[No ; if not handled while it is cold. Take it into a warm room and let it remain for a day or two before handling it in any way.—Ed.]

The Illinois State Fair.—D. R. Rosebrough, Casey, Ills., on Sept. 27, 1888, writes :

I have just returned from the State Fair, and so far as bees and honey are concerned, it was a failure. There were only three or four exhibits of bees and honey, but it was in small amounts, and in bad condition. The best exhibit of honey and bees was from Piatt county. Dadant's comb foundation took the "blue ribbon." I could not take any honey this year, as I had none to take, and that was likely the reason why there was not more exhibited ; but I am in hopes of having some honey next year. I think that the bee-keepers of Illinois should arise in their might, and not allow our sister States to excel us in this line ; so next year I want to see a dozen or more bee-keepers with honey at our State Fair. All other exhibits of agricultural products, except honey, were grand.

Bee-Keeping in Ontario.—Mr. R. F. Holtermann, of Brantford, Ont., Vice-President of the Ontario Bee-Keepers' Association, sends the following report of bee-keeping in Ontario :

The past winter was passed fairly well by the bees. Spring dwindling was excessive, owing to severe weather. The clover yield was a total failure in most localities, Linden the same, and at its close showers and warm weather gave us some thistle honey in buckwheat localities ; the fall flow was fairly good. On an average not sufficient honey has been secured for winter, yet colonies are otherwise in good condition. Whilst the average is so low, we hear of isolated cases where a yield of 30 to 40 and even 60 pounds per colony has been obtained ; and, on the other hand, colonies had to be fed in the height of the honey season. Increase has been but slight, and all colonies remaining should be carefully preserved and cared for. There has been practically no comb honey taken, and the extracted honey will be off the market before the end of the present month.

AN ENGLISH OPINION.

The Rev. L. L. Langstroth.—In an article noticing the receipt of a cabinet photograph of Father Langstroth, from Mr. T. B. Reynolds, of Dayton, O., the *British Bee Journal* for Sept. 20, remarks as follows :

The photograph is a full-length, cabinet size, and gives a good idea of the general appearance and intelligent countenance of one who still retains so many admirers and friends in both hemispheres. It gives us much pleasure to note that, though long past the allotted threescore years and ten, and though for many years he has passed through much physical suffering, he continues to look so hearty and well, and it would appear as if many years were still in prospect before the "grand old man" is called away from our midst. The name of the Rev. L. L. Langstroth has for so many years been "a household word" with bee keepers, that we feel assured that many will feel inclined to indulge in the enjoyment of being able to look into that calm, intelligent, and benevolent face which is now presented to them.

We feel a spirit of gratitude pervading our hearts that we have been permitted to look, as it were, upon his living presence. Our memory passes back to that sentence which well-nigh thirty years ago he penned: "Debarred to a great extent by ill-health from the appropriate duties of my profession, and compelled to seek an employment calling me as much as possible into the open air, I cherish the hope that my labors in an important department of rural economy may prove serviceable to the community." Truly, whatever loss there may have been to his fellow men in his inability to follow his high and holy calling, there has been a clear, and a great, and an abiding gain to the bee-keeping world ; and we are ready to subscribe to that which his friend, the Rev. Robert Baird, said of him : "He well deserves the name of Benefactor—ininitely more so than many who in all countries and in all ages have received that honorable title." And how feelingly Mr. Langstroth directs the attention of those of his own profession to the study of the economy of the honey-bee: "The attention of ministers of the gospel is particularly invited to this branch of natural history. An intimate acquaintance with the bee-hive, while beneficial to them in many ways, might lead them in their preaching to imitate more closely the example of Him who illustrated His teachings by "the birds of the air, and the lilies of the field," as well as the common walks of life, and the busy pursuits of men.

The "old man eloquent" is still with us, and his voice is ever and anon heard in the exercise of his sacred calling. It was but a very short time since—only a few months ago—that his good man visited Mr. James Heddon, of Dowagiac, Mich. Mr. Heddon says: "Needing eighty years of age, and not in the enjoyment of very robust, physical health, I was astonished to find his mental powers as young and vigorous as those of a man of middle age." On this occasion he preached in the Congregational Church, and Mr. Heddon proceeds to say: "I think I may safely say that many years have passed away since our city has been honored with such beneficent and well-delivered sermons. His voice is round, full, and melodious, fully equal to four times the capacity of any church in the city." We can only breathe a hope that one whom bee-keepers have learned to love and reverence may long be spared to us.

[The last sentence calls forth our most hearty response.—Ed.]

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, \$1.00 per 100, or \$8.50 per 1,000.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in Cheshire's pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being available, it must be sent by express.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

CLUBBING LIST.

We Club the American Bee Journal for a year, with any of the following papers or books, at the prices quoted in the LAST column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	Club
The American Bee Journal.....	1 00	1 00
and Gleanings in Bee-Culture.....	2 00	1 75
Bee-Keepers' Magazine.....	1 50	1 40
Bee-Keepers' Guide.....	1 50	1 40
Bee-Keepers' Review.....	1 50	1 40
The Apiculturist.....	1 75	1 60
Canadian Bee Journal.....	2 00	1 80

Hastings' Perfection Feeder.—This excellent Feeder will hold 2 quarts, and the letting down of the feed is regulated

Patented Oct. 18, 1887.

by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for \$3.50, and it can be obtained at this office. Postage 10 cents extra.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2 00	3 00	3 50
1,000 Labels.....	3 00	4 00	5 00

Samples mailed free, upon application.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, Ills., is published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Clover Seeds.—We are selling Alsike Clover Seed at the following prices: \$3.00 per bushel; \$2.25 per peck; 25 cents per lb. White Clover Seed: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. Sweet, or Melilot, Clover Seed: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Cork for Winter Packing.—Its advantages are that it never becomes musty, and it is odorless. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Exchange.—We will accept Honey and Beeswax in exchange for Bee-Keepers' Supplies in any quantity. Those desiring to make a trade are invited to correspond with us, stating quantity, quality, and price, and the goods they want in exchange.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 10 cents per pound for bag and postage.

We Want 20,000 subscribers. Out of the 300,000 bee-keepers in America, certainly this is not an extravagant desire! It is only one out of every fifteen! We confidently ask those who appreciate the AMERICAN BEE JOURNAL, to show it by sending us one or more new subscribers. We will give them full value for their money.

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1, postpaid.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

Conventions.—The time for holding Bee-Keepers' Conventions has now arrived, and we cannot give any better advice than this: Let each one attend who can do so, and take part in making these meetings interesting and instructive. If you have not already obtained the "Bee-Keeper's Convention Hand-Book," do so at once to post yourself up on how to conduct such meetings correctly. It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for Discussion—List of Premiums for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents. We will club this book and the AMERICAN BEE JOURNAL for one year for \$1.25. It also contains a lot of blank leaves on which you can note important matters as they come up. Do not fail to send for a copy of it.

Nature's Way.—This is the title of a 15-cent pamphlet entitled, "G. M. Doolittle's Method of Rearing Queens"—which is called "The nearest approach to Nature's way yet devised." It describes his method, and points out its advantages. For sale at this office.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the BEE JOURNAL, and will send two or more free of cost to any one who will use them, and try to get up a club. Sample copies will be sent free upon application.

Simmins' Non-Swarming System.—We have a few of these books left, and we will club them with the AMERICAN BEE JOURNAL for one year, both postpaid, for \$1.25. The subscription to the BEE JOURNAL can be for next year, this year, or may begin anew at any time.

We Have some copies of the old edition of Cook's Manual left, which we will sell at the old price, \$1.25. The price of the new edition is \$1.50 per copy; a notice of which may be found on page 579.

We will Present a Pocket Dictionary for two subscribers with \$3.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

Queens.—We can mail a Tested Italian Queen (bred for the best results as well as for beauty) for \$2.00; Untested Queens \$1.00 each, or \$9.00 per dozen. Orders solicited.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for \$1.50.

Honey and Beeswax Market.

CHICAGO.

HONEY.—New crop arriving slowly, but demand is limited. White clover comb, 17@18c. Extracted, 7@9c.
BEEWAX.—22c.
Sep. 12. S. T. FISH & CO., 189 S. Water St.

CHICAGO.

HONEY.—For white comb 1-lb., 18c. Very little inquiry for anything outside of 1-lb., and when it is wanted it is at a lower price. Extracted, the best grades, 7@8c., and some held higher. Offerings are small and demand slow.
BEEWAX.—22c.
R. A. BURNETT,
161 South Water St.
Sep. 12.

DENVER.

Sep. 7. J. M. CLARK & CO., 1409 Fifteenth St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb., 15@17c.; 2-lbs., 14@16c. Fair white 1-lb., 14@16c.; 2-lbs., 13@15c. Extracted, white, 7@8c.
BEEWAX.—23@26c.
Sep. 17. THURBER, WHYLAND & CO.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb., 17@18c.; 2-lbs., 13@14c. Fair white 1-lb., 15@16c.; 2-lbs., 12c. Buckwheat 1-lb., 11@12c.; 2-lbs., 10@11c. White extracted, 7@8c.; buckwheat, 5@6c.; California extracted, white sage, 7@8c., amber, 7@7½c. Demand good and prices firm. New comb honey is arriving quite freely.
BEEWAX.—23@23½c.
Sep. 26. HILDRETH BROS. & SEGLKEN,
28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—White 1-lb. sections, 11@12½c.; 2-lbs., 12½@1 c.; amber, 8@10c. Extracted, white, 5½@6c.; light amber, 5¼@5½c.; amber and candied, 4½@5c. Receipts light and market firm for best qualities.
BEEWAX.—Dull at 19½@22½c.
Sep. 22. O. B. SMITH & CO., 423 Front St.

DETROIT.

HONEY.—Best white comb, 17@18c.; dark, 16c.—Extracted, 8@10c. Market bare of all kinds.
BEEWAX.—21@22c.
Sep. 24. M. H. HUNT, Bell Branch, Mich.

CINCINNATI.

HONEY.—We quote extracted at 4½@8c. per lb. Comb honey, 12@16c. Demand slow.
BEEWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Sep. 18. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—Choice 1-lb. sections, 18c.; dark 1-lb., 14c.; 2-lbs., 12c.; dark, 13c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock fair.
BEEWAX.—None in market.
Sep. 27. HAMBLIN & BEARSS, 514 Walnut St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 17½@18c.; 2-lbs., 14@15c. Fair 1-lb., 14½@15½c.; 2-lbs., 11@12c. Extracted, fancy white clover, 7½@8c.; California white in 60-lb. cans, 8c.; light amber in same cans, 7½c.; amber, 7c. Buckwheat in kegs and barrels, 5½@6c. Cuban, in barrels and ½-barrels, 65c. per gallon.
Sep. 26. F. G. STROHMMEYER & CO., 122 Water St.

BOSTON.

HONEY.—We quote: New 1-lb. sections, 18@20c.; 2-lbs., 14@16c. New extracted, 8@10c.
BEEWAX.—25 cts. per lb.
Aug. 24. BLAKE & RIPLEY, 57 Chatham Street.

KANSAS CITY.

HONEY.—We quote: New white 1-lb., 18c.; light 1-lb., 16c. California white 1-lb., 18c.; light 1-lb., 16c.; white 2-lbs., 16c.; light 2-lbs., 14c. Extracted, white, 8c.; amber, 7c.
BEEWAX.—18@20c.
Sep. 5. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—We quote: Extracted, 4½@5½c.; if in cans, 8@9c. White clover comb, 14@15c. Market is steady and receipts light.
BEEWAX.—21c. for prime.
Sep. 6. D. G. TUTT & CO., Commercial St.

MILWAUKEE.

HONEY.—New white 1-lb. sections 18c., and very fine, 20c.; 1-lb., 15@18c.; old 2 and 3 lbs., not salable, 1½@14c.; dark 1 lb., old or new, 12@13c. Extracted: new white in kegs and ½-barrels, 8@9c.; old, in same packages, 7@8c.; in tin, 8@9c.; dark in barrels or ½-barrels, 6@6½c. Arrivals of new crop small; demand not urgent, and only very moderate trade.
BEEWAX.—22@23c.
Aug. 31. A. V. BISHOP, 142 W. Water et.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6 cents; light amber, 5½c.; amber, 5¼@5½c. Comb, 1-lb., 13@14c.; 2-lbs., 10@12c.
BEEWAX.—20@22c.
Sep. 24. SCHAUCHT & LEMCKE, 122-124 Davis St.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

The Presidential Candidates.

Among the many interesting publications brought out by the campaign, "The Presidential Candidates" is one of the best. It is of the size and style of *Harper's Weekly*. It contains portraits and sketches of all the twelve candidates, and the portraits of Mrs. Cleveland, Mrs. Harrison, Mrs. Morton and Mrs. Thurman. The large pictures of Mr. Cleveland and Mr. Harrison are very striking, and the best we have seen. The many sketches of the lives are exceedingly interesting. White all the portraits are of great interest, those of Belya Lockwood, the Suffragist Candidate, and that of Mrs. Thurman, will attract unusual attention. Altogether this is a very valuable publication at this time. It is sold by the newsdealers, or sent by J. A. & R. A. Reid, of Providence, R. I., for 10 cents.

☞ The Washab County Bee-Keepers' Association will hold their fall meeting in the Court House at Washab, Ind., on Oct. 20, 1888, at 10 a.m. All beekeepers are cordially invited to meet with us.
HENRY CRUPE, Sec.

Advertisements.

We have some ELEGANT RIBBON BADGES, having a rosette and gold Bee, for bee-keepers' use at Fairs, Conventions, etc. Price 50 cents each, by mail, postpaid.

THOS. G. NEWMAN & SON,

923 & 925 West Madison-Street, - CHICAGO, ILLS.

Dadant's Foundation Factory, wholesale and retail. See advertisement in another column.

Jones' Frame Pliers.

FOR taking frames out of hives, or moving them in any way desired. It is made of Japanned iron, and can be utilized in many ways. It has a long claw for loosening frames, and a hook which may be used for carrying other frames besides the one held by the Pliers. Price, 40 cents., by mail. By express, 30 cents.

923 & 925 W. Madison St., - CHICAGO, ILL.

Mention the American Bee Journal.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. Oct. 17, 1888. No. 42.

EDITORIAL BUZZINGS.

The Columbus Convention has monopolized a large space in this issue of the BEE JOURNAL. Next week we hope to give the remaining portion. In order to do this we omit the Queries and nearly all the correspondence. As that convention presents the newest matter for the craft in America, we must give it in time to be fresh as well as seasonable.

The Alabama State Fair occurs at Montgomery on Oct. 22, and in the Bee and Honey Department the premiums amount to \$68, besides diplomas. Capt. W. H. Black makes an exhibit there. His 16 colonies last spring have increased to 38, besides giving over 1,000 pounds of surplus honey in one-pound sections. That is a little over 62 pounds per colony, spring count. That is a report not to be ashamed of in this exceedingly poor season!

On Mountain Sides.—A California paper thus moralizes over the fruit-bees controversy and its results:

The irrepressible conflict between fruit-grower and apiarist has ended in the latter fleeing to the mountains, taking the little busy bees to gather the nectar from the delicious mountain flowers. The orchardist charged that the bees punctured the ripening fruit with their lancet tongues, and while the bee-master knew this to be an error, he had no choice but to go among the hills where fruit-growing is not yet a leading industry.

Nay! Rather say that the rich mountain flowers have enticed the bee-keepers to the delicious bee-pasturage provided by Nature away up the mountain sides, leaving the valleys to the raisin-growers—thus solving the problem to the advantage of both the fruit-growers and bee-men. How much better to have it so, than to quarrel over it.

