $K_f$ ) is taken from Table 20. Before using this table, calculate the value of  $L_e/n$ . Be sure to use the appropriate belt cross-section column when selecting the correction factor.

14) Beginning with the driver sheave, determine the number of belts ( $N_b$ ) needed to satisfy the conditions at each loaded sheave using:  $N_b = T_T/T_r K_f$ . Note:  $T_T$  is tight side tension as determined in Step 9 or 11 and 12.  $T_r$  is allowable tight side tension as shown in Tables 18-21.  $K_f$  is the length-flex correction factor from Table 20. The sheave that requires the largest number of belts is the number of belts required for the drive. Any fraction of a belt should be treated as a whole belt.

**Table 16. Allowable Tight Side Tension for an AA Section**

Belt Speed (fpm)	Sheave Effective Diameter (in.)							
	3.0	3.5	4.0	4.5	5.0	5.5	6.0	6.5

60	...	0.99	0.92	0.88	...	...	...	...	...

**Tension Ratings:** The tension rating formulas are:

$$\text{AA } T_r = 118.5 - \frac{318.2}{d} - 0.8380S^2 - 25.76 \log S$$

$$\text{BB } T_r = 186.3 - \frac{665.1}{d} - 1.269S^2 - 39.02 \log S$$

$$\text{CC } T_r = 363.9 - \frac{2060}{d} - 2.400S^2 - 73.77 \log S$$

$$\text{DD } T_r = 783.1 - \frac{7790}{d} - 5.078S^2 - 156.1 \log S$$

where  $T_r$  = the allowable tight side tension for a double-V belt drive, lbf  
(not corrected for tension ratio or length-flex correction factor)

$d$  = pitch diameter of small sheave, inch

$S$  = belt speed, fpm/1000

**Table 21. Tension Ratio/Arc of Contact Factors**

Arc of Contact, $\theta$ (deg.)	Design $\frac{R}{R-1}$	Arc of Contact, $\theta$ (deg.)	Design $\frac{R}{R-1}$

190	1.22	60	2.41
180	1.25	50	2.77

**Minimum Sheave Size:** The recommended minimum sheave size depends on the rpm of the faster shaft. Minimum groove diameters for each belt cross section are listed in [Table 14](#).

**Light Duty V-Belts ANSI/RMA IP-23.**— Light duty V-belts are typically used with fractional horsepower motors or small engines, and are designed primarily for fractional horsepower service. These belts are intended and specifically designed for use with small diameter sheaves and drives of loads and service requirements that are within the capacity of a single belt.

Fig. 8. Light Duty V-Belt Cross Sections

The four belt cross sections and sheave groove sizes are 2L, 3L, 4L, and 5L. The 2L is generally used only by OEMs and is not covered in the RMA standards.

**Belt Cross Sections.**— Nominal dimensions of the four cross sections are given in [Fig. 8](#).

**Belt Size Designation.**— V-belt sizes are identified by a standard belt number, consisting of a letter-numeral combination. The first number and letter identify the cross section; the remaining numbers identify length as shown in [Table 22](#). For example, a 3L520 belt has a 3L cross section and a length of 52.0 in.

**Table 22. Light Duty V-Belt Standard Dimensions ANSI/RMA IP-23, 1968**

<sup>a</sup>Total indicator reading.  
All dimensions in inches.

**Horsepower Ratings:** The horsepower ratings for light duty V-belts can be calculated from the following formulas:

$$3L \quad HP = r \left( \frac{0.2164d^{0.91}}{r^{0.09}} - 0.2324 - 0.0001396r^2d^3 \right)$$

$$4L \quad HP = r \left( \frac{0.4666d^{0.91}}{r^{0.09}} - 0.7231 - 0.0002286r^2d^3 \right)$$

$$5L \quad HP = r \left( \frac{0.7748d^{0.91}}{r^{0.09}} - 1.727 - 0.0003641r^2d^3 \right)$$

where  $d = d_0 - 2a$ ;  $d_0$  = effective outside diameter of small sheave, in.;  $r$  = rpm of the faster shaft divided by 1000. The corrected horsepower rating is obtained by dividing the horsepower rating by the combined correction factor (Table 24), which accounts for drive geometry and service factor requirements.

**Table 24. Combined Correction Factors**

Type of Driven Unit	Speed Ratio	
	Less than 1.5	1.5 and Over
Fans and blowers	1.0	0.9
Domestic laundry machines	1.1	1.0
Centrifugal pumps	1.1	1.0
Generators	1.2	1.1
Rotary compressors	1.2	1.1
Machine tools	1.3	1.2
Reciprocating pumps	1.4	1.3
Reciprocating compressors	1.4	1.3
Woodworking machines	1.4	1.3

**V-Ribbed Belts ANSI/RMA IP-26.**— V-ribbed belts are a cross between flat belts and V-belts. The belt is basically flat with V-shaped ribs projecting from the bottom, which guide the belt and provide greater stability than that found in a flat belt. The ribs operate in grooved sheaves.

V-ribbed belts do not have the wedging action of a V-belt and thus operate at higher tensions. This design provides excellent performance in high-speed and serpentine applications, and in drives that utilize small diameter sheaves. The V-ribbed belt comes in five cross sections: H, J, K, L, and M, specified by effective length, cross section and number of ribs.

**Belt Cross Sections:** Nominal dimensions of the five cross sections are given in Table 25.

**Table 25. Nominal Dimensions of V-Ribbed Belt Cross Sections  
ANSI/RMA IP-26, 1977**

Cross Section	$h_b$	$S_g$	Standard Number of Ribs
H	0.12	0.063	...
J	0.16	0.092	4, 6, 10, 16, 20
K	0.24	0.140	...
L	0.38	0.185	6, 8, 10, 12, 14, 16, 18, 20
M	0.66	0.370	6, 8, 10, 12, 14, 16, 18, 20

All dimensions in inches.

**Table 26. V-Ribbed Belt Sheave and Groove Dimensions ANSI/RMA IP-26, 1977**

Face width =  $S_g(N_g - 1) + 2S_e$ , where  $N_g$  is number of grooves

Cross Section	Minimum Recommended Outside Diameter	$\alpha$ Groove Angle $\pm 0.25$ (deg)	$S_g^a$	$r_t$ +0.005, -0.000	$2a$	$r_b$	$h_g$ (min)	$d_B$ $\pm 0.0005$	$S_e$

J	0.80	40	0.092 $\pm 0.001$	0.008	0.030	0.015 +0.000 -0.005	0.071	0.0625	0.125 +0.030 -0.015
K	1.50	40	0.140 $\pm 0.002$	0.010	0.038	0.020 +0.000 -0.005	0.122	0.1093	0.125 +0.050 -0.000
L	3.00	40	0.185 $\pm 0.002$	0.015	0.058	0.015 +0.000 -0.005	0.183	0.1406	0.375 +0.075 -0.030
M	7.00	40	0.370 $\pm 0.003$	0.030	0.116	0.030 +0.000 -0.010	0.377	0.2812	0.500 +0.100 -0.040

<sup>a</sup> Summation of the deviations from  $S_g$  for all grooves in any one sheave shall not exceed  $\pm 0.010$  in.

Other Sheave Tolerances <sup>a</sup>				
Outside Diameter		Radial Runout <sup>b</sup>		Axial Runout <sup>b</sup>
Outside Diameter:		Outside Diameter:		
Up through 2.9 in.	$\pm 0.010$ in.	Up through 2.9 in.	0.005 in.	
Over 2.9 in. to and including 8.0 in.	$\pm 0.020$ in.	Over 2.9 in. to and including 10.0 in.	0.010 in.	
For each additional inch of outside diameter over 8.0 in., add $\pm 0.0025$ in.		For each additional inch of outside diameter over 10.0 in., add 0.0005 in.		

<sup>a</sup> Variations in pitch diameter between the grooves in any one sheave must be within the following limits: Up through 2.9 in. outside diameter and up through 6 grooves, 0.002 in. (add 0.001 in. for each additional groove); over 2.9 in. to and including 19.9 in. and up through 10 grooves, 0.005 in. (add 0.0002 in. for each additional groove); over 19.9 in. and up through 10 grooves, 0.010 in. (add 0.0005 in. for each additional groove). This variation can be obtained by measuring the distance across two measuring balls or rods placed in the grooves diametrically opposite each other. Comparing this "diameter-over-balls or -rods" measurement between grooves will give the variation in pitch diameter.

<sup>b</sup> Total indicator reading.

All dimensions in inches

**Belt Size Designation:** Belt sizes are identified by a standard belt number, which consists of belt effective length to the nearest tenth of an inch, a letter designating cross section, and the number of ribs. For example, 540L6 signifies a 54.0 in. effective length, L belt, 6 ribs wide.

**Sheave Dimensions.:** Groove angles and dimensions for sheaves and face widths of sheaves for multiple belt drives are given in [Table 26](#), along with various tolerance values.

**Cross Section Selection.:** Use the chart ([Fig. 9](#)) as a guide to the V-ribbed belt cross section for any combination of design horsepower and speed of the faster shaft. When the intersection of the design horsepower and speed of the faster shaft falls near a line between two areas on the chart, the possibilities in both areas should be explored. Special circumstances (such as space limitations) may lead to a choice of belt cross section different from that indicated in the chart. H and K cross sections are not included because of their specialized use. Belt manufacturers should be contacted for specific data.

Fig. 9. Selection of V-Ribbed Belt Cross Section

**Horsepower Ratings.:** The horsepower rating formulas are:

$$\mathbf{J: HP} = d_p r \left[ \frac{0.1240}{(d_p r)^{0.09}} - \frac{0.08663}{d_p} - 0.2318 \times 10^{-4} (d_p r)^2 \right] + 0.08663 r \left[ 1 - \frac{1}{K_{SR}} \right]$$

$$\mathbf{L: HP} = d_p r \left[ \frac{0.5761}{(d_p r)^{0.09}} - \frac{0.8987}{d_p} - 1.018 \times 10^{-4} (d_p r)^2 \right] + 0.8987 r \left[ 1 - \frac{1}{K_{SR}} \right]$$

$$\mathbf{M: HP} = d_p r \left[ \frac{1.975}{(d_p r)^{0.09}} - \frac{6.597}{d_p} - 3.922 \times 10^{-4} (d_p r)^2 \right] + 6.597 r \left[ 1 - \frac{1}{K_{SR}} \right]$$

In these equations,  $d_p$  = pitch diameter of the small sheave, in.;  $r$  = rpm of the faster shaft divided by 1000;  $K_{SR}$  = speed ratio factor given in the accompanying [Table 30](#). These formulas give the maximum horsepower per rib recommended, corrected for the speed ratio. To obtain the horsepower per rib for an arc of contact other than 180 degrees, and for belts longer or shorter than the average length, multiply the horsepower obtained from these formulas by the length correction factor ([Table 28](#)) and the arc of contact correction factor ([Table 29](#)).

1.10	113	0.77
1.20	106	0.74
1.30	99	0.71
1.40	91	0.67
1.50	83	0.63

*Number of Ribs:* The number of ribs required for an application is obtained by dividing the design horsepower by the corrected horsepower rating for one rib.

Arc of contact on the small sheave may be determined by the following formulas:

$$\text{Exact Formula: Arc of Contact (deg)} = 2 \cos^{-1} \left( \frac{D_o - d_o}{2C} \right)$$

$$\text{Approximate Formula: Arc of Contact (deg)} = 180 - \frac{(D_o - d_o)60}{C}$$

$D_o$  = effective outside diameter of large sheave, inch;  $d_o$  = effective outside diameter of small sheave, inch; and,  $C$  = center distance, inch.

<sup>a</sup>  $D_p/d_p$ , where  $D_p$  ( $d_p$ ) is the pitch diameter of the large (small) sheave.

**Variable Speed Belts ANSI/ RMA IP-25.**— For drives that require more speed variation than can be obtained with conventional industrial V-belts, standard-line variable-speed drives are available. These drives use special wide, thin belts. Package units of standard-line variable-speed belts and sheaves, combined with the motor and output gearbox, are available in ranges from approximately  $\frac{1}{2}$  through 100 horsepower.

The speed ranges of variable-speed drives can be much greater than those drives using classical V-belts. Speed ranges up to 10:1 can be obtained on lower horsepower units.

This section covers 12 variable speed belt cross sections and sheave groove sizes designed 1422V, 1922V, 2322V, 1926V, 2926V, 3226V, 2530V, 3230V, 4430V, 4036V, 4436V, and 4836V. The industry supplies many other sizes that are not listed in this section.

*Belt Cross Sections and Lengths:* Nominal dimensions of the 12 cross sections are given in **Table 31**, and lengths in **Table 32**.

<sup>a</sup>The effective width ( $b_e$ ), a reference dimension, is the same as the ideal top width of closed variable-speed sheave ( $b_g$ ) and the ideal top width of the companion sheave ( $b_g$ ).

Other Sheave Tolerances		
Outside Diameter	Radial Runout <sup>a</sup>	Axial Runout <sup>a</sup>
Up through 4.0 in. outside diameter For each additional inch of outside diameter add $\pm 0.005$ in.	$\pm 0.020$ in. Up through 10.0 in. outside diameter For each additional inch of outside diameter add 0.0005 in.	0.010 in. Up through 5.0 in. outside diameter For each additional inch of outside diameter add 0.001 in.

<sup>a</sup>Total indicator reading.

Surface Finish			
Machined Surface Area	Max Surface Roughness Height, $R_a$ (AA) ( $\mu$ in.)	Machined Surface Area	Max Surface Roughness Height, $R_a$ (AA) ( $\mu$ in.)
V-Sheave groove sidewalls	125	Straight bores with 0.002 in. or less total tolerance	125
Rim edges and ID, hub ends and OD	500	Taper and straight bores with total tolerance over 0.002 in.	250

All dimensions in inches, except where noted.

**Belt Size Designation:** Variable-speed belt sizes are identified by a standard belt number. The first two digits denote the belt top width in sixteenths of an inch; the third and fourth digits indicate the angle of the groove in which the belt is designed to operate. Letter V (for variable) follows the first four digits. The digits after the V indicate pitch length to the nearest 0.1 in. For example, 1422V450 is a belt of  $\frac{7}{8}$  in. ( $\frac{14}{16}$  in.) nominal top width designed to operate in a sheave of 22 degree groove angle and having a pitch length of 45.0 in.

**Sheave Groove Data:** A variable speed sheave is an assembly of movable parts, designed to permit one or both flanges of the sheave to be moved axially causing a radial movement of the variable speed belt in the sheave groove. This radial movement permits stepless speed variation within the physical limits of the sheave and the belt. A companion sheave may be a solid sheave having a constant diameter and groove profile or another variable sheave. Variable speed sheave designs should conform to the dimensions in Table 33 and Fig. 10. The included angle of the sheaves, top width, and clearance are boundary dimensions. Groove angles and dimensions of companion sheaves should conform to Table 33 and Fig. 11. Various tolerance values are also given in Table 33.

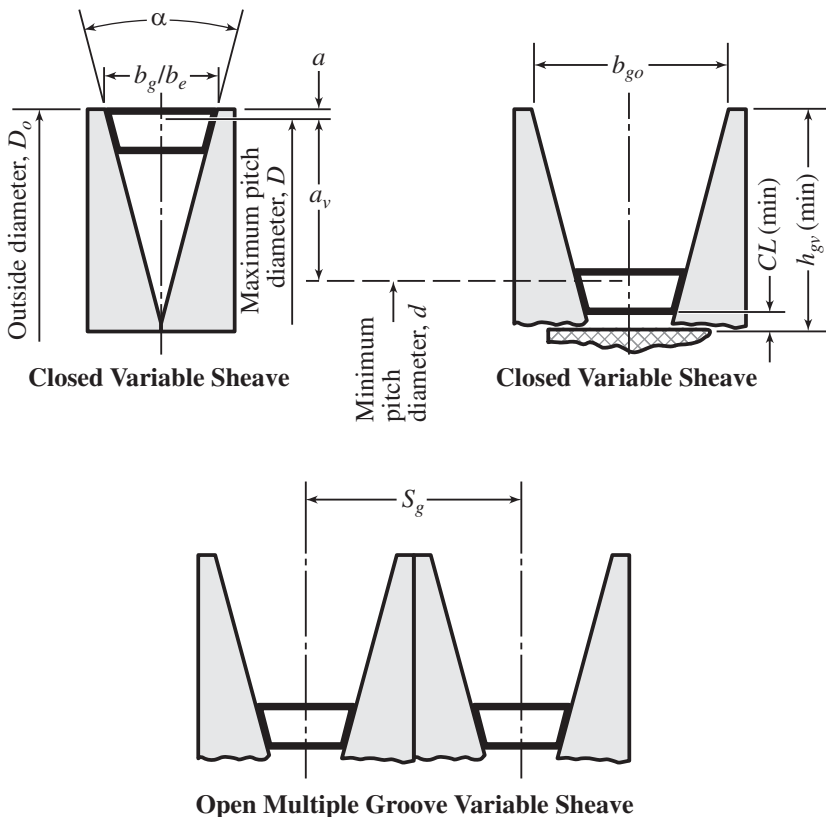

Fig. 10. Variable Sheaves

**Variable-Speed Drive Design:** Variable-speed belts are designed to operate in sheaves that are an assembly of movable parts. The sheave design permits one or both flanges of the sheave to be moved axially, causing a radial movement of the variable-speed belt in the sheave groove. The result is a stepless speed variation within the physical limits of the sheave and the variable-speed belt. Therefore, besides transmitting power, variable-speed belt drives provide speed variation.

Fig. 11. Companion Sheaves

The factors that determine the amount of pitch diameter change on variable-speed sheaves are belt top width, belt thickness, and sheave angle. This pitch diameter change, combined with the selected operating pitch diameters for a sheave, determines the possible speed variation.

The range of output speeds from a variable-speed sheave drive is established by the companion sheave and is a function of the ratio of the pitch diameter of the companion sheave to the maximum and minimum pitch diameters of the variable sheave. Speed variation is usually obtained by varying the center distance between the two sheaves. This type of drive seldom exceeds a speed variation of 3:1.

For a single variable-speed sheave drive, the speed variation

$$\text{Speed variation} = \frac{\text{PD Max}}{\text{PD Min}} \text{ (of variable sheave)}$$

For a dual variable-speed sheave drive, which is frequently referred to as a compound drive because both sheaves are variable, the speed variation is

$$\text{Speed variation} = \frac{DR(DN)}{dr(dn)}$$

where  $DR$  = max driver PD

$DNm$  = max driven PD

$dr$  = min driver PD

$dn$  = min driven PD

With this design, the center distance is generally fixed and speed variation is usually accomplished by mechanically altering the pitch diameter of one sheave. In this type of drive, the other sheave is spring loaded to make an opposite change in the pitch diameter and to provide the correct belt tension. Speed variations of up to 10:1 are common on this type of drive.

**Speed Ratio Adjustment:** All speed ratio changes must be made while the drives are running. Attempting to make adjustments while the unit is stopped creates unnecessary and possibly destructive forces on both the belt and sheaves. In stationary control drives, the belt tension should be released to allow the flanges to adjust without belt force interference.

**Cross Section Selection:** Selection of a variable speed belt cross section is based on the drive design horsepower and speed variation. Table 33 shows the maximum pitch diameter variation ( $2av$ ) that each cross section can attain.

**Horsepower Ratings:** The general horsepower formulas for variable-speed belts are:

$$1422V \text{ HP} = d_p r \left[ 0.4907(d_p r)^{-0.09} - \frac{0.8378}{d_p} - 0.000337(d_p r)^2 \right] + 0.8378r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$1922 \text{ VHP} = d_p r \left[ 0.8502(d_p r)^{-0.09} - \frac{1.453}{d_p} - 0.000538(d_p r)^2 \right] + 1.453r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$2322 \text{ VHP} = d_p r \left[ 1.189(d_p r)^{-0.09} - \frac{2.356}{d_p} - 0.000777(d_p r)^2 \right] + 2.356r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$1926 \text{ VHP} = d_p r \left[ 1.046(d_p r)^{-0.09} - \frac{1.833}{d_p} - 0.000589(d_p r)^2 \right] + 1.833r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$2926 \text{ VHP} = d_p r \left[ 1.769(d_p r)^{-0.09} - \frac{4.189}{d_p} - 0.001059(d_p r)^2 \right] + 4.189r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$3226 \text{ VHP} = d_p r \left[ 2.073(d_p r)^{-0.09} - \frac{5.236}{d_p} - 0.001217(d_p r)^2 \right] + 5.236r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$2530 \text{ VHP} = d_p r \left[ 2.395(d_p r)^{-0.09} - \frac{6.912}{d_p} - 0.001148(d_p r)^2 \right] + 6.912r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$3230 \text{ VHP} = d_p r \left[ 2.806(d_p r)^{-0.09} - \frac{7.854}{d_p} - 0.001520(d_p r)^2 \right] + 7.854r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$4430 \text{ VHP} = d_p r \left[ 3.454(d_p r)^{-0.09} - \frac{7.854}{d_p} - 0.002196(d_p r)^2 \right] + 9.818r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$4036 \text{ V HP} = d_p r \left[ 3.566(d_p r)^{-0.09} - \frac{9.687}{d_p} - 0.002060(d_p r)^2 \right] + 9.687r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$4436 \text{ V HP} = d_p r \left[ 4.041(d_p r)^{-0.09} - \frac{11.519}{d_p} - 0.002297(d_p r)^2 \right] + 11.519r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$4836 \text{ V HP} = d_p r \left[ 4.564(d_p r)^{-0.09} - \frac{13.614}{d_p} - 0.002634(d_p r)^2 \right] + 13.614r \left( 1 - \frac{1}{K_{SR}} \right)$$

In these equations,  $d_p$  = pitch diameter of small sheave, in.;  $r$  = rpm of faster shaft divided by 1000;  $K_{SR}$  = speed ratio factor given in the accompanying **Table 34**. These formulas give the basic horsepower rating, corrected for the speed ratio. To obtain the horsepower for arcs of contact other than 180 degrees and for belts longer or shorter than average length, multiply the horsepower obtained from these formulas by the arc of contact correction factor (**Table 36**) and the length correction factor (**Table 35**).

**Table 34. Speed Ratio Correction Factors**

**Rim Speed:** The material and design selected for sheaves must be capable of withstanding the high rim speeds that may occur in variable-speed drives. The rim speed is calculated as follows: Rim speed (fpm) =  $(\pi/12) (D_o)$  (rpm).

**Arc of Contact:** Arc of contact on the small sheave may be determined by the formulas:

$$\text{Exact Formula: Arc of Contact (deg)} = 2 \cos^{-1} \left( \frac{D-d}{2C} \right)$$

$$\text{Approximate Formula: Arc of Contact (deg)} = 180 - \frac{(D-d)60}{C}$$

where  $D$  = Pitch diameter of large sheave or flat pulley, inch or mm

$d$  = Pitch diameter of small sheave, inch or mm

$C$  = Center distance, inch or mm

**Table 36. Arc of Contact Correction Factors**

**60 Degree V-Belts.**— 60 degree V-belts are ideal for compact drives. Their 60 degree angle and ribbed top are specifically designed for long life on small diameter sheaves. These belts offer extremely smooth operation at high speeds (in excess of 10,000 rpm) and can be used on drives with high speed ratios. They are available in 3M, 5M, 7M, and 11M (3, 5, 7, 11 mm) cross sections (top widths) and are commonly found in the joined configuration, which provides extra stability and improved performance. They are specified by cross section and nominal length; for example, a 5M315 designation indicates a belt having a 5 mm cross section and an effective length of 315 mm.

Industry standards have not yet been published for 60 degree V-belts. Belt manufacturers should be contacted for specific applications, specifications, and additional information.

**SAE Standard V-Belts.**— The data for V-belts and pulleys shown in Table 37 cover nine sizes, three of which — 0.250, 0.315, and 0.440 — were added in 1977 to conform to existing practice. This standard was reaffirmed in 1987.

V-belts are produced in a variety of constructions in a basic trapezoidal shape and are to be dimensioned in such a way that they are functional in pulleys dimensioned as described in the standard. Standard belt lengths are in increments of  $\frac{1}{2}$  inch (12.7 mm) up to and including 80 inches (203.2 cm). Standard lengths above 80 inches up to and including 100 inches (254 cm) are in increments of 1 inch (2.54 cm), without fractions. Standard belt length tolerances are based on the center distance and are as follows: For belt lengths of 50 inches (127 cm) or less,  $\pm 0.12$  inch; over 50 to 60 inches (127–152.4 cm), inclusive,  $\pm 0.16$  inch; over 60 to 80 inches (152.4–203.2 cm), inclusive,  $\pm 0.19$  inch; and over 80 to 100 inches (203.2–254 cm), inclusive,  $\pm 0.22$  inch.

**Belt Storage and Handling.**— To achieve maximum belt performance, proper belt storage procedures should always be practiced. If belts are not stored properly, their performance can be adversely affected. Four key rules are:

- 1) Do not store belts on floors unless they are protected by appropriate packaging.
- 2) Do not store belts near windows where the belts may be exposed to direct sunlight or moisture.

	Over 8.00	38				0.666		

All dimensions in inches.

<sup>a</sup>Pulley effective diameters below those recommended should be used with caution, because power transmission and belt life may be reduced.

<sup>b</sup>The  $X$  dimension is radial;  $2X$  is to be subtracted from the effective diameter to obtain “pitch diameter” for speed ratio calculations.

<sup>c</sup>These values are intended for adjacent grooves of the same effective width ( $W$ ). Choice of pulley manufacture or belt design parameter may justify variance from these values. The  $S$  dimension should be the same on all multiple groove pulleys in a drive using matched belts. © 1990, SAE, Inc.

3) Do not store belts near electrical devices that may generate ozone (transformers, electric motors, etc.).

4) Do not store belts in areas where solvents or chemicals are present in the atmosphere.

Belts should be stored in a cool, dry environment. When stacked on shelves, the stacks should be short enough to avoid excess weight on the bottom belts, which may cause distortion. When stored in containers, the container size and contents should be sufficiently limited to avoid distortion.

*V-Belts:* A common method is to hang the belts on pegs or pin racks. Very long belts stored this way should use sufficiently large pins or crescent shaped “saddles” to prevent their weight from causing distortion.

*Joined V-belts, Synchronous Belts, V-Ribbed Belts:* Like V-belts, these belts may be stored on pins or saddles with precautions taken to avoid distortion. However, belts of this

The machines listed above are representative samples only. Select the group listed above whose load characteristics most closely approximate those of the machine being considered.

type up to approximately 120 inch (3.05 m) are normally shipped in a “nested” configuration and should be stored in the same manner. Nests are formed by laying a belt on its side on a flat surface and placing as many belts inside the first belt as possible without undue force. When the nests are tight and are stacked with each rotated 180° from the one below, they may be stacked without damage.

Belts of this type over 120 in. may be “rolled up” and tied for shipment. These rolls may be stacked for easy storage. Care should be taken to avoid small bend radii which could damage the belts.

**Variable Speed Belts:** Variable speed belts are more sensitive to distortion than most other belts, and should not be hung from pins or racks but stored on shelves in the sleeves in which they are shipped.

**Service Factors:** Service factors for V-belts are listed in **Table 38**.

### Synchronous Belts

**Synchronous Belts ANSI/RMA IP-24.**— Synchronous belts are also known as timing or positive-drive belts. These belts have evenly spaced teeth on their surfaces, which mesh with teeth on pulleys or sprockets to produce a positive, no-slip transmission of power. Such designs should not be confused with molded notched V-belts, which transmit power by means of the wedging action of the V-shape. Synchronous belts are used where driven shaft speeds must be synchronized to the rotation of the driver shaft and to eliminate the noise and maintenance problems of chain drives.

*Standard Timing Belts:* Conventional trapezoidal, or rectangular tooth, timing belts come in six cross sections, which relate to the pitch of the belt. Pitch is the distance from center to center of the teeth. The six basic cross sections or pitches are MXL (mini extra light), XL (extra light), L (light), H (heavy), XH (extra heavy), and XXH (double extra heavy) (Fig. 12). Belts are specified by pitch length, cross section (pitch), and width.

Double-sided timing belts have identical teeth on both sides of the belt and are used where synchronization is required from each belt face. They are available in XL, L, and H cross sections.

*Size Designations:* Synchronous belt sizes are identified by a standard number. The first digits specify the belt length to 0.1 inch (2.54 mm) followed by the belt section (pitch) designation. The digits following the belt section designation represent the nominal belt width times 100. For example, an L section belt 30.000 inches pitch length and 0.75 inch in width would be specified as a 300L075 synchronous belt.

Fig. 12. Standard Synchronous Belt Sections

The RMA nomenclature for double-sided belts is the same as for single-sided belts with the addition of the prefix “D” in front of the belt section. However, some manufacturers use their own designation system for double-sided belts.

*Standard Sections:* Belt sections are specified in terms of pitch. Table 40 gives the Standard Belt Sections and their corresponding pitches.

Synchronous belts will not slip, and therefore must be belted for the highest loadings anticipated in the system. A minimum service factor of 2.0 is recommended for equipment subject to chocking.

**Pitch Lengths:** Standard belt pitch lengths, belt length designations, and numbers of teeth are shown in **Table 42**. Belt length tolerances are also given in this table; these tolerances apply to all belt sections and represent the total manufacturing tolerance on belt length.

**Nominal Tooth Dimensions:** **Table 40** shows the nominal tooth dimensions for each of the standard belt sections. Tooth dimensions for single- and double-sided belts are identical.

*Widths.*: Standard belt widths, width designations, and width tolerances are shown in Table 43.

*Length Determination.*: The pitch length of a synchronous belt is determined by placing the belt on a measuring fixture having two pulleys of equal diameter, a method of applying force, and a means of measuring the center distance between the two pulleys. The position of one of the two pulleys is fixed and the other is movable along a graduated scale.

*Synchronous Belt Pulley Diameters.*: Table 44 lists the standard pulley diameters by belt section (pitch). Fig. 13 defines the pitch, pitch diameter, outside diameter and pitch line differential.

Fig. 13. Synchronous Belt Pulley Dimensions

All dimensions in inches.

\* Usually not available in all widths — consult supplier.

**Widths:** Standard pulley widths for each belt section are shown in Table 41. The nominal pulley width is specified in terms of the maximum standard belt width the pulley will accommodate. The minimum pulley width, whether flanged or unflanged, is also shown in Table 41, along with flange dimensions and various pulley tolerances.

**Pulley Size Designation:** Synchronous belt pulleys are designated by the number of grooves, the belt section, and a number representing 100 times the nominal width. For example, a 30 groove L section pulley with a nominal width of 0.75 in. would be designated by 30L075. Pulley tolerances are shown in Table 45.

**Table 45. Pulley Tolerances (All Sections)**

Outside Diameter Range	Outside Diameter Tolerance	Pitch to Pitch Tolerance	
		Adjacent Grooves	Accumulative Over 90 Degrees
Up thru 1.000	+0.002 -0.000	±0.001	±0.003
Over 1.000 to and including 2.000	+0.003 -0.000	±0.001	±0.004
Over 2.000 to and including 4.000	+0.004 -0.000	±0.001	±0.005
Over 4.000 to and including 7.000	+0.005 -0.000	±0.001	±0.005
Over 7.000 to and including 12.000	+0.006 -0.000	±0.001	±0.006
Over 12.000 to and including 20.000	+0.007 -0.000	±0.001	±0.007
Over 20.000	+0.008 -0.000	±0.001	±0.008
Radial Runout <sup>a</sup>		Axial Runout <sup>a</sup>	
For outside diameters 8.0 in. and under 0.005 in. For each additional inch of outside diameter add 0.0005 in.		For outside diameters 1.0 in. and under 0.001 in. For each additional inch of outside diameter up through 10.0 in., add 0.001 in. For each additional inch of outside diameter over 10.0 in., add 0.0005 in.	

<sup>a</sup>Total indicator reading.

All dimensions in inches.

**Cross Section Selection:** The chart (Fig. 14) may be used as a guide to the selection of a synchronous belt for any combination of design horsepower and speed of the faster shaft. When the intersection of the design horsepower and speed of the faster shaft falls near a line between two areas on the chart, the possibilities in both areas should be explored. Special circumstances (such as space limitations) may result in selection of a belt cross section different from that indicated in the chart. Belt manufacturers should be contacted for specific data.

**Torque Ratings:** It is customary to use torque load requirements rather than horsepower load when designing drives using the small pitch MXL section belts. These belts operate on small diameters resulting in relatively low belt speeds, so torque is essentially constant for all rpm. The torque rating formulas for MXL sections are:

$$Q_r = d[1.13 - 1.38 \times 10^{-3} d^2] \text{ for belt width} = 0.12 \text{ in.}$$

$$Q_r = d[1.88 - 2.30 \times 10^{-3} d^2] \text{ for belt width} = 0.19 \text{ in.}$$

$$Q_r = d[2.63 - 3.21 \times 10^{-3} d^2] \text{ for belt width} = 0.25 \text{ in.}$$

where  $Q_r$  = the maximum torque rating (lbf-in.) for a belt of specified width having six or more teeth in mesh and a pulley surface speed of 6500 fpm or less. Torque ratings for drives with less than six teeth in mesh must be corrected as shown in Table 46.  $d$  = pitch diameter of smaller pulley, inch.

Fig. 14. Selection of Synchronous Belt Cross Section

Table 46. Teeth in Mesh Factor

Teeth in Mesh	Factor $K_z$	Teeth in Mesh	Factor $K_z$
6 or more	1.00	3	0.40
5	0.80	2	0.20
4	0.60		

**Horsepower Rating Formulas:** The horsepower rating formulas for synchronous belts, other than the MLX section, are determined from the following formulas, where the number in parentheses is the belt width in inches.

$$XL(0.38) \text{ HP} = dr[0.0916 - 7.07 \times 10^{-5}(dr)^2]$$

$$L(1.00) \text{ HP} = dr[0.436 - 3.01 \times 10^{-4}(dr)^2]$$

$$H(3.00) \text{ HP} = dr[3.73 - 1.41 \times 10^{-3}(dr)^2]$$

$$XH(4.00) \text{ HP} = dr[7.21 - 4.68 \times 10^{-3}(dr)^2]$$

$$XXH(5.00) \text{ HP} = dr[11.4 - 7.81 \times 10^{-3}(dr)^2]$$

where  $HP$  = the maximum horsepower rating recommended for the specified standard belt width having six or more teeth in mesh and a pulley surface speed of 6500 fpm or less. Horsepower ratings for drives with less than six teeth in mesh must be corrected as shown in Table 46.  $d$  = pitch diameter of smaller pulley, inch;  $r$  = rpm of faster shaft divided by 1000. Total horsepower ratings are the same for double-sided as for single-sided belts. Contact manufacturers for percentage of horsepower available for each side of the belt.

**Finding the Required Belt Width:** The belt width should not exceed the small pulley diameter or excessive side thrust will result.

**Torque Rating Method (MXL Section):** Divide the design torque by the teeth in mesh factor to obtain the corrected design torque. Compare the corrected design torque with the torque rating given in Table 47 for the pulley diameter being considered. Select the narrowest belt width that has a torque rating equal to or greater than the corrected design torque.

**Table 47. Torque Rating for MXL Section (0.080 in. Pitch)**

Belt Width, (in.)	Rated Torque (lbf-in.) for Small Pulley (Number of Grooves and Pitch Diameter, in.)									
	10MXL 0.255	12MXL 0.306	14MXL 0.357	16MXL 0.407	18MXL 0.458	20MXL 0.509	22MXL 0.560	24MXL 0.611	28MXL 0.713	30MXL 0.764
0.12	0.29	0.35	0.40	0.46	0.52	0.57	0.63	0.69	0.81	0.86
0.19	0.48	0.58	0.67	0.77	0.86	0.96	1.05	1.15	1.34	1.44
0.25	0.67	0.80	0.94	1.07	1.20	1.34	1.47	1.61	1.87	2.01

**Horsepower Rating Method (XL, L, H, XH, and XXH Sections):** Multiply the horsepower rating for the widest standard belt of the selected section by the teeth in mesh factor to obtain the corrected horsepower rating. Divide the design horsepower by the corrected horsepower rating to obtain the required belt width factor. Compare the required belt width factor with those shown in [Table 48](#). Select the narrowest belt width that has a width factor equal to or greater than the required belt width factor.

**Table 48. Belt Width Factor**

Belt Section	Belt Width (in.)											
	0.12	0.19	0.25	0.38	0.50	0.75	1.00	1.50	2.00	3.00	4.00	5.00

XL (0.200)	...	...	0.62	1.00	...	...	...	...	...	...	...	...
L (0.375)	...	...	...	...	0.45	0.72	1.00	...	...	...	...	...
H (0.500)	...	...	...	...	...	0.21	0.29	0.45	0.63	1.00	...	...
XH (0.875)	...	...	...	...	...	...	...	0.45	0.72	1.00	...	...
XXH (1.250)	...	...	...	...	...	...	...	0.35	0.56	0.78	1.00	...

**Drive Selection:** Information on design and selection of synchronous belt drives is available in engineering manuals published by belt manufacturers. Manufacturers should be consulted on such matters as preferred stock sizes, desirable speeds, center distances, etc.

**Minimum Pulley Size:** The recommended minimum pulley size depends on the rpm of the faster shaft. Minimum sheave diameters for each cross-section belt are listed in [Table 44](#).

**Selection of Flanged Pulleys:** To determine when to use flanged pulleys, consider the following conditions:

- 1) On all two-pulley drives, the minimum flanging requirements are two flanges on one pulley, or one flange on each pulley on opposite sides.
- 2) On drives where the center distance is more than eight times the diameter of the small pulley, both pulleys should be flanged on both sides.
- 3) On vertical shaft drives, one pulley should be flanged on both sides and other pulleys in the system should be flanged on the bottom side only.
- 4) On drives with more than two pulleys, the minimum flanging requirements are two flanges on every other pulley, or one flange on every pulley, alternating sides around the system.

**Service Factors:** Service factors for synchronous belts in [Table 39](#).

**Gravity Idler.**— The gravity type of idler used in conjunction with many belt drives, consists of a weighted idler pulley, so pivoted from a long arm that the idler runs near the small pulley against the loose side of the belt, in such a way as to increase the arc of contact of the belt on this pulley. These idlers are of special value on difficult drives where there is a large difference in the diameter of the driver and driven pulleys.

## TRANSMISSION CHAINS

### Types of Chains

In addition to the standard roller and inverted tooth types, a wide variety of drive chains of different construction is available. Such chains are manufactured to various degrees of precision ranging from unfinished castings or forgings to chains having certain machined parts. Practically all of these chains as well as standard roller chains can be equipped with attachments to fit them for conveyor use. A few such types are briefly described in the following paragraphs. Detailed information about them can be obtained from the manufacturers.

**Types of Chains.**— *Detachable Chains:* The links of this type of chain, which are identical, are easily detachable. Each has a hook-shaped end in which the bar of the adjacent link articulates. These chains are available in malleable iron or pressed steel. The chief advantage is the ease with which any link can be removed.

*Cast Roller Chains:* Cast roller chains are constructed, wholly or partly, of cast metal parts and are available in various styles. In general the rollers and side bars are accurately made castings without machine finish. The links are usually connected by means of forged pins secured by nuts or cotters. Such chains are used for slow speeds and moderate loads, or where the precision of standard roller chains is not required.

*Pintle Chains:* Unlike the roller chain, the pintle chain is composed of hollow-cored cylinders cast or forged integrally with two offset side bars and each link identical. The links are joined by pins inserted in holes in the ends of the side bars and through the cored holes in the adjacent links. Lugs prevent turning of the pins in the side bars ensuring articulation of the chain between the pin and the cored cylinder.

### Standard Roller Transmission Chains

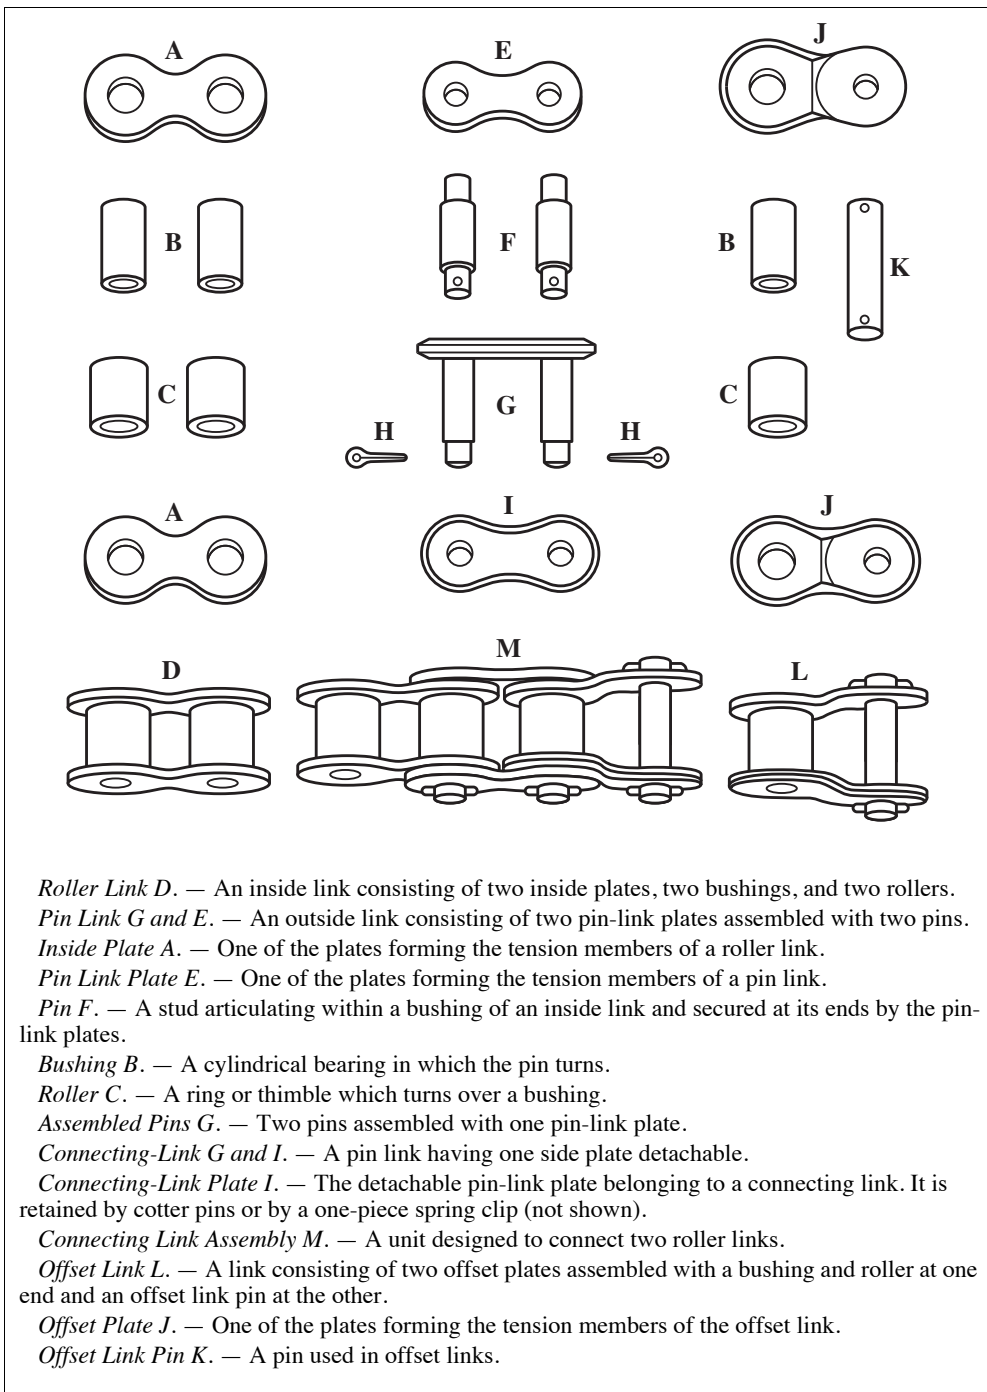

A roller chain is made up of two kinds of links: roller links and pin links alternately spaced throughout the length of the chain as shown in [Table 1](#).

Roller chains are manufactured in several types, each designed for the particular service required. All roller chains are so constructed that the rollers are evenly spaced throughout the chain. The outstanding advantage of this type of chain is the ability of the rollers to rotate when contacting the teeth of the sprocket. Two arrangements of roller chains are in common use: the single-strand type and the multiple-strand type. In the latter type, two or more chains are joined side by side by means of common pins which maintain the alignment of the rollers in the different strands.

**Types of Roller Chains.**— *Standard roller chains* are manufactured to the specifications in the American National Standard for precision power transmission roller chains, attachments, and sprockets ANSI/ASME B29.1M-1993 and, where indicated, the data in the subsequent tables have been taken from this standard. These roller chains and sprockets are commonly used for the transmission of power in industrial machinery, machine tools, motor trucks, motorcycles, tractors, and similar applications. In tabulating the dimensional information in ANSI/ASME B29.1M, customary inch-pound units were used. Metric (SI) units are given in separate tabulations in the Standard.

*Nonstandard roller chains*, developed individually by various manufacturers prior to the adoption of the ANSI standard, are similar in form and construction to standard roller chains but do not conform dimensionally to standard chains. Some sizes are still available from the originating manufacturers for replacement on existing equipment. They are not recommended for new installations, since their manufacture is being discontinued as rapidly as possible.

**Table 1. ANSI Nomenclature for Roller Chain Parts**  
**ANSI/ASME B29.1M-1993 (R1999)**

*Standard double-pitch roller chains* are like standard roller chains, except that their link plates have twice the pitch of the corresponding standard-pitch chain. Their design conforms to specifications in the ANSI Standard for double-pitch power transmission roller chains and sprockets ANSI/ASME B29.3M-1994. They are especially useful for low speeds, moderate loads, or long center distances.

## Transmission Roller Chain

**Standard Roller Chain Nomenclature, Dimensions and Loads.**— Standard nomenclature for roller chain parts are given in Table 1. Dimensions for Standard Series roller chain are given in Table 2.

Table 2. ANSI Roller Chain Dimensions ASME/ANSI B29.1M-1986

Pitch $P$	Max. Roller Diameter $D_r$	Standard Series					Heavy Series
		Standard Chain No.	Width $W$	Pin Diameter $D_p$	Thickness of Link Plates $LPT$	Measuring Load, <sup>a</sup> lb	Thickness of Link Plates $LPT$

3.000	1.875	240	1.875	0.937	0.375	1000	0.500

<sup>a</sup>For single-strand chain.

<sup>b</sup>Bushing diameter. This size chain has no rollers.

All dimensions are in inches.

Roller Diameters  $D_r$  are approximately  $\frac{5}{8}P$ .

The width  $W$  is defined as the distance between the link plates. It is approximately  $\frac{5}{8}$  of the chain pitch.

Pin Diameters  $D_p$  are approximately  $\frac{5}{16}P$  or  $\frac{1}{2}$  of the roller diameter.

Thickness  $LPT$  of Inside and Outside Link Plates for the standard series is approximately  $\frac{1}{8}P$ .

Thickness of Link Plates for the heavy series of any pitch is approximately that of the next larger pitch Standard Series chain.

Maximum Height of Roller Link Plates =  $0.95P$ .

Maximum Height of Pin Link Plates =  $0.82P$ .

Maximum Pin Diameter = nominal pin diameter + 0.0005 inch.

Minimum Hole in Bushing = nominal pin diameter + 0.0015 inch.

Maximum Width of Roller Link = nominal width of chain +  $(2.12 \times \text{nominal link plate thickness.})$

Minimum Distance between Pin Link Plates = maximum width of roller link + 0.002 inch.

**Chain Pitch:** Distance in inches between centers of adjacent joint members. Other dimensions are proportional to the pitch.

**Tolerances for Chain Length:** New chains, under standard measuring load, must not be underlength. Overlength tolerance is  $0.001/(\text{pitch in inches})^2 + 0.015$  inch per foot. Length measurements are to be taken over a length of at least 12 inches.

**Measuring Load:** The load in pounds under which a chain should be measured for length. It is equal to 1 percent of the ultimate tensile strength, with a minimum of 18 pounds and a maximum of 1000 pounds for both single and multiple-strand chain.

**Minimum Ultimate Tensile Strength:** For single-strand chain, equal to or greater than  $12,500 \times (\text{pitch in inches})^2$  pounds. The minimum tensile strength or breaking strength of a multiple-strand chain is equal to that of a single-strand chain multiplied by the number of strands. Minimum ultimate tensile strength is indicative only of the tensile strength quality of the chain, not the maximum load that can be applied.

**Standard Roller Chain Numbers.**— The right-hand figure in the chain number is zero for roller chains of the usual proportions, 1 for a lightweight chain, and 5 for a rollerless bushing chain. The numbers to the left of the right-hand figure denote the number of  $\frac{1}{8}$  inches in the pitch. The letter *H* following the chain number denotes the heavy series; thus the number 80*H* denotes a 1-inch pitch heavy chain. The hyphenated number 2 suffixed to the chain number denotes a double strand, 3 a triple strand, 4 a quadruple strand chain and so on.

**Heavy Series:** These chains, made in  $\frac{3}{4}$ -inch and larger pitches, have thicker link plates than those of the regular standard. Their value is only in the acceptance of higher loads at lower speeds.

**Light-weight Machinery Chain:** This chain is designated as No. 41. It is  $\frac{1}{2}$  inch pitch;  $\frac{1}{4}$  inch wide; has 0.306-inch diameter rollers and a 0.141-inch pin diameter. The minimum ultimate tensile strength is 1500 pounds.

**Multiple-strand Chain:** This is essentially an assembly of two or more single-strand chains placed side by side with pins that extend through the entire width to maintain alignment of the different strands.

**Types of Sprockets.**— Four different designs or types of roller-chain sprockets are shown by the sectional views, Fig. 1. Type *A* is a plain plate; type *B* has a hub on one side only; type *C*, a hub on both sides; and type *D*, a detachable hub. Also used are shear pin and slip clutch sprockets designed to prevent damage to the drive or to other equipment caused by overloads or stalling.

Fig. 1. Types of Sprockets

**Attachments.**— Modifications to standard chain components to adapt the chain for use in conveying, elevating, and timing operations are known as “attachments.” The components commonly modified are: 1) the link plates, which are provided with extended lugs which may be straight or bent ; and 2) the chain pins, which are extended in length so as to project substantially beyond the outer surface of the pin link plates.

Hole diameters, thicknesses, hole locations and offset dimensions for straight link and bent link plate extensions and lengths and diameters of extended pins are given in Table 3.

**Table 3. Straight and Bent Link Plate Extensions and Extended Pin Dimensions  
ANSI/ASME B29.1M-1993 (R1999)**

Chain No.	Straight Link Plate Extension			Bent Link Plate Extension				Extended Pin	
	<i>B</i> min.	<i>D</i>	<i>F</i>	<i>B</i> min.	<i>C</i>	<i>D</i>	<i>F</i>	<i>D<sub>p</sub></i> Nominal	<i>L</i>
35	0.102	0.375	0.050	0.102	0.250	0.375	0.050	0.141	0.375
40	0.131	0.500	0.060	0.131	0.312	0.500	0.060	0.156	0.375
50	0.200	0.625	0.080	0.200	0.406	0.625	0.080	0.200	0.469
60	0.200	0.719	0.094	0.200	0.469	0.750	0.094	0.234	0.562
80	0.261	0.969	0.125	0.261	0.625	1.000	0.125	0.312	0.750
100	0.323	1.250	0.156	0.323	0.781	1.250	0.156	0.375	0.938
120	0.386	1.438	0.188	0.386	0.906	1.500	0.188	0.437	1.125
140	0.448	1.750	0.219	0.448	1.125	1.750	0.219	0.500	1.312
160	0.516	2.000	0.250	0.516	1.250	2.000	0.250	0.562	1.500
200	0.641	2.500	0.312	0.641	1.688	2.500	0.312	0.781	1.875

All dimensions are in inches.

**Sprocket Classes.**— The American National Standard ANSI/ASME B29.1M-1993 provides for two classes of sprockets designated as Commercial and Precision. The selection of either is a matter of drive application judgment. The usual moderate to slow speed commercial drive is adequately served by Commercial sprockets. Where extreme high speed in combination with high load is involved, or where the drive involves fixed centers, critical timing, or register problems, or close clearance with outside interference, then the use of Precision sprockets may be more appropriate.

As a general guide, drives requiring Type A or Type B lubrication (see page 2575) would be served by Commercial sprockets. Drives requiring Type C lubrication may require Precision sprockets; the manufacturer should be consulted.

**Keys, Keyways, and Set Screws.**— To secure sprockets to the shaft, both keys and set screws should be used. The key is used to prevent rotation of the sprocket on the shaft. Keys should be fitted carefully in the shaft and sprocket keyways to eliminate all backlash, especially on the fluctuating loads. A set screw should be located over a flat key to secure it against longitudinal displacement.

Where a set screw is to be used with a parallel key, the following sizes are recommended by the American Chain Association. For a sprocket bore and shaft diameter in the range of:

$\frac{1}{2}$  through  $\frac{7}{8}$  inch, a  $\frac{1}{4}$ -inch set screw

$\frac{15}{16}$  through  $1\frac{3}{4}$  inches, a  $\frac{3}{8}$ -inch set screw

$1\frac{13}{16}$  through  $2\frac{1}{4}$  inches, a  $\frac{1}{2}$ -inch set screw

$2\frac{5}{16}$  through  $3\frac{1}{4}$  inches, a  $\frac{5}{8}$ -inch set screw

$3\frac{3}{8}$  through  $4\frac{1}{2}$  inches, a  $\frac{3}{4}$ -inch set screw

$4\frac{3}{4}$  through  $5\frac{1}{2}$  inches, a  $\frac{7}{8}$ -inch set screw

$5\frac{3}{4}$  through  $7\frac{3}{8}$  inches, a 1-inch set screw

$7\frac{1}{2}$  through  $12\frac{1}{2}$  inches, a  $1\frac{1}{4}$ -inch set screw

**Sprocket Diameters.**— The various diameters of roller chain sprockets are shown in Fig. 2. These are defined as follows.

*Pitch Diameter:* The pitch diameter is the diameter of the pitch circle that passes through the centers of the link pins as the chain is wrapped on the sprocket.

Fig. 2. Sprocket Diameters

Because the chain pitch is measured on a straight line between the centers of adjacent pins, the chain pitch lines form a series of chords of the sprocket pitch circle. Sprocket pitch diameters for one-inch pitch and for 9 to 108 teeth are given in Table 4. For lower (5 to 8) or higher (109 to 200) numbers of teeth use the following formula in which  $P$  = pitch,  $N$  = number of teeth:  $\text{Pitch Diameter} = P \div \sin(180^\circ \div N)$ .

**Table 4. ANSI Roller Chain Sprocket Diameters ANSI/ASME B29.1M-1993 (R1999)**

These diameters and caliper factors apply only to chain of 1-inch pitch. For any other pitch, multiply the values given below by the pitch.									
Caliper Dia. (even teeth) = Pitch Diameter – Roller Dia.									
Caliper Dia. (odd teeth) = Caliper factor × Pitch – Roller Dia.									
See Table 5 for tolerances on Caliper Diameters.

<sup>a</sup>For 5-8 and 109-200 teeth see text, pages 2558, 2560.

**Bottom Diameter:** The bottom diameter is the diameter of a circle tangent to the curve (called the seating curve) at the bottom of the tooth gap. It equals the pitch diameter minus the diameter of the roller.

**Caliper Diameter:** The caliper diameter is the same as the bottom diameter for a sprocket with an even number of teeth. For a sprocket with an odd number of teeth, it is defined as the distance from the bottom of one tooth gap to that of the nearest opposite tooth gap. The caliper diameter for an even tooth sprocket is equal to pitch diameter-roller diameter. The caliper diameter for an odd tooth sprocket is equal to caliper factor-roller diameter. Here, the caliper factor =  $PD \cos(90^\circ \div N)$ , where  $PD$  = pitch diameter and  $N$  = number of teeth. Caliper factors for 1-in. pitch and sprockets having 9-108 teeth are given in Table 4. For other tooth numbers use above formula. Caliper diameter tolerances are minus only and are equal to  $0.002P\sqrt{N} + 0.006$  inch for the Commercial sprockets and  $0.001P\sqrt{N} + 0.003$  inch for Precision sprockets. Tolerances are given in Table 5.

**Table 5. Minus Tolerances on the Caliper Diameters of Precision Sprockets  
ANSI/ASME B29.1M-1993 (R1999)**

3.000	0.027	0.030	0.033	0.036	0.039

Minus tolerances for Commercial sprockets are twice those shown in this table.

**Outside Diameter:** OD is the diameter over the tips of teeth. Sprocket ODs for 1-in. pitch and 9-108 teeth are given in Table 4. For other tooth numbers the OD may be determined by the following formulas in which  $O$  = approximate OD;  $P$  = pitch of chain;  $N$  = number of sprocket teeth:  $O = P [0.6 + \cot(180^\circ \div N)]$ , for turned sprocket;  $O$  = pitch diameter – roller diameter +  $2 \times$  whole depth of topping hob cut, for topping hob cut sprocket.\*

All dimensions are in inches.  $r_f \text{ max} = 0.04P$  for max. hub diameter.

\*This dimension was added in 1984 as a desirable goal for the future. It should in no way obsolete existing tools or sprockets. The whole depth  $WD$  is found from the formula:  $WD = \frac{1}{2}D_c + P[0.3 - \frac{1}{2} \tan(90 \text{ deg} \div N_a)]$ , where  $N_a$  is the intermediate number of teeth for the topping hob. For teeth range 5,  $N_a = 5$ ; 6, 6; 7-8, 7.47; 9-11, 9.9; 12-17, 14.07; 18-34, 23.54; 35 and over, 56.

**Proportions of Sprockets.**— Typical proportions of single-strand and multiple-strand cast roller chain sprockets, as provided by the American Chain Association, are shown in Table 7. Typical proportions of roller chain bar-steel sprockets, also provided by this association, are shown in Table 8.

**Table 7. Typical Proportions of Single-Strand and Multiple-Strand Cast Roller Chain Sprockets**

 $C = 0.5P$   
 $G = 2T$   
 $C' = 0.9P$   
 $R = 0.4P$  for single-strand sprockets  
 $R = 0.5T$  for multiple-strand sprockets  
 All dimensions in inches. Where *P* = chain pitch and *W* = nominal chain width.

**Table 8. Typical Proportions of Roller Chain Bar-steel Sprockets**

$H = Z + D/6 + 0.01 PD$   
 For *PD* up to 2 inches, *Z* = 0.125 inch; for 2-4 inches, *Z* = 0.187 inch; for 4-6 inches, 0.25 inch; and for over 6 inches, 0.375 inch.  
 Hub length *L* = 3.3*H*, normally, with a minimum of 2.6*H*.  
 Hub diameter *HD* = *D* + 2*H*, but not more than the maximum hub diameter *MHD* given by the formula:

$$MHD = P \left( \cot \frac{180^\circ}{N} - 1 \right) - 0.030$$

where: *P* = Chain pitch, in inches; *N* = Number of sprocket teeth

When sprocket wheels are designed with spokes, the usual assumptions made in order to determine suitable proportions are as follows: 1) That the maximum torque load acting on a sprocket is the chain tensile strength times the sprocket pitch radius; 2) that the torque load is equally divided between the arms by the rim; and 3) that each arm acts as a cantilever beam.

The arms are generally elliptical in cross section, the major axis twice the minor axis.

**Selection of Chain and Sprockets.**— The smallest applicable pitch of roller chain is desirable for quiet operation and high speed. The horsepower capacity varies with the chain pitch as shown in Table 9. However, short pitch with high working load can often be obtained by the use of multiple-strand chain.

The small sprocket selected must be large enough to accommodate the shaft. Table 10 gives maximum bore and hub diameters consistent with commercial practice for sprockets with up to 25 teeth.

After selecting the small sprocket, the number of teeth in the larger sprocket is determined by the desired ratio of the shaft speed. Overemphasis on the exactness in the speed ratio may result in a cumbersome and expensive installation. In most cases, satisfactory operation can be obtained with a minor change in speed of one or both shafts.

**Table 9. Horsepower Ratings for Roller Chain—1986**

To properly use this table the following factors must be taken into consideration: 1) Service factors 2) Multiple Strand Factors 3) Lubrication  <i>Service Factors:</i> See Table 15. <i>Multiple Strand Factors:</i> For two strands, the multiple strand factor is 1.7; for three strands, it is 2.5; and for four strands, it is 3.3. <i>Lubrication:</i> Required type of lubrication is indicated at the bottom of each roller chain size section of the table. For a description of each type of lubrication, see page 2575. Type A — Manual or Drip Lubrication Type B — Bath or Disc Lubrication Type C — Oil Stream Lubrication  To find the required horsepower table rating, use the following formula:  $\text{Required hp Table Rating} = \frac{\text{hp to be Transmitted} \times \text{Service Factor}}{\text{Multiple-Strand Factor}}$

**Center Distance between Sprockets.**—The center-to-center distance between sprockets, as a general rule, should not be less than  $1\frac{1}{2}$  times the diameter of the larger sprocket and not less than 30 times the pitch nor more than about 50 times the pitch, although much depends upon the speed and other conditions. A center distance equivalent to 80 pitches may be considered an approved maximum. Very long center distances result in catenary tension in the chain. If roller-chain drives are designed correctly, the center-to-center distance for some transmissions may be so short that the sprocket teeth nearly touch each other, assuming that the load is not too great and the number of teeth is not too small. To

avoid interference of the sprocket teeth, the center distance must, of course, be somewhat greater than one-half the sum of the outside diameters of the sprockets. The chain should extend around at least 120 degrees of the pinion circumference, and this minimum amount of contact is obtained for all center distances provided the ratio is less than  $3\frac{1}{2}$  to 1. Other things being equal, a fairly long chain is recommended in preference to the shortest one allowed by the sprocket diameters, because the rate of chain elongation due to natural wear is inversely proportional to the length, and also because the greater elasticity of the longer strand tends to absorb irregularities of motion and to decrease the effect of shocks.

If possible, the center distance should be adjustable in order to take care of slack due to elongation from wear and this range of adjustment should be at least one and one-half pitches. A little slack is desirable as it allows the chain links to take the best position on the sprocket teeth and reduces the wear on the bearings. Too much sag or an excessive distance between the sprockets may cause the chain to whip up and down — a condition detrimental to smooth running and very destructive to the chain. The sprockets should run in a vertical plane, the sprocket axes being approximately horizontal, unless an idler is used on the slack side to keep the chain in position. The most satisfactory results are obtained when the slack side of the chain is on the bottom.

**Center Distance for a Given Chain Length.**— When the distance between the driving and driven sprockets can be varied to suit the length of the chain, this center distance for a tight chain may be determined by the following formula, in which  $c$  = center-to-center distance in inches;  $L$  = chain length in pitches;  $P$  = pitch of chain;  $N$  = number of teeth in large sprocket;  $n$  = number of teeth in small sprocket.

$$c = \frac{P}{8} (2L - N - n + \sqrt{(2L - N - n)^2 - 0.810(N - n)^2})$$

This formula is approximate, but the error is less than the variation in the length of the best chains. The length  $L$  in pitches should be an even number for a roller chain, so that the use of an offset connecting link will not be necessary.

**Idler Sprockets.**— When sprockets have a fixed center distance or are non-adjustable, it may be advisable to use an idler sprocket for taking up the slack. The idler should preferably be placed against the slack side between the two strands of the chain. When a sprocket is applied to the tight side of the chain to reduce vibration, it should be on the lower side and so located that the chain will run in a straight line between the two main sprockets. A sprocket will wear excessively if the number of teeth is too small and the speed too high, because there is impact between the teeth and rollers even though the idler carries practically no load.