Bulletin No. 39, issued by the Agricultural College of Michigan, on Sept. 1, 1888, contains "experiments with insecticides," by Prof. A. J. Cook (who is well-known to our readers), having charge of the Department of Zoology and Entomology at the College. The experiments were made for the purpose of destroying the Codling Moths, Curculio, Aots, and other insects. The Bulletin also gives valuable information concerning the planting of trees, etc., and advises the planting of Linden trees instead of Maples and Locusts, which are so susceptible to injury. He says:

Our American linden or basswood is a tree of rare beauty, and a more vigorous and rapid grower than either maple or elm. It is attacked very rarely by insects, and so far as I have observed I should say that ten transplanted basswoods live and thrive to one of maple. Last but not least, the linden is a very valuable honey-tree, as the honey from basswood is usually very plentiful and of most excellent quality, as we should expect from the delicious fragrance of the beautiful flowers. When we plant a linden, then, we are adorning our street, or grounds, with a tree that will very likely live and thrive, a tree that will surprise us with its rapid growth and development, and a tree that will bless the coming generation with the valuable product which it so bountifully yields. I believe there is no native deciduous tree that offers such inducements for transplanting as does the American linden.

Unless we conclude then to plant lindens exclusively, and such a course has much to recommend it, I should say plant all our beautiful trees: linden, maple, elm, oak, tulip, chestnut, ash, willow and even poplar, then, as with the man who practices mixed husbandry, and like the maid who divides her eggs among several baskets, we shall be almost sure to win at some point, and not to lose in all.

If it is thought that trees of one kind when planted in a single or double straight row look the best, then I say plant linden. If we plant irregularly, and pay some heed to grouping, which I have done, we can then plant all kinds of trees with excellent effect. Were it not for the inconvenience of this style of planting, when we come to use our mowers to cut the grass along the way side, I should certainly advise this irregular planting and grouping. Owing to the enhanced beauty, I prefer it even with the inconvenience thrown in.

To conclude, I say then, either plant lindens or else all our desirable native species. If we must set maples, then practice great care that we may resist the borers and save our trees.

Some Texas Honey-Plants.—J. C. Bell, Belton, Tex., on Sept. 29, 1888, writes:

As requested on page 620, I have sent Prof. Burrill three stalks or stems with flowers for name. The old stalk came up from an old root that lives through the winter. The two tender stalks came from the same root after the August rains. The second crop does not secrete honey as well as the first. I also sent one white bloom for name that is very fine for bees; it grows wild here, and blooms the second time when it rains in the summer.

[The plant sent by Mr. Bell sometime ago proves to be *Salvia azurea*, variety *grandiflora*, occurring from Kansas well southward in Texas. The determination has been made from some specimens recently received direct from Mr. Bell. Like all the

sages, this plant is a good honey-producer. Another plant sent by the same person is the prickly poppy—*Argemone platyceras*—not known to be specially useful for honey.—T. J. BURRILL.]

What a Commission Merchant Has to Say About Honey.

In conversation with J. T. Carson, a commission merchant of Louisville, Ky., last week, some points of special value to bee-keepers were brought out. He reports the honey crop unusually short so far as his information goes, and he usually handles quite large quantities. Comb honey sells in Louisville much more rapidly than extracted, and that in one-pound sections much better than that put up in larger packages.

Bee-keepers should be careful to not leave honey on the hives until it gets a yellowish cast, as that which is the whitest and cleanest sells first.

Shipping crates for comb honey should have glass at one end, but do not need it on two ends or two sides, as one side is just as good, and there is less liability of breakage.

Mr. Carson has all his honey shipped by freight, as express companies not only charge more, but their agents are so often hurried that it is not handled as safely as by the freight hands. A large shipment of comb honey put up in an unsalable shape hung on the Louisville market for over a year, while that put up neatly in one-pound sections found ready sale.

Good comb honey could be sold in Louisville at 20 cents less 5 per cent. commission and freight. As the honey crop has been very light, those who have any may expect good prices and prompt returns.—*Indiana Farmer*.

A Trusty Guide.—Under this heading the *Prairie Farmer* gives Prof. Cook's new "Manual" the following superb notice, which we most fully endorse:

A new edition of the "Bee-Keepers' Guide, or Manual of the Apiary," is on our desk. This is the fifteenth thousand of the deservedly popular Guide of the Professor. Let none fear to trust this guide up the steep and rugged paths of bee-keeping, for it will ultimately land them on the summit of success. His feet are freshly shod, his Alpine-tock newly pointed, and you can lean on his arm with safety. On the way, with magnifying glass in hand, he will show you the wonderful mechanism of this useful insect; its tongue, which does not talk, but laps and sucks up the nectar into its haversack, and its many-jointed legs, which gather and carry the pollen. This Apian way is bordered with many beautiful flowers, for which the bee acts as marriage-priest, and they are fully described and illustrated. Let all who can, take a trip with this Guide, for they will remember the pleasant "outing" many years to come.

Mr. T. B. Blow will only visit bee-keepers who may invite him to do so—he will not thrust himself upon them. If any wish to have such a visitor, they may send the invitation to this office. We expect him to call here within a few days.

GLEAMS OF NEWS.

Rhode Island State Fair.—In the Providence Evening *Telegram* we notice the following as the awards in the department of "bees, honey and wax :"

The judge of this department was L. C. Root.

Awards—S. A. Dexter, Providence, comb honey, third ; Samuel W. Lewis, Olneyville, package of comb honey, first ; liquid extracted honey, second ; extracted honey, third ; granulated extracted honey in glass, first ; 10 pounds of wax, second.

A. C. Miller, Drownville, 10 pounds of comb honey, second ; 10 pounds of liquid extracted honey, second ; display of drones, third ; hatching queen-cells with bees, second ; complete hive for comb honey, second ; complete hive for extracted honey, second ; thin foundation for honey boxes, first.

Samuel Cushman, Pawtucket, comb honey, first ; assortment of comb honey, first ; one pound of comb honey, second ; display of comb honey, first ; 200 pounds of extracted honey, first ; 10 pounds of the same, first ; variety of extracted honey, first ; package of the same, first ; drones, workers, etc., first ; hatching queens in cells, third ; display of queens, first ; hatching colony, first ; hive for comb honey, first ; hive for extracted honey, first ; extracted honey, first ; display of apiary improvements, second ; largest exhibit, first.

Mrs. S. M. Lackey, Providence, 200 pounds of extracted honey, third ; variety of extracted honey, second ; beeswax, first ; drones, queens, etc., second ; hatching cells, second ; display of queens, etc., second ; hive of comb honey, third ; hive of extracted honey, third ; honey extractor, second ; 10 pounds of comb for brood, first.

Judge L. C. Root makes the following report on this department :

The bee-keepers of Rhode Island have reason to be proud of their exhibition in this department. While they all rank well, I should be unjust to myself, to the society and to the bee-keepers of Rhode Island if I did not express my personal gratification at the marked standard of excellence to which Mr. Samuel Cushman, of Pawtucket, has attained as manifested in his exhibit. In the average of his exhibits I observed a most marked degree of neatness, attractiveness and mechanical skill which is the very foundation of success in our business.

A New Enemy.—In the new entomological periodical published by the Government at Washington, D. C., entitled *Insect Life*, No. 3 for September, 1888, we notice the following under the caption of "A New Enemy to Honey-Bees," which is worth making a note of. It reads as follows :

Several predaceous bugs have been recorded from time to time as feeding upon honey-bees, and in Bulletin 12 of this division (page 44) we mention the fact that the common wheel bug (*Prionidus cristatus*) was in the habit of lurking about the hives and preying upon the bees at Winchester, Va. Last summer we received information from Mr. J. W. Lanford, of Lawrence County, S. C., that another bug had been captured by him in the act of piercing the honey-bee, and that his neighbors had noticed the same insect lurking about their hives. The specimen captured in the act was forwarded to us, and proved to be *Euthyrhynchus floridanus*, a species which is rather common throughout the South.

Postal Reform.—*Farm Life* comments thus on this matter : "The Senate Committee to whom was referred the bill reducing the postage on fourth-class matter from 16 to 8 cents per pound, have reported favorably, giving the reasons why the change is advisable. The objection that the lower rate would lessen the revenue is clearly shown to have no foundation. While *Farm Life* is in favor of the 4 cent rate, it may be that a trial of the 8 cent rate will the better prepare the way for the adoption of the desired reform. The arguments now used by the Senate Committee will be found equally effective in a year or two for the lower rate. Four cents a pound for merchandise, and one cent an ounce for letters are the rates demanded by the people, and these they are certain to have before the agitation ends. We append a small part of the Senate report :

On the present estimated volume of fourth class matter (excluding seeds, etc.), the immediate loss by the proposed reduction of the rate would fall considerably short of \$1,000,000 annually, a sum that seems insignificant in the present magnitude of the postal revenue. The stimulus of a lower rate would, however, greatly augment the number of parcels mailed, bringing a corresponding increase of revenue. Moreover, the carriage of fourth-class matter incidentally involves much extra revenue, through circulars, money-orders, postal notes, registered letters, and ordinary written correspondence connected with the transactions ; and this extra revenue, arising almost wholly from exceedingly profitable sources, would increase just in proportion to the increase of fourth-class matter. It may well be doubted, therefore, whether there would be any decrease of revenue from this source at the very outset, and in the end there would surely be a very large increase.

The measure would not involve a proportionate outlay, since usually merchandise is carried within restricted areas, and to a large degree over "star routes," the cost of which is not sensibly affected by the weight of the mails.

"The United States, while having the cheapest letter and newspaper postage, and in many respects the best postal service of any country in the world, is far behind nearly every other leading government in providing facilities for the carriage of merchandise and miscellaneous articles in the mails.

"We are almost alone in being without the parcels post system, which has become a marked feature in the postal establishments of other countries. Under this system, merchandise and other matter of almost every description are carried in the mails at a small fraction of the charge, and in quantities greatly in excess of that allowed on fourth-class matter in this country. The present charge of 16 cents a pound is prohibitory in its effects, often compelling people to deny themselves of small articles, whether of necessity or comfort, which they cannot procure otherwise than through the mails. The hardship falls most heavily upon those living in the rural districts, where the home markets are scantily supplied, and where the usual means of private transportation do not exist."

Fall Flowers and Honey.—Mrs. L. Harrison, in the *Prairie Farmer* for last week, thus speaks of the fall flowers, prairies and fall honey of Illinois :

The hope so fondly cherished, that fall flowers would yield sufficient honey for winter stores, has been realized. In a letter before me from a lady bee-keeper of South Evanston, Ills., is the following : "I shall not have to do any feeding ; the hives are loaded in the brood-chamber, yes, crowded with honey ; and the queens have been making up the time they lost in the spring. If honey and young bees will insure good wintering, I ought not to lose any."

On the prairies, where corn and sky meet, and wet places are tile drained, there may not be a sufficiency of fall bloom to yield honey for the support of the bees during the coming winter. Timber-lands, and those along water-courses, subject to overflow, where Spanish-needles and motherwort flourish, are the best bee-pastures in the fall.

I am an old settler of the State of Illinois ; came here in 1836, and have lived here and in the vicinity ever since. I was born in Ohio, and it is a good State to be born in, if one only emigrates soon enough, as I did, in time to enjoy the beautiful prairies in their pristine loveliness. On these meadows roses, lilies, Indian pinks and lady-slippers, with many more, budded and blossomed and nodded in the breeze, with no fear that the cruel reaper would cut them down. There were two kinds of lady-slippers, yellow and delicate pink-and-white ones. I have not seen one for years, but it would give me more pleasure to see one than the rarest exotic.

An old settler of this county said that he was like the mountain that said to Mahomet, "I cannot come to you, so you must come to me," and invited the old settlers to picnic on his grounds. More than one hundred responded to the call, and on the way thither on the cars, some remarked : "I rode over this ground when there was not a single house." And now, what a change ! Farm houses and towns. My old friends, the prairie flowers, had given place to corn and stubble-fields ; the plow, reaper and mower had ruthlessly cut them down, and they waved there no more. The cabin, lye-hopper and old bee-gum have disappeared, and large, commodious farm-houses occupy their sites. In lieu of the buzzing of the wheel, the note of the organ and the whirr of the sewing-machine are heard. The sound of the flail is heard no more in the land, nor the tread of horses on the ground threshing-floor, but instead there falls on the ear the whirr of the steam-thresher, as the stream of clean grain runs into a sack, while the clean, bright straw is deposited on the stack.

There are some "old settlers" among the flowers yet remaining, that the reaper and plow have not destroyed. Golden-rods and asters have taken up their abode under the protection of hedges, fences, and rough, un-tillable land. Tile drove them from wet places, and now they are on the ragged-edge. May the day be far distant when they are driven from the highways and fences !

The Credit Belongs to the Bees.

—Farmers say that honey is their only product that is free from vermin. Let due credit be given the bees for this. They certainly take great pains to "comb" it.—*Binghamton Republican*.

We will Present a Pocket Dictionary for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

INTERNATIONAL.

Report of the North American Bee-Keepers' Convention.

Written for the American Bee Journal
BY W. Z. HUTCHINSON.

The North American Bee-Keepers' Society convened its Nineteenth Annual Convention on Oct. 3, 1888, in the Representative Hall, at the State House in Columbus, Ohio.

The meeting was called to order at 11 a.m., with President A. B. Mason in the chair. As no programme had been prepared, a committee was appointed to prepare one. The following members then paid their dues :

J. S. Barb, Bristolville, O.
J. A. Bayard, Athens, O.
E. M. Bennet, South Charlestown, O.
Dr. H. Besse, Delaware, O.
J. H. Boyden, Saline, Mich.
Jno. Calvert, Medina, O.
Asher M. Coe, Coe Ridge, O.
E. H. Collins, Mattsville, Ind.
Prof. A. J. Cook, Agricultural Coll., Mich.
J. Y. Detwiler, New Smyrna, Fla.
W. J. Dixon, Monday, O.
G. M. Doolittle, Borodino, N. Y.
Frank A. Eaton, Bluffton, O.
Henry Hastings, Kenton, O.
B. Helphry, Utica, O.
R. F. Holtermann, Brantford, Ont.
Marcus Holtz, Tiffin, O.
W. Z. Hutchinson, Flint, Mich.
C. E. Jones, Delaware, O.
D. B. Lovett, Crestline, O.
David Lucas, Jewett, O.
Dr. A. B. Mason, Auburndale, O.
N. W. McLain, Hinsdale, Ills.
J. J. McWhorter, South Lyons, Mich.
Dr. C. C. Miller, Marengo, Ills.
F. Minnick, Bessemer, Wis.
J. F. Moore, Rockaway, O.
S. R. Morris, Bloomingsburg, O.
Adam Rickenbacher, Gahanna, O.
A. I. Root, Medina, O.
E. R. Root, Medina, O.
R. R. Ryan, Bradshaw, Nebr.
Jno. Short, Moline, Mich.
J. H. Smith, Kenton, O.
R. L. Taylor, Lapeer, Mich.
Dr. G. L. Tinker, New Philadelphia, O.
Samuel Utz, Kenton, O.
P. S. Van Rensseler, La Cairne, O.
G. W. Webster, Lake Helen, Fla.
B. Wells, Fostoria, O.
Rnbt. B. Woodward, Somerset, O.
S. P. Yoder, East Lewistown, O.

LIFE MEMBER.

Thomas G. Newman, Chicago, Ills.

LADY MEMBERS.

Miss Dema Bennett, Bedford, O.
Mrs. Prof. Cook, Agricultural Coll., Mich.
Mrs. M. George, Bowling Green, O.
Mrs. D. B. Lovett, Crestline, O.
Mrs. A. B. Mason, Auburndale, O.
Mrs. Mary McPherson, Ohio.
Mrs. E. R. Palmer, Exeter, Mich.
Miss Kate Perkins, Flushing, O.
Mrs. E. R. Root, Medina, O.
Mrs. M. Stover, Roscoe, O.
Mrs. Catherine Springer, Fostoria, O.
Miss Mary Statelar, Somersford, O.
Miss Sarah Statelar, Somersford, O.

After the members had paid their dues, the remainder of the forenoon was employed in what might be called

An Experience Meeting.

Miss Dema Bennett had received many reports, and nearly all reported failure. A few had reported getting 100 pounds per colony from peppergre.

Dr. Tinker reported almost no honey from white clover. The greatest yield had been from yellow poplar. The honey from this source is dark, and many mistake it for honey-dew.

Prof. Cook stated that he had received some heart's-ease honey from Iowa. When first received it was very strong in flavor. No one would want it upon the table. In three or four weeks the strong flavor had passed away.