**Length of Driving Chain.**— The total length of a block chain should be given in multiples of the pitch, whereas for a roller chain, the length should be in multiples of twice the pitch, because the ends must be connected with an outside and inside link. The length of a chain can be calculated accurately enough for ordinary practice by the use of the following formula, in which  $L$  = chain length in pitches;  $C$  = center distance in pitches;  $N$  = number of teeth in large sprocket;  $n$  = number of teeth in small sprocket:

$$L = 2C + \frac{N}{2} + \frac{n}{2} + \left(\frac{N-n}{2\pi}\right)^2 \times \frac{1}{C}$$

Hobs designed for a given roller diameter ( $D_r$ ) and chain pitch ( $P$ ) will cut any number of teeth.

$P$  = Pitch of Chain

$P_n$  = Normal Pitch of Hob =  $1.011P$  inches

$D_s$  = Minimum Diameter of Seating Curve =  $1.005D_r + 0.003$  inches

$F$  = Radius Center for Arc  $GK$   $TO = OU = P_n \div 2$

$H = 0.27P$   $E = 0.03P$  = Radius of Fillet Circle

$Q$  is located on line passing through  $F$  and  $J$ . Point  $J$  is intersection of line  $XY$  with circle of diameter  $D_s$ .  $R$  is found by trial and the arc of this radius is tangent to arc  $KG$  at  $K$  and to fillet radius.

$OD$  = Outside Diameter =  $1.7(\text{Bore} + D_r + 0.7P)$  approx.

$D_h$  = Pitch Diameter =  $OD - D_s$ ;  $M$  = Helix Angle;  $\sin M = P_n \div \pi D_h$

$L$  = Lead =  $P_n \div \cos M$ ;  $W$  = Width = Not less than  $2 \times \text{Bore}$ , or  $6D_r$ , or  $3.2P$

To the length obtained by this formula, add enough to make a whole number (and for a roller chain, an even number) of pitches. If a roller chain has an odd number of pitches, it will be necessary to use an offset connecting link.

Another formula for obtaining chain length in which  $D$  = distance between centers of shafts;  $R$  = pitch radius of large sprocket;  $r$  = pitch radius of small sprocket;  $N$  = number of teeth in large sprocket;  $n$  = number of teeth in small sprocket;  $P$  = pitch of chain and sprockets; and  $l$  = required chain length in inches, is:

$$l = \frac{180^\circ + 2\alpha}{360^\circ} NP + \frac{180^\circ - 2\alpha}{360^\circ} nP + 2D \cos \alpha \quad \text{where } \sin \alpha = \frac{R-r}{D}$$

**Cutting Standard Sprocket Tooth Form.**— The proportions and seating curve data for the standard sprocket tooth form for roller chain are given in Table 11. Either formed or generating types of sprocket cutters may be employed.

**Hobs:** Only one hob will be required to cut any number of teeth for a given pitch and roller diameter. All hobs should be marked with pitch and roller diameter to be cut. Formulas and data for standard hob design are given in Table 12.

**Space Cutters:** Five cutters of this type will be required to cut from 7 teeth up for any given roller diameter. The ranges are, respectively, 7–8, 9–11, 12–17, 18–34, and 35 teeth and over. If less than 7 teeth is necessary, special cutters conforming to the required number of teeth should be used.

The regular cutters are based upon an intermediate number of teeth  $N_a$ , equal to  $2N_1N_2 \div (N_1 + N_2)$  in which  $N_1$  = minimum number of teeth and  $N_2$  = maximum number of teeth for which cutter is intended; but the topping curve radius  $F$  (see diagram in Table 13) is designed to produce adequate tooth height on a sprocket of  $N_2$  teeth. The values of  $N_a$  for the several cutters are, respectively, 7.47, 9.9, 14.07, 23.54, and 56. Formulas and construction data for space cutter layout are given in Table 13 and recommended cutter sizes are given in Table 14.

Range of Teeth	$F$	Chord $xy$	$yz$	Angle $Yab$
7–8	$0.8686D_r - 0.0015$	$0.2384D_r + 0.0003$	$0.0618D_r$	$24^\circ$
9–11	$0.8554D_r - 0.0015$	$0.2800D_r + 0.0003$	$0.0853D_r$	$18^\circ 10'$
12–17	$0.8364D_r - 0.0015$	$0.3181D_r + 0.0004$	$0.1269D_r$	$12^\circ$
18–34	$0.8073D_r - 0.0015$	$0.3540D_r + 0.0004$	$0.1922D_r$	$5^\circ$
35 up	$0.7857D_r - 0.0015$	$0.3850D_r + 0.0004$	$0.2235D_r$	$0^\circ$

$E$  (same for all ranges) =  $1.3025D_r + 0.0015$ ;  $G$  (same for all ranges) =  $1.4D_r$

See Table 14 for recommended cutter sizes.

Angle  $Yab$  is equal to  $180^\circ \div N$  when the cutter is made for a specific number of teeth. For the design of cutters covering a range of teeth, angle  $Yab$  was determined by layout to ensure chain roller clearance and to avoid pointed teeth on the larger sprockets of each range. It has values as given below for cutters covering the range of teeth shown. The following formulas are for cutters covering the standard ranges of teeth where  $N_a$  equals intermediate values given on page 2572.

$$W = 1.4D_r \cos(Yab) \quad V = 1.4D_r \sin(Yab)$$

$$yz = D_r \left[ 1.4 \sin \left( 17^\circ + \frac{116^\circ}{N_a} - Yab \right) - 0.8 \sin \left( 18^\circ - \frac{56^\circ}{N_a} \right) \right]$$

$$F = D_r \left[ 0.8 \cos \left( 18^\circ - \frac{56^\circ}{N_a} \right) + 1.4 \cos \left( 17^\circ + \frac{116^\circ}{N_a} - Yab \right) - 1.3025 \right] - 0.0015 \text{ in.}$$

For other points, use the value of  $N_a$  for  $N$  in the standard formulas in Table 11.

**Table 14. Recommended Space Cutter Sizes for Roller-Chain Sprockets**

Where the same roller diameter is commonly used with chains of two different pitches it is recommended that stock cutters be made wide enough to cut sprockets for both chains.

*Marking of Cutters.*— All cutters are to be marked, giving pitch, roller diameter and range of teeth to be cut.

*Bores for Sprocket Cutters* (recommended practice) are approximately as calculated from the formula:

$$\text{Bore} = 0.7 \sqrt{(\text{Width of Cutter} + \text{Roller Diameter} + 0.7 \text{ Pitch})}$$

and are equal to 1 inch for  $\frac{1}{4}$ - through  $\frac{3}{4}$ -inch pitches;  $1\frac{1}{4}$  inches for 1- through  $1\frac{1}{2}$ -inch for  $1\frac{3}{4}$ - through  $2\frac{1}{4}$ -inch pitches;  $1\frac{3}{4}$  inches for  $2\frac{1}{2}$ -inch pitch; and 2 inches for 3-inch pitch.

*Minimum Outside Diameters of Space Cutters* for 35 teeth and over (recommended practice) are approximately as calculated from the formula:

$$\text{Outside Diameter} = 1.2(\text{Bore} + \text{Roller Diameter} + 0.7 \text{ Pitch}) + 1 \text{ in.}$$

*Shaper Cutters:* Only one will be required to cut any number of teeth for a given pitch and roller diameter. The manufacturer should be referred to for information concerning the cutter form design to be used.

**Sprocket Manufacture.**— Cast sprockets have cut teeth, and the rim, hub face, and bore are machined. The smaller sprockets are generally cut from steel bar stock, and are finished all over. Sprockets are often made from forgings or forged bars. The extent of finishing depends on the particular specifications that are applicable. Many sprockets are made by welding a steel hub to a steel plate. This process produces a one-piece sprocket of desired proportions and one that can be heat-treated.

**Sprocket Materials.**— For large sprockets, cast iron is commonly used, especially in drives with large speed ratios, since the teeth of the larger sprocket are subjected to fewer chain engagements in a given time. For severe service, cast steel or steel plate is preferred.

The smaller sprockets of a drive are usually made of steel. With this material the body of the sprocket can be heat-treated to produce toughness for shock resistance, and the tooth surfaces can be hardened to resist wear.

Stainless steel or bronze may be used for corrosion resistance, and Formica, nylon or other suitable plastic materials for special applications.

**Roller Chain Drive Ratings.**— In 1961, under auspices of The American Sprocket Chain Manufacturers Association (now called American Chain Association), a joint research program was begun to study pin-bushing interaction at high speeds and to gain further data on the phenomenon of chain joint galling among other research areas. These studies have shown that a separating film of lubricant is formed in chain joints in a manner similar to that found in journal bearings. These developments appear in ANSI/ASME B29.1M-1993, and are contained in **Table 9**. The ratings shown in **Table 9** are below the galling range.

The horsepower ratings in **Table 9** apply to lubricated, single-pitch, single-strand roller chains, both ANSI Standard and Heavy series. To obtain ratings of multiple-strand chains, a multiple-strand factor is applied.

The ratings in **Table 9** are based upon: 1) a service factor of 1; 2) a chain length of approximately 100 pitches; 3) use of recommended lubrication methods; and 4) a drive arrangement where two aligned sprockets are mounted on parallel shafts in a horizontal plane.

Under these conditions, approximately 15,000 hours of service life at full load operation may be expected.

**Table 15. Roller Chain Drive Service Factors**

Type of Driven Load	Type of Input Power		
	Internal Combustion Engine with Hydraulic Drive	Electric Motor or Turbine	Internal Combustion Engine with Mechanical Drive
Smooth	1.0	1.0	1.2
Moderate Shock	1.2	1.3	1.4
Heavy Shock	1.4	1.5	1.7

Substantial increases in rated speed loads can be utilized, as when a service life of less than 15,000 hours is satisfactory, or when full load operation is encountered only during a portion of the required service life. Chain manufacturers should be consulted for assistance with any special application requirements.

The horsepower ratings shown in **Table 9** relate to the speed of the smaller sprocket and drive selections are made on this basis, whether the drive is speed reducing or speed increasing. Drives with more than two sprockets, idlers, composite duty cycles, or other unusual conditions often require special consideration. Where quietness or extra smooth operation are of special importance, small-pitch chain operating over large diameter sprockets will minimize noise and vibration.

When making drive selection, consideration is given to the loads imposed on the chain by the type of input power and the type of equipment to be driven. Service factors are used to compensate for these loads and the *required* horsepower rating of the chain is determined by the following formula:

$$\text{Required hp Table Rating} = \frac{\text{hp to be Transmitted} \times \text{Service Factor}}{\text{Multiple-Strand Factor}}$$

*Service Factors:* The service factors in **Table 15** are for normal chain loading. For unusual or extremely severe operating conditions not shown in this table, it is desirable to use larger service factors.

*Multiple-Strand Factors:* The horsepower ratings for multiple-strand chains equal single-strand ratings multiplied by these factors: for two strands, a factor of 1.7; for three strands, 2.5; and for four strands, 3.3.

**Lubrication.**— It has been shown that a separating wedge of fluid lubricant is formed in operating chain joints much like that formed in journal bearings. Therefore, fluid lubricant must be applied to ensure an oil supply to the joints and minimize metal-to-metal contact. If supplied in sufficient volume, lubrication also provides effective cooling and impact damping at higher speeds. For this reason, it is important that lubrication recommendations be followed. *The ratings in Table 9 apply only to drives lubricated in the manner specified in this table.*

Chain drives should be protected against dirt and moisture and the oil supply kept free of contamination. Periodic oil change is desirable. A good grade of non-detergent petroleum base oil is recommended. Heavy oils and greases are generally too stiff to enter and fill the chain joints. The following lubricant viscosities are recommended: For temperatures of 20° to 40°F, use SAE 20 lubricant; for 40° to 100°, use SAE 30; for 100° to 120°, use SAE 40; and for 120° to 140°, use SAE 50.

There are three basic types of lubrication for roller chain drives. The recommended type shown in Table 9 as Type A, Type B, or Type C is influenced by the chain speed and the amount of power transmitted. These are *minimum* lubrication requirements and the use of a better type (for example, Type C instead of Type B) is acceptable and may be beneficial. Chain life can vary appreciably depending upon the way the drive is lubricated. The better the chain lubrication, the longer the chain life. For this reason, it is important that the lubrication recommendations be followed when using the ratings given in Table 9. The types of lubrication are as follows:

*Type A — Manual or Drip Lubrication:* In manual lubrication, oil is applied copiously with a brush or spout can at least once every eight hours of operation. Volume and frequency should be sufficient to prevent overheating of the chain or discoloration of the chain joints. In drip lubrication, oil drops from a drip lubricator are directed between the link plate edges. The volume and frequency should be sufficient to prevent discoloration of the lubricant in the chain joints. Precautions must be taken against misdirection of the drops by windage.

*Type B — Bath or Disc Lubrication:* In bath lubrication, the lower strand of the chain runs through a sump of oil in the drive housing. The oil level should reach the pitch line of the chain at its lowest point while operating. In disc lubrication, the chain operates above the oil level. The disc picks up oil from the sump and deposits it onto the chain, usually by means of a trough. The diameter of the disc should be such as to produce rim speeds of between 600 and 8000 feet per minute.

*Type C — Oil Stream Lubrication:* The lubricant is usually supplied by a circulating pump capable of supplying each chain drive with a continuous stream of oil. The oil should be applied inside the chain loop evenly across the chain width, and directed at the slack strand.

The chain manufacturer should be consulted when it appears desirable to use a type of lubricant other than that recommended.

**Installation and Alignment.**— Sprockets should have the tooth form, thickness, profile, and diameters conforming to ASME/ANSI B29.1M. For maximum service life small sprockets operating at moderate to high speeds, or near the rated horsepower, should have hardened teeth. Normally, large sprockets should not exceed 120 teeth.

In general a center distance of 30 to 50 chain pitches is most desirable. The distance between sprocket centers should provide at least a 120 degree chain wrap on the smaller sprocket. Drives may be installed with either adjustable or fixed center distances. Adjustable centers simplify the control of chain slack. Sufficient housing clearance must always be provided for the chain slack to obtain full chain life.

Accurate alignment of shafts and sprocket tooth faces provides uniform distribution of the load across the entire chain width and contributes substantially to optimum drive life.

Shafting, bearings, and foundations should be suitable to maintain the initial alignment. Periodic maintenance should include an inspection of alignment.

**Example of Roller Chain Drive Design Procedure.**— The selection of a roller chain and sprockets for a specific design requirement is best accomplished by a systematic step-by-step procedure such as is used in the following example.

*Example:* Select a roller chain drive to transmit 10 horsepower from a countershaft to the main shaft of a wire drawing machine. The countershaft is  $1\frac{15}{16}$ -inches diameter and operates at 1000 rpm. The main shaft is also  $1\frac{15}{16}$ -inches diameter and must operate between 378 and 382 rpm. Shaft centers, once established, are fixed and by initial calculations must be approximately  $22\frac{1}{2}$  inches. The load on the main shaft is uneven and presents “peaks,” which place it in the heavy shock load category. The input power is supplied by an electric motor. The driving head is fully enclosed and all parts are lubricated from a central system.

*Step 1. Service Factor:* From **Table 15** the service factor for heavy shock load and an electric motor drive is 1.5.

*Step 2. Design Horsepower:* The horsepower upon which the chain selection is based (design horsepower) is equal to the specified horsepower multiplied by the service factor,  $10 \times 1.5 = 15$  hp.

*Step 3. Chain Pitch and Small Sprocket Size for Single-Strand Drive:* In **Table 9** under 1000 rpm, a  $\frac{5}{8}$ -inch pitch chain with a 24-tooth sprocket or a  $\frac{3}{4}$ -inch pitch chain with a 15-tooth sprocket are possible choices.

*Step 4. Check of Chain Pitch and Sprocket Selection:* From **Table 10** it is seen that only the 24-tooth sprocket in Step 3 can be bored to fit the  $1\frac{15}{16}$ -inch diameter main shaft. In **Table 9** a  $\frac{5}{8}$ -pitch chain at a small sprocket speed of 1000 rpm is rated at 15.5 hp for a 24-tooth sprocket.

*Step 5. Selection of Large Sprocket:* Since the driver is to operate at 1000 rpm and the driven at a minimum of 378 rpm, the speed ratio  $1000/378 = 2.646$ . Therefore, the large sprocket should have  $24 \times 2.646 = 63.5$  (use 63) teeth.

This combination of 24 and 63 teeth will produce a main drive shaft speed of 381 rpm which is within the limitation of 378 to 382 rpm established in the original specification.

*Step 6. Computation of Chain Length:* Since the 24- and 63-tooth sprockets are to be placed on  $22\frac{1}{2}$ -inch centers, the chain length is determined from the formula:

$$L = 2C + \frac{N}{2} + \frac{n}{2} + \left(\frac{N-n}{2\pi}\right)^2 \times \frac{1}{C}$$

where  $L$  = chain length in pitches;  $C$  = shaft center distance in pitches;  $N$  = number of teeth in large sprocket; and  $n$  = number of teeth in small sprocket.

$$L = 2 \times 36 + \frac{63 + 24}{2} + \left(\frac{63 - 24}{6.28}\right)^2 \times \frac{1}{36} = 116.57 \text{ pitches}$$

*Step 7. Correction of Center Distance:* Since the chain is to couple at a whole number of pitches, 116 pitches will be used and the center distance recomputed based on this figure using the formula on page 2569 where  $c$  is the center distance in inches and  $P$  is the pitch.

$$\begin{aligned} c &= \frac{P}{8}(2L - N - n + \sqrt{(2L - N - n)^2 - 0.810(N - n)^2}) \\ &= \frac{5}{64}(2 \times 116 - 63 - 24 + \sqrt{(2 \times 116 - 63 - 24)^2 - 0.810(63 - 24)^2}) \\ &= \frac{5}{64}(145 + 140.69) = 22.32 \text{ inches, say } 22\frac{3}{8} \text{ inches} \end{aligned}$$

## BALL AND ACME LEADSCREWS

### Leadscrew Overview

Leadscrew assemblies convert rotary motion into linear travel and are well suited to precise control using electric motors. Acme leadscrews, much like machine screws, are threaded to allow a mating nut to be pushed or pulled along the axis of the screw as the shaft is rotated. Ball screws are threaded to allow ball bearings to support the attached nut. The nut has raceways that allow the ball bearings to recirculate as the nut travels down the axis of the shaft. Both provide efficient and accurate linear positioning for motion control applications. Each has strengths and weaknesses that makes each type of technology more suitable for different types of applications.

**Ball Screws.**— Ball screws generally require lower-torque motors than similarly sized Acme screws due to their higher efficiency in converting energy into linear movement. This efficiency is generally above 90 percent compared to 40 percent for Acme screws with plastic nuts and 25 percent for acme screws with bronze-nuts. Ball screws can handle higher loading with high travel rates and lower backlash, though both technologies offer various anti-backlash nut assemblies. Ball screw life is more easily predicted using ball bearing load data. Compared to acme screws, ball screw assemblies exhibit a lower degradation in positional accuracy over time due to wear on the contact surfaces. Ball screws are more expensive and can be noisier than acme screws. Ball screws may back drive the shaft in vertical orientations.

Fig. 1a. Ball Screw Cross Section

Fig. 1b. Ball Screw Detail

**Acme Screws.**— Acme screws with plastic nuts generally have an initial lower cost and lower noise levels compared to ball screws. Bronze-nut acme screws offer the lowest leadscrew cost as well as the lowest leadscrew performance characteristics. Due to their low efficiency, bronze-nut acme screws may not back drive in some applications where a ball screw would. Loading and travel rates are lower than ball screws. Also, compared to ball screws, lubrication requirements are higher and predicting travel life of acme screws is more difficult due to higher variations in friction and heat build up.

Fig. 2a. Acme Leadscrew with Anti-backlash Nut.

Fig. 2b. Acme Screw Detail

**General Leadscrew Design Considerations.**— The following design criteria should be considered when selecting leadscrews.

*Load:* The load is the weight “as seen by the screw.” For vertical applications such as lifting or jacking the load equals the weight of the load being moved. For horizontal applications the “load seen” equals the weight of the load times the coefficient of friction of the supporting media. Another way to determine the load in an actual application is to attach a scale to the load and pull it. Base the load on the moving force required, not on the higher starting (breakaway) force.

*Tension and Compression Load:* For reduced screw thread sizes, design for tension loads whenever possible. Compression load designs must factor in column strength to prevent buckling.

*Back-drive:* When a ball screw or acme nut is forced to move linearly along the shaft by an applied force, or gravity in vertical orientation, it forces or back-drives the shaft making it rotate. With their higher efficiency and lower initial start up (breakway) friction value, ball screw assemblies in vertical orientations may back-drive their shafts.

*Driving Torque:* The driving torque ( $T_d$ ) is the amount of force required to rotate the screw and move a load.

$$T_d = \frac{P \times L}{2\pi e}$$

where  $T_d$  = driving torque (lb-in.)

$P$  = load (lbs)

$L$  = lead of screw (in./revolution)

$e$  = ball bearing screw efficiency (approximately 0.90 for ball screws, 0.40 for acme screws with plastic nuts, and 0.25 for acme screws with bronze nuts.)

*Accuracy:* Several factors affect accuracy. One factor is the lead deviation in inches per foot. Typical values can range from 0.005 in/ft to 0.001 in./ft. Backlash may also be a consideration in applications that require precise positioning in both directions and in CNC applications. A final consideration is accuracy versus time degradation due to screw wear and ball bearing fatigue. This is especially important in systems that require precise positioning but do not have closed-loop feedback controls. Ball screws have an advantage in long term accuracy since the useful life of ball screws is determined by metal fatigue rather than the ordinary wear characteristics of a conventional screw. Due to rolling contact, very little dimensional change occurs over the life of a ball bearing screw, thus eliminating the need for frequent compensating adjustments.

*Lead:* The distance the nut travels with one rotation of the screw.

*Speed:* When rapid travel is required, design for screws with a high lead to reduce shaft speed to avoid rotational and vibrational side effects.

*Life:* The recommended operating loads for ball screw assemblies are based on a predicted life of one million inches of travel, providing the assembly is lubricated. However, it is possible to operate at greater loads if a reduced life is acceptable. The load should not exceed the maximum static load shown in manufacturer design tables.

*Backlash:* Backlash, end play, positional inaccuracy, or lost motion between the nut and the screw can be eliminated by utilizing a preloaded nut assembly. Backlash can also be reduced, at increased cost, in ball screws by changing the conformity ratio (ball track radius/ball diameter) as well as using ogival (gothic) ball tracks. Fig. 3 illustrates the contact points between a preloaded ball screw assembly and the shaft.

Fig. 3. Contact Points in a Preloaded Anti-Backlash Ball Screw Assembly

*End Supports:* End support type, free or fixed, and the number of end supports for a lead-screw shaft can have a significant impact on the speed and load capacity of the assembly.

*Environment:* Temperature extremes, dirty, dusty conditions, corrosive compounds, and metal chips can cause serious problems with lead screw assemblies. For applications in such conditions the use of wipers, boots, or both should be considered. Stainless steel or plated assemblies should be considered for corrosive applications. Corrosive environments can also attack lubricants and thus indirectly damage the assemblies.

*Wipers:* Brush type wipers maximize ball screw performance by helping to spread lubricant over the length of the screw and preventing internal ball nut contamination from foreign materials. Bellows and telescopic wipers are recommended for severely “dirty” environments.

*Lubrication:* Ball screws must be lubricated and kept clean. Failure to lubricate can substantially reduce bearing life. Oil and grease can be used but grease is not recommended for low temperature or high speed applications.

*PV Value:* Speed and load limits for acme leadscrew assemblies using plastic nuts are generally limited by heat build-up. The factor which affects heat generation in an application is the product of the pressure (lbs/in<sup>2</sup>) on the nut, and the surface velocity at the thread major diameter. This product is called the *PV* value.

*CNC Considerations:* CNC machine tools require the elimination of backlash and the minimization of elastic deflection to achieve high system stiffness, response, and repeatability of positioning.

**Ball Screw Selection.**— Many types and styles of ball screws and ball screw assemblies are offered by manufacturers. Consult the vendor’s specific data sheets for precise design criteria. The selection of the correct ball screw and nut for a particular application involves four factors, all of which are interrelated. These are: the equivalent load measured in pounds, the required life measured in linear inches of travel, travel speed measured in inches per minute, and the length between bearings measured in inches.

Fig. 4. Ball Screw Detail

*Design Overview:* To design a ball screw assembly many interrelated factors such as load, bearing length, life, and speed must be considered. Changing one parameter will influence others and generally an iterative approach to balancing these requirements is required. An example is the choice of a fine lead vs. coarse lead. A fine line lead provides better positioning sensitivity and lower drive torque, but also requires a higher rotary speed to achieve the same linear rate of speed. A coarse lead results in lower rotary speed, but requires a higher drive torque that may require a larger motor and related drive components. **Table 1** identifies some of these design interrelationships.

**Table 1. Ball Screw Design Factor Interrelationships**

Increase In	Affects	How	Increase In	Affects	How
Screw Length	Critical speed	Decreases	End Mounting Rigidity	Critical speed	Increases
	Compression load	Decreases		Compression load	Increases
Screw Diameter	Critical speed	Increases	Load	System stiffness	Increases
	Inertia	Increases		Life	Decreases
	Compression load	Increases	Preload	Positioning accuracy	Increases
	Stiffness	Increases		System stiffness	Increases
	Spring Rate	Increases		Drag torque	Increases
	Load capacity	Increases	Angular Velocity	Critical speed	Decreases
Lead	Drive torque	Increases	Nut length	Load capacity	Increases
	Angular velocity	Decreases		Stiffness	Increases
	Load capacity	Increases	Ball diameter	Life	Increases
	Positioning accuracy	Decreases		Stiffness	Increases
	Ball diameter	Increases		Load capacity	Increases

**Screws, Power Transmission.**— The square form of thread has a somewhat higher efficiency than threads with sloping sides, although when the angle of the thread form is comparatively small, as in the case of an Acme thread, there is little increase in frictional losses. The Acme thread has superseded the square form on many classes of equipment requiring lead-screws or other power transmitting screws, because the former has practical advantages in regard to cutting and also in compensating for wear between the screw and nut. Multiple thread screws are much more efficient than single-thread screws, as the efficiency is affected by the helix angle of the thread.

*Force Required to Turn Screw:* In determining the force which must be applied at the end of a given lever-arm in order to turn a screw (or nut surrounding it), there are two conditions to be considered:

1) When rotation is such that the load *resists* the movement of the screw, as in raising a load with a screw jack,  $F = L \times \frac{l + 2r\pi\mu}{2r\pi - \mu l} \times \frac{r}{R}$ .

2) When rotation is such that the load *assists* the movement of the screw, as in lowering a load,  $F = L \times \frac{2r\pi\mu - l}{2r\pi + \mu l} \times \frac{r}{R}$ .

In these formulas,  $F$  = force applied at end of lever-arm;  $L$  = load moved by screw;  $R$  = length of lever-arm;  $l$  = lead of screw thread;  $r$  = mean or pitch radius of screw;  $\mu$  = coefficient of friction. If lead  $l$  is large in proportion to the diameter so that the helix angle is large,  $F$  will have a negative value, indicating that the screw will turn due to the load alone. The efficiency between a screw and nut increases quite rapidly for helix angles up to 10 or 15 degrees (measured from a plane perpendicular to the screw axis). The efficiency remains nearly constant for angles between about 25 and 65 degrees, and the angle of maximum efficiency is between 40 and 50 degrees. A screw will not be self-locking if the efficiency exceeds 50 percent.

## ELECTRIC MOTORS

**Classes of NEMA Standards.**— National Electrical Manufacturers Association Standards, available from the Association at 1300 North 17th Street, Rosslyn, VA 22209, are of two classes: 1) *NEMA Standard*, which relates to a product commercially standardized and subject to repetitive manufacture, which standard has been approved by at least 90 percent of the members of the Subdivision eligible to vote thereon; and 2) *Suggested Standard for Future Design*, which may not have been regularly applied to a commercial product, but which suggests a sound engineering approach to future development and has been approved by at least two-thirds of the members of the Subdivision eligible to vote thereon.

*Authorized Engineering Information* consists of explanatory data and other engineering information of an informative character not falling within the classification of NEMA Standard or Suggested Standard for Future Design.

**Mounting Dimensions and Frame Sizes for Electric Motors.**— Dimensions for foot-mounted electric motors as standardized in the United States by the National Electrical Manufacturers Association (NEMA) include the spacing of bolt holes in the feet of the motor, the distance from the bottom of the feet to the center-line of the motor shaft, the size of the conduit, the length and diameter of shaft, and other dimensions likely to be required by designers or manufacturers of motor-driven equipment. The Standard provides dimensions for face-mounted and flange-mounted motors by means of standard motor frame numbers.

Standard dimensions also are given where the motor is to be mounted upon a belt-tightening base or upon rails.

The NEMA standards also prescribe lettering for dimension drawings, mounting and terminal housing locations and dimensions, symbols and terminal connections, and provision for grounding of field wiring. In addition, the standards give recommended knock-out and clearance hole dimensions; tolerances on shaft extension diameters and keyseats; methods of measuring shaft run-out and eccentricity, also face runout of mounting surfaces; and tolerances of face-mounted and flanged-mounted motors.

**Design Letters of Polyphase Integral-horsepower Motors.**— Designs A, B, C, and D motors are squirrel-cage motors designed to withstand full voltage starting and developing locked-rotor torque and breakdown torque, drawing locked-rotor current, and having a slip as specified below:

*Design A:* Locked-rotor torque as shown in **Table 2**, breakdown torque as shown in **Table 3**, locked-rotor current higher than the values shown in **Table 1**, and a slip at rated load of less than 5 percent. Motors with 10 or more poles may have a slightly greater slip.

**Table 1. NEMA Standard Locked-rotor Current of 3-phase 60-hertz Integral-horsepower Squirrel-cage Induction Motors Rated at 230 Volts**

Horse-power	Locked-rotor Current, Amps.	Design Letters	Horse-power	Locked-rotor Current, Amps.	Design Letters	Horse-power	Locked-rotor Current, Amps.	Design Letters
½	20	B, D	7½	127	B, C, D	50	725	B, C, D
¾	25	B, D	10	162	B, C, D	60	870	B, C, D
1	30	B, D	15	232	B, C, D	75	1085	B, C, D
1½	40	B, D	20	290	B, C, D	100	1450	B, C, D
2	50	B, D	25	365	B, C, D	125	1815	B, C, D
3	64	B, C, D	30	435	B, C, D	150	2170	B, C, D
5	92	B, C, D	40	580	B, C, D	200	2900	B, C

*Note:* The locked-rotor current of a motor is the steady-state current taken from the line with the rotor locked and with rated voltage and frequency applied to the motor.

For motors designed for voltages other than 230 volts, the locked-rotor current is inversely proportional to the voltages. For motors larger than 200 hp, see NEMA Standard MG 1-12.34.

<sup>a</sup>These values represent the upper limit of application for these motors.

*Note:* The locked-rotor torque of a motor is the minimum torque which it will develop at rest for all angular positions of the rotor, with rated voltage applied at rated frequency.

The locked-rotor torque of Design D, 60- and 50-hertz 4-, 6-, and 8-pole single-speed, polyphase squirrel-cage motors rated 150 hp and smaller, with rated voltage and frequency applied is 275 percent of full-load torque, which represents the upper limit of application for these motors.

For motors larger than 200 hp, see NEMA Standard MG 1-12.37.

7 1/2-200, incl.	...	190	190	190	...	...	...	...

<sup>a</sup>Design A values are in excess of those shown.

These values represent the upper limit of the range of application for these motors. For above 200 hp, see NEMA Standard MG1-12.38.

*Design B:* Locked-rotor torque as shown in Table 2, breakdown torque as shown in Table 3, locked-rotor current not exceeding that in Table 1, and a slip at rated load of less than 5 percent. Motors with 10 or more poles may have a slightly greater slip.

*Design C:* Locked-rotor torque for special high-torque applications up to values shown in Table 2, breakdown torque up to values shown in Table 3, locked-rotor current not exceeding values shown in Table 1 and a slip at rated load of less than 5 percent.

*Design D:* Locked-rotor torque as indicated in Table 2, locked-rotor current not greater than that shown in Table 1 and a slip at rated load of 5 percent or more.

**Torque and Current Definitions.**— The definitions which follow have been adopted as standard by the National Electrical Manufacturers Association.

*Locked-Rotor or Static Torque:* The locked-rotor torque of a motor is the minimum torque which it will develop at rest for all angular positions of the rotor, with rated voltage applied at rated frequency.

*Breakdown Torque:* The breakdown torque of a motor is the maximum torque which the motor will develop, with rated voltage applied at rated frequency, without an abrupt drop in speed (see Table 4).

*Full-Load Torque:* The full-load torque of a motor is the torque necessary to produce its rated horsepower at full load speed. In pounds at 1-foot radius, it is equal to the horsepower times 5252 divided by the full-load speed.

*Pull-Out Torque:* The pull-out torque of a synchronous motor is the maximum sustained torque which the motor will develop at synchronous speed with rated voltage applied at rated frequency and with normal excitation.

*Pull-In Torque:* The pull-in torque of a synchronous motor is the maximum constant torque under which the motor will pull its connected inertia load into synchronism at rated voltage and frequency, when its field excitation is applied.

*Pull-Up Torque:* The pull-up torque of an alternating current motor is the minimum torque developed by the motor during the period of acceleration from rest to the speed at which breakdown torque occurs. For motors which do not have a definite breakdown torque, the pull-up torque is the minimum torque developed up to rated speed.

*Locked Rotor Current:* The locked rotor current of a motor is the steady-state current taken from the line with the rotor locked and with rated voltage (and rated frequency in the case of alternating-current motors) applied to the motor.

**Table 4. NEMA Standard Breakdown Torque of Polyphase Wound-rotor Motors with Continuous Ratings — 60- and 50-hertz**

Horsepower	Speed, rpm			Horsepower	Speed, rpm		
	1800	1200	900		1800	1200	900
	Percent of Full-load Torque				Percent of Full-load Torque		
1	...	...	250	7½	275	250	225
1½	...	...	250	10	275	250	225
2	275	275	250	15	250	225	225
3	275	275	250	20-200, incl.	225	225	225
5	275	275	250	...	...	...	...

These values represent the upper limit of the range of application for these motors.

**Standard Direction of Motor Rotation.**— The standard direction of rotation for all non-reversing direct-current motors, all alternating-current single-phase motors, all synchronous motors, and all universal motors, is *counterclockwise* when facing that end of the motor opposite the drive.

This rule does not apply to two- and three-phase induction motors, as in most applications the phase sequence of the power lines is rarely known.

**Motor Types According to Variability of Speed.**—Five types of motors classified according to variability of speed are:

*Constant-speed Motors:* In this type of motor the normal operating speed is constant or practically constant; for example, a synchronous motor, an induction motor with small slip, or a direct-current shunt-wound motor.

*Varying-speed Motor:* In this type of motor, the speed varies with the load, ordinarily decreasing when the load increases; such as a series-wound or repulsion motor.

*Adjustable-speed Motor:* In this type of motor, the speed can be varied gradually over a considerable range, but when once adjusted remains practically unaffected by the load; such as a direct-current shunt-wound motor with field resistance control designed for a considerable range of speed adjustment.

The base speed of an adjustable-speed motor is the lowest rated speed obtained at rated load and rated voltage at the temperature rise specified in the rating.

*Adjustable Varying-speed Motor:* This type of motor is one in which the speed can be adjusted gradually, but when once adjusted for a given load will vary in considerable degree with the change in load; such as a direct-current compound-wound motor adjusted by field control or a wound-rotor induction motor with rheostatic speed control.

*Multispeed Motor:* This type of motor is one which can be operated at any one of two or more definite speeds, each being practically independent of the load; such as a direct-current motor with two armature windings or an induction motor with windings capable of various pole groupings. In the case of multispeed permanent-split capacitor and shaded pole motors, the speeds are dependent upon the load.

**Pull-up Torque.**—NEMA Standard pull up torques for single-speed, polyphase, squirrel-cage integral-horsepower motors, Designs A and B, with continuous ratings and with rated voltage and frequency applied are as follows: When the locked-rotor torque given in [Table 2](#) is 110 percent or less, the pull-up torque is 90 percent of the locked-rotor torque; when the locked-rotor torque is greater than 110 percent but less than 145 percent, the pull-up torque is 100 percent of full-load torque; and when the locked-rotor torque is 145 percent or more, the pull-up torque is 70 percent of the locked-rotor torque.

For Design C motors, with rated voltage and frequency applied, the pull-up torque is not less than 70 percent of the locked-rotor torque as given in [Table 2](#).

### Types and Characteristics of Electric Motors

**Types of Direct-Current Motors.**—Direct-current motors may be grouped into three general classes: series-wound; shunt-wound; and compound-wound.

In the *series-wound motor* the field windings, which are fixed in the stator frame, and the armature windings, which are placed around the rotor, are connected in series so that all current passing through the armature also passes through the field. In the *shunt-wound motor*, both armature and field are connected across the main power supply so that the armature and field currents are separate. In the *compound-wound motor*, both series and shunt field windings are provided and these may be connected so that the currents in both are flowing in the same direction, called *cumulative compounding*, or so that the currents in each are flowing in opposite directions, called *differential compounding*.

**Characteristics of Series-wound Direct-Current Motors.**—In the series-wound motor, any increase in load results in more current passing through the armature and the field windings. As the field is strengthened by this increased current, the motor speed decreases. Conversely, as the load is decreased the field is weakened and the speed increases and at very light loads may become excessive. For this reason, series-wound direct-current motors are usually directly connected or geared to the load to prevent “run-away.” (A series-wound motor, designated as series-shunt wound, is sometimes provided with a light shunt field winding to prevent dangerously high speeds at light loads.) The increase in armature current with increasing load produces increased torque, so that the

series-wound motor is particularly suited to heavy starting duty and where severe overloads may be expected. Its speed may be adjusted by means of a variable resistance placed in series with the motor, but due to variation with load, the speed cannot be held at any constant value. This variation of speed with load becomes greater as the speed is reduced. Series-wound motors are used where the load is practically constant and can easily be controlled by hand. They are usually limited to traction and lifting service.

**Shunt-wound Direct-Current Motors.**— In the shunt-wound motor, the strength of the field is not affected appreciably by change in the load, so that a fairly constant speed (about 10 to 12 percent drop from no load to full load speed) is obtainable. This type of motor may be used for the operation of machines requiring an approximately constant speed and imposing low starting torque and light overload on the motor.

The shunt-wound motor becomes an adjustable-speed motor by means of field control or by armature control. If a variable resistance is placed in the field circuit, the amount of current in the field windings and hence the speed of rotation can be controlled. As the speed increases, the torque decreases proportionately, resulting in nearly constant horsepower. A speed range of 6 to 1 is possible using field control, but 4 to 1 is more common. Speed regulation is somewhat greater than in the constant-speed shunt-wound motors, ranging from about 15 to 22 percent. If a variable resistance is placed in the armature circuit, the voltage applied to the armature can be reduced and hence the speed of rotation can be reduced over a range of about 2 to 1. With armature control, speed regulation becomes poorer as speed is decreased, and is about 100 percent for a 2 to 1 speed range. Since the current through the field remains unchanged, the torque remains constant.

*Machine Tool Applications:* The adjustable-speed shunt-wound motors are useful on larger machines of the boring mill, lathe, and planer type and are particularly adapted to spindle drives because constant horsepower characteristics permit heavy cuts at low speed and light or finishing cuts at high speed. They have long been used for planer drives because they can provide an adjustable low speed for the cutting stroke and a high speed for the return stroke. Their application has been limited, however, to plants in which direct-current power is available.

**Adjustable-voltage Shunt-wound Motor Drive.**— More extensive use of the shunt-wound motor has been made possible by a combination drive that includes a means of converting alternating current to direct current. This conversion may be effected by a self-contained unit consisting of a separately excited direct-current generator driven by a constant speed alternating-current motor connected to the regular alternating-current line, or by an electronic rectifier with suitable controls connected to the regular alternating-current supply lines. The latter has the advantage of causing no vibration when mounted directly on the machine tool, an important factor in certain types of grinders.

In this type of adjustable-speed, shunt-wound motor drive, speed control is effected by varying the voltage applied to the armature while supplying constant voltage to the field. In addition to providing for the adjustment of the voltage supplied by the conversion unit to the armature of the shunt-wound motor, the amount of current passing through the motor field may also be controlled. In fact, a single control may be provided to vary the motor speed from minimum to base speed (speed of the motor at full load with rated voltage on armature and field) by varying the voltage applied to the armature and from base speed to maximum speed by varying the current flowing through the field. When so controlled, the motor operates at constant torque up to base speed and at constant horsepower above base speed.

*Speed Range:* Speed ranges of at least 20 to 1 below base speed and 4 or 5 to 1 above base speed (a total range of 100 to 1, or more) are obtainable as compared with about 2 to 1 below normal speed and 3 or 4 to 1 above normal speed for the conventional type of control. Speed regulation may be as great as 25 percent at high speeds. Special electronic controls, when used with this type shunt motor drive, make possible maintenance of motor

speeds with as little variation as  $\frac{1}{2}$  to 1 percent of full load speed from full load to no load over a line voltage variation of  $\pm 10$  percent and over any normal variation in motor temperature and ambient temperature.

*Applications:* These direct-current, adjustable-voltage drives, as they are sometimes called, have been applied successfully to such machine tools as planers, milling machines, boring mills and lathes, as well as to other industrial machines where wide, stepless speed control, uniform speed under all operating conditions, constant torque acceleration and adaptability to automatic operation are required.

**Compound-wound Motors.**— In the compound-wound motor, the speed variation due to load changes is much less than in the series-wound motor, but greater than in the shunt-wound motor (ranging up to 25 percent from full load to no load). It has a greater starting torque than the shunt-wound motor, is able to withstand heavier overloads, but has a narrower adjustable speed range. Standard motors of this type have a cumulative-compound winding, the differential-compound winding being limited to special applications. They are used where the starting load is very heavy or where the load changes suddenly and violently as with reciprocating pumps, printing presses and punch presses.

**Types of Polyphase Alternating-Current Motors.**— The most widely used polyphase motors are of the induction type. The “*squirrel cage*” induction motor consists of a wound stator which is connected to an external source of alternating-current power and a laminated steel core rotor with a number of heavy aluminum or copper conductors set into the core around its periphery and parallel to its axis. These conductors are connected together at each end of the rotor by a heavy ring, which provides closed paths for the currents induced in the rotor to circulate. The rotor bars form, in effect, a “squirrel cage” from which the motor takes its name.

*Wound-rotor Type of Induction Motor:* This type has, in addition to a squirrel cage, a series of coils set into the rotor which are connected through slip-rings to external variable resistors. By varying the resistance of the wound-rotor circuits, the amount of current flowing in these circuits and hence the speed of the motor can be controlled. Since the rotor of an induction motor is not connected to the power supply, the motor is said to operate by transfer action and is analogous to a transformer with a short-circuited secondary that is free to rotate. Induction motors are built with a wide range of speed and torque characteristics which are discussed under “Operating Characteristics of Squirrel-cage Induction Motors.”

*Synchronous Motor:* The other type of polyphase alternating-current motor used industrially is the *synchronous motor*. In contrast to the induction motor, the rotor of the synchronous motor is connected to a direct-current supply which provides a field that rotates in step with the alternating-current field in the stator. After having been brought up to synchronous speed, which is governed by the frequency of the power supply and the number of poles in the rotor, the synchronous motor operates at this constant speed throughout its entire load range.

**Operating Characteristics of Squirrel-cage Induction Motors.**— In general, squirrel-cage induction motors are simple in design and construction and offer rugged service. They are essentially constant-speed motors, their speed changing very little with load and not being subject to adjustment. They are used for a wide range of industrial applications calling for integral horsepower ratings. According to the NEMA (National Electrical Manufacturers Association) Standards, there are four classes of squirrel-cage induction motors designated respectively as *A*, *B*, *C*, and *D*.

*Design A* motors are not commonly used since *Design B* has similar characteristics with the advantage of lower starting current.

*Design B:* motors may be designated as a general purpose type suitable for the majority of polyphase alternating-current applications such as blowers, compressors, drill presses, grinders, hammer mills, lathes, planers, polishers, saws, screw machines, shakers, stokers,

etc. The starting torque at 1800 rpm. is 250 to 275 percent of full load torque for 3 hp (2.24 kW) and below; for 5–75 hp (3.73–56 kW) ratings the starting torque ranges from 185 to 150 percent of full load torque. They have low starting current requirements, usually no more than 5 to 6 times full load current and can be started at full voltage. Their slip (difference between synchronous speed and actual speed at rated load) is relatively low.

*Design C* motors have high starting torque (up to 250 percent of full load torque) but low starting current. They can be started at full voltage. Slip at rated load is relatively low. They are used for compressors requiring a loaded start, heavy conveyors, reciprocating pumps and other applications requiring high starting torque.

*Design D* motors have high slip at rated load, that is, the motor speed drops off appreciably as the load increases, permitting use of the stored energy of a flywheel. They provide heavy starting torque, up to 275 percent of full load torque, are quiet in operation and have relatively low starting current. Applications are for impact, shock and other high peak loads or flywheel drives such as trains, elevators, hoists, punch and drawing presses, shears, etc.

*Design F* motors are no longer standard. They had low starting torque, about 125 percent of full-load torque, and low starting current. They were used to drive machines which required infrequent starting at no load or at very light load.

**Multiple-Speed Induction Motors.**— This type has a number of windings in the stator so arranged and connected that the number of effective poles and hence the speed can be changed. These motors are for the same types of starting conditions as the conventional squirrel-cage induction motors and are available in designs that provide constant horsepower at all rated speeds and in designs that provide constant torque at all rated speeds.

Typical speed combinations obtainable in these motors are 600, 900, 1200 and 1800 rpm; 450, 600, 900 and 1200 rpm; and 600, 720, 900 and 1200 rpm.

Where a gradual change in speed is called for, a wound rotor may be provided in addition to the multiple stator windings.

**Wound-Rotor Induction Motors.**— These motors are designed for applications where extremely low starting current with high starting torque are called for, such as in blowers, conveyors, compressors, fans and pumps. They may be employed for adjustable-varying speed service where the speed range does not extend below 50 percent of synchronous speed, as for steel plate-forming rolls, printing presses, cranes, blowers, stokers, lathes and milling machines of certain types. The speed regulation of a wound rotor induction motor ranges from 5 to 10 percent at maximum speed and from 18 to 30 percent at low speed. They are also employed for reversing service as in cranes, gates, hoists and elevators.

**High-Frequency Induction Motors.**— This type is used in conjunction with frequency changers when very high speeds are desired, as on grinders, drills, routers, portable tools or woodworking machinery. These motors have an advantage over the series-wound or universal type of high speed motor in that they operate at a relatively constant speed over the entire load range. A motor-generator set, a two-unit frequency converter or a single unit inductor frequency converter may be used to supply three-phase power at the frequency required. The single unit frequency converter may be obtained for delivering any one of a number of frequencies ranging from 360 to 2160 cycles and it is self-driven and self-excited from the general polyphase power supply.

**Synchronous Motors.**— These are widely used in electric timing devices; to drive machines that must operate in synchronism; and also to operate compressors, rolling mills, crushers which are started without load, paper mill screens, shredders, vacuum pumps and motor-generator sets. Synchronous motors have an inherently high power factor and are often employed to make corrections for the low power factor of other types of motors on the same system.

**Types of Single-Phase Alternating-Current Motors.**— Most of the single-phase alternating-current motors are basically induction motors distinguished by different arrangements for starting. (A single-phase induction motor with only a squirrel-cage rotor has no starting torque.) In the *capacitor-start* single-phase motor, an auxiliary winding in the stator is connected in series with a capacitor and a centrifugal switch. During the starting and accelerating period the motor operates as a two-phase induction motor. At about two-thirds full-load speed, the auxiliary circuit is disconnected by the switch and the motor then runs as a single-phase induction motor. In the *capacitor-start, capacitor-run* motor, the auxiliary circuit is arranged to provide high effective capacity for high starting torque and to remain connected to the line but with reduced capacity during the running period. In the *single-value capacitor* or *capacitor split-phase* motor, a relatively small continuously-rated capacitor is permanently connected in one of the two stator windings and the motor both starts and runs like a two-phase motor.

In the *repulsion-start* single-phase motor, a drum-wound rotor circuit is connected to a commutator with a pair of short-circuited brushes set so that the magnetic axis of the rotor winding is inclined to the magnetic axis of the stator winding. The current flowing in this rotor circuit reacts with the field to produce starting and accelerating torques. At about two-thirds full load speed the brushes are lifted, the commutator is short circuited and the motor runs as a single-phase squirrel-cage motor. The *repulsion* motor employs a repulsion winding on the rotor for both starting and running. The *repulsion-induction* motor has an outer winding on the rotor acting as a repulsion winding and an inner squirrel-cage winding. As the motor comes up to speed, the induced rotor current partially shifts from the repulsion winding to the squirrel-cage winding and the motor runs partly as an induction motor.

In the *split-phase* motor, an auxiliary winding in the stator is used for starting with either a resistance connected in series with the auxiliary winding (*resistance-start*) or a reactor in series with the main winding (*reactor-start*).

The *series-wound* single-phase motor has a rotor winding in series with the stator winding as in the series-wound direct-current motor. Since this motor may also be operated on direct current, it is called a *universal* motor.

**Characteristics of Single-Phase Alternating-Current Motors.**— Single-phase motors are used in sizes up to about  $7\frac{1}{2}$  horsepower (5.6 kW) for heavy starting duty chiefly in home and commercial appliances for which polyphase power is not available. The *capacitor-start* motor is available in normal starting torque designs for such applications as centrifugal pumps, fans, and blowers and in high-starting torque designs for reciprocating compressors, pumps, loaded conveyors, or belts. The *capacitor-start, capacitor-run* motor is exceptionally quiet in operation when loaded to at least 50 percent of capacity. It is available in low-torque designs for fans and centrifugal pumps and in high-torque designs for applications similar to those of the capacitor-start motor.

The *capacitor split-phase* motor requires the least maintenance of all single-phase motors, but has very low starting torque. Its high maximum torque makes it potentially useful in floor sanders or in grinders where momentary overloads due to excessive cutting pressure are experienced. It is also used for slow-speed direct connected fans.

The *repulsion-start, induction-run* motor has higher starting torque than the capacitor motors, although for the same current, the capacitor motors have equivalent pull-up and maximum torque. Electrical and mechanical noise and the extra maintenance sometimes required are disadvantages. These motors are used for compressors, conveyors and stokers starting under full load. The *repulsion-induction* motor has relatively high starting torque and low starting current. It also has a smooth speed-torque curve with no break and a greater ability to withstand long accelerating periods than capacitor type motors. It is particularly suitable for severe starting and accelerating duty and for high inertia loads such as laundry extractors. Brush noise is, however, continuous.

The *repulsion* motor has no limiting synchronous speed and the speed changes with the load. At certain loads, slight changes in load cause wide changes in speed. A brush shifting arrangement may be provided to adjust the speed which may have a range of 4 to 1 if full rated constant torque is applied but a decreasing range as the torque falls below this value. This type of motor may be reversed by shifting the brushes beyond the neutral point. These motors are suitable for machines requiring constant-torque and adjustable speed.

The *split-phase* and *universal* motors are limited to about  $\frac{1}{3}$  hp (0.25 kW) ratings and are used chiefly for small appliance and office machine applications.

**Motors with Built-in Speed Reducers.**— Electric motors having built-in speed-changing units are compact and the design of these motorized speed reducers tends to improve the appearance of the machines which they drive. There are several types of these speed reducers; they may be classified according to whether they are equipped with worm gearing, a regular gear train with parallel shafts, or planetary gearing.

The claims made for the worm gearing type of reduction unit are that the drive is quiet in operation and well adapted for use where the slow-speed shaft must be at right angles to the motor shaft and where a high speed ratio is essential.

For very low speeds, the double reduction worm gearing units are suitable. In these units two sets of worm gearing form the gear train, and both the slow-speed shaft and the armature shaft are parallel. The intermediate worm gear shaft can be built to extend from the housing, if required, so as to make two countershaft speeds available on the same unit.

In the parallel-shaft type of speed reducer, the slow-speed shaft is parallel with the armature shaft. The slow-speed shaft is rotated by a pinion on the armature shaft, this pinion meshing with a larger gear on the slow-speed shaft.

Geared motors having built-in speed-changing units are available with constant-mesh change gears for varying the speed ratio.

Planetary gearing permits a large speed reduction with few parts; hence, it is well adapted for geared-head motor units where economy and compactness are essential. The slow-speed shaft is in line with the armature shaft.

### Factors Governing Motor Selection

**Speed, Horsepower, Torque and Inertia Requirements.**— Where more than one speed or a range of speeds are called for, one of the following types of motors may be selected, depending upon other requirements: For direct-current, the standard shunt-wound motor with field control has a 2 to 1 range in some designs; the adjustable speed motor may have a range of from 3 to 1 up to 6 to 1; the shunt motor with adjustable voltage supply has a range up to 20 to 1 or more below base speed and 4 or 5 to 1 above base speed, making a total range of up to 100 to 1 or more. For polyphase alternating current, multi-speed squirrel-cage induction motors have 2, 3 or 4 fixed speeds; the wound-rotor motor has a 2 to 1 range. The two-speed wound-rotor motor has a 4 to 1 range. The brush-shifting shunt motor has a 4 to 1 range. The brush-shifting series motor has a 3 to 1 range; and the squirrel-cage motor with a variable-frequency supply has a very wide range. For single-phase alternating current, the brush-shifting repulsion motor has a  $2\frac{1}{2}$  to 1 range; the capacitor motor with tapped winding has a 2 to 1 range and the multi-speed capacitor motor has 2 or 3 fixed speeds. Speed regulation (variation in speed from no load to full load) is greatest with motors having series field windings and entirely absent with synchronous motors.

*Horsepower:* Where the load to be carried by the motor is not constant but follows a definite cycle, a horsepower-time curve enables the peak horsepower to be determined as well as the root-mean-square-average horsepower, which indicates the proper motor rating from a heating standpoint. Where the load is maintained at a constant value for a period of from 15 minutes to 2 hours depending on the size, the horsepower rating required will usually not be less than this constant value. When selecting the size of an induction motor, it should be kept in mind that this type of motor operates at maximum efficiency when it is

loaded to full capacity. Where operation is to be at several speeds, the horsepower requirement for each speed should be considered.

*Torque:* Starting torque requirements may vary from 10 percent of full load to 250 percent of full load torque depending upon the type of machine being driven. Starting torque may vary for a given machine because of frequency of start, temperature, type and amount of lubricant, etc., and such variables should be taken into account. The motor torque supplied to the machine must be well above that required by the driven machine at all points up to full speed. The greater the excess torque, the more rapid the acceleration. The approximate time required for acceleration from rest to full speed is given by the formula:

$$\text{Time} = \frac{N \times WR^2}{T_a \times 308} \text{ seconds}$$

where  $N$  = full load speed in rpm.

$T_a$  = torque = average foot-pounds available for acceleration.

$WR^2$  = inertia of rotating part in pounds feet squared ( $W$  = weight and  $R$  = radius of gyration of rotating part).

308 = combined constant converting minutes into seconds, weight into mass and radius into circumference.

If the time required for acceleration is greater than 20 seconds, special motors or starters may be required to avoid overheating.

The running torque  $T_r$  is found by the formula:

$$T_r = \frac{5250 \times \text{HP}}{N} \text{ foot pounds}$$

where  $HP$  = horsepower being supplied to the driven machine

$n$  = running speed in r.p.m.

5250 = combined constant converting horsepower to foot-pounds per minute and work per revolution into torque.

The peak horsepower determines the maximum torque required by the driven machine and the motor must have a maximum running torque in excess of this value.

*Inertia:* The inertia or flywheel effect of the rotating parts of a driven machine will, if large, appreciably affect the accelerating time and, hence, the amount of heating in the motor. If synchronous motors are used, the inertia ( $WR^2$ ) of both the motor rotor and the rotating parts of the machine must be known since the pull-in torque (torque required to bring the driven machine up to synchronous speed) varies approximately as the square root of the total inertia of motor and load.

**Space Limitations in Motor Selection.**— If the motor is to become an integral part of the machine which it drives and space is at a premium, a partial motor may be called for. A complete motor is one made up of a stator, a rotor, a shaft, and two end shields with bearings. A *partial motor* is without one or more of these elements. One common type is furnished without drive-end end shield and bearing and is directly connected to the end or side of the machine which it drives, such as the headstock of a lathe. A so-called *shaftless type of motor* is supplied without shaft, end shields or bearings and is intended for built-in application in such units as multiple drilling machines, precision grinders, deep well pumps, compressors and hoists where the rotor is actually made a part of the driven machine. Where a partial motor is used, however, proper ventilation, mounting, alignment and bearings must be arranged for by the designer of the machine to which it is applied.

Sometimes it is possible to use a motor having a smaller frame size and wound with Class B insulation, permitting it to be subjected to a higher temperature rise than the larger-frame Class A insulated motor having the same horsepower rating.

**Temperatures.**— The applicability of a given motor is limited not only by its load starting and carrying ability, but also by the temperature which it reaches under load. Motors are given temperature ratings which are based upon the type of insulation (Class A or Class B are the most common) used in their construction and their type of frame (open, semienclosed, or enclosed).

*Insulating Materials:* Class A materials are: cotton, silk, paper, and similar organic materials when either impregnated or immersed in a liquid dielectric; molded and laminated materials with cellulose filler, phenolic resins, and other resins of similar properties; films and sheets of cellulose acetate and other cellulose derivatives of similar properties; and varnishes (enamel) as applied to conductors.

Class B insulating materials are: materials or combinations of materials such as mica, glass fiber, asbestos, etc., with suitable bonding substances. Other materials shown capable of operation at Class B temperatures may be included.

*Ambient Temperature and Allowable Temperature Rise:* Normal ambient temperature is taken to be 40°C (104°F). For open general-purpose motors with Class A insulation, the normal temperature rise on which the performance guarantees are based is 40°C (104°F).

Motors with Class A insulation having protected, semiprotected, drip-proof, or splash-proof, or drip-proof protected enclosures have a 50°C (122°F) rise rating.

Motors with Class A insulation and having totally enclosed, fan-cooled, explosion-proof, waterproof, dust-tight, submersible, or dust-explosion-proof enclosures have a 55°C (131°F) rise rating.

Motors with Class B insulation are permissible for total temperatures up to 110°C (230°F) for open motors and 115°C (239°F) for enclosed motors.

**Motors Exposed to Injurious Conditions.**— Where motors are to be used in locations imposing unusual operating conditions, the manufacturer should be consulted, especially where any of the following conditions apply: exposure to chemical fumes; operation in damp places; operation at speeds in excess of specified overspeed; exposure to combustible or explosive dust; exposure to gritty or conducting dust; exposure to lint; exposure to steam; operation in poorly ventilated rooms; operation in pits, or where entirely enclosed in boxes; exposure to inflammable or explosive gases; exposure to temperatures below 10°C (50°F); exposure to oil vapor; exposure to salt air; exposure to abnormal shock or vibration from external sources; where the departure from rated voltage is excessive; and or where the alternating-current supply voltage is unbalanced.

Improved insulating materials and processes and greater mechanical protection against falling materials and liquids make it possible to use general-purpose motors in many locations where special-purpose motors were previously considered necessary. *Splash-proof motors* having well-protected ventilated openings and specially treated windings are used where they are to be subjected to falling and splashing water or are to be washed down as with a hose. Where climatic conditions are not severe, this type of motor is also successfully used in unprotected outdoor installations.

If the surrounding atmosphere carries abnormal quantities of metallic, abrasive, or non-explosive dust or acid or alkali fumes, a *totally enclosed fan-cooled motor* may be called for. In this type, the motor proper is completely enclosed but air is blown through an outer shell that completely or partially surrounds the inner case. If the dust in the atmosphere tends to pack or solidify and close the air passages of open splash-proof or totally enclosed fan-cooled motors, *totally enclosed (nonventilated) motors* are used. This type, which is limited to low horsepower ratings, is also used for outdoor service in mild or severe climates.

**Table 1. Characteristics and Applications of D.C. Motors, 1–300 hp**

Type	Starting Duty	Maximum Momentary Running Torque	Speed Regulation	Speed Control <sup>a</sup>	Applications
Shunt-wound, constant-speed	Medium starting torque. Varies with voltage supplied to armature, and is limited by starting resistor to 125 to 200% full-load torque	125 to 200%. Limited by commutation	8 to 12%	Basic speed to 200% basic speed by field control	Drives where starting requirements are not severe. Use constant-speed or adjustable-speed, depending on speed required. Centrifugal pumps, fans, blowers, conveyors, elevators, wood- and metalworking machines
Shunt-wound, adjustable speed			10 to 20%, increases with weak fields	Basic speed to 60% basic speed (lower for some ratings) by field control	
Shunt-wound, adjustable voltage control			Up to 25%. Less than 5% obtainable with special rotating regulator	Basic speed to 2% basic speed and basic speed to 200% basic speed	Drives where wide, stepless speed control, uniform speed, constant-torque acceleration and adaptability to automatic operation are required. Planers, milling machines, boring machines, lathes, etc.
Compound wound, constant-speed	Heavy starting torque, Limited by starting resistor to 130 to 260% of full-load torque	130 to 260%. Limited by commutation	Standard compounding 25%. Depends on amount of series winding	Basic speed to 125% basic speed by field control	Drives requiring high starting torque and fairly constant speed. Pulsating loads. Shears, bending rolls, pumps, conveyors, crushers, etc.
Series-wound, vary-speed	Very heavy starting torque. Limited to 300 to 350% full-load torque	300 to 350%. Limited by commutation	Very high. Infinite no-load speed	From zero to maximum speed, depending on control and load	Drives where very high starting torque is required and speed can be regulated. Cranes, hoists, gates, bridges, car dumpers, etc.

<sup>a</sup> Minimum speed below basic speed by armature control limited by heating.

**Table 2. Characteristics and Applications of Polyphase AC Motors**

Polyphase Type	Ratings hp	Speed Regulation	Speed Control	Starting Torque	Breakdown Torque	Applications
General-purpose squirrel cage, normal stg current, normal stg torque. Design B	0.5 to 200	Less than 5%	None, except multi-speed types, designed for two to four fixed speeds	100 to 250% of full-load	200 to 300% of full-load	Constant-speed service where starting torque is not excessive. Fans, blowers, rotary compressors, centrifugal pumps, woodworking machines, machine tools, line shafts
Full-voltage starting, high stg torque, normal stg current, squirrel-cage, Design C	3 to 150	Less than 5%	None except multi-speed types, designed for two to four fixed speeds	200 to 250% of full-load	190 to 225% of full-load	Constant-speed service where fairly high starting torque is required at infrequent intervals with starting current of about 500% full-load. Reciprocating pumps and compressors, conveyors, crushers, pulverizers, agitators, etc.
Full-voltage starting, high stg-torque, high-slip squirrel cage, Design D	0.5 to 150	Drops about 7 to 12% from no load to full load	None, except multi-speed types, designed for two to four fixed speeds	275% of full-load depending on speed and rotor resistance	275% of full-load Will usually not stall until loaded to its maximum torque, which occurs at standstill	Constant-speed service and high-starting torque if starting not too frequent, and for taking high-peak loads with or without flywheels. Punch presses, die stamping, shears, bulldozers, bailers, hoists, cranes, elevators, etc.
Wound-rotor, external-resistance starting	0.5 to several thousand	With rotor rings short-circuited drops about 3% for large to 5% for small sizes	Speed can be reduced to 50% of normal by rotor resistance. Speed varies inversely as the load	Up to 300% depending on external resistance in rotor circuit and how distributed	200% when rotor slip rings are short circuited	Where high-starting torque with low-starting current or where limited speed control is required. Fans, centrifugal and plunger pumps, compressors, conveyors, hoists, cranes, ball mills, gate hoists, etc.
Synchronous	25 to several thousand	Constant	None, except special motors designed for two fixed speeds	40% for slow speed to 160% for medium speed 80% p-f designs. Special high-torque designs	Pull-out torque of unity-p-f motors 170%; 80%-p-f motors 225%. Special designs up to 300%	For constant-speed service, direct connection to slow-speed machines and where power-factor correction is required.

In addition to these special-purpose motors, there are two types of *explosion-proof motors* designed for hazardous locations. One type is for operation in hazardous dust locations (Class II, Group *G* of the National Electrical Code) and the other is for atmospheres containing explosive vapors and fumes classified as Class I, Group *D* (gasoline, naphtha, alcohols, acetone, lacquer-solvent vapors, natural gas).

### Electric Motor Maintenance

**Electric Motor Inspection Schedule.**— Frequency and thoroughness of inspection depend upon such factors as 1) importance of the motor in the production scheme; 2) percentage of days the motor operates; 3) nature of service; and 4) winding conditions.

The following schedules, recommended by the General Electric Company, and covering both AC and DC motors are based on average conditions in so far as duty and dirt are concerned.

**Weekly Inspection.**— 1) *Surroundings.* Check to see if the windings are exposed to any dripping water, acid or alcoholic fumes; also, check for any unusual amount of dust, chips, or lint on or about the motor. See if any boards, covers, canvas, etc., have been misplaced that might interfere with the motor ventilation or jam moving parts.

2) *Lubrication of sleeve-bearing motors.* In sleeve-bearing motors check oil level, if a gage is used, and fill to the specified line. If the journal diameter is less than 2 inches, the motor should be stopped before checking the oil level. For special lubricating systems, such as wool-packed, forced lubrication, flood and disk lubrication, follow instruction book. Oil should be added to bearing housing only when motor is at rest. A check should be made to see if oil is creeping along the shaft toward windings where it may harm the insulation.

3) *Mechanical condition.* Note any unusual noise that may be caused by metal-to-metal contact or any odor as from scorching insulation varnish.

4) *Ball or roller bearings.* Feel ball- or roller-bearing housings for evidence of vibration, and listen for any unusual noise. Inspect for creepage of grease on inside of motor.

5) *Commutators and brushes.* Check brushes and commutator for sparking. If the motor is on cyclic duty it should be observed through several cycles. Note color and surface condition of the commutator. A stable copper oxide-carbon film (as distinguished from a pure copper surface) on the commutator is an essential requirement for good commutation. Such a film may vary in color all the way from copper to straw, chocolate to black. It should be clean and smooth and have a high polish. All brushes should be checked for wear and pigtail connections for looseness. The commutator surface may be cleaned by using a piece of dry canvas or other hard, nonlinting material that is wound around and securely fastened to a wooden stick, and held against the rotating commutator.

6) *Rotors and armatures.* The air gap on sleeve-bearing motors should be checked, especially if they have been recently overhauled. After installing new bearings, make sure that the average reading is within 10 percent, and reading should be less than 0.020 inch (0.51 mm). Check air passages through punchings and make sure they are free of foreign matter.

7) *Windings.* If necessary clean windings by suction or mild blowing. After making sure that the motor is dead, wipe off windings with dry cloth, note evidence of moisture, and see if any water has accumulated in the bottom of frame. Check if any oil or grease has worked its way up to the rotor or armature windings. Clean with carbon tetrachloride in a well-ventilated room.

8) *General.* This is a good time to check the belt, gears, flexible couplings, chain, and sprockets for excessive wear or improper location. The motor starting should be checked to make sure that it comes up to proper speed each time power is applied.

**Monthly or Bimonthly Inspection.**— 1) *Windings.* Check shunt, series, and commutating field windings for tightness. Try to move field spools on the poles, as drying out may have caused some play. If this condition exists, a service shop should be consulted. Check motor cable connections for tightness.

2) *Brushes*. Check brushes in holders for fit and free play. Check the brush-spring pressure. Tighten brush studs in holders to take up slack from drying out of washers, making sure that studs are not displaced, particularly on DC motors. Replace brushes that are worn down almost to the brush rivet, examine brush faces for chipped toes or heels, and for heat cracks. Damaged brushes should be replaced immediately.

3) *Commutators*. Examine commutator surface for high bars and high mica, or evidence of scratches or roughness. See that the risers are clean and have not been damaged.

4) *Ball or roller bearings*. On hard-driven, 24-hour service ball- or roller-bearing motors, purge out old grease through drain hole and apply new grease. Check to make sure grease or oil is not leaking out of the bearing housing. If any leakage is present, correct the condition before continuing to operate.

5) *Sleeve bearings*. Check sleeve bearings for wear, including end-play bearing surfaces. Clean out oil wells if there is evidence of dirt or sludge. Flush with lighter oil before refilling.

6) *Enclosed gears*. For motors with enclosed gears, open drain plug and check oil flow for presence of metal scale, sand, or water. If condition of oil is bad, drain, flush, and refill as directed. Rock rotor to see if slack or backlash is increasing.

7) *Loads*. Check loads for changed conditions, bad adjustment, poor handling, or control.

8) *Couplings and other drive details*. Note if belt-tightening adjustment is all used up. Shorten belt if this condition exists. See if belt runs steadily and close to inside (motor edge) of pulley. Chain should be checked for evidence of wear and stretch. Clean inside of chain housing. Check chain-lubricating system. Note inclination of slanting base to make sure it does not cause oil rings to rub on housing.

**Annual or Biannual Inspection.**— 1) *Windings*. Check insulation resistance by using either a megohmmeter or a voltmeter having a resistance of about 100 ohms per volt. Check insulation surfaces for dry cracks and other evidence of need for coatings of insulating material. Clean surfaces and ventilating passages thoroughly if inspection shows accumulation of dust. Check for mold or water standing in frame to determine if windings need to be dried out, varnished, and baked.

2) *Air gap and bearings*. Check air gap to make sure that average reading is within 10 percent, provided reading should be less than 0.020 inch (0.51 mm). All bearings, ball, roller, and sleeve should be thoroughly checked and defective ones replaced. Waste-packed and wick-oiled bearings should have waste or wicks renewed, if they have become glazed or filled with metal or dirt, making sure that new waste bears well against shaft.

3) *Rotors (squirrel-cage)*. Check squirrel-cage rotors for broken or loose bars and evidence of local heating. If fan blades are not cast in place, check for loose blades. Look for marks on rotor surface indicating foreign matter in air gap or a worn bearing.

4) *Rotors (wound)*. Clean wound rotors thoroughly around collector rings, washers, and connections. Tighten connections if necessary. If rings are rough, spotted, or eccentric, refer to service shop for refinishing. See that all top sticks or wedges are tight. If any are loose, refer to service shop.

5) *Armatures*. Clean all armature air passages thoroughly if any are obstructed. Look for oil or grease creeping along shaft, checking back to bearing. Check commutator for surface condition, high bars, high mica, or eccentricity. If necessary, remachine the commutator to secure a smooth fresh surface.

6) *Loads*. Read load on motor with instruments at no load, full load, or through an entire cycle, as a check on the mechanical condition of the driven machine.

## ADHESIVES AND SEALANTS

By strict definition, an adhesive is any substance that fastens or bonds materials to be joined (adherends) by means of surface attachment. The bond durability depends on the strength of the adhesive to the substrate (adhesion) and the strength within the adhesive (cohesion). Besides bonding a joint, an adhesive may serve as a seal against foreign matter. When an adhesive performs both bonding and sealing functions, it is usually referred to as an *adhesive sealant*. Joining materials with adhesives offers significant benefits compared with mechanical methods of uniting two materials.

Among these benefits are that an adhesive distributes a load over an area rather than concentrating it at a point, resulting in a more even distribution of stresses. The adhesive bonded joint is therefore more resistant to flexural and vibrational stresses than, for example, a bolted, riveted, or welded joint. Another benefit is that an adhesive forms a seal as well as a bond. This seal prevents the corrosion that may occur with dissimilar metals, such as aluminum and magnesium, or mechanically fastened joints, by providing a dielectric insulation between the substrates. An adhesive also joins irregularly shaped surfaces more easily than does a mechanical fastener. Other benefits include negligible weight addition and virtually no change to part dimensions or geometry.

Most adhesives are available in liquids, gels, pastes, and tape forms. The growing variety of adhesives available can make the selection of the proper adhesive or sealant a challenging experience. In addition to the technical requirements of the adhesive, time and costs are also important considerations. Proper choice of an adhesive is based on knowledge of the suitability of the adhesive or sealant for the particular substrates. Appropriate surface preparation, curing parameters, and matching the strength and durability characteristics of the adhesive to its intended use are essential. The performance of an adhesive-bonded joint depends on a wide range of these factors, many of them quite complex. Adhesive suppliers can usually offer essential expertise in the area of appropriate selection.

Adhesives can be classified as structural or nonstructural. In general, an adhesive can be considered structural when it is capable of supporting heavy loads; nonstructural when it cannot support such loads. Many adhesives and sealants, under various brand names, may be available for a particular bonding application. It is always advisable to check the adhesive manufacturers' information before making an adhesive sealant selection. Also, testing under end-use conditions is always suggested to help ensure bonded or sealed joints meet or exceed expected performance requirements.

Though not meant to be all-inclusive, the following information correlates the features of some successful adhesive compositions available in the marketplace.

### Bonding Adhesives

Reactive-type bonding adhesives are applied as liquids and react (cure) to solids under appropriate conditions. The cured adhesive is either a thermosetting or thermoplastic polymer. These adhesives are supplied as two-component no-mix, two-component mix, and one-component no-mix types, which are discussed in the following paragraphs.

### Two-Component No-Mix Adhesives

**Types of Adhesives.**— *Anaerobic (Urethane Methacrylate Ester) Structural Adhesives:* Anaerobic structural adhesives are mixtures of acrylic esters that remain liquid when exposed to air but harden when confined between metal substrates. These adhesives can be used for large numbers of industrial purposes where high reliability of bond joints is required. Benefits include: no mixing is required (no pot-life or waste problems), flexible/durable bonds are made that withstand thermal cycling, have excellent resistance to solvents and severe environments, and rapid cure at room temperatures (eliminating

expensive ovens). The adhesives are easily dispensed with automatic equipment. An activator is usually required to be present on one surface to initiate the cure for these adhesives. Applications for these adhesives include bonding of metals, magnets (ferrites), glass, thermosetting plastics, ceramics, and stone.

*Acrylic Adhesives:* Acrylic adhesives are composed of a polyurethane polymer backbone with acrylate end groups. They can be formulated to cure through heat or the use of an activator applied to the substrate surface, but many industrial acrylic adhesives are cured by light. Light-cured adhesives are used in applications where the bond geometry allows light to reach the adhesive and the production rate is high enough to justify the capital expense of a light source. Benefits include: no mixing is required (no pot-life or waste problems); formulations cure (solidify) with activator, heat, or light; the adhesive will bond to a variety of substrates, including metal and most thermoplastics; and tough and durable bonds are produced with a typical resistance to the effects of temperatures up to 180°C. Typical applications include automobile body parts (steel stiffeners), assemblies subjected to paint-baking cycles, speaker magnets to pole plates, and bonding of motor magnets, sheet steel, and many other structural applications. Other applications include bonding glass, sheet metal, magnets (ferrite), thermosetting and thermoplastic plastics, wood, ceramics, and stone.

### Two-Component Mix Adhesives

**Types of Adhesives.—***Epoxy Adhesives:* Two-component epoxy adhesives are well-established adhesives that offer many benefits in manufacturing. The reactive components of these adhesives are separated prior to use, so they usually have a good shelf life without refrigeration. Polymerization begins upon mixing, and a thermoset polymer is formed. Epoxy adhesives cure to form thermosetting polymers made up of a base side with the polymer resin and a second part containing the catalyst. The main benefit of these systems is that the depth of cure is unlimited. As a result, large volume can be filled for work such as potting, without the cure being limited by the need for access to an external influence such as moisture or light to activate the curing process.

For consistent adhesive performance, it is important that the mix ratio remain constant to eliminate variations in adhesive performance. Epoxies can be handled automatically, but the equipment involves initial and maintenance costs. Alternatively, adhesive components can be mixed by hand. However, this approach involves labor costs and the potential for human error. The major disadvantage of epoxies is that they tend to be very rigid and consequently have low peel strength. This lack of peel strength is less of a problem when bonding metal to metal than it is when bonding flexible substrates such as plastics.

Applications of epoxy adhesives include bonding, potting, and coating of metals, bonding of glass, rigid plastics, ceramics, wood, and stone.

*Polyurethane Adhesives:* Like epoxies, polyurethane adhesives are available as two-part systems or as one-component frozen premixes. They are also available as one-part moisture-cured systems. Polyurethane adhesives can provide a wide variety of physical properties. Their flexibility is greater than that of most epoxies. Coupled with the high cohesive strength, this flexibility provides a tough polymer able to achieve better peel strength and lower flexural modulus than most epoxy systems. This superior peel resistance allows use of polyurethanes in applications that require high flexibility. Polyurethanes bond very well to a variety of substrates, though a primer may be needed to prepare the substrate surface. These primers are moisture-reactive and require several hours to react sufficiently for the parts to be used. Such a time requirement may cause a production bottleneck if the bond-strength requirements are such that a primer is needed.

Applications for polyurethane adhesives include bonding of metals, glass, rubber, thermosetting and thermoplastic plastics, and wood.

### One-Component No-Mix Adhesives

**Types of Adhesives.**— *Light-Curable Adhesives:* Light-curing systems use a unique curing mechanism. The adhesives contain photoinitiators that absorb light energy and dissociate to form radicals. These radicals then initiate the polymerization of the polymers, oligomers, and monomers in the adhesive. The photoinitiator acts as a chemical solar cell, converting the light energy into chemical energy for the curing process. Typically, these systems are formulated for use with ultraviolet light sources. However, newer products have been formulated for use with visible light sources.

One of the biggest benefits that light-curing adhesives offer to the manufacturer is the elimination of the work time to work-in-progress trade-off, which is embodied in most adhesive systems. With light-curing systems, the user can take as much time as needed to position the part without fear of the adhesive curing. Upon exposure to the appropriate light source, the adhesive then can be fully cured in less than 1 minute, minimizing the costs associated with work in progress. Adhesives that utilize light as the curing mechanism are often one-part systems with good shelf life, which makes them even more attractive for manufacturing use.

Applications for light-curable adhesives include bonding of glass, and glass to metal, tacking of wires, surface coating, thin-film encapsulation, clear substrate bonding, and potting of components,

*Cyanoacrylate Adhesives (Instant Adhesives):* Cyanoacrylates or instant adhesives are often called Superglue™. Cyanoacrylates are one-part adhesives that cure rapidly, as a result of the presence of surface moisture, to form high-strength bonds, when confined between two substrates. Cyanoacrylates have excellent adhesion to many substrates, including most plastics and they achieve fixture strength in seconds and full strength within 24 hours. These qualities make cyanoacrylates suitable for use in automated production environments. They are available in viscosities ranging from water-thin liquids to thixotropic gels.

Because cyanoacrylates are a relatively mature adhesive family, a wide variety of specialty formulations is now available to help the user address difficult assembly problems. One of the best examples is the availability of polyolefin primers, which allow users to obtain high bond strengths on difficult-to-bond plastics such as polyethylene and polypropylene. One common drawback of cyanoacrylates is that they form a very rigid polymer matrix, resulting in very low peel strengths. To address this problem, formulations have been developed that are rubber-toughened. Although the rubber toughening improves the peel strength of the system to some extent, peel strength remains a weak point for this system, and, therefore, cyanoacrylates are poor candidates for joint designs that require high peel resistance. In manufacturing environments with low relative humidity, the cure of the cyanoacrylate can be significantly retarded.

This problem can be addressed in one of two ways. One approach is to use accelerators that deposit active species on the surface to initiate the cure of the product. The other approach is to use specialty cyanoacrylate formulations that have been engineered to be surface-insensitive. These formulations can cure rapidly even on dry or slightly acidic surfaces.

Applications for cyanoacrylate adhesives include bonding of thermoplastic and thermosetting plastics, rubber, metals, wood, and leather, also strain relief of wires.

*Hot-Melt Adhesives:* Hot-melt adhesives are widely used in assembly applications. In general, hot-melt adhesives permit fixturing speeds that are much faster than can be achieved with water- or solvent-based adhesives. Usually supplied in solid form, hot-melt adhesives liquify when exposed to elevated temperatures. After application, they cool quickly, solidifying and forming a bond between two mating substrates. Hot-melt adhesives have been used successfully for a wide variety of adherends and can greatly reduce both the need for clamping and the length of time for curing. Some drawbacks with hot-

melt adhesives are their tendency to string during dispensing and relatively low-temperature resistance.

Applications for hot-melt adhesives are bonding of fabrics, wood, paper, plastics, and cardboard.

**Rubber-Based Solvent Cements:** Rubber-based solvent cements are adhesives made by combining one or more rubbers or elastomers in a solvent. These solutions are further modified with additives to improve the tack or stickiness, the degree of peel strength, flexibility, and the viscosity or body. Rubber-based adhesives are used in a wide variety of applications such as contact adhesive for plastics laminates like counter tops, cabinets, desks, and tables. Solvent-based rubber cements have also been the mainstay of the shoe and leather industry for many years.

Applications for rubber-based solvent cements include bonding of plastics laminates, wood, paper, carpeting, fabrics, and leather.

**Moisture-Cured Polyurethane Adhesives:** Like heat-curing systems, moisture-cured polyurethanes have the advantage of a very simple curing process. These adhesives start to cure when moisture from the atmosphere diffuses into the adhesive and initiates the polymerization process. In general, these systems will cure when the relative humidity is above 25 percent, and the rate of cure will increase as the relative humidity increases.

The dependence of these systems on the permeation of moisture through the polymer is the source of their most significant process limitations. As a result of this dependence, depth of cure is limited to between 0.25 and 0.5 in. (6.35 and 12.7 mm). Typical cure times are in the range of 12 to 72 hours. The biggest use for these systems is for windshield bonding in automobile bodies.

Applications for moisture-cured polyurethane adhesives include bonding of metals, glass, rubber, thermosetting and thermoplastic plastics, and wood.

### Retaining Compounds

The term *retaining compounds* is used to describe adhesives used in circumferential assemblies joined by inserting one part into the other. In general, retaining compounds are anaerobic adhesives composed of mixtures of acrylic esters that remain liquid when exposed to air but harden when confined between cylindrical machine components. A typical example is a bearing held in an electric motor housing with a retaining compound. The first retaining compounds were launched in 1963, and the reaction among users of bearings was very strong because these retaining compounds enabled buyers of new bearings to salvage worn housings and minimize their scrap rate.

The use of retaining compounds has many benefits, including elimination of bulk needed for high friction forces, ability to produce more accurate assemblies and to augment or replace press fits, increased strength in heavy press fits, and reduction of machining costs. Use of these compounds also helps in dissipating heat through assembly, and eliminating distortion when installing drill bushings, fretting corrosion and backlash in keys and splines, and bearing seizure during operation.

The major advantages of retaining compounds for structural assemblies are that they require less severe machining tolerances and no securing of parts. Components are assembled quickly and cleanly, and they transmit high forces and torques, including dynamic forces. Retaining compounds also seal, insulate, and prevent micromovements so that neither fretting corrosion nor stress corrosion occurs. The adhesive joint can be taken apart easily after heating above 450°F (230°C) for a specified time.

Applications for retaining compounds include mounting of bearings in housings or on shafts, avoiding distortion of precision tooling and machines, mounting of rotors on shafts, inserting drill jig bushings, retaining cylinder linings, holding oil filter tubes in castings, retaining engine-core plugs, restoring accuracy to worn machine tools, and eliminating keys and set screws.

### Threadlocking

The term *threadlocker* is used to describe adhesives used in threaded assemblies for locking the threaded fasteners by filling the spaces between the nut and bolt threads with a hard, dense material that prevents loosening. In general, thread-lockers are anaerobic adhesives comprising mixtures of acrylic esters that remain liquid when exposed to air but harden when confined between threaded components. A typical example is a mounting bolt on a motor or a pump. Threadlocker strengths range from very low strength (removable) to high strength (permanent).

It is important that the total length of the thread is coated and that there is no restriction to the curing of the threadlocker material. (Certain oils or cleaning systems can impede or even completely prevent the adhesive from curing by anaerobic reaction.) The liquid threadlocker may be applied by hand or with special dispensing devices. Proper coating (wetting) of a thread is dependent on the size of the thread, the viscosity of the adhesive, and the geometry of the parts. With blind-hole threads, it is essential that the adhesive be applied all the way to the bottom of the threaded hole. The quantity must be such that after assembly, the displaced adhesive fills the whole length of the thread.

Some threadlocking products cured by anaerobic reaction have a positive influence on the coefficient of friction in the thread. The values are comparable with those of oiled bolts. Prestress and installation torque therefore can be defined exactly. This property allows threadlocking products cured by anaerobic reaction to be integrated into automated production lines using existing assembly equipment. The use of thread-lockers has many benefits including ability to lock and seal all popular bolt and nut sizes with all industrial finishes, and to replace mechanical locking devices. The adhesive can seal against most industrial fluids and will lubricate threads so that the proper clamp load is obtained. The materials also provide vibration-resistant joints that require handtool dismantling for servicing, prevent rusting of threads, and cure (solidify) without cracking or shrinking.

The range of applications includes such uses as locking and sealing nuts on hydraulic pistons, screws on vacuum cleaner bell housings, track bolts on bulldozers, hydraulic-line fittings, screws on typewriters, oil-pressure switch assembly, screws on carburetors, rocker nuts, machinery driving keys, and on construction equipment.

### Sealants

The primary role of a sealant composition is the prevention of leakage from or access by dust, fluids, and other materials to assembly structures. Acceptable leak rates can range from a slight drip to bubbletight to molecular diffusion through the base materials. Equipment users in the industrial market want trouble-free operation, but it is not always practical to specify zero leak rates. Factors influencing acceptable leak rates are toxicity, product or environmental contamination, combustibility, economics, and personnel considerations. All types of fluid seals perform the same basic function: they seal the process fluid (gas, liquid, or vapor) and keep it where it belongs. A general term for these assembly approaches is gasketing. Many products are being manufactured that are capable of sealing a variety of substrates.

**Types of Sealants.**—*Anaerobic Formed-in-Place Gasketing Materials:* Mechanical assemblies that require the joining of metal-to-metal flange surfaces have long been designed with prefabricated, precut materials required to seal the imperfect surfaces of the assembly. Numerous gasket materials that have been used to seal these assemblies include paper, cork, asbestos, wood, metals, dressings, and even plastics. Fluid seals are divided into static and dynamic systems, depending on whether or not the parts move in relationship to each other. Flanges are classed as static systems, although they may be moved relative to each other by vibration, temperature, and/or pressure changes, shocks, and impacts.

The term *anaerobic formed-in-place gasketing* is used to describe sealants that are used in flanged assemblies to compensate for surface imperfections of metal-to-metal compo-

nents by filling the space between the substrates with a flexible, nonrunning material. In general, anaerobic formed-in-place gaskets are sealants made up of mixtures of acrylic esters that remain liquid when exposed to air but harden when confined between components. A typical example is sealing two halves of a split crankcase.

The use of anaerobic formed-in-place gaskets has many benefits, including the ability to seal all surface imperfections, allow true metal-to-metal contact, eliminate compression set and fastener loosening, and add structural strength to assemblies. These gaskets also help improve torque transmission between bolted flange joints, eliminate bolt retorquing needed with conventional gaskets, permit use of smaller fasteners and lighter flanges, and provide for easy disassembly and cleaning.

Applications in which formed-in-place gasketing can be used to produce leakproof joints include pipe flanges, split crankcases, pumps, compressors, power takeoff covers, and axle covers. These types of gaskets may also be used for repairing damaged conventional gaskets and for coating soft gaskets.

*Silicone Rubber Formed-in-Place Gasketing:* Another type of formed-in-place gasket uses room-temperature vulcanizing (RTV) silicone rubbers. These materials are one-component sealants that cure on exposure to atmospheric moisture. They have excellent properties for vehicle use such as flexibility, low volatility, good adhesion, and high resistance to most automotive fluids. The materials will also withstand temperatures up to 600°F (320°C) for intermittent operation.

RTV silicones are best suited for fairly thick section (gap) gasketing applications where flange flexing is greatest. In the form of a very thin film, for a rigid metal-to-metal seal, the cured elastomer may abrade and eventually fail under continual flange movement. The RTV silicone rubber does not unitize the assembly, and it requires relatively clean, oil-free surfaces for sufficient adhesion and leakproof seals.

Because of the silicone's basic polymeric structure, RTV silicone elastomers have several inherent characteristics that make them useful in a wide variety of applications. These properties include outstanding thermal stability at temperatures from 400 to 600°F (204 to 320°C), and good low-temperature flexibility at -85 to -165°F (-65 to -115°C). The material forms an instant seal, as is required of all liquid gaskets, and will fill large gaps up to 0.250 in. (6.35 mm) for stamped metal parts and flanges. The rubber also has good stability in ultraviolet light and excellent weathering resistance.

Applications for formed-in-place RTV silicones in the automotive field are valve, camshaft and rocker covers, manual transmission (gearbox) flanges, oil pans, sealing panels, rear axle housings, timing chain covers, and window plates. The materials are also used on oven doors and flues.

### **Tapered Pipe-thread Sealing**

Thread sealants are used to prevent leakage of gases and liquids from pipe joints. All joints of this type are considered to be dynamic because of vibration, changing pressures, or changing temperatures.

Several types of sealants are used on pipe threads including noncuring pipe dopes, which are one of the oldest methods of sealing the spiral leak paths of threaded joints. In general, pipe dopes are pastes made from oils and various fillers. They lubricate joints and jam threads but provide no locking advantage. They also squeeze out under pressure, and have poor solvent resistance. Noncuring pipe dopes are not suitable for use on straight threads.

Another alternative is solvent-drying pipe dopes, which are an older method of sealing tapered threaded joints. These types of sealant offer the advantages of providing lubrication and orifice jamming and they also extrude less easily than noncuring pipe dopes. One disadvantage is that they shrink during cure as the solvents evaporate and fittings must be retorqued to minimize voids. These materials generally lock the threaded joint together by friction. A third type of sealer is the trapped elastomer supplied in the form of a thin tape

incorporating polytetrafluorethylene (PTFE). This tape gives a good initial seal and resists chemical attack, and is one of the only materials used for sealing systems that will seal against oxygen gas.

Some other advantages of PTFE are that it acts as a lubricant, allows for high torquing, and has a good resistance to various solvents. Some disadvantages are that it may not provide a true seal between the two threaded surfaces, and it lubricates in the off direction, so it may allow fittings to loosen. In dynamic joints, tape may allow creep, resulting in leakage over time. The lubrication effect may allow overtightening, which can add stress or lead to breakage. Tape also may be banned in some hydraulic systems due to shredding, which may cause clogging of key orifices.

**Anaerobic Pipe Sealants.**— The term *anaerobic pipe sealants* is used to describe anaerobic sealants used in tapered threaded assemblies for sealing and locking threaded joints. Sealing and locking are accomplished by filling the space between the threads with the sealant. In general, these pipe sealants are anaerobic adhesives consisting of mixtures of acrylic esters that remain liquid when exposed to air but harden when confined between threaded components to form an insoluble tough plastics. The strength of anaerobic pipe sealants is between that of elastomers and yielding metal.

Clamp loads need be only tight enough to prevent separation in use. Because they develop strength by curing after they are in place, these sealants are generally forgiving of tolerances, tool marks, and slight misalignment. These sealants are formulated for use on metal substrates. If the materials are used on plastics, an activator or primer should be used to prepare the surfaces.

Among the advantages of these anaerobic sealers are that they lubricate during assembly, they seal regardless of assembly torque, and they make seals that correspond with the burst rating of the pipe. They also provide controlled disassembly torque, do not cure outside the joint, and are easily dispensed on the production line. These sealants also have the lowest cost per sealed fitting. Among the disadvantages are that the materials are not suitable for oxygen service, for use with strong oxidizing agents, or for use at temperatures above 200°C (392°F). The sealants also are typically not suitable for diameters over M80 or 80 mm (approximately 3 inches).

The many influences faced by pipe joints during service should be known and understood at the design stage, when sealants are selected. Sealants must be chosen for reliability and long-term quality. Tapered pipe threads must remain leak-free under the severest vibration and chemical attack, also under heat and pressure surges.

Applications of aerobic sealants are found in industrial plant fluid power systems, the textile industry, chemical processing, utilities and power generation facilities, petroleum refining, and in marine, automotive, and industrial equipment. The materials are also used in the pulp and paper industries, in gas compression and distribution, and in waste-treatment facilities.

## O-RINGS

An O-ring is a one-piece molded elastomeric seal with a circular cross-section that seals by distortion of its resilient elastic compound. Dimensions of O-rings are given in ANSI/SAE AS568A, Aerospace Size Standard for O-rings. The standard ring sizes have been assigned identifying dash numbers that, in conjunction with the compound (ring material), completely specifies the ring. Although the ring sizes are standardized, ANSI/SAE AS568A does not cover the compounds used in making the rings; thus, different manufacturers will use different designations to identify various ring compounds. For example, 230-8307 represents a standard O-ring of size 230 (2.484 in. ID by 0.139 in. width) made with compound 8307, a general-purpose nitrile compound. O-ring material properties are discussed at the end of this section.

When properly installed in a groove, an O-ring is normally slightly deformed so that the naturally round cross-section is squeezed diametrically out of round prior to the application of pressure. This compression ensures that under static conditions, the ring is in contact with the inner and outer walls enclosing it, with the resiliency of the rubber providing a zero-pressure seal. When pressure is applied, it tends to force the O-ring across the groove, causing the ring to further deform and flow up to the fluid passage and seal it against leakage, as in Fig. 1(a). As additional pressure is applied, the O-ring deforms into a D shape, as in Fig. 1(b). If the clearance gap between the sealing surface and the groove corners is too large or if the pressure exceeds the deformation limits of the O-ring material (compound), the O-ring will extrude into the clearance gap, reducing the effective life of the seal. For very low-pressure static applications, the effectiveness of the seal can be improved by using a softer durometer compound or by increasing the initial squeeze on the ring, but at higher pressures, the additional squeeze may reduce the ring's dynamic sealing ability, increase friction, and shorten ring life.

Fig. 1.

The initial diametral squeeze of the ring is very important in the success of an O-ring application. The squeeze is the difference between the ring width  $W$  and the gland depth  $F$  (Fig. 2) and has a great effect on the sealing ability and life of an O-ring application.

Fig. 2. Groove and Ring Details

The ideal squeeze varies according to the ring cross-section, with the average being about 20 percent, i.e., the ring's cross-section  $W$  is about 20 percent greater than the gland depth  $F$  (groove depth plus clearance gap). The groove width is normally about 1.5 times larger than the ring width  $W$ . When installed, an O-ring compresses slightly and distorts into the free space within the groove. Additional expansion or swelling may also occur due to contact of the ring with fluid or heat. The groove must be large enough to accommodate the maximum expansion of the ring or the ring may extrude into the clearance gap or rupture the assembly. In a dynamic application, the extruded ring material will quickly wear and fray, severely limiting seal life.

To prevent O-ring extrusion or to correct an O-ring application, reduce the clearance gap by modifying the dimensions of the system, reduce the system operating pressure, install antiextrusion backup rings in the groove with the O-ring, as in Fig. 3, or use a harder O-ring compound. A harder compound may result in higher friction and a greater tendency of the seal to leak at low pressures. Backup rings, frequently made of leather, Teflon, metal, phenolic, hard rubber, and other hard materials, prevent extrusion and nibbling where large clearance gaps and high pressure are necessary.

Fig. 3. Preferred Use of Backup Washers

The most effective and reliable sealing is generally provided by using the diametrical clearances given in manufacturers' literature. However, the information in Table 1 may be used to estimate the gland depth (groove depth plus radial clearance) required in O-ring applications. The radial clearance used (radial clearance equals one-half the diametral clearance) also depends on the system pressure, the ring compound and hardness, and specific details of the application.

**Table 1. Gland Depth for O-Ring Applications**

Standard O-Ring Cross-Sectional Diameter (in.)	Gland Depth (in.)	
	Reciprocating Seals	Static Seals
0.070	0.055 to 0.057	0.050 to 0.052
0.103	0.088 to 0.090	0.081 to 0.083
0.139	0.121 to 0.123	0.111 to 0.113
0.210	0.185 to 0.188	0.170 to 0.173
0.275	0.237 to 0.240	0.226 to 0.229

Source: Auburn Manufacturing Co. When possible, use manufacturer recommendations for clearance gaps and groove depth.

Fig. 4 indicates conditions where O-ring seals may be used, depending on the fluid pressure and the O-ring hardness. If the conditions of use fall to the right of the curve, extrusion of the O-ring into the surrounding clearance gap will occur, greatly reducing the life of the ring. If conditions fall to the left of the curve, no extrusion of the ring will occur, and the ring may be used under these conditions. For example, in an O-ring application with a 0.004-in. diametral clearance and 2500-psi pressure, extrusion will occur with a 70 durometer O-ring but not with an 80 durometer O-ring. As the graph indicates, high-pressure applications require lower clearances and harder O-rings for effective sealing.

Fig. 4. Extrusion Potential of O-Rings as a Function of Hardness and Clearance

Recommended groove width, clearance dimensions, and bottom-of-groove radius for O-ring numbers up to 475 (25.940-in. ID by 0.275-in. width) can be found using [Table 2](#) in conjunction with [Fig. 5](#). In general, except for ring cross-sections smaller than  $\frac{1}{16}$  in., the groove width is approximately  $1.5W$ , where  $W$  is the ring cross-sectional diameter. Straight-sided grooves are best for preventing extrusion of the ring or nibbling; however, for low-pressure applications (less than 1500 psi) sloped sides with an angle up to  $5^\circ$  can be used to simplify machining of the groove. The groove surfaces should be free of burrs, nicks, or scratches. For static seals (i.e., no contact between the O-ring and any moving parts), the groove surfaces should have a maximum roughness of 32 to 63  $\mu\text{in. rms}$  for liquid-sealing applications and 16 to 32  $\mu\text{in. rms}$  for gaseous-sealing applications. In dynamic seals, relative motion exists between the O-ring and one or more parts and the maximum groove surface roughness should be 8 to 16  $\mu\text{in. rms}$  for sliding contact applications (reciprocating seals, for example) and 16 to 32  $\mu\text{in. rms}$  for rotary contact applications (rotating and oscillating seals).

In dynamic seal applications, the roughness of surfaces in contact with O-rings (bores, pistons, and shafts, for example) should be 8 to 16  $\mu\text{in. rms}$ , without longitudinal or circumferential scratches. Surface finishes of less than 5  $\mu\text{in. rms}$  are too smooth to give a good seal life because they wipe too clean, causing the ring to wear against the housing in the absence of a lubricating film. The best-quality surfaces are honed, burnished, or hard chromium plated. Soft and stringy metals such as aluminum, brass, bronze, Monel, or free machining stainless steel should not be used in contact with moving seals. In static applica-

tions, O-ring contacting surfaces should have a maximum surface roughness of 64 to 125  $\mu\text{in. rms}$ .

**Table 2. Diametral Clearance and Groove Sizes for O-Ring Applications**

ANSI/SAE AS568 Number	Tolerances		Diametral Clearance, $D$		Groove Width, $G$			Bottom of Groove Radius, $R$
	$A$	$B$	Reciprocating & Static Seals	Rotary Seals	Backup Rigs			
					None	One	Two	
001	+0.001 -0.000	+0.000 -0.001	0.002 to 0.004	0.012 to 0.016	0.063	0.149	0.207	0.005 to 0.015
002					0.073			
003					0.083			
004 to 012					0.094			
013 to 050	+0.002 -0.000	+0.000 -0.002	0.002 to 0.005	0.016 to 0.020	0.141	0.183	0.245	0.010 to 0.025
102 to 129					0.188	0.235	0.304

201 to 284					0.375	0.475	0.579	
309 to 395	+0.003	+0.000	0.003 to 0.007	0.020				
425 to 475	-0.000	-0.003	0.004 to 0.010					

Source: Auburn Manufacturing Co. All dimensions are in inches. Clearances listed are minimum and maximum values; standard groove widths may be reduced by about 10 percent for use with ring compounds that free swell less than 15 percent. Dimension  $A$  is the ID of any surface contacted by the outside circumference of the ring;  $B$  is the OD of any surface contacted by the inside circumference of the ring.

Fig. 5. Installation data for use with Table 2. Max and Min are maximum and minimum piston and bore diameters for O.D. and I.D., respectively.

The preferred bore materials are steel and cast iron, and pistons should be softer than the bore to avoid scratching them. The bore sections should be thick enough to resist expansion and contraction under pressure so that the radial clearance gap remains constant, reducing the chance of damage to the O-ring by extrusion and nibbling. Some compatibility problems may occur when O-rings are used with plastics parts because certain compounding ingredients may attack the plastics, causing crazing of the plastics surface.

O-rings are frequently used as driving belts in round bottom or V-grooves with light tension for low-power drive elements. Special compounds are available with high resistance to stress relaxation and fatigue for these applications. Best service is obtained in drive belt applications when the initial belt tension is between 80 and 200 psi and the initial installed stretch is between 8 and 25 percent of the circumferential length. Most of the compounds used for drive belts operate best between 10 and 15 percent stretch, although polyurethane has good service life when stretched as much as 20 to 25 percent.

**Table 3. Typical O-Ring Compounds**

Nitrile	General-purpose compound for use with most petroleum oils, greases, gasoline, alcohols and glycols, LP gases, propane and butane fuels. Also for food service to resist vegetable and animal fats. Effective temperature range is about $-40^{\circ}$ to $250^{\circ}\text{F}$ ( $-40$ to $121^{\circ}\text{C}$ ). Excellent compression set, tear and abrasion resistance, but poor resistance to ozone, sunlight and weather. Higher-temperature nitrile compounds with similar properties are also available.
Hydrogenated Nitrile	Similar to general-purpose nitrile compounds with improved high-temperature performance, resistance to aging, and petroleum product compatibility.
Polychloroprene (Neoprene)	General-purpose compound with low compression set and good resistance to elevated temperatures. Good resistance to sunlight, ozone, and weathering, and fair oil resistance. Frequently used for refrigerator gases such as Freon. Effective temperature range is about $-40^{\circ}$ to $250^{\circ}\text{F}$ ( $-40$ to $121^{\circ}\text{C}$ ).
Ethylene Propylene	General-purpose compound with excellent resistance to polar fluids such as water, steam, ketones, and phosphate esters, and brake fluids, but not resistant to petroleum oils and solvents. Excellent resistance to ozone and flexing. Recommended for belt-drive applications. Continuous duty service in temperatures up to $250^{\circ}\text{F}$ ( $121^{\circ}\text{C}$ ).
Silicone	Widest temperature range ( $-150^{\circ}$ to $500^{\circ}\text{F}$ or $-101$ to $260^{\circ}\text{C}$ ) and best low-temperature flexibility of all elastomeric compounds. Not recommended for dynamic applications, due to low strength, or for use with most petroleum oils. Shrinkage characteristics similar to organic rubber, allowing existing molds to be used.
Polyurethane	Toughest of the elastomers used for O-rings, characterized by high tensile strength, excellent abrasion resistance, and tear strength. Compression set and heat resistance are inferior to nitrile. Suitable for hydraulic applications that anticipate abrasive contaminants and shock loads. Temperature service range of $-65^{\circ}$ to $212^{\circ}\text{F}$ ( $-54$ to $100^{\circ}\text{C}$ ).
Fluorosilicone	Wide temperature range ( $-80^{\circ}$ to $450^{\circ}\text{F}$ or $-62$ to $232^{\circ}\text{C}$ ) for continuous duty and excellent resistance to petroleum oils and fuels. Recommended for static applications only, due to limited strength and low abrasion resistance.
Polyacrylate	Heat resistance better than nitrile compounds, but inferior low temperature, compression set, and water resistance. Often used in power steering and transmission applications due to excellent resistance to oil, automatic transmission fluids, oxidation, and flex cracking. Temperature service range of $-20^{\circ}$ to $300^{\circ}\text{F}$ ( $-29$ to $149^{\circ}\text{C}$ ).
Fluorocarbon (Viton)	General-purpose compound suitable for applications requiring resistance to aromatic or halogenated solvents or to high temperatures ( $-20^{\circ}$ to $500^{\circ}\text{F}$ or $-29$ to $260^{\circ}\text{C}$ with limited service to $600^{\circ}\text{F}$ or $316^{\circ}\text{C}$ ). Outstanding resistance to blended aromatic fuels, straight aromatics, and halogenated hydrocarbons and other petroleum products. Good resistance to strong acids (temperature range in acids $-20^{\circ}$ to $250^{\circ}\text{F}$ or $-29$ to $121^{\circ}\text{C}$ ), but not effective for use with very hot water, steam, and brake fluids.

**Ring Materials.**— Thousands of O-ring compounds have been formulated for specific applications. Some of the most common types of compounds and their typical applications are given in [Table 3](#). The Shore A durometer is the standard instrument used for measuring the hardness of elastomeric compounds. The softest O-rings are 50 and 60 Shore A and stretch more easily, exhibit lower breakout friction, seal better on rough surfaces, and need less clamping pressure than harder rings. For a given squeeze, the higher the durometer hardness of a ring, the greater the associated friction because a greater compressive force is exerted by hard rings than soft rings.

The most widely used rings are medium-hard O-rings with 70 Shore A hardness, which have the best wear resistance and frictional properties for running seals. Applications that involve oscillating or rotary motion frequently use 80 Shore A materials. Rings with a hardness above 85 Shore A often leak more because of less effective wiping action. These harder rings have a greater resistance to extrusion, but for small sizes may break easily during installation. O-ring hardness varies inversely with temperature, but when used for continuous service at high temperatures, the hardness may eventually increase after an initial softening of the compound.

O-ring compounds have thermal coefficients of expansion in the range of 7 to 20 times that of metal components, so shrinkage or expansion with temperature change can pose problems of leakage past the seal at low temperatures and excessive pressures at high temperatures when a ring is installed in a tight-fitting groove. Likewise, when an O-ring is immersed in a fluid, the compound usually absorbs some of the fluid and consequently increases in volume. Manufacturer's data give volumetric increase data for compounds completely immersed in various fluids. For confined rings (those with only a portion of the ring exposed to fluid), the size increase may be considerably lower than for rings completely immersed in fluid. Certain fluids can also cause ring shrinkage during "idle" periods, i.e., when the seal has a chance to dry out. If this shrinkage is more than 3 to 4 percent, the seal may leak.

Excessive swelling due to fluid contact and high temperatures softens all compounds approximately 20 to 30 Shore A points from room temperature values and designs should anticipate the expected operating conditions. At low temperatures, swelling may be beneficial because fluid absorption may make the seal more flexible. However, the combination of low temperature and low pressure makes a seal particularly difficult to maintain. A soft compound should be used to provide a resilient seal at low temperatures. Below –65°F, only compounds formulated with silicone are useful; other compounds are simply too stiff, especially for use with air and other gases.

Compression set is another material property and a very important sealing factor. It is a measure of the shape memory of the material, that is, the ability to regain shape after being deformed. Compression set is a ratio, expressed as a percentage, of the unrecovered to original thickness of an O-ring compressed for a specified period of time between two heated plates and then released. O-rings with excessive compressive set will fail to maintain a good seal because, over time, the ring will be unable to exert the necessary compressive force (squeeze) on the enclosing walls. Swelling of the ring due to fluid contact tends to increase the squeeze and may partially compensate for the loss due to compression set. Generally, compression set varies by compound and ring cross-sectional diameter, and increases with the operating temperature.

## ROLLED STEEL, WIRE, SHEET-METAL, WIRE ROPE

### Rolled Steel Sections

**Lengths of Angles Bent to Circular Shape.**— To calculate the length of an angle-iron used either inside or outside of a tank or smokestack, the following table of constants may be used: Assume, for example, that a stand-pipe, 20 feet inside diameter, is provided with a 3 by 3 by  $\frac{3}{8}$  inch angle-iron on the inside at the top. The circumference of a circle 20 feet in diameter is 754 inches. From the table of constants, find the constant for a 3 by 3 by  $\frac{3}{8}$  inch angle-iron, which is 4.319. The length of the angle then is  $754 - 4.319 = 749.681$  inches. Should the angle be on the outside, add the constant instead of subtracting it; thus,  $754 + 4.319 = 758.319$  inches.

Size of Angle	Const.	Size of Angle	Const.	Size of Angle	Const.
$\frac{1}{4} \times 2 \times 2$	2.879	$\frac{5}{16} \times 3 \times 3$	4.123	$\frac{1}{2} \times 5 \times 5$	6.804
$\frac{5}{16} \times 2 \times 2$	3.076	$\frac{3}{8} \times 3 \times 3$	4.319	$\frac{3}{8} \times 6 \times 6$	7.461
$\frac{3}{8} \times 2 \times 2$	3.272	$\frac{1}{2} \times 3 \times 3$	4.711	$\frac{1}{2} \times 6 \times 6$	7.854
$\frac{1}{4} \times 2\frac{1}{2} \times 2\frac{1}{2}$	3.403	$\frac{3}{8} \times 3\frac{1}{2} \times 3\frac{1}{2}$	4.843	$\frac{3}{4} \times 6 \times 6$	8.639
$\frac{5}{16} \times 2\frac{1}{2} \times 2\frac{1}{2}$	3.600	$\frac{1}{2} \times 3\frac{1}{2} \times 3\frac{1}{2}$	5.235	$\frac{1}{2} \times 8 \times 8$	9.949
$\frac{3}{8} \times 2\frac{1}{2} \times 2\frac{1}{2}$	3.796	$\frac{3}{8} \times 4 \times 4$	5.366	$\frac{3}{4} \times 8 \times 8$	10.734
$\frac{1}{2} \times 2\frac{1}{2} \times 2\frac{1}{2}$	4.188	$\frac{1}{2} \times 4 \times 4$	5.758	$1 \times 8 \times 8$	11.520
$\frac{1}{4} \times 3 \times 3$	3.926	$\frac{3}{8} \times 5 \times 5$	6.414	...	...

**Standard Designations of Rolled Steel Shapes.**— Through a joint effort, the American Iron and Steel Institute (AISI) and the American Institute of Steel Construction (AISC) have changed most of the designations for their hot-rolled structural steel shapes. The present designations, standard for steel producing and fabricating industries, should be used when designing, detailing, and ordering steel. The accompanying Table 1 compares the present designations with the previous descriptions.

**Table 1. Hot-Rolled Structural Steel Shape Designations (AISI and AISC)**

Present Designation	Type of Shape	Previous Designation
W 24 × 76	W shape	24 WF 76
W 14 × 26	W shape	14 B 26
S 24 × 100	S shape	24 I 100
M 8 × 18.5	M shape	8 M 18.5
M 10 × 9	M shape	10 JR 9.0
M 8 × 34.3	M shape	8 × 8 M 34.3
C 12 × 20.7	American Standard Channel	12 [20.7
MC 12 × 45	Miscellaneous Channel	12 × 4 [45.0
MC 12 × 10.6	Miscellaneous Channel	12 JR [10.6
HP 14 × 73	HP shape	14 BP 73
L 6 × 6 × $\frac{3}{4}$	Equal Leg Angle	$\angle 6 \times 6 \times \frac{3}{4}$
L 6 × 4 × $\frac{3}{8}$	Unequal Leg Angle	$\angle 6 \times 4 \times \frac{3}{8}$
WT 12 × 38	Structural Tee cut from W shape	ST 12 WF 38
WT 7 × 13	Structural Tee cut from W shape	ST 7 B 13
St 12 × 50	Structural Tee cut from S shape	ST 12 I 50
MT 4 × 9.25	Structural Tee cut from M shape	ST 4 M 9.25
MT 5 × 4.5	Structural Tee cut from M shape	ST 5 JR 4.5
MT 4 × 17.15	Structural Tee cut from M shape	ST 4 M 17.15
PL $\frac{1}{2} \times 18$	Plate	PL 18 × $\frac{1}{2}$
Bar 1	Square Bar	Bar 1
Bar 1 $\frac{1}{4} \varnothing$	Round Bar	Bar 1 $\frac{1}{4} \varnothing$
Bar $2\frac{1}{2} \times \frac{1}{2}$	Flat Bar	Bar $2\frac{1}{2} \times \frac{1}{2}$
Pipe 4 Std.	Pipe	Pipe 4 Std.
Pipe 4 X-Strong	Pipe	Pipe 4 X-Strong
Pipe 4 XX-Strong	Pipe	Pipe 4 XX-Strong
TS 4 × 4 × .375	Structural Tubing: Square	Tube 4 × 4 × .375
TS 5 × 3 × .375	Structural Tubing: Rectangular	Tube 5 × 3 × .375
TS 3 OD × .250	Structural Tubing: Circular	Tube 3 OD × .250

**Table 2a. Steel Wide-Flange Sections**

Wide-flange sections are designated, in order, by a section letter, nominal depth of the member in inches, and the nominal weight in pounds per foot; thus:

**W 18 × 64**

indicates a wide-flange section having a nominal depth of 18 inches, and a nominal weight per foot of 64 pounds. Actual geometry for each section can be obtained from the values below.

Designation	Area, A inch <sup>2</sup>	Depth, d inch	Flange		Web Thick- ness, t <sub>w</sub> inch	Axis X-X			Axis Y-Y		
			Width, b <sub>f</sub> inch	Thick- ness, t <sub>f</sub> inch		I inch <sup>4</sup>	S inch <sup>3</sup>	r inch	I inch <sup>4</sup>	S inch <sup>3</sup>	r inch

**Table 2d. Steel Wide-Flange Sections**

Wide-flange sections are designated, in order, by a section letter, nominal depth of the member in inches, and the nominal weight in pounds per foot; thus:  
**W 8 × 67**  
 indicates a wide-flange section having a nominal depth of 8 inches, and a nominal weight per foot of 67 pounds. Actual geometry for each section can be obtained from the values below.

These angles are commonly designated by section symbol, width of each leg, and thickness, thus:

$$L\ 3 \times 3 \times \frac{1}{4}$$

indicates a 3 × 3-inch angle of  $\frac{1}{4}$ -inch thickness.

Data taken from the "Manual of Steel Construction," 8th Edition, 1980, with permission of the American Institute of Steel Construction.

**Table 6. Steel Angles with Unequal Legs**

These angles are commonly designated by section symbol, width of each leg, and thickness, thus:

$$L 7 \times 4 \times \frac{1}{2}$$

indicates a 7 × 4-inch angle of 1/2-inch thickness.

Structural sections are available in 6061-T6 aluminum alloy. Data supplied by The Aluminum Association.

### Wire and Sheet-Metal Gages

The thicknesses of sheet metals and the diameters of wires conform to various gaging systems. These gage sizes are indicated by numbers, and the following tables give the decimal equivalents of the different gage numbers. Much confusion has resulted from the use of gage numbers, and in ordering materials it is preferable to give the exact dimensions in decimal fractions of an inch. While the dimensions thus specified should conform to the gage ordinarily used for a given class of material, any error in the specification due, for example, to the use of a table having "rounded off" or approximate equivalents, will be apparent to the manufacturer at the time the order is placed. Furthermore, the decimal method of indicating wire diameters and sheet metal thicknesses has the advantage of being self-explanatory, whereas arbitrary gage numbers are not. The decimal system of indicating gage sizes is now being used quite generally, and gage numbers are gradually being discarded. Unfortunately, there is considerable variation in the use of different gages. For example, a gage ordinarily used for copper, brass and other non-ferrous materials, may at times be used for steel, and vice versa. The gages specified in the following are the ones ordinarily employed for the materials mentioned, but there are some minor exceptions and variations in the different industries.

**Wire Gages.**— The wire gage system used by practically all of the steel producers in the United States is known by the name Steel Wire Gage or, to distinguish it from the Standard Wire Gage (S.W.G.) used in Great Britain, it is called the United States Steel Wire Gage. It is the same as the Washburn and Moen, American Steel and Wire Company, and Roebling wire gages. The name has the official sanction of the Bureau of Standards at Washington but is not legally effective. The only wire gage which has been recognized in Acts of Congress is the Birmingham Gage (also known as Stub's Iron Wire). The Birmingham Gage is, however, nearly obsolete in both the United States and Great Britain, where it originated. Copper and aluminum wires are specified in decimal fractions. They were formerly universally specified in the United States by the American or Brown & Sharpe Wire Gage. Music spring steel wire, one of the highest quality wires of several types used for mechanical springs, is specified by the piano or music wire gage.

In Great Britain one wire gage has been legalized. This is called the Standard Wire Gage (S.W.G.), formerly called Imperial Wire Gage.

**Gages for Rods.**— Steel wire rod sizes are designated by fractional or decimal parts of an inch and by the gage numbers of the United States Steel Wire Gage. Copper and aluminum rods are specified by decimal fractions and fractions. Drill rod may be specified in decimal fractions but in the carbon and alloy tool steel grades may also be specified in the Stub's Steel Wire Gage and in the high-speed steel drill rod grade may be specified by the Morse Twist Drill Gage (Manufacturers' Standard Gage for Twist Drills). For gage numbers with corresponding decimal equivalents see the tables of American Standard Straight Shank Twist Drills, for example, page 907, and [Table 5a](#) on page 2628.

**Gages for Wall Thicknesses of Tubing.**— At one time the Birmingham or Stub's Iron Wire Gage was used to specify the wall thickness of the following classes of tubing: seamless brass, seamless copper, seamless steel, and aluminum. The Brown & Sharpe Wire Gage was used for brazed brass and brazed copper tubing. Wall thicknesses are now specified by decimal parts of an inch but the wall thickness of steel pressure tubes and steel mechanical tubing may be specified by the Birmingham or Stub's Iron Wire Gage. In Great Britain the Standard Wire Gage (S.W.G.) is used to specify the wall thickness of some kinds of steel tubes.

**Table 1. Wire Gages in Approximate Decimals of an Inch**

<sup>a</sup> Also known as Washburn and Moen, American Steel and Wire Co. and Roebbling wire gages. A greater selection of sizes is available and is specified by what are known as split gage numbers. They can be recognized by  $\frac{1}{2}$  fractions which follow the gage number; i.e.,  $4\frac{1}{2}$ . The decimal equivalents of split gage numbers are in the Steel Products Manual entitled: *Wire and Rods, Carbon Steel* published by the American Iron and Steel Institute, Washington, DC.

<sup>a</sup>Gauge is Birmingham Wire Gauge (same as Stub's Iron Wire Gauge)

**Strength and Stiffness of Perforated Metals.**— It is common practice to use perforated metals in equipment enclosures to provide cooling by the flow of air or fluids. If the perforated material is to serve also as a structural member, then calculations of stiffness and strength must be made that take into account the effect of the perforations on the strength of the panels.

The accompanying table provides equivalent or effective values of the yield strength  $S^*$ ; modulus of elasticity  $E^*$ ; and Poisson's ratio  $\nu^*$  of perforated metals in terms of the values for solid material. The  $S^*/S$  and  $E^*/E$  ratios, given in the accompanying table for the standard round hole staggered pattern, can be used to determine the safety margins or deflections for perforated metal use as compared to the unperforated metal for any geometry or loading condition.

Perforated material has different strengths depending on the direction of loading; therefore, values of  $S^*/S$  in the table are given for the width (strongest) and length (weakest) directions. Also, the effective elastic constants are for plane stress conditions and apply to the in-plane loading of thin perforated sheets; the bending stiffness is greater. However, since most loading conditions involve a combination of bending and stretching, it is more convenient to use the same effective elastic constants for these combined loading conditions. The plane stress effective elastic constants given in the table can be conservatively used for all loading conditions.

### Mechanical Properties of Materials Perforated with Round Holes in IPA Standard Staggered Hole Pattern

Value in parentheses specifies holes per square inch instead of center distance.  $S^*/S$  = ratio of yield strength of perforated to unperforated material;  $E^*/E$  = ratio of modulus of elasticity of perforated to unperforated material;  $\nu^*$  = Poisson's ratio for given percentage of open area.

IPA is Industrial Perforators Association.

**Sheet-Metal Gages.**— Thicknesses of steel sheets given in **Table 2** are based upon a weight of 41.82 pounds per square foot per inch of thickness, which is known as the Manufacturers' Standard Gage for Sheet Steel. This gage differs from the older United States Standard Gage for iron and steel sheets and plates, established by Congress in 1893, based upon a weight of 40 pounds per square foot per inch of thickness which is the weight of wrought-iron plate.

<sup>a</sup> Manufacturers' Standard Gage for Sheet Steel

<sup>b</sup> B.G. is the Birmingham Gage for sheets and hoops.

*The United States Standard Gage* (not shown above) for iron and steel sheets and plates was established by Congress in 1893 and was primarily a *weight* gage rather than a thickness gage. The equivalent thicknesses were derived from the weight of wrought iron. The weight per cubic foot was taken at 480 pounds, thus making the weight of a plate 12 inches square and 1 inch thick, 40 pounds. In converting weight to equivalent thickness, gage tables formerly published contained thicknesses equivalent to the basic weights just mentioned. For example, a No. 3 U.S. gage represents a wrought-iron plate having a weight of 10 pounds per square foot; hence, if the weight per square foot per inch thick is 40 pounds, the plate thickness for a No. 3 gage =  $10 \div 40 = 0.25$  inch, which was the original thickness equivalent for this gage number. Because this and the other thickness equivalents were derived from the weight of wrought iron, they are not correct for steel.

Zinc sheets are usually ordered by specifying decimal thickness although a zinc gage exists and is shown in [Table 2](#).

Most sheet-metal products in Great Britain are specified by the British Standard Wire Gage (Imperial Wire Gage). Black iron and steel sheet and hooping, and galvanized flat and corrugated steel sheet, however, are specified by the Birmingham Gage (B.G.), which was legalized in 1914, and are also shown in [Table 2](#). This Birmingham Gage should not be confused with the Birmingham or Stub's Iron Wire Gage mentioned previously.

Thicknesses of aluminum, copper, and copper-base alloys were formerly designated by the American or Brown & Sharpe Wire Gage but now are specified in decimals or fractions of an inch. American National Standard B32.1-1952 (R1988) entitled Preferred Thicknesses for Uncoated Thin Flat Metals (see accompanying [Table 3](#)) gives thicknesses that are based on the 20- and 40-series of preferred numbers in American National Standard Preferred Numbers — ANSI Z17.1 (see Handbook page [661](#)) and are applicable to uncoated, thin, flat metals and alloys. Each number of the 20-series is approximately 12 percent greater than the next smaller one, and each number of the 40-series is approximately 6 percent greater than the next smaller one.

The American National Standard ANSI B32.1-1952 (R1994) lists preferred thicknesses that are based on the 20- and 40-series of preferred numbers and states that those based on the 40-series should provide adequate coverage. However, where intermediate thicknesses are required, the Standard recommends that thicknesses be based on the 80-series of preferred numbers (see Handbook page [661](#)).

Thicknesses for copper and copper-base alloy flat products below  $\frac{1}{4}$  inch thick are specified by the 20-series of American National Standard Preferred Numbers given in ANSI B32.1. Although the table in ANSI B32.1 gives only the 20- and 40-series of numbers, it states that when intermediate thicknesses are required they should be selected from thicknesses based on the 80-series of numbers (see Handbook page [661](#)).

**Metric Sizes for Flat Metal Products.**— American National Standard B32.100-2005 (R2010) establishes a preferred series of metric thicknesses, widths, and lengths for flat metal products of rectangular cross section; the thickness and width values are also applicable to base metals that may be coated in later operations. The standard also establishes a preferred series of metric sizes for round and hexagonal metal products.

The First Choice of sizes of this standard are derived from Renard's R5 series of preferred numbers (see *American National Standard for Preferred Numbers* on page 661, also ANSI B4.2 or ISO 497) in which each preferred number is approximately 60 percent larger than the preceding number in the series. The Second Choice series are derived from the R10 series in which each number is approximately 25 percent larger than the preceding, and Third Choice sizes are generally from the R20 series in which each number is approximately 12.5 percent larger than the preceding number.

Table 4a gives preferred metric diameters from 1 to 500 millimeters for round metal products; Table 4b lists the preferred thicknesses; Table 4c lists the preferred widths. Wherever possible, sizes should be selected from the First Choice series shown in the tables. Second and Third Choice series are also shown. For preferred metric diameters less than 1 millimeter, preferred across flat metric sizes of square and hexagon metal products, preferred across flat metric sizes of rectangular metal products, and preferred metric lengths of metal products, reference should be made to the B32.100-2005 Standard.

**Wire Drawing History.**— Wire drawing is the process used for producing wire by drawing a wire or rod of larger diameter through a plate or die provided with a hole which reduces the size to the desired dimension. Previous to wire drawing, wire was made by hammering or beating metal into thin sheets or plates, which were cut into continuous strips. These strips were then afterwards rounded by hammering. There is evidence that wire was produced by a simple hammering process as early as 2000 B.C., and perhaps earlier. The history of the art does not clearly indicate when simple hammering was superseded by the method of drawing through a die, but records are available to show that wire drawing on a commercial scale was practiced in France in 1270, in Germany in 1350, and in England in 1466. The first wire-drawing mill in America was built in 1775, in Norwich, Conn., by Nathaniel Niles, who was granted a loan of \$1500 by the court for this purpose.

**Shaped Wire.**— Shaped wire is any wire not round in section; it may be square, rectangular, hexagonal, triangular, half-round, oval, etc. Some sections of shaped wire may be either rolled or drawn. Shaped wire is a specialty, subject to agreement between purchaser and manufacturer as to size, finish, temper, and weight of coils and packages.

### Strength and Properties of Wire Rope

**Wire Rope Construction.**—Essentially, a wire rope is made up of a number of strands laid helically about a metallic or non-metallic core. Each strand consists of a number of wires also laid helically about a metallic or non-metallic center. Various types of wire rope have been developed to meet a wide range of uses and operating conditions. These types are distinguished by the kind of core; the number of strands; the number, sizes, and arrangement of the wires in each strand; and the way in which the wires and strands are wound or laid about each other. The following descriptive material is based largely on information supplied by the Bethlehem Steel Co.

*Rope Wire Materials:* Materials used in the manufacture of rope wire are, in order of increasing strength: iron, phosphor bronze, traction steel, plow steel, improved plow steel, and bridge rope steel. Iron wire rope is largely used for low-strength applications such as elevator ropes not used for hoisting, and for stationary guy ropes.

Phosphor bronze wire rope is used occasionally for elevator governor-cable rope and for certain marine applications as life lines, clearing lines, wheel ropes and rigging.

Traction steel wire rope is used primarily as hoist rope for passenger and freight elevators of the traction drive type, an application for which it was specifically designed.

Ropes made of galvanized wire or wire coated with zinc by the electro-deposition process are used in certain applications where additional protection against rusting is required. As will be noted from the tables of wire-rope sizes and strengths, the breaking strength of galvanized wire rope is 10 percent less than that of ungalvanized (bright) wire rope. Beth-anized (zinc-coated) wire rope can be furnished to bright wire rope strength when so specified.

Galvanized carbon steel, tinned carbon steel, and stainless steel are used for small cords and strands ranging in diameter from  $\frac{1}{64}$  to  $\frac{3}{8}$  inch and larger.

Marline clad wire rope has each strand wrapped with a layer of tarred marline. The cladding provides hand protection for workers and wear protection for the rope.

*Rope Cores:* Wire-rope cores are made of fiber, cotton, asbestos, polyvinyl plastic, a small wire rope (independent wire-rope core), a multiple-wire strand (wire-strand core) or a cold-drawn wire-wound spring.

*Fiber* (manila or sisal) is the type of core most widely used when loads are not too great. It supports the strands in their relative positions and acts as a cushion to prevent nicking of the wires lying next to the core.

*Cotton* is used for small ropes such as sash cord and aircraft cord.