R. L. Taylor said—My story is like that of the other members. My crop is about 5 pounds of surplus per colony. My bees are in two apiaries nine miles apart. All the white honey was secured in one locality, and all the fall honey in the other. In the northern part of the county the fall flow was bountiful. If I had moved my bees 20 miles I might have secured from 25,000 to 40,000 pounds of surplus. This honey that was secured in the northern part of the county was almost as white as my clover honey. I think it came from asters and button-ball. The flavor is good ; it reminds me of fine maple syrup.

R. F. Holtermann reported that bees wintered poorly in Canada. Clover and linden yielded but lightly. But very little comb honey had been taken, and the extracted would all be off the markets in October. The fall flow had been fair. In localities the flow from thistle had been good.

Mrs. Mary McPherson made her living by keeping bees, poultry, etc. She had learned the business under protest. Her husband had told her that she might sometime be left to support herself and children. His words had proved true. Last season she was left a widow. From 32 colonies she had secured 800 pounds of comb honey. She did all the work, besides caring for her poultry and doing her house-work. She was up in the morning as soon as it was light enough to see, and she said she would like to have a private settlement with the man who said bee-keeping was nice and easy work—just suited to ladies.

J. Y. Detwiler rehearsed the troubles that had befallen the bee-keepers of Florida. The frost of 1886 had injured the mangrove. It had recovered in a measure, and was beginning to yield. This year he had 1,200 pounds from 40 colonies. Large black ants

give much trouble. They work at night, and sometimes destroy full colonies. Mr. Detwiler preferred to keep bees in the North, even with the risks of wintering, to keeping them in Florida ; but he liked the climate of Florida, his home is there, and he should stay.

The convention then adjourned until 2 p.m.

AFTERNOON SESSION.

The afternoon session was called to order at 2 p.m. by President Mason.

Reunion Song.

We naturally feel a little pride in the fact that when we need poetry, songs or music it is not necessary to leave our ranks in search of the talent necessary for their manufacture. The afternoon session was opened by singing "The Bee-Keepers' Reunion Song"—the words by Eugene Secor, and the music by Dr. C. C. Miller. Many of the members joined in the singing, and all were pleased with the sentiments expressed, as well as with the music.

After the singing the convention took up for discussion this subject :

The Best Age of Bees to Go into Winter Quarters.

Dr. G. L. Tinker preferred young bees ; those that had had one flight. He would put the bees in as early as Nov. 10, as they are then likely to become quiet and remain so. As an experiment he had taken some of the bees out of the cellar, and allowed them to fly, then returned them to the cellar, and as a result they became restless and wintered very poorly.

Dr. C. C. Miller—I suppose that if we should try to find out what class of the human family suffered most in a severe winter, we would learn that it was the old folks and the children. I do not know as I disagree with Dr. Tinker. I am not sure, however, that I want very young bees. In the fall we have all ages of bees in the hives. Some of them will die within a week, others in two weeks, others in a month, and so on. If it were possible, I believe it would be an advantage to have sifted out all the bees that would die before spring.

R. L. Taylor—I would like to ask at what time the Doctor would have the queen stop laying ?

Dr. C. C. Miller—We have but little control over this. We might prolong breeding by feeding.

R. L. Taylor—One year I fed the bees in the fall. October was warm, there was brood in the hives early in November, and the young bees certainly did no harm, as the bees wintered unusually well.

A. I. Root—We were once told that we must have young bees for winter—must feed if necessary. We tried taking away the queen in the fall, but the bees wintered well.

Prof. Cook would not care to have the queen lay after Sept. 1.

E. R. Root—In 1886-87 we wintered 200 colonies without loss, and they were almost all old bees; we had foul brood in the apiary, and but little brood was reared.

Dr. A. B. Mason preferred bees that had done a little work before winter had begun.

Prof. A. J. Cook—I think that we ought to have brood up to September. In 1871 we had no brood in July and August, and the bees wintered poorly. I do not care to have the bees begin to breed before the first of April.

R. L. Taylor—I do not want my bees to breed in the cellar. One year, towards spring, I found a colony in the cellar that had one comb full of brood. I was pleased with it. I kept watch of it. When put out, the bees seemed to lose heart. They did not go ahead and prosper. Other colonies that did not breed until taken from the cellar outstripped this one.

There was quite a long discussion as to how early in the spring it was best for bees to begin breeding. Some said two months before the white clover harvest was soon enough, and others would have them begin sooner.

Upon a vote being taken, it was found that the convention was about equally divided. One-half thought that two months before white clover was soon enough, and the other half preferred to have them commence sooner.

The convention next listened to the reading of an essay by Prof. G. W. Webster, of Lake Helen, Fla., upon

The Honey-Plants of Florida.

Probably no State in the Union presents such a variety of soil and vegetable production, and consequently of bee-forage as Florida. Here in Volusia county, in what is generally called South Florida, there are at least seven distinct classes of land, each class having its own peculiar flora. These classes are commonly distinguished as High Hammock, Low Hammock, High Pine, Low Pine (or Flatwoods), Scrub, Cypress Swamps, and the Mangrove Islands.

A narrow strip of hammock along the St. John's river, a wider one running north and south along the coast, and a few small bodies scattered through the county, comprise the hammock land. The largest portion of high pine land is a strip 5 to 10 miles wide running north and south through the county, and near the St.

John's river. Between the high pine land and the hammock along the coast, there is a strip of low pine land 10 to 15 miles wide.

Scrub lands are scattered about in various parts of the county, sometimes several thousand acres in a body. Small bodies of cypress swamp are to be found in nearly all parts of the county. The Mangrove islands are found in the salt water of the Indian and Hillsborough rivers, along the coast. Hammock lands furnish bee-forage from cabbage and saw-palmetto, yellow jasmine, grapevines, and many other vines and shrubs. High pine furnishes almost nothing except where it is cultivated in orange groves, or other crops. Cow-peas keep bees busy during a part of the season, and the wild partridge-pea (*Cassia chamæcrista*) is said to be a good honey-plant; and sometimes *Pelastemon Feazi* is said to yield honey.

Cypress swamps are mostly located in the "low pine" lands, and furnish nothing that I know of except where there are whortleberries or ilex growing around their borders. Flatwoods are covered with large quantities of saw-palmetto, which is the best honey-plant in Florida, aside from the mangrove. *Ilex glaber*, a species of holly, with black berries, commonly called gallberry, is found along the borders of streams, lakes and swamps. It does not grow in sufficient quantities to yield a large amount of honey, but we sometimes get a flow of it just before the palmetto, and it produces a little better quality of honey.

Scrub yields a good quality of honey from the scrub or spruce pine, and a poor quality from a shrub called, sometimes, crooked-wood (*Andromeda ferruginea*). Palmetto is also found in the scrub, as well as whortleberries, red-bay, and some other shrubs that help a little. The orange yields abundantly, and the honey is of fair flavor. Settlements are mostly on high pine and hammock land, which would consequently locate the orange groves there also.

Our own apiary of about 40 colonies is located on high pine land. Our first surplus honey is from the spruce pine in January or February. In February or March comes the orange, and in April the andromeda. Two or three weeks later, in May, comes our best yield from gallberry and palmetto, which closes the season so far as surplus is concerned. In fact it is necessary to leave 25 or 30 pounds of honey in each hive when taking the last honey in June. Otherwise the bees are liable to need feeding during the fall or early winter, and in my opinion feeding does not pay in the pine woods of Florida.

During the summer and early autumn sufficient honey is gathered to keep up breeding, but by November surplus honey is generally considerably diminished. One common cause of loss of colonies here is undoubtedly lack of stores; another cause is the loss of queens in swarming time, many young queens being lost before they get to laying. During April and May the green dragon-fly is very destructive to bees; sometimes hundreds of them may be seen around the apiary, darting in every direction, seizing the bees as they return heavily laden, and devouring them at their leisure, as they fly about; and no doubt they get many young queens during their mating flight.

There is about as much trouble in wintering bees here as there is in the Northern States, owing, I think, to the many mild days during the winter, which tempt bees abroad when there is nothing for them to get. The bees become chilled or worn out, and fail to return. Our experience here has been a yield from 40 to 50 pounds of extracted honey per colony, the seasons varying as they are cold or warm, wet or dry.

Mangrove Region of Florida.

Bee-keeping near the coast, in the mangrove region, is entirely a different affair, and requires different methods. Before the great freeze of three years ago, very large yields were sometimes obtained. Several bee-keepers reported a yield of over 300 pounds each from their best colonies; and sometimes whole apiaries yielded an average of over 200 pounds per colony. The freeze killed much of the mangrove, and there are probably not over one-fourth of the bees there now that were there then.

The mangrove is slowly recovering from the effects of the freeze, and during the past season some apiaries have done fairly well. The great trouble seems to be in wintering the bees so as to have plenty of workers when the mangrove is in blossom, which is not generally before the middle of June, and lasts until sometime in August. Where there are many large apiaries the yield of honey from palmetto, orange groves and the hammock lands is not sufficient to keep the bees breeding during the late winter and spring.

One man, who was taking care of about 100 colonies, told me that he thought 60 pounds of honey should be left in the hive to winter on. It was then the last week in April, and he said that he had already fed five barrels of sugar. In March his bees had got well advanced in brood-rearing, on orange blossoms and yaupon (*Ilex cassine*), but in April the honey failed,

and the bees carried out large quantities of young brood. While we were talking we could hear the bees working on the two or three species of wild grape that were just coming into blossom in the hammock. I also noticed bees very busy on *Ilex decidua* and *Eugenia dichotoma*, two shrubs or small trees that are plentiful in places near the coast.

About the same time I visited two apiaries belonging to J. Y. Detwiler—one at his home on the east side of the Hillsborough river, opposite New Smyrna, and the other on Orange Island, 12 or 14 miles further south. His home apiary did not seem to be doing much, there being but little hammock within reach of it, but the one on Orange Island, having access to plenty of hammock, were rearing brood and storing honey. He had not fed either apiary except perhaps to give weak colonies frames of honey from the strong ones.

I spent several weeks on the Hillsborough river in June and July, and visited the apiaries of Mr. Detwiler, the Messrs. Brown on the east side of the river, W. S. Hart (in charge of E. S. Contant) at Hawk's Park, A. E. Marsh, near Oak Hill, and others. Two story hives were generally used, and so far as I learned, no honey was extracted from the lower story, and it seemed to be the general opinion that both stories should be left full of sealed honey for winter use.

I think that the palmetto yield must have been much shortened the past season by dry weather, and the mangrove itself, although its roots stand in water, and are washed by the tide every day, seems to need rain in order to produce a good yield. I heard bee-keepers complaining that they were getting little honey on account of the dry weather, while only a few miles distant, others who had been in the track of storms, were getting a good flow. The best yield heard of was 150 or 160 pounds per colony. Some got but very little. One man said that he fed two barrels of sugar and one-half a barrel of honey, and extracted two and one-half barrels of honey. Difference in location, rainfall, condition of bees, and I have no doubt in management, all conspire to make a difference in results.

I have no doubt that large quantities of honey will be produced from the mangrove, but it will be done by acquired skill and untiring perseverance.

Further south *Satureia rigida*, commonly called wild penny-royal, is said to be a very superior honey-plant, blossoming during the winter. I have collected specimens of it within less than two miles of our own apiary,

where it blossoms in April, but not in sufficient quantities to yield much honey.

The Grading of Florida Honey.

I wish to speak in regard to the grading of Florida honey. Some dealers still unjustly class it as "Southern honey," a name that has been applied to a very inferior article produced in some parts of the South, by the old-fashioned method of melting and mashing comb, bee-bread, brood and dead bees, and running the filthy mass through a cloth strainer. Mangrove honey is nearly as clear and white as the best white clover honey, and has a mild and pleasant flavor. Orange, palmetto, and gallberry honey—our principal honey-plants in the interior—are, in my opinion, much superior to buckwheat honey, and they are certainly much lighter in color than buckwheat, or even golden-rod, and should be graded and sold on their merits as mangrove, orange or palmetto, as the case may be.

GEO. W. WEBSTER.

Mangrove and Palmetto Honey.

After the reading of Prof. Webster's essay, the following discussion ensued:

Prof. Cook—I think that something ought to be done in the way of recognizing the difference between mangrove honey and the ordinary Southern honey. The mangrove honey is certainly fine honey, and ought not to suffer from having the name "Southern" honey given to it.

J. Y. Detwiler—If this convention would recognize the superior quality of palmetto and mangrove honey, and urge the editors to make a distinction between this and other Southern honey, in their market quotations, it would be a great help to the bee-keepers of Florida.

Upon motion of Dr. Miller, it was voted that the editors of the bee-papers be requested to quote mangrove and palmetto honey under their proper names, and to continue to keep these names in their quotations. If there is no honey of these kinds in the market, simply say, "None in the market."

The attention of the meeting was next turned to a discussion of the

Lessons of the Season.

Dr. C. C. Miller recounted the failures of the past season. Not only had the honey crop been a light one, but he had been called upon to bear troubles and afflictions, still, he had been happy; he thought that the greatest lesson he had learned was that of being contented under adverse circumstances.

R. F. Holtermann became disgusted with bees the first year he kept them,

and the next year the average honey crop was 200 pounds per colony. He had learned that it was best to "stick to it."

Prof. Cook thought that one lesson of the season was in that it showed the desirability of combining bee-keeping with some other business. He called attention to the amount of honey that Mr. Taylor could have secured by moving his bees. This should teach us what might be done by moving bees to better pastures.

The convention now took a recess of ten minutes.

When called to order, the members were once more pleased, set to laughing this time by Dr. Miller's singing a song entitled, "Dot Happy Bee-Man," the words being written by Eugene Secor, and music by Dr. Miller.

The next topic taken up for discussion was,

The Time for Putting Bees into Winter Quarters.

Dr. Mason had put bees into the cellar on Oct. 19, and others later; and there was no particular difference in regard to the amount of stores consumed, or in the wintering of the bees. The average consumption of stores was six or seven pounds per colony.

E. R. Root said that their colonies consumed, on an average, about 12 pounds per colony.

Prof. Cook had done considerable weighing of bees. Out-of-doors the consumption of stores per colony averaged about 15 pounds; in the cellar, 8 pounds. He knew that bees *could* winter well in a light cellar, but as a general thing he did not think they would.

Dr. Mason knew that light was injurious. He had had bees continue to leave their hives on account of the light, until the hives were depopulated.

Dr. Miller had had bees remain quiet in the cellar with the sun shining upon the hives. If the bees are uneasy, the light will disturb them; otherwise it probably will not. He did not advise light in a cellar.

Prof. Cook—This may not be exactly the place to talk of hives, but I have noticed that bees have wintered the best in the "New Heddon Hives," and I have wondered if others have noticed it. I have been at a loss to account for this, as it has been without exception. Sometimes I have thought that it might be because the combs were $\frac{1}{2}$ an inch above the bottom-board; and again, I have been inclined to attribute it to the fact that the upper story was filled with honey, while the lower one was empty.

Frank A. Eaton had never succeeded in wintering bees in the cellar until he began raising the hives from the bottom-boards.

R. L. Taylor—My experience with the Heddon hive has been similar to that of Prof. Cook's; but I do not attribute it to the same cause as he does. I think that it is caused by the space between the upper and lower cases. As cold weather comes on, the cluster contracts. With large combs small clusters of bees become isolated and chilled; they may not be killed outright, but their vitality is impaired. With the Heddon hive the center of the cluster is where the break comes in the frames, and all the bees can readily keep in the cluster.

Dr. Tinker—Mr. Taylor may be stating facts when talking of single-walled hives, but with properly constructed chaff hives his views would be untenable.

R. L. Taylor—In breeding up bees in the spring, I have decidedly the best results with the new Heddon hive, as compared with the Langstroth-Heddon hive.

The convention then adjourned until 7 p.m.

EVENING SESSION.

The convention was called to order at 7 p.m., with President Mason in the chair. The first question brought up for discussion was,

Sections Open on all Sides.

Dr. Tinker led the discussion, and spoke in substance as follows: Open-side sections afforded better ventilation. If the surplus apartment is divided into too small apartments, the ventilation is deficient, and more time is required for ripening the honey; hence not so much honey is secured. The combs are built out square and true to the edges, and the sections filled full. Italian bees, with closed-side sections, often draw in the comb—make it thinner—as they approach the uprights to the sections, connecting the comb to the uprights by merely a narrow ledge. With open-side sections this is avoided.

A. I. Root had noticed this drawing in of the comb as it approached the sides, but did not think that this was always the case. He recounted the experiments of Mr. A. Rice in the house apiary. He placed small sections inside of ordinary brood-frames, hung them the usual distance apart, and the bees filled them most completely. Later he tried the ordinary sections, wide frames and separators. After trying them he was led to exclaim: "I wish that the little scamps would fill out the sections as well as they used to in the old brood-frames!"

R. L. Taylor asked, why not get rid of the Italians, keep such bees as would fill out the sections whether open-sided or not?

Dr. Tinker admitted that black bees and some hybrids would give no trouble in this direction.

Frank A. Eaton—There is one objection to open-side sections, and that is in crating, the corners catch and tear the combs.

Dr. Miller had produced and shipped thousands and thousands of pounds of comb honey, and the sections were well filled, and bore transportation without loss from breakage, and they were close-sided sections.

Dr. Tinker still clung to the idea that more honey could be secured by using sections with open sides, and that with care in handling there need be but little if any damage done to the combs.

Next came a discussion upon,

How Can Safety be Secured in the Mating of Queens?

A. I. Root said that the appearance of hives had much to do with it. King birds sometimes probably catch them. Sometimes queens cannot fly. They leave the hive and cannot get back. To know whether a queen can fly, toss her up in the air.

Prof. Cook had scarcely lost any queens until the present season, when the loss was nearly one-half. Previous to this season the hives had stood in the shade of evergreens. These trees had been of different sizes, character and appearance. This year they were all cut away.

R. L. Taylor thought that bees and queens were guided in finding their hives by the larger surrounding objects, trees, etc., rather than by the hives themselves.

Dr. Miller did not think that increasing distance between the hives aided the bees very much. He would place the hives in groups.

Following this came a lively little discussion upon

The Use of Chaff Hives.

E. R. Root led in the discussion, very fairly presenting the good and bad features. They afforded protection from cold, also from the direct heat of the sun's rays. The bees are always ready for winter, so far as protection is concerned, and the cool nights of late summer do not drive the bees from the supers. With chaff hives there is no laborious carrying of bees in and out of the cellar. Mr. Root said that by referring to their statistics, they found that cellar wintering of bees predominated in Michigan, Wisconsin, Iowa and Minnesota; as far south as southern Ohio chaff hives and cellars held about equal sway; south of this, chaff-hive wintering of bees greatly out-numbered other methods.

Dr. Tinker thought that the saving in stores in the spring would alone pay for the expense of chaff hives.

Frank A. Eaton emphasized the point of leaving the bees in the cellar until the danger from cold is over; then the bees make rapid progress, and chaff hives are not needed.

Dr. Tinker replied that we often have frosts after warm weather has been "on deck" several weeks.

R. L. Taylor admitted that there might be a saving of honey by having the bees protected early in the year, but for actual work in the apiary, producing either comb or extracted honey, he could not endure using a chaff hive, and did not see how any man could. Their capacity is limited—only 50 sections can be used upon one hive, and it is often desirable to put on 100. Only one set of extracting combs can be used, and it is often desirable to use several. The hives are heavy and unwieldy, and if it were desirable to move an apiary to more desirable pasturage, chaff hives would almost prohibit it.

Dr. Mason called attention to the fact that 80 sections can be placed in a chaff hive.

R. L. Taylor—Oh, yes, if you put them in wide frames; but I can't "play" with my bees in any such way as that. When I said 50 sections, I meant when they are in cases so that you can work with them.

John Calvert called attention to the single-story chaff hives. It overcame most of the objections urged against the chaff hive.

R. L. Taylor—Yes; but the trouble is, the chaff hives do not do what is claimed for them. They do not winter the bees. A single-walled hive is just as good for wintering bees; with it the sun can warm up the bees; with a chaff hive it does not.

Dr. Mason would prefer to winter the bees in the cellar, but valued protection for them in the spring. If he wintered his bees out-of-doors, he would use chaff hives.

Mr. Chase mentioned that Mr. Shane had two apiaries. In one the bees are protected in the spring by packing; in the other they are not. The packed apiary always comes out ahead, and gives the best results.

Frank A. Eaton did not get in a hurry to take the bees from the cellar. They were left in until chaff hives were not needed.

The following interesting letters were then read:

DAYTON, O., Oct. 2, 1888.

MY DEAR FRIENDS:—I am very sorry to say that I cannot be present at your meeting at Columbus. I have taken

such a heavy cold that it will not be safe for me to leave home. It oppresses me so much that I cannot even commit to paper the essay which I have prepared.

I am more disappointed than I can well express, for I was looking forward to a very happy time in seeing again many of my old friends.

Wishing you a pleasant and profitable meeting, and desiring to be kindly remembered to you all, I remain very sincerely your friend,

L. L. LANGSTROTH.

PEORIA, Ills., Oct. 3, 1888.

I regret exceedingly that I am not meeting with you to-day. My poor health would not justify the outlay of strength necessary to travel all night to reach Columbus. I hope that Father Langstroth is there. I imagine I see him now, with his hand upon his cane, with his benignant face beaming upon all.

MRS. L. HARRISON.

FOREST CITY, Iowa, Oct. 1, 1888.

Travel, reading, observation and conversation with bee-keepers in various parts of the State lead me to think that the crop of honey is light in Iowa this year. While the season has been better than last as regards the condition in which the bees will be at the beginning of winter, and perhaps also as to the quantity of surplus, it is mostly fall honey and off color, though the quality is good.

The severe drouth of 1887 so killed the white clover that it required all this season to regain its foothold in the pastures. I doubt if it is fully re-established now. So we got no white clover honey worth speaking of. Basswood (linden, if you like the word better) blossomed very full in 1887. This was its off year, and the yield light. The fall flowers yielded fairly well. Bees seem to be in good condition. I have not heard of any foul brood.

The Chapman honey-plant was tried to some extent. There is no doubt about the fondness of bees for it, but whether it would pay to cultivate for honey, is another question. A fine exhibit of bees, honey and implements was made at our State Fair, and at some of the local fairs. The art of bee-keeping seems to be keeping step to the music of progress in other departments of rural life.

EUGENE SECOR.

Upon taking a vote, it was decided to hold the next meeting at Brantford, Ont.

The convention adjourned until 9:30 a.m. the next day

SECOND DAY.

MORNING SESSION.

President Mason called the convention to order at 9:30 a.m. The first topic discussed was,

The Width of Sections.

J. H. Smith made several widths of sections, but sold ten thousand of the inch and seven-eighths to one thousand of any other width.

E. R. Root said that their experience was that of Mr. Smith's.

Frank A. Eaton said that it all depended upon whether separators were used. One inch and seven-eighths was the proper width with separators; if they are not used, the sections must be narrower.

Dr. Tinker preferred that the space between the top-bars and between the bottom-bars should be $\frac{3}{8}$ of an inch, instead of the usual $\frac{1}{2}$ of an inch.

The next topic was,

When Shall Bees be Put Out of the Cellar?

Dr. Besse—When there is something for them to do. When they can gather pollen.

Dr. Miller—About two weeks after the right time. [Laughter and cries of "good;" "that's it."] I suspect that we put our bees in too late, and take them out too early. I used to take them out at the blossoming of the soft maple, but it has several times fooled me. Freezing weather came on again after the maples had blossomed.

Next came a discussion in regard to the subject of

Securing More Complete Organization Among Bee-Keepers.

Dr. C. C. Miller—We have local societies, State societies, and the North American Society; and the latter is largely local. Unless something is done to make it more completely a representative body, we might just as well kill it and done with it. I would suggest that the State and local societies send delegates, and pay their expenses.

Prof. A. J. Cook—The State and local societies will not do this, and I do not believe that this society is yet ready to die. Suppose that we do have a large local attendance, we also have a scattering attendance from abroad. We could have the different States represented by essays from their best men.

A. I. Root mentioned that religious bodies send delegates to meetings and conventions and pay their expenses. Apicultural societies might do the same. He would give more to see a man and hear him talk than he would to have an essay from him.

Upon motion it was voted that all State and local societies be invited to send delegates to the North American Society's conventions.

Next came an interesting talk by Prof. A. J. Cook, upon,

Experiments in Apiculture.

With one or two exceptions, the Michigan Agricultural College is the only one that has experimented in apiculture. Until lately there has been a lack of time in conducting the College apiary. At last an able assistant has been secured, and the passage of the Hatch bill has provided the funds, and the prospects are that much more will be done. One line of work will be that of crossing different varieties of bees; another, that of determining the value of special planting for honey; and the third will be in regard to the adulteration of honey. Rocky Mountain bee-plant, Chapman honey-plant, pleurisy-root, and perhaps others will be tried. Considerable is hoped for the Rocky Mountain bee-plant, as it flourishes in a drouthy climate. At present the bees at the College are a cross between the Syrians and the Carniolans, and they seem to possess the good qualities of both.

Prof. Cook feels sure that bee-keepers do not adulterate honey, neither does he believe that it is done by grocers. He considers them no more honest than many other classes, but adulteration does not pay. He does not believe that the chemist can tell positively in regard to adulteration, and experiments are to be made to determine, if possible, whether adulteration can be detected.

A. I. Root asked how Prof. Cook knew that their bees were a cross between the Syrians and Carniolans.

Prof. Cook—We do not know positively. There are no bees nearer than three miles. Besides, I have studied the characteristics of each race, and I cannot fail to recognize them.

Mr. Thomas G. Newman then addressed the convention in substance as follows upon the

The Importance of Experiments in Apiculture.

Mr. President, Ladies and Gentlemen:

The announcement just made by Prof. Cook, that he intends to commence the making of careful experiments on the four important points enumerated will give great delight to the devotees of our pursuit, because the promised experiments will cover the ground of not only the value of the different varieties of bees, but also the necessary pasturage to be provided, and the application of the most successful methods to be employed in

the management of the apiary for profit.

We know but a very little of the arts and sciences—only just what has been found out *by experiments*, or by accident! We have seen only that which we had eyes to see; and the value of experiments—of training—of delving into the unknown—of studying the possibilities—lies in the opening of our intellectual eyes to see what there is in Nature all around our pathway! Was Stephenson a genius? Was Franklin brilliant? No; but both of them were full of observation, perseverance and intelligence, and these characteristics were diligently aided by common sense.

It has been well remarked that if necessity was the *mother* of invention, surely an American was its *father*! Success lies in working with Nature, for it contains the secrets of all inventions. Here we may study, delve, guess, invent or copy to our heart's content. The human arm suggested the lever to Archimides. The human skull was well studied by Michael Angelo, who designed the dome of St. Peters. The waves of the fury-lashed ocean led Napier to invent the shape of the "bow" of a steamship best suited to plow the waves and triumphantly ride over its tempest-tossed bosom. The latter let us more fully describe, that we may learn a valuable lesson therefrom.

The first steamships built in Scotland dared not to venture out of the firths and rivers in stormy weather. But David Napier, the celebrated marine engineer, thought that they could be so built that they could navigate the ocean in all kinds of weather, and accordingly he determined to know and personally observe the difficulties to be encountered and overcome.

Sailing packets were then running between Glasgow and Belfast, and he selected a stormy period of the year to make that voyage, in order to study the waves when driven with fury, for St. George's Sea is noted for its dangers, and the number of its shipwrecks. He stood for hours at the "bow" of the packet, watching the breaking of the waves—now and then leaving that chosen post to inquire of the captain if he considered the sea *rough*. When assured that so far it was nothing unusual, he returned to his post with disappointment.

The drenching spray he cared naught about, but the "ordinary weather" made him impatient. At last the wind increased—it blew a gale—and wave after wave "swept the packet from stem to stern." With this he was delighted, and dripping with salt water he made his way to the captain and asked, "Captain, do you

think it is rough *now*? who replied, "I never faced a worse sea, sir!"

Napier exclaimed, "Well; if that is all, I think I can master it!" He went below to meditate, and on his return to Glasgow, he began to *experiment*—just as Prof. Cook now promised us to do, but in another line. He aimed to discover the shape of the "bow" which would go through the water with the least resistance.

His observations, taken while being drenched with the waves at the "bow" of the packet, convinced him that the round bow of the sailing vessel was not calculated for a fast steamship.

Repeated *experiments* led him to believe that the fine wedge-shaped "bow" would revolutionize the world in the matter of steamship building. Then it often required several days to sail between Glasgow and Belfast! Now it requires but nine hours—all because of the experience and *experiments* of that undaunted marine engineer.

Now our modern "Napier," who has taken special pains to find out what necessity requires, will retire to his quiet haunts at the State Agricultural College, away up in Michigan, to meditate and *experiment* on the four important points which he enumerated a few minutes since! Let us hope that he will discover and bring to light matters and methods as important to progressive bee-culture as did Napier to ocean travelers, but a few years ago.

We all are aware that the survey precedes the building of the railroad, and the reconnaissance locates the field and line of battle. Just so is it with us, at this time. Prof. Cook knows the difficulties to be encountered—he has "studied the waves of adversity" which have repeatedly dashed over our chosen pursuit, and caused much consternation. He has "surveyed the line" upon which it is to be hoped we can all ride to success; and located the plan of battle which may give us the victory. We shall anxiously await the result of his meditations.

Bee-Pasturage.

One of the cardinal points is that of providing pasturage for the bees. He proposes to plant ten acres of the Rocky Mountain bee-plant—to plant broadcast, and let it take care of and perpetuate itself. This matter of planting for honey has been a pet theory for years, with me, and I hail the day for an *experiment* on a large scale, feeling assured that it is one of "the winning cards."

Those depending on the wild pastures for bee-forage should not fail to plant for honey, and thus secure a

good crop every season, as the years come and go. If *drouth* comes and finds them depending on streams which dry up, they are then the sufferers.

They should have pastures for the bees, with plants having deep roots to go and seek the moisture below, or else have pastures that can be watered from convenient wells or ponds, and thus aid Nature to secrete the nectar in the dry times.

Every season teaches some new and useful lesson. Those who heed these lessons are on the rise. Those who do not are on the down grade. Will apiarists be content to repeat each year the mistakes of the former one? If they are wise, No. If they are heedless and unprogressive, Yes.

Honey Adulteration.

It has been asked here and elsewhere if extracted honey is now being adulterated? I answer, No. It will not pay to adulterate honey at its present very low price, and hence it is not practiced, for even the thieves and adulterators will not ply their nefarious business when it is unprofitable to do so.

As to the adulteration of comb honey, the truth about that is out at last. Wiley, Evans & Co., have been driven to the wall, in two ways; first by their having been forced to confess that there was nothing upon which they could build their "bogus comb-honey" story, except the wild imagination of a diseased brain; and the fun of perpetrating a very *un-scientific* pleasure!

And, in the second place, immediate sale of the small crop of honey had made bare the great marts of trade, and while the demand was urgent, and the prices high, not a single pound of the bogus comb honey could be found! More than anything else, this shows the falsity of the claim, and exposes the *lie* about "combs being made of paraffine, filled with glucose, and sealed by machinery?"

Not a crate—not a section—not a pound—not a cell of the bogus "comb honey" can be found on the markets! Not even the advanced prices can bring it to the front! If it was in existence, how the manufacturers of the bogus stuff would jump at the chance to sell it! How they would run the machinery night and day to fill the demand!

The citadel is stormed!

The giant is slain!

Comb honey is vindicated!

Prof. Wiley's lie is exposed!

The peddlers of the lies are rebuked!

The "prince of lies" is defeated.

The honey crop failure did it.

THOMAS G. NEWMAN.

A. I. Root mentioned that Dr. Miller had secured large quantities of honey from 200 acres of cucumbers raised near him. This showed that honey could be secured from *that* plant.