*Asbestos cores* can be furnished for certain special operations where the rope is used in oven operations.

*Polyvinyl plastics cores* are offered for use where exposure to moisture, acids, or caustics is excessive.

*Wire-strand core* often referred to as WSC, consists of a multiple-wire strand that may be the same as one of the strands of the rope. It is smoother and more solid than the independent wire rope core and provides a better support for the rope strands.

The *independent wire rope core*, often referred to as IWRC, is a small  $6 \times 7$  wire rope with a wire-strand core and is used to provide greater resistance to crushing and distortion of the wire rope. For certain applications it has the advantage over a wire-strand core in that it stretches at a rate closer to that of the rope itself.

Wire ropes with wire-strand cores are, in general, less flexible than wire ropes with independent wire-rope or non-metallic cores.

Ropes with metallic cores are rated  $7\frac{1}{2}$  percent stronger than those with non-metallic cores.

*Wire-Rope Lay:* The lay of a wire rope is the direction of the helical path in which the strands are laid and, similarly, the lay of a strand is the direction of the helical path in which the wires are laid. If the wires in the strand or the strands in the rope form a helix similar to the threads of a right-hand screw, i.e., they wind around to the right, the lay is called right hand and, conversely, if they wind around to the left, the lay is called left hand. In the *regular lay*, the wires in the strands are laid in the opposite direction to the lay of the strands in the rope. In right-regular lay, the strands are laid to the right and the wires to the left. In left-regular lay, the strands are laid to the left, the wires to the right. In *Lang lay*, the wires and strands are laid in the same direction, i.e., in right Lang lay, both the wires and strands are laid to the right and in left Lang they are laid to the left.

Alternate lay ropes having alternate right and left laid strands are used to resist distortion and prevent clamp slippage, but because other advantages are missing, have limited use.

The regular lay wire rope is most widely used and right regular lay rope is customarily furnished. Regular lay rope has less tendency to spin or untwist when placed under load and is generally selected where long ropes are employed and the loads handled are frequently removed. Lang lay ropes have greater flexibility than regular lay ropes and are more resistant to abrasion and fatigue.

In preformed wire ropes the wires and strands are preshaped into a helical form so that when laid to form the rope they tend to remain in place. In a non-preformed rope, broken wires tend to "wicker out" or protrude from the rope and strands that are not seized tend to spring apart. Preforming also tends to remove locked-in stresses, lengthen service life, and make the rope easier to handle and to spool.

*Strand Construction:* Various arrangements of wire are used in the construction of wire rope strands. In the simplest arrangement six wires are grouped around a central wire thus making seven wires, all of the same size. Other types of construction known as "filler-wire," Warrington, Seale, etc. make use of wires of different sizes. Their respective patterns of arrangement are shown diagrammatically in the table of wire weights and strengths.

**Specifying Wire Rope.**— In specifying wire rope the following information will be required: length, diameter, number of strands, number of wires in each strand, type of rope construction, grade of steel used in rope, whether preformed or not preformed, type of center, and type of lay. The manufacturer should be consulted in selecting the best type of wire rope for a new application.

**Properties of Wire Rope.**— Important properties of wire rope are strength, wear resistance, flexibility, and resistance to crushing and distortion.

*Strength:* The strength of wire rope depends upon its size, kind of material of which the wires are made and their number, the type of core, and whether the wire is galvanized or not. Strengths of various types and sizes of wire ropes are given in the accompanying tables together with appropriate factors to apply for ropes with steel cores and for galvanized wire ropes.

*Wear Resistance:* When wire rope must pass back and forth over surfaces that subject it to unusual wear or abrasion, it must be specially constructed to give satisfactory service.

Such construction may make use of 1) relatively large outer wires; 2) Lang lay in which wires in each strand are laid in the same direction as the strand; and 3) flattened strands.

The object in each type is to provide a greater outside surface area to take the wear or abrasion. From the standpoint of material, improved plow steel has not only the highest tensile strength but also the greatest resistance to abrasion in regularly stocked wire rope.

*Flexibility:* Wire rope that undergoes repeated and severe bending, such as in passing around small sheaves and drums, must have a high degree of flexibility to prevent premature breakage and failure due to fatigue. Greater flexibility in wire rope is obtained by

1) using small wires in larger numbers; 2) using Lang lay; and 3) preforming, that is, the wires and strands of the rope are shaped during manufacture to fit the position they will assume in the finished rope.

*Resistance to Crushing and Distortion:* Where wire rope is to be subjected to transverse loads that may crush or distort it, care should be taken to select a type of construction that will stand up under such treatment.

Wire rope designed for such conditions may have 1) large outer wires to spread the load per wire over a greater area; and 2) an independent wire core or a high-carbon cold-drawn wound spring core.

**Standard Classes of Wire Rope.**— Wire rope is commonly designated by two figures, the first indicating the number of strands and the second, the number of wires per strand, as:  $6 \times 7$ , a six-strand rope having seven wires per strand, or  $8 \times 19$ , an eight-strand rope having 19 wires per strand. When such numbers are used as designations of standard wire rope classes, the second figure in the designation may be purely nominal in that the number of wires per strand for various ropes in the class may be slightly less or slightly more than the nominal as will be seen from the following brief descriptions. (For ropes with a wire strand core, a second group of two numbers may be used to indicate the construction of the wire core, as  $1 \times 21$ ,  $1 \times 43$ , and so on.)

*$6 \times 7$  Class (Standard Coarse Laid Rope):* Wire ropes in this class are for use where resistance to wear, as in dragging over the ground or across rollers, is an important requirement. Heavy hauling, rope transmissions, and well drilling are common applications. These wire ropes are furnished in right regular lay and occasionally in Lang lay. The cores may be of fiber, independent wire rope, or wire strand. Since this class is a relatively stiff type of construction, these ropes should be used with large sheaves and drums. Because of the small number of wires, a larger factor of safety may be called for.

Fig. 1a.  
 $6 \times 7$  with fiber core

Fig. 1b.  
 $6 \times 7$  with  $1 \times 7$  WSC

Fig. 1c.  
 $6 \times 7$  with  $1 \times 19$  WSC

Fig. 1d.  
 $6 \times 7$  with IWRC

As shown in Figs. 1a through Figs. 1d, this class includes a  $6 \times 7$  construction with fiber core; a  $6 \times 7$  construction with  $1 \times 7$  wire strand core (sometimes called  $7 \times 7$ ); a  $6 \times 7$  construction with  $1 \times 19$  wire strand core; and a  $6 \times 7$  construction with independent wire rope core. Table 1 provides strength and weight data for this class.

Two special types of wire rope in this class are: aircraft cord, a  $6 \times 6$  or  $7 \times 7$  Bethanized wire rope of high tensile strength and sash cord, a  $6 \times 7$  iron rope used for a variety of purposes where strength is not an important factor.

**Table 1. Weights and Strengths of 6 × 7 (Standard Coarse Laid) Wire Ropes, Preformed and Not Preformed**

Dia., Inches	Approx. Weight per Ft., Pounds	Breaking Strength, Tons of 2000 Lbs.			Dia., Inches	Approx. Weight per Ft., Pounds	Breaking Strength, Tons of 2000 Lbs.		
		Impr. Plow Steel	Plow Steel	Mild Plow Steel			Impr. Plow Steel	Plow Steel	Mild Plow Steel
¼	0.094	2.64	2.30	2.00	¾	0.84	22.7	19.8	17.2
⅜	0.15	4.10	3.56	3.10	⅞	1.15	30.7	26.7	23.2
½	0.21	5.86	5.10	4.43	1	1.50	39.7	34.5	30.0
⅝	0.29	7.93	6.90	6.00	1¼	1.90	49.8	43.3	37.7
¾	0.38	10.3	8.96	7.79	1½	2.34	61.0	53.0	46.1

**6 × 19 Class (Standard Hoisting Rope):** This rope is the most popular and widely used class. Ropes in this class are furnished in regular or Lang lay and may be obtained preformed or not preformed. Cores may be of fiber, independent wire rope, or wire strand. As can be seen from Table 2 and Figs. 2a through 2h, there are four common types: 6 × 25 filler wire construction with fiber core (not illustrated), independent wire core, or wire strand core (1 × 25 or 1 × 43); 6 × 19 Warrington construction with fiber core; 6 × 21 filler wire construction with fiber core; and 6 × 19, 6 × 21, and 6 × 17 Seale construction with fiber core.

**6 × 37 Class (Extra Flexible Hoisting Rope):** For a given size of rope, the component wires are of smaller diameter than those in the two classes previously described and hence have less resistance to abrasion. Ropes in this class are furnished in regular and Lang lay with fiber core or independent wire rope core, preformed or not preformed.

filler wire construction with fiber core or independent wire rope core, a special large shovel and dredge rope.

*8 × 19 Class (Special Flexible Hoisting Rope):* This rope is stable and smooth-running, and is especially suitable, because of its flexibility, for high speed operation with reverse bends. Ropes in this class are available in regular lay with fiber core.

As shown in [Table 4](#) and [Figs. 4a](#) through [4d](#), there are four common types: 8 × 25 filler wire construction, the most flexible but the least wear resistant rope of the four types; Warrington type in 8 × 19 construction, less flexible than the 8 × 25; 8 × 21 filler wire construction, less flexible than the Warrington; and Seale type in 8 × 19 construction, which has the greatest wear resistance of the four types but is also the least flexible.

Also in this class, but not shown in [Table 4](#), are elevator ropes made of traction steel and iron.

**18 × 7 Non-rotating Wire Rope:** This rope is specially designed for use where a minimum of rotating or spinning is called for, especially in the lifting or lowering of free loads with a single-part line. It has an inner layer composed of 6 strands of 7 wires each laid in left Lang lay over a fiber core and an outer layer of 12 strands of 7 wires each laid in right regular lay. The combination of opposing lays tends to prevent rotation when the rope is stretched. However, to avoid any tendency to rotate or spin, loads should be kept to at least one-eighth and preferably one-tenth of the breaking strength of the rope. Weights and strengths are shown in [Table 5](#).

**Flattened Strand Wire Rope:** The wires forming the strands of this type of rope are wound around triangular centers so that a flattened outer surface is provided with a greater area than in the regular round rope to withstand severe conditions of abrasion. The triangular shape of the strands also provides superior resistance to crushing. Flattened strand wire

rope is usually furnished in Lang lay and may be obtained with fiber core or independent wire rope core. The three types shown in Table 6 and Figs. 6a through 6c are flexible and are designed for hoisting work.

Source: Rope diagrams, Bethlehem Steel Co. All other data, U.S. Simplified Practice Recommendation 198-50.

**Flat Wire Rope:** This type of wire rope is made up of a number of four-strand rope units placed side by side and stitched together with soft steel sewing wire. These four-strand units are alternately right and left lay to resist warping, curling, or rotating in service. Weights and strengths are shown in Table 7.

**Simplified Practice Recommendations.**— Because the total number of wire rope types is large, manufacturers and users have agreed upon and adopted a U.S. Simplified Practice Recommendation to provide a simplified listing of those kinds and sizes of wire rope which are most commonly used and stocked. These, then, are the types and sizes which are most generally available. Other types and sizes for special or limited uses also may be found in individual manufacturer's catalogs.

**Sizes and Strengths of Wire Rope.**— The data shown in Tables 1 through 7 have been taken from U.S. Simplified Practice Recommendation 198-50 but do not include those wire ropes shown in that Simplified Practice Recommendation which are intended primarily for marine use.

**Wire Rope Diameter:** The diameter of a wire rope is the diameter of the circle that will just enclose it, hence when measuring the diameter with calipers, care must be taken to obtain the largest outside dimension, taken across the opposite strands, rather than the smallest dimension across opposite "valleys" or "flats." It is standard practice for the nominal diameter to be the minimum with all tolerances taken on the plus side. Limits for diam-

eter as well as for minimum breaking strength and maximum pitch are given in Federal Specification for Wire Rope, RR-R—571a.

*Wire Rope Strengths:* The strength figures shown in the accompanying tables have been obtained by a mathematical derivation based on actual breakage tests of wire rope and represent from 80 to 95 percent of the total strengths of the individual wires, depending upon the type of rope construction.

**Table 7. Weights and Strengths of Standard Flat Wire Rope, Not Preformed**

**Safe Working Loads and Factors of Safety.**— The maximum load for which a wire rope is to be used should take into account such associated factors as friction, load caused by bending around each sheave, acceleration and deceleration, and, if a long length of rope is to be used for hoisting, the weight of the rope at its maximum extension. The condition of the rope — whether new or old, worn or corroded — and type of attachments should also be considered.

Factors of safety for standing rope usually range from 3 to 4; for operating rope, from 5 to 12. Where there is the element of hazard to life or property, higher values are used.

## SHAFT ALIGNMENT

### Introduction

Shaft alignment is the positioning of the rotational centers of two or more shafts so that the shafts are co-linear when the machines are operating. The purpose of shaft alignment is to increase the operating life span of rotating machinery and to achieve high motor efficiency. It is not easy to detect misalignment when machines are running, but secondary effects of misalignment can be observed, such as excessive radial and axial vibration; high temperature in casings, bearings, or lubricant; loose, broken or missing coupling bolts or foundation bolts; cracks in shafts; and excessive amounts of lubricant leakage.

There are no universally accepted specifications for shaft alignment, however, there are defined limits for shaft-to-shaft alignment of coupled machines. The limits are defined in terms of two measures of misalignment, *angularity* and *offset*.

**Angular Misalignment.**— Angular misalignment is the difference in the slope of one shaft, as compared to slope of the other shaft. The units are expressed as rise/run. Rise is measured in mils (1 mil = 0.001 inch), and the run (distance along shaft) is measured in inches. The process of correcting this type of alignment problem is sometimes called *gap* or *face alignment*.

Fig. 1. Shafts in Angular Misaligned Position

**Offset Misalignment.**— Offset misalignment is the distance between the shaft centers of rotation measured at the plane of power transmission or coupling center. The units of measurement are mils.

Fig. 2. Shafts in Offset Misaligned Position

There are four alignment parameters to be measured and corrected; vertical angularity, vertical offset, horizontal angularity, and horizontal offset. Values in **Table 1** may be used as a general guide for acceptable limits of misalignment. Proper shaft alignment is especially critical when shafts are running at high speeds, thus the allowable limits of misalignment decrease as shaft speeds increase.

**Table 1. Misalignment Tolerance Guide**

RPM	Offset Misalignment (Mils)		Angular Misalignment (mils/inch)	
	Excellent	Acceptable	Excellent	Acceptable
600	±2.00	±4.00	0.80	1.25
900	±1.50	±3.00	0.70	1.00
1200	±1.25	±2.00	0.50	0.80
1800	±1.0	±1.50	0.30	0.50
3600	±0.50	±0.75	0.20	0.30
≥4000	±0.50	±0.75	0.10	0.25

When the shafts of two machines require alignment, the process generally calls for one of the machines to be permanently mounted and the other one to be movable. The fixed unit is usually the driven machinery, such as the pump in a pump-motor pair. The second machine (usually the motor) is moved into approximate alignment (by eye and straight edge, for example) in preparation for measurements that will determine the magnitude and direction of moves required to put it in final alignment with the fixed machine. It is the movable machine whose shaft will be aligned with the shaft of the fixed machinery. The position of the movable machine is adjusted vertically by adding and/or removing shims from under its feet, and horizontally by making small lateral moves as required until satisfactory final alignment is obtained.

### Shaft Alignment with Dial Indicators

The material that follows describes the process of shaft alignment when dial indicators are used to measure the alignment data.

**Instruments and Methods.**—Numbers of instruments are available for making shaft measurements and calculating moves, but the most important requirement for any shaft alignment system is repeatability of the readings. Dial indicators and lasers are two choice measuring systems.

*Dial indicators* provide accurate and reliable measurement of shaft alignment. They are the most useful because they can be used to measure bearing alignment, shaft runout, and soft foot directly. Measurement accuracy down to 0.001 inch (1 mil) or 0.025 mm may be achieved if care is taken in mounting and reading the indicators correctly, and controlling or accounting for such variables as indicator sag, axial endplay in the shaft, and vibration from outside sources. The data obtained from properly installed dial indicators are converted by equations described later in this section into the vertical and horizontal movements required to bring the movable unit into alignment with the fixed unit.

*Laser measurement systems* are another popular choice for shaft alignment work, although the cost of such systems is much greater than dial indicators. Accuracy of 0.0001 inch (0.0025 mm) or greater is possible, and setup and operation is generally faster and simpler than with dial indicators. Many laser systems can perform some or all of the calculations required to obtain the horizontal and vertical moves. Lasers may not be safe for use in explosive environments.

**Runout Check.**—A runout test of either or both couplings is important only if there is a runout problem. Seldom will the runout of a pump or motor coupling be enough to detect with the eye alone. Standard practice is to position a rim and face indicator setup on the uncoupled couplings (one at a time) and roll said couplings through several 360° turns while monitoring the indicators. The indicator bracket should be firmly attached to a static object close to the pump or motor coupling being checked. Usually a magnetic base designed to hold indicators is used for this purpose if the two couplings involved are more than five or six inches apart. For an ordinary pump and motor, however, it is frequently convenient to mount the indicator jig to the motor to check the runout on the pump and then vice-versa for the motor.

Fig. 3 shows a profile view on the left and a motor- or pump-eye view (right) of a typical runout check setup involving the use of indicators attached to a magnetic base. Assume the rim indicator to have been adjusted to zero, the coupling being checked is rotated several full turns. Repeated turns deliver repeated readings of a maximum minus of  $-0.XXX$  inch at one extreme, and a maximum plus of  $0.XXX$  inch at the other extreme. Assuming there is no paint or rust, etc. involved, at least three possibilities exist.

- 1) the coupling was bored off-center
- 2) the shaft is bent
- 3) a combination of the above two conditions

## SHAFT ALIGNMENT

Fig. 3. Indicators set up for a runout check. In field applications, mount the face dial as near as possible to the rim indicator. The face indicator is drawn at the 6 o'clock position in both views for clarity.

Concerning **Item 3**) in the previous list, it is possible (however unlikely) for a coupling that was bored off center and would have shown up as coupling runout with a rim indicator test except that a slight bend in the shaft has canceled out what would normally have been evident due to the off-center bored coupling. This odd situation can cause vibration even when a standard test proves there is no misalignment. Coupling runout can also be caused by too large a coupling bore, with the slack being taken up by set screws.

*Interpreting the Indicators:* The actual amount of runout registered by the rim indicator is *half of the difference between the plus and minus reading extremes*.

*Example:* A rim indicator is mounted as shown in **Fig. 3** and set on zero. Then, several full turns of the shaft reveals a maximum minus of  $-0.006$  inch and a maximum plus of  $+0.012$  inch on the indicator. The total variation is  $0.018$  inch and half of  $0.018$  is  $0.009$ . Thus, the result of **Items 1), 2), or 3)** is  $0.009$  inch of eccentricity, or  $0.018$  inch TIR (total indicator reading) of coupling runout. *Note:* Much less coupling runout than is described above is usually expected.

If the face indicator shows zero at all points around a coupling while the rim indicator moves between  $+0.XXX$  inch and  $-0.XXX$  inch, it is probable that the coupling was bored off-center. If the rim indicator shows practically zero movement while the face indicator moves between  $-0.XXX$  inch and  $+0.XXX$  inch, the cause could be **Item 2)** or **3)** above, or the coupling was bored essentially centered, but at an angle other than perpendicular to the face of the coupling, as is shown in **Fig. 4**.

Fig. 4. Coupling Bore Centered but Not Perpendicular to Coupling Face  
Face Indicator Shown, Rim Indicator Not Shown

In **Fig. 4**, both the indicators shown will alternate from plus to minus and back again as the coupling being checked is rotated. Even if the shaft centerline goes through the center of the coupling, it will do so at an angle other than perpendicular to the face of the coupling. The result is serious coupling runout on the face indicator and less serious runout on the rim indicator.

Face runout can easily show up when there is none. If a machine has sleeve bearings and if the shaft is not axially restrained by a thrust bearing during the runout test, severe face runout will likely be indicated when little, if any, exists.

*Note:* Unacceptable runout of either or both couplings should be of little concern in the alignment process. The extended centerlines of the two shafts can be aligned even when

there is serious coupling runout. A runout check is mainly to have recorded information if excessive vibration occurs.

**Soft Legs.**— One of the most often overlooked precautions relevant to motor alignment is the firming up of the soft legs. For the motor in Fig. 5, one leg (D) is  $\frac{1}{2}$  inch short. In alignment jargon, the short leg is said to be *soft*. It is also clear that if a  $\frac{1}{2}$  inch shim were placed under the short leg, all four motor feet would firmly support the motor. On the other hand, if the motor were tightened down without the use of proper shims, its support would be very spongy and would produce non-repeatable indicator readings.

Fig. 5. Profile (a) and Overhead (b) Views of Motor with Soft Foot

On an ordinary electric motor any of the four motor feet may be either raised or lowered via the placement or removal of shims, as applicable, to render the motor equally supported by all four feet. Geometry may allow a certain freedom of choice, so it is practical to be very selective about which motor foot or feet will receive additional shims during the firming up of the motor.

When a soft leg involves only a few thousandths of an inch, it is much less obvious than in Fig. 5. By using what is known to some mechanics as the rock-a-bye method, it is possible to detect a slight amount of instability in the motor supports. With the bolts inserted, but only partly threaded in, alternately apply heel-of-the-hands pressure on or above two motor feet at a diagonal. If no rock-a-bye is evident when heel-of-the-hands pressure is alternately applied above feet A and D, switch to B and C. If rock-a-bye is found, remove applicable shims if possible or add shims under one or both of the unstable feet.

For the  $\frac{1}{2}$  inch (12.7 mm) gap shown in Fig. 5, downward heel-of-the-hands pressure at points A and D would yield more movement than the indicators could handle. On more subtle soft feet, it takes an experienced feel to detect only a few mils of rock-a-bye at a motor foot. When feel becomes too little to be certain, it is time to apply indicators.

On units where 0.010 inch (0.254 mm) or more of movement is evident, a tapered wedge gauge can be inserted under the motor foot as the motor is gently rocked. When the motor will no longer rock, the approximate thickness of the wedge gauge under the motor foot will be the amount of shim material to insert under that foot. If a single foot requires more shim thickness than is desirable, put half the thickness under the soft foot and the other half under the opposite diagonal foot; then, a second slight amount of shim placed under one of the two feet should remove any unwanted slack. During the rock-a-bye test, trial and error shimming will eliminate any obvious soft feet in a few tries. The careful step-by-step elimination of unwanted slack in the support feet of a motor or other movable unit should result in a very stable movable unit.

On larger motors, leverage proportional to resistance should be used, involving anything from a small pry-bar to hydraulics. When the rock-a-bye method gets so involved, it is advisable to have dial indicators mounted at the applicable motor feet and/or at the motor coupling, with the indicator button on top of the pump coupling or comparable static object, to register any movement.

A heavy duty version of the rock-a-bye method is to have all the hold-down bolts tight and then loosen them one at a time while monitoring the indicators.

Fig. 6. Rim Indicator Mounted to Test for Soft Feet

Fig. 6 shows a profile view (left) and overhead view (right) of the motor previously shown. In this figure, the indicator illustrated is mounted exactly as the rim indicator will later be mounted for checking alignment, and any soft leg activity will register the same as in the line-up process. Once a motor gets a clean bill of health from this soft foot check, it is safe to proceed with the normal procedures of motor alignment. Mount the indicators in the most convenient manner that will apply to the problem at hand and select the proper formula as discussed in the material that follows. Be sure all the bolts are tight before making the first (vertical) indicator reading

*Other Mounting Issues:* Any combination of the mounting conditions illustrated in Fig. 7 will produce soft motor feet, even if the motor feet are machined properly. The motor, base, or shims will need alterations to circumvent the illustrated problems. Depending on the magnitude of the angle in a problem of this sort, wedge-shaped shims or machine work on the motor or the base may be required.

Sometimes on relatively unimportant equipment, it is permissible to simply fold shims in various thicknesses to take up the slack. This method should not be used as common practice; but as an emergency measure, it is very effective.

Fig. 7. Mounting Conditions That Produce Soft Motor Feet.

**Mounting Dial Indicators, Perpendicular vs. Otherwise.**— When indicators are mounted to get a rim reading on a coupling, the indicator stem should be set to aim straight through the center of the shaft, and at a perpendicular to the axis of the shaft. This center shot at a perpendicular does not have to be absolutely perfect, but it should be close enough so that a closer than casual visual inspection can find no flaw. This is close enough for practical purposes.

Fig. 8. Indicator Stem Orientation, Correct at A and B, Incorrect at C and D

In Fig. 8 observe the rim indicator settings at positions A, B, C, and D. Indicators at positions A and B are set correctly, indicators at C and D are not. A slight tilt in the mounting of the indicators will make too little difference to matter, but any tilt over a few degrees should be avoided.

Just as important, the face indicator should be set perpendicular to the coupling face with the centerline of the indicator stem parallel to the axis of the fixed unit coupling shaft.

Fig. 9a shows a setup with rim and face indicators set at odd angles that will cause incorrect readings. Note the difference between the arrangement of Fig. 9a, and the correct one shown in Fig. 9b.

Fig. 9a. Incorrect Positioning of Dial Indicators    Fig. 9b. Correct Positioning of Dial Indicators

**Preparations.**— Before starting an alignment process several important factors need to be considered, among them the following. Is temperature rise in the coupled machinery a consideration? What is the indicator sag of the dial indicators in use? Is coupling runout a consideration? Are there improperly supported or “soft feet” in the movable machine? Are the motor feet, jack bolts, and shims clean? Can the movable unit be moved laterally far enough to permit alignment, or is movement restricted by bolts (“bolt bound”) or nearby obstructions? Is the driving unit powered off and locked out?

*Thermal Effects:* Metals increase in length as temperature increases, and decrease in length as temperature decreases. Rotating equipment at rest slowly attains the temperature of the surrounding environment, the *ambient* or room temperature. In service, machinery such as electric motors and fuel-burning engines generate heat and increase in temperature during operation; other machinery such as pumps may warm or cool during operation.

If initial alignment adjustments are made when machines are at *ambient* or room temperature, thermal movement will occur in various parts of the machines as they reach operating temperature. The various dimensions will not increase or decrease uniformly. In a motor-pump combination, for example, the motor shaft height above the base may increase while the pump shaft height may decrease.

The amount of thermal expansion can be estimated by the formula  $\Delta e = \alpha H \Delta T$ :

where  $\Delta e$  = change in height of shaft

$H$  = vertical height or distance between shaft centerline and shims

$\alpha$  = expansion coefficient of material in  $\mu\text{in}/\text{in}\text{-}^\circ\text{F}$  (for stainless steel 7.4, mild steel 6.3, cast iron 5.9, bronze 10, and aluminum 12.6). *Note:*  $1 \mu\text{in}/\text{in}\text{-}^\circ\text{F} = 1.8 \mu\text{m}/\text{m}\text{-}^\circ\text{C}$

$\Delta T$  = the difference between operating temperature and ambient (initial measurement) temperature

*Example 1(a):* A pump is to be installed and aligned with a motor. The cast iron pump delivers fresh water at  $34^\circ\text{F}$  and is at present at  $75^\circ\text{F}$ . The pump shaft centerline is 12 inches above the baseline of the pump. The carbon steel motor is also at  $75^\circ\text{F}$  and is expected to rise to  $140^\circ\text{F}$  when in operation. The motor shaft centerline is 12 inches above the base of the motor. At operating temperature, compare the expected thermal growth of the pump and motor shaft centerlines.

For the pump, the change in shaft height:

$$\Delta e = \alpha H \Delta T = 0.0000059 \times 12 \times (34 - 75) = -0.002903 \text{ inch}$$

For the motor, the change in shaft height is:

$$\Delta e = \alpha H \Delta T = 0.0000063 \times 12 \times (140 - 75) = 0.004914 \text{ inch}$$

These calculations indicate that the pump and motor shafts, if they were in alignment at ambient temperature, would be misaligned at operating temperature by approximately 0.0078 inch difference in elevation.

*Indicator Bracket Sag:* Indicator sag, indicator bracket sag, or jig sag are all terms commonly used to describe the effect on indicator readings of the weight of the dial indicator(s) in combination with the length, weight, and orientation of the indicator bracket. Dial indicators are designed to be used in the vertical position and indicator bracket sag is especially significant in measurements that are made when the dial indicator is inverted in the vertical plane. Consider a rim indicator and bracket mounted on a shaft with the indicator zeroed at the 12 o'clock position; when the shaft and fixture are rotated to put the dial indicator in the 6 o'clock position, the reading will indicate a non-zero negative value, which is the indicator fixture sag factor.

Indicator bracket sag is dependent on the mounting arrangement of the indicators, and is difficult to measure accurately on equipment that is being aligned because the effect of shaft misalignment will combine with the indicator bracket sag to produce incorrect results.

To measure indicator fixture sag, set up the indicator and mounting components on the machinery to be aligned exactly as if doing alignment, and tighten everything down. Then, remove the bracket and indicator from the machine and remount in exactly the same manner on a rigid fixture, such as a piece of pipe supported by V-blocks. Zero the indicator at the 12 o'clock (reference) position, then without changing the setup carefully rotate the fixture and read the indicator at the 6 o'clock (reading) position. At the reading position, the indicator displays the total indicator reading (TIR) and this value is the *total sag factor*. The actual sag in the indicator bracket is equal to one half of the total indicator reading.

When the indicator bracket sag has been determined, it can be accounted for in measurements taken during the alignment procedure. One procedure is to add the indicator bracket sag factor to the indicator value when the indicator is "zeroed" at the reference position, so that the sag factor is accounted for throughout subsequent calculations. For example, if an indicator is zeroed at the 12 o'clock position and reads 0.006 inch at the 6 o'clock position, set the indicator to positive 0.006 at the 12 o'clock reference position to account for the sag factor in further measurements. If the reference position used for checking indicator sag is the 6 o'clock position (indicator zeroed at 6 o'clock position), the positive reading found at the 12 o'clock position is the sag factor that must be subtracted from indicator value when the indicator is zeroed at the 6 o'clock (reference) position.

**Alignment Procedures for Machinery.**— The *face and rim method* and the *reverse dial indicator method* are the techniques most commonly used for aligning machinery shafts. The usual shaft alignment procedure is to establish one machine as fixed, and the other as the movable machine. The driven machinery is usually the fixed unit. The shaft of the movable unit is positioned, as required, to align with the shaft of the fixed unit. Most aligning specialists recommend vertical alignment first, and then horizontal alignment. It is important to verify in advance that the movable unit has sufficient horizontal clearance and freedom of movement to obtain the required horizontal position before starting on the vertical alignment.

*Vertical Moves:* Vertical adjustments are accomplished by adding or removing shims from under the machine feet. Use as few shims as possible. Too many shims under a foot may cause it to act like a soft foot by creating a spring effect; usually a maximum of four shims are allowed. Shims should be measured by micrometer before placing. If possible, apply a single shim that is the total thickness required under the foot. Insert the shims all the way until the shim slot bottoms out on the bolt, then pull the shim back about a quarter inch before tightening the bolts. If alignment is not possible with four shims, then use fewer,

amounting to the required thickness. Tighten bolts to their prescribed torque each time after placing shims to avoid any movement when working on the other side of the machine.

Never loosen all hold-down bolts at the same time. A maximum of two bolts are allowed to be loosened at a time. Loosening all hold-down bolts will lose the entire alignment. Loosen the bolts from either the left or right side of the machine. Then, raise that side just enough to make the shim change. Raising the machine too high can bend the foot. Once the machine is lifted, remove all shims and add or subtract the number of shims required to make the necessary vertical move. Be very cautious at this point not to get confused among a lot of loose shims.

**Horizontal Moves:** It is preferable to utilize a base plate with jackbolts for horizontal moves. If jack bolts are not available, a small hydraulic jack, pipe clamps, or pony clamps can be used. The most accurate method for measuring the horizontal move is to place dial indicators around the machine at convenient locations, such as at machine feet. The indicators can be located anywhere convenient as long as the dimensions used in the alignment calculations reflect the actual position at which measurements are made. When the indicators are mounted, adjust the dials to zero, and move the unit the distance and direction indicated by the calculations. Once the horizontal move has been completed, a final set of readings should be taken to verify both vertical and horizontal alignment.

**Safety:** Shaft alignment should not be performed when machines are running. Before shaft alignment, all sources of power to the machine should be off and verified. Energy sources must be locked out by electrical controls; steam valves, gas main valve, and fuel oil valve must be shut down before shaft alignment.

**Rim and Face Alignment Procedure.**— Figs. 10 and 11 show dial indicator arrangements for rim and face alignment that are typical of those used in the remainder of this section. Fig. 10 illustrates a chain indicator jig, but it could be of any type. The arrangement in Fig. 11 represents an equivalent setup. In each figure, two dial indicators are shown, one for the rim reading and the other for the face reading. Darkened squares, triangles or circles are simply to indicate attachment points.

Fig. 10.

Fig. 11.

Starting on page 2649, a number of different indicator arrangements are illustrated in Figs. 1a through 16a. Each arrangement is associated with a specific equation and a chart that facilitates understanding the dial and face readings and the corresponding tasks of determining where shims need to be added or removed and what horizontal moves are required. To use this system, the mechanic needs to set up the rim and face indicators in the most convenient manner, then turn to the figure of the matching indicator arrangement and use the formulas provided.

**Example Aligning a Motor with a Pump by the Rim and Face Method:** A 10-horsepower (7.5 kW) electric motor needs to be precision aligned to a specific pump. Both the pump and motor are to be mounted on a base that when finished will look similar to Fig. 12. Not shown are the intake and discharge piping, electrical fixtures, and other incidentals including shims under the motor feet.

The shims are omitted to visually explain why the motor will usually have a little less distance from the motor shaft centerline to the base than the pump has. This set up is desirable because with the motor shaft a little lower than the pump shaft, the motor can be shimmed up until both shafts share a common elevation. If the motor shaft is higher than the pump shaft, it can be very difficult to alter the position of the pump because of the rigidly connected piping.

Fig. 12. Pump and Motor are to be Aligned

The motor in Fig. 12 is in its approximate finished position about 8 inches (203.2 mm) from the pump. The spool piece shown in Fig. 12 is to be bolted between the motor and pump couplings after alignment is complete. The spool piece (not shown in Fig. 13) is 8 inches long and there is an  $8\frac{1}{8}$  inch (206.4 mm) space between pump and motor couplings.

Fig. 13 shows a viable mounting of dial indicators in the process of procuring readings from the zero setting at 12 o'clock (broken lines) to the 6 o'clock position (solid lines). Some calibrated eyeballing, a scale measure and some straight edging are used to align the motor initially to the pump.

Fig. 13. Alignment Setup for Pump and Motor

There are many ways to mount and adjust dial indicators to measure the remaining misalignment between the two units. Several are correct and only a few are optimum. The mounting of the pair of dial indicators between the motor and pump shown in Fig. 13 is as good as any and commonly used. Many other arrangements are shown starting on page 2649.

Although there seem to be four dial indicators in Fig. 13, there are only two. The two indicators with broken lines are drawn at the initial 12 o'clock position where they are zeroed with about half the indicator stems exposed, (both indicator pointers are shown at 12 o'clock). Then the motor and pump shafts are both turned 180° to the 6 o'clock position (those indicators are drawn with solid lines, and the pointers are shown set to the 3 o'clock and 9 o'clock positions in Fig. 13). In real life alignments, the pointers might be aimed anywhere on the dial face, but the dial face will rotate 360°, so the zero can be manually adjusted to align with the pointer no matter which direction the needle points.

*Solution for Vertical Alignment:* Once a motor has been aligned with straight edges and such, it is probably close enough to use dial indicators. The dials most often used have a stem range of just over 0.200 inch (roughly  $\frac{7}{32}$  inch). These dial indicators (usually two) are positioned with the buttons of the indicators against the rim and face of the pump coupling respectively, as shown in Fig. 13. The seasoned millwright/mechanic will adjust the indicator jig/bracket in such manner that the stem on each of the indicators has freedom to travel inward or outward about 0.100 inch. This adjustment is made at the 12 o'clock position, shown by broken lines in Fig. 13.

A good arrangement is for the rim indicator in Fig. 13 to register a minus  $r$  reading at the 6 o'clock position and the face indicator to register a plus  $f$  reading (see bottom right of Fig. 1b on page 2650). Readings on both indicators show that the motor needs to be raised, involving the simple task of determining how much shim material to add under each foot. For the indicator arrangement in Fig. 13, the required shim thickness can be determined by using the equations below.

$$F = \frac{\pm r}{-2} + \frac{\pm f \times B}{A} \quad \text{and} \quad R = \frac{\pm r}{-2} + \frac{\pm f \times C}{A}$$

where  $F = \pm$ change in shim thickness needed under the front feet

$R = \pm$ change in shim thickness needed under the rear feet

$r =$  plus or minus rim indicator reading

$f =$  plus or minus face indicator reading

$A =$  diameter of face indicator path on coupling

$B =$  distance from rim indicator path to front feet

$C =$  distance from rim indicator path to rear feet

The equations use the gathered data to calculate the correct shim placement. With either equation, a positive solution indicates that shims equal to the calculated value are added, and a negative solution indicates that shims equal to the calculated value are removed.

The rim and face indicator setup depicted in Fig. 13 is one of the sixteen arrangements described in the material that follows. Each of these formats has its own similar but unique formula; just plug the variables into the formulas that matches the current indicator format and calculate the shims required.

*Solution for Horizontal Alignment:* Fig. 14 shows a top view of the motor in Fig. 13, with indicators in the reading positions for horizontal alignment. The rim and face indicators are zeroed at the position  $180^\circ$  opposed to that shown in Fig. 14.

The directions corresponding to horizontal movement of the motor in Fig. 14 are indicated by east and west arrows. Magnetic-mount dial indicators (not shown) may be set up to monitor the horizontal movements. The dimensions  $B$  and  $C$  represent the distances from the rim indicator path to the locations of the monitoring indicators or jackbolts.

If jackbolts (or monitor indicators) are positioned on the west side as indicated in Fig. 14, the  $B$  and  $C$  dimensions are used in the equations. If jackbolts (or monitor indicators) are positioned at a different location on the east side (for example, jackbolts shown by dashed lines in Fig. 14), the east-side set of dimensions,  $B'$  and  $C'$ , are used in the equations.

The equations are the same as previously used in the vertical alignment procedure. Per the indicator arrangement in Fig. 14, a positive solution demands a move eastward, and a negative solution requires a westward move.

$F = \pm$ east-west movement needed at the front monitoring location

$R = \pm$ east-west movement needed at the rear monitoring location

$r =$  plus or minus rim indicator reading

$f =$  plus or minus face indicator reading

$A =$  diameter of face indicator path

$B =$  distance from rim indicator path to front monitoring location

$C =$  distance from rim indicator path to rear monitoring location

Fig. 14. Top View of Motor from Fig. 13

*Side to Side Adjustment Using Jackbolts:* Avoid using jackbolts that are longer than necessary. Make sure internal and external threads are clean and lubricated enough to be functional. Then, if heavy resistance is encountered when adjusting jackbolts, it indicates a mechanically-bound condition, not a rusty jackbolt thread. Before advancing jackbolts on one side of the movable unit, back off the jackbolts on the opposite side about  $1\frac{1}{2}$  turns to provide enough space to make the movement without creating a mechanical bind.

Jackbolts should not be left in a “bind” against the movable unit to assist in keeping the movable unit in alignment. After alignment is complete, the jackbolts should be removed and stored for future use. This action will prevent jackbolt corrosion, and leave the jackbolt nuts vacant to receive a tap and lubrication, prior to being used again.

On movable units outfitted with jackbolts, one complete ( $360^\circ$ ) turn of a jackbolt will advance the thread an amount equal to the pitch of the screw thread. For inch-threaded screws, pitch equals 1 divided by the number of threads per inch ( $1 \div \text{TPI}$ ). The axial travel per head flat is the pitch divided by the number of flats on the bolt head.

*Example:* A jackbolt has a  $\frac{1}{2}$ -13 thread. Find the axial travel per revolution and per flat for square-head and hex-head bolts. The thread has 13 threads per inch.

$$\text{advance per revolution (full turn) of bolt} = \frac{1}{\text{TPI}} = \frac{1}{13} = 0.0769 \text{ inch}$$

$$\text{advance per flat (1/4 turn) of square-head bolt} = \frac{1}{\text{TPI} \times 4} = \frac{1}{(13 \times 4)} = 0.0192 \text{ inch}$$

$$\text{advance per flat (1/6 turn) of hex-head bolt} = \frac{1}{\text{TPI} \times 6} = \frac{1}{(13 \times 6)} = 0.0128 \text{ inch}$$

*Example:* A motor needs to be moved 0.064 inch east at the front jackbolt and 0.091 inch east at the rear. The square-head jackbolts are  $\frac{5}{8}$ -11. How many turns of the front and rear jackbolts are needed to bring the unit into approximate alignment?

$$\text{one full turn of jackbolt} = \frac{1}{11} = 0.0909 \text{ inch}$$

$$\text{full turns at front jackbolt} = \frac{0.064}{0.0909} = 0.7040 \approx \frac{3}{4} \text{ turn or 3 flats}$$

$$\text{full turns at rear jackbolt} = \frac{0.091}{0.0909} = 1.0011 \text{ turn} \approx 1 \text{ turn or 4 flats}$$

### Practical Rim and Face Dial Indicator Arrangements for Shaft Alignment

This phase of millwright/machinist work is usually referred to as motor-to-pump alignment. The true objective is to correctly align the axis of one shaft to the axis of another by any of a rather wide range of dial indicator mountings, depending on a myriad of varying situations. These motor to pump scenarios can be duplicated on almost any shaft that is axially in close proximity to another shaft that has to share a common axis. Addressed here is standard rim and face pump alignment.

There are sixteen indicator arrangements to select from in this rim and face section. Units are aligned as closely as possible with a straight edge before using the dial indicators. At the first indicator reading, a neat sketch of the scenario is made, along with a carefully measured dimensioning schedule such as that shown in Fig. 1a. Based on indicator readings, select the applicable block from the second illustration, Fig. 1b, that matches the current plus or minus ( $\pm$ ) indicator reading. The dashed lines in Fig. 1b represent the centerline of the movable unit shaft. The two heavy round dots on the dashed lines (to the right of the couplings) represent points directly above or below the movable unit shim locations, and indicate that the movable unit must be raised or lowered at that location. The diagrams will help clarify the results of the shim calculations made using the appropriate formulas. Be certain to use minus signs any time they are called for in the formulas.

*Note:* In all the rim and face formats that follow, the axial location of the rim indicator always dictates the beginning point of the dimensions that are used in the various formulas. Also, the dial indicator arrangements in Figs. 1a through Figs. 16a are shown in the reading position, after having been zeroed at the position  $180^\circ$  opposite that shown and then rotated into the position shown.

**1st Arrangement.**— Fig. 1a illustrates the most universally accepted method of mounting dial indicators for shaft alignment, and it is also the same arrangement that was used in the preceding example, illustrated by Figs. 13 and 14.

When a reading of the rim and face indicators has been made, find the diagram in Fig. 1b that corresponds to the signs (positive or negative) of the readings obtained (positive rim value and negative face value, for example). The appropriate diagram will provide a visual clue to the meaning of the indicator readings, and indicate the direction that the motor feet must be moved to obtain alignment of the movable shaft with the fixed shaft.

Finally, use the equations adjacent to Fig. 1a to calculate the exact thickness of shims that need to be added or removed at each foot.

Fig. 1a. Dial Indicator Arrangement 1

In the rim and face format in Fig. 1a,  $r$  and  $f$  represent the values of the rim and face indicators in their reading positions. The  $F$  and  $R$  below the motor are the front and rear feet, corresponding to the  $F$  and  $R$  values in the formulas that represent the needed plus or minus ( $\pm$ ) shim packs. The formulas adjacent to Fig. 1a, are used to calculate the necessary addition or subtraction of shims required on the front or rear feet.

Fig. 1b. Interpreting Dial Indicator Readings for Indicator Arrangement 1

Indicators are shown in the reading position. Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example 1(a), Vertical Alignment:* Calculate the necessary shims for a pump and motor alignment where dimensions are  $A = 4$  inches,  $B = 6.5$  inches, and  $C = 18$  inches. The two indicator dials read  $r = \text{minus } (-) 0.014$  inch and  $f = \text{plus } (+) 0.021$  inch respectively.

*Solution:* The lower left block in Fig. 1b corresponds to a negative rim reading and a positive face reading. The figure indicates that both the front and rear feet will require shims, and that the rear feet will require more shims than the front feet. Shims on front and rear feet will be as follows:

$$\begin{aligned}
 F &= \frac{\pm r}{-2} + \frac{\pm f \times B}{A} & R &= \frac{\pm r}{-2} + \frac{\pm f \times C}{A} \\
 &= \frac{-0.014}{-2} + \frac{0.021 \times 6.5}{4} & &= \frac{-0.014}{-2} + \frac{0.021 \times 18}{4} \\
 &= 0.007 + 0.034125 & &= 0.007 + 0.0945 \\
 &= 0.041 \text{ inch} & &= 0.102 \text{ inch}
 \end{aligned}$$

The calculations indicate that 0.041 inch of shims is required under both front feet, and 0.102 inch of shims is required under both rear feet.

*Example 1(b), Horizontal Alignment:* Fig. 1a shows the indicators in the reading position for horizontal alignment, if the figure is thought of as a view looking down at the motor from the top. Assuming the same data obtained in the previous example, the two indicator dials read  $r = \text{minus } (-) 0.014$  inch and  $f = \text{plus } (+) 0.021$  inch respectively. Calculate the necessary horizontal movement required to align the motor to the pump.

*Solution:* The equations adjacent to Fig. 1a apply, as in the previous example. The dimensions  $B$  and  $C$  in Fig. 1a are the respective distances from the rim indicator path on the coupling to the locations at the front and rear of the motor, not necessarily the feet, where the horizontal adjustments will be made. These locations could be the front and rear jackbolts, or they could be magnetic base monitoring indicators placed conveniently near the front and rear feet, as discussed previously with respect to Fig. 14.

The diagram in the lower left corner of Fig. 1b indicates the direction of the move when the figure is viewed as if looking at the motor from the top. If  $B$  and  $C$  are 6.5 and 18 inches, respectively, then the equations indicate that the front and rear of the motor must be moved in the same direction, +0.041 inch and +0.102 inch respectively, to attain alignment.

**2nd Arrangement.**— Rim and face indicators are placed as shown in Fig. 2a. This arrangement is commonly used when the space between couplings is limited.

Fig. 2a. Dial Indicator Arrangement 2

Fig. 2b. Interpreting Dial Indicator Readings for Indicator Arrangement 2

Indicators are shown in the reading position. Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. The generic graph gives a picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 4.75$  inches,  $B = 7.75$  inches, and  $C = 17.25$  inches. The two indicator dials read  $r = \text{plus (+)} 0.004$  inch and  $f = \text{minus (-)} 0.022$  inch respectively.

*Solution:* The lower right block in Fig. 2b corresponds to a positive rim reading and a negative face. The diagram indicates that shims will be required under both the front and rear feet. Calculations confirm this, as follows:

$$\begin{aligned} F &= \frac{\pm r}{-2} + \frac{\pm f \times B}{-A} & R &= \frac{\pm r}{-2} + \frac{\pm f \times C}{-A} \\ &= \frac{0.004}{-2} + \frac{-0.022 \times 7.75}{-4.75} & &= \frac{0.004}{-2} + \frac{-0.022 \times 17.25}{-4.75} \\ &= -0.002 + 0.036 & &= -0.002 + 0.07989 \\ &= 0.034 \text{ inch} & &= 0.078 \text{ inch} \end{aligned}$$

**3rd Arrangement.**— Place rim and face indicators as shown in Fig. 3a.

Fig. 3a. Dial Indicator Arrangement 3

Fig. 3b. Interpreting Dial Indicator Readings for Indicator Arrangement 3

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 4.25$  inches,  $B = 8.875$  inches, and  $C = 28.75$  inches. The two indicators read  $r = \text{plus (+)} 0.042$  inch and  $f = \text{minus (-)} 0.036$  inch respectively.

*Solution:* Only the lower left block in Fig. 3b corresponds to a negative face reading and a positive rim reading. The diagram indicates that shims will be required under both front and rear feet. The required shim thickness for front and rear feet is calculated as follows:

$$\begin{aligned}
 F &= \frac{\pm r}{2} + \frac{\pm f \times B}{-A} & R &= \frac{\pm r}{2} + \frac{\pm f \times C}{-A} \\
 &= \frac{0.042}{2} + \frac{-0.036 \times 8.875}{-4.25} & &= \frac{0.042}{2} + \frac{-0.036 \times 28.75}{-4.25} \\
 &= 0.021 + 0.075 & &= 0.021 + 0.244 \\
 &= 0.096 \text{ inch} & &= 0.265 \text{ inch}
 \end{aligned}$$

**4th Arrangement.**— Place rim and face indicators as shown in Fig. 4a.

Fig. 4a. Dial Indicator Arrangement 4

Fig. 4b. Interpreting Dial Indicator Readings for Indicator Arrangement 4

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 3.5$  inches,  $B = 8.25$  inches, and  $C = 19.25$  inches. The two indicators read  $r = \text{minus } (-) 0.011$  inch and  $f = \text{minus } (-) 0.019$  inch respectively.

*Solution:* According to the top left block in Fig. 4b, the negative rim and negative face values indicate that the motor needs to have shims removed from beneath both the front and rear feet. The calculations that follow confirm that 0.05 inch needs to be removed from beneath the front feet, and 0.11 inch from below the rear feet. This adjusting may be difficult if the motor is sitting on its base without shims.

$$\begin{aligned} F &= \frac{\pm r}{2} + \frac{\pm f \times B}{A} \\ &= \frac{-0.011}{2} + \frac{-0.019 \times 8.25}{3.5} \\ &= -0.0055 + (-0.04479) \\ &= -0.050 \text{ inch} \end{aligned}$$

$$\begin{aligned} R &= \frac{\pm r}{2} + \frac{\pm f \times C}{A} \\ &= \frac{-0.011}{2} + \frac{-0.019 \times 19.25}{3.5} \\ &= -0.0055 + (-0.1045) \\ &= -0.110 \text{ inch} \end{aligned}$$

**5th Arrangement.**—Place rim and face indicators as shown in Fig. 5a. In the figure, notice that the origin of the dimensions  $B$  and  $C$  is the line of the rim indicator.

Fig. 5a. Dial Indicator Arrangement 5

Fig. 5b. Interpreting Dial Indicator Readings for Indicator Arrangement 5

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 4.0$  inches,  $B = 5.50$  inches, and  $C = 17$  inches. The two indicator dials read  $r = \text{plus (+)} 0.042$  inch and  $f = \text{minus (-)} 0.036$  inch respectively.

*Solution:* The top right block in Fig. 5b corresponds to the positive rim value and a negative face value of the indicators, and indicates that both ends of the motor need to be moved down. This requirement is confirmed by the negative shim numbers that provide the exact distance as follows:

$$\begin{aligned} F &= \frac{\pm r}{-2} + \frac{\pm f \times B}{A} & R &= \frac{\pm r}{-2} + \frac{\pm f \times C}{A} \\ &= \frac{0.042}{-2} + \frac{-0.036 \times 5.50}{4.0} & &= \frac{0.042}{-2} + \frac{-0.036 \times 17.0}{4.0} \\ &= -0.021 + (-0.0495) & &= -0.021 + (-0.153) \\ &= -0.0705 \text{ inch} & &= -0.174 \text{ inch} \end{aligned}$$

**6th Arrangement.**— Place rim and face indicators as shown in Fig. 6a.

$$F = \frac{\pm r}{-2} + \frac{\pm f \times B}{-A}$$

$$R = \frac{\pm r}{-2} + \frac{\pm f \times C}{-A}$$

Fig. 6a. Dial Indicator Arrangement 6

Fig. 6b. Interpreting Dial Indicator Readings for Indicator Arrangement 6

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 4.75$  inches,  $B = 6.25$  inches, and  $C = 31.75$  inches. The two indicator dials:  $r = \text{minus } (-) 0.024$  inch and  $f = \text{plus } (+) 0.005$  inch respectively.

*Solution:* The top left block in Fig. 6b describes the situation of negative rim and positive face values. The generic graph suggests that both the front and rear feet need some shims to be removed, but the calculations below require that some positive movement of the front feet is required. If in doubt, follow the numbers; the graphs are not drawn to scale. The formulas call for 0.005 inch added under the front feet and the rear feet to be lowered by 0.021 inch:

$$\begin{aligned} F &= \frac{\pm r}{-2} + \frac{\pm f \times B}{-A} \\ &= \frac{-0.024}{-2} + \frac{0.005 \times 6.25}{-4.75} \\ &= 0.012 - 0.006578 \\ &= 0.005 \text{ inch} \end{aligned}$$

$$\begin{aligned} R &= \frac{\pm r}{-2} + \frac{\pm f \times C}{-A} \\ &= \frac{-0.024}{-2} + \frac{0.005 \times 31.75}{-4.75} \\ &= 0.012 + (-0.03342) \\ &= -0.021 \text{ inch} \end{aligned}$$

**7th Arrangement.**— Place rim and face indicators as shown in Fig. 7a.

Fig. 7a. Dial Indicator Arrangement 7

Fig. 7b. Interpreting Dial Indicator Readings for Indicator Arrangement 7

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 12.375$  inches,  $B = 14.875$  inches, and  $C = 47.75$  inches. The two indicator dials:  $r = \text{minus } (-) 0.002$  inch and  $f = \text{plus } (+) 0.001$  inch respectively.

*Solution:* This motor is almost in alignment. The upper right block of Fig. 7b corresponds to the negative rim and positive face condition. The graph suggests both the front and rear motor feet be lowered, depending on the magnitude of the variables. The formula solution dictates exactly how much the movable unit needs to be lowered at both front and rear shim points. Shims on front and rear feet will be as follows:

$$\begin{aligned} F &= \frac{\pm r}{2} + \frac{\pm f \times B}{-A} \\ &= \frac{-0.002}{2} + \frac{0.001 \times 14.875}{-12.375} \\ &= -0.001 + (-0.001) \\ &= -0.002 \text{ inch} \end{aligned}$$

$$\begin{aligned} R &= \frac{\pm r}{2} + \frac{\pm f \times C}{-A} \\ &= \frac{-0.002}{2} + \frac{0.001 \times 47.75}{-12.375} \\ &= -0.001 + (-0.003858) \\ &= -0.005 \text{ inch} \end{aligned}$$

**8th Arrangement.**— Place rim and face indicators as shown in Fig. 8a.

Fig. 8a. Dial Indicator Arrangement 8

Fig. 8b. Interpreting Dial Indicator Readings for Indicator Arrangement 8

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 12.375$  inches,  $B = 14.875$  inches, and  $C = 47.75$  inches. The two indicator dials:  $r = \text{minus } (-) 0.042$  inch and  $f = \text{minus } (-) 0.002$  inch respectively.

*Solution:* In Fig. 8b, the top right block conforms to negative rim and negative face values. The graph suggests both the front and rear motor feet be lowered. The formula dictates exactly how much the movable unit is to be lowered at both front and rear shim points. Shims removed on front and rear feet will be as follows:

$$\begin{aligned} F &= \frac{\pm r}{2} + \frac{\pm f \times B}{A} \\ &= \frac{-0.042}{2} + \frac{-0.002 \times 14.875}{12.375} \\ &= -0.021 + (-0.002) \\ &= -0.023 \text{ inch} \end{aligned}$$

$$\begin{aligned} R &= \frac{\pm r}{2} + \frac{\pm f \times C}{A} \\ &= \frac{-0.042}{2} + \frac{-0.002 \times 47.75}{12.375} \\ &= -0.021 + (-0.0077) \\ &= -0.029 \text{ inch} \end{aligned}$$

**9th Arrangement.**—Place rim and face indicators as shown in Fig. 9a. The driven unit here could be any of several devices including the “catch” drum for a centrifugal clutch.

Fig. 9a. Dial Indicator Arrangement 9

Fig. 9b. Interpreting Dial Indicator Readings for Indicator Arrangement 9

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 10.375$  inches,  $B = 22.0$  inches, and  $C = 48.0$  inches. The two indicator dials read  $r = 0.00$  inch and  $f = \text{plus (+)} 0.017$  inch respectively.

*Solution:* In Fig. 9b, the center block of the bottom row represents zero rim and positive face values. The graph suggests both the front and rear motor feet be moved up by adding shims, depending on the magnitude of the variables. The formula solution below dictates that the front feet be moved up 0.036 inch and the rear feet be moved up 0.079 inch:

$$\begin{aligned}
 F &= \frac{\pm r}{-2} + \frac{\pm f \times B}{A} & R &= \frac{\pm r}{-2} + \frac{\pm f \times C}{A} \\
 &= \frac{0.00}{-2} + \frac{0.017 \times 22}{10.375} & &= \frac{0.00}{-2} + \frac{0.017 \times 48}{10.375} \\
 &= -0.00 + 0.036 & &= -0.00 + 0.079 \\
 &= 0.036 \text{ inch} & &= 0.079 \text{ inch}
 \end{aligned}$$

**10th Arrangement.**—Fig. 10a illustrates an arrangement used for taking two separate readings with one dial indicator.

Fig. 10a. Dial Indicator Arrangement 10

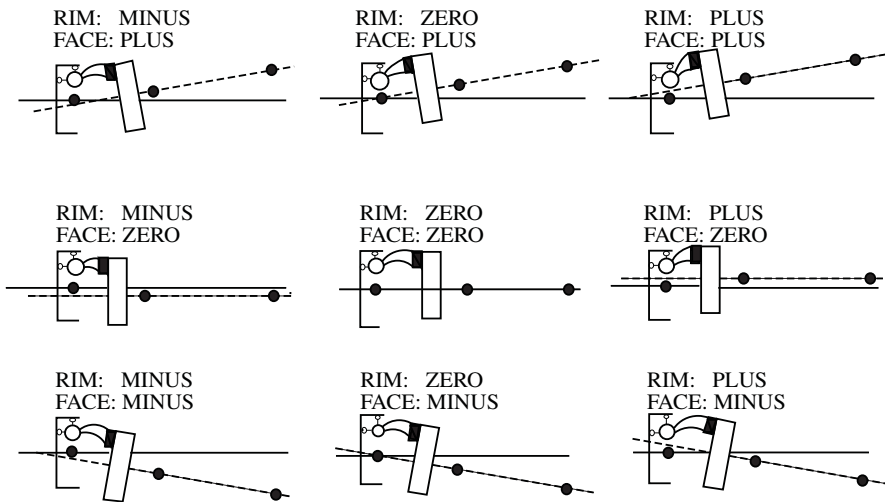

Fig. 10b. Interpreting Dial Indicator Readings for Indicator Arrangement 10

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 5.50$  inches,  $B = 14.0$  inches, and  $C = 35.0$  inches. The indicator readings are  $r = \text{plus (+)} 0.030$  inch and  $f = \text{plus (+)} 0.022$  inch, respectively.

*Solution:* In Fig. 10b locate the block illustrating the positive rim and positive face condition. The graph suggests both the front and rear motor feet be lowered. The formula solution dictates exactly how much the movable unit is to be lowered at both front and rear shim points:

$$\begin{aligned}
 F &= \frac{\pm r}{-2} + \frac{\pm f \times B}{-A} & R &= \frac{\pm r}{-2} + \frac{\pm f \times C}{-A} \\
 &= \frac{0.030}{-2} + \frac{0.022 \times 14}{-5.5} & &= \frac{0.030}{-2} + \frac{0.022 \times 35}{-5.5} \\
 &= -0.015 + (-0.056) & &= -0.015 + (-0.140) \\
 &= -0.071 \text{ inch} & &= -0.155 \text{ inch}
 \end{aligned}$$

**11th Arrangement.**— Place rim and face indicators as shown in Fig. 11a.

Fig. 11a. Dial Indicator Arrangement 11

Fig. 11b. Interpreting Dial Indicator Readings for Indicator Arrangement 11

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the necessary shims for a pump and motor alignment where dimensions are  $A = 6.50$  inches,  $B = 16.625$  inches, and  $C = 42.0$  inches. The two indicator dials read  $r = 0.000$  inch and  $f = \text{minus } (-) 0.026$  inch respectively.

*Solution:* The center block in the last row of Fig. 11b describes the zero rim and negative face value condition. The motor is too low because of angularity (face reading), but the elevation is correct at the axial position of the rim indicator reading. The graph suggests both the front and rear motor feet be moved up. The formula solution dictates exactly how much the movable unit is raised at both front and rear shim points:

$$\begin{aligned} F &= \frac{\pm r}{2} + \frac{\pm f \times B}{-A} & R &= \frac{\pm r}{2} + \frac{\pm f \times C}{-A} \\ &= \frac{0.00}{2} + \frac{-0.026 \times 16.625}{-6.50} & &= \frac{0.00}{2} + \frac{-0.026 \times 42}{-6.50} \\ &= 0.00 + 0.0665 & &= 0.00 + 0.168 \\ &= 0.0665 \text{ inch} & &= 0.168 \text{ inch} \end{aligned}$$

**12th Arrangement.**— The set up in Fig. 12a could be one indicator with two stems, or one indicator taking separate face and rim readings at the same location.

Fig. 12a. Dial Indicator Arrangement 12

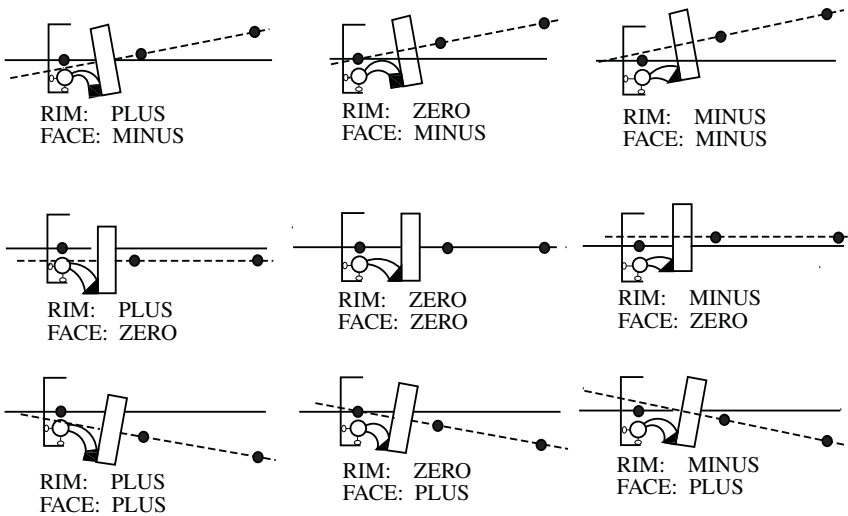

Fig. 12b. Interpreting Dial Indicator Readings for Indicator Arrangement 12

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 23.0$  inches,  $B = 41.0$  inches, and  $C = 96.0$  inches. The two indicator readings are  $r = \text{plus (+)}0.004$  inch and  $f = \text{minus (-)}0.003$  inch, respectively.

*Solution:* For practical purposes, this unit is already within tolerance by most standards. However, the block in the upper left corner of Fig. 12b illustrates the positive rim and negative face condition. The graph suggests both the front and rear motor feet be lowered. Removal of 0.003 inch of shim at the front and 0.011 inch at the rear feet will reduce misalignment to less than a mil on the next reading.

$$\begin{aligned} F &= \frac{\pm r}{2} + \frac{\pm f \times B}{A} \\ &= \frac{0.004}{2} + \frac{-0.003 \times 41}{23.0} \\ &= 0.002 + (-0.005) \\ &= -0.003 \text{ inch} \end{aligned}$$

$$\begin{aligned} R &= \frac{\pm r}{2} + \frac{\pm f \times C}{A} \\ &= \frac{0.004}{2} + \frac{-0.003 \times 96}{23.0} \\ &= 0.002 + (-0.013) \\ &= -0.011 \text{ inch} \end{aligned}$$

**13th Arrangement.**— In Fig. 13a, the indicator jig is mounted on the static unit and two separate readings are taken from surfaces of the inside of a centrifugal clutch drum on the movable unit.