Dr. Miller—I think no one person, unless it is Mr. Root, has done so much planting for honey as I have. Because Prof. Cook finds some plant valuable for honey, it does not follow that we shall all find it valuable; still, we are glad he is doing something in this line. Does the Professor expect to cultivate his Rocky Mountain honey-plant?

Prof. Cook—No; we cannot do much in the line of cultivation. A plant to be of value must be able to take care of itself, a sort of "root hog or die" plant.

A. I. Root—What better does Prof. Cook expect to find the Rocky Mountain honey-plant than is buckwheat?

Prof. Cook—It will stand drouth. It is brought up on dry weather. A dry locality is its home.

Dr. Mason said that he had been in attendance at the Ohio Centennial for the past five weeks, and it was astonishing to see the amount of belief there is in the adulteration of honey.

R. F. Holtermann then gave the following address on the

Value of United Experiments in Apiculture.

Who amongst bee-keepers does not look back with deep and heartfelt gratitude to such men as Huber, Dzierzon, Langstroth, Quinby, and a host of others? and it takes but a moment of reflection to bring to our mind's eye a picture of these men toiling day after day, yes, year after year, to gain a perfect and reliable knowledge of the natural history and habits of the honey-bee. What vast benefits apiculture has derived, and what great strides it has made to make it an important branch of agriculture, not only the bee-keeper but every well-informed citizen knows.

Why is it that so much credit is due these men? Because they stand out and above other men of their day—because they were leaders and benefactors. True, they stood comparatively alone, and had to follow their researches too often unaided, and not only with no one to cheer and help them, but rather, with those about them to sneer and misunderstand. Now these men are leaving, and have left a rich legacy to posterity. They have not followed their own selfish aims and ambitions, but in some instances have gained no temporal advancement, and for our benefit.

Are we then making the best use of our advantages? Are we doing our duty faithfully, are we making use of that intelligence which we so right-

fully claim as characteristic of bee-keepers, and are we with these advantages—so much greater in our age than those of our fathers—preparing a legacy for posterity? We are doing much, but not all that we might.

The Manager of our Bee-Keepers' Union uses the old and true motto, "In union there is strength;" this is pre-eminently true of researches or experiments. We have not the plea that our forefathers had; we have numbers who are only waiting to do such work in union, and we have organizations and means of advertising and reaching them, that our fathers never had. Let us then organize and do the most that skill and energy can devise.

Every branch in agriculture is ahead of us. How many associations are performing experiments through its members. Let us then cast aside in this matter all other motives, and together aim at the elevation and perfection of our chosen pursuit, laying aside all petty jealousies, all desires to self-elevation, and in *union* conduct the experiments decided upon to investigate, no matter who may have led us in that direction.

I believe that one of our greatest failures has been, coming to conclusions too rapidly. A new and (as far as theory goes) grand idea impresses us, or the result of one season's experience leads us to believe we have made a discovery which will immortalize our names, and we advance and defend that discovery only to lead others and ourselves astray. Now if we want to be of the greatest use, we must keep under, these our sanguine and selfish dispositions, and in the calm light of reason and lofty desire to advance and elevate apiculture, unite and decide upon some line of experiment; and right here is the difficult question to decide, what shall that be?

I had the honor of being appointed one of a committee by the "Ontario Agricultural and Experimental Union," to decide upon a line of experiment for those of its members interested in bee-keeping. After study the committee felt that so important was it to decide upon the most practical and easily conducted experiments, that we decided upon consulting the members of the North American Bee-Keepers' Society, and the members of the Ontario Bee-Keepers' Association in convention, before taking any decided step in the matter.

The thought was, to have two or three lines of experimentation, and these for the different seasons of the year. For instance, we have men who are able, and have the time and means at their disposal, to make minute and scientific researches of practical value. Again, we have those who have many

colonies who can conduct researches, where a large number of colonies are advantageous, but who cannot undertake anything which will require a great outlay of time.

Again, those who have fewer colonies, who are plain, practical men, and could conduct ordinarily careful experiments, in spring, summer, autumn and winter, and those again who could only conduct them during one or more of these seasons. Every opportunity should be given to every bee-keeper to join in something. In wintering bees, especially, there should be no drones in the hive. I hesitate to set forth what we shall experiment upon—my desire is rather to rivet your attention upon the grand possibilities before us, knowing that practical minds here, will do the rest.

Of course we can never take the place of a man who can devote his life's energies to experimental work, and can secure what necessary means are required to conduct his labors properly—at the same time we can attain results that he never can, and in a shorter time.

Let us lose no time. Let a line of work be decided upon for the coming winter and the coming year. How vast a work can we accomplish, how great our sphere of usefulness by earnest, careful and conscientious work!

In one year, in certain directions, we can make more progress by this method, than before in ten. But I need not point out to a bee-keeper the advantage to be secured by united, whole-souled organization to accomplish any work; no more fitting example of this can be found than in the homes, the occupants of which we are the "masters." R. F. HOLTERMANN.

The convention then adjourned until 2 p.m.

OHIO.

The Report of the Ohio State Convention.

The Ohio State Bee-Keepers' Association held its sixth annual meeting in conjunction with the North American Bee-Keepers' Society on Oct. 3, 4, and 5, 1888, at Columbus, O. A special business session was held on Oct. 4, for the election of officers for the coming year, which resulted as follows:

President, H. R. Boardman, of East Townsend; Vice-President, John Calvert, of Medina; Secretary and Treasurer, Miss Dema Bennett, of Bedford.

On motion the convention adjourned to hold the next annual meeting at Cleveland, O., on the call of the executive committee.

FRANK A. EATON, Sec.

CORRESPONDENCE.

SPANISH-NEEDLE.

Good Flow of Fall Honey—A Streak of Luck.

Written for the American Bee Journal
BY JOS. M. HAMBAUGH.

Having two out-apiaries in connection with my home apiary and farm work combined, has made this one of the busiest seasons on record. Did I sit down and pine over the discouraging results of last year? Hardly. I simply made the best of circumstances, and set myself to work with renewed zeal, notwithstanding the taunts of the "wiseacres" and "knowing ones," who from the beginning said, "I told you that you would get bee-stung."

Well, my bees were divided as before stated, into three yards, the ones at home composed of Italians and hybrids, and all three yards were accessible to linden timber. White clover was a complete failure, and many colonies had to be fed to bridge them over from fruit-bloom to basswood, and when this bloom came—which was the most profuse I ever saw in this section—the bees seemed to revel in their glory, and our long-pent-up enthusiasm was boundless.

We were too sure, however, for though the surplus receptacles were quickly filled, the nectar seemed exceedingly crude, and we waited patiently to see the white cappings appear—the apiarist's criterion for ripe honey. The golden plumes began to drop, and seed-balls appear, and yet our honey was uncapped.

On July 19 the attention of the bees was drawn to the river bottom, only from one-half to a mile distant, and having adverse experience with honeydew and dark honey, I concluded that I would not allow the linden honey to mix with it, and I extracted, and now comes the problem of getting rid of about 1,000 pounds of unripe linden honey.

It was about this time that button-bush began to yield quite a showing for honey, and brood-rearing and swarming was the order of the day, where colonies were not given plenty of room, and this served to put all the colonies in splendid condition for the fall harvest. It was a sight to see the seething mass of insects issuing from a 3-story, 10-frame Simplicity hive, with one inch blocks under the front corners to give them vent, and one would wonder how many of the 8-frame divisible brood-chamber hives it

would take to produce the same results.

Never in my memory have I seen honey come in as lively as it did during the *cereopsis* or Spanish-needle flow; and the beauty of it was, it seemed to be "already cooked," and almost as soon as the cells were filled, they were sealed. One colony produced 73 pounds of honey in five days' time; another one, 86 pounds in ten days; and the gross receipts from 42 colonies at the home apiary was 2,009 pounds of honey at one extracting, and they had been extracted from but 5 to 8 days previous—an average of 47 pounds per colony.

My other apiaries did remarkably well, but the Italians and hybrids "get away" with the ordinary bee by odds. The total product of one Italian colony of bees was 264 pounds. I am not prepared to give any report just yet, but it will aggregate nearly 10,000 pounds. So please do not class me among "blasted hopes" and one of the "bee-stung."

Spring, Ills., Oct. 8, 1888.

CONVENTION DIRECTORY.

1888	Time and Place of Meeting.
Oct. 20.	Wabash County, at Wabash, Ind. Henry Cripe, Sec., North Manchester, Ind.
Nov. 14.	Alabama State, at Montgomery, Ala. J. M. Jenkins, Wetumpka, Ala.
Nov. 21, 22.	Pan-Handle, at Wheeling, W. Va. W. L. Kinsey, Sec., Blaine, O.
Dec. —.	Michigan State, at Jackson, Mich. H. D. Cutting, Sec., Clinton, Mich.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

More than Half a Crop.—Daniel Sheldon, Strawberry Point, Iowa, on Oct. 5, 1888, says:

Although the first bloom of white clover yielded but little honey here, basswood, second bloom of white clover, horse-mint, golden-rod, etc., have kept the industrious little workers busy until they have secured more than half a crop in this section. Beekeepers are not discouraged here. I have had uniform success in cellar wintering of bees. I raise the hives up on inch blocks, keep the temperature at about 40°, and remove the dead bees frequently.

Buckwheat and Alsike Clover.—C. A. Bunch, La Paz, Ind., on Oct. 8, 1888, writes:

As I believe that buckwheat always produces nectar in this locality, I value the plant very much. I do not think that it produces a large amount of honey, though it puts the bees in good condition for golden-

rod, which out-stripped all plants and honey or nectar-producing trees here this season. There was ten acres of buckwheat in less than one-half mile of my apiary, which was alive with bees almost every morning until 9 a.m., and on some warm, misty days until later or nearly noon, although August and September were very dry months, with very little rain. I think that my 28 colonies stored some over 200 pounds of honey from buckwheat in one-pound sections, which is not so bad, I think, considering the season we have had. I have had a small amount of Alsike clover on my place for the last two years, which seems to be good as a honey-plant, as well as for pasture. I expect to sow a half bushel of Alsike clover next spring.

No Surplus Honey.—Henry A. Hyle, Redwood, N. Y., on Oct. 5, 1888, says:

I now have 5 colonies of bees, but I received no surplus honey this year, and I will have to feed my bees pretty well to make up for the lack of honey for winter stores. I lost 4 colonies last winter. I have a good location for keeping bees, and after three years' experience. I think that I am safe in keeping more bees than heretofore.

Hardly an Average Fall Crop.—W. M. Woodward, Custer Park, Ills., on Oct. 6, 1888, writes:

The honey crop has been slow here. There was none at all until corn tasseled, when honey began to come slowly from corn, and has continued to come from heart's-ease and other fall flowers. The fall crop is hardly an average one, but a great blessing for these times.

Molasses Barrels and Jugs for Honey.—F. C. Erkel, Le Sueur, Minn., on Oct. 7, 1888, writes:

My bees have done as well as could be expected considering the season. I moved 35 colonies last spring, by wagon, 12 miles, on 2 or 3 feet of hay, and found the combs all in good condition with one exception, and they were not very bad. I got no honey from clover this year, but the bees made things lively for a few days on basswood, but it did not last long; however, they filled up below in the hive, and I got some nice white comb honey.

Autumn flowers yielded well, and I obtained considerable comb honey from that source, besides a little more than doubling my stock. The bees were determined to swarm late, and kept me busy putting them back. I have more than I want now, and think that I shall kill 15 or 20 colonies and extract the honey. I have a great deal to learn about bees yet, especially how to produce comb honey. I would like the following questions answered in the BEE JOURNAL: 1. My 10-frame Langstroth hives are nearly all full. Would it not be advisable to extract from two or three frames before getting them ready for the cellar? 2. Would it be advisable to put extracted honey in second-hand molasses barrels, such as can be bought at groceries? 3. How would common one-gallon jugs do to put extracted honey in, if the honey was heated to keep from granulating?

[1. Yes.

2. If you do not care to preserve the flavor, the molasses barrels may be used. If you do want the flavor preserved, use new kegs or new barrels.

3. If it granulates, you will find it troublesome to liquefy and handle it.—Ed.]

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4 1/4 x 4 1/4 and 5 1/4 x 5 1/4. Price, \$1.00 per 100, or \$8.50 per 1,000.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in *Cheshire's* pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being mailable, it must be sent by express.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows :

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 120 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

CLUBBING LIST.

We Club the American Bee Journal for a year, with any of the following papers or books, at the prices quoted in the LAST column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	Club
The American Bee Journal.....	1 00	...
and Gleanings in Bee-Culture.....	2 00	1 75
Bee-Keepers' Magazine.....	1 50	1 40
Bee-Keepers' Guide.....	1 50	1 40
Bee-Keepers' Review.....	1 50	1 40

Hastings' Perfection Feeder.—

This excellent Feeder will hold 2 quarts, and the letting down of the feed is regulated

Patented Oct. 18, 1887.

by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for \$3.50, and it can be obtained at this office. Postage 10 cents extra.

Red Labels for Pails.—

We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2 00	3 00	3 50
1,000 Labels.....	3 00	4 00	5 00

Samples mailed free, upon application.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, Ills., is published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Clover Seeds.—

We are selling Alsike Clover Seed at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. White Clover Seed: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. Sweet, or Melilot, Clover Seed: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Cork for Winter Packing.—

Its advantages are that it never becomes musty, and it is odorless. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Exchange.—

We will accept Honey and Beeswax in exchange for Bee-Keepers' Supplies in any quantity. Those desiring to make a trade are invited to correspond with us, stating quantity, quality, and price, and the goods they want in exchange.

Alfalfa Clover.—

For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 10 cents per pound for bag and postage.

We Want 20,000 subscribers.

Out of the 300,000 bee-keepers in America, certainly this is not an extravagant desire! It is only one out of every fifteen! We confidently ask those who appreciate the AMERICAN BEE JOURNAL, to show it by sending us one or more new subscribers. We will give them full value for their money.

A Home Market for honey can be

made by judiciously distributing the pamphlets, "Honey as Food and Medicine. Such will create a demand in any locality a remunerative prices. See list on the second page of this paper.

A Modern BEE-FARM, and its

Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1, postpaid.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

Conventions.—The time for holding Bee-Keepers' Conventions has now arrived, and we cannot give any better advice than this: Let each one attend who can do so, and take part in making these meetings interesting and instructive. If you have not already obtained the "Bee-Keepers' Convention Hand Book," do so at once to post yourself up on how to conduct such meetings correctly. It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for Discussion—List of Premiums for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents. We will club this book and the AMERICAN BEE JOURNAL for one year for \$1.25. It also contains a lot of blank leaves on which you can note important matters as they come up. Do not fail to send for a copy of it.

Nature's Way.—This is the title of a 15-cent pamphlet entitled, "G. M. Doolittle's Method of Rearing Queens"—which is called "The nearest approach to Nature's way yet devised." It describes his method, and points out its advantages. For sale at this office.

Can You Do Anything that will do more to advance and defend the pursuit of bee-keeping, than to aid its Weekly Exponent and Defender? The AMERICAN BEE JOURNAL is the pioneer bee-paper of America, and is fully entitled to the active support of every progressive apiarist, for it works constantly and faithfully for the best interests of the pursuit. We therefore specially request all our readers to use their influence to double our subscription list during the coming autumn. Reader, will you please send us a new subscription with your renewal or before that time? A good weekly at one dollar a year is surely cheap enough to command patronage.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Queens.—We can mail a Tested Italian Queen (bred for the best results as well as for beauty) for \$2.00; Untested Queens \$1.00 each, or \$9.00 per dozen. Orders solicited.

We Have some copies of the old edition of Cook's Manual left, which we will sell at the old price, \$1.25. The price of the new edition is \$1.50 per copy; a notice of which may be found on page 579.

Honey and Beeswax Market.

CHICAGO.

HONEY.—New crop arriving slowly, but demand is limited. White clover comb, 17@18c. Extracted, 7@9c.

BEESWAX.—22c. S. T. FISH & CO., 189 S. Water St. Sep. 12.

CHICAGO.

HONEY.—For white comb 1-lbs., 18c. Very little inquiry for anything outside of 1-lb., and when it is wanted it is at a lower price. Extracted the best grades, 7@8c., and some held higher. Offerings are small and demand slow.

BEESWAX.—22c. R. A. BURNETT, 161 South Water St. Sep. 12.

DENVER.

HONEY.—Colorado, new 1-lb. sections., 13@15c. Extracted, 7@8c.

BEESWAX.—20@3c. J. M. CLARK & CO., 1409 Fifteenth St. Sep. 7.

NEW YORK.

HONEY.—We quote: Fancy white 1-lbs., 15@17c.; 2-lbs., 14@16c. Fair white 1-lbs., 14@16c.; 2-lbs., 13 to 5c. Extracted, white, 7@8c.

BEESWAX.—23@3c. THURBER, WHYLAND & CO. Sep. 17.

NEW YORK.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 13@14c. Fair white 1-lbs., 15@16c.; 2-lbs., 12c. Buckwheat 1-lbs., 11@12c.; 2-lbs., 10@11c. White extracted, 7@8c.; buckwheat, 5@6c.; California extracted, white sage, 7@8c.; amber, 7@7½c. Demand good and prices firm. New comb honey is arriving quite freely.

BEESWAX.—23@2½c. HILDKRETH BROS. & SEGELKEN, 28 & 30 W. Broadway, near Duane St. Oct. 10.

SAN FRANCISCO.

HONEY.—White 1-lb. sections, 11@12½c.; 2-lbs., 12½@13c.; amber, 8@10c. Extracted, white, 5@6c.; light amber, 5@5½c.; amber and candied 4½@5c. Receipts light and market firm for best qualities.

BEESWAX.—Dull at 19½@22½c. O. B. SMITH & CO., 423 Front St. Sep. 22.

DETROIT.

HONEY.—Best white comb 17@18c.; dark, 16c.—Extracted, 8@10c. Market bare of all kinds.

BEESWAX.—21@22c. M. H. HUNT, Bell Branch, Mich. Sep. 24.

CINCINNATI.

HONEY.—We quote extracted at 4½@8c. per lb. Comb honey, 12@16c. Demand slow.

BEESWAX.—Demand is good—20@22c. per lb. for food to choice yellow, on arrival.

Sep. 18. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—Choice 1-lb. sections, 18c; dark 1-lbs., 14c.; 2-lbs., 13c.; dark, 13c. White extracted in 50-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock fair.

BEESWAX.—None in market. HAMLIN & BEARSS, 514 Walnut St. Sep. 27.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 17@18c.; 2-lbs., 14@15c. Fair 1-lbs., 14½@15½c.; 2-lbs., 1@12c. Extracted, fancy white clover, 7½@8c. California white in 60-lb. cans, 8c.; light amber in same cans, 7½c.; amber, 7½c. Buckwheat in kegs and barrels, 5½@6c. Cuban, in barrels and ½-barrels, 65c. per gallon.

Sep. 26. F. G. STROHMMEYER & CO., 122 Water St.

BOSTON.

HONEY.—We quote: Best white clover 1-pounds, 16@17c.; best 2-lbs., 15@16c. Extracted, 8c.

KANSAS CITY.

HONEY.—White 1-lbs., 17@18c.; dark, 14@15c.; California white 1-lbs., 17c.; dark, 14c. Extracted white 8c.; amber, 7c.

BEESWAX.—None in market. CLEMONS, CLOON & CO., cor 4th & Walnut. Oct. 11.

ST. LOUIS.

HONEY.—We quote: Extracted, 4½@5½c.; if in cans, 8@9c. White clover comb, 14@15c. Market is steady and receipts light.

BEESWAX.—21c. for prime. D. G. TUTT & CO., Commercial St. Sep. 6.

MILWAUKEE.

HONEY.—New white 1-lb. sections 18c., and very fine, 20c.; 1-lbs. 15@18c.; old 2 and 3 lbs., not salable, 1½@14c.; dark 1-lb., old or new, 12@13c. Extracted, new white in kegs and ½-barrels, 8@9c.; old, in same packages, 7@8c.; in tin, 8@9c.; dark in barrels or ½-barrels, 6@6½c. Arrivals of new crop small; demand not urgent, and only very moderate trade.

BEESWAX.—22@25c. A. V. BISHOP, 142 W. Water St. Aug. 31.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6 cents; light amber, 5½c.; amber, 5¼@5½c. Comb, 1-lbs. 13@14c.; 2-lbs., 10, 13c.

BEESWAX.—20@22c. SCHUCHT & LEMCKE, 122-124 Davis St. Sep. 24.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Simmins' Non-Swarming System.—We have a few of these books left, and we will club them with the AMERICAN BEE JOURNAL for one year, both postpaid, for \$1.25. The subscription to the BEE JOURNAL can be for next year, this year, or may begin anew at any time.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for \$1.50.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Convention Notices.

The Wabash County Bee-Keepers' Association will hold their fall meeting in the Court House at Wabash, Ind., on Oct. 20, 1888, at 10 a.m. All beekeepers are cordially invited to meet with us. HENRY CRIFE, Sec.

The Pac-Handle Bee-Keepers' Association will hold its next meeting in the K. of P. Hall on Main St., between 11th & 12th Streets, in Wheeling, W. Va., on Nov. 21 and 22, 1888. All beekeepers are cordially invited. W. L. KINSEY, Sec.

The Alabama State Bee-Keepers' Association will meet at 10 a.m. on Wednesday, Nov. 14, 1888, at the office of the Secretary of the State Fair (in the Fair Building), in Montgomery, Ala. Members are urged to attend, and all persons interested in bees and honey are cordially invited. J. M. JENKINS, Sec.

Advertisements.

The American Apiculturist

Will be mailed from Oct. 1, 1888, to Jan. 1, 1890, for 75 cents. The "Bee-Keeper's Handy-Book" will be re-written the coming year, and all will be published in THE APICULTURIST during the year 1889. The first article will be presented in the Nov., 1888, issue.

Our method for rearing QUEENS in full colonies will be published in pamphlet form, and a copy given to each subscriber. Address,

AMERICAN APICULTURIST,
4241t WENHAM, Essex Co., MASS.

Dadants' Foundation Factory, wholesale and retail. See advertisement in another column.

WANTED,

Beeswax.—We will pay 20 cents per pound, delivered here, for Yellow Beeswax. To avoid mistakes, the name of the shipper should always be on each package.

THOS. G. NEWMAN & SON,
923 & 925 West Madison St., CHICAGO, ILL.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. Oct. 24, 1888. No. 43.

EDITORIAL BUZZINGS.

There's always a River to cross,
Always an effort to make,
If there's anything good to win,
Any rich prize to take;
Yonder's the fruit we crave,
Yonder the charming scene;
But deep and wide, with a troubled tide,
Is the river that lies between.

What a Woman Can Do.—Mrs. J. N. Heater, of Columbus, Nebr., is one of the best-known exhibitors of Honey and Bee-Supplies in America. Speaking of her exhibit at the State Fair at Lincoln, the *Columbus Journal* remarks thus: "Aside from its newspapers, mills and banks, there is probably no single business represented in Columbus that better advertises the city than the business transacted by Mrs. J. N. Heater." And of her attractive exhibit at the State Fair, the *Lincoln Journal* says:

Each succeeding year the apiary department finds Mrs. Heater, of Columbus, present with a large showing of comb and extracted honey, wax, implements, and beekeepers' supplies.

The exhibit is in the form of a large pyramid of jars of honey arranged around an ornamented velvet back-ground, bearing the name and residence of the exhibitor.

This exhibit shows to advantage what well-directed intelligent study and years of experience can do in this direction, and all who visit the State Fair should not fail to visit Apiary Hall and inspect this exhibition.

Good exhibits of bees, honey and beeswax at Fairs, will do more to educate the people, and help the sale of honey than anything else. The apiarian exhibit at Columbus, Ohio, Centennial was a greater attraction than almost any other display. Realizing this fact, the managers of the Fair put up a building especially for it this year, and it pays well.

A Friend of the Bees.—The Washington, D. C., *Star* of Oct. 8, 1888, contains the following announcement:

Mr. J. P. Miller visited the Agricultural Department to-day to secure the co-operation of the Commissioner of Agriculture in obtaining legislation to protect the public and the bee-keepers against spurious honey. As credentials, Mr. Miller brought an interesting colony of Italian bees with him in a case, and placed them on exhibition in the Museum "Zoo."

Mr. Miller stated to a *Star* reporter that what the bee-keepers want is a law similar to the oleomargarine law, requiring manufacturers of artificial honey to stamp their wares, so that the public will not be deceived in purchasing it. The artificial honey, he said, is composed of three-fourths of glucose and one-fourth of real honey. This, he said, was not injurious, but he did not think it ought to be sold as real honey. The bee-keepers, he said, did not fear the competition of the artificial product. What they did fear was that the adulterated article would make people suspicious of all honey.

The reporter for the *Star* confounds the terms "artificial" and adulterated—the stuff he describes as one-fourth of honey and three-fourths glucose is the ordinary adulterated article, and it should not be allowed to be sold without being labeled "glucose honey," as suggested by Mr. Miller.

But now, when liquid honey is sold for about the same price as the best grade of glucose, there is but little danger of any one taking the trouble to adulterate it, when it will not pay them handsomely to do so. Those who sophisticate, do so for profit, not for the fun of doing so.

The pursuit of bee-keeping is to-day suffering far more from the effects of the lying done by Wiley, Evans & Co., than it is from adulteration. These fellows adulterate the truth and lie about the product; and in that way cause public distrust, and suspicions concerning all the honey produced—whether in or out of the comb!

Arkadelphia Bee-Suit.—Concerning this lawsuit the Bee-Keepers' *Guide* has the following letter from the present Mayor of the city of Arkadelphia, dated Sept. 28, 1888, which brands the whole thing as a "persecution," and says that it was "more personal malice than anything else:"

DEAR SIR:—In reply to yours of the 25th inst., and referring to the Z. A. Clark beehive, I would state that the case came up for trial at the last term of the Circuit Court. The attorney for Mr. Clark waived a jury trial, but submitted the case to the Judge on certain points of law questioning the right of the city authorities to declare bees as a nuisance, *per se*. Judge Hearn, of our Circuit Court, took the matter under advisement, and on the following week rendered his decision in favor of Mr. Clark.

The city attorney has taken an appeal to the Supreme Court of the State, which, I think, will affirm the decision of the Circuit Court, as Judge Hearn supported all the points of law offered by the Hon. Sam Williams, who is Mr. Clark's attorney (or rather represented the Bee-Keepers' Union in this case), and was determined that he would give an opinion that would hold.

My sympathies had been with Mr. Clark, and I was one of his bondsmen on the ap-

peal. His persecution was the work of my predecessor in office, and I thought it more personal malice than anything else.

I state this to free myself from any odium attachable to this case. Mr. Clark's friends used my name and elected me as Mayor as a rebuke to the party that persecuted him.

Yours truly,

L. J. WENER.

We are expecting to hear the result of the appeal every day, and shall give it to our readers at the earliest possible moment. In the above letter Mayor Weber says he thinks the Supreme Court "will affirm the decision of the Circuit Court," and declare that the pursuit of bee-keeping is **no nuisance**.

English Artificial Honey.—One of our exchanges, while enumerating a number of artificial things, says that a man by the name of Lyle has taken out a patent in England (Patent No. 8,863) for making "artificial honey." This is what he says about it:

C. Lyle patented a mixture of grape sugar, fruit sugar and glucose (dextrose, levulose and glucose), with the addition of fruit essences, and thinks this compound is equal to any natural honey.

It certainly is not less palatable than the honey analyzed at the controlling station at Berlin, Germany, which had been imported from Holland, and was found to be made up of glucose and oleomargarine.

The proof of the letter is found in Mittheil, a. d. Chem. Tech. Versuchsanstalt in Berlin, 1886, page 14. The proof of the former can be found in the English Patent Office files for 1885.

While we have no desire to injure the feelings of our English brethren, or make an offset for the "fun" they have been "poking" at Americans about "adulterating bee-farms" in this country (which, however, exist only in imagination) we would like to have them look this matter up, and tell us what there is in it. We especially commend it to the consideration of our friends and co-laborers, Mr. Thomas W. Cwman, editor of the *British Bee Journal*, and Herr Vogel, editor of the *Bienen Zeitung*. Let us hear from these gentlemen about these dextrose-levulose-glucose-oleomargarine combinations! Are they any more tangible than the adulterating bee-farms? Let the light shine upon them!!

Commenting upon an item on page 595, on the best place to keep comb honey, Mr. H. M. Moyer, of Hill Church, Pa., says: "Ventilation is as important as heat. If I put comb honey in a close room, with temperature at 80° to 85°, and no ventilation, it will sweat; but if I give it plenty of air, it will be all right." The "point is well taken"—let it be ventilated.

The Pamphlet Report of the Columbus Convention is now issued, and copies have been sent to each member, as well as to the Colleges, Agricultural and Horticultural Societies and periodicals devoted to the industry. Copies can be obtained at this office, by mail, postpaid, for 25 cents. This pamphlet contains the new bee-songs and words, as well as a portrait of the President of the Association.

GLEAMS OF NEWS.

Paris World's Fair.—It has been previously announced in these columns that Prof. N. W. McLain has been entrusted by the Department of Agriculture with the work of preparing and forwarding to Paris an exhibit of apiarian products and supplies, as well as methods and machinery employed in the pursuit of bee-keeping. Some are inquiring for the particulars concerning this great enterprise, and we will here quote from the *New York Mail and Express* the following:

The Universal Exposition of 1889, at Paris, promises to be one of the largest and most successful of the world's fairs held in recent years. Elaborate arrangements for the reception and display of the exhibits are well under way, and unusual facilities both for the transportation of goods from this country and their care are assured.

The French government extended a formal invitation to the United States to take part in the Exposition. The invitation was accepted by a joint resolution of the Senate and House of Representatives, and the governors of the several States and Territories were requested to invite the people to assist in the proper representation of the products of American industry, and of the natural resources of the country.

The President was directed to appoint a commissioner-general and an assistant commissioner-general, to make all of the arrangements for exhibits, and represent the government at the Exposition. He was also directed to appoint nine scientific experts as assistants to the commission, each to be assigned to one of the nine groups into which the exhibits will be divided.

Provision was made for the salaries of the commissioners and the necessary assistants, and the sum of \$250,000 was appropriated to be used under the direction of the Secretary of State to defray all expenses. The action of Congress was approved May 10, and the President has appointed General William B. Franklin, Commissioner-General, and Mr. Somerville P. Tuck, Assistant Commissioner-General.

The Exposition will open May 5, and close Oct. 31, 1889, and there will be no charge for space occupied by exhibitors. The commission will forward and return all articles received, free of freight charges.

Goods of exhibitors who are unable to go to Paris, or send representatives, will be cared for free of all expense, except that of unpacking and repacking. There will be no duties to pay except on goods that are sold or consumed.

The exhibition is to be divided into nine groups or departments, as follows:

1. Works of art.
2. Education, and processes used therein.
3. Plain and decorative house furniture.
4. Textile fabrics.
5. The raw and manufactured products of mining, forestry, chemistry, etc.
6. Apparatus and methods of mechanical industries.
7. Food products.
8. Agriculture, vine culture and fish culture.
9. Horticulture.

The French government has appropriated 43,000,000 francs toward the expenses of the Exposition.

The buildings for the exposition are now nearly completed. They occupy the Champ-de-Mars and the Trocadero Palace and Park on the banks of the Seine. In the Park at

the entrance to the exhibition on the Champ-de-Mars the wonderful Eiffel Tower is now in course of erection. It is to be entirely of iron, and 1,000 feet in height. Its object is to show the triumph of modern engineering skill. It will be furnished with an elevator of American manufacture.

On the right of the tower is the Palace of Liberal Arts, and on the left the fine Palace of Fine Arts. Large gardens occupy the centre of the square, and at the back is the main building, or the gallery of machines, as it is called. The buildings are magnificent structures of glass and iron, lighted by electricity, and fitted with every modern convenience.