Fig. 13a. Dial Indicator Arrangement 13

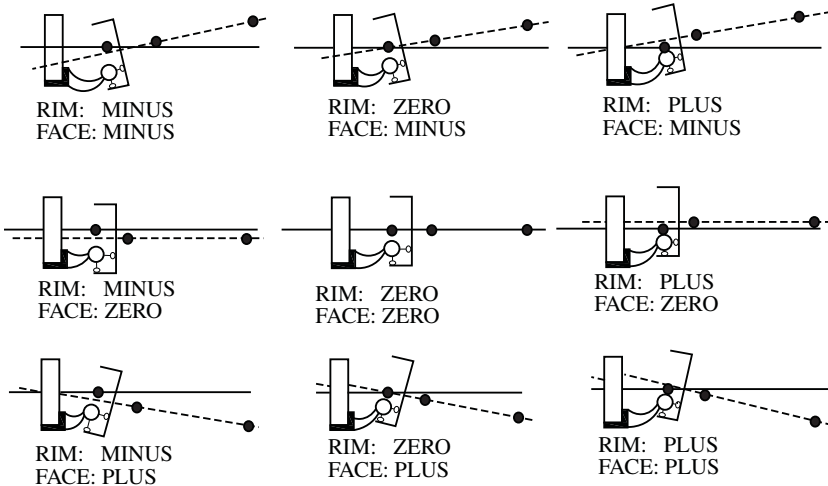

Fig. 13b. Interpreting Dial Indicator Readings for Indicator Arrangement 13

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 23.0$  inches,  $B = 20.0$  inches, and  $C = 75.0$  inches. The indicator readings are  $r = \text{plus } (+) 0.004$  inch and  $f = \text{minus } (-) 0.003$  inch, respectively.

*Solution:* The positive rim and negative face condition is illustrated in the top right block of Fig. 13b. The graph suggests that both the front and rear motor feet needs to be lowered. The formula solution dictates exactly how much the movable unit is to be lowered at both front and rear shim points:

$$\begin{aligned}
 F &= \frac{\pm r}{-2} + \frac{\pm f \times B}{A} & R &= \frac{\pm r}{-2} + \frac{\pm f \times C}{A} \\
 &= \frac{0.004}{-2} + \frac{-0.003 \times 20}{23.0} & &= \frac{0.004}{-2} + \frac{-0.003 \times 75}{23.0} \\
 &= -0.002 + (-0.0026) & &= -0.002 + (-0.00978) \\
 &= -0.005 \text{ inch} & &= -0.012 \text{ inch}
 \end{aligned}$$

**14th Arrangement.**— Place rim and face indicators as shown in Fig. 14a.

Fig. 14a. Dial Indicator Arrangement 14

Fig. 14b. Interpreting Dial Indicator Readings for Indicator Arrangement 14

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 4.625$  inches,  $B = 10.75$  inches, and  $C = 32.5$  inches. The two indicator dials read  $r = \text{minus } (-) 0.014$  inch and  $f = \text{plus } (+) 0.036$  inch respectively.

*Solution:* In Fig. 14b, the negative rim and positive face condition is shown in the top left block. The graph suggests that both the front and rear motor feet should be lowered, depending on the magnitude of the variables. The formula solution dictates exactly how much the movable unit is to be lowered at both front and rear shim points:

$$\begin{aligned} F &= \frac{\pm r}{-2} + \frac{\pm f \times B}{-A} \\ &= \frac{-0.014}{-2} + \frac{0.036 \times 10.75}{-4.625} \\ &= 0.007 + (-0.0837) \\ &= -0.077 \text{ inch} \end{aligned}$$

$$\begin{aligned} R &= \frac{\pm r}{-2} + \frac{\pm f \times C}{-A} \\ &= \frac{-0.014}{-2} + \frac{0.036 \times 32.5}{-4.625} \\ &= 0.007 + (-0.25297) \\ &= -0.246 \text{ inch} \end{aligned}$$

**15th Arrangement.**— Place rim and face indicators as shown in Fig. 15a.

Fig. 15a. Dial Indicator Arrangement 15

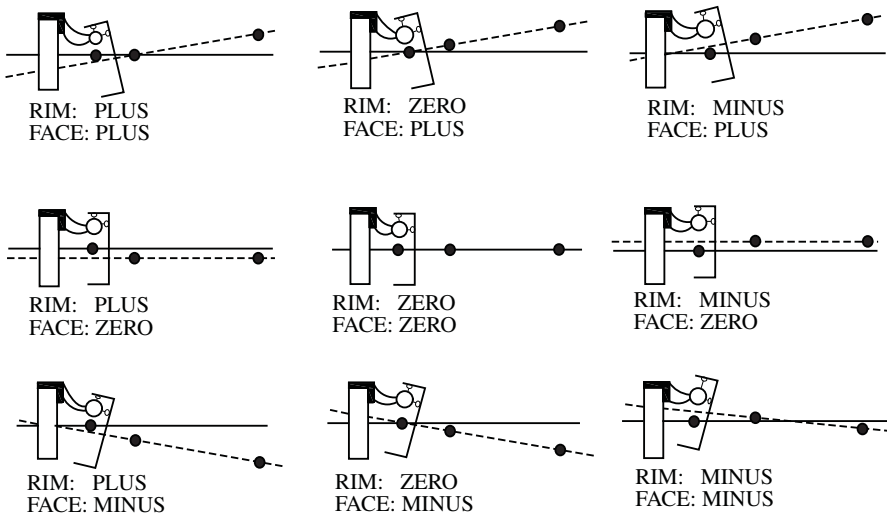

Fig. 15b. Interpreting Dial Indicator Readings for Indicator Arrangement 15

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 6.0$  inches,  $B = 38.0$  inches, and  $C = 84.0$  inches. The two indicator dials reads  $r = \text{minus } (-) 0.002$  inch and  $f = \text{plus } (+) 0.003$  inch respectively.

*Solution:* The negative rim and positive face condition is found in the top right corner of Fig. 15b. The graph suggests that both the front and rear motor feet need to be lowered. The formula solution dictates exactly how much the movable unit is to be lowered at both front and rear shim points:

$$\begin{aligned} F &= \frac{\pm r}{2} + \frac{\pm f \times B}{-A} \\ &= \frac{-0.002}{2} + \frac{0.003 \times 38.0}{-6.0} \\ &= -0.001 + (-0.019) \\ &= -0.020 \text{ inch} \end{aligned}$$

$$\begin{aligned} R &= \frac{\pm r}{2} + \frac{\pm f \times C}{-A} \\ &= \frac{-0.002}{2} + \frac{0.003 \times 84.0}{-6.0} \\ &= -0.001 + (-0.042) \\ &= -0.043 \text{ inch} \end{aligned}$$

**16th Arrangement.**— Place rim and face indicators as shown in Fig. 16a.

Fig. 16a. Dial Indicator Arrangement 16

Fig. 16b. Interpreting Dial Indicator Readings for Indicator Arrangement 16

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 16.0$  inches,  $B = 26.0$  inches, and  $C = 54.0$  inches. The two indicator dials read  $r = \text{minus } (-) 0.002$  inch and  $f = \text{minus } (-) 0.006$  inch respectively.

*Solution:* The rim and face numbers indicate that the whole movable machine is one mil high (from the rim indicator,  $\frac{1}{2} = 0.002 = 0.001$ ), and the angularity from the face indicator say that for every 16 inches of axial length from the rim indicator there is an upward incline toward the rear of 0.006 inch. In Fig. 16b, locate the block with negative rim and negative face values. The graph suggests both the front and rear motor feet be lowered. The formula solution dictates that the movable unit is to be lowered at both front and rear shim points:

$$\begin{aligned}
 F &= \frac{\pm r}{2} + \frac{\pm f \times B}{A} & R &= \frac{\pm r}{2} + \frac{\pm f \times C}{A} \\
 &= \frac{-0.002}{2} + \frac{-0.006 \times 26}{16} & &= \frac{-0.002}{2} + \frac{-0.006 \times 54.0}{16} \\
 &= -0.001 + (-0.00975) & &= -0.001 + (-0.02025) \\
 &= -0.011 \text{ inch} & &= -0.021 \text{ inch}
 \end{aligned}$$

**Rim and Face Method Extended to Motors with Extra Feet.**— Fig. 17 illustrates an alignment problem that is complicated by the fact that the motor has ten feet. The indicator

arrangement used matches the arrangement illustrated in Fig. 14a. In this problem the solution is obtained by using the same equations as were used to obtain the solution of Fig. 14a, adapted slightly to deal with the additional feet.

Shim calculations for motor to pump alignment when the motor has more than four feet are performed in the same manner as the examples previously used. However, care must be used in determining the dimensions used in the equations. As in all the previous examples, the horizontal dimensions are measured from the location of the rim indicator. Distances to motor feet to the right of the rim indicator are assigned positive values, and distances measured to feet that are to the left of the rim indicator are assigned negative values in the formulas. The revised equations for this arrangement are shown beside Fig. 17. In the equations,  $S_F$  is the shim requirement at foot F,  $S_{F1}$  is the shim requirement at foot F1, etc.

Fig. 17. Shaft Alignment When More than Four Feet are Involved

Dimensions are measured from the path of the rim indicator. Dimensions to locations left of the rim indicator enter the equations as minus (−) values, and dimension to the right of the rim indicator enter the equations as positive (+) quantities.

$$S_F = \frac{\pm r}{-2} + \frac{\pm f \times (-F)}{-A}$$

$$S_{F1} = \frac{\pm r}{-2} + \frac{\pm f \times (-F1)}{-A}$$

$$S_{F2} = \frac{\pm r}{-2} + \frac{\pm f \times F2}{-A}$$

$$S_{F3} = \frac{\pm r}{-2} + \frac{\pm f \times F3}{-A}$$

$$S_R = \frac{\pm r}{-2} + \frac{\pm f \times R}{-A}$$

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 4.5$  inches,  $F = 22.0$  inches,  $F1 = 10.0$  inches,  $F2 = 8.0$  inches,  $F3 = 24.0$  inches, and  $R = 46.0$  inches. The two indicator dials read  $r = \text{minus } (-)0.054$  inch and  $f = \text{plus } (+)0.032$  inch, respectively.

*Solution, Vertical Alignment:*

$$S_F = \frac{\pm r}{-2} + \frac{\pm f \times (-F)}{-A} = \frac{-0.054}{-2} + \frac{0.032 \times (-22)}{-4.5} = 0.027 + 0.156 = 0.183 \text{ inch}$$

$$S_{F1} = \frac{\pm r}{-2} + \frac{\pm f \times (-F1)}{-A} = \frac{-0.054}{-2} + \frac{0.032 \times (-10)}{-4.5} = 0.027 + 0.071 = 0.098 \text{ inch}$$

$$S_{F2} = \frac{\pm r}{-2} + \frac{\pm f \times F2}{-A} = \frac{-0.054}{-2} + \frac{0.032 \times 8}{-4.5} = 0.027 + (-0.156) = -0.030 \text{ inch}$$

$$S_{F3} = \frac{\pm r}{-2} + \frac{\pm f \times F3}{-A} = \frac{-0.054}{-2} + \frac{0.032 \times 24}{-4.5} = 0.027 + (-0.171) = -0.144 \text{ inch}$$

$$S_R = \frac{\pm r}{-2} + \frac{\pm f \times R}{-A} = \frac{-0.054}{-2} + \frac{0.032 \times 46}{-4.5} = 0.027 + (-0.327) = -0.300 \text{ inch}$$

The calculations show that more shims are required under the two pairs of front feet,  $F$  and  $F1$ , and need to be reduced for the other three pairs of rear feet. The top left figure in Fig. 14b (negative rim and positive face indicator readings) confirms that the numerical solution appears reasonable.

*Solution, Horizontal Alignment:* The horizontal alignment solution follows the same procedure as the vertical solution above, and will use the same equations if the indicator set up shown in Fig. 17 is used.

The dimensions  $F$ ,  $F1$ ,  $F2$ ,  $F3$ , and  $R$  are the distances from the rim indicator path to the respective locations where the move occurs, whether it be the location of the hold-down bolts, or another location where a monitoring dial indicator is mounted. See *Solution for Horizontal Alignment* on page 2647 for additional information on this subject.

## FLUID POWER

### Introduction

A fluid is a substance which deforms continuously when subjected to a shear stress. Fluid power systems convert mechanical or potential energy into fluid energy, and usually perform work with the fluid energy. The fluid used can be either a liquid or a gas. When liquids are used, it is a hydraulic system, and when a gas is used it is a pneumatic system.

**Properties of Liquids and Gases.**— One of the main differences between liquids and gases has to do with compressibility. Compressibility is a measure of the relative volume change of a substance with a change in pressure. Liquids are only slightly compressible, and are usually considered to be incompressible for the purposes of fluid power calculations. Gases, on the other hand, are very compressible under normal conditions.

Specific weight is the weight of a fluid per unit of volume. Mass density of a fluid is the mass contained within a unit of volume. When a fluid is pressurized, its density and specific weight increase, and when a fluid is heated, its density and specific weight decrease. Liquids are affected very little by these factors, while gases are very much affected. Specific gravity is the ratio between specific weight or density at actual versus standard conditions. Specific gravity changes with specific weight or density. Standard conditions are taken to be 4°C for water, and 0°C for air. Other fluids may have different standard conditions. Standard symbols and equations for these properties are shown below. [Tables 2, 3](#) and [4](#) contain the properties of some common fluids.

### Fluid Property Symbols and Equations

Specific weight: lbf/ft<sup>3</sup>, N/m<sup>3</sup>

$$\gamma = \rho g = \frac{w}{V}$$

Density

$$\rho = \frac{m}{V}$$

slugs/ft<sup>3</sup>, kg/m<sup>3</sup>

$\rho$

lbfm/ft<sup>3</sup>

$$\rho_{\text{lbfm}} = \rho g_c$$

Gravitational Constant: lbfm-ft/lbf-s<sup>2</sup>

$$g_c = 32.2$$

Specific Gravity: dimensionless

$$\text{SG} = \frac{\gamma}{\gamma_c} = \frac{\rho}{\rho_c}$$

The control specific weight  $\gamma_c$  for liquids is water, and for gases is air.

The density of dry air at 32 degrees F and atmospheric pressure (29.92 inches of mercury or 14.70 pounds per square inch) is 0.08073 pound per cubic foot.

The density of air at any other temperature or pressure is

$$\rho = \frac{1.325 \times B}{T}$$

in which  $\rho$  = density in pounds per cubic foot;  $B$  = height of barometric pressure in inches of mercury;  $T$  = absolute temperature in degrees Rankine. (When using pounds as a unit care must be exercised to differentiate between pounds mass and pounds force. See [Acceleration of Gravity g Used in Mechanics Formulas on page 142](#).)

The absolute zero from which all temperatures must be counted when dealing with the weight and volume of gases is assumed to be -459.7 degrees F. Hence, to obtain the absolute temperature  $T$  used in the preceding formula, add the value 459.7 to the temperature observed on a regular Fahrenheit thermometer.

In obtaining the value of  $B$ , 1 inch of mercury at 32 degrees F may be taken as equal to a pressure of 0.491 pound per square inch.

Table 2. Density of Air at Different Pressures and Temperatures

Temp. of Air, °F	Gage Pressure, Pounds

200	93.3	1.869	963.243	60.12	9440
212	100	1.86	958.605	59.83	9400

**Table 4. Properties of Common Fluids at Atmospheric Pressure**

Fluid	Temperature		Density		Specific Weight		Specific Gravity
	°F	°C	slug/ft <sup>3</sup>	kg/m <sup>3</sup>	lbf/ft <sup>3</sup>	N/m <sup>3</sup>	
Air	68	20	$2.33 \times 10^{-3}$	1.205	0.075	11.8	1
Nitrogen	68	20	$2.26 \times 10^{-3}$	1.165	...	...	0.9669
Water	68	20	1.936	998.2	62.4	$9.81 \times 10^3$	1
Seawater	68	20	1.987	1024	63.9	$10.03 \times 10^3$	1.025

**Pressure.**— Pressure,  $p$ , is defined as the average force per unit area,  $A$ , exerted by a fluid.

$$p = \frac{F}{A}$$

The pressure at a point in a static fluid is the same in all directions, and the same at all points in that fluid. The pressure exerted by a fluid on a solid surface is always perpendicular to that surface. Pressure measured relative to atmospheric pressure is called gauge pressure.

Pressure measured relative to a perfect vacuum is called absolute pressure. The relationship between absolute pressure and gauge pressure is given in the following equation:

$$P_a = P_g + P_{atm}$$

where  $P_a = 14.696$  psi (US); and,  $P_a = 101.325$  kPa (SI).

The change in pressure in a non-moving liquid due to a change in elevation is dependent on the specific weight of the fluid and can be calculated using the following equations. Elevation is always taken to be positive in the upward direction relative to the reference plane. The pressure caused by elevation is independent of the shape and size of the container and its free surface.

$p = \gamma h$  where  $\gamma$  is specific weight (lbf/ft<sup>3</sup> or N/m<sup>3</sup>),  $h$  is elevation (ft or m), and  $p$  is pressure (lbf/ft<sup>2</sup> or N/m<sup>2</sup>)

$p = \frac{\gamma h}{144}$  where  $\gamma$  is specific weight (lbf/ft<sup>3</sup>),  $h$  is elevation (ft), and  $p$  is pressure (psi)

For ideal gases, the relationship between pressure, temperature, and specific volume can be found in the following equations. Specific volume is the volume occupied by a unit mass of a fluid.

$$PV = 1545.3nT \quad \text{For fps units}$$

$$PV = 8314nT \quad \text{For SI units}$$

in which  $P$  = absolute pressure in pounds per square foot or Pa (N/m<sup>2</sup>)

$V$  = volume in cubic feet or cubic meter

$T$  = absolute temperature in degrees R or degrees K

$n$  = number of pound moles or kg moles. A mole is the mass of substance, in appropriate units, divided by its molecular weight. The equations above are general forms that apply to any gas that behaves the ideal gas law.

**Viscosity.**—Viscosity is a liquid property that indicates its resistance to flow. It is a measure of a fluid's resistance to a shearing force. High viscosity fluids require a greater force to shear at a given rate than low viscosity fluids. This is the most important property of fluids when designing and analyzing fluid power systems. An ideal fluid has zero viscosity, and gases have nearly zero viscosity. For most fluids, viscosity varies significantly with temperature. It is relatively unaffected by changes in pressure, unless they are extreme. Newtonian fluids are those whose viscosity is independent of velocity gradient.

Viscosity index is the change in viscosity relative to change in temperature. Absolute, or dynamic, viscosity relates shearing stress in a fluid to the velocity gradient. Kinematic viscosity is the ratio of a fluid's absolute viscosity to its mass density. Absolute viscosity is often measured in centipoise (cP), and kinematic viscosity in centistokes (cSt).

Equations and conversion factors for absolute and kinematic viscosity are given below. The absolute and kinematic viscosity of various fluids can be found in [Table 5](#).

$$\text{Absolute viscosity: } \mu = \frac{F dy}{A dv} \text{ lbf-s/ft}^2 \text{ or N-s/m}^2 \text{ (Pa-s)}$$

Units may be expressed in centipoise, cP

$$\text{cP} = 2.09 \times 10^{-5} \text{ lbf-s/ft}^2$$

$$\text{cP} = 1 \times 10^{-3} \text{ Pa-s}$$

$$\text{Kinematic viscosity: } \nu = \frac{\mu}{\rho} \text{ ft}^2/\text{s} \text{ or m}^2/\text{s}$$

Units may be expressed in centistokes, cSt

$$\text{cSt} = 1.07 \times 10^{-5} \text{ ft}^2/\text{s}$$

$$\text{cSt} = 1 \times 10^{-6} \text{ m}^2/\text{s}$$

**Table 5. Viscosity of Common Fluids at Atmospheric Pressure**

Fluid	Absolute Viscosity			Kinematic Viscosity		
	lbf-s/ft <sup>2</sup>	Pa-s	cP	ft <sup>2</sup> /s	m <sup>2</sup> /s	cSt
Air	3.75 x 10 <sup>-7</sup>	1.80 x 10 <sup>-5</sup>	0.018	1.64 x 10 <sup>-4</sup>	1.52 x 10 <sup>-5</sup>	15.24
Nitrogen	3.75 x 10 <sup>-7</sup>	1.80 x 10 <sup>-5</sup>	0.018	1.64 x 10 <sup>-4</sup>	1.52 x 10 <sup>-5</sup>	15.24
Water	2.09 x 10 <sup>-5</sup>	1.00 x 10 <sup>-3</sup>	1	1.07 x 10 <sup>-5</sup>	1.00 x 10 <sup>-6</sup>	1
Seawater	2.26 x 10 <sup>-5</sup>	1.08 x 10 <sup>-3</sup>	1.08	1.13 x 10 <sup>-5</sup>	1.05 x 10 <sup>-6</sup>	1.15
Mercury	3.34 x 10 <sup>-5</sup>	1.60 x 10 <sup>-3</sup>	1.6	1.27 x 10 <sup>-6</sup>	1.18 x 10 <sup>-7</sup>	0.118

Properties based on temperature 68°F or 20°C.

## Fluid Circuits

Fluid circuits contain compressed and flowing fluid, either liquid or gas, and convey it to perform work. They usually employ a valve to stop and/or control the direction of flow.

**Standard Fluid Circuit Components.**— Fluid circuits typically include fluid preparation components, valves, actuators, and connecting lines. Pneumatic circuits also normally include provisions for gas to be exhausted to the atmosphere, through a silencer, to a reclassifying filter, or to an exhaust manifold where it can be ducted elsewhere. Quick exhausting of gas is essential for fast pneumatic circuit response. Hydraulic circuits are generally closed, that is, recirculating fluid rather than discharging it.

**Fluid Circuit Types.**— There are two main fluid circuit types, which are classified in terms of how the valve functions.

*Open and Closed Center Circuits:* Open center circuits permit nearly unrestricted flow through the valve and back to the source when the valve is de-energized. Closed center circuits block flow through the valve when the valve is de-energized. This type of circuit is recommended when you have multiple circuits on a single supply.

*Flow Control Circuits:* To control the speed of an actuator in a pneumatic circuit, use flow controls. Flow controls always generate some heat in hydraulic circuits, so with hydraulics they should be avoided where possible and other methods used. There are three types of flow control circuits: meter-in, meter-out, and bleed-off (or bypass). Pneumatic and some hydraulic systems use meter-in and meter-out circuits, while many hydraulic circuits use bleed-off types.

Meter-in circuits have a flow control valve before an actuator. Meter-in control can be used for actuator speed control. For hydraulic systems, a regulated bypass circuit is recommended rather than a restrictive flow control to reduce generated heat.

Meter-out circuits are best for pneumatic actuator speed control, and are required for applications with large negative loads on actuators. For example when lowering a heavy weight, a meter-out circuit is best. Flow control is placed after the actuator to restrict flow coming out. Because the positive side of the actuator sees full system pressure and flow, the mechanical system is very stable under loading. Care must be taken to avoid overloading actuators when using meter-out circuits.

**Fluid Component Symbols and Circuit Diagrams.**— Fluid power circuits are documented through the use of circuit diagrams or schematics. The components in a circuit are represented symbolically and connected with lines representing pipe or tubing. The symbols are used to identify and represent the function of the components. Symbols for fluid power components have been standardized by ANSI Y32.10 and ISO 1219. Some common symbols can be found in [Table 6](#).

Directional control valve symbols show the valve's positions, methods of actuation, flow paths, and ports. The valve positions are represented by boxes. The methods of left and right valve actuation are represented by symbols on each end of the valve symbol. The flow path for each position is shown within its respective position box. Ports are marked on the position box that corresponds to the de-energized state of the valve.

**Table 6. Selected ANSI Fluid Component Symbols**

Solid Line Main Line Conductor, Physical Outline, or Shaft	Dashed Line Pilot Line for Control	Dotted Line Exhaust or Drain Line	Center Line Enclosure Outline
 <p>Circle Device, Connector, or Component</p>	 <p>Triangle Indicates Flow Direction<sup>a</sup>: (See footnote <sup>a</sup>)</p>	 <p>Square Reservoir (Closed, Open)</p>	 <p>Oval Accumulator or Receiver</p>

**Table 6. (Continued) Selected ANSI Fluid Component Symbols**

 Diamond Fluid Conditioner (Filter, Strainer)	 Arrow Through Symbol at 45° Indicates Component Can Be Adjusted	 Pump, Fixed Capacity (One direction of flow)	 Pump, Variable Capacity (Two directions of flow)
 Single Acting Air Cylinder	 Single Acting Spring Return Air Cylinder	 Double Acting Air Cylinder	 Double Acting Rotary Actuator
 Pressure Regulator, Adjustable and Relieving	 Pressure Gauge	 Temperature Gauge	 Cooler
 Check Valve	 Shut-off Valve	 Flow Control Valve, Adjustable	 Pressure Control Valve
 Pressure Relief Valve	 Directional Valve Two Port, Two Position (2/2) Two Way, Normally Open	 Directional Valve Three Port, Two Position (3/2) Two Way, Normally Closed	 Directional Valve Five Port, Two Position (5/2) Four Way, Normally Open
 Directional Valve Five Port, Three Position (5/3) Four Way, Normally Closed	 Directional Valve Two Position, Three Way, Normally Open, With Manual Actuation and Spring Return	 Directional Valve Two Position, Three Way, Normally Open, With Single Solenoid and Spring Return	 Directional Valve Two Position, Three Way, Normally Open, With Double Solenoids and Manual Overrides

<sup>a</sup> A pneumatic direction symbol is shown as an outline; a hydraulic symbol is filled.

**Fluid Circuit Analysis Considerations.**— When designing or analyzing a fluid circuit, one must consider fluid type, flow rate, velocity, pressure, and temperature. Fluid type and temperature will determine how it behaves as it is manipulated. Excessive velocities can lead to noise, vibration, and stresses. Pressure and flow rate will determine what size and type of pipe, tube, and components can be used. Also important to consider is the structural integrity of the system, including the weight of components, connections, and fluid. Every component in a fluid circuit, with the exceptions of pumps and compressors, will cause energy to be lost from the fluid. Friction, gravity, directional change, and restriction are all causes of lost energy. A careful analysis of energy added and lost from a fluid circuit must be completed as part of the design process.

**Safety Notes.**— When designing fluid circuits, safety should be of paramount importance. The logic of all circuits should be checked for proper performance during startup, shut-down, pressure loss, emergency stops, and other foreseeable events. Before selecting any control element, it is important to first know the safety category for the function being controlled by the fluid circuit. The manufacturer can assist in selecting components with the proper safety functions and ratings. It is important to note that any compressed gas other than air is an asphyxiation hazard. Air quality monitoring devices should be used when the volume of available gas has the potential to create an unsafe environment in the event of a leak. Some fluids can be incompatible with materials used in the circuit. Check material

compatibility of seals, tubing, and other components. Check the temperature ratings of any components against the expected temperature of the fluid application.

### Pressure and Flow

Fluids are often delivered at a much higher pressure than needed. This pressure can be measured through a variety of means and brought down to a set level using a pressure regulator. When delivery pressure fluctuates, the installation of a regulator set at a lower pressure can stabilize pressure downstream for the fluid power components in the circuit.

**Pressure Generation.**— Pressure is raised in fluids in a variety of ways, the most common being pumps, compressors, and diffusers. Diffusers are sometimes contained within pumps, and are commonly part of HVAC systems.

*Compressors, Fans, Blowers, and Pumps:* Liquids have their pressures increased by pumps, while gases have their pressures increased by compressors, fans, and blowers. Compressors and some types of fans and blowers are similar to pumps, but the compression of gases is subject to the laws of thermodynamics. More information about gas compressors, fans, and blowers can be found in the section *Pneumatics* starting on page 2728.

*Diffusers:* Diffusers use a gradual enlargement of a pipe to convert velocity energy into pressure. Diffusers are used both to raise pressure and to decrease velocity of a fluid. They are used in pipelines to reduce the energy loss when the pipe goes through an enlargement. More on the energy loss of sudden versus gradual enlargement can be found later in this text. The pressure increase generated by a diffuser can be calculated using the following equation:

$$\Delta p = p_o - p_i = \gamma \left[ \frac{(v_i^2 - v_o^2)}{2g} - h_l \right]$$

where  $p_o$  and  $v_o$  are pressure and velocity at the outlet,  $p_i$  and  $v_i$  are pressure and velocity at the inlet, and  $h_l$  is the energy loss through the diffuser.

**Pressure Measurement.**— Pressure is measured in the US in terms of pounds per square inch (psi). Where pressures are quite low, inches of water gauge (inH<sub>2</sub>O, or in.w.g.) is used. In SI units, pressure is measured in pascals (Pa), kilopascals (kPa), and Megapascals (MPa). Other units of pressure are bars and mmH<sub>2</sub>O. Pressure is usually expressed relative to atmospheric pressure (gauge pressure), as opposed to absolute pressure. Negative gauge pressure is a vacuum. Some common pressure unit conversions are given in the following table.

### Pressure Conversions

US	SI
1 inH <sub>2</sub> O = 0.036 psi	1 mmH <sub>2</sub> O = 9.81 Pa
1 psi = 6895 Pa	1 Pa = 0.000145 Psi
1 psi = 144 psf	1 Pa = 1 N/m <sup>2</sup>
1 atm = 14.7 psi	1 bar = 100,000 Pa
1 atm = 1.01 bar	1 bar = 0.99 atm
1 inHg = 0.49 psi	1 mmHg = 133 Pa

*Manometers:* Manometers are devices which expose a static column of relatively dense fluid (mercury and oils are commonly used) to a differential pressure. These are used for liquid pressure measurement. In many cases, one end is exposed to a pressurized fluid while the other is left open to atmospheric pressure. The change in elevation of the column of fluid can be used to calculate the pressure of the fluid being measured by using the relationship between pressure and elevation.

Commercial manometers are calibrated and can be purchased in a variety of ranges. Piezometer tubes are types of manometers used for relatively low pressures. They consist of a vertical glass tube inserted into the wall of a pipe or pressure vessel. Its end is open to atmosphere or some known pressure reservoir. The height of the liquid in the tube is read against a calibrated scale and is related to pressure in the pipe or vessel.

**Barometers:** Barometers are used to measure atmospheric pressure. They operate on the same principle as manometers, where the change in height of a column of gauge fluid (commonly mercury) is used to calculate a change in pressure. Commercial barometers are calibrated and generally measure in the range between 25.5 and 32.5 inches (650-825 mm) of mercury. Corresponding pressures in pound per square inch and pound per square foot are given in **Table 7**.

**Table 7. Relation Between Barometric Pressure, and Pressures in Pounds per Square Inch and Square Foot**

Barometer, Inches	Pressure in Psi <sup>a</sup>	Pressure in Psf <sup>a</sup>	Barometer, Inches	Pressure in Psi <sup>a</sup>	Pressure in Psf <sup>a</sup>	Barometer, Inches	Pressure in Psi <sup>a</sup>	Pressure in Psf <sup>a</sup>
28.00	13.75	1980	29.25	14.36	2068	30.50	14.98	2156
28.25	13.87	1997	29.50	14.48	2086	30.75	15.10	2174
28.50	13.99	2015	29.75	14.61	2103	31.00	15.22	2192
28.75	14.12	2033	30.00	14.73	2121	31.25	15.34	2210
29.00	14.24	2050	30.25	14.85	2139	...	...	...

<sup>a</sup> Psi is pound per square inch; Psf is pound per square foot

**Pressure Gauges:** The most common method of measuring pressure in a fluid power circuit is by using a pressure gauge. There are gauges for liquids and gauges for gases. There are a variety of methods of construction of pressure gauges, including elastic diaphragm, dead weight, magnetic, and Bourdon tube gauges. Commercial gauges are normally calibrated to read zero at standard atmospheric pressure and temperature. Pressure gauges are available in a variety of ranges and units.

Some are capable of reading vacuum, or negative gauge pressure. Liquid filled gauges provide more stable readouts when vibration or pulsation is present in the system. The use of a snubber is recommended when fluid pressure pulsates.

**Pressure Transducers:** These are used when the display needs to be decoupled from the measurement device. Transducers convert pressures to electrical signals which can be transmitted to remote displays. Pressure transducers can be linear differential transformers, piezoelectric, quartz resonators, or solid state devices.

**Pressure Regulation.**— Fluids are often delivered at pressures higher than needed. Pressure regulators are used where pressure needs to be lowered and controlled. There are regulators for liquids and others for gases. A pressure regulator is a device generally comprised of three elements; a pressure reducing or restrictive element, a sensing element, and a force generator (usually a spring). In operation, the force generator opens the valve. Pressure introduced into the inlet port then flows through the valve and applies pressure to the sensing device (usually a diaphragm or piston). The pressure acts on the sensing element to produce a force which opposes the opening force and closes the valve. Regulators may be manually or electronically adjusted, and may include a pressure gauge or sensor.

In some cases, pressure may fluctuate due to variable supply and/or demand. This may be undesirable where work is being performed. A pressure reservoir with a regulator after it is a desirable source for most fluid circuits because the combination can buffer pressure variations and supply multiple circuits.

When choosing a pressure regulator, there are many factors to consider. The allowable ranges of inlet and outlet pressures must be known when sizing a regulator. The maximum flow rate and any porting requirements are also factors. It is also important to consider the

chemical properties of the fluid before determining the best materials for your application. There are a wide range of materials available to suit all applications. A non-relieving regulator is preferred for use with hazardous, explosive, or expensive gases since a relieving regulator will vent excess pressure to atmosphere.

The temperature range that the regulator will see is also a factor. Extreme operating temperatures may affect flow capacity and/or the spring rate.

**Flow Measurement.**— There are many ways to measure the flow of liquid or gas. Measurement can be in terms of velocity, volume flow rate, or mass flow rate. When selecting a flow meter, one must consider the viscosity and chemical compatibility of the fluid being measured, the desired output units, the range of flow values being measured, the desired accuracy, and the maximum pressure encountered by the unit. The ratio of the maximum to the minimum flow rate a meter can measure within the expected accuracy is called “turn-down.”

When designing a pipe system, it is often beneficial to run a bypass system of pipes with valves to allow service of a flow meter without interrupting system flow. Flow meters should be placed in straight sections of pipe for best measurement results. The length of straight pipe before and after each meter will depend on its type, the pipe diameter, and the type of nearest fitting or bend.

*Pitot Tubes:* Some pitot tubes are available to measure liquids and others are made for gases. These devices measure fluid flow velocity directly as a function of the height of a stationary column of fluid pushed out of the flow stream into a narrow tube. Most of the fluid flows past the device, but a small amount is captured in the static tube. Pitot tubes can be permanently installed in a pipe or duct, or used as a portable device for insertion as needed. The location of the capture tip of the pitot tube is critical, since flow velocity in a pipe varies across its cross section. Pitot-static tubes have ports perpendicular to the fluid flow direction to measure the static pressure of the fluid. Velocity is then calculated using the following equation:

$$v = \sqrt{\frac{2(p_t - p_s)}{\rho}}$$

where  $v$  is fluid velocity at the collection point;  $p_s$  is static pressure; and  $p_t$  is the stagnation pressure measured as a function of displacement of the fluid in the tube.

*Cup Anemometer:* Air velocity is often measured with one of these devices. They consist of several cups arranged about a shaft that is free to spin. As air flows perpendicularly to the cups, the device rotates at a speed dependent on the air flow velocity.

*Hot Wire Anemometer:* These devices employ a thin wire inserted into a gas stream. The wire is heated by current passing through it, and the gas flowing by tends to dissipate this heat. Some hot wire anemometers apply a fixed current, and thus the change in resistance of the wire (related to temperature change) is related to flow velocity. Others vary the current to maintain a fixed temperature, and thus the current required is related to flow velocity. Hot wire anemometers tend to break when used with liquids, so hot film probes are used in liquid applications.

*Venturi Meters:* These flow-through meters measure the pressure drop across a restriction and relate that to volume flow rate. The restriction is called a “throat” and has a gradual contraction followed by a gradual expansion. Venturi meters are more expensive than orifice meters, but cause less pressure loss in the system. Overall pressure loss is generally 5% - 20% of the measured differential pressure. Many venturi meters are available for measuring liquids, and others are meant for gases. They are suitable for contaminated fluids and slurries. The lengths of straight pipe required upstream and downstream of a Venturi meter for accurate flow measurement are given in ISO 5167-1. Flow rate  $Q$  through a venturi is calculated using the following equation:

$$Q = C \left( \sqrt{\frac{2\Delta p}{\rho}} \right) \frac{A_1}{\sqrt{\left(\frac{A_1}{A_2}\right)^2 - 1}}$$

where  $\Delta p$  is the measured differential pressure,  $A_1$  is the area at the upstream pressure tap, and  $A_2$  is the area at the throat. Coefficient  $C$  is generally 1 for ideal fluids, and 0.90 to 0.98 for viscous fluids.

*Orifice Plates and Meters:* These are the most widely used method of flow measurement in industry. Similar to venturi meters, these flow-through devices measure pressure drop across a restriction. The restriction is generally a hole in a plate placed across the flow path. This causes sudden contraction and expansion. The placement of the pressure measurement point is critical and dependent on the shape of the orifice. These meters generally create a larger energy loss than venturi meters due to the turbulence created by sudden changes in diameter, but are very cost effective. The relevant standard covering orifice plates is ISO 5167. Flow through an orifice meter can be calculated using the following equation.

$$Q = C_f A_o \sqrt{\frac{2\Delta p}{\rho}}$$

where  $A_o$  is the area of the orifice. The coefficient  $C_f$  is generally between 0.6 and 0.9, and depends on the Reynolds number as well as pipe and orifice diameter. Tabulations of coefficient  $C_f$  can be found in various reference sources.

*Flow Nozzle Meters:* Similar to venturi and orifice meters, these flow-through devices measure pressure drop caused by flow restriction. Flow nozzles have a smooth elliptical inlet leading to a throat section with a sharp outlet. The geometry of these nozzles has been highly standardized by ASME and ISO. The nozzle tends to have a well-rounded intake, and therefore creates a much lower energy loss than an orifice meter. This higher efficiency means greater flow capacity when compared to most other differential meters of the same size. Energy loss does tend to be higher than with venturi tubes. Nozzle meters are available in standard and long radius configurations, with different discharge coefficients. Flow is calculated similarly to orifice and venturi meters, using Bernoulli's equation and the appropriate coefficient.

*Variable Area Flow Meters:* These devices are extremely common in industry, and are available for measuring liquids or gases. There are tube and vane types. Tube meters have a weighted float that is suspended in the flowing fluid. The clearance space between the float and the tube forms an annular passage or orifice. Since the tube is tapered, the area of this orifice is larger when the float is near the top than it is when the float is near the bottom. Volumetric flow is measured based on the height the float is carried to. As a result, these meters must be installed vertically. Vane type meters use a vane to obstruct a bend in the pipe. It is normally closed, and fluid flow swings it open. Both tube and vane meters are for use with clean fluids at moderate pressures. Some types allow the float or vane to be viewed against a calibrated scale. In those cases, the fluid must be clear enough to see the float. Other types of variable area flow meters are suitable for high pressures and opaque fluids, and use sensors to detect the position of the float or vane and display the result remotely. Due to the restriction caused by the float or vane in the fluid stream, some energy is lost by fluid flowing through these meters.

*Elbow Meters:* These meters are simply a bend in a pipe through which the fluid flows. These meters are sometimes the only choice where space constraints do not allow the other types of meters. Pressure differential is measured between a point on the outside radius and a point on the inside radius. Because the fluid is moving faster along the outside radius, it will generate higher pressure.

*Turbine Flow Meters:* These meters allow fluid flowing through to turn a turbine rotor. The speed at which the rotor turns is indicative of the fluid velocity. The speed of the rotor is mechanically or electronically monitored. Because the turbine obstructs the fluid stream to some extent, some energy is lost due to restriction. These meters can be used for liquids or gases. Care must be taken when using these meters in a fluid that is non-lubricating, since the bearings that support the rotor may prematurely wear. Turbine flowmeters are less accurate at low flow rates due to drag, and should be operated above 5% of rated flow. Use in dirty fluids should generally be avoided to reduce the possibility of wear and damage. Two-phase flow and abrupt transitions from gas to liquid should be avoided because this can damage the mechanism.

*Vortex Shedding Flow Meters:* These are flow-through meters used for both liquids and gases. Placement of a blunt obstruction, called a *bluff body*, in the fluid stream causes vortices to be shed at a frequency dependent on the flow velocity. The shedding frequency is independent of fluid properties such as density, viscosity, conductivity, etc., however the flow must be turbulent for vortex shedding to occur. Sensors electronically monitor the shedding vortices. The obstruction need not be very large, and varies between manufacturers. Therefore, the energy lost by the fluid varies greatly from device to device. The advantage of this type of meter is that it is suitable for a wide range of fluids and gases. However, if a fluid includes substances likely to stick to or coat the bluff body, the meter's characteristics will change and accuracy will be compromised. The minimum measured flow rate should be at least twice the minimum rate detectable by the meter. The maximum flow capacity of the meter should be at least five times the anticipated maximum flow rate. The energy loss through a vortex meter is about half that of an orifice plate. The installed cost of vortex meters is competitive with that of orifice meters in sizes under six inches.

*Magnetic Flow Meters:* For use with conducting fluids only, magnetic flow meters use electrodes to detect the voltage generated in a fluid as it moves between two electromagnetic coils. The voltage generated is dependent on fluid velocity. Since there is nothing obstructing flow, these flow-through meters cause less energy loss than obstructing types. Another advantage of these meters is their suitability for a wide variety of fluids because their function is not affected by temperature, viscosity, or specific gravity.

*Ultrasonic Flow Meters:* These flow-through devices are attached to the outside of a pipe or tube, and therefore do not restrict flow or cause energy loss in the fluid. There are meters for gases and for fluids. Ultrasonic signals are transmitted through the pipe and fluid. The time it takes the signal to reach the receiver depends on the flow rate of the fluid. Some ultrasonic flow meters measure across the pipe, while others measure axially. A special type of ultrasonic flow meter, called a "Doppler" meter, is used for fluids with particulate content which may obstruct traversing ultrasonic signals. These meters measure the time it takes for signals to be reflected back from the fluid.

*Positive Displacement Flow Meters:* These are not flow-through devices, but instead allow fluid to fill a volumetrically calibrated chamber before the fluid is released. These meters can utilize a wide variety of mechanisms to capture and release volumes of fluid, one of the most common being diaphragm types typical to home gas meters. Other designs incorporate gears, pistons, and nutating disks (wobble plates). These meters are most often used for liquids, but can be used for gases as well.

*Coriolis Mass Flow Meters:* These flow-through devices measure mass flow rate directly, as opposed to measuring volume flow rate or velocity. By routing fluid through looping geometry, Coriolis force is generated and measured with sensors. Measurement results depend on the vibration of the tubes, so changes in tube rigidity due to temperature and pressure changes will affect calibration of the meter. These factors can be compensated for, but pitting, cracking, coating, erosion, or corrosion of the tubes cannot. Some energy is lost as the looping geometry causes changes in direction and velocity. These devices can be outfitted to monitor density of the fluid.

**Thermal Mass Flow Meters:** These devices are used almost exclusively for gas flow applications. Resistance temperature detectors (RTD) exhibit a linear change in resistance with respect to temperature. To measure mass flow rate, two RTD probes are used. One probe measures the fluid temperature, while the second probe is maintained at a higher temperature. As fluid flows by the heated probe, it dissipates the heat. The energy required to maintain the heated probe temperature is proportional to mass flow rate of the fluid. Some fluid energy is lost due to the obstruction of the probes in the fluid stream.

**Flow Control.**—Flow control is accomplished with manual or automatic valves, for both liquids and gases. Monitoring and control are often combined into a single device, in which flow is measured and the results are used to control a proportional valve to regulate flow. There are many types of flow controllers available, including manual needle valves and fully automated flow controllers. When density and viscosity is known and constant, and temperature is known, mass flow control can be performed. Mass flow controllers are usually used with gases, but some are available for liquids. Commercial flow control devices range in accuracy and flow capacity, and often contain proprietary control software and flow measurement technology.

**Coefficient of Velocity,  $C_v$ .**— $C_v$  is defined as the flow rate in U.S. gallons per minute (gpm) of water at 60°F with a pressure drop across the device of 1 psi. This is directly applicable to hydraulic components, but  $C_v$  is also applied to pneumatic devices as an indication of their flow capacity. This value is normally used when matching valves to actuators, or sizing other fluid power devices.

Flow capacity of valves in a circuit must be equal to or greater than flow required by the devices they supply. For actuators, higher  $C_v$  values can also indicate faster movement capability.

$C_v$  is typically used in the United States and calculated using English units. The SI system has its own flow coefficient,  $K_v$ , which is calculated using metric units. These two values are not equivalent.  $K_v$  is defined as the flow rate in cubic meters per hour ( $m^3/h$ ) of water at a temperature of 16°C, with a pressure drop across the valve of 1 bar.

$C_v$  is commonly used by manufacturers for both English and metric products, and is normally provided in catalogs. The equations used to calculate  $C_v$  and  $K_v$  are listed below. The equations for liquids are simpler than those for gases, because gases are compressible.

*Conversion:*  $C_v = 1.157K_v$     $K_v = 0.864C_v$

### $C_v$ and $K_v$ Equations for Liquids

for Non-choked Turbulent Flow when  $\Delta p < F_L^2(p_i - F_F P_v)$

$$C_v = Q \sqrt{\frac{SG}{\Delta p}} \qquad K_v = Q \sqrt{\frac{SG}{\Delta p}}$$

for Choked Turbulent Flow when  $\Delta p \geq F_L^2(p_i - F_F P_v)$

$$C_v = \frac{Q}{F_L} \sqrt{\frac{SG}{p_i - F_F P_v}} \qquad K_v = \frac{Q}{F_L} \sqrt{\frac{SG}{p_i - F_F P_v}}$$

for Laminar or Transitional Flow

$$C_v = \frac{Q}{F_R} \sqrt{\frac{SG}{\Delta p}} \qquad K_v = \frac{Q}{F_R} \sqrt{\frac{SG}{\Delta p}}$$

**$C_v$  and  $K_v$  Equations for Gases**for Non-choked Turbulent Flow when  $x < F_\gamma x_T$ 

$$C_v = \frac{Q}{1360 p_i Y \sqrt{\frac{SG p_i T_i Z}{\Delta p}}} \quad K_v = \frac{Q}{482 p_i Y \sqrt{\frac{SG p_i T_i Z}{\Delta p}}}$$

for Choked Turbulent Flow when  $x \geq F_\gamma x_T$ 

$$C_v = \frac{Q}{907 p_i \sqrt{\frac{SG p_i T_i Z}{F_\gamma \Delta p}}} \quad K_v = \frac{Q}{321.5 p_i \sqrt{\frac{SG p_i T_i Z}{F_\gamma \Delta p}}}$$

for Laminar or Transitional Flow

$$C_v = \frac{Q}{N_1 F_R \sqrt{\frac{M T_i}{\Delta p (p_i + p_o)}}} \quad K_v = \frac{Q}{N_2 F_R \sqrt{\frac{M T_i}{\Delta p (p_i + p_o)}}}$$

$$N_1 = 1730 \text{ for } T_s = 0^\circ\text{C}$$

$$N_2 = 4920 \text{ for } T_s = 0^\circ\text{C}$$

$$N_1 = 1840 \text{ for } T_s = 15^\circ\text{C}$$

$$N_2 = 5200 \text{ for } T_s = 15^\circ\text{C}$$

The following definitions apply to equations for  $C_v$  and  $K_v$  given above: $Q$  = flow in gpm for liquids, and flow in SCFM for gasses

SG = specific gravity

 $\Delta p = p_i - p_o$  is the pressure differential between upstream and downstream,  $p_i$  is inlet absolute pressure (psia or bar), and  $p_o$  is outlet absolute pressure (psia or bar) $F_F$  = liquid critical pressure ratio factor (ranges between 0.68 to 0.96) $F_L$  = liquid pressure recovery factor.  $F_L$  depends on valve geometry and ranges between 0.6 for ball valves and 0.9 for globe valves $P_v$  = absolute vapor pressure of the liquid at inlet temperature $x = \frac{\Delta p}{p_i}$  is the ratio of the pressure differential to the inlet absolute pressure $F_\gamma$  = specific heat ratio factor.  $F_\gamma = 1$  for air, otherwise  $F_\gamma = \frac{\gamma}{1.4}$  $x_T$  = choked flow pressure differential ratio factor, experimentally determined, that varies from 0.3 to 0.9 depending on valve geometry $Y$  = expansion factor for gases.  $Y = 1 - \frac{x}{3 F_\gamma x_T}$  for normal flow, and ranges from $Y = 1$  to  $Y = 0.667$  at choked flow $Z$  = compressibility factor (assume  $Z = 1$  for ideal gasses) $F_R$  = Reynolds number factor that depends on valve characteristics, and is limited to  $F_R \leq 1$  $M$  = molecular mass of fluid in kg/kg-mol or lb/lb-mol $T_i$  = absolute inlet temperature for the gas, °C $T_s$  = absolute reference temperature for the gas, °C

For additional information on flow equations see International Electrotechnical Commission standard IEC 60534.

### Pipe, Tubing, and Fittings

Design of pipe systems must be undertaken with great care. Safety, performance, reliability, and cost are all significantly affected by selection of appropriate pipe sizes, materials, and connection methods. For many applications, the design must comply with codes and standards. Organizations such as ISO, ASTM, NSF, NFPA, AWWA, AFSA, and IAPMO should be consulted when working with pipe. Tubing systems are also covered by standards in cases of sanitary, food, medical, and high pressure applications.

**Metal Pipe.**—Metal pipe is ideal for applications where structural strength is needed. Metal pipe is also resistant to high temperatures and is non-combustible. Extremely low temperatures should be avoided. Metal pipe systems may need proper grounding to prevent shocks and accelerated corrosion. A wide range of materials is available.

*Materials:* Steel is the most commonly used metal pipe material for general use. Steel pipe is highly resistant to shock and vibration from water hammer or external sources. To carry a given pressure, steel pipe can be made with a thinner wall than pipes made from other materials, and as a result the pipe will have a larger flow capacity. Carbon steel pipes are susceptible to corrosion and oxidation, so additional allowance should be made when calculating flow capacity. Galvanized steel can inhibit atmospheric corrosion to some extent, but the coating can break down when exposed to constant moisture. Stainless steel pipes cost more, but are resistant to corrosion and oxidation. Stainless steel is also compatible with a wide variety of chemicals.

Ductile iron pipe is commonly used for water and sewer applications. It combines the physical strength of mild steel with the long life of gray cast iron. It has superseded cast iron pipe in the water handling industry. In addition to the benefits of long life, corrosion resistance, high structural strength, and tight joints, ductile iron is also readily machinable. Although somewhat corrosion resistant when in contact with water, these pipes are often internally lined or coated to inhibit corrosion further.

Copper pipe is commonly used in household and industrial supply lines for both liquids and gases. It costs more than steel pipe, but is much easier to join. It is extremely thermally conductive, which makes it a top choice for heat exchangers and other thermal applications. Copper resists corrosion, is unaffected by UV radiation, and inhibits the growth of bacteria. It will corrode in the presence of high or low pH liquids.

Connecting pipes and fittings of different metals is not recommended because galvanic corrosion to occur. Protective coatings should be employed where necessary to prevent contamination or failure of the joint.

*Schedules and Classes:* Schedule number designations for steel pipe, previously called “Iron Pipe Sizes (IPS)” are an indicator of wall thickness. Schedules range from 10 to 160, with higher numbers designating thicker walls. Schedules 40 and 80 are the most commonly used. From the IPS system, designations like STD, XS or XHY (extra heavy or strong), and XXS or XXHY (double extra strong or heavy) are still used. For a given pipe size, all schedules have the same outside diameter.

Higher schedule pipes of the same diameter have smaller flow areas. The nominal pipe size (NPS) is given, along with the schedule or IPS designation to indicate the full dimensional characteristics of the pipe.

Ductile iron pipe ranges in size from 3 to 64 inches and in pressure classes from 150 psi to 350 psi, although custom sizes and pressure ratings can be obtained.

Copper pipe is classified as copper tube. Information on copper tube can be found in the section *Metal Tube* starting on page 2689. Copper pipe is suitable for water and steam service at pressures up to 250 psi (1750 kPa) and temperatures up to 406°F (208°C).

*Sizes:* Nominal sizes for commercial steel pipe are generally given in inches. Actual diameter of the pipe can be different from the nominal designation, so refer to **Table 8** for actual dimensions of common pipe sizes up to 6 inches in diameter. This is the Nominal

Pipe Size (NPS) system. ISO has designated metric equivalent pipes for customary US pipe sizes. As with US pipe, metric pipe dimensions often differ from the nominal size designations.

Sizes of ductile iron pipe follow the Ductile Iron Pipe Sizes (DIPS) standard. These sizes and dimensions can be found in **Table 9**. Flanged pipes are normally furnished with a maximum length of 19' - 6". The minimum length varies with pipe size. The minimum class thickness for ductile iron flanged pipe to be threaded is Special Thickness Class 53 for sizes up through 54 and pressure class 350 for 60 and 64 sizes. Greater pipe wall thicknesses are available.

*Pressure Ratings:* When working with ductile iron pipe applications, the designer should choose the appropriate class of pipe to carry the anticipated working pressure.

When working with other types of metal pipe, wall thickness must be selected or calculated based on working pressure. ANSI/ASME Standard B31.1-1998: "Power Piping" details a method of calculating the minimum wall thickness for pipes. The maximum working pressure for a pipe is often provided by the manufacturer, and can be calculated using US standard units in the following equation:

$$P_{\max} = \frac{2S(0.875t - A)}{D - 2Y(0.875t - A)}$$

where  $S$  is the allowable tensile stress in psi,  $t$  is the wall thickness in inches,  $D$  is the outer diameter in inches,  $A$  is an allowance for corrosion and threading, and  $Y$  is a temperature factor given in **Table 10**. A factor of safety should be used when selecting allowable stress. Allowance  $A$  is added to compensate for corrosion, erosion, threads, and bends, which thin the walls of the pipe. Allowance  $A = 0.05$  for threaded steel up to 3/8" OD and for unthreaded steel up to 1/2 OD.  $A = 0.065$  for unthreaded steel larger than 3/8" OD. For threaded steel larger than 3/8" OD,  $A$  is equal to the thread depth.

Wall thickness based on pressure requirement can be calculated using the following equation and **Table 10**. This is for straight pipe, and wall thickness tolerances should be taken into account.

$$t = \frac{pD_o}{2(S + pY)} + A$$

where  $D_o$  is the outside diameter of the pipe,  $p$  is internal pressure,  $Y$  is the temperature coefficient given in **Table 10**,  $A$  is the allowance discussed above, and  $S$  is the maximum allowable stress in the material.  $S$  should be modified to account for welds and joints according to the standards, and a factor of safety should be used.

The temperature at which material properties are given must be considered. Many hydraulic systems run at a temperature of approximately 100°F (38°C). A factor of safety of 3 to 4 should be used when calculating pressure ratings. If the tube is carrying liquid, the pressure rating must be derated to account for the pressure spikes that occur during valve closures. Derating for pressure spikes (water hammer) is often 20%. Derating to account for fittings is usually also done, with 25% additional reduction a typical value.

*Connections:* There are many types of connections for metal pipe, the most common of which are threaded, flanged, welded, and soldered.

Threaded connections on pipes normally use tapered threads per the standard for either American National Pipe Thread (NPT) or British Standard Pipe Thread (BSP). Metric pipe uses ISO standard pipe threads. These threads are detailed in *PIPE AND HOSE THREADS* starting on page 2008. Sealing is accomplished through thread interlocking and the use of a sealing compound or PTFE tape. The compound or tape lubricates the threads and ensures that spiral leak paths through the threads are blocked. Tape must be used in just the right amount to be effective. Too much tape can cause the joint to fail. Tape should not be used on bull plugs on heat exchangers. Tape is available in several thicknesses. Thicker

tape should be used on higher pressure or larger size installations. Always follow the manufacturer's recommendations when using liquid thread compounds, and always verify chemical compatibility with the process fluid.

Threaded connections are specified by the nominal pipe size and the type of thread (NPT, BSP or other).

Threaded pipe connections require the rotation of one of the pipes in the joint. When this is not practical, a threaded union may be used. Unions are comprised of two halves that form a flange connection.

Flanged connections are commonly used on large piping systems. For process and utilities, the two most common flange standards are ANSI B16.5 and BS 1560. Wellhead flanges are specified by API 6A. Flanges of different standards are not normally joined. There are three commonly used types of flange facings: Ring Type Joint (RTJ), Raised

$$^a \text{If } D_o \div t < 6, \text{ calculate } Y = \frac{D_i}{D_i + D_o}.$$

Face (RF), and Flat Face (FF). RTJ facings use ring type metal gaskets and are for the most severe duties, such as with high pressure gas piping. Raised face flanges have a nonmetallic gasket that fits within the bolts of the flange.

The face has a series of grooves into which the gasket flows upon compression. A flat face flange also uses a series of grooves, but the nonmetallic gasket fits over the entire face of the flange. Flat face flanges are used for the lowest pressure duties. The way in which the flange is attached to the pipe determines the flange type. Weld-Neck (WN) flanges are butt-welded to the pipe, and are used on high pressure and hazardous applications. Socket Weld (SW) flanges are fillet welded onto the pipe and are also suitable for high pressures, but are limited to pipe sizes of 1½ inch or less. Slip-On Weld (SO) flanges are used for low pressure, low hazard applications. The pipe is welded both to the hub and the bore of the flange. This weld configuration makes it impractical to radiographically inspect the welds. Composite lap joint flanges are used to save material expense on alloy pipe systems, where a backing flange of an inexpensive material is added to a hub welded to the pipe. Swivel ring flanges, like composite lap joint flanges, use a hub welded to the pipe. A swivel ring

fits over the hub for the purpose of bolting the joint together. The swivel ring flange facilitates flange alignment. There are a number of compact flange designs that include tapered sections or proprietary designs. Always comply with the manufacturer's specifications when using this type of flange connection.

Flanges are specified using the nominal pipe size, type and facing, pressure class, material, schedule, and applicable standard. Since surface condition is critical to flange sealing, all surfaces must be carefully inspected before use, and all scratches, rust, and burrs removed. Gasket selection must be done with consideration of temperature, internal pressure, cycling conditions, vibration, material compatibility, erosive/corrosive potential of the media, and potential to leach substances into the fluid. Gaskets may be ring-type, spiral wound, or sheet. They must be inspected carefully before use for damage, and should never be trimmed or re-used. Bolts must be of the proper material and grade for the joint, and tightened gradually according to standard procedure. Lubricant of the proper type should be used if recommended, and a torque wrench should be employed upon final tightening to ensure proper compression.

Welded and soldered pipe connections should be made according to applicable standards and safety precautions. Steel pipe is often welded, while copper pipe is typically joined by soldering. In soldered pipe joints, capillary fittings are used.

*Expansion with Temperature:* Metal pipe expands and contracts with temperature by an amount dependent on both temperature change and material. This must be considered when designing pipe systems where temperature will change between installation and operation, or when the fluids pumped will be above or below installation temperature. Use the factors in the following table to calculate length increase or decrease for each pipe run.

**Linear Expansion and Contraction Factors per 100 Feet of Pipe**

Temperature Change, °F	Pipe Material				
	Steel	Copper	PVC	FRP	PP & PVDF
0	0	0	0	0	0
20	0.15	0.25	0.62	0.26	2.00
40	0.30	0.45	1.30	0.52	4.00
60	0.46	0.65	2.20	0.78	6.00
80	0.61	0.87	2.80	1.05	8.00
100	0.77	1.10	3.50	1.31	10.00
120	0.92	1.35	4.25	1.57	12.00
140	1.08	1.57	4.80	1.83	14.00
160	1.24	1.77	5.50	2.09	16.00
180	1.40	2.00	6.30	2.35	18.00
200	1.57	2.25	7.12	2.62	20.00

Multiply length of pipe by the table factor and divide by 100 for the increase or decrease in length.

**Plastic Pipe.**— Plastic pipe is lighter and less expensive than metal pipe, and can be more chemically inert. It is generally non-conductive and thermally insulative. Due to its smooth inner surfaces, it can offer better flow characteristics than metal pipe. However, plastic pipe can be affected by ultraviolet radiation and extreme temperatures. The most common plastic pipe is suitable for nonflammable liquids up to 150 psi (1000 kPa) and temperatures up to 140°F (60°C). Plastic pipe expands with temperature much more than metal pipe.

*Materials:* Many types of plastics are available as plastic pipe. Polyvinyl chloride (PVC), acrylonitrile butadiene styrene (ABS), and polyethylene (PE) are the most common in the USA. Crosslinked polyethylene (PEX) is common in Europe and gaining popularity in the USA.

PVC and chlorinated PVC (CPVC) are related, but CPVC can withstand a wider range of temperatures. PVC is limited to 140°F while CPVC can be used up to 190°F. PVC has inherently superior fire retarding properties due to its chlorine content. The ignition temperature of PVC is as high as 455°C. PVC and CPVC are highly resistant to oxidation and are very durable. PVC is resistant to acids, bases, and most inorganic chemicals. PVC swells or dissolves in aromatic hydrocarbons, ketones, and cyclic ethers. These plastics crack when frozen, and CPVC requires more mechanical support than PVC.

ABS pipes are used mainly in applications where rigidity and impact strength are needed. ABS can be tailored to a wide range of needs by altering its chemical composition. It is suitable for water transport and has good resistance to a wide range of diluted inorganic acids, organic acids, salts, animal fats and oils. ABS is not resistant to organic solvents, alcohol, gasoline, acetic acid or vegetable oils. ABS is resistant to temperatures up to 70°C, but its pressure capacity must be derated with elevated temperature. ABS is non-toxic and is used for food and beverage applications.

PE pipes can be joined through heat fusion, and are common in municipal water applications. They are extremely slippery when wet. PE Water Service lines are typically ½ to 3 nominal diameter pipe or tubing in accordance with AWWA C901, ASTM D2239, ASTM D3035, or ASTM D2737. PE water distribution lines are typically 4 to 12 nominal diameter pipe in accordance with AWWA C906, ASTM D3035, or ASTM F714. Install PE pressure pipe in accordance with ASTM D2774. PE pipe may be cold bent. The allowable bend ratio is determined by the pipe diameter ( $D$ ) and the Standard Dimension Ratio ( $SDR$ ) in accordance with [Table 11](#).

**Table 11. Cold Bend Radius, Polyethylene Pipe**

Standard Dimension Ratio, $SDR$	Minimum Bend Radius to Centerline of Pipe
7 through 9	20 × Pipe Outside Diameter
11 through 13.5	25 × Pipe Outside Diameter
17 through 21	27 × Pipe Outside Diameter
Fitting in Bend	100 × Pipe Outside Diameter

PEX is gaining popularity for residential water service because it is flexible, does not corrode, is easy to work and connect, and is resistant to scale and chlorine. It is made from crosslinked HDPE and subject to ASTM F876. It can be bent according to table, as well as used with compression tube fittings. Standard PEX does admit some oxygen, so an added oxygen barrier may be needed in some applications. PEX can be used at temperatures from below freezing to almost boiling.

**Table 12. Bend Radius, PEX Pipe or Tube**

PEX Size, inch	Outside Diameter, inch	Minimum Bend Radius, inch
⅜	0.500	4
½	0.625	5
⅝	0.750	6
¾	0.875	7
1	1.125	9

*Schedules:* Schedule number designations for plastic pipe are an indicator of wall thickness. Schedules 40 and 80 are the most commonly used, and 120 is also widely available. For a given nominal pipe size, all schedules have the same outside diameter. Therefore, higher schedule pipes of the same diameter have smaller flow areas. The nominal pipe size

(NPS) is given, along with the schedule or IPS designation to indicate the full dimensional characteristics of the pipe.

*Sizes:* Plastic pipe size designations are often tied to the outside diameter, as they are for steel pipe according to the NPS system. PVC has its own ASTM pipe sizing standard, while CPVC is available in either ASTM standard sizing or CPVC-CTS (Copper Tube Standard). Dimensions for schedule 40, 80, and 120 PVC pipe are given in [Table 13](#). Alternative sizing methods are the Standard Inside Dimension Ratio (SIDR) method and the Standard Dimension Ratio (SDR) method. The SDR method uses OD and wall thickness, and SIDR uses ID and wall thickness. The SIDR method is useful when designing flow-critical applications. The SDR method is useful when pressure rating is of primary concern. PEX is most commonly sized as tube, which is covered in the section *Plastic Tube* starting on page [2691](#).

**Table 13. PVC Pipe Dimensions, Schedule 40, 80, and 120, Sizes Up To 12"**

*Pressure Ratings:* Pressure rating of plastic pipe is highly dependent on material, as well as wall thickness. Most commercially available plastic pipe will be rated by the manufacturer. PEX pressure ratings are 160 psi at 74°F and 100 psi at 180°F.

Pressure ratings for polyethylene pipes depend on the material formulation. Pressure ratings of standard sizes of PVC pipe are given in [Table 14](#). Pressure ratings must be derated with elevated temperature. Derating factors for PVC pipe are given in [Table 15](#). Further derating must be done to account for water hammer, and this is often 20%.

*Connections:* Some plastic pipe is threaded for use with threaded fittings. Threading normally follows the NPT standard. If the pipe is not threaded, a variety of other connection methods may be used. PVC pipe is usually bonded into socket fittings using solvent cement. PE pipe can be joined using heat fusion and electrofusion. In some cases, tube fittings may be used to connect plastic pipe.

*Expansion with Temperature:* Plastic pipe expands and contracts with temperature by an amount dependent on both temperature change and material. This must be considered

**Table 14. Pressure Ratings of Schedule 40, 80, 120 PVC Pipe Up To 12" at 73.4°F**

when designing pipe systems where temperature will change between installation and operation, or when the fluids pumped will be above or below installation temperature. Plastics expand much more than metals, so this may become a factor in selecting one over the other. Use the factors in **Table 16** to calculate length increase or decrease for each pipe run. To use the tabulated factors, use the equation  $\Delta L = \alpha L_0 \Delta T$  where  $L_0$  is the length at the installation temperature, and  $\Delta T$  is the difference between the installation temperature and the temperature in question.

**Table 16. Coefficient of Linear Expansion ( $\alpha$ ) for Common Pipe Materials**

Material	Coefficient of Linear Expansion	
	$10^{-6}$ in/in °F	$10^{-6}$ m/m °C

Copper	9.3	16.8
Stainless Steel	9.9	17.8
ABS	35	63
HDPE	67	120
PE	83	150
CPVC	44	79

**Pipe Fittings.**— Pipe fittings are used to connect pipes together either permanently or non-permanently. Pipe systems should be designed to minimize the number of fittings because they cause pressure loss, require pressure derating, and are a potential source of leaks.

*Materials:* Pipe fittings are available in a variety of materials, and should be selected for compatibility with the pipe material and the substance being transported. Dissimilar metals should be avoided to prevent galvanic corrosion. Plastic fittings are also available for use with plastic pipe.

*Types:* Pipe fittings may be threaded, slip, or interference type connections. Interference connections, like compression or stab fittings, are used with plastic pipe and with metal and plastic tubing. PEX pipe is typically connected using either a copper crimp ring or expansion fittings with outer expansion rings. In the crimping method, a copper crimp ring is put over the pipe near the end, a copper fitting is inserted into the pipe end, and a crimping tool is used to crimp the ring over the pipe and fitting. In the expansion fitting method, an expansion tool is used to open the diameter of the pipe, into which an expansion fitting is inserted. The pipe shrinks over the fitting as it cools, and then a plastic expansion ring is pressed over the pipe and fitting. Compression fittings can be used as an alternative; that method is discussed in the section *Tube Fittings on page 2694*.

The most common types of pipe fittings are illustrated in **Table 17**. These examples are by no means exhaustive of the types and shapes available.

**Table 17. Common Pipe Fittings**

*Pressure Considerations:* Pipe fittings have pressure ratings that must be considered during the selection process. Low pressure pipe fittings are generally rated to 150 psi. Medium pressure fittings are commonly found rated to 300 psi. High pressure fittings are rated as high as 3,000 psi, and extreme pressure fittings can be found rated to 6,000 psi or even higher. Pressure rating depends on schedule, size, material, and connection type.

**Metal Tube.**— Metal tube is generally smaller and thinner than metal pipe. The same considerations in terms of material properties, mechanical stresses, and environmental factors apply to both tube and pipe.

*Material:* Steel tubing is usually made from carbon steel (plain or galvanized) or stainless steels (304 or 316). It is used in a variety of applications to carry liquids or gases. Stainless steel is known for its corrosion resistance when exposed to a variety of materials.

Copper tubing is typically offered as either soft annealed or hard drawn. Annealed tubing is easy to bend, while drawn tubing is stiff. Drawn tubing has a higher pressure rating than annealed. Flare fittings may be installed on annealed temper tube, but not on drawn temper; both types can be soldered or brazed. Copper tube types and applications are given in [Table 18](#).

**Table 18. Copper Tubing Types and Applications**

Tube Type	Standard	Applications	Commercially Available Sizes
K	ASTM B88	Domestic Water Fire Protection Solar Fuel/Fuel Oil HVAC Compressed Air Natural Gas, LP Gas Vacuum	<ul style="list-style-type: none"> <li>• Straight Lengths:     <math>\frac{1}{4}</math> inch to 12 inch</li> <li>• Coils:     <math>\frac{1}{4}</math> inch to 2 inch</li> </ul>

OXY/MED	ASTM B819	Medical Gas Compressed Medical Air Vacuum	<ul style="list-style-type: none"> <li>• Straight Lengths:     <math>\frac{1}{4}</math> inch to 8 inch</li> </ul>

*Sizes:* Steel tubing is highly standardized, with designations of outside diameter and wall thickness. Imperial and metric sizes are available. A selection of Imperial sizes and pressure ratings of stainless steel tubing is given in [Table 19](#).

The system of Copper Tube Sizes (CTS) depends on type. Types K, L, M, DWV (Drain Waste Vent), and OXY/MED all have an outside diameter  $\frac{1}{8}$ " larger than the nominal size designation. Type ACR (Air Conditioning & Refrigeration) tubing outside diameter is equal to the nominal size designation. Dimensions of copper tube are found in [Table 20](#).

*Pressure Ratings:* Pressure ratings for stainless steel tubes were given in [Table 19](#). Allowable maximum pressure for metal tubes can be calculated as it was for metal pipes.

**Table 19. Stainless Steel Tube Specifications, Selected Sizes**

Tube OD (in)	Wall Thickness (in)	Working Pressure (psig)
1/16	0.014	8100
	0.020	12000

	0.065	3300
1	0.083	3100
1 1/4	0.095	2800
	0.12	3600
1 1/2	0.12	3000
	0.134	3400
2	0.134	2500
	0.188	3600

Alternatively, the maximum working pressure of metal tubing can be calculated using the Barlow formula for thin-walled cylinders as given in the following equation. This formula is typically used for steel tubing connected with flare fittings.

$$p_{\max} = \frac{2St}{D}$$

where  $S$  is the ultimate tensile strength,  $t$  is wall thickness, and  $D$  is outer diameter. A factor of safety between 1.5 and 10 should be applied.

If the tube is carrying liquid, the pressure rating must be derated to account for the pressure spikes that occur during valve closures. The amount of reduction of working pressure is called the “water hammer factor” and is typically 20%. The types of fittings being used must be carefully considered when working with elevated pressures, and further derating of the system may be required. For pressure ratings of copper tube, consult the “Copper Tube Handbook,” available from the Copper Development Association Inc.

**Plastic Tube.**— Plastic tube is often selected for its flexibility, clarity, or non-conductivity. When selecting from the wide variety of available tubing materials, one must consider the operating temperature range in the application, the media being transported, the environment in which the tubing will be located, the pressures involved, whether there will be vacuum, whether there are any standards or certifications needed, whether standard tubing tolerances will be acceptable, and whether the tubing must be transparent. Temperature must be considered not only for extremes, but also for slight variations from 73°F (22°C) because most plastic tubing expands and softens even with slight changes in temperature.

**Table 20. Copper Tube and Pipe Dimensions**

12	12.125	11.315	11.565	11.617	...	...	...

**Materials:** Some of the more popular tubing materials are polyvinyl chloride (PVC), low density polyethylene (LDPE), high density polyethylene (HDPE), polypropylene (PP), nylon (PA 6, 6/6, 11, 12), silicone, polyurethane, fluoropolymers (PTFE, FEP, PFA, PVDF, ETFE), and polyetheretherketone (PEEK). PEX tube is also common in Europe for water applications.

PVC can be rigid or flexible, and can be transparent. Exposure to water can cause clouding of clear PVC over time. Flexibility will depend on the amount of plasticizer present, so a variety of durometers are available. Flexible PVC is rated for fairly low pressures, unless reinforced with braiding.

LDPE is low cost, light weight, relatively transparent, and flexible. It is suitable for air, water, and some chemicals. Caution should be used when barbed fittings are employed

because LDPE has poor environmental crack resistance, which can be accentuated when solvents are present.

HDPE is similar to LDPE in terms of material compatibility. It is fairly opaque, and is more dense and rigid than LDPE.

Polypropylene has high impact resistance combined with good stiffness and excellent chemical resistance. PP is often mixed with polyethylene or rubber to improve its impact and low temperature properties. PP is more heat resistant than PE, with an operating range up to 60°C.

Nylons can be used at elevated temperatures. They cost more than PE and PP, but exhibit superior abrasion resistance and stiffness. Types 11 and 12 are more flexible than type 6, and have better chemical resistance to acids and bases.

Silicone tubing is suitable for elevated temperatures and can be sterilized using heat. It is extremely soft and flexible, and is non-toxic. There are different ways to cure silicone tubing, so material properties may vary.

Polyurethane tubing is flexible and can be relatively transparent. This type of tubing has good abrasion resistance and tensile strength. It is flexible at low temperatures and holds its properties over time. There are two types of polyurethane: esters and ethers. Esters have good chemical and oil resistance. Ethers have good water compatibility and are suitable for outdoor applications. Both can be made FDA compliant.

Fluoropolymers are chemically inert and often chosen for harsh applications or high purity applications. They are also suitable for high temperatures in the 300 – 500 °F (148 – 260 °C) range. Rigidity varies with composition, but they are generally stiff but bendable. FEP is flexible and transparent.

PEEK is fairly rigid but bendable, has excellent mechanical stability and chemical compatibility, and can be used to 100 °C. It is often used where stainless steel tubing has material compatibility issues.

PEX tubing is of the same material and properties as PEX piping, discussed in the section *Plastic Pipe* starting on page 2685. It comes in a variety of colors, or a natural hazy clear state.

There are many more materials than those listed. In addition, there are many brand-name and proprietary formulations.

*Sizes:* Most plastic tubing is sized according to OD, ID, and wall thickness. A wide variety of sizes are available for each material. PEX tubing is sized according to the Copper Tube Size standard for outer diameter. Standard PEX dimensions are given in [Table 21](#).

**Table 21. Standard PEX Dimensions**

Nominal PEX Size inch	Outside Diameter inch	Inside Diameter inch	Wall Thickness, inch
$\frac{3}{8}$	0.500	0.350	0.070
$\frac{1}{2}$	0.625	0.475	0.070
$\frac{5}{8}$	0.750	0.574	0.083
$\frac{3}{4}$	0.875	0.677	0.097
1	1.125	0.863	0.125

All dimensions are in inches.

*Pressure Ratings:* Care must be taken when using plastic tubing because pressure ratings are generally much lower than with metal tubing. In addition, if vacuum is to be used in the system, the tubing must be vacuum rated to ensure that it does not collapse.

Pressure rating will depend on material, diameter, and wall thickness. Consult the manufacturer's pressure rating when specifying plastic tubing.

**Tube Fittings.**— Tube fittings are used to connect tubing to tubing, or tubing to pipes or other objects. Tube fittings are generally non-permanent connections, although they may permanently deform the end of the tube.

*Materials:* Fitting materials should be chosen for compatibility with the tubing and the fluid being transported. Combining dissimilar metals should be avoided to prevent galvanic corrosion. Metal fittings and plastic fittings are widely available. Some plastic fittings have metal ferrules, and some metal fittings can have elastomeric seals. It is critical to check material compatibility with all components of a fitting. Plastic fittings are used with plastic tubing that is softer than the fitting material. Steel fittings are used with steel or plastic tubing. Brass fittings are used with copper, aluminum, and plastic tubing.

*Types:* There are many types of tube fittings, including proprietary and name-brand fittings. The most common general types are barbed, compression, flare, and push-in.

*Barbed fittings* are used with soft plastic tubing which can expand enough to fit over the barb end but have elastic memory enough to seal over the barb or barbs. A clamp should be employed to hold the tube on if pressures are moderate. Pressure in the system should not exceed 150 psi when using barbed connections. To specify a barbed fitting connection, one must know the tube inner diameter, process pressure, material compatibility, and whether the tubing is suitable for use with barbed fittings.

*Compression fittings* are used on metal tubing and stiff plastic tubing. Metal and plastic compression fittings are available. They are suitable for high pressures when constructed out of high strength material and combined with a high pressure rated tube. There are numerous designs available, but all include at least one ferrule, a nut, and a fitting body. When the nut is tightened, the ferrule swages the tube to form a pressure tight seal. The tube does not need to rotate during tightening. Compression fittings can be re-used if care is taken not to damage the ferrule or tube end. To specify a compression fitting, one must know the tube outer diameter, wall thickness, process pressure, and material compatibility requirements. To ensure proper sealing, the tube should be clean and cut square without burrs. The tube material must always be softer than the fitting material. Plastic compression fittings are used with softer plastic tubing, and stainless compression fittings are generally used with stainless tubing. Brass fittings can be used with firmer plastic, aluminum, and copper tubing. Carbon steel compression fittings are used with carbon steel tubing.

*Flare fittings* are typically used with metal tubing which is forced over a flared seat and secured with a nut to create a leak-tight seal. They are similar to compression fittings but have a sleeve instead of a ferrule. A flaring tool is used on the end of the tubing to create the proper flare for the fitting being used. These fittings are suitable for high pressures, even greater than with compression fittings. The most common flare fitting standards in use today are the 45° SAE fitting, and the 37° JIC fitting. The 37° style generally has a higher pressure rating for a given size tubing. The 45° style is generally used for low pressure refrigeration applications, while the 37° style is used for high pressure hydraulic applications. SAE and JIC fittings are incompatible due to the different flare angles. Flare fittings can be reused if care is taken not to damage the flared end of the tubing. Stainless steel fittings are used with flareable seamless stainless tubing. Brass fittings are used with flareable seamless copper. Carbon steel fittings are used with flareable welded and seamless carbon steel tubing. Aluminum fittings are used with seamless aluminum tubing.

*Push-in fittings* are popular for pneumatic connections, but are also made for liquid applications. These fittings have an internal gripping ring and usually an o-ring. The tube must be cut square and be burr-free. A leak-free seal is created when the end of the tube is pushed into the fitting. To release the tubing, the end of the fitting must be compressed axially to release the gripping mechanism. These fittings normally have elastomeric, plastic, and stainless steel components, regardless of the body material, so material compatibility can become an issue. These fittings can be selected to accept plastic or metal tubing, and pressure ratings vary. Pressure capability of push-in fittings is generally less than compression fittings but greater than or equivalent to barbed fittings.

Many other fittings and couplings are available. Couplings attach to the ends of two tubes and have a leak-free means of connecting the halves of the coupling together. Couplings are available with and without shut-off valves to prevent spillage when disconnected.

### Flow and Energy Loss in Pipe, Tube, and Fittings

Fluids experience energy loss due to friction when flowing through pipes and fittings. The energy lost is dependent on the length and diameter of the pipe/tube, the surface conditions, and the number and shape of any bends or restrictions.

**Flow Rates.**— The principal of continuity for constant flow dictates that the volumetric flow rate (or mass flow rate) remains the same along a pipe, even if the pipe expands, contracts, or is restricted. This means that velocity changes with flow area. One can calculate the velocity before or after a change in flow area if the velocity on the other side of the change is known.

$$Q_i = A_i v_i = Q_o = A_o v_o$$

where  $A$  is the cross sectional flow area,  $Q$  is volumetric flow rate, and  $v$  is velocity.

The behavior of a fluid, and its energy losses through pipe and fittings, is dependent upon whether it follows a laminar, transitional, or turbulent flow regime. To determine what flow regime is present, the dimensionless Reynolds number is calculated with the following equations. If the Reynolds number is less than 2000, the flow is laminar. If the Reynolds number is greater than 4000, flow is turbulent. Between those values lies the transitional flow regime. Note that the Reynolds number is dependent on fluid viscosity.

$$R_e = \frac{\rho v D}{\mu}$$

where  $D$  is the flow diameter,  $\rho$  is the density,  $v$  is the mean velocity,  $\mu$  is the absolute viscosity of the fluid.

$$R_e = \frac{v D}{\nu} = \frac{Q D}{A \nu}$$

where  $Q$  is the volumetric flow rate,  $A$  is the cross sectional area of flow, and  $\nu$  is the kinematic viscosity.

For general liquid piping applications, the U.S. Army Corps of Engineers manual "Liquid Process Piping" recommends a flow velocity of  $7 \pm 3$  ft/s ( $2.1 \pm 0.9$  m/s) with a maximum velocity of 7 ft/s at discharge points including pump suction lines and drains.

All formulas for calculating the mean velocity of flow through a pipe or tube are approximate. The following is a formula for low viscosity liquids that will yield results within 5-10% of actual if applied to carefully laid pipe in fair condition:

$$v = C \sqrt{\frac{hd}{L + 54d}}$$

where  $C$  is taken from **Table 22**,  $h$  is total head in feet,  $d$  is the inside diameter of a round pipe in feet, and  $L$  is the total length of the pipe in feet. Length, where pressure drop due to bends and fittings is a factor, is equivalent length. See *Energy Loss in Pipe and Tube Bends* on page 2700, and *Energy Loss in Fittings and Valves* on page 2701 for more on this topic.

For air, the following velocity equation can be used to estimate flow:

$$v = \sqrt{\frac{25,000 dp}{L}} \quad p = \frac{Lv^2}{25,000 d}$$

where  $v$  = velocity of air in feet per second

$p$  = loss of pressure due to flow through the pipes in ounces per square inch

$d$  = inside diameter of pipe in inches

$L$  = length of pipe in feet

**Table 22. Values of Coefficient C**

Dia. of Pipe		C	Dia. of Pipe		C	Dia. of Pipe		C
Feet	Inches		Feet	Inches		Feet	Inches	
0.1	1.2	23	0.8	9.6	46	3.5	42	64
0.2	2.4	30	0.9	10.8	47	4.0	48	66
0.3	3.6	34	1.0	12.0	48	5.0	60	68
0.4	4.8	37	1.5	18.0	53	6.0	72	70
0.5	6.0	39	2.0	24.0	57	7.0	84	72
0.6	7.2	42	2.5	30.0	60	8.0	96	74
0.7	8.4	44	3.0	36.0	62	10.0	120	77

The quantity of air discharged in cubic feet per second is the product of the velocity as obtained from the preceding formula and the area of the pipe in square feet. The horsepower required to drive air through a pipe equals the volume of air in cubic feet per second multiplied by the pressure in pounds per square foot, and this product divided by 550.

**Volume of Air Transmitted Through Pipes, in CFM**

Velocity of Air in Feet per Second	Actual Inside Diameter of Pipe, Inches									
	1	2	3	4	6	8	10	12	16	24

**Flow of Compressed Air in Pipes.**— When there is a comparatively small difference of pressure at the two ends of a pipe, the volume of flow in cubic feet per minute is found by the formula:

$$V = 58 \sqrt{\frac{pd^5}{WL}}$$

where  $V$  = volume of air in cubic feet per minute

$p$  = difference in pressure at the two ends of the pipe in pounds per square inch

$d$  = inside diameter of pipe in inches

$W$  = weight in pounds of one cubic foot of entering air

$L$  = length of pipe in feet

**Flow in Branched (Parallel) Pipes.**— Pipe systems commonly have parallel sections to allow some fluid to bypass a component. The principle of continuity dictates that in a steady flow situation, total flow into a branched system is equal to total flow exiting the branched system. The following are the governing equations for branching pipe systems.

$$Q_i = A_1 v_1 + A_2 v_2$$

where  $Q_i$  is the total flow rate entering the branching system.  $A_1$  and  $v_1$  are the cross sectional area and flow velocity of the first branch, and subscript 2 refers to the second branch.

Head loss is equal in all branches and equal to the total head loss across the network:

$$h_L = h_{L1} = h_{L2}$$

**Energy Loss in Pipes.**— As fluid moves through straight pipe and tube, some energy is lost to friction. The relationship between pressures and velocities at two ends of a pipe is governed by Bernoulli's equation:

$$\frac{p_1}{\gamma_1} + \frac{v_1^2}{2g} + z_1 = \frac{p_2}{\gamma_2} + \frac{v_2^2}{2g} + z_2$$

where  $p$  is pressure,  $v$  is velocity,  $z$  is elevation, and  $g$  is acceleration due to gravity.

For inviscid, incompressible liquid flow moving through a pipe, Bernoulli's equation simplifies because the specific weight of the fluid is assumed to be the same at both points of interest.

*Darcy-Weisbach Equation and the Moody Diagram:* This equation can be used to calculate friction loss in Newtonian liquids for all flow regimes. It requires the use of a friction factor, which is dimensionless and can be determined using the equation for laminar flow, the Colebrook equation for turbulent flow, or graphically through the use of the Moody diagram (Fig. 18). The Darcy-Weisbach equation is:

$$h_L = \frac{fLv^2}{2gD}$$

where  $h_L$  is head loss in units of length,  $L$  is pipe length,  $v$  is average fluid velocity,  $D$  is inside diameter of the pipe, and  $f$  is the friction factor.

The friction factor for laminar flow is  $f = \frac{64}{Re}$ . The Colebrook equation for turbulent

flow is  $\frac{1}{\sqrt{f}} = -2 \log_{10} \left( \frac{\epsilon}{3.7D} + \frac{2.51}{Re \sqrt{f}} \right)$  where  $\epsilon$  is the pipe roughness, and  $D$  is the inside

diameter. This applies when the pipe is completely full of fluid. Calculators are available online for this factor, or it can be solved numerically.

Moody's diagram was generated experimentally. A chart of surface roughness of common pipe and tube materials can be found in Table 23 for use with the turbulent flow equation and Moody diagram.

**Table 23. Surface Roughness of Common Pipe and Tube**

Material	Surface Roughness		Material	Surface Roughness	
	ft × 10 <sup>-6</sup>	m × 10 <sup>-6</sup>		ft × 10 <sup>-6</sup>	m × 10 <sup>-6</sup>
Glass	0.0003	0.0001	Ductile Iron (Coated)	400	120
Plastic	0.0003–0.0023	0.0001–0.0007	Concrete (Smooth)	400	120
Drawn Metal Tubing	5	2	Galvanized Iron	500	150

Fig. 18. Moody Diagram

**Hazen-Williams Equation for Water Flow:** For the special case of 60°F water in pipes between 2 inch and 6 feet in diameter, at velocities less than 10 ft/s, the Hazen-Williams formula or nomograph (Fig. 19) can be used. The coefficient values of common pipes can be found in Table 24. The nomograph is read by aligning a straightedge with the known values and reading the unknowns at the intersection points. The Hazen-Williams formula for US units is:

$$v = 1.32 C_h R^{0.63} \left( \frac{h_L}{L} \right)^{0.54}$$

where  $v$  is average velocity (ft/s),  $R$  is hydraulic radius (ft),  $L$  is length of pipe (ft),  $h_L$  is head loss (ft), and  $C_h$  is the Hazen-Williams coefficient (see Table 24). The Hazen-Williams formula for SI units, with  $R$ ,  $h$ , and  $L$  in meters, and  $v$  in m/s is:

$$v = 0.85 C_h R^{0.63} \left( \frac{h_L}{L} \right)^{0.54}$$

A solution of the Hazen-Williams equations may be found by use of the nomograph in Fig. 19, based on the Hazen-Williams formula and using  $C_h = 100$ . For larger or smaller values of  $C_h$ , the discharge or velocity obtained from the nomograph is multiplied by the ratio of the given value of  $C_h$  to 100. If the discharge or velocity is given, it should be multiplied by the ratio of 100 to the known value of  $C_h$  before the nomograph is used.

*Example:* By using Fig. 19, determine the discharge, in cubic feet per second (cfs), from a 12-inch pipe for which  $C_h = 120$  when the loss of head is 5 feet per 1000 feet.

*Solution:* The discharge corresponding to the given diameter and loss of head for a value of  $C_h = 100$  is found first. A straightedge passing through 12 on the diameter line and 5 on the loss-of-head line will intersect the discharge line at 2.5 cfs. Therefore, the discharge is  $2.5 \times 120 = 3.0$  cfs.

Fig. 19. Nomograph for Hazen-Williams equations in which  $C_h = 100$ .

**Table 24. Hazen-Williams Coefficient, Selected Values**

Pipe Type	$C_h$	Pipe Type	$C_h$
Corrugated Metal	60	Copper	130 – 140
ABS Plastic	130	Drawn metal	130 – 140
Aluminum	130 – 150	Ductile iron pipe	140

Concrete	100 – 140		
lined, steel forms	140		
lined, wooden forms	120		

**Energy Loss for Gas Flow:** Bernoulli's equation can be applied to examine pressure loss for gas flow through pipes. Gas flowing through pipes can be considered incompressible and treated like a liquid if the pressure ratio is small enough. Pressure ratio is calculated using the following equation. Engineering judgment should be used when applying this equation. In different industries, different values are used to make the decision how to treat gas flow.

$$PR\% = 100 \left( \frac{p_1 - p_2}{p_1} \right)$$

where  $p$  is pressure at the point of interest and  $PR\%$  is the pressure ratio.

Pressure drop for gas flow in pipes can be calculated most easily if certain assumptions are made. One can assume flow is isothermal, the gas is perfect, the pipe is straight and horizontal, the friction factor is constant, and flow is steady. This simplifies the pressure drop equation to the following form:

$$p_i^2 - p_o^2 = Z_m RT \left( \frac{\dot{m}}{A} \right)^2 \left( f \frac{L}{D} \right)$$

where  $p_i$  and  $p_o$  are the inlet and outlet pressures,  $Z_m$  is the mean compressibility factor,  $R$  is the gas constant,  $T$  is temperature,  $A$  is pipe cross sectional area,  $f$  is the friction factor,  $L$  is pipe length,  $D$  is inner diameter, and  $\dot{m}$  is mass flow rate.

Alternative methods of calculation include the Weymouth and Panhandle formula, and the Renouard equation for natural gas flow.

**Energy Loss in Pipe and Tube Bends.**— The energy lost by fluid in a pipe bend is caused by both friction and momentum changes as the direction of flow changes. This loss depends on the bend angle, the curvature ratio (bend mean radius divided by pipe diameter,  $R/D$ ), the roughness of the pipe, and the angle of bend. To compute the energy lost by liquids in bends, use the following equations and [Table 25](#).

$$h_l = K_b \frac{V^2}{2g} \quad K_b = f \frac{L_e}{D}$$

where the head loss,  $h_l$ , is expressed in units of length;  $V$  is the average velocity in the pipe; and  $K_b$  is the bend loss coefficient;  $f$  is the friction factor given in the Moody diagram, ([Fig. 18](#)); and  $L_e/D$  is given in [Table 25](#).  $K_b$  increases with relative roughness (or screwed connections) and bend angle, but decreases with the curvature ratio.

**Table 25. Bend Equivalent Length Ratio,  $L_e/D$** 

Bend Type	Bend Angle	$R/D$	$L_e/D$	Bend Type	Bend Angle	$R/D$	$L_e/D$
Radius Bend	90°	1	20	Miter Bend	30°	...	8
		2	12		45°	...	15
		3	12		60°	...	25
		4	14		90°	...	60
		6	17		Close Return Bend	180°	...
		8	24				
		10	30				
		12	34				
		16	42				

$R/D$  is the bend mean radius divided by pipe diameter

The loss of head due to a bend in the pipe is most frequently given as the equivalent length of straight pipe, which would cause the same loss in head as the bend. Experiments show that a right-angle bend should have a radius of about three times the diameter of the pipe. Assuming this curvature, then, if  $d$  is the diameter of the pipe in inches, and  $L$  is the length of straight pipe in feet that causes the same loss of head as the bend in the pipe, the following formula gives the equivalent length of straight pipe that should be added to simulate a right-angle bend:

$$L = 4d \div 3$$

**Energy Loss in Fittings and Valves.**— There are two standard ways to calculate the energy lost in fittings and valves: the resistance coefficient method, and the equivalent length method. The method chosen will depend on what information is provided with the fitting to be analyzed.

*Resistance Coefficient Method:* Resistance coefficients are commonly reported by the manufacturers of liquid fittings and valves. The following equations and **Table 26** (or manufacturer's data) can be used to calculate friction loss in terms of resistance coefficient. There are methods that use up to 3 different resistance coefficients to improve the accuracy of the calculation.

$$h_l = K_F \left( \frac{v^2}{2g} \right) \quad K_F = f \frac{L_e}{D}$$

where  $v$  is average velocity,  $h_l$  is head loss in units of length,  $K_F$  is the resistance coefficient for the fitting or valve,  $f$  is the friction factor given in the Moody diagram, **Fig. 18**, and  $L_e/D$  is the equivalent length ratio given in **Table 26**.

**Table 26. Equivalent Length Ratio ( $L_e/D$ ) for Liquid Fittings and Valves**

Fitting or Valve Type	$L_e/D$	Fitting or Valve Type	$L_e/D$
Elbow	30	Swing Check Valve	100
Street Elbow	50	Ball Check Valve	150
Long Radius Elbow	20	Foot Valve (hinged)	75
45° Elbow	16	Ball Valve	3
Close Return Bend	50	Gate Valve	8
Tee (Flow Thru Run)	20	Gate Valve, 1/2 Closed	160
Tee (Flow Thru Branch)	60	Butterfly Valve (< 8")	45
		Globe Valve	340

Valves fully open unless otherwise specified.

**Equivalent Length Method:** Pressure loss can be calculated for systems based on the equivalent length of straight pipe representing all pipe, fittings, and valves in the circuit. Equivalent lengths of some common fittings and valves for liquids can be found in [Table 27](#).

**Table 27. Equivalent Length in Feet of Selected Pipe Fittings and Valves for Liquid**

Nominal Pipe Size (in.)	Elbows					Standard Tee		
	90° Std.	45° Std.	90° Long Radius	90° Street	45° Street	Square Corner	Flow thru Run	Flow thru Branch
¼	0.9	0.5	0.6	1.5	0.8	1.7	0.6	1.8
½	1.6	0.8	1.0	2.6	1.3	3.0	1.0	4.0
¾	2.1	1.1	1.4	3.4	1.8	3.9	1.4	5.1
1	2.6	1.4	1.7	4.4	2.3	5.0	1.7	6.0

6	15.2	8.1	12.5	25.3	13.1	28.8	12.5	32.2
8	20.0	10.6	16.5	33.3	17.3	37.9	16.5	39.9
10	25.1	13.4	20.7	41.8	21.7	47.6	20.7	50.1
12	29.8	15.9	24.7	49.7	25.9	56.7	24.7	59.7

Energy loss, in terms of pressure, for gas flow through fittings is often found using tabulated values of pressure drops for fittings of different sizes. The equivalent length method can also be used, with pressure loss calculated in terms of the total equivalent length of all pipe and fittings. [Table 28](#) includes some equivalent lengths of selected pneumatic fittings and valves.

**Table 28. Selected Pneumatic Fittings and Valves, Equivalent Lengths**

Pipe Size, inch	Elbow	Long Radius Elbow	Close Return Bend	Gate Valve	Globe Valve
½	0.84	0.41	1.30	0.31	2.50
¾	1.20	0.57	1.80	0.44	3.50
1	1.60	0.77	2.30	0.57	4.70

2	3.60	1.70	5.30	1.30	10.60
3	5.70	3.00	8.50	2.10	17.10
4	7.90	3.90	11.80	3.00	23.70

**Entrance, Exit, Enlargement, and Contraction Losses for Subsonic Flow.**— Any change in diameter of a pipe will cause energy losses in the fluid.

**Sudden Enlargement:** Sudden enlargement of a pipe or tube causes minor losses due to turbulence. The friction loss, in terms of head, due to sudden enlargement can be approximated using the following equations:

$$h_l = \frac{(v_i - v_o)^2}{2g} = K \left( \frac{v_i^2}{2g} \right)$$

$$K = \left[ 1 - \left( \frac{A_i}{A_o} \right) \right]^2$$

where head loss  $h_l$  is measured in units of length;  $v_i$  is velocity entering the enlargement;  $v_o$  is velocity leaving the enlargement;  $K$  is the loss coefficient for sudden enlargement;  $A_i$  and  $A_o$  are the areas before and after the enlargement. The equation for  $K$  is only valid if velocity at the inlet is less than 4 ft/sec (1.2 m/s). For faster flow rates, a graph of experimentally determined  $K$  values must be used.

**Gradual Enlargement:** Gradual enlargement causes less energy loss than sudden enlargement because it causes less turbulence. Diffusers are gradual enlargement devices. Velocity decreases while pressure increases. Gradual enlargements generally have a conical section that joins two different pipe diameters. The divergence angle is the included angle in the cone. The following two equations give approximations of head loss in a gradual enlargement.  $K_L$  is the Gibson loss coefficient (see Fig. 20).  $K_D$  is the resistance coefficient (see Fig. 21). Both depend on the ratio of areas and the angle of divergence. The formulas to calculate this loss ignore the effects of friction inside the conical section. If the enlargement is very gradual, the effects of friction can become significant. Therefore, an included angle of  $6^\circ$  or more is recommended in the conical section to mitigate the effects of friction. For area ratios up to 6:1 with angles of divergence of  $40^\circ$  or more, head loss may be less with a sudden expansion than with a gradual one. These two effects are clearest on the graph of  $K_L$  (Fig. 20).

$$h_l = K_D \frac{v_i^2}{2g} \quad h_l = K_L \frac{(v_i^2 - v_o^2)}{2g}$$

Fig. 20. Head Loss Coefficient  $K_L$ , Conical Diffuser

**Sudden Contraction:** Sudden contraction causes energy loss due to turbulence. This head loss can be calculated by using the following equation and Fig. 22. Because loss varies with the square of velocity, small changes in flow can greatly affect energy loss.

$$h_l = K_C \frac{v_o^2}{2g}$$

where  $v_o$  is the velocity at the outlet and  $K_C$  is the loss coefficient.  $D_i/D_o$  is the ratio of the inlet diameter to the outlet diameter.

## ENERGY LOSSES FOR SUBSONIC FLOW

Fig. 21. Head Loss Coefficient  $K_D$ , Conical DiffuserFig. 22. Head Loss Coefficient  $K_C$ , Sudden Contraction

**Gradual Contraction:** Gradual contraction, like gradual enlargement, reduces losses by reducing turbulence. Like with gradual enlargement, if the angle is shallow enough, friction losses become significant. Included angles greater than  $15^\circ$  avoid this effect. Good performance can be achieved with included angles as high as  $60^\circ$ . To approximate head loss due to gradual contraction, use the following equation and Fig. 23.

$$h_l = K_G \frac{v_o^2}{2g}$$

where  $v_o$  is the velocity at the outlet and  $K_G$  is the loss coefficient.  $D_i/D_o$  is the ratio of the inlet diameter to the outlet diameter. By rounding the exposed edge of the contraction, one can reduce the head loss even further.

Fig. 23. Head Loss Coefficient  $K_G$ , Conical Gradual Contraction

**Exit Loss:** Discharge into a static volume of fluid causes minor losses as the fluid loses its kinetic energy as its velocity drops to zero. This is called exit loss, and is calculated in terms of head using the following equation:

$$h_l = \frac{v_i^2}{2g}$$

where  $v_i$  is the velocity in the pipe before entering the reservoir.

**Entrance Loss:** Entrance into a pipe from a static volume of fluid causes energy loss due to contraction turbulence. This is called entrance loss, and it is reduced by breaking the corners of the inlet with chamfers, or preferably, radii. Entrance head loss is calculated using the following equation and Table 29.

$$h_l = K_E \frac{v_o^2}{2g}$$

where  $v_o$  is the velocity in the pipe exiting the reservoir, and  $K_E$  is the resistance coefficient for entrance.

**Table 29. Entrance Head Loss Coefficient,  $K_E$** 

Condition	$K_E$	Condition	$K_E$

### Fluid Power Valves

There are many types of pneumatic and hydraulic valves. Valves can be normally open or normally closed. Normally open valves allow flow when the valve is not energized. Normally closed valves block flow when not energized. Valves may be actuated manually or automatically. Automatic valves typically change state using solenoids, often assisted by energy from either internal or external pilot pressure. An external pilot supply should be used to control valve when the supply pressure to the valve is insufficient to shift the valve or when the medium being controlled by the valve would damage the shifting mechanism.

Automatic valves can be equipped with manual overrides which permit the operator to actuate the valve manually.

**Valve Types.**— There are many valves types commercially available. The most common types are check valves, foot valves, ball valves, gate valves, globe valves, butterfly valves, relief valves, and directional control valves.

*Check Valves and Foot Valves:* Check valves are constructed to allow flow in one direction and stop flow in the other direction. This type of valve is essential in pipe and tube systems where backflow could cause damage or flooding. The two most common types of check valves are ball type and swing type. Ball check valves create a higher energy loss due to restriction around the ball. Check valves have a “minimum cracking pressure” that is the pressure required to open the valve and allow flow. This may be expressed as a minimum pressure or a minimum flow velocity, depending on the application.

Foot valves are commonly used on the intake lines of pumps that draw fluid from an open reservoir. They are comprised of a check valve outfitted with a low-loss strainer to keep out debris. The strainer should be cleaned regularly to prevent suction line restriction.

*Restriction Valves:* There are several types of valves that are used to reduce flow or to stop flow entirely. Ball valves contain a sphere with a hole through it inside the valve body. When the sphere is turned, the through-hole can be aligned to allow full flow or to obstruct flow partially or completely. These valves are fully actuated with one quarter turn, and are typically used for on/off control rather than throttling. Gate valves have a blade or gate that is cranked into or out of the flow path to allow full flow, partial flow, or no flow. Globe valves are true throttling valves, and can be used even in high flow applications. Due to their design, they cause a significantly higher pressure drop than other types of valves, even when fully open. Butterfly valves consist of a disk that can be turned to fully or partially block flow. When fully open, the disk is still in the flow path, but is turned to present its edge to the flow.

*Relief Valves:* Pressure relief valves are used to protect the fluid circuit and its components from dangerously high pressures. A pressure relief valve opens to relieve pressure at a predetermined set point. These valves can be selected such that they close again when the system pressure has returned to a safe level. Since pressure relief valves are safety devices, their design and use is covered by various codes. The information and calculations required to properly size pressure relief valves is quite extensive and beyond the scope of this text. Most major pressure relief valve manufacturers also offer sizing software. In liquid pumping systems, the relief valve should discharge to the suction reservoir in a way that prevents gases from entering the suction line to the pump.

*Directional Control:* Directional control valves are used to change the direction of flow. They can also be used to stop and start flow. Directional control valves are functionally described in terms of the number of ports, the number of positions (usually 2 or 3), the number of paths (passing and non-passing) the fluid can take through the valve, and the valve's de-energized state. The number of paths the fluid can take through the valve is said to be the number of “ways.” Three way valves have one output and four way valves have two outputs. Generally, three way valves operate single acting linear actuators and four way valves operate double acting linear actuators. Some of the most commonly used directional control valves are:

- Two port, two position (2/2) two way valves have one inlet and one outlet port. They perform a basic on/off function.
- Three port, two position (3/2) two way valves have one inlet, one outlet, and one exhaust port. These valves switch flow between inlet and exhaust, and are commonly used to pressurize and exhaust a single actuator supply line.
- Five port, two position (5/2) four way valves are typically used to control pressure and exhaust to two output lines. This is ideal for controlling double acting cylinders. 5/2 valves are also available with four ports. Five ported valves have separate exhaust ports

for each supply port. Flow controls can be installed on each exhaust port and thus the speed of an actuator can be controlled in each direction.

- Five port, three position (5/3) four way valves also can control pressure and exhaust to two output lines. These valves often have the center position normally closed when the valve is de-energized. This valve is also excellent for control of double acting cylinders. The closed position makes it possible to 'jog' actuators.

Directional control valves can be either manually controlled or automatically controlled. Manual control valves are outfitted with buttons, levers, or knobs. Automatic control valves are electrically operated solenoids. Solenoid valves are most commonly actuated using spools or poppets. These valves can be single or double acting. Single acting valves normally have spring returns. Double acting valves use fluid pressure on either side of the valve to actuate back and forth.

Automatic control valves can be either direct acting or pilot operated. Direct acting solenoid valves open and close the valve. They are used in systems with low flow capacities or low pressure differentials across the valve. The sealing surface that opens and closes the main valve orifice is connected to the solenoid plunger. Direct acting valves can operate with a zero pressure differential, or up to the maximum rated pressure differential (MOPD) regardless of fluid pressure. Pressure drop across the valve is not required to hold the valve open.

Pilot operated valves use system fluid pressure to open and close the valve. In a normally closed valve, the sealing surface is opened when the pilot is energized. When a normally open valve is energized, fluid pressure builds up behind the sealing surface, forcing it to close the valve. Pneumatic solenoid valves are generally pilot operated. When vacuum or air with insufficient pressure is the medium, separate pilot lines must be provided with sufficient positive pressure to actuate the valve.

**Energy Loss in Valves.**— Energy is lost in all valves due to restriction, friction, and changes in direction of flow. The type of valve and its specific geometry will determine the amount of energy lost. Manufacturers will generally provide equivalent length of straight pipe values or resistance coefficients for their valves. Equivalent length is added to the pipe circuit when calculating pressure drop through the system. Resistance coefficient  $K$  is used in previous equations for friction loss. Some values for equivalent lengths are given in [Tables 27 and 28](#).

**Valve Selection and Sizing.**— Valves should be selected by first considering their function and selecting a type. Compatibility with the fluid must be carefully evaluated, since most valves include seals and mechanical components of different materials. The temperature and pressure range of the system should be taken into account. The cleanliness of the fluid matters when selecting valves with small or sensitive internal components. A fluid filter (with its own pressure drop) may be required. Pressure drop across the valve should be examined at the operating flow rate to determine if it meets the valve's minimum pressure differential requirement in the case of pilot operated valves.

Valves are usually sized based on Coefficient of Velocity ( $C_v$ ). These values are normally listed in manufacturer's catalogs.  $C_v$  and its calculation is covered in *Coefficient of Velocity,  $C_v$*  on page 2678. Using  $C_v$  to size valves is industry standard practice, but be aware that it is only an approximation. Energy loss in the circuit due to pipe and tubing runs, fittings, and other components will cause deviation of system performance from ideal. Valve switching response time can also be a factor to consider when selecting a valve. To select the proper size valve for an actuator to perform a specific task, first calculate the  $C_v$  of the actuator, and then select a valve that has a corresponding or greater  $C_v$ .

### Fluid Power Actuators

**Linear Actuators.**— When a gas, typically air, is used in a linear actuator, it is called a gas cylinder or air cylinder. When a liquid is used, it is typically called a hydraulic ram or cylinder. These are essentially the same in form and function. Linear actuators can be either single or double acting.

*Single Acting Cylinders:* Single acting actuators with spring return use a spring to push the actuator to its free state when fluid pressure is removed. The free state of a single acting cylinder is usually fully retracted. A fluid pressure differential is used to extend the cylinder. Single acting cylinders use half the fluid of double acting cylinders. Single acting cylinders can be actuated with three way valves.

*Double Acting Cylinders:* These cylinders require pressure differentials on both the extend and retract strokes. When pressure equalizes across the cylinder, the state of the actuator becomes indeterminate. Double acting cylinders are most commonly actuated using four way valves. Double acting cylinders use twice the fluid of single acting cylinders, which matters most in pneumatic applications where that air is exhausted and lost.

*Selection of Linear Actuators:* Linear actuators are available with a variety of options. In addition to single and double acting versions, some cylinders are available with a magnet embedded in the piston to enable position sensing. For applications with side loading, a double rod cylinder or external bearing may be needed. When a cylinder is guiding a load that should not rotate, anti-rotation options such as a non-round rod or integral guide rods are commonly used. For heavy loads or high speeds, internal or external end cushions are usually offered to soften the impacts and allow the cylinder to withstand higher kinetic energy movements.

*Force Exerted by Linear Actuators:* The force exerted by a linear actuator is calculated using the following equation:

$$F = \eta p A$$

where  $\eta_{\text{hydraulic}} = 0.9$  and  $\eta_{\text{pneumatic}} = 1$ , and  $A$  is the effective area of the cylinder. Effective area on the retract stroke is the piston area minus the rod area.

It is good practice to oversize the load-carrying capacity of an actuator by 25% to ensure smooth operation and account for losses in the system. For high speed operation, oversizing by 50% is not uncommon. For a spring return cylinder, the force on the retraction stroke will be equal to the spring force rather than a function of air pressure. For applications where rapid retraction speed is critical, double acting cylinders may be the best choice.

*Speed of Linear Actuators:* The speed achieved by an unloaded linear actuator depends on the effective area of the cylinder and the flow rate of the fluid. Actuation velocity can be calculated for an unloaded cylinder using the following equation:

$$v = \frac{231 Q}{A}$$

where  $v$  is velocity in inches per minute,  $Q$  is flow rate in gallons per minute, and  $A$  is piston active area in square inches. Active area is reduced by the area of the rod when a rod is present on the acting side of the cylinder.

Most manufacturers provide graphs of actuator speed vs. loading for their products. Fluid supply can be characterized by Coefficient of Velocity ( $C_v$ ) factor. Valves and circuits with a higher  $C_v$  will be capable of moving an actuator faster because they can provide more air flow.

If the  $C_v$  of a valve and other system components is known, it can be used to determine the time required to extend or retract a cylinder. It is common to oversize the speed of an actuator by 25% in critical applications to account for losses.

**Kinetic Energy and Linear Actuators:** Kinetic energy is generated when a load is moved. When a moving load is stopped, the kinetic energy is absorbed by the mechanism that stops it. Actuators can have either internal or external stops. External stops can generally withstand greater impacts than internal stops. Manufacturers normally publish the kinetic energy limits of their actuators.

**Safe Loading of Linear Actuators:** Rod failure and piston wear is of concern when linear actuators are used in compression or are subjected to side loading. Side loading can be a result of external forces, eccentrically mounted loads, or mounting and operating a cylinder at some angle rather than vertical. It is critical to align connections to a cylinder such that side loading due to misalignment or eccentric loading is minimized. Compliant connections are often used to eliminate overconstraint and resultant loading. When rod bending or buckling is a risk, the use of external bearings or double rod cylinders can help reduce the risk. For horizontal cylinder installations, center trunnion mounting can help reduce the side loading on the cylinder. Another way to reduce premature failure due to side loading is to limit the extension stroke of a cylinder so that it cannot fully extend.

The potential for buckling must be evaluated for any cylinder in compression. To increase the buckling strength of a cylinder, increase the piston rod diameter. Critical buckling load is calculated as shown in the following equation.

Equivalent length is used to calculate critical buckling load rather than actual rod length. The equivalent length is dependent on the end conditions of the cylinder. The length  $L$  used to calculate equivalent length is assumed to be the distance at maximum extension between the exposed end of the piston rod and the nearest point of fixation.

$$F_{cr} = \frac{\pi^2 EI}{L_e^2} \quad I = \frac{\pi r^2}{4}$$

where  $F_{cr}$  is the critical buckling load,  $E$  is the modulus of elasticity for the rod material, and  $L_e$  is given in **Table 30**.

**Table 30. Equivalent Length, Linear Actuator**

Actuator and Load Fixations	Equivalent Length $L_e$
Actuator Rigidly Mounted, Load Free	$2L$
Actuator and Load Pin Connected	$L$
Actuator Rigidly Mounted, Load Pinned	$0.7L$
Actuator and Load Rigidly Mounted	$0.5L$

**Intensifiers and Hydraulic Presses.**— Intensifiers use the energy in a relatively large volume (work cylinder) of moderate pressure fluid to displace a smaller piston (ram). The two pistons are usually mechanically linked, so their stroke is the same. Intensifiers will hold a fixed pressure without additional input energy. The intensifier ratio, output pressure, and stroke are found using the following equations.

$$R_I = \frac{p_o}{p_i} \quad p_o = \frac{p_i A_i}{A_o} \quad S_1 = \frac{V_w + V_C}{A_r} + l$$

$$V_C = 0.1 V_{oil} \frac{P_r}{1000} \quad S_2 = \frac{V_o + V_C}{A_r} + X + l$$

where  $R_I$  = the intensifier ratio

$p_o$  and  $p_i$  = output and input pressures

$A_o$  and  $A_i$  = the two different piston areas

$S_1$  = the stroke of a single pressure intensifier

$V_w$  = the volume of the work cylinder

$V_C = 0.1 V_{oil} \frac{P_r}{1000}$  is the compressibility allowance, where  $p_r$  is the pressure in the high pressure circuit, and  $V_{oil}$  is the total volume of oil in the high pressure circuit

$l$  = any pretravel of the work cylinder required

$A_r$  = the area of the ram

$S_2$  = the stroke of a dual pressure intensifier

$V_o$  = the oil volume required to move the work cylinder through the high pressure portion of the stroke

$X$  = the stroke required to close the high pressure seal on the intensifier (often assumed to be 2 inches)

Intensifiers can be either pneumatically driven or fully hydraulic. Fully hydraulic intensifiers are more efficient than air driven ones. They operate on the same principle, with liquid used on both sides of the actuator. Commercial hydraulic intensifiers are generally powered by electric motors or diesel engines. Hydraulic intensifiers can be either single or dual pressure. A single pressure intensifier is used when the work cylinder requires a high pressure for the entire stroke. A dual pressure intensifier is recommended if the high pressure is required only during the last portion of the work cylinder stroke. For best economy, select the smallest driving cylinder bore size for a given intensifier ratio. Minimize pressure losses by keeping lines short and by sizing lines and fittings as large as practical. Size the lines so that fluid velocity does not exceed 7 ft/sec. Self-bleeding boosters be used wherever possible to ensure that air does not build up in the system and cause "spongy" operation.

Hydraulic presses, like intensifiers, use two pistons of different diameters. They operate on a shared fluid volume. When a force is applied to the small cylinder to create pressure, that pressure is reflected in the large cylinder. When the large cylinder is exposed to high pressure, it can exert a lot more force than was applied to the small cylinder. The mechanical advantage of the press is the ratio of output to input force. Hydraulic presses are subject to the following equations:

$$p_1 = p_2 = \frac{F_1}{A_1} = \frac{F_2}{A_2} \quad F_1 s_1 = F_2 s_2 \quad R = \frac{F_1}{F_2} = \frac{A_1}{A_2} = \frac{s_1}{s_2}$$

where  $F$  is force,  $p$  is pressure, and  $A$  is area,  $s$  is stroke, and  $R$  is the gear ratio of the press. Note that the stroke of the smaller diameter cylinder will be greater than that of the larger diameter cylinder.

**Rotary Actuators.**— These actuators use fluid pressure to induce rotary motion, and tend to be double acting. Rotary actuators can have either internal or external stops. External stops can generally withstand greater impacts than internal stops. Stops on rotary actuators are often adjustable. Rotary actuators can be hydraulic, pneumatic, or a combination of both.

*Types:* Rotary actuators come in two main types: vane and rack and pinion. Vane type actuators offer the smallest package and zero backlash, but are usually capable of only up to 270° of rotation. They employ a rotary vane mechanism to turn the actuator under fluid pressure. Rack and pinion actuators use one or more linear actuators to move racks back and forth, thereby turning a pinion shaft. They can be outfitted to have multiple stopping positions, and are capable of 360° rotation. Many packaging options are available for both vane and rack and pinion types, with many mounting and output shaft options.

*Sizing Rotary Actuators:* When sizing rotary actuators, one must know the accuracy and actuation time required, the required angle of rotation, any resisting torque, and the moment of inertia of any mass loading about the center of rotation. Torque values for both directions of rotation as a function of input pressure are normally provided by manufactur-

ers. Manufacturers sometimes publish the  $C_v$  of their actuators, or it can be calculated using the rotary swept volume. Kinetic energy is of particular concern with rotary actuators. Manufacturers normally publish the kinetic energy limits of their actuators. Although cushions are normally provided as part of rotary actuators, it is recommended to use proportional valves to decelerate rotating loads where loading is significant. Kinetic energy is calculated using the following equation:

$$KE = \frac{1}{2}I\omega^2$$

where  $\omega$  is the angular velocity (peak) in radians/sec, and  $I$  is the mass moment of inertia of the load carried on the rotary actuator shaft.

**Shock Absorbers and Hydraulic Dampers.**— These devices are special types of linear actuators that are used to control applied loads. Pneumatic and hydraulic types are commercially available. All have frequency limitations that should be examined when sizing them for an application.

*Pneumatic Shock Absorbers and Gas Springs:* Pneumatic shock absorbers and gas springs use the compressibility of gas (usually nitrogen) to resist an applied force. Shock absorbers are used to decelerate an applied load over a distance, and are generally quite small. Gas springs are used mostly to counterbalance loads and often have very long strokes. Some gas springs have intermediate holding positions.

Shock absorbers are normally used when no return assistance is required and no restriction of velocity is required. There are some available with an orifice in the piston that provides velocity control. Shock absorbers often have a spring to provide a return function and assist in decelerating loads. They also usually have a mechanical stop, such as an adjustable nut, to prevent overcompression.

Shock absorbers are sized according to impact speed, stroke, and energy absorbing capacity. The energy absorbed will be the sum of the kinetic energy of the moving load and any external thrust provided by a driving mechanism. Vertical applications will also need to resist the weight of the applied load. Kinetic and thrust energies are calculated using the following equations:

$$E_{total} = KE + E_t$$

$$KE = \frac{1}{2}mv^2 = \text{Kinetic energy of a linear impact, where } m \text{ is mass and } v \text{ is velocity.}$$

$$E_t = Fs = \text{Thrust energy of a linear impact, where } F \text{ is applied force and } s \text{ is the shock absorber stroke.}$$

$$KE = \frac{1}{2}I\omega^2 = \text{Kinetic energy of a rotary impact, where } I \text{ is moment of inertia and is angular velocity.}$$

$$E_t = \frac{Ts}{R} = \text{Thrust energy of a rotary impact, where } T \text{ is applied torque and } R \text{ is radius from the moment center and impact point.}$$

$$KE = mgh = \text{Kinetic energy of a falling weight impact, where } m \text{ is mass and } h \text{ is height.}$$

$$E_t = mgs = \text{Thrust energy of a falling weight impact.}$$

Gas springs are used when return assistance or load support (counterbalance) is required throughout the range of motion. If the gas spring is the quick return type, the force increases as the piston moves. If an orifice is present in the piston through which the gas can escape, they can limit velocity and provide a more constant force over the full stroke.

Gas springs can be either push or pull (tension or traction) type, depending on where the gas chamber is relative to the piston rod. Gas springs usually have a reservoir of oil near the rod outlet of the cylinder that is used to lubricate the rod seal. They are designed to be stored and installed with the rod pointing down, at an angle of 60° or less from vertical to ensure that the seal is lubricated. The oil also serves to dampen the end of stroke. When they cannot be installed rod down, special gas springs with provisions for lubrication are required. Due to their long, narrow form factor, side loading should be avoided.

Sizing gas springs is done with consideration of the required stroke, compressed length, diameter, compressed force, and extended force. Extended force is normally given at a point short of full extension because they should never be fully extended in operation to minimize the chances of buckling. Hysteresis is the difference between the actual and rated output force of a spring caused by friction. *K* factor, or progression, is the spring rate of a gas spring, and is calculated based on the following equation:

$$K = \frac{F_2}{F_1} \text{ where } F_2 \text{ is force at the compressed position, and } F_1 \text{ is the uncompressed force.}$$

Progression occurs because as the rod enters the chamber during compression, it reduces the available volume for the gas to occupy. This causes a pressure increase.

*Hydraulic Dampers (Hydraulic Shock Absorbers)*: These devices are used to safely control the speed of applied loads. Dampers consist of a piston in a pressure tube containing a hydraulic fluid. When force is applied to the piston rod to move the piston, the damping fluid must pass through orifices in the piston. As a result, the damping force is dependent on the piston speed. As the fluid is forced through the orifices, kinetic energy is converted into thermal energy. Using valving on the orifices, it is possible to regulate the damping forces in each direction independently. Hydraulic dampers are usually self-contained, sealed units. They can be single or double acting. In some designs, the damping speed is adjustable over a range by turning the rod while fully extended. Hydraulic dampers are sized according to diameter, stroke length, and required damping characteristics. When extreme speeds and forces are required, cavitation/foaming of the oil can introduce gas bubbles into the chamber and cause a drop in damping capacity.

### Hydraulics

**Hydraulic Fluids.**—Hydraulic systems use liquids as their medium. Water is a common hydraulic medium in general cases. When actuators are involved, petroleum based oils are the most common type of hydraulic fluid, but silicones, synthetics, and water based fluids are also common. Hydraulic fluids can be broken down in these major categories: hydraulic fluids based on mineral oils and related hydrocarbons (ISO 11158), environmentally acceptable hydraulic fluids (ISO 15380), fire-resistant, water-free hydraulic fluids (ISO 12922), and fire-resistant, water-containing hydraulic fluids (ISO 12922).

When selecting a hydraulic fluid, one must consider viscosity, viscosity index, lubricity, compressibility, flammability, foaming resistance, resistance to rust/oxidation, resistance to bacterial growth, pour point, flash point, chemical compatibility with system seals/components, cleanliness, cost, and environmental impact. The manufacturer of the hydraulic components should be consulted as well.

Viscosity at the required temperatures is the most important selection factor. Many petroleum products are graded according to the ISO Viscosity Classification System, approved by the international standards organization (ISO). Each ISO viscosity grade number corresponds to the mid-point of a viscosity range expressed in centistokes (cSt) at 40°C. A chart of viscosity related to the various systems of grading fluids is given in [Fig. 24](#).

**Fluid Conditioning and Stabilization.**—To provide useful work, fluid must have energy added in the form of pressure. Pumps are usually used to pressurize fluid, unless gravity

Viscosities can be related horizontally

Fig. 24. Hydraulic Fluid Viscosity Chart

The viscosity/temperature relationships are based on 95 VI oils and are usable only for mono grade engine oils, gear oils and other 95 VI oils. Crankcase oils and gear oils are based on 100°C viscosity. The “W” grades are classified mono grade engine oils, gear oils and other 95 VI oils. ISO oils and AGMA grades are based on 40°C viscosity.

can perform the needed energy. Strainers and filters are needed to keep contaminants out of sensitive components, and accumulators are used to stabilize the fluid pressure and act as reservoirs. In some cases, cooling must be provided, either passively or actively.

**Strainers and Filters:** Despite being closed systems, hydraulic circuits can become contaminated with particles due to component wear and incoming fluid contaminants. Filters are generally installed after a pump. Installation in the suction line, while more protective, would cause pressure loss in the suction line and jeopardize pump efficiency. An additional coarse strainer that creates very little pressure drop is often placed in the suction line to protect the pump. The pressure drop induced by a commercial filter is normally provided by the manufacturer.

Hydraulic filters must be capable of handling the pressures and temperatures encountered in the system.

Chemical compatibility of the filter membrane, body, and seals must also be considered. The filter must be rated for the maximum system flow rate and must be able to handle the viscosity of fluid used in the system. The allowable particle size that can pass through the filter will determine the membrane type. Hydraulic filters are available as in-line, in-tank,

and other configurations. Regular maintenance will be required, so filters must be chosen and installed to facilitate membrane replacement.

*Liquid Pulsation (Water Hammer):* Valves and reciprocating pumps are often the culprits when water hammer occurs. Water hammer is a pressure spike in a fluid circuit caused by a sudden stoppage of flow. A valve closing can cause a shock wave in the liquid, resulting in noise. Reciprocating pumps cause acceleration and deceleration of the fluid that result in pressure variations. Hydraulic water hammer can be severe enough to burst pipes. Pulsation dampeners are recommended when water hammer is likely. An equation for the pressure rise that can occur due to water hammer follows:

$$\Delta p = \frac{Q}{20d^2} \sqrt{SGb}$$

where  $p$  is pressure in psi,  $Q$  is flow rate in GPM,  $SG$  is specific gravity,  $b$  is bulk modulus in psi, and  $d$  is pipe inside diameter, in inches, upstream of the point of interest.

Accumulators and pulsation dampeners are used to store pressurized hydraulic fluid, which contains potential energy. This fluid and its energy can then be released to smooth out intermittent system cycles, dampen pulsations, absorb shocks, and compensate for leaks in the system.

*Accumulators:* Pressurization against an accumulation of fluid can be accomplished through weight loading, spring loading, or compressed gas loading. Hydro-pneumatic, or gas loaded, accumulators are the most common. The three most common of this class are piston, bladder, and diaphragm accumulators. In these, a piston, bladder, or diaphragm separates the fluid from the compressed gas.

When a hydro-pneumatic accumulator has a closed volume of gas, the change in volume of hydraulic fluid is equal to the change in volume of the gas. The equation for polytropic processes can then be used to calculate accumulator volume or pressure, depending on which values are known. The polytropic exponent,  $n$ , depends on the type of process. For slow gas expansion and compression processes which occur almost isothermally, the polytropic exponent can be assumed to be  $n = 1$ . For rapid processes, the adiabatic exponent can be taken as  $n = 1.4$  for Nitrogen and air. For pressures above 3000 psi the real gas behavior deviates considerably from the ideal one, which reduces the effective fluid volume. In such cases the adiabatic exponent used is greater than 1.4.

The equation for polytropic processes is:

$$p_0 V_0^n = p_1 V_1^n = p_2 V_2^n = \text{Constant}$$

where  $p_0$  is the gas precharge pressure,  $p_1$  is the minimum working pressure, and  $p_2$  is the maximum working pressure.  $V_0$ ,  $V_1$ , and  $V_2$  are the gas volumes in each of the states.

For low pressure applications of less than 150 psi, absolute gas pressures must always be used in the equation for required gas volume. These equations are assuming ideal gas behavior. Correction factors must be used to take into account real gas behavior. Those correction factors can range from 1 to 2 depending on the pressures involved.

$$V_0 = \frac{\Delta V}{\left(\frac{p_0}{p_1}\right)^{\frac{1}{n}} - \left(\frac{p_0}{p_2}\right)^{\frac{1}{n}}}$$

where  $V_0$  is the precharge volume of gas, and  $\Delta V = V_1 - V_2$

Precharge pressure for energy storage is generally about 90% of system minimum working pressure. For shock absorption, precharge is usually 60% to 90% of median working pressure; for pulsation dampening, precharge is usually 60% to 80% of median working pressure. A small amount of fluid should remain inside the accumulator at minimum working pressure to prevent the mechanical components from rubbing or impacting. Therefore

the precharge pressure should be slightly lower than the minimum working system pressure.