It is expected that the total number of exhibitors from all countries will reach 30,000; it is estimated that 12,000,000 persons will enter the grounds and buildings. Some idea of the magnitude of the exhibition may be gained from the fact that the total area of buildings and enclosed grounds, which is to be lighted by electricity, is 3,000,000 square feet. The space allotted to the United States is about 75,000 square feet. W. B. Franklin is the United States Commissioner-General, and the office of the United States Commission to the Paris Exposition of 1889, is at 35 Wall Street, New York City, N. Y.

Unfavorable Weather for the Queens.—Henry Alley, Wenham, Mass., on Oct. 8, 1888, writes as follows about the unfavorable fall weather in the East:

This has been the worst fall I ever knew for the queen business. I have lost more than 200 queens, for the reason that they could not take a flight to mate. There have been but three favorable days since Aug. 25, for queens to fly—cold, cloudy and rainy all the time. I have had to purchase 600 pounds of sugar to feed to bees for winter. Had the weather been as good as it generally is in September, I would have had honey to sell from the fall crop. As it is, I had to buy sugar. Golden-rod never was more abundant.

A Race Between Pigeons and Bees.—Prof. J. P. Miller, who is exhibiting bees at the Casino Museum at Pittsburg, Pa., sends us the following item from the *Pittsburg Press* of Sept. 22, 1888, which we give for what it is worth:

The oddest race I ever heard of was one lately flown in northern Germany between bees and pigeons, says a correspondent in the *London Illustrated Sporting and Dramatic News*. Twelve pigeons and 12 bees (4 drones and 8 working bees) were taken an hour's distance from their home at Hamm and freed simultaneously. My informant tells me that a drone won the race, arriving four seconds in advance of the pigeon, the three other drones and a second pigeon came next together, and the eight working bees preceded the remaining ten pigeons by a length, I am told, but what sort of a length I do not know. If a bee beat a pigeon a length—that is to say, by a bee's length—it would be a very precise judge who did not give the result a dead heat. I should certainly have supposed that a bee would not have had a 1,000 to 1 chance with a pigeon, but I confess that I have no idea of the bee's best record for an hour's flight.

Do Not Ship Honey to Us without first corresponding with us about it. We have received several undesirable lots without previous notice, or correspondence of any kind.

Fall Honey for Winter Stores.—

The Orange Judd *Farmer* for Oct. 6, contains the following very characteristic article on the above subject, and the joy experienced by bee-keepers over the crop of fall honey secured. It says:

Bee-keepers are smiling, yes, almost laughing, and with good reason, because after the failure of the first and second flow of honey, and while bee-keepers were in their last days of grace, the bees have filled their hives full, even to overflowing. No feeding had to be done to keep the bees from starving during the winter. Such is the experience of Mrs. L. Harrison, the Queen bee of Peoria, Ills., as given the O. J. *Farmer*. She continues: There is one consolation to be derived from the poor season, and that is this, that bees usually pass the following winter in safety. Queens have had plenty of room to deposit eggs, and young bees crowd the hives. They are full of vitality, and will keep the poor old bees warm, and well they may, for the old ones have worn their wings, until they are all ragged and torn, in carrying home supplies to rear the young, and for food in winter.

Those who have been fortunate enough to secure honey for sale, should demand a good price for it, as there is very little to be had in this country or England. I know of but one apiary in Illinois where white honey was secured, and that is located in the river bottom, and the honey was gathered from button-bush, which grows in the water; so it was not injured by two previous years of drouth.

Frank Leslie's Sunday Magazine for November continues the beautiful story, "Genevieve; or, The Children of Port Royal," and in addition provides a charming Thanksgiving story, by Fannie Aymar Matthews, entitled, "A Leaf from the Log of the *Nautic*." There is also a story, "A Charm of Halloween," by Mrs. Alexander. "The Story of Zenana Missions" is well told by Emma Raymond Pitman. The pictorial features of the number are as abundant as ever, and some of the pictures are very beautiful. The last page is occupied with an exquisite composition by C. Wenham Smith, organist of Plymouth Church, Brooklyn, to Faber's hymn, "Pilgrims of the Night."

Can You Do Anything that will do more to advance and defend the pursuit of bee-keeping, than to aid its Weekly Exponent and Defender? The AMERICAN BEE JOURNAL is the pioneer bee-paper of America, and is fully entitled to the active support of every progressive apiarist, for it works constantly and faithfully for the best interests of the pursuit. We therefore specially request all our readers to use their influence to double our subscription list during the coming autumn. Reader, will you please send us a new subscription with your renewal or before that time? A good weekly at one dollar a year is surely cheap enough to command patronage.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for \$1.50.

Reunion Song.—Through the kindness of Mr. A. I. Root, in loaning us the plate for this Song, which was composed for the Columbus Convention, we are enabled to present the words and music to our readers. The words are expressive, the air is pleasant, and the whole melodious. Thousands will learn to sing it, and it will be heard at nearly all the conventions hereafter.

EUGENE SECOR. **BEE KEEPER'S REUNION SONG.** C. C. MILLER.

1. The la - hors of sum - mer are end - ed, Its triumphs and fail - ures are past, The
 2. We think of the mer - cies un - numbered, Vouchsafed by our Father a - bove, Whose

INTERNATIONAL.

Report of the North American Bee-Keepers' Convention.

Written for the American Bee Journal

BY W. Z. HUTCHINSON.

SECOND DAY.

AFTERNOON SESSION.

President Mason called the meeting to order at 2 p. m., and the next business in order was the

Election of Officers.

Considerable time was spent in balloting, and the results were as follows:

PRESIDENT—Dr. A. B. Mason, Auburndale, O.
 VICE-PRESIDENTS—Thos. G. Newman, Chicago, Ill.
 Prof. G. W. Webster, Lake Helen, Fla.
 Joseph Nysewander, Des Moines, Iowa.
 R. L. Taylor, Lapeer, Mich.
 O. L. Hershiser, Jamestown, N. Y.
 Martin Emigh, Holbrook, Ont.
 Frank A. Eaton, Bluffton, Ohio.
 F. Minnick, Bessemer, Wis.

SECRETARY—R. F. Holtermann, Brantford, Ont.

TREASURER—Dr. C. C. Miller, Marengo, Ills.

After the election of officers, the topic announced for discussion was,

Comb Honey—Swarming, etc.

Dr. Miller was called upon, but said that he did not know as he could give anything new upon the subject. Some one asked him if he could tell how to prevent swarming. He replied: "No; I do not know how to prevent swarming. I can prevent increase, but not swarming. Who knows how to prevent swarming?" No answer.

Dr. Besse asked him how he liked contracting the brood-nest.

Dr. Miller—I practiced contraction of the brood-nest—practiced it quite severely, too, at times, but I am not sure that I prefer it. I may yet go back to having the same number of hives in the apiary all the year around.

Dr. Tinker—If we have the brood-chamber too large, it becomes, to a certain extent, a store-chamber. There is more economy and comfort in having the brood in one apartment, and the honey in another. When the first swarm issues I hive it upon the old stand, putting the old hive to one side. As soon as I have time to attend to it, the bees are shaken from the combs of the old colony down in front of the newly-hived swarm. The combs thus deprived of bees are placed over some other colony. By this management there is no increase, and rousing

swarms are secured. As the bees hatch out, the cells are filled with honey. A queen-excluding honey-board must be used under the set of combs placed over another colony. When a queen-excluder is used, the bees will not destroy the queen-cells.

In reply to an inquiry, Dr. Tinker said that in hiving swarms he filled frames half full of foundation.

An Acknowledgement from Mr. Cowan.

President Mason reported that Mr. Cowan, upon receipt of the letter informing him of his election as an honorary member, had replied, thanking the Society most cordially through him as its President.

Honey-Dew for Winter-Stores.

In reply to an inquiry as to whether we should use honey-dew for winter stores, Prof. Cook replied that, if it were palatable to the taste, he should consider it safe. He objected most strongly to the use of the term "bug-juice," as applied to honey-dew. Such terms give an unpleasant impression that is prejudicial. He urged all editors to cut out the term whenever it be found in correspondence.

Mr. Thomas G. Newman, by request, gave the following address concerning the work undertaken by the

National Bee-Keepers' Union.

MR. PRESIDENT:—It is a well-known fact—one firmly established in the minds of all, that "in Union there is strength." Of course we cannot approve of any Union to carry out an illegitimate or unlawful work; but a Union to defend our pursuit from the unjust attacks of ignorant or prejudiced persons, is not only desirable, but very necessary to our well-being and general prosperity.

Look for a moment at the object and aim of the Union of the Atlantic States a century ago, and see how the grand design has been carried out even to a grander achievement. See the millions of freemen of to-day, who inhabit this "land of the free and home of the brave," gathered from every land and clime, who are enjoying the blessings of "peace and plenty," entirely free from oppression or tyranny, and increasing in wealth and power—all resulting from a bond of union only a hundred years old.

Then these sparsely inhabited States—thirteen in number—were weak and almost powerless. The Union has made them strong and powerful—it has developed strength! A strength which says to all—both friend and foe—"Hands off;" we are able to defend ourselves, and take care of our rights!"

For this cause, and for this purpose, does the National Bee-Keepers' Union exist! To form a "bond of Union"—to throw a safe-guard around the pursuit as well as its devotees. It does not seek a quarrel, but when one is forced upon any of its members, it sets up a "Rock of Defense" by its very existence and glorious record. *Never yet* has it suffered a defeat in all the trials it has defended before the courts! That, surely, is a record to be proud over—but it is more than that. It is a *warning* to ignorant and jealous enemies to beware how they trifle with the pursuit of apiculture, and to keep their *hands off* the interests of its devotees. It warns them that the bee-keepers, as well as the bees, have a sting, with which to torture their enemies!

The Union not only seeks to obtain decisions from the highest courts of America, but also to have on record these decisions to be quoted as precedents in all the courts of law, and by all the lawyers who practice therein. In the case lately tried in New York, the Judge stated that there were no precedents to guide the decision, and hence he ruled adversely to the bees, as did one in Canada, likening an apiary to a pig-sty, or a manure pit.

Now we are beginning to make history—to record decisions—to provide precedents! When "ignorance" assails the bees, and charges them with eating up the clover (as they did in the sheep-bees case), the records and courts decide that the bees are not only innocent of the charge, but that they benefit the pastures by fructifying the flowers, and thus *increase* the product!

When "prejudice" comes into court with the charge that the bees injure the fruit, the decisions say, *No!* Birds and wasps are the depredators, the bees have no means of opening the skin of grape or peach. They only take what is running to waste after the fruit is punctured by bird or wasp!

When "jealousy" throws a charge into court against the bees, saying that they are a *nuisance* and must be removed, the Judge says, *No.* It has been decided that bee-keeping *per se* is not a nuisance—they may remain!

When "ignorance" complains that the bees "eat up young ducks," as it did at Arkadelphia, common-sense replies most emphatically that the charge is *madness*, and derides the accuser, sarcastically averring that it may as well be charged with eating elephants, or destroying the mountains!

What the Union has done is a guarantee for the future. It may not always triumph over prejudice and envy and ignorance, but it will defend the pursuit, and uphold the right. It

is for bee-keepers to say whether it deserves both their moral and financial support or not. If it does, they should render both in unstinted measure. It is to the interest of all to do so, and the interest of all is the interest of every individual engaged in the pursuit of bee-culture.

As the Union has made the speaker *its servant* (without salary or emoluments), he may speak thus plainly, for he will never require or take any assistance from the Union, except that assistance which comes to every devotee of the pursuit in a general way, by its influence in favor of justice and right!

The Union is yours—support it.

THOMAS G. NEWMAN.

The following resolution was passed by a unanimous vote:

Resolved, That it is the sense of this Society that the National Bee-Keepers' Union has been productive of good, and deserves the hearty, moral and financial support of all bee-keepers, and that the General Manager deserves and receives the hearty gratitude of this Association for his very earnest, efficient and disinterested services.

The convention then adjourned until 7 p.m.

EVENING SESSION.

President Mason had no more than called the meeting to order before he pulled Mr. Root "over the coals" for careless proof-reading. Mr. Root had allowed the words "manufactured stock" to appear in his market quotations. For once the joke, and it was a serious one, too, was on Mr. Root, and everybody had something to say; the talking and laughing over this mishap proved so interesting that considerable time slipped by unheeded. Finally attention was turned to the consideration of the proposed

Constitution and By-Laws for the Society.

This was prepared last year by Mr. Thomas G. Newman, and referred to a committee to report at this meeting.

The committee reported the matter back to the convention without recommendation. Then, with but a very little discussion or consideration, it was voted to adopt the new Constitution and By-Laws, and the North American Bee-Keepers' Society will hereafter be known as the

International American Bee-Association,

with the following Constitution and By-Laws:

ARTICLE I.—*Name*.

This organization shall be known as "The International American Bee-

Association," and shall include in its territory all of the United States and Canada.

ARTICLE II.—*Object*.

Its object shall be to promote the general interests of the pursuit of bee-culture throughout the North American Continent; to form a fraternal bond of union for the instruction and protection of its members; to diffuse a general knowledge of the value and uses of honey both for food and medicine; to create a market for this God-given sweet, and to assist in its distribution evenly over the American Continent—and thereby enhancing its commercial value.

ARTICLE III.—*Membership*.

1. This Association shall consist of its officers, life members, annual members, honorary members, delegates from affiliated local associations, and ex-presidents.

2. Any person interested in Apiculture may become a Life Member, upon the payment to the Secretary of the sum of ten dollars, and receiving a majority vote at any annual meeting of this Association.

3. Any person interested in Apiculture may become an Annual Member upon the payment to the Secretary of one dollar, and receiving a majority vote, at any annual meeting. Ladies interested in apiculture may be admitted free upon a majority vote.

4. Annual Members shall be entitled to vote, hold office, and discuss any question before the Association, subject to the By-Laws of the Association.

5. Any persons interested in bee-culture may become Honorary Members by a majority vote at any regular meeting.

6. Delegates from affiliated local Associations shall be admitted free, and have all the rights of annual members.

ARTICLE IV.—*Officers*.

1. The officers of this Association shall consist of a President, First Vice-President, Secretary and Treasurer, and their term of office shall be one year, or until their successors shall be elected and installed. These officers shall constitute the executive committee.

2. The Presidents of all the Local Associations, in affiliation with the International Association, shall be *ex-officio* Vice-Presidents of this Association.

ARTICLE V.—*Affiliation*.

Any State, District, Territory or Province in North America may become affiliated to the "International

American Bee-Association" upon the annual payment of five dollars, which shall be due on the first day of January in each year.

ARTICLE VI.—*Meetings*.

The Annual Convention of this Association shall be held at such time and place as shall be agreed upon at the previous Annual Convention. Ten members shall constitute a quorum for the transaction of business, but a less number may engage in discussion, and adjourn until some future day.

ARTICLE VII.—*Special Meetings*.

Special Meetings may be called by the President, Secretary, and Treasurer, who shall constitute the executive committee.

ARTICLE VIII.—*Vacancies in Office*.

Vacancies in office by death, resignation, or otherwise, shall be filled by the President until the next annual meeting.

ARTICLE IX.—*Amendments*.

This Constitution may be amended at any Annual Convention, by a two-thirds vote of all the members in attendance.

BY-LAWS.

ARTICLE I.—The officers of this Association shall be elected by a majority ballot; or, if so decided, by a vote of two-thirds of those present, the officers may be elected by a show of hands.

ART. II.—It shall be the duty of the President to call and preserve order in all meetings of the Association; to call for all reports of officers and standing committees; to put to vote all motions regularly seconded; to decide all questions of order according to the Constitution and By-Laws of the Association, and in accordance with Parliamentary usage; to provide for counting the votes at all elections; and at the expiration of his term of office, to deliver an address before the Association.

ART. III.—It shall be the duty of the First Vice-President (or in his absence one of the other Vice-Presidents), in the absence of the President, to perform the duties of that office.