*Pulsation Dampeners & Snubbers:* Pulsating flow can wreak havoc with hydraulic devices in a circuit. A pulsation dampener is a type of accumulator that absorbs these pressure variations and stabilizes the downstream flow velocity. They absorb only the portion of fluid accelerated above the mean flow rate, store the excess fluid momentarily, and then discharge it during the portion of the cycle where flow rate drops below mean. These devices are less effective at higher frequencies. For best results, dampeners are placed as close as possible to a pump or source of pulsation. Snubbers are generally placed before gauges. Suction stabilizing dampeners are placed soon after the supply reservoir to protect a pump from acceleration head variations.

The diaphragm and bladder types of pulsation dampener are extremely common. The diaphragm or bladder is pressurized on one side with a gas (nitrogen is common) to about 70–80% of system peak pressure. A pulsation dampener can be as simple as a section of elastic tubing in a circuit that can expand and contract as pressure builds and subsides. Sometimes pulsations can be dampened by placing a restriction in the line to limit fluid flow. This method is less preferred because dangerous levels of pressure may occur behind the restriction.

Gauge snubbers vary in their method of dampening. Less expensive ones often restrict flow using a porous disc, while more expensive snubbers use a piston mechanism to dampen pulsations.

The most common application for a pulsation dampener involves a reciprocating piston pump system. Since the dampener must absorb and store the volume of fluid above the mean discharge volume of the pump, this excess fluid volume is the sizing criterion. A simplex pump (one piston) displaces a volume of fluid above mean equal to about 60% of total displacement. A duplex pump (two pistons) displaces a fluid volume above mean equal to about 30% of total displacement. A triplex pump displaces a fluid volume above mean equal to about 4% of total displacement. Piston displacement is calculated by multiplying face area by stroke. The following equation is used to calculate the volume of gas required for the pulsation dampener.

$$V_g = \frac{V_p}{p_g X C_p}$$

where  $V_g$  is the volume of gas required,  $V_p$  is the piston displacement volume,  $p_g$  is the gas precharge percent (as a decimal),  $X$  is the level of dampening desired (as a decimal), and  $C_p$  is the pump constant. The level of dampening is the residual peak to peak pulsations, such that lower values correspond to more damping.

The precharge percentage of system pressure is typically 70–80%, as mentioned earlier, so as a decimal this would be expressed as 0.7–0.8. The level of dampening desired is expressed as the percentage of residual peak to peak pulsations. So, for 5% residual pulsations, this would be expressed in decimal form as 0.05. Conservative values for the pump constant are 1.5 (Simplex), 2 (Duplex), and 7 (Triplex).

Snubbers, on the other hand, are sized primarily based on the pressure range they are going to experience in operation. The pressure spikes must be quantified when selecting a snubber.

**Head.**— The energy added to a liquid by a pump or by gravity is often quantified in terms of head. Head has units of length, usually feet or meters. Pressure can be calculated from head, and vice-versa, through use of the following equations:

$$p = 0.434 \times h \times \text{SG} \text{ where } h \text{ is head in feet, } p \text{ is pressure in psi}$$

$$p = 0.0981 \times h \times \text{SG} \text{ Where } h \text{ is head in meters, } p \text{ is pressure in bar}$$

$$h = 2.31p \div \text{SG} \text{ where } h \text{ is head in feet, } p \text{ is pressure in psi}$$

$h = 10.197p \div SG$  where  $h$  is head in meters,  $p$  is pressure in bar

For water at 70°F (20°C), head and pressure equivalents can be found in **Tables 31** and **32**.

Bernoulli's equation is commonly used in the design of hydraulic systems. In terms of head, it takes the following form. This equation assumes steady flow, so additional terms are used in cases of pulsating flow as with reciprocating pumps.

$$h_1 = h_2 + h_L \quad \text{or} \quad z_1 + \frac{v_1^2}{2g} + \frac{p_1}{\gamma} = z_2 + \frac{v_2^2}{2g} + \frac{p_2}{\gamma} + h_L$$

where  $h_L$  is minor loss of head due to viscous and turbulent shear stresses and other factors. The terms of this equation are explored further in this section.

**Elevation Head:** This is the vertical distance between the point of concern and the free surface of the fluid. This head is considered positive if the free surface is above the point of concern, and negative if the point of concern is above the free surface. No equation is required. When applied to a suction line, when the pump is above the fluid free surface (negative head) this is often referred to as "suction lift." Elevation head is often represented by the letter  $z$  or as  $h_z$ .

**Pressure Head:** The equivalent head imparted by the pressure applied to the fluid at its free surface. This is calculated using the following equation:

$$h_p = \frac{p}{\gamma} \quad \text{where } p \text{ is applied absolute pressure and } \gamma \text{ is specific weight.}$$

**Static Head:** This term is used to include static effects like elevation and pressure head, while excluding dynamic effects like friction and velocity head.

**Dynamic or Velocity Head:** The head imparted by the specific kinetic energy of the fluid. This value is proportional to the square of the fluid's velocity. Velocity head is calculated using the following equation:

$$h_v = \frac{v^2}{2g}$$

**Acceleration Head:** This head is critical when evaluating the suction side of reciprocating positive displacement pumps and other pumps with pulsating flow. It is also important to consider during startup of a kinetic pump. Acceleration head is subtracted from the *NPSHA*, which is covered in the section *NPSHR and NPSHA* starting on page 2722.

Acceleration head is the head required to accelerate the fluid in the line. It must be considered when evaluating cavitation risk at the inlet and peak loads on the pump components at discharge. It is calculated using the following equation and Table 33.

$$h_a = \frac{LVNC}{gk}$$

where  $h_a$  is acceleration head in feet,  $L$  is the length of the suction line in feet,  $V$  is the average liquid velocity in the suction line (ft/sec),  $N$  is the speed of the pump in RPM,  $g$  is the gravitational constant, and  $C$  and  $k$  are given in Table 33.

**Table 33. Acceleration Head Constants**

Pump Type	Constant $C$	Fluid Type	Constant $k$
Single Acting Simplex	0.4	Non-Compressible (degassed)	1.4
Single Acting Duplex	0.2	Most Liquids	1.5
Double Acting Duplex	0.115	Compressible	2.5
Triplex	0.066		
Quintuplex	0.04		
Septuplex	0.028		

**Friction Head:** The head required to overcome friction effects in the line due to surface roughness and restrictions. Restrictions can include fittings, valves, and other devices. Velocity of the fluid is directly proportional to friction head. Friction head is calculated as the sum of all energy losses incurred in the pipe system and fittings. These equations were given in section *Energy Loss in Pipes* on page 2697, and following pages.

**Vapor Pressure Head:** This head term ( $h_{vp}$ ) is used on the suction line to evaluate the potential for cavitation. It is the head equal to the vapor pressure of the liquid being used, and is calculated using the equation for pressure head. The vapor pressure is equal to the saturation pressure at a given temperature. The vapor pressure head of water at 68°F (20°C) is 0.84 ft (2.338 kPa). When the pressure of a liquid drops below its vapor pressure, it boils.

**Discharge from Tanks.**— To calculate the velocity of discharge of liquid from a tank the following equations can be used:

For a non-pressurized tank,

$$v_o = C_v \sqrt{2gh}$$

where  $v_o$  is velocity through the discharge orifice,  $h$  is the height of the free surface of liquid in the tank above the orifice, and  $C_v$  is coefficient of velocity for the discharge orifice (see Table 34).

For a tank at gauge pressure  $p$ ,

$$v_o = C_V \sqrt{2g \left[ \left( \frac{p}{\gamma} \right) + h \right]}$$

The time required to drain a tank can be calculated using the following equation if the tank has a constant cross-sectional area and is not replenished. Strategies to reduce turbulence as a fluid exiting a tank into a mouthpiece or discharge tube include employing a re-entrant mouthpiece that protrudes into the tank, or using a convergent-divergent mouthpiece.

$$t = \frac{2A_t(\sqrt{z_1} - \sqrt{z_2})}{C_d A_o \sqrt{2g}}$$

where  $t$  is time in seconds,  $A_t$  is the cross-sectional area of the tank,  $A_o$  is the cross-sectional area of the discharge orifice,  $z_1$  and  $z_2$  are the initial and final liquid heights in the tank, and  $C_d$  is the coefficient of discharge for the type of orifice used (see [Table 34](#)).

**Table 34. Discharge and Velocity Coefficients**

Orifice Type	$C_d$	$C_V$
Sharp Edged	0.62	0.98
Round Edged	0.98	0.98
Short Tube (Fluids separates from walls)	0.61	0.61
Sharp Tube (No fluid separation)	0.82	0.82
Sharp Tube with Rounded Entrance	0.97	0.98
Re-entrant Tube, $L < 0.5d$	0.54	0.99
Re-entrant Tube, $2 \leq L \leq 3$	0.72	0.72
Smooth, Well-Tapered Nozzle	0.98	0.99

**Pumps.**— Pumps are used to move fluid. More generally, pumps add pressure energy to fluid through a variety of means. Pumps fall into two general classifications: positive displacement pumps and kinetic (dynamic) pumps. Some pumps are meant to be submerged completely in the fluid being pumped, while others are not.

*Positive Displacement Pumps:* Positive displacement pumps move a fixed amount of fluid during each discharge stroke or revolution. Flow rate is directly related to the speed of the moving parts of the pump, and for many of these pumps flow pulsates as the cavity or cavities discharge and refill. These pumps are suitable for low to moderate flow rates, for moving highly viscous fluids, and generating very high pressures. Because of the high pressure capability of these pumps, they tend to be sturdily built and the use of a pressure relief valve is recommended in fluid circuits employing these pumps. Positive displacement pumps can be further broken down into reciprocating and rotary types. The most common types of reciprocating pumps are: bladder, diaphragm, peristaltic, and piston or plunger pumps. Commonly encountered rotary types are: gear, lobe, vane, screw, and progressive cavity pumps. Metering pumps are positive displacement pumps that have a precisely controlled discharge volume. This volume is normally adjustable through stroke adjustment.

Bladder pumps deliver pulsing flow, usually by inflating and deflating a bladder arranged axially along a pumping chamber. Diaphragm pumps deliver pulsing flow from a single cavity, but can be arranged in multiples to provide smoother flow. Peristaltic pumps deliver pulsing flow, and have the advantage of completely containing the fluid within a section of tubing that runs through the pump mechanism. The pump uses a series of rollers to progressively pinch the tube and move the fluid ahead of the pinch point.

Piston pumps and plunger pumps deliver pulsing flow. Axial piston pumps are designed with multiple pistons arranged axially to the motor. A tilted washplate turns and actuates the pistons in sequence. More pistons in the pump produce smoother flow. Radial piston pumps have pistons arranged radially around a central cam that actuates them in sequence. Reciprocating piston and plunger pumps used for fluid transfer are typically either single acting or double acting, which means the piston delivers fluid on one or both directions of movement. These are driven with a crank arrangement or other reciprocating mechanism. A simplex pump has one cylinder, and a duplex pump has two cylinders. Arrangements with more cylinders are possible.

Gear pumps deliver pulsing flow at high pressures and fairly high flow capacities. They rely on close clearances to capture the fluid. This means that the fluid being moved must be free of particulate matter. These pumps perform best with viscous fluids. Lobe pumps deliver pulsing flow. They are similar to gear pumps, but the lobes in mesh do not contact one another. These pumps are often used to move fluid with large particulate inclusions. The lobes are often non-metallic, and are suitable for handling delicate items in a fluid stream. Vane pumps deliver pulsing flow at moderately high pressures. They are comprised of a rotating set of vanes that capture and release fluid inside a round housing.

Screw pumps deliver smooth flow at moderately high pressures. They are commonly found in single, double, and triple screw configurations. Single screw pumps are sometimes called progressing-cavity pumps. Direct acting pumps are driven by a fluid with a differential pressure, and generally use a piston. They can use air, steam, or a liquid as the driver. These pumps are suitable for high pressure, low flow applications. They have the disadvantage of consuming high volumes of drive fluid.

*Kinetic Pumps:* Kinetic pumps generate momentum in a fluid, which is then transformed into pressure. These pumps do not have a fixed discharge volume, and therefore do not impart a pulsation to the fluid being moved. The most common type of kinetic pump is the centrifugal pump. Other types of kinetic pumps include air lifts, hydraulic rams, turbine pumps, and jet pumps

Centrifugal pumps use a one or more spinning impellers to accelerate a fluid radially from the inlet. The fluid is then slowed by a spiral volute, converting the velocity energy into pressure energy. Centrifugal pumps can be radial, axial, and mixed flow types. The pump specific speed determines which would be the best type for a given application. Some centrifugal pumps are configured to handle fluids with solids. In those cases, a grinder can be integrated into the pump. Centrifugal pumps are used mainly in high flow applications with moderate heads. Multistage versions are suitable for high head applications. The size of a centrifugal pump is designated by the discharge port size, inlet port size, impeller diameter, and number of stages. Therefore, a  $1 \times 2 \times 5$  pump would be a single stage pump with a 1 inch discharge, a 2 inch inlet, and a 5 inch impeller. If the pump case is supported at the centerline of the shaft, it is said to be "centerline mounted". This mounting configuration is ideal for high temperature applications because shaft alignment with the driver is maintained as the case expands due to heat. Foot mounted pumps are supported under the case, and frame mounted pumps are supported under the bearing housing.

Air lift pumps use a stream of air bubbles injected into the submerged base of a pipe to entrain the fluid. The fluid rises with the air bubbles. These pumps are used when only light suction is needed.

Hydraulic ram pumps operate cyclically to deliver pulsing flow. A hydraulic ram is typically comprised of a spring or weight loaded normally open valve, and a check valve. Flowing water with kinetic energy creates pressure against the normally open valve until it closes. This elevated pressure sends fluid through the check valve to a higher elevation. The check valve then prevents the fluid from reversing. Once pressure is relieved, the normally open valve opens once more and the cycle begins again.

Turbine pumps are comprised of a series of progressive impellers. Each stage, or impeller, increases the energy of the fluid. Jet pumps are commonly used in home water well sys-

tems. These pumps are comprised of a centrifugal pump located above, with a jet assembly down in the well. The centrifugal pump pressurizes the water, which is then passed through a nozzle. The jet created by the nozzle entrains additional water and lifts it up toward the pump inlet. In the suction line there is also a diffuser, which slows the water and converts velocity to pressure energy.

*The Effect of Viscosity on Pumps:* Viscosity affects positive displacement pumps, resulting in higher friction head values for a given flow rate. When centrifugal pumps handle fluids more viscous than water, the pumping efficiency decreases and the flow for a given head also decreases. Centrifugal pump performance is typically rated at values achieved when pumping cool water. For computing centrifugal pump performance, some correction factors for viscous fluids can be found in Fig. 25. To use the chart, enter at capacity, go straight up to the head curve, over horizontally to the viscosity curve, and then straight up to the correction factor curve. The correction factors are applied according to the following equations:

$Q_v = C_Q Q_{water}$  where  $Q_v$  is the corrected viscous capacity,  $C_Q$  is the capacity correction factor, and  $Q_{water}$  is the flow rate achieved while pumping cool water.

$h_v = C_h h_{water}$  where  $h_v$  is the corrected viscous head,  $C_h$  is the head correction factor, and  $h_{water}$  is the head achieved while pumping cool water.

$\eta_v = C_\eta \eta_{water}$  where  $\eta_v$  is the corrected viscous efficiency,  $C_\eta$  is the efficiency correction factor, and  $\eta_{water}$  is the efficiency achieved while pumping cool water.

$P_v = \frac{P_{water}}{C_\eta}$  where  $P_v$  is the corrected viscous pumping power, and  $P_{water}$  is the power achieved while pumping cool water.

*Pump Capacity:* Flow rate through a pump is known as capacity. For positive displacement pumps, flow rate is simply related to cavity volume and cycle rate. For centrifugal pumps, a change in impeller diameter or speed results in a capacity change according to the affinity laws discussed later in *Affinity and Similarity* on page 2726.

Centrifugal pumps are intended to be used at or near rated capacity. When operated below this capacity, the pump experiences higher axial thrust loads, elevated temperatures, and there is a potential for gases to become trapped in the pump case. Another effect, called *recirculation*, can also occur in which flow reversals occur at the inlet or discharge tips of the impeller. This can result in pressure pulsations which can damage the pump. In cases where demand is likely to fall below pump capacity, a parallel pump arrangement can be considered, or a bypass installed in the discharge line of the pump to allow the pump to operate at higher flow than demanded.

*Total Suction Head:* This is the sum of all the heads imparted on the fluid in the suction line supplying a pump. It includes static and dynamic heads, unless otherwise specified. The general equation for total suction head is:  $h_{t(s)} = h_z + h_p + h_v - h_f$  where  $h_z$  is static head,  $h_p$  is pressure head,  $h_v$  is velocity head, and  $h_f$  is friction head. All are taken with respect to the suction line. Acceleration head can also be subtracted when dealing with reciprocating pumps.

*Total Discharge Head:* This is the sum of all the heads imparted on the fluid in the discharge line exiting a pump. The general equation for total discharge head is:  $h_{t(d)} = h_z + h_p + h_v + h_f$ . Here the terms are taken with respect to the discharge line. Acceleration head can also be added for reciprocating pumps.

Fig. 25. Centrifugal Pump Viscosity Correction Factors

SSU are Saybolt Universal Seconds. ASTM D2161 covers conversion of kinematic viscosity to SSU at a given temperature. BEP is *Best Efficiency Point*.

*System Head or Total Dynamic Head (TDH)*: This is equal to the difference between total discharge head and total suction head:  $h_t = h_{t(d)} - h_{t(s)}$

For centrifugal pumps, a change in impeller diameter or speed results in a change in head according to the affinity laws discussed in *Affinity and Similarity* on page 2726.

Using the following equation, head can be calculated from impeller and fluid speeds for radial and mixed-flow pumps where the incoming fluid velocity is nearly zero.

$$h_t = \frac{\eta_i v_i v_f}{g}$$

where  $\eta_i$  is impeller efficiency (typically 0.85 – 0.95),  $v$  is tangential impeller velocity at a given radius, and  $v_f$  is the tangential velocity of the fluid.

*NPSHR and NPSHA: Net Positive Suction Head Required* is the minimum fluid energy required at the pump inlet for normal operation. *NPSHR* is measured when the pump total head is reduced by 3% due to cavitation. *NPSHR* depends on flow rate as well as the characteristics of the pump and suction line. This value is normally provided by pump manufacturers for one or more flow rates. To some extent, *NPSHR* depends on the characteristics of the valves used on the pump inlet and discharge ports. If *NPSHR* for one flow rate is known, it can be calculated for another flow rate using the equation:

$$\frac{NPSHR_2}{NPSHR_1} = \left(\frac{Q_2}{Q_1}\right)^2$$

*Net Positive Suction Head Available* is the actual fluid energy at the pump inlet, which can be calculated for the suction line as the difference between total suction head and the vapor pressure head using the following equation. For reciprocating pumps, acceleration head ( $h_a$ ) must be accounted for as well.

$$NPSHA = h_z + h_p + h_v - h_f - h_{vp} - h_a$$

where all terms are taken with respect to the suction line.

*Cavitation:* Cavitation occurs when the pressure of the fluid in the inlet of a pump drops below its vapor pressure for a given temperature. A fluid whose pressure drops below its vapor pressure boils, or vaporizes, degrading pumping performance. The symptoms of cavitation include noise, vibration, and pitting of pump surfaces. In extreme cases, structural damage can occur. If  $NPSHA < NPSHR$ , the fluid will cavitate excessively and the pump will not run as expected. An additional margin is recommended, with recommendations ranging from 10% to 200% depending on application. If the liquid has been exposed to gas other than its own vapor, additional margin of *NPSHR* over *NPSHA* is needed to prevent cavitation. If *NPSHR* is not yet known, the designer must aim for a *NPSHA* as high as reasonably possible, and certainly above zero.

Cavitation can be caused by a variety of conditions, including: high pump speeds, high fluid temperatures, low suction head, and fluids with high vapor pressures. When working at high altitudes, the effect of altitude on vapor pressure must be taken into account when calculating suction head. If *NPSHA* is zero or negative, the suction head is by definition below the fluid's vapor pressure. To increase *NPSHA* and prevent cavitation, the inlet pressure can be increased through a variety of methods: pressurizing the fluid source or using a booster pump, raising the fluid source, reducing the flow rate, cooling the fluid, shortening and/or widening the suction line, and reducing suction line losses due to friction or turns. Additional strategies include adding a suction line stabilizer (pulsation dampener) to the suction line, or adding a section of highly flexible hose to the suction line to allow some dampening.

*Hydraulic (Pump) Power:* Hydraulic power, or pump power, is a function of mass flow rate and total dynamic head (added head). This is the energy imparted to the fluid per unit time by the pump. Typical units for power are horsepower or kilowatts. The equations for hydraulic power are given below. These equations assume the density of water is 62.4 lbm/ft<sup>3</sup> (1000 kg/m<sup>3</sup>).

**Hydraulic Kilowatt**

In the equations that follow,  $Q$  is in l/s;  $\dot{m}$  is in kg/s; and  $\dot{V}$  is in m<sup>3</sup>/s.

$$KW = 9.81 \frac{h_t Q(SG)}{1000} = 9.81 \frac{h_t \dot{m}}{1000} = 9.81 h_t \dot{V}(SG) \text{ where } h_t \text{ is in meters}$$

$$KW = \frac{\Delta p Q}{1000} = \frac{\Delta p \dot{m}}{1000(SG)} = \Delta p \dot{V} \text{ where } \Delta p \text{ is in kPa}$$

$$KW = \frac{WQ(SG)}{1000} = \frac{W\dot{m}}{1000} = W\dot{V}(SG) \text{ where } W \text{ is in J/kg}$$

**Hydraulic Horsepower**

In the equations that follow,  $Q$  is in gal/min;  $\dot{m}$  is in lbm/s; and  $\dot{V}$  is in ft<sup>3</sup>/s.

$$HP = \frac{h_t Q(SG)}{3956} = \frac{h_t \dot{m} g}{550 g_c} = \frac{h_t \dot{V}(SG)}{8.814} \text{ where } h_t \text{ is in feet}$$

$$HP = \frac{\Delta p Q}{1714} = \frac{\Delta p \dot{m} g}{238.3(SG)g_c} = \frac{\Delta p \dot{V}}{3.819} \text{ where } \Delta p \text{ is in psi}$$

$$HP = \frac{\Delta p Q}{246800} = \frac{\Delta p \dot{m} g}{34320(SG)g_c} = \frac{\Delta p \dot{V}}{550} \text{ where } \Delta p \text{ is in psf}$$

$$HP = \frac{WQ(SG)}{3956} = \frac{W\dot{m}}{550} = \frac{W\dot{V}(SG)}{8.814} \text{ where } W \text{ is in ft-lbf/lbm}$$

For centrifugal pumps, a change in impeller diameter or speed results in a change in power according to the affinity laws discussed in *Affinity and Similarity* on page 2726. Required power for centrifugal pumps is directly proportional to the specific gravity of the liquid being pumped. It is influenced also by viscosity.

*Pump Efficiency:* Pump efficiency is the ratio of the actual power delivered by the pump driver (usually a motor) and the power the pump ideally delivers to the fluid. Losses occur in the system due to friction between the fluid and the pump, as well as friction and/or slip within the pump mechanism. Since hydraulic power is a function of mass flow rate, efficiencies of pumps are often given in terms of flow rate, speed, or specific speed. Drive power to a pump is often called “brake horsepower” (bhp). Pump efficiency is defined by the following equation:

$$\eta_p = \frac{P_{hydraulic}}{P_{brake}}$$

where  $P_{hydraulic}$  is the power delivered to the fluid, and  $P_{brake}$  is the drive power to the pump.

For positive displacement pumps, volumetric efficiency is often used to measure performance. This is the ratio of volumetric flow rate input to displacement per unit time delivered by the pump. Torsional efficiency is also commonly used for positive displacement pumps. This is the ratio of actual to ideal torque required to drive the pump. Overall efficiency of a positive displacement pump is the ratio of actual energy delivered, to the input power to the pump.

Volumetric efficiency is calculated using the following equation:

$$\eta_V = 1 - \left( \Delta p \beta \frac{C}{D} \right) + L_V$$

where  $\beta$  is the compressibility factor of the fluid,  $C/D$  is the pumping chamber clearance to displacement ratio, and  $L_V$  is the fluid loss to slippage back through the pump valves before they can seal.  $\Delta p = p_d - p_s$  where  $p_d$  is pressure at discharge and  $p_s$  is pressure at suction.

Centrifugal pumps are intended for use near their best efficiency. When operated below peak efficiency, a phenomenon called “recirculation” can occur, which causes flow reversal at the inlet or discharge tips of the impeller. This can be very detrimental to performance and damaging to the pump.

*Specific Speed:* Centrifugal pumps are characterized in terms of specific speed. Specific speed is the speed of an ideal pump needed to raise a unit of volume through a unit of head in a unit of time. It assumes the ideal pump is geometrically similar to the pump being evaluated. Specific speed is used to determine the geometry (type of impeller) needed for a given set of input and output requirements. It is calculated using the following equations where  $n$  is rotation in RPM:

$$\eta_s = \frac{n \sqrt{Q}}{h_t^{0.75}} \text{ where } Q \text{ is in gal/min, and } h_t \text{ is total dynamic head in feet.}$$

$$\eta_s = \frac{n \sqrt{\dot{V}}}{h_t^{0.75}} \text{ where } \dot{V} \text{ is in m}^3/\text{sec, and } h_t \text{ is in meters.}$$

Low specific speeds produce the largest heads. In US units, specific speeds range from approximately 500 to 1500 RPM for radial vane pumps, 1500 – 4000 for Francis vane, 4000 – 9000 for mixed flow impeller designs, and above 9000 for axial flow impellers. When specific speed is low for a given style, efficiency suffers, and a multi-stage pump should be used. Once specific speed has been calculated from a given head, drive speed, and flow rate, the appropriate type of impeller can be selected. In addition, pump efficiency, *NPSHR*, maximum speed, and suction lift can be determined using specific speed. It is good practice to select a centrifugal pump that has the highest specific speed, since that will yield the smallest pump.

*Critical Speed:* Critical speed is related to static deflection of the shaft in the horizontal position. When operated within about 20% of critical speed, the pump will vibrate excessively and damage can occur. The wet critical speed must be well above the operating speed of the pump in order to ensure smooth running. Centrifugal pumps have a “dry” critical speed and a “wet” critical speed. Wet critical speed is normally higher (smaller deflections experienced) than dry critical speed. As the pump shaft support components (bearings or bushings) wear, the wet critical speed drops. When a pump is operated away from its best efficiency, higher deflections are likely, causing critical speed to drop. Dry critical speed can be determined using the following equations:

$$n_c = \frac{187.7}{\sqrt{y}}$$

where  $y$  is shaft deflection in inches, and  $n_c$  is critical speed in RPM. Shaft deflection is typically limited to 0.006 inches in commercial pumps. This leads to a critical speed value of 2423 RPM.

$$n_c = \frac{946}{\sqrt{y}}$$

where  $y$  is shaft deflection in mm. A maximum shaft deflection of 0.15mm leads to a critical speed of 2442 RPM.

*Pump Shaft Loading:* Piston pumps carry the entire piston compression force on their drive rod. The axial load on the rod is easily calculated as force = pressure/area. Buckling of the load bearing members and/or piston rod may also need consideration. Many pumps are rated based on the maximum discharge plunger load that can be carried when the suction pressure is zero. If the piston is massive, or pump speeds high, the force to accelerate the piston must be taken into account.

For radially driven pumps, the torque on the motor shaft driving a pump depends upon the type of pump being driven. Pumps which produce pulsating flow must accelerate the fluid during each cycle, and therefore experience variable shaft torque. Centrifugal pumps experience a steady torque on the shaft, which can be calculated either from brake power and speed or from the change in momentum of the fluid being pumped. Torque can be calculated using the following equations:

$$T = \frac{63025P}{n}$$

where  $T$  is torque in in-lbf,  $P$  is brake horsepower, and  $n$  is rotation in RPM.

$$T = \frac{9549P}{n}$$

where  $T$  is torque in N-m,  $P$  is brake power in kW, and  $n$  is rotation in RPM.

$$T = \frac{\dot{m}}{g_c} (v_{t(d)}r - v_{t(i)}r_i)$$

where  $T$  is torque,  $\dot{m}$  is mass flow rate,  $v_{t(d)}$  and  $v_{t(i)}$  are tangential velocity at the discharge and inlet,  $r$  is the radius of the impeller, and  $r_i$  is the radius at the inlet. When the inlet is central to the impeller, the tangential velocity at the inlet is zero.

If a pump is driven using a belt or chain, overhung loads on both the motor and the pump shafts should be calculated. Additional bearing support or larger shafts may be required.

In centrifugal pumps and some rotary positive displacement pumps, axial thrust is generated that must be accommodated by the pump drive shaft. In some multi-stage centrifugal pumps, mounting the impellers in opposing directions can balance the thrust load and reduce axial load transferred to the drive shaft. In other cases, a hydraulic balancing device is used. This type of device is piped to the suction line or reservoir and exerts an opposing force to the thrust generated by the impellers.

For axially driven reciprocating pumps, the axial loading on the drive shaft must be considered, as well as radial loading, moment loading, and torque. Axial and radial/moment loading on the motor shaft can be calculated using simple trigonometric relationships. Torque required to axially drive the motor will depend on how the pump is being driven. In some cases, a lead screw or equivalent mechanism is used and the lead screw equation for torque is applicable.

*Pump Curves:* Pump performance can be shown graphically by plotting various performance parameters as a function of flow rate. These graphs are usually supplied by pump manufacturers and usually include efficiency, power requirement, dynamic head, and *NPSHR*. These values are given as a function of the pump alone, and normally are measured in a way that minimizes the influence of suction/discharge line effects. Pump curves are also normally generated using water as the fluid. Since hydraulic power is a function of the fluid's specific gravity, care must be taken when planning to pump a fluid with a different specific gravity. In those cases, the pump's power rating should be multiplied by the specific gravity of the planned fluid.

The performance of a centrifugal pump is generally based on capacity (gal/min or m<sup>3</sup>/h), added fluid head (ft or m), input power (bhp or kW), efficiency (%), and speed (rpm). It is common to plot centrifugal pump curves for a range of impeller diameters together for a fixed speed. This allows selection of the diameter when looking at operating points.

**System Head Curves:** System performance curves display the influence of suction and discharge line configurations. On a system head curve, head requirements of the system are plotted versus capacity. The curve represents a total static head plus friction losses. When system head is variable, as with changing reservoir levels or when there is switching between lines through valving, multiple system head curves will be represented on the graph.

**Operating Point:** The operating point is the intersection of the pump curve and the system curve on a graph that sets head against flow rate. From this graph, the flow rate and head of the pump/system combination can be easily determined. An example of the operating point on a graph can be seen in Fig. 26. A pump/system combination will have multiple viable operating points if there are multiple pump curves given for different speeds and/or geometries. The designer should choose the operating point with the highest pump efficiency. Another case where multiple operating points are seen is in systems where the system head varies and multiple system head curves are present. The designer should ensure that the pump can meet the system requirements at all operating points. When dealing with centrifugal pumps, the pump curve chosen for the operating point will in turn determine the speed and/or impeller. It is good practice to select a centrifugal pump with the largest impeller diameter that will meet the application needs while operating at or near its maximum rated speed.

Fig. 26. Operating Point of a Pump

The operating point of a pump in a system can be changed by throttling the discharge line. The suction line should never be throttled because it could lead to cavitation. When a pump is throttled, the operating point moves along the pump curve as the flow rate is reduced. Operating point can also be changed through the use of a variable speed drive. Changing the viscosity of the fluid being pumped also moves the operating point in the direction of less flow for a given head.

**Combining Pumps in Series or Parallel:** When one pump discharges into the suction line of another pump, this is a series system. Pumps in series are capable of producing higher discharge heads than single pumps. A slight increase in flow rate will also be seen when pumps are combined in series. To generate a pump curve for pumps in series, the head of each pump is added at each flow rate to create a new curve. This curve is then graphed together with the system curve to find a new operating point. Multistage pumps contain multiple impellers in one pump body to achieve a similar effect as a series of pumps.

A system of pumps in parallel experiences an increase primarily in flow capacity, with only a slight increase in head. Parallel pump systems have the advantage of increased reliability, and the ability to efficiently adjust to variations in demand. When demand varies, flow rate moves away from the operating point, resulting in decreased efficiency.

When two or more parallel pumps are used, they can be engaged and disengaged to keep the system flow rate near demand.

**Affinity and Similarity:** Comparing centrifugal pumps can be done if one assumes the efficiencies of the two pumps are the same. This becomes less true as the difference in size

between pumps grows. Note that as the specific speed increases, the accuracy of the affinity equations decreases. To estimate the efficiency of a very different size pump, the following equation can be used.

$$\left(\frac{D_L}{D_S}\right)^n = \frac{1 - \eta_S}{1 - \eta_L}$$

where subscript  $L$  denotes the larger pump, and  $S$  denotes the smaller pump.  $D$  is impeller diameter and  $n$  is speed.

The affinity equations (assuming equal efficiencies) which allow comparison between pumps are as follows:

- When the impeller diameter is constant while the speed changes:

$$\frac{n_2}{n_1} = \frac{Q_2}{Q_1} \quad \left(\frac{n_2}{n_1}\right)^2 = \frac{h_2}{h_1} = \left(\frac{Q_2}{Q_1}\right)^2 \quad \left(\frac{n_2}{n_1}\right)^3 = \frac{P_2}{P_1} = \left(\frac{Q_2}{Q_1}\right)^3$$

- When the speed is constant and the impeller size changes:

$$\frac{D_2}{D_1} = \frac{Q_2}{Q_1} \quad \left(\frac{D_2}{D_1}\right)^2 = \frac{h_2}{h_1} \quad \left(\frac{D_2}{D_1}\right)^3 = \frac{P_2}{P_1}$$

- When flow is assumed to be turbulent and the percentage of wide open flow is assumed to be the same, similarity can be used as follows:

$$\frac{Q_2}{Q_1} = \frac{n_2}{n_1} \left(\frac{D_2}{D_1}\right)^3 \quad \frac{h_2}{h_1} = \left(\frac{n_2}{n_1}\right)^2 \left(\frac{D_2}{D_1}\right)^2 \quad \frac{P_2}{P_1} = \frac{\rho_2}{\rho_1} \left(\frac{n_2}{n_1}\right)^3 \left(\frac{D_2}{D_1}\right)^5$$

*Startup Conditions:* Priming is necessary for all types of pumps to begin operation. During priming, the inlet chamber is flooded with fluid, and gas is purged from the pump mechanism. Submersible pumps are generally self-priming, as are some types of non-submersible pumps.

The torque requirements of centrifugal pumps at startup are greatly different from running torque requirements. Full-load torque is required for starting against full discharge pressure. To reduce the startup torque required, the designer can pipe the discharge back to the suction line, and close it off from any head inherent in the running discharge line. This equalizes discharge and suction pressure and eliminates the load on the pump during startup. Using valves, this loop can be closed off and the pump discharge connected to the discharge pipe system once the pump gets up to running speed.

*Piping Considerations:* To ensure peak performance of hydraulic systems, some points to consider are:

- Make piping runs as short and direct as possible.
- Design for minimum fluid velocities and accelerations.
- Use long radius bends rather than elbows to redirect piping where possible.
- Design pipe systems to preclude the collection of vapor bubbles, except where venting is provided.
- Include pulsation dampeners and suction stabilizers where acceleration head is high or the fluid needs degassing. A suction stabilizer is a device placed on the suction line of a pump that both absorbs pulsations and separates free gases from the liquid being pumped.
- Always ensure that  $NPSHA \gg NPSHR$ .
- Include strainers only when absolutely necessary, and ensure regular maintenance is conducted.
- Provide a relief valve that is adequately sized.
- Pipe a bypass line around the pump with valves so that the pump may be started with low load. This must be done slowly to avoid shock to the system.

- In systems with high static discharge heads, install a check valve at the pump discharge to prevent static pressure from loading the pump during startup.

### Pneumatics

Pneumatic systems use compressed and flowing gas, usually air, to perform work. Many pneumatic components, such as valves, actuators, and compressors share similarities with components used with liquids. In many cases, pneumatic components and calculations can be found in earlier sections.

**Gas Consumption Calculation and Measurement.**— It is common practice to exhaust air used in pneumatic circuits to atmosphere through silencers, or to an exhaust manifold and/or filter. Since that air is lost, and compression of air costs money, air consumption should be evaluated and limited as much as possible when designing a pneumatic circuit. Silencers are essential to limit noise produced by exhausting air.

In US units, the volumetric flow rate of gases is normally expressed in cubic feet per minute (cfm). Velocity in US units is normally expressed in feet per minute. SI units for gas volumetric flow are cubic meters per second and meters per second for velocity. Liters per second is used for volumetric flows in low ranges.

*Gas Consumption:* Compressors and devices using compressed air are often rated in terms of free air delivery (f.a.d.), which is the quantity of air used per unit time assuming the air is at standard atmospheric pressure and temperature. These values are 14.7 psia (0.101 MPa) and 60°F (15°C). When conditions differ from standard, the following equation can be used:

$$Q_a = \frac{Q_s p_s T_a}{(p_{atm} + p_a) T_s}$$

where  $Q_a$  is actual volumetric flow rate,  $Q_s$  is flow rate at standard conditions,  $p_s$  is standard absolute atmospheric pressure,  $p_{atm}$  is actual absolute atmospheric pressure,  $p_a$  is actual gage pressure,  $T_a$  and  $T_s$  are actual and standard absolute temperature (°R or K).

This equation is often used in another form to calculate the flow of free air required to supply a given compressed air flow. When the free air is at standard temperature, this takes the form of the following equation:

$$Q_s = \frac{Q_a (p_{atm} + p_a)}{p_s}$$

where  $Q_s$  is the free air flow at standard temperature,  $Q_a$  is the compressed air flow,  $p_a$  is actual gage pressure, and  $p_s$  is the absolute standard pressure. The ratio of absolute pressure to absolute standard pressure is known as the *compression ratio*. In US units, the free flow is normally given in units of SCFM and compressed air flow is in units of CFM.

**Fans and Blowers.**— Fans and blowers add energy to air. When static pressure is very low, fans are typically used. Blowers are appropriate when static pressure is higher.

*Types of Fans and Blowers:* Axial propeller fans have a number of blades arranged around a spinning shaft. They move air axially through themselves with very low pressure and velocity increase. Axial fans are normally used to move large quantities of air against static pressures below 0.4 psig (3kPa). A diffuser can be added after a fan to increase static pressure output. Axial propeller fans are the least expensive of the fan types, but are not as efficient as centrifugal fans. Vane-axial blowers are similar to propeller fans, but have highly optimized casing geometry that creates much higher pressures than propeller fans.

Centrifugal fans and blowers use a rotating impeller to accelerate air radially outward from a central intake. Significant velocity energy is added, which is then converted to pressure energy when the air is slowed using a volute. The inlet and volute geometry is usually organized so that air enters and exits the centrifugal device axially. Scroll casings are

arranged such that the air exiting the device is radial. Centrifugal fans are appropriate up to a static pressure of approximately 2 psi (15 kPa). Forward-curved centrifugal fans (squirrel cage fans) are the most common type, but with an efficiency of approximately 75% they are the least efficient of all the centrifugal designs. Backward-curved centrifugal fans are less likely to overload than forward-curved fans, and their increased efficiency over forward-curved centrifugals makes up for their increased cost. Radial blade fans are commonly found in industrial cooling applications where a large volume of air is required at moderate pressure. Centrifugal blowers look more like centrifugal pumps than fans. The impeller is typically gear-driven. The two most common types of centrifugal blowers are pressure blowers and volume blowers. Pressure blowers are designed to draw or push air at high pressures, rated in static pressure water gauge (SPWG). Volume blowers are designed to draw or push larger volumes of air, rated in cubic feet of air per minute (CFM), at lower static pressures than pressure blowers.

Cross-flow fans and blowers have air enter and exit the impeller tangentially. The pressure produced by these impellers is low. Mixed-flow fans and blowers use impellers that impart both axial and radial momentum to a gas. These impellers can be housed in either axial or scroll-type casings to output either axial or radial flow. Positive displacement blowers are essentially positive displacement pumps used for moving air. Positive displacement pumps are described earlier in this text.

*Fan and Blower Calculations:* When selecting a fan or blower, one must consider the cleanliness and type of gas being moved, the pressure differential or velocity needed, the volumetric flow rate required, the energy loss in the ductwork or system, the noise produced, and the cost.

Fan capacity is a measure of the maximum volumetric flow rate of the fan or blower. Total pressure of a fan or blower is the difference between the inlet and outlet pressures, and it is also the sum of static pressure and velocity pressure. Static and velocity pressures are often measured in inches of water (in. w.g.). Fan static, velocity, and total pressures at standard conditions can be calculated using the following equations:

$$p_{s(\text{in. w.g.})} = \frac{P_{\text{psig}}}{0.0361}$$

$$p_{v(\text{in. w.g.})} = \left( \frac{v_{\text{fpm}}}{4005} \right)^2$$

$$p_t = p_s + p_v = \frac{p}{\gamma} + \frac{\rho v^2}{2}$$

where  $p_s$  is static pressure, and the specific weight of water is assumed to be 0.0361 lbf/in<sup>3</sup>;  $p_v$  is velocity pressure;  $v_{\text{fpm}}$  is velocity in fpm; and  $p_t$  is total pressure.

When a fan is connected to ductwork, the pressure drop through the duct and fittings should be taken into account using the following equations, by using the Moody diagram given in Fig. 18, or by using friction loss graphs like those published by ASHRAE. The Darcy-Weisbach equation (see *Darcy-Weisbach Equation and the Moody Diagram* on page 2697) should be used for “non-standard” duct type such as flex duct.

$$p_{f(\text{in. w.g.})} = \frac{(3.9 \times 10^{-9}) v_{\text{fpm}}^{2.43} L_{\text{ft}}}{Q_{\text{CFM}}^{0.61}}$$

where  $p_f$  is friction pressure of air moving through ducts. This assumes clean, galvanized, circular ducts with a specific roughness of 0.0005 ft.

$$p_{f(\text{in. w.g.})} = K \left( \frac{v_{\text{fpm}}}{4005} \right)^2$$

where  $p_f$  is friction pressure of air moving through fittings. The loss coefficient  $K$  can be found in **Table 35**.

**Table 35. Loss Coefficients, Air Duct Fittings**

Compressibility factor is the ratio of total pressure that would be developed with an incompressible fluid to the total pressure developed with a compressible gas. When fan total pressure is less than 12 in.w.g., the compressibility factor can be assumed to be equal to 1 (incompressible flow). Power output is the product of capacity, total pressure, and compressibility factor. Total efficiency is the ratio of power output to power input. Static efficiency is the product of total efficiency and the ratio of static pressure to total pressure. These values can be calculated using the following equations. Fan efficiency grades have been established to classify fan performance.

$$P_o = K_p Q p_t$$

where  $P_o$  is output power imparted to the gas,  $K_p$  is compressibility factor, and  $p_t$  is fan total pressure.

$$\eta_t = \frac{P_o}{P_B}$$

where  $P_B$  is power supplied to the driver.

$$\eta_t = \frac{Q_{CFM} P_{I(\text{in. w.g.})}}{6356 P_B} \quad \eta_s = \frac{Q_{CFM} P_s (\text{in w.g.})}{6356 P_B}$$

The fan laws of similarity and affinity rely on the fact that two geometrically similar impellers of different sizes are homologous. These laws can be used to compare similar fans, and are expressed in the following equations. It is essential to make sure that the fans under consideration have the same efficiency. When one fan is compared at different speeds:

$$\frac{Q_2}{Q_1} = \frac{n_2}{n_1} \quad \frac{P_2}{P_1} = \left(\frac{n_2}{n_1}\right)^2 \quad \frac{P_{o2}}{P_{o1}} = \frac{P_{B2}}{P_{B1}} = \left(\frac{n_2}{n_1}\right)^3$$

When two similar fans are compared:

$$\frac{Q_2}{Q_1} = \left(\frac{n_2}{n_1}\right) \left(\frac{D_2}{D_1}\right)^3 \quad \frac{P_2}{P_1} = \left(\frac{P_2 Q_2}{P_1 Q_1}\right)$$

Sizing of fans and blowers is similar in process to that of pumps, where graphs are commonly used. The performance graph is usually a constant-speed plot with capacity on the X axis and a variety of performance factors on the Y axis. As part of the selection process, a graph of the system is also generated, with capacity as the X axis and head (energy loss in the system) on the Y axis. As with pumps, the operating point of a fan is found at the intersection of the performance graph and the system graph. When multiple system curves are applicable, as with variable duct geometry or variable static pressure, there will be multiple operating points. When multiple performance curves are available, as with adjustable impeller vane angle, damper control, or variable speed, there will be multiple operating points. A slightly undersized fan is preferable to an oversized fan because of lower cost and increased stability.

Operating a fan or blower at much lower than rated capacity can result in pulsations and instability due to a variety of factors. This should be avoided. To ensure stable fan and blower operation, the engineer should select an operating point where the slope of the pressure/capacity performance curve has opposite sign as the system curve. This is usually the case, except at or above design capacity. Pulsation can be avoided by selecting an operating point to the right of the surge point. If this is not possible, speed control, impeller geometry control, inlet dampers, exhaust dampers, and bleed lines may be employed. Changing a fan's speed cannot be used to stabilize a fan operating in an unstable condition. According to affinity, if an operating point for a fan is in an unstable region to the left of the peak, it will remain in an unstable region at any speed.

Multiple fans may be called for in some applications to avoid pressure buildup in a space or to fit a space constraint. When demand or system conditions are highly variable, multiple fans may serve the need better than a single fan. Because operating point is based on capacity, if capacity varies the operating point will move along the performance curve and may depart from reasonable efficiency for the fan or blower. In these cases, one fan is sized for one operating point, and additional fans are called into service as needed to provide additional capacity. Fans or blowers in parallel and series follow the same additive rules as pumps. Instability can occur in parallel fan systems when the combined performance curve intersects the system curve at a point where the individual operating points are widely separated. In that condition, the fans may suddenly exchange loading and shock the mechanism and/or ductwork. To avoid this, fans in parallel must be carefully matched to the system.

**Compressors.**— When significant air pressure must be generated, in excess of 10 psig (68.9 kPa), a compressor is employed. The most common pressures range from 60 to 110 psig (413.7 – 758.4 kPa). There are many standards covering compressors, including those by ANSI, ASME, API, SAE, and CAGI.

*Compression of Air:* The formula for the relationship between pressure, temperature, and volume of air just given indicates that when the pressure remains constant the volume is directly proportional to the absolute temperature. If the temperature remains constant, the volume is inversely proportional to the absolute pressure. Theoretically, air (as well as other gases) can be expanded or compressed according to different laws.

*Adiabatic Expansion or Compression* takes place when the air is expanded or compressed without transmission of heat to or from it, as, for example, if the air could be expanded or compressed in a cylinder of an absolutely nonconducting material.

Let:  $P_1$  = initial absolute pressure in pounds per square foot

$V_1$  = initial volume in cubic feet

$T_1$  = initial absolute temperature in degrees R

$P_2$  = absolute pressure in pounds per square foot, after compression

$V_2$  = volume in cubic feet, after compression

$T_2$  = absolute temperature in degrees R, after compression

Then:

$$\frac{V_2}{V_1} = \left(\frac{P_1}{P_2}\right)^{0.71} \quad \frac{P_2}{P_1} = \left(\frac{V_1}{V_2}\right)^{1.41} \quad \frac{T_2}{T_1} = \left(\frac{V_1}{V_2}\right)^{0.41}$$

$$\frac{V_2}{V_1} = \left(\frac{T_1}{T_2}\right)^{2.46} \quad \frac{P_2}{P_1} = \left(\frac{T_2}{T_1}\right)^{3.46} \quad \frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{0.29}$$

These formulas are also applicable if all pressures are in pounds per square inch; if all volumes are in cubic inches; or if any other consistent set of units is used for pressure or volume.

 *Example 2:* A volume of 165 cubic feet of air, at a pressure of 15 pounds per square inch, is compressed adiabatically to a pressure of 80 pounds per square inch. What will be the volume at this pressure?

$$V_2 = V_1 \left(\frac{P_1}{P_2}\right)^{0.71} = 165 \left(\frac{15}{80}\right)^{0.71} = 50 \text{ cubic feet, approx.}$$

*Isothermal Expansion or Compression* takes place when a gas is expanded or compressed with an addition or transmission of sufficient heat to maintain a constant temperature.

Let:  $P_1$  = initial absolute pressure in pounds per square foot

$V_1$  = initial volume in cubic feet

$P_2$  = absolute pressure in pounds per square foot, after compression

$V_2$  = volume in cubic feet, after compression

$R = 53.3$

$T$  = temperature in degrees Rankine maintained during isothermal expansion or contraction

Then:

$$P_1 \times V_1 = P_2 \times V_2 = RT$$

 *Example 3:* The same volume of air as in **Example 2** is compressed isothermally from 15 to 80 pounds per square inch. What will be the volume after compression?

$$V_2 = \frac{P_1 \times V_1}{P_2} = \frac{15 \times 165}{80} = 31 \text{ cubic feet}$$

 *Work Required in Compression of Air:* The total work required for compression and expulsion of air, adiabatically compressed, is:

$$\text{Total work in foot-pounds} = 2.44P_1V_1 \left[ \left( \frac{P_2}{P_1} \right)^{0.29} - 1 \right]$$

$P_1$  = initial absolute pressure in pounds per square foot;  $P_2$  = absolute pressure in pounds per square foot, after compression; and,  $V_1$  = initial volume in cubic feet.

The total work required for isothermal compression is:

$$\text{Total work in foot-pounds} = P_1V_1 \log_e \frac{V_1}{V_2}$$

in which  $P_1$ ,  $P_2$ , and  $V_1$  denote the same quantities as in the previous equation, and  $V_2$  = volume of air in cubic feet, after compression.

The work required to compress air isothermally, that is, when the heat of compression is removed as rapidly as produced, is considerably less than the work required for compressing air adiabatically, or when all the heat is retained. In practice, neither of these two theoretical extremes is obtainable, but the power required for air compression is about the median between the powers that would be required for each. The accompanying table gives the average number of foot-pounds of work required to compress air.

*Horsepower Required to Compress Air:* In the accompanying tables is given the horsepower required to compress one cubic foot of free air per minute (isothermally and adiabatically) from atmospheric pressure (14.7 pounds per square inch) to various gage pressures, for one-, two-, and three-stage compression. The formula for calculating the horsepower required to compress, adiabatically, a given volume of free air to a given pressure is:

$$\text{HP} = \frac{144NPVn}{33,000(n-1)} \left[ \left( \frac{P_2}{P} \right)^{\frac{n-1}{Nn}} - 1 \right]$$

where  $N$  = number of stages in which compression is accomplished

$P$  = atmospheric pressure in pounds per square inch

$P_2$  = absolute terminal pressure in pounds per square inch

$V$  = volume of air, in cubic feet, compressed per minute, at atmospheric pressure

$n$  = exponent of the compression curve = 1.41 for adiabatic compression

For different methods of compression and for one cubic foot of air per minute, this formula may be simplified as follows:

For one-stage compression:  $\text{HP} = 0.015P(R^{0.29} - 1)$

For two-stage compression:  $\text{HP} = 0.030P(R^{0.145} - 1)$

For three-stage compression:  $\text{HP} = 0.045P(R^{0.0975} - 1)$

For four-stage compression:  $\text{HP} = 0.060P(R^{0.0725} - 1)$

In these latter formulas  $R = \frac{P_2}{P}$  = number of atmospheres to be compressed

The formula for calculating the horsepower required to compress isothermally a given volume of free air to a given pressure is:

$$\text{HP} = \frac{144PV}{33000} \left( \log_e \frac{P_2}{P} \right)$$

Natural logarithms are obtained by multiplying common logarithms by 2.30259 or by using a handheld calculator.

The work and power required for air compression can be found in [Tables 36 to 39](#).

Stress and heat are what limits the maximum compression of any single stage of a compressor. The volumetric efficiency drops as pressure rise increases, further limiting the

<sup>a</sup> Mean Effective Pressure (MEP) is defined as that single pressure rise, above atmospheric, which would require the same horsepower as the actual varying pressures during compression.

maximum compression of a single stage. Multi-stage compressors are used when a single stage cannot develop enough pressure. Multi-stage axial compressors use a series of axial fans to deliver very large flow rates. Perfect intercooling is impractical, so it is important to note that for every 10°F temperature increase, the horsepower requirement increases nearly 1%.

*Compressor Types:* Compressors can be centrifugal, multi-stage centrifugal, multi-stage axial, or positive displacement. Centrifugal compressors are similar to centrifugal blowers. Positive displacement compressors are essentially positive displacement pumps, used to deliver high pressures at moderate flow rates. These compressors can employ a variety of mechanisms, like pistons, lobes, screws, and vanes. Small positive displacement compressors are often sold to homes and businesses.

Positive displacement compressors compress a fixed amount of gas within a closed chamber by decreasing its volume. Volumetric efficiency is affected by leakage and mechanical losses. Positive displacement compressors tend to be selected for low to moderate flow applications with high compression requirements. Compressor types in this category include: reciprocating piston, rotary vane, rolling piston, rotary twin-screw, and orbiting scroll compressors. Screw compressors are commonly used in the range between 100 and 150 psig. Reciprocating compressors can be either single acting or double acting, and are commonly used for pressures in excess of 200 psig. These types of compressors deliver a pulsating flow of gas, unlike other types of compressors. Multi-stage positive displacement compressors with intercooling are common at pressures exceeding 80 psig.

Many state laws and general good practice requires the use of an appropriately sized relief valve ahead of the first stop valve in positive displacement compressors. This relief valve should be set to release at 125% of the maximum discharge pressure of the compressor, or at the maximum working pressure of the compressor, whichever is lower.

Dynamic compressors impart momentum to the gas by means of a spinning rotor. This momentum energy is converted to pressure energy when the gas is slowed again. This is a constant flow process. Dynamic compressors are subject to the fan laws, and the specific speed is used to select the geometry. Dynamic compressors tend to be selected for moderate to high flow applications with low to moderate compression requirements. Multi-stage dynamic compressors can provide high flow and high compression.

*Compressor Sizing:* When sizing a compressor for a given application, one must analyze the piping system to the point of use to account for any pressure drops between it and the compressor. Any pressure loss must be added to the compressor range to make sure the desired pressure is delivered at the point of use. If the pressure drop is significant (exceeding 10%) the change in specific weight of the gas should be taken into account.

The maximum capacity of a compressor should exceed the maximum mean air consumption of the system.

Because the maximum capacity of an air compressor will exceed the minimum air consumption in the system, the compressor must modulate its capacity during normal work. This will cause variation of system pressure, or pressure pulsation. As a result, a receiver should be installed after the compressor to stabilize system pressure.

Like with fans and pumps, compressors are usually sized by graphing the characteristic curve. Discharge pressure, head, or pressure ratio is graphed against inlet flow rate. For dynamic compressors, the graph includes values at various speeds and efficiencies. The system curve(s) is then plotted over the characteristic curve(s) and the intersection is the operating point. Multiple operating points may be encountered. Each stage of compression will have its own characteristic curve, and in an ideal case each stage will operate at a high efficiency.

For dynamic compressors, inlet pressure variation has a direct effect on horsepower. To correctly size the compressor drive, the full range of inlet pressures must be considered as well as discharge pressures. Dynamic compressors are subject to a minimum flow rate

called the surge limit. Surge is seen to the left of the characteristic curve(s). The demand limits of the application must be considered and operation below the surge limit prevented.

**Gas Conditioning and Stabilization.**— In order to provide consistent, clean, dry gas supply; dryers, filters, oilers, receivers, silencers, and exhaust cleaners are used to condition and stabilize pressurized gas.

*Filters:* Compressed gas used to perform work normally needs to be very clean to avoid fouling the devices in the system. Filters of various types are employed to clean compressed air. Most manufacturers offer a range of high efficiency coalescing compressed air filters for the removal of water and oil aerosols, solid particulates and micro-organisms, and dust filters for the removal of dry particulate and micro-organisms from industrial compressed air systems. Filters are selected and sized based on what contaminant is to be removed, output cleanliness level, pressure capacity, flow capacity, pressure drop, and mounting method. Filters require regular preventative maintenance.

*Dryers:* Compressed air supplies for pneumatic systems normally have moisture removed to prevent fouling and corrosion of the system components. For this purpose, compressed air dryers are employed. Dryer type and size is selected according to required air quality, pressure, dew point, and delivery volume. There are several types of commercial dryers available: refrigerated, desiccant, membrane, and deliquescent.

A refrigerated dryer uses a compressor, heat exchanger, and refrigerant to pull liquid out of the gas. Normally a coalescing prefilter is installed immediately upstream of a refrigerated dryer to remove lubricating oil and other contaminants that have the potential to foul the dryer's heat exchangers.

A desiccant dryer passes compressed air through a pressure vessel filled with a media such as activated alumina, silica gel, molecular sieve or other desiccant material which pulls water out of the gas. Normally the desiccant can be regenerated.

A membrane dryer requires no electricity to operate. Water vapor permeates a membrane of hollow fibers and is swept out with redirected dry air to exhaust, while the bulk of the dry air is passed back into the pressurized system.

Normally a coalescing prefilter is installed immediately upstream of a membrane dryer to remove lubricating oil and other contaminants that have potential to foul the dryer's membrane.

A deliquescent dryer typically consists of a pressure vessel filled with a hygroscopic media that absorbs water vapor. The media gradually dissolves, or deliquesces. The vessel must be regularly drained and new media must be added.

*Lubricators:* In some cases a small amount of oil or other lubricant is added to the compressed air supply to lubricate components like actuators. Manufacturers will specify whether their components are "oil-free" or not.

Lubricators are often combined with filters and regulators to form filter-regulator-lubricator (FRL) units. Lubricators usually introduce a fine mist of lubricant into the air stream with particles in the micron range.

*Receivers:* Most compressed gas systems have gas introduced in a pulsating supply. Receivers are essentially pressure vessels that act as reservoirs for the compressed gas. These reservoirs act to stabilize the system pressure by absorbing pressure pulsations. They also stabilize the system at times of fluctuating demand by supplying excess gas when demand peaks, and storing it when demand drops. Receivers are most effective when placed close to the pressure source in the system. A pressure regulator is placed after the receiver to provide constant pressure to the downstream components. Secondary receivers are often placed near high demand to further stabilize the system pressure. Receivers may have valves at the bottom where collected condensate may be drained.

*Silencers and Exhaust Cleaners:* When air is the gas employed, it is usually exhausted to atmosphere after it is used to perform work. When compressed air is released, significant

noise can be produced. Silencers or mufflers are used to minimize this effect. The most common silencers are sintered metal, and they are very effective. Silencers are chosen based on port size, pressure, flow requirement, construction, material, and noise reduction level. Exhaust cleaners may be required in some cases where contaminants are present. The proper cleaning system will depend on the contaminant type and level, flow rate, pressure, and construction.

**Nozzles.**— These devices include a restriction through which a gas passes from a region of higher pressure to a region of lower pressure, typically atmospheric. Nozzles are used to accelerate and direct a gas to perform some function. Analysis of nozzles is greatly simplified if one assumes that there is zero heat transfer during discharge, or the discharge is adiabatic. Real nozzles are not adiabatic, but this assumption is generally safe to make. Flow rate of gas through a nozzle is calculated using the following equation:

$$\dot{m} = \rho v_n A_n$$

where  $A_n$  is the cross sectional area of the nozzle,  $v_n$  is velocity through the nozzle, and  $\dot{m}$  is the mass flow rate. In the following equations,  $v_n$  and  $p_n$  are nozzle outlet velocity and exit pressure ( $p_n =$  atmospheric normally),  $v_t$  and  $p_t$  are source (tank) velocity and pressure,  $\gamma$  is specific weight, and  $k$  is the adiabatic exponent given in Table 40. Pressures are absolute.

**Table 40. Adiabatic Gas Exponent and Critical Pressure Ratio**

Gas	$k$	Critical Pressure Ratio	Gas	$k$	Critical Pressure Ratio
Air	1.4	0.528	Nitrogen	1.41	0.527
Ammonia	1.32	0.542	Oxygen	1.4	0.528
Carbon Dioxide	1.3	0.546	Propane	1.15	0.574

Flow rate through a converging nozzle reaches a maximum at a critical pressure ratio. At this ratio, the nozzle velocity is equal to the speed of sound for that gas at those conditions. For subsonic flow, an increase in nozzle cross sectional area causes flow velocity to decrease. For supersonic flow, an increase in nozzle area causes flow velocity to increase. To calculate the critical pressure ratio use the following equation:

$$\left(\frac{p'_n}{p_t}\right)_c = \left(\frac{2}{k+1}\right)^{\frac{k}{k-1}}$$

If a converging nozzle's pressure ratio ( $p_n/p_t$ ) is greater than the critical pressure ratio, use the following equation to calculate flow.

$$W = A_n \sqrt{\frac{p_t \gamma_i 2 g k \left(\frac{2}{k+1}\right)^{\frac{2}{k-1}}}{k+1}}$$

where  $W$  is the weight flow rate.

If a converging nozzle is not operating above the critical pressure ratio, then velocity is equal to sonic velocity and the following equations are used:

Pressure at the nozzle throat is equal to the critical pressure:

$$p_n = p'_n = p_t \left(\frac{2}{k+1}\right)^{\frac{k}{k+1}}$$

$$\dot{m} = A_n \sqrt{k p_i \rho_i} \left(\frac{2}{k+1}\right)^{\frac{k+1}{2(k-1)}}$$

where subscript  $i$  indicates inlet conditions,  $\dot{m}$  is the mass flow in kg/s,  $A$  is nozzle area in  $m^2$ , and  $p$  is pressure in Pa.

Flow rate faster than the speed of sound is possible with a converging-diverging nozzle. Analysis of this type of nozzle is beyond the scope of this text.

*Velocity of Escaping Compressed Air:* For a large container with a small orifice or hole from which the air escapes, the velocity of escape (theoretical) may be calculated from the formula:

$$v_2 = \sqrt{2g \cdot \frac{k}{k-1} \cdot 53.3(459.7 + F) \left[ 1 - \left( \frac{p_2}{p_1} \right)^{\frac{k-1}{k}} \right]}$$

In this formula,  $v_2$  = velocity of escaping air in feet per second;  $g$  = acceleration due to gravity, 32.16 feet per second squared;  $k$  = 1.41 for adiabatic expansion or compression of air;  $F$  = temperature, degrees F;  $p_2$  = atmospheric pressure = 14.7 pounds per square inch; and  $p_1$  = pressure of air in container, pounds per square inch. In applying the preceding formula, when the ratio  $p_2/p_1$  approximately equals 0.53, under normal temperature conditions at sea level, the escape velocity  $v_2$  will be equal to the velocity of sound. Increasing the pressure  $p_1$  will not increase the velocity of escaping air beyond this limiting velocity unless a special converging diverging nozzle design is used rather than an orifice.

The accompanying **Table 41** provides velocity of escaping air for various values of  $p_1$ . These values were calculated from the preceding formula simplified by substituting the appropriate constants:

$$v_2 = 108.58 \sqrt{(459.7 + F) \left[ 1 - \left( \frac{14.7}{p_1} \right)^{0.29} \right]}$$

**Table 41. Velocity of Escaping Air at 70-Degrees F**

Pressure Above Atmospheric Pressure			Theoretical Velocity, Feet per Second	Pressure Above Atmospheric Pressure			Theoretical Velocity, Feet per Second
Atmospheres	Inches Mercury	lbs per sq. in.		Atmospheres	Inches Mercury	lbs per sq. in.	
0.010	0.30	0.147	134	0.408	12.24	6.00	769
0.068	2.04	1.00	344	0.500	15.00	7.35	833
0.100	3.00	1.47	413	0.544	16.33	8.00	861
0.136	4.08	2.00	477	0.612	18.37	9.00	900
0.204	6.12	3.00	573	0.680	20.41	10.0	935
0.272	8.16	4.00	650	0.816	24.49	12.0	997
0.340	10.20	5.00	714	0.884	26.53	13.0	1025

The theoretical velocities in **Table 41** must be reduced by multiplying by a “coefficient of discharge,” which varies with the orifice and the pressure. The coefficients in **Table 42** are used for orifices in thin plates and short tubes.

**Table 42. Coefficients of Discharge**

Type of Orifice	Pressures in Atmospheres Above Atmospheric Pressure			
	0.01	0.1	0.5	1
Orifice in thin plate	0.65	0.64	0.57	0.54
Orifice in short tube	0.83	0.82	0.71	0.67

### Vacuum

Vacuum is any pressure lower than atmospheric. It can be measured in psi or Pa as a negative gauge pressure, or as a positive absolute pressure. Other common units for vacuum are inches of mercury (inHg), millimeters of mercury (mmHg), millibar, and torr. A perfect vacuum has zero absolute pressure, or  $-14.7$  psi ( $-29.92$  inHg). Flow in low to medium vacuum (down to  $10^{-4}$  torr) is characterized as viscous flow, while in high (below  $10^{-4}$  torr) and ultra-high vacuum (below  $10^{-8}$  torr) it is characterized as molecular flow.

**Tubing and Fittings for Vacuum Applications.**— Tubing and fittings used for vacuum applications must be rated for vacuum use to prevent collapse. When working with vacuum, the resistance to flow created by tubing and fittings is discussed in terms of conductance. Conductance can be calculated as follows:

$$C = \frac{Q}{\Delta p}$$

where  $C$  is conductance in l/sec,  $p$  is pressure in torr, and  $Q$  is flow rate in torr-l/sec. For dry air at  $20^\circ\text{C}$  in the molecular flow region of vacuum, estimate conductance of long tubes as follows:

$$C = 75 \frac{D^3}{L}$$

where  $L$  is tube length in inches,  $D$  is tube inner diameter in inches, and  $C$  is in l/sec.

Effective pumping speed at the end of a tube with conductance  $C$  can be calculated using the following equation:

$$\frac{1}{S_{\text{eff}}} = \frac{1}{C} + \frac{1}{S}$$

where  $S$  is the pumping speed of the pump by itself, and  $C$  is conductance of the tube.

The conductance of tubes in series and parallel can be combined according to the following equations.

Conductance changes with pressure, so effective pumping speed is best calculated piecemeal at incremental pressures.

$C_p = C_1 + C_2$  where  $C_p$  is the conductance of tubes 1 and 2 in parallel.

$\frac{1}{C_s} = \frac{1}{C_1} + \frac{1}{C_2}$  where  $C_s$  is the conductance of tubes 1 and 2 in series.

**Vacuum Pumps and Generators.**— Vacuum pumps are essentially compressors in reverse. Where deep or continuous vacuum is required on a large evacuation volume, it is common to use a fast evacuation pump to remove the gas, and then a deep vacuum pump is used to reach the desired vacuum level. Vacuum deeper than  $-14.7$  psi ( $-29.92$  inHg) is not possible.

Vacuum generators usually use a venturi to generate vacuum when compressed air is supplied. Single and multi-stage units are widely available to generate vacuum as deep as  $-25$  inHg ( $-85$  kPa). Suction flow for vacuum generators is moderate, with values of 7 SCFM (200 l/min) commercially available. Vacuum generators consume compressed air, so these tend to be more costly to run than vacuum pumps. Vacuum generators are sometimes combined into devices called “vacuum ejectors” which provide a puff of positive air pressure when the vacuum is halted. This provides a positive release function when picking and placing components using vacuum.

*Types of Vacuum Pumps:* Vacuum pumps can employ pistons, vanes, and lobes like compressors or pumps. There are also turbomolecular pumps, diffuser pumps, chemical reaction pumps, gettering pumps, ion pumps, and cryogenic pumps. Vacuum pumps tend to fall into two main categories: transfer pumps and capture pumps.

Coarse vacuum pumps used for rapid evacuation are commonly rotary vane-type positive displacement pumps. These pumps are usually flooded with oil, which lubricates, cools, and seals the pump. The oil is discharged with the gas. To achieve deep vacuum, vane pumps in series are sometimes used, as are screw pumps. Where the presence of oil is objectionable, multi-stage oil-free pumps are employed, but are not as efficient as oil sealed pumps.

Turbomolecular pumps in general use rotors to accelerate gas molecules, similar to centrifugal pumps. Drag pumps are an example of this type of vacuum pump.

Diffuser, or jet pumps are the most commonly used type of vacuum pump for high vacuum applications. In these pumps, a high velocity jet of fluid is used to transfer momentum to gas in a channel. This type of pump can sustain a vacuum level up to 1 torr, but must be used in combination with an evacuation pump. Multi-stage diffuser pumps are available.

Cryogenic pumps cool gases until they condense into a liquid or solid. In practice, a cooled pump is used, rather than cooling an entire reservoir or chamber. Helium is often used as the refrigerant, and cooling to temperatures of 10 Kelvin are possible.

Gettering pumps use specially treated surfaces, called "gettering" surfaces. In vacuum, these surfaces are capable of holding greater amounts of gas than would occupy a section of free space of the same cross sectional area. Ion pumps use electron bombardment to ionize inert gases that would not normally be affected by gettering surfaces.

*Selection Factors:* The type of pump or generator required by an application depends on whether the system must provide rapid evacuation, long term maintenance of vacuum, high suction flow rate, and/or deep vacuum. Diffuser pumps cannot be exposed to gas at atmospheric pressure once they are at operating temperature. To prevent the risk of damage, a system of valves must be engineered to prevent this condition. Filters should always be used with vacuum generators to protect them from contamination.

*Sizing Vacuum Pumps and Generators:* Vacuum pump performance is rated in terms of throughput, pumping speed, and vacuum pressure capability. They are rated for either intermittent or continuous duty. Throughput is the product of volumetric flow rate and pressure. Pumping speed has units of volume/time and is the mean volume flow through the cross section of the inlet port of a vacuum pump.

Determination of the pumping speed is described in ISO 21360-1. Vacuum pump performance curves are plots of pumping speed as a function of inlet pressure. The lowest pressure that can be achieved by a vacuum pump can be calculated using the following equation:

$$p_{\min} = p_0 e^{\left(\frac{-S_{\text{eff}} t}{V}\right)} + \frac{Q_o}{S_{\text{eff}}} + \frac{Q_D}{S_{\text{eff}}} + \frac{Q_K}{S_{\text{eff}}}$$

where  $p_{\min}$  is the deepest vacuum achievable,  $p_0$  is the initial pressure,  $t$  is time,  $S_{\text{eff}}$  is the effective pumping speed, and  $V$  is the evacuation volume.  $Q_o$ ,  $Q_D$ , and  $Q_K$  are outgassing, diffusion, and permeation flow rates.

The time required to reach a certain pressure depends on the pumping speed, the volume being evacuated, and the initial pressure. It can be calculated using the following equation. Effective pumping speed changes as the pressure decreases, so the following equations are best applied piecemeal using pumping speed values at increments as the pressure varies.

$$t = \frac{V}{S_{\text{eff}}} \ln\left(\frac{p_0}{p_1}\right)$$

where  $t$  is pumpdown time,  $V$  is volume,  $S_{\text{eff}}$  is effective pumping speed,  $p_0$  is initial pressure (absolute), and  $p_1$  is final pressure.

Minimum achievable pressure is affected by ambient air pressure according to the following relationship:

$$p'_{\min} = p_{\text{atm}} \frac{p_r}{29.92}$$

where  $p'_{\min}$  is the adjusted achievable vacuum (psi),  $p_{\text{atm}}$  is atmospheric pressure (psi), and  $p_r$  is the rated achievable vacuum (inHg). Most vacuum pumps are rated at sea level atmospheric pressure.

Vacuum generators are sized according to the level of vacuum required and the required suction flow rate.

Vacuum level generated is often expressed as a percentage of input pressure. Input tube diameter and air pressure must be known. A variety of options are available, including ejection, vacuum monitoring, and valving. Multi-stage generators are used to create deeper vacuum than single stage units. Some vacuum generators are optimized for high flow, while others for deep vacuum. Deep vacuum is desirable when picking up a heavy object with a leak-free seal. High suction flow is desirable when picking up objects where a leak-free seal is not possible.

*Vacuum Accessories:* Many accessories are used with vacuum pumps and generators to filter, regulate, control, exploit, measure, and stabilize vacuum. It is important to note that vacuum rated greases must be used when grease is exposed to vacuum.

*Filters:* Filters are critical when using vacuum, because contaminants can be sucked into the vacuum lines and damage the pump, generator, valve, or other components. Selection is based on body type, tube diameter, and maximum particle size that can pass through the filter. Fine filters are typically used with vacuum systems. They must be regularly replaced or cleaned to prevent clogging.

*Regulators:* Like pressure regulators, these devices are essential for limiting and stabilizing vacuum pressure in a circuit. They may be manually or automatically controlled. These devices are outfitted with a gauge or digital readout. Vacuum regulators are sized with respect to range and accuracy of measurement, maximum flow rate, and port size.

*Valves:* Many pressure valves can be used to control vacuum. However, if the valve uses air pressure to cause switching, an external pilot line with positive pressure must be provided.

*Grippers:* There are a wide variety of grippers available for the purpose of picking up objects with vacuum. Their primary purpose is to provide a leak-free seal to maximize the effect of the vacuum system. Compliant grippers include suction cups, bellows, and vacuum pads of all shapes and sizes. Miniature valves are often used in applications with multiple grippers to restrict flow if no part is present.

*Measurement:* Vacuum gauges and switches are used to measure the level of vacuum. They may be analog or digital, and measure in absolute or gauge pressure.

*Level Compensators:* These compliant devices are used when multiple grippers are employed in picking up a part. They provide some degree of shock and vibration dampening. Level compensators are available in a wide variety of sizes and stroke lengths.

Ampere	A	Kilovolt-ampere	kVA	Microfarad	μF		
Ampere-hour	Ah	Kilowatt	kW	Microwatt	μW	Volt	V
Coulomb	C			Milliamper	mA	Volt-ampere	VA
Farad	F	Kilowatthour	kWh	Millifarad	mF	Volt-coulomb	VC
Henry	H	Megawatt	MW	Millihenry	mH	Watt	W
Joule	J	Megohm	MΩ	Millivolt	mV	Wattour	Wh
Kilovolt	kV	Microampere	μA	Ohm	Ω		

Only the most commonly used terms have been included. These forms are recommended for those whose familiarity with the terms used makes possible a maximum of abbreviations. For others, less contracted combinations made up from this list may be used. For example, the list gives the abbreviation of the term "feet per second" as "fps." To some, however, ft per sec will be more easily understood.

Abbreviations should be used sparingly and only where their meaning will be clear. If there is any doubt, then spell out the term or unit of measurement.

The following points are good practice when preparing engineering documentation. Terms denoting units of measurement should be abbreviated in text only when preceded by the amounts indicated in numerals: "several inches," "one inch," "12 in." A sentence should not begin with a numeral followed by an abbreviation. The use of conventional signs for abbreviations in text should be avoided: use "lb," not "#" or "in," not ".

Symbols for the chemical elements are listed in the table on page 359.

## Mathematical Signs and Commonly Used Abbreviations

+	Plus (sign of addition)	$\pi$	Pi (3.1416)
+	Positive	$\Sigma$	Sigma (sign of summation)
-	Minus (sign of subtraction)	$\omega$	Omega (angles measured in radians)
-	Negative	$g$	Acceleration due to gravity (32.16 ft/s <sup>2</sup> or 9.81 m/s <sup>2</sup> )
$\pm$ ( $\mp$ )	Plus or minus (minus or plus)	$i$ (or $j$ )	Imaginary quantity ( $\sqrt{-1}$ )
$\times$	Multiplied by (multiplication sign)	sin	Sine
$\cdot$	Multiplied by (multiplication sign)	cos	Cosine
$\div$	Divided by (division sign)	tan	Tangent
/	Divided by (division sign)	cot	Cotangent
:	Is to (in proportion)	sec	Secant
=	Equals	csc	Cosecant
$\neq$	Is not equal to	vers	Versed sine
$\equiv$	Is identical to	covers	Covered sine
$\cong$ or $\approx$	Approximately equals	$\sin^{-1} a$	Angle the sine of which is $a$
>	Greater than	arcsin $a$ or asin $a$	
<	Less than	$(\sin a)^{-1}$	Reciprocal of $\sin a$ ( $1 \div \sin a$ )
$\geq$	Greater than or equal to	$\sin^n x$	$n$ th power of $\sin x$
$\leq$	Less than or equal to	sinh $x$	Hyperbolic sine of $x$
$\rightarrow$	Approaches as a limit; implies	cosh $x$	Hyperbolic cosine of $x$
$\propto$	Varies directly as	$\Delta$	Delta (increment of)
$\therefore$	Therefore	$\delta$	Delta (variation of)
$::$	Equals (in proportion)	$d$	Differential (in calculus)
$\sqrt{a}$	Square root of $a$	$\partial$	Partial differentiation (in calculus)
$\sqrt[3]{a}$	Cube root of $a$	$\int$	Integral (in calculus)
$\sqrt[4]{a}$	4th root of $a$	$\int_b^a$	Integral between the limits $a$ and $b$
$\sqrt[n]{a}$	$n$ th root of $a$ (also $a^{1/n}$ )	$n!$	Factorial $n! = n \times (n-1)!$ ; $0! = 1$ ; $1! = 1$ Ex: $5! = 5 \times 4 \times 3 \times 2 \times 1 = 120$
$a^2$	$a$ squared (2nd power of $a$ )	$\sphericalangle$	Angle
$a^3$	$a$ cubed (3rd power of $a$ )	L	Right angle
$a^4$	4th power of $a$	$\perp$	Perpendicular to
$a^n$	$n$ th power of $a$	$\triangle$	Triangle
$a^{-n}$	$1 \div a^n$	$\circ$	Circle
$\frac{1}{n}$	Reciprocal value of $n$	$\square$	Parallelogram
log	Logarithm	$^\circ$	Degree (circular arc or temperature)
$\log_e$	Natural or Napierian logarithm	'	Minutes or feet
ln	Natural or Napierian logarithm	"	Seconds or inches
$e$	Base of natural logarithms (2.71828)	$a'$	$a$ prime
lim	Limit value (of an expression)	$a''$	$a$ double prime
$\infty$	Infinity	$a_1$	$a$ sub one
$\alpha$	Alpha	$a_2$	$a$ sub two
$\beta$	Beta	$a_n$	$a$ sub $n$
$\gamma$	Gamma	( )	Parentheses
$\theta$	Theta	[ ]	Brackets
$\phi$	Phi	{ }	Braces
$\mu$	Mu (coefficient of friction)	$ K $	Absolute value of $K$ , size of $K$ irrespective of sign

commonly used to  
denote angles

**Letter Symbols for Mechanics and Time-Related Phenomena**

Acceleration, angular	$\alpha$ (alpha)	Height	$h$
Acceleration, due to gravity	$g$	Inertia, moment of	$I$ or $J$
Acceleration, linear	$a$	Inertia, polar (area) moment of <sup>a</sup>	$J$
Amplitude <sup>a</sup>	$A$	Inertia, product (area) moment of <sup>a</sup>	$I_{xy}$
		Length	$L$ or $l$
	$\alpha$ (alpha)	Load per unit distance <sup>a</sup>	$q$ or $w$
	$\beta$ (beta)	Load, total <sup>a</sup>	$P$ or $W$
Angle	$\gamma$ (gamma)	Mass	$m$
	$\theta$ (theta)	Moment of force, including bending moment	$M$
	$\phi$ (phi)	Neutral axis, distance to extreme fiber from <sup>a</sup>	$c$
	$\psi$ (psi)	Period	$T$
Angle, solid	$\Omega$ (omega)	Poisson's ratio	$\mu$ (mu) or $\nu$ (nu)
Angular frequency	$\omega$ (omega)	Power	$P$
Angular momentum	$L$	Pressure, normal force per unit area	$p$
Angular velocity	$\omega$ (omega)	Radius	$r$
Arc length	$s$	Revolutions per unit of time	$n$
Area	$A$	Second moment of area (second axial moment of area)	$I_a$
Axes, through any point <sup>a</sup>	$X-X, Y-Y,$ or $Z-Z$	Second polar moment of area	$I_p$ or $J$
Bulk modulus	$K$	Section modulus	$Z$
Breadth (width)	$b$	Shear force in beam section <sup>a</sup>	$V$
Coefficient of expansion, linear <sup>a</sup>	$\alpha$ (alpha)	Spring constant (load per unit deflection) <sup>a</sup>	$k$
Coefficient of friction	$\mu$ (mu)	Statical moment of any area about a given axis <sup>a</sup>	$Q$
Concentrated load (same as force)	$F$	Strain, normal	$\epsilon$ (epsilon)
Deflection of beam, max <sup>a</sup>	$\delta$ (delta)	Strain, shear	$\gamma$ (gamma)
Density	$\rho$ (rho)	Stress, concentration factor <sup>a</sup>	$K$
Depth	$d, \delta$ (delta), or $t$	Stress, normal	$\sigma$ (sigma)
Diameter	$D$ or $d$	Stress, shear	$\tau$ (tau)
Displacement <sup>a</sup>	$u, v, w$	Temperature, absolute <sup>b</sup>	$T,$ or $\theta$ (theta)
Distance, linear <sup>a</sup>	$s$	Temperature <sup>b</sup>	$t,$ or $\theta$ (theta)
Eccentricity of application of load <sup>a</sup>	$e$	Thickness	$d, \delta$ (delta), or $t$
Efficiency <sup>a</sup>	$\eta$ (eta)	Time	$t$
Elasticity, modulus of	$E$	Torque	$T$
Elasticity, modulus of, in shear	$G$	Velocity, linear	$v$
Elongation, total <sup>a</sup>	$\delta$ (delta)	Volume	$V$
Energy, kinetic	$E_k, K, T$	Wavelength	$\lambda$ (lambda)
Energy, potential	$E_p, V,$ or $\Phi$ (phi)	Weight	$W$
Factor of safety <sup>a</sup>	$N$ or $n$	Weight per unit volume	$\gamma$ (gamma)
Force or load, concentrated	$F$	Work	$W$
Frequency	$f$		
Gyration, radius of <sup>a</sup>	$k$

## MEASURING UNITS

### Metric Systems of Measurement

A metric system of measurement was first established in France in the years following the French Revolution, and various systems of metric units have been developed since that time. All metric unit systems are based, at least in part, on the International Metric Standards, which are the meter and kilogram, or decimal multiples or submultiples of these standards.

In 1795, a metric system called the centimeter-gram-second (cgs) system was proposed, and was adopted in France in 1799. In 1873, the British Association for the Advancement of Science recommended the use of the cgs system, and since then it has been widely used in all branches of science throughout the world. From the base units in the cgs system are derived the following:

*Unit of velocity* = 1 centimeter per second

*Acceleration due to gravity (at Paris)* = 981 centimeters per second per second

*Unit of force* = 1 dyne =  $\frac{1}{981}$  gram

*Unit of work* = 1 erg = 1 dyne-centimeter

*Unit of power* = 1 watt = 10,000,000 ergs per second

Another metric system called the MKS (meter-kilogram-second) system of units was proposed by Professor G. Giorgi in 1902. In 1935, the International Electrotechnical Commission (IEC) accepted his recommendation that this system of units of mechanics should be linked with the electromagnetic units by the adoption of a fourth base unit. In 1950, the IEC adopted the ampere, the unit of electric current, as the fourth unit, and the MKSA system thus came into being.

A gravitational system of metric units, known as the technical system, is based on the meter, the kilogram as a force, and the second. It has been widely used in engineering. Because the standard of force is defined as the weight of the mass of the standard kilogram, the fundamental unit of force varies due to the difference in gravitational pull at different locations around the earth. By international agreement, a standard value for acceleration due to gravity was chosen (9.81 meters per second squared) that for all practical measurements is approximately the same as the local value at the point of measurement.

**The International System of Units (SI).**—The Conference Generale des Poids et Mesures (CGPM), which is the body responsible for all international matters concerning the metric system, adopted in 1954 a rationalized and coherent system of units based on the four MKSA units (see above), including the *kelvin* as the unit of temperature and the *candela* as the unit of luminous intensity. In 1960, the CGPM formally named this system the *Système International d'Unites*, for which the abbreviation is SI in all languages. In 1971, the 14th CGPM adopted a seventh base unit, the *mole*, which is the unit of quantity (“amount of substance”).

In the period since the first metric system was established in France toward the end of the 18th century, most of the countries of the world have adopted a metric system. At the present time, most of the industrially advanced metric-using countries are changing from their traditional metric system to SI. Those countries that are currently changing or considering change from the English system of measurement to metric have the advantage that they can convert directly to the modernized system. The United Kingdom, which can be said to have led the now worldwide move to change from the English system, went straight to SI.

The use of SI units instead of the traditional metric units has little effect on everyday life or trade. The units of linear measurement, mass, volume, and time remain the same, viz. meter, kilogram, liter, and second.

The SI, like the traditional metric system, is based on decimal arithmetic. For each physical quantity, units of different sizes are formed by multiplying or dividing a single base value by powers of 10. Thus, changes can be made very simply by adding zeros or shifting decimal points. For example, the meter is the basic unit of length; the kilometer is a multiple (1000 meters); and the millimeter is a sub-multiple (one-thousandth of a meter).

In the older metric systems, the simplicity of a series of units linked by powers of ten is an advantage for plain quantities such as length, but this simplicity is lost as soon as more complex units are encountered. For example, in different branches of science and engineering, energy may appear as the erg, the calorie, the kilogram-meter, the liter-atmosphere, or the horsepower-hour. In contrast, the SI provides only one basic unit for each physical quantity, and universality is thus achieved.

As mentioned before, there are seven base units, which are for the basic quantities of length, mass, time, electric current, thermodynamic temperature, amount of substance, and luminous intensity, expressed as the meter (m), the kilogram (kg), the second (s), the ampere (A), the kelvin (K), the mole (mol), and the candela (cd). The units are defined in the accompanying [Table 1](#).

The SI is a coherent system. A system is said to be coherent if the product or quotient of any two unit quantities in the system is the unit of the resultant quantity. For example, in a coherent system in which the foot is the unit of length, the square foot is the unit of area, whereas the acre is not.

Other physical quantities are derived from the base units. For example, the unit of velocity is the meter per second (m/s), which is a combination of the base units of length and time. The unit of acceleration is the meter per second squared (m/s<sup>2</sup>). By applying Newton's second law of motion—force is proportional to mass multiplied by acceleration—the unit of force is obtained, that is, the kilogram-meter per second squared (kg·m/s<sup>2</sup>). This unit is known as the newton, or N. Work, or force times distance is the kilogram-meter squared per second squared (kg·m<sup>2</sup>/s<sup>2</sup>), which is the joule (1 joule = 1 newton-meter), and energy is also expressed in these terms. The abbreviation for joule is J. Power or work per unit time is the kilogram-meter squared per second cubed (kg·m<sup>2</sup>/s<sup>3</sup>), which is the watt (1 watt = 1 joule per second = 1 newton-meter per second). The abbreviation for watt is W. The term horsepower is not used in the SI and is replaced by the watt, which together with multiples and submultiples—kilowatt and milliwatt, for example—is the same unit as that used in electrical work.

The use of the newton as the unit of force is of particular interest to engineers. In practical work using the English or traditional metric systems of measurements, it is a common practice to apply weight units as force units. Thus, the unit of force in those systems is that force that when applied to unit mass produces an acceleration  $g$  rather than unit acceleration. The value of gravitational acceleration  $g$  varies around the earth, and thus the weight of a given mass also varies. In an effort to account for this minor error, the kilogram-force and pound-force were introduced, which are defined as the forces due to “standard gravity” acting on bodies of one kilogram or one pound mass, respectively. The standard gravitational acceleration is taken as 9.80665 meters per second squared or 32.174 feet per second squared. The newton is defined as “that force, which when applied to a body having a mass of one kilogram, gives it an acceleration of one meter per second squared.” It is independent of  $g$ . As a result, the factor  $g$  disappears from a wide range of formulas in dynamics. However, in some formulas in statics, where the weight of a body is important rather than its mass,  $g$  does appear where it was formerly absent (the weight of a mass of  $W$  kilograms is equal to a force of  $Wg$  newtons, where  $g$  = approximately 9.81 meters per second squared). Details concerning the use of SI units in mechanics calculations are given on [page 143](#) and throughout the MECHANICS section in this Handbook. The use of SI units in strength of materials calculations is covered in the section on that subject.

Decimal multiples and sub-multiples of the SI units are formed by means of the prefixes given in the following table, which represent the numerical factors shown.

### Factors and Prefixes for Forming Decimal Multiples of SI Units

Factor by which the unit is multiplied	Prefix	Symbol	Factor by which the unit is multiplied	Prefix	Symbol
$10^{12}$	tera	T	$10^{-2}$	centi	c
$10^9$	giga	G	$10^{-3}$	milli	m
$10^6$	mega	M	$10^{-6}$	micro	$\mu$
$10^3$	kilo	k	$10^{-9}$	nano	n
$10^2$	hecto	h	$10^{-12}$	pico	p
10	deka	da	$10^{-15}$	femto	f
$10^{-1}$	deci	d	$10^{-18}$	atto	a

For more information on SI practice, the reader is referred to the following publications:

*Metric Practice Guide*, published by the American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

*ISO International Standard 1000*. This publication covers the rules for use of SI units, their multiples and sub-multiples. It can be obtained from the American National Standards Institute 25 West 43rd Street, New York, NY 10036.

*The International System of Units*, Special Publication 330 of the National Institute of Standards and Technology—Gaithersburg, MD 20899.

**Binary Multiples.**— The International Electrotechnical Commission has assigned the following prefixes to represent exponential binary multiples. This avoids confusion with standard SI decimal prefixes when representing powers of 2, as in bits and bytes.

Symbol	Name	Binary Power	Symbol	Name	Binary Power	Symbol	Name	Binary Power
Ki	kibi	$2^{10}$	Gi	gibi	$2^{30}$	Pi	pebi	$2^{50}$
Mi	mebi	$2^{20}$	Ti	tebi	$2^{40}$	Ei	exbi	$2^{60}$

*Example 1:*  $2 \text{ Ki} = 2 \times 2^{10} = 2 \times 1024 = 2048$ . This does *not* equal  $2 \text{ K} = 2 \times 10^3 = 2000$ .

*Example 2:*  $1 \text{ mebibyte} = 1 \times 2^{20} = 1,048,576$  bytes. Again this does *not* equal  $1 \text{ megabyte} = 1 \times 10^6 = 1,000,000$  bytes, a value that is often confused with  $1,048,576$  bytes.

**Table 1. International System (SI) Units**

Physical Quantity	Name of Unit	Unit Symbol	Definition
<b>Basic SI Units</b>			
Length	meter	m	Distance traveled by light in vacuo during $1/299,792,458$ of a second.
Mass	kilogram	kg	Mass of the international prototype which is in the custody of the Bureau International des Poids et Mesures (BIPM) at Sèvres, near Paris.
Time	second	s	The duration of $9,192,631,770$ periods of the radiation corresponding to the transition between the two hyperfine levels of the ground state of the cesium-133 atom.
Electric Current	ampere	A	The constant current which, if maintained in two parallel rectilinear conductors of infinite length, of negligible circular cross section, and placed at a distance of one meter apart in a vacuum, would produce between these conductors a force equal to $2 \times 10^{-7}$ N/m length.
Thermodynamic Temperature	degree kelvin	K	The fraction $1/273.16$ of the thermodynamic temperature of the triple point of water.
Amount of Substance	mole	mol	The amount of substance of a system which contains as many elementary entities as there are atoms in $0.012$ kilogram of carbon 12.
Luminous Intensity	candela	cd	Luminous intensity, in the perpendicular direction, of a surface of $1/600,000$ square meter of a black body at the temperature of freezing platinum under a pressure of $101,325$ newtons per square meter.

**Table 1. (Continued) International System (SI) Units**

Physical Quantity	Name of Unit	Unit Symbol	Definition
<b>SI Units Having Special Names</b>			
Force	newton	$N = \text{kg}\cdot\text{m}/\text{s}^2$	That force which, when applied to a body having a mass of one kilogram, gives it an acceleration of one meter per second squared.
Work, Energy, Quantity of Heat	joule	$J = N\cdot\text{m}$	The work done when the point of application of a force of one newton is displaced through a distance of one meter in the direction of the force.
Electric Charge	coulomb	$C = A\cdot\text{s}$	The quantity of electricity transported in one second by a current of one ampere.
Electric Potential	volt	$V = W/A$	The difference of potential between two points of a conducting wire carrying a constant current of one ampere, when the power dissipated between these points is equal to one watt.
Electric Capacitance	farad	$F = C/V$	The capacitance of a capacitor between the plates of which there appears a difference of potential of one volt when it is charged by a quantity of electricity equal to one coulomb.
Electric Resistance	ohm	$\Omega = V/A$	The resistance between two points of a conductor when a constant difference of potential of one volt, applied between these two points, produces in this conductor a current of one ampere, this conductor not being the source of any electromotive force.
Magnetic Flux	weber	$\text{Wb} = V\cdot\text{s}$	The flux which, linking a circuit of one turn produces in it an electromotive force of one volt as it is reduced to zero at a uniform rate in one second.
Inductance	henry	$H = V\cdot\text{s}/A$	The inductance of a closed circuit in which an electromotive force of one volt is produced when the electric current in the circuit varies uniformly at the rate of one ampere per second.
Luminous Flux	lumen	$\text{lm} = \text{cd}\cdot\text{sr}$	The flux emitted within a unit solid angle of one steradian by a point source having a uniform intensity of one candela.
Illumination	lux	$\text{lx} = \text{lm}/\text{m}^2$	An illumination of one lumen per square meter.

**Standard of Length.**— In 1866 the United States, by act of Congress, passed a law making legal the meter, the only measure of length that has been legalized by the United States government. The United States yard is defined by the relation: 1 yard =  $\frac{3600}{3937}$  meter. The legal equivalent of the meter for commercial purposes was fixed as 39.37 inches, by law, in July 1866, and experience having shown that this value was exact within the error of observation, the United States Office of Standard Weights and Measures was, in 1893, authorized to derive the yard from the meter by the use of this relation. The United States prototype meters Nos. 27 and 21 were received from the International Bureau of Weights and Measures in 1889. Meter No. 27, sealed in its metal case, is preserved in a fireproof vault at the Bureau of Standards.

Comparisons made prior to 1893 indicated that the relation of the yard to the meter, fixed by the Act of 1866, was by chance the exact relation between the international meter and the British imperial yard, within the error of observation. A subsequent comparison made between the standards just mentioned indicates that the legal relation adopted by Congress is in error 0.0001 inch; but, in view of the fact that certain comparisons made by the English Standards Office between the imperial yard and its authentic copies show variations as great if not greater than this, it cannot be said with certainty that there is a difference between the imperial yard of Great Britain and the United States yard derived from the meter. The bronze yard No. 11, which was an exact copy of the British imperial yard both in form and material, had shown changes when compared with the imperial yard in 1876 and 1888, which could not reasonably be said to be entirely due to changes in Bronze No. 11. On the other hand, the new meters represented the most advanced ideas of standards, and it therefore seemed that greater stability as well as higher accuracy would be secured by accepting the international meter as a fundamental standard of length.

### U.S. Customary Unit System

The USCS is originated from the foot-pound-second unit system or English unit system. The USCS system and English unit system are the same for the measures of length and mass, but vary for the measure of capacity. The U.S. gallon is defined as 231 cubic inches and bushel as 2150.42 cubic inches, whereas the corresponding English units are 277.42 cubic inches and 2219.36 cubic inches.

### Fundamental Constants

Name	Symbol	USCS units	SI units

*Example:* A tape measure reads 17 feet 8 inches. How many inches is this? *Solution:* Read down the first column of **Table 3** to find 10 ft 0 inch = 120 inches. Next, find the intersection of the 7 ft row and the 8 inch column to get 92 inches. Add both results to get 120 inches + 92 inches = 212 inches.

*Example:* Convert  $78\frac{3}{4}$  inches to feet. *Solution:* From Table 4, find 70 inches = 5.8333 feet and add to that  $8\frac{3}{4}$  inches = 0.7292 feet found in Table 5 at the intersection of the  $\frac{3}{4}$  inch row and the 8 inch column. Thus,  $78\frac{3}{4}$  inches =  $5.8333 + 0.7292 = 6.5625$  feet.

900	274,320	90	27,432	9	2,743.2	0.9	274.32	0.09	27.432
1,000	304,800	100	30,480	10	3,048.0	1.0	304.80	0.10	30.480

Based on 1 inch = 25.4 millimeters, exactly. All values in this table are exact.

*Example 1:* Convert 293 feet,  $5\frac{7}{64}$  inches to mm.

$$\begin{array}{rcl}
 200 \text{ ft} & = & 60,960.0 \text{ mm} \\
 90 \text{ ft} & = & 27,432.0 \text{ mm} \\
 3 \text{ ft} & = & 914.4 \text{ mm} \\
 5 \text{ inch} & = & 127.0 \text{ mm} \\
 \frac{7}{64} \text{ inch} & = & 18.653 \text{ mm} \\
 \hline
 293 \text{ ft } 5\frac{7}{64} \text{ inch} & = & 89,452.053 \text{ mm}
 \end{array}$$

*Example 2:* Convert 71.86 feet to mm.

$$\begin{array}{rcl}
 70.0 \text{ feet} & = & 21,336.0 \text{ mm} \\
 1.0 \text{ feet} & = & 304.8 \text{ mm} \\
 0.80 \text{ feet} & = & 243.84 \text{ mm} \\
 0.06 \text{ feet} & = & 18.288 \text{ mm} \\
 \hline
 71.86 \text{ feet} & = & 21,902.928 \text{ mm}
 \end{array}$$

Based on 1 inch = 25.4 millimeters, exactly. All values in this table are exact. *Example:* Convert  $21\frac{23}{64}$  inches to millimeters. *Solution:* From the first page of this table, find 20 inches = 508.0 millimeters and add to that  $1\frac{23}{64}$  inches = 34.528125 millimeters found at the intersection of the 1- inch column and the row containing  $\frac{23}{64}$  inch. Thus,  $21\frac{23}{64}$  inches = 508.0 + 34.528125 = 542.528125 mm, exactly.

1.000	25.4000	...	...	...	...	...	...	...	...	...

Based on 1 inch = 25.4 millimeters, exactly. All values in this table are exact. Use **Table 8a** to obtain whole inch and other decimal equivalents to add to decimal equivalents above. *Example:* Convert 10.9983 in. to mm. *Solution:* 10.9983 in. = 254.0 + 25.3492 + 0.00762 = 279.35682 mm.

460	11.684	11.7094	11.7348	11.7602	11.7856	11.811	11.8364	11.8618	11.8872	11.9126
470	11.938	11.9634	11.9888	12.0142	12.0396	12.065	12.0904	12.1158	12.1412	12.1666
480	12.192	12.2174	12.2428	12.2682	12.2936	12.319	12.3444	12.3698	12.3952	12.4206
490	12.446	12.4714	12.4968	12.5222	12.5476	12.573	12.5984	12.6238	12.6492	12.6746
500	12.7	12.7254	12.7508	12.7762	12.8016	12.827	12.8524	12.8778	12.9032	12.9286

Use the small table below to convert microinches to micrometers for ranges higher than given in the main table above. Appropriate quantities chosen from both tables are simply added to obtain the higher converted value:

μin.	μm	μin.	μm	μin.	μm	μin.	μm	μin.	μm
600	15.24	800	20.32	1000	25.4	1500	38.1	2100	53.34
700	17.78	900	22.86	1200	30.48	1800	45.72	2400	60.96
								3000	76.2

Both tables based on 1 microinch = 0.0254 micrometer, exactly. All values in both parts of this table are exact; figures to the right of the last place figures are all zeros.

**Example:** Convert 1375 μin. to μm:

$$\begin{array}{rcl}
 \text{From lower portion of Table 13a:} & 1200 \mu\text{in.} & = & 30.48 \mu\text{m} \\
 \text{From upper portion of Table 13a:} & 175 \mu\text{in.} & = & 4.445 \mu\text{m} \\
 \hline
 & 1375 \mu\text{in.} & = & 34.925 \mu\text{m}
 \end{array}$$

MICRON TO MICROINCH CONVERSION

5.00	196.8504	197.2441	197.6378	198.0315	198.4252	198.8189	199.2126	199.6063	200.0000	200.3937

The table given below can be used with the preceding main table to obtain higher converted values, simply by adding appropriate quantities chosen from each table:

μm	μin.	μm	μin.	μm	μin.	μm	μin.	μm	μin.
10	393.7008	20	787.4016	30	1181.1024	40	1574.8032	50	1968.5039
15	590.5512	25	984.2520	35	1378.9528	45	1771.6535	55	2165.3543

Both portions of **Table 13b** are based on 1 microinch = 0.0254 micrometer, exactly.

*Example:* Convert 23.55 μm to μin.:

$$\begin{array}{r}
 \text{From above table: } 20.00 \mu\text{m} = 787.4016 \mu\text{in} \\
 \text{From main table: } 3.55 \mu\text{m} = 139.7638 \mu\text{in} \\
 \hline
 23.55 \mu\text{m} = 927.1654 \mu\text{in}
 \end{array}$$

## Units of Volume

Table 21. Cubic Measure and Conversion Factors

Metric System	U.S. System
1 <i>cubic meter</i> ( $m^3$ ) =	1 <i>cubic yard</i> ( $yd^3$ ) =
<b>1000</b> cubic decimeters (liters)	<b>27</b> cubic feet
<b>1,000,000</b> cubic centimeters	201.97403 U.S. gallons
1.30795 cubic yards	<b>46,656</b> cubic inch
35.314667 cubic feet	0.7646 cubic meter
61,023.74 cubic inches	1 <i>cubic foot</i> ( $ft^3$ ) =
264.17205 U.S. gallons	<b>1728</b> cubic inches
219.96925 British Imperial gallons	7.4805 U.S. gallons
1 <i>liter</i> ( <i>l</i> ) or 1 <i>cubic decimeter</i> ( $dm^3$ ) =	6.23 British Imperial gallons
1 liter = volume of 1 kg water at 39.2°F	0.02831685 cubic meter
<b>0.001</b> cubic meter	28.31685 liters
<b>1000</b> cubic centimeters	1 <i>cubic inch</i> ( $in^3$ ) =
<b>10</b> deciliters	0.55411256 U.S. fluid ounce
0.03531466 cubic foot	<b>16.387064</b> cubic centimeters
61.023744 cubic inches	
0.2642 U.S. gallon	
0.21997 British Imperial gallon	
1.0566882 U.S. quarts	
33.814 U.S. fluid ounces	
1 <i>cubic centimeter</i> ( $cm^3$ ) =	
<b>0.001</b> liter	
<b>1000</b> cubic millimeters	
0.061024 cubic inch	
1 <i>cubic millimeter</i> = <b>0.001</b> cubic centimeters	
1 <i>hectoliter</i> ( <i>hl</i> ) = <b>100</b> liters	
1 <i>deciliter</i> ( <i>dl</i> ) = <b>10</b> centiliters	
1 <i>centiliter</i> ( <i>cl</i> ) = <b>10</b> milliliters	
	<b>Shipping Measure</b>
	For measuring internal capacity of a vessel:
	1 <i>register ton</i> = 100 cubic feet
	For measurement of cargo:
	1 <i>shipping ton</i> =
	Approximately 40 cubic feet of merchandise is considered a shipping ton, unless that bulk would weigh more than 2000 pounds, in which case the freight charge may be based upon weight
	40 <i>cubic feet</i> =
	32.143 U.S. bushels
	31.16 Imperial bushels
	<b>U.S. Liquid Measure</b>
1 <i>British Imperial gallon</i> =	1 <i>U.S. gallon</i> =
0.1605 cubic foot	0.13368 cubic foot
277.42 cubic inches	<b>231</b> cubic inches
1.2009 U.S. gallon	<b>128</b> U.S. fluid ounces
<b>160</b> Imperial fluid ounces	<b>4</b> U.S. quarts
<b>4</b> Imperial quarts	<b>8</b> U.S. pints
<b>8</b> Imperial pints	0.8327 British Imperial gallon
<b>4.54609</b> liters	<b>3.785411784</b> liters
1 <i>quart</i> =	1 <i>quart</i> =
<b>2</b> Imperial pints	<b>2</b> U.S. pints
<b>8</b> Imperial gills	<b>8</b> U.S. gills
<b>40</b> Imperial fluid ounces	<b>32</b> U.S. fluid ounces
69.354 cubic inches	<b>57.75</b> cubic inches
<b>1.1365225</b> liters	0.9463529 liters
1 <i>pint</i> =	1 <i>pint</i> =
<b>4</b> Imperial gills	<b>4</b> U.S. gills
<b>20</b> Imperial fluid ounces	<b>16</b> U.S. fluid ounces
34.678 cubic inches	<b>28.875</b> cubic inches
<b>568.26125</b> milliliters	473.176 milliliters
1 <i>gill</i> =	1 <i>gill</i> =
<b>5</b> Imperial fluid ounces	<b>1/2</b> cup = <b>4</b> U.S. fluid ounces
8.669 cubic inches	<b>7.21875</b> cubic inches
142.07 milliliters	118.29 milliliters

Note: Figures in **Bold** indicate exact conversion values

**Pitot Tube.**— A pitot tube is a small, transparent, open tube bent at a right angle. It is a hollow tube that is placed longitudinally in the direction of fluid flow, allowing the flow to enter one end at the fluid's velocity of approach. When the fluids enter the pitot tube, it comes to a stop, and all of the velocity head is converted to pressure head. The difference between the total and static energies is the kinetic energy of the fluid. The velocity of the fluid can be calculated by using the Bernoulli equation.

$$\frac{p_1}{\rho} + \frac{v_1^2}{2} = \frac{p_2}{\rho} \qquad v_1 = \sqrt{\frac{2(p_2 - p_1)}{\rho}} \quad (\text{SI}) \qquad v_1 = \sqrt{\frac{2(p_2 - p_1)g_c}{\rho}} \quad (\text{US})$$

## Units of Mass and Weight

Table 29. Mass and Weight Conversion Factors

Metric System	Avoirdupois or Commercial Weight
1 <i>metric ton (t)</i> = <b>1000</b> kilograms 2204.6223 pounds 0.9842 gross or long ton (of 2240 pounds) 0.9072 net or short ton (of 2000 pounds)	1 <i>gross or long ton</i> = <b>2240</b> pounds 1.016 metric ton 1016 kilograms
1 <i>kilogram (kg)</i> = <b>1000</b> grams = <b>10</b> hectograms 2.2046 pounds 35.274 ounces avoirdupois	1 <i>net or short ton</i> = <b>2000</b> pounds 1 <i>pound</i> = <b>16</b> ounces <b>7000</b> grains <b>0.45359237</b> kilogram 453.6 grams
1 <i>hectogram (hg)</i> = <b>10</b> dekagrams	1 <i>ounce</i> = $\frac{1}{16}$ pound 16 drachms <b>437.5</b> grains 28.3495 grams 0.2780139 newton
1 <i>dekagram (dag)</i> = <b>10</b> grams	1 <i>grain Avoirdupois</i> = <b>1</b> grain apothecaries' weight = <b>1</b> grain Troy weight 0.064799 gram
1 <i>gram (g)</i> = <b>10</b> decigrams 0.0022046 pound 0.03215 ounce Troy 0.03527 ounce avoirdupois 15.432 grains	
1 <i>decigram (dg)</i> = <b>10</b> centigrams	
1 <i>centigram (cg)</i> = <b>10</b> milligrams	

## Troy Weight

Used for Weighing Gold and Silver

1 <i>pound Troy</i> = 12 ounces Troy = 5760 grains $\frac{141.733}{175}$ avoirdupois pound
1 <i>ounce Troy</i> = 20 pennyweights = 480 grains 31.103 grams
1 <i>pennyweight</i> = 24 grains
1 <i>grain Troy</i> = <b>1</b> grain avoirdupois <b>1</b> grain apothecaries' weight 0.0648 gram
1 <i>carat (used in weighing diamonds)</i> = 3.086 grains <b>200</b> milligrams = $\frac{1}{5}$ gram
1 <i>gold karat</i> = $\frac{1}{24}$ proportion pure gold

## Apothecaries' Weight

1 <i>pound</i> = 12 ounces = 5760 grains
1 <i>ounce</i> = 8 drachms = 480 grains 31.103 grams
1 <i>drachm</i> = 3 scruples = 60 grains
1 <i>scruple</i> = 20 grains

## Old Weight Measures

Measures for weight seldom used in the United States:

1 <i>gross or long ton</i> = 20 hundred-weights
1 <i>hundred-weight</i> = 4 quarters = 112 pounds
1 <i>quarter</i> = 28 pounds
1 <i>stone</i> = 14 pounds
1 <i>quintal</i> = 100 pounds

Note: Figures in **Bold** indicate exact conversion values

**Poundal.**— The expression “poundal” is sometimes used in connection with calculations in mechanics. Many mechanical handbooks, however, do not define it, because of its limited use. A poundal is a unit of force, and is defined as that force which, acting on a mass of one pound for one second, produces a velocity of one foot per second. A foot-poundal is a unit of energy equal to the energy resulting when a force of one poundal acts through a distance of one foot. In order to reduce foot-poundals to foot-pounds, multiply the number of foot-poundals by 0.03108. Dividing the number of foot-poundals by 32.16 (acceleration due to gravity) will also give foot-pounds.

### Units of Energy, Power, and Heat

**Table 44a. Energy Conversion Factors**

1 <i>horsepower-hour</i> =	1 <i>kilowatt-hour</i> =
0.746 kilowatt-hour	1000 watt-hours
1,980,000 foot-pounds	1.34 horsepower-hour
2545 Btu (British thermal units)	2,655,200 foot-pounds
2.64 pounds of water evaporated at 212°F	3,600,000 joules
17 pounds of water raised from 62° to 212°F	3415 Btu
	3.54 pounds of water evaporated at 212°F
	22.8 pounds of water raised from 62° to 212°F

**Table 44b. Power Conversion Factors**

1 <i>horsepower</i> =	1 <i>kilowatt</i> =	1 <i>watt</i> =
746 watts	1000 watts	1 joule/second
0.746 kilowatt	1.34 horsepower	0.00134 horsepower
33,000 foot-pounds/minute	2,654,200 foot-pounds/hour	0.001 kilowatt
550 foot-pounds/second	44,200 foot-pounds/minute	3.42 Btu/hour
2545 Btu/hour	737 foot-pounds/second	44.22 foot-pounds/minute
42.4 Btu/minute	3415 Btu/hour	0.74 foot-pounds/second
0.71 Btu/second	57 Btu/minute	0.0035 pound of water evaporated per hour at 212°F
2.64 pounds of water evaporated per hour at 212°F	0.95 Btu/second	
	3.54 pounds of water evaporated per hour at 212°F	

**Table 44c. Heat Conversion Factors**

**Conduction.**— Whenever the molecules of a working substance, whether liquid, solid, or vapor, are restrained so that no appreciable relative translatory motion occurs among them, the kinetic energies of the various molecules will be largely due to vibration. If a temperature difference exists in the working substance, some adjacent molecules will necessarily be at different temperatures, hence will possess different degrees of vibratory motion. In this case the molecule which is vibrating most rapidly will transfer some of its motion to the slower-moving molecule next to it, the one then undergoing a decrease in temperature and the other an increase. In this way, thermal energy will be transferred by the mechanism of conduction from the region of higher to the region of lower temperature. The process will continue spontaneously until the entire system has reached a uniform equilibrium temperature.

In contrast to radiation, conduction only occurs when a working substance is present and when the molecules of that working substance retain practically fixed positions with respect to one another. Thus, conductive heat flow would always occur through solids, but would take place in liquids and vapors only if special conditions prevented or greatly reduced the normal translatory motion of the molecules within these materials.

**Fuel Oil, Coal and Gas Equivalents.**— One gallon of fuel oil equals 13.1 pounds of coal, equals 160 cubic feet of natural gas. One barrel of fuel oil equals 0.278 ton of coal, equals 6806 cubic feet of natural gas. One pound of fuel oil equals 1.75 pounds of coal, equals 21.3 cubic feet of natural gas. One pound of coal equals 0.763 gallon of oil, equals 12.2 cubic feet of natural gas. One ton of coal equals 3.6 barrels of oil, equals 24,500 cubic feet of natural gas. The heating value of the average mid-continent fuel oil having a Baume gravity of 26.9 is 19,376 British thermal units per pound of oil, and 143,950 British thermal units per gallon of oil. The specific gravity and the heat value may be expressed approximately by means of a simple formula, as follows: BTU per pound =  $18,650 + 40 \times (\text{Degrees Baume} - 10)$ .

## Units of Temperature

There are two thermometer scales in general use: the Fahrenheit ( $^{\circ}\text{F}$ ), which is used in the United States and in other countries still using the English system of units, and the Celsius ( $^{\circ}\text{C}$ ) or Centigrade used throughout the rest of the world.

In the Fahrenheit thermometer, the freezing point of water is marked at 32 degrees on the scale and the boiling point, at atmospheric pressure, at 212 degrees. The distance between these two points is divided into 180 degrees. On the Celsius scale, the freezing point of water is at 0 degrees and the boiling point at 100 degrees. The following formulas may be used for converting temperatures given on any one of the scales to the other scale:

$$^{\circ}\text{F} = \frac{9}{5}^{\circ}\text{C} + 32 \quad \text{C} = \frac{5}{9}(^{\circ}\text{F} - 32)$$

Tables on the pages that follow can be used to convert degrees Celsius into degrees Fahrenheit or vice versa, and to convert the absolute temperatures of Kelvin and Rankine scales. In the event that the conversions are not covered in the tables, use those applicable portions of the formulas given above and in Table 52 for converting.

Table 52. Temperature Conversion Formulas

To Convert	To	Use Formula	To Convert	To	Use Formula
Celsius, $t_C$	K, $t_K$	$t_K = t_C + 273.15$	Kelvin, $t_K$	$^{\circ}\text{C}$ , $t_C$	$t_C = t_K - 273.15$
	$^{\circ}\text{F}$ , $t_F$	$t_F = 1.8 t_C + 32$		$^{\circ}\text{F}$ , $t_F$	$t_F = 1.8 t_K - 459.67$
	$^{\circ}\text{R}$ , $t_R$	$t_R = 9(t_C + 273.15)/5$		$^{\circ}\text{R}$ , $t_R$	$t_R = 9/5 \times t_K$
Fahrenheit, $t_F$	K, $t_K$	$t_K = (t_F + 459.67)/1.8$	Rankine, $t_R$	K, $t_K$	$t_K = 5/9 \times t_R$
	$^{\circ}\text{C}$ , $t_C$	$t_C = (t_F - 32)/1.8$		$^{\circ}\text{C}$ , $t_C$	$t_C = 5/9 \times t_R - 273.15$
	$^{\circ}\text{R}$ , $t_R$	$t_R = t_F + 459.67$		$^{\circ}\text{F}$ , $t_F$	$t_F = t_R - 459.67$

Kelvin temperatures are expressed by K without use of the degree symbol ( $^{\circ}$ ).

**Absolute Temperature and Absolute Zero.**— A point has been determined on the thermometer scale, by theoretical considerations, that is called the *absolute zero* and beyond which a further decrease in temperature is inconceivable. This point is located at  $-273.15$  degrees Celsius or  $-459.67$  degrees F. A temperature reckoned from this point, instead of from the zero on the ordinary thermometers, is called absolute temperature. The absolute temperature scale corresponding to Celsius is the Kelvin scale; the absolute scale corresponding to Fahrenheit is the Rankine. 0 K and 0  $^{\circ}\text{R}$  are both absolute zero. Conversions from Celsius and Fahrenheit are obtained as follows:

$$\text{K} = ^{\circ}\text{C} + 273.15 \quad ^{\circ}\text{R} = ^{\circ}\text{F} + 459.67$$

**Measures of the Quantity of Thermal Energy.**— The unit of quantity of thermal energy used in the United States is the British thermal unit, which is the quantity of heat or thermal energy required to raise the temperature of one pound of pure water one degree F. (American National Standard abbreviation, Btu; conventional British symbol, B.Th.U.) The French thermal unit, or *kilogram calorie*, is the quantity of heat or thermal energy required to raise the temperature of one kilogram of pure water one degree C. One kilogram calorie = 3.968 British thermal units = 1000 gram calories. The number of foot-pounds of mechanical energy equivalent to one British thermal unit is called the *mechanical equivalent of heat* and equals 778 foot-pounds.

In the modern metric or SI system of units, the unit for thermal energy is the *joule* (J); a commonly used multiple being the kilojoule (kJ), or 1000 joules. See page 2749 for an explanation of the SI System. One kilojoule = 0.9478 Btu. Also in the SI System, the *watt* (W), equal to joule per second (J/s), is used for power, where 1 watt = 3.412 Btu per hour.

Table converts °C → °F and °R, or °F → °C and K. Find “convert from” temperature in bold column and read result from °F and °R or °C and K columns. Example 1: 183 °C = 361.4 °F and 821.1 °R. Example 2: 183 °F = 83.9 °C and 357.0 K.

Multiply	By	To Obtain
Momentum		
kilogram-meter/second	7.233011	pound-foot/second
kilogram-meter/second	86.79614	pound-inch/second
pound-foot/second	0.1382550	kilogram-meter/second (kg • m/s)
pound-inch/second	0.01152125	kilogram-meter/second (kg • m/s)

**Miscellaneous Measuring Units**

1 *great gross* = 12 gross = 144 dozen  
 1 *gross* = 12 dozen = 144 units  
 1 *dozen* = 12 units

1 *quire* = 24 sheets  
 1 *ream* = 20 quires = 480 sheets  
 1 *ream printing paper* = 500 sheets  
 1 *score* = 20 units

**Ohm's Law.**— The following figure represents basic electrical relationships. This chart has been formatted in such a way that each variable has been related to the other three variables. This figure is simply for reference.

*Key to variables:*  
 V = Voltage (Volts)  
 R = Resistance (Ohms)  
 I = Current (Amps)  
 W = Power (Watts)

Circular Model of Electrical Relations

**Wind Chill Temperature.**— Windchill temperature is a measure of the combined cooling effect of wind and temperature. The formula below is used for calculating wind chill by the National Weather Service (NWS) in the United States:

$$\text{Wind Chill Temperature } ^\circ\text{F} = 35.74 + 0.6215T - 35.75(V^{0.16}) + 0.4275T(V^{0.16})$$

where  $T$  = air temperature in  $^\circ\text{F}$

$V$  = wind speed in miles per hour (mph) measured at NWS standard height, 33 feet

The formula calculates the chilling effect of wind on the human body at 5 feet above the ground and assumes no influence caused by sunlight (that is, as if the temperature and wind speed measurements were made at night in clear sky conditions.) Windchill temperature is only defined for temperatures at or below 50 degrees F and wind speeds above 3 mph. Bright sunshine may increase the windchill temperature by 10 to 18 degrees F.

### Wind Velocity to Pressure

$V$	$P$	$V$	$P$	$V$	$P$
5	0.1	35	4.9	65	16.9
10	0.4	40	6.4	70	19.6
15	0.9	45	8.1	75	22.5
20	1.6	50	10.0	80	25.6
25	2.5	55	12.1	100	40.0
30	3.6	60	14.4		

The formula is  $P = 0.004V^2$  where  $V$  = wind velocity, mph;  $P$  = pressure, lbs/sq ft.

### Phonetic Alphabet

A	Alfa	J	Juliett	S	Sierra	1	One
B	Bravo	K	Kilo	T	Tango	2	Two
C	Charlie	L	Lima	U	Uniform	3	Three

I	India	R	Romeo	0	Zero	9	Nine

**Daylight Savings Time.**— The Congress of the United States of America extended Daylight Savings Time (DST) by about a month, effective from 2007. Before 2007, DST began at 2:00 AM on the first Sunday in April and ended at 2:00 AM on the last Sunday in October.

Beginning 2007, DST begins at 2:00 AM on the second Sunday in March and ends at 2:00 AM on the first Sunday in November.

**Bel.**— The *bel* is the fundamental division of a logarithmic scale for expressing the ratio of two amounts of power. The number of bels denoting such a ratio is the logarithm to the base 10 of this ratio. Thus, if  $P_1$  and  $P_2$  are two amounts of power, and  $N$  the number of bels

denoting their ratio, then  $N = \log \frac{P_1}{P_2}$  bels .

The *decibel* is one-tenth of a bel and is commonly abbreviated as db. This unit is used extensively in the measurement of sound volume in telephone and radio transmission and reception, and in noise measurements of various kinds.

 specifications 2177  
 spur gear replacement by helical gears 2265, 2267  
 thrust 2211  
 tooth proportions 2151  
 tooth thickness measurement 2251  
 troubleshooting 2226  
 wire diameter 2246
- Helical milling**  
 development of helix 2120  
 helix angle 2121  
 lead of helix 2120
- Helical overlap** 2143
- Helix** 2120  
 angle 2121, 2143  
 angle factor 2190  
 angles, screw threads 1896–1905  
 constructing 67  
 end mills with welden shanks 854  
 lead and diameter 2136–2137  
 lead and pitch radius 2137  
 lead angle 2121  
 lead for given angle 2132–2134  
 measurement of angle 2120  
 number of tooth 2137
- Herringbone gearing** 2226  
 failures 2226
- Hertz stress** 2143
- Hertzian contact area** 2437
- Hexagon**  
 area 74  
 distance across corners 83  
 moment of inertia 228  
 radius of gyration 228  
 section modulus 228
- High-energy-rate metal forming** 1396
- Highest point of single tooth contact (HPSTC)** 2143, 2173
- High-speed steels** 434–436, 1052  
 annealing rehardening 486  
 as cutting tool materials 1052  
 cobalt 935–936  
 cobaltcrom 484  
 cooling period 492  
 cutters 875  
 drawing 486  
 hardening molybdenum 487  
 heat treatment 484  
 annealing 487  
 cutting efficiency 485  
 equipment 489  
 hardening temperatures 485  
 preheating tungsten 484  
 quenching  
 molybdenum 488  
 tungsten 485–486  
 subzero treatment 493  
 tempering molybdenum 488  
 time for through hardening 485  
 molybdenum 434, 439, 487–489  
 hardening 487
- High-speed steels** (continued)  
 quenching straightening 486  
 tempering 486  
 tool 436  
 tungsten 436, 439, 484, 487  
 tungsten annealing 487
- High-strength, low-alloy (HSLA) steels**  
 (see *HSLA steels*)
- Hob tip radius, maximum** 2172
- Hobs**  
 change gears for relieving 2105  
 roller chain sprocket 2571–2572  
 tip radius, maximum 2172  
 worm gear 2207
- Hoisting chain and wire rope** 2629
- Holders for NC, insert** 815–821, 831–833
- Hold-on or dolly bars for riveting** 1784
- Hole circles**  
 adapting equations for geometry 684  
 coordinates for 682–694  
 Type “A” 682, 686, 688  
 Type “B” 683, 690, 692
- Hole sizes, tapping** 2090–2091
- Holes**  
 accuracy of drilled 935  
 difficulties in reaming 891  
 for riveted joints 1779  
 for tapping 2080–2087  
 in glass, drilling 1107  
 sizes for self-tapping screws 1759
- Hollow**  
 circle, moment of inertia 229  
 circle, radius of gyration 229  
 circle, section modulus 229  
 cylinder, radius of gyration 222  
 mills, feeds and speeds 1207  
 sphere, radius of gyration 223
- Homopolymers** 541
- Honing process** 1308–1310  
 adjustments 1309–1310  
 carbide tools 1041–1042  
 rotative speeds in 1308–1310  
 stock removal, rate of 1308  
 tolerances 1310
- Hooke's law** 549  
 plastics 543
- Horsepower** 141  
 air compression 2733  
 calculating by dynamometer 2473  
 chain transmission 2563–2567  
 converted into kilowatts 2783–2784  
 disk clutches 2463  
 drilling different materials 1125  
 dynamometer test 2472–2474  
 electric motor 2589  
 ratings 2582  
 equivalents 2783–2784  
 formulas 178  
 friction wheels 2473–2475  
 gearing 2261–2262  
 hour equivalents 2783  
 machining 1119–1127  
 nonmetallic gears 2261–2262

- Horsepower** (continued)  
 planing and shaping 1119-1123  
 roller chains 2563-2567  
 set-screw transmitting capacity 1749  
 shafting 287-289  
 spade drilling 1125-1126  
 to compress air 2733-2736  
 torque equivalent 287-289  
 V-belt drives 2503
- Hose connection screw threads** 2020-2024  
 ANSI Standards 2020  
 basic dimension 2023  
 tolerances 2023
- Hot-working, tool steels for** 437
- HSLA steels** 388-389  
 application 408  
 chemical compositions 409  
 composition 408  
 elongation 409  
 formability 409  
 properties 408  
 tensile strength 409  
 toughness 409  
 weldability 409  
 yield strength 409
- Hunting tooth ratio** 2210
- Hydrant screw thread** 2022-2024
- Hydraulic press** 1416
- Hydrodynamic film lubrication** 2437
- Hydroforming process** 1391
- Hydrometer, Baumé's, and specific gravity** 369
- Hyperbola**  
 area 77  
 area construction 67  
 eccentricity 56  
 foci 56  
 general equation 56  
 major and minor axis 56
- Hypocycloidal curves, areas** 70
- Hypoid gears** 2141, 2192, 2194-2195  
 applications of 2195
- Hypotenuse** 90
- Hysteresis** 301
- 
- I**
- I-beam**  
 aluminum 2619  
 standard structural steel 2614  
 structural  
 moment of inertia 2610-2614  
 section modulus 2610-2614  
 steel 2610  
 weight per foot 2610-2614
- Ignition temperature** 364
- Impact force of** 175
- Impact strength, Izod**  
 carbon and alloy steels 412-413  
 plastics 378
- Impulse** 176-178  
 angular momentum 177
- Inch**  
 decimals of, into millimeters 2761-2762  
 into centimeter and millimeter 2758  
 millimeters into decimals of 3, 2757, 2763-2764
- Inclinable-frame press** 1415
- Inclined plane** 161, 171  
 force for moving body on 161  
 forces on 160  
 motion on 171
- Inconel metals** 536-537
- Indexable**  
 carbide inserts 813  
 insert holder  
 boring 819-821  
 chamfering 819-821  
 end cutting edge angle 818  
 facing 819-821  
 grooving 819-821  
 identification system 814, 816  
 insert shape 818  
 lead angle 818  
 NC 815-821, 831-833  
 planing 819-821  
 plunge angle 819  
 rake angle 818  
 selection 818  
 shank sizes 816  
 shape 819  
 tracing 819-821  
 turning and backfacing 819-821  
 turning and facing 819-821
- Indexing**  
 head angular position for  
 milling end mills and angular cutters 870-873  
 reamer teeth for irregular spacing 883
- Indicator drop method** 878
- Induction**  
 annealing 477  
 brazing 1494  
 hardening 456, 475, 477  
 equipment 475  
 gear teeth 477  
 normalizing 477
- Inertia** 141  
 electric motor 2590  
 moment of 225-247  
 polar 236-237
- Injection mold design** 573
- Injection molding** 572  
 plastics 579
- Injection molding, metal** 1444
- Insert configuration** 1667
- Insert length data** 1667-1672
- Insert length selection** 1674-1675
- Insert radius compensation** 831
- Inserts**  
 hardmetal materials 834-844  
 holders for NC 815-821, 831-833  
 indexable 813-821, 831-833  
 radius compensation, NC 831-833  
 screw thread 1766