ART. IV.—It shall be the duty of the Secretary to call the names of the members of the Association at the opening of each annual meeting, and to receive the annual dues; to report all proceedings of the Association, and record the same, when approved, in the Secretary's book; to conduct all correspondence of the Association, and to file and preserve all papers belonging to the same; to take and record the name and address of every person who becomes a member of the Association,

and transfer the moneys received for dues to the Treasurer, after taking his receipt for the same; to make out and publish annually, as far as practicable, a statistical table showing the number of colonies owned in the spring and fall, and the amount of honey and wax produced (together with such other information as may be deemed beneficial) by each member of the Association; and to give notice of all meetings of the Association in all the newspapers, at least four weeks before the time of such meeting.

ART. V.—It shall be the duty of the Treasurer to receive from the Secretary the funds of the Association, and give a receipt for the same; to pay them out upon the order of the executive committee, and to render a written report of all receipts and expenditures of the Association at each Annual Convention.

ART. VI.—The Secretary shall have power to choose an Assistant-Secretary if deemed necessary.

ART. VII.—The Association shall be mainly governed by the following order of business:

Call to Order.

Calling the Roll of Officers and Members.

Reading the Minutes of the Annual, and Special Meetings, if any.

Reception of New Members and the Collection of Annual Dues.

Secretary's Report.

Treasurer's Report.

Report of Standing Committees.

Reports from Affiliated Societies.

President's Address.

Election of Officers.

Selection of the Time and Place for holding the next Convention.

Miscellaneous Business.

Discussion of Apicultural Topics.

Installation of Officers.

Adjournment.

ART. VIII.—1. A committee of five may be elected, who shall have power to organize itself into a "Honey Company," and its duties shall be to inaugurate plans for the marketing and sale of the products of the apiary. Every member of the International American Bee-Association, and its affiliated branches, shall be entitled to the benefits of the Honey Company, subject to the terms of its By-Laws.

2. This Honey Company shall make Annual Reports of the state of the market, amount of business done, and of its financial condition, to the Annual Convention of the International American Bee-Association.

ART. IX.—1. The Secretary of each local Affiliated Society shall, through its Secretary or President, on the first day of August in each year, report to the Secretary of the International American Bee-Association, the number

of its members, stating the aggregate number of colonies of bees in their apiaries in the previous fall, the number in the spring, the increase since, and the approximate number of pounds of honey produced (stating comb and extracted separately), and any other desirable information concerning the probable honey-production of those not members of the Society, but within the territory of the affiliated local association.

2. If the annual Affiliation Fee be not promptly paid, and the Local Report withheld, the "International American Bee-Association" may at any time within one month of the dates mentioned, withdraw the privileges of affiliation, which comprise the following:

(1.) The President of each Affiliated Society is *ex-officio* a Vice-President of the International American Bee-Association.

(2.) It shall be entitled to receive from the International Bee-Association two Silver Medals, to be offered as Prizes for Honey, open for competition to all its members, one for the best in the comb, and the other for the best out of the comb.

(3.) The members of all the Affiliated Societies shall be entitled to the facilities which may be provided from time to time by the Honey Company, for the sale of Honey and Beeswax, upon the terms stated in the By-Laws of the Company.

(4.) Each Affiliated Society shall be entitled to the services of a Judge to award premiums at its Bee and Honey Show, upon the payment of his actual railroad and hotel expenses.

(5.) Each Affiliated Society shall be entitled to elect one Delegate to each 25 of its members, or fraction thereof, who may represent it at the Annual Convention of the International American Bee-Association—all expenses of such Delegates to be borne by themselves or the local society, or both conjointly, as they may provide. Such Delegates shall be entitled to vote, hold office, and take part in all the deliberations of the International Bee-Association.

ART. X.—A Defense Committee of seven shall be appointed for the purpose of considering the applications of members for Defense from unjust lawsuits by those who are prejudiced against the pursuit. This committee shall be the officers annually elected by the National Bee-Keepers' Union, which is hereby declared to be affiliated to the International American Bee-Association. Its President is hereby made a Vice-President of this Association, and its General Manager also a delegate to the International Convention.

ART. XI.—An Expert Committee of three shall be annually elected and fully empowered to prepare Examination Blanks, and make all necessary arrangements for the examination of candidates for Diplomas as Experts in the art of bee-keeping. This committee shall be empowered in the name of this Association, to award Diplomas of three grades upon candidates, according to their proficiency in the art of bee-keeping, and the management of an apiary.

ART. XII.—1. The Executive Committee of this Association shall cause the Constitution and By-Laws to be printed in appropriate form, and every person joining the Association shall be entitled to a copy of the same.

2. It shall also select subjects for discussion, and appoint members to deliver addresses or read essays, and the same shall be published with the call for the next Annual Meeting.

3. It shall also provide free Badges for all members, and procure Medals for the Honey Shows of Affiliated Associations, and Diplomas for experts.

4. The Executive Committee shall also provide a place of meeting for the Annual Convention, and see that all necessary arrangements are made to carry out the demands of the Constitution and By-Laws.

ART. XIII.—No member shall be entitled to the floor more than five minutes in the discussion of any motion, resolution or petition, without obtaining the consent of the Association, nor a second time, unless by the consent of the President, or a majority of the members present.

ART. XIV.—All Committees shall be elected by ballot, by a plurality vote, except by special resolution.

ART. XV.—These By-Laws may be amended by a two-thirds vote of all the members present at any annual meeting of the Association.

The next and last topic discussed was,

The Wintering of Bees.

Dr. Miller—Most of the points have been touched upon. The bees must have good food, must be brought into the cellar early in the fall; the temperature kept at from 40° to 45°; not to be taken out too soon. I believe this covers most of the ground.

Dr. Tinker—In the early part of the winter I think that a temperature of 41° is better than 45° for the cellar. If anything breaks up the hibernation, and sets the bees to eating, it is injurious; and it makes no difference, so far as results are concerned, whether they eat honey or pollen. After February the temperature should be higher.

Vice-President R. F. Holtermann, of Brantford, gave this report for Ontario :

The past winter was passed fairly well by the bees. Spring dwindling was excessive, owing to severe weather. The clover yield was a total failure in most localities, linden the same, and at its close showers and warm weather gave us some thistle honey in buckwheat localities; the fall flow was fairly good. On an average not sufficient honey has been secured for winter, yet colonies are otherwise in good condition. Whilst the average is so low, we hear of isolated cases where a yield of 30 to 40 and even 60 pounds per colony has been obtained; and, on the other hand, colonies had to be fed in the height of the honey season.

Increase has been but slight, and all colonies remaining should be carefully preserved and cared for. There has been practically no comb honey taken, and the extracted honey will be off the market before the end of the present month.

R. F. HOLTERMANN.

BRANTFORD, Ont., Oct. 1, 1888.

It was voted that Thomas G. Newman & Son publish in pamphlet form the report of the proceedings, and mail copies to each member of the Association, and that they be paid \$20 for the work.

It was also voted that the Secretary be paid the balance (\$7) in the treasury for his services.

The following resolution was passed by a unanimous vote :

Resolved, That we extend our thanks to the Hon. Fred Blenkner, Third Assistant Sergeant-at-Arms of the House of Representatives, and through him to the House of Representatives, for the free use of the Hall of the House for holding this convention.

The convention then adjourned to meet in social intercourse during the next day, at the Bee and Honey Hall on the Centennial Grounds; and the next meeting will be held at the call of the executive committee, at Brantford, Ont.

W. Z. HUTCHINSON, Sec.

Convention Notices.

☞ The Pan-Handle Bee-Keepers' Association will hold its next meeting in the K. of P. Hall on Main St., between 11th & 12th Streets, in Wheeling, W. Va., on Nov. 21 and 22, 1888. All bee-keepers are cordially invited.

W. L. KINSEY, Sec.

☞ The next regular meeting of the Stark Co. Bee-Keepers' Society will be held in Grange Hall at Canton, Ohio, on Saturday, Nov. 3, 1888, at 10 a.m. Matters of importance to bee-culture will be discussed. Every bee-keeper is requested to be there.

MARK THOMSON, Sec.

☞ The Alabama State Bee-Keepers' Association will meet at 10 a.m. on Wednesday, Nov. 14, 1888, at the office of the Secretary of the State Fair (in the Fair Building), in Montgomery, Ala. Members are urged to attend, and all persons interested in bees and honey are cordially invited.

J. M. JENKINS, Sec.

CORRESPONDENCE.

REPORT FOR 1888.

Results in the Apiary for the Past Season.

Written for the American Bee Journal

BY G. M. DOOLITTLE.

My bees wintered fairly well during the winter of 1887-88, my loss being only 3 colonies out of 60—two dying out of those wintered out-doors, and one out of those wintered in the cellar. The winter was very severe, and there was only one day warm enough for the bees to fly between Nov. 1, 1887, and April 26, 1888, that being on March 27. Had that day in March not occurred, my loss would have been very heavy among those wintered on the summer stands, for previous to this they were getting very uneasy.

Those from the cellar which were put out on April 27 and 28, were very quiet, and could apparently have endured another month of confinement, without serious results. With April 26 came extremely warm weather for the time of year, the mercury standing near the nineties for three or four days in succession.

About the middle of May it came off cold, so that frost and snow were the order of the day for nearly two weeks, and as this bad weather came before any brood to any extent had hatched in those put out from the cellar, these colonies "spring dwindled" to an extent greater than was ever known to me. In front of some of the colonies the alighting-board and ground were covered with dead bees, the most of which were those that had come through the winter; while the bottom-boards to the hives were covered with young bees which did not seem to have vitality enough to exist without their older sisters. From this source I lost two other colonies, while several more were so materially weakened that they were good for little else save using for nuclei later on in the season. Others no better in any way before the freezing weather than were those which dwindled, held right on during the same time, scarcely losing a bee, and came out splendid colonies.

Here, again, I am out at open sea, for the experience of the past spring has taken all of the conceit out of me, and I candidly confess that I do not know what causes "spring dwindling;" for all that dwindled, and those which did not dwindle, were wintered exactly alike, and were as near "alike as two peas," as far as I could see. Not a colony of those wintered out-doors

seemed to suffer a bit from the effect of this disease, if disease it be.

The hard maple gave the bees plenty of pollen, and the willows furnished considerable honey, so that brood-rearing went on fairly well the latter part of May. Apple trees blossomed on June 1, but owing to cold weather, which now came again, no honey was obtained from this source. On the nights of June 1, 2, 3 and 6, ice formed on the tin roofs of the bee-hive covers, so as to stand up like brass buttons, and again brood-rearing came to a stand still, and all colonies which had drones hatched, killed them off, unless the hive was well stocked with honey.

Clover opened about June 20, but with the exception of the Alsike variety, it did not yield any honey, and as but little of that variety is grown here, nothing more than a living was obtained from that source. Locust gave a little honey also, while some was obtained from sumach, but from none of these sources did the bees get enough to commence work in the sections, except a few of the strongest ones.

Very few swarms issued, only about one third of the colonies casting swarms, which was the lightest swarming I ever knew. Basswood opened on July 8, but the bees did not seem to get more than a living till July 13, when the honey began to come in quite lively. The yield of honey was fairly good from that date for nearly two weeks, when it drew to a close, gradually, the bees following the bloom to the tops of the hills five to seven miles away.

Teasel yielded very little honey this year, although now and then a bee would be seen coming in, covered with teasel dust, all through the basswood yield. As usual buckwheat gave no surplus honey, and as this plant has failed to yield any honey for so long a time, I have got through counting on it for any surplus.

By sales of bees and queens my stock was reduced to just 17 queens of the original number with which I went into winter quarters, and as I used all of the colonies from which I took queens to form my numerous queen-rearing colonies, 17 colonies and the few increase from them was all I worked for comb honey.

The result in honey from the 17 colonies in the spring, is 1,233 pounds, all of which is comb honey, as I have not extracted a pound of honey this season. This gives an average of 72½ pounds of honey for each old colony, spring count, which was worked for honey.

On Aug. 1, I began getting the brood out of the various nuclei, leaving only enough in each to keep them along,

so that when I got through with them I should have little left in each hive save the combs. This brood was given to the stronger nuclei, which together with brood taken from the colonies which did not swarm, was used to build up colonies for winter, so that I now have 60 colonies again for winter.

All of the colonies worked for honey have an abundance for winter, after an equalization of the whole, but the united brood and colonies which were built up in that way had to be fed in order that they might winter without danger from starvation. As my average yield of honey during the past 14 years has been not far from 80 pounds per colony, it will be seen that this year has been about an average season for honey in this part of New York State.

Borodino, N. Y., Oct. 1, 1888.

EXPERIMENTS

In the Prevention of Natural Swarming, etc.

Written for the American Bee Journal
BY W. M. WOODWARD.

I was deeply interested in the experiments of Mr. C. H. Dibbern, on page 612, on the

Prevention of Swarming.

I had been going over the same ground, and will give the experiments and results:

I had a strain of Albino bees and hybrids, which would swarm every six weeks, both old and young queens, and I was, after three seasons, becoming anxious for some way to control them. I caught at the Simmins' "non-swarming" idea as a possible way out of the trouble. It seemed to me feasible, and the only way that I conceived worthy of further trial, for they would build cells as long as they had anything to build with, and I had tried every way in former years without success. I therefore set myself about testing what this heralded plan would do.

I prepared 10 colonies as follows: Two colonies on nine 7-inch frames were given an extra set of combs beneath, about ten days before swarming began. Two more were fitted up the same with starters only. Also six extra Langstroth hives (with 9 frames) were fitted up with clean combs, and two placed beneath and four above, one each way on strong colonies of black bees, and two each way on hybrids.

This I thought would give the plan a fair test. The results were as follows: My first swarm was from a 7-inch frame hive, single tier; the sec-

ond from one with an extra set of starters below. The other one with starters remained sometime longer, but swarmed without building any comb to speak of.

The 2 colonies fitted with an extra set of 7-inch combs below performed as follows: One swarmed early, I think the third or fourth swarm, without apparently occupying the extra hive at all. The other swarmed and went back; and, as the queen had used but the upper or original hive for brood, I now changed them, putting the brood below, and they remained.

The two Langstroth hives given to the black bees, one above and the other below, both proved effectual. *But*—only one black colony out of 14 or 15 swarmed until very late, long after these experiments had closed. The 4 hybrid colonies fitted with Langstroth hives, one above and the others below, all swarmed; but one, after going back the third time, remained; and one other was changed from below and put above, at the beginning of the honey-flow from corn, about July 20, and swarmed when the extra hive was nearly filled for extracting. I have no doubt this last would have proved successful had I not removed a case of sections from between the two hives when they needed it; but although they had made a start in theirs, the rest had done nothing, and I thought they would only black their combs, and so I took it off. They swarmed in three or four days afterward.

One conclusion which I arrived at was this: That bees could not be induced to build comb below, to any extent, after they had ceased to build once in their hive. I tried the same experiment later on with swarms, by putting an extra hive with foundation or starters beneath, and in no instance did I succeed in getting another set of combs built, or even drawn out. I found it necessary to change them to the top, when they were built and filled with honey.

Another conclusion at which I arrived was, that the extra hive is always better *above* than *below* the brood. It seems to prevent swarming better, and also prevents the combs from being loaded with bee-bread.

Still another conclusion was, that about 9 Langstroth frames gives the most prolific queens that I have all the room for brood that they want. Only one of all these queens occupied the second story, and when she swarmed, I overhauled the hive and placed the fullest frames of brood in one hive, and two were given to a weak colony. Yet I judged that the brood could as well all have been placed in nine full frames.

In a word, the Simmins' non-swarming method has proven a great hoax. Still I think that I have a "leader" in the right direction. I was able, by the use of an extra tier of drawn combs, to hold off swarming. I believe that swarming can be prevented. If so, it will be by working colonies just as for extracted honey, until well started; and working, by the tiering-up plan, into comb honey at the time of raising the upper story.

The only way I was able to prevent increase was, by breaking up every colony that swarmed, giving all of the bees to the swarm, and using the brood where it could be disposed of to the best advantage. By this means I succeeded in keeping the bees together strong enough to gather the fall crop of honey.

Value of Comb Foundation.

I have heretofore written very strongly in favor of full sheets of comb foundation in the brood-nest. I still use it as a general rule; but with the above bees it has only aggravated this disposition to swarm, as they positively will not do anything outside the brood-nest if they can crowd in there.

I have found that I could keep them together about two weeks longer by using narrow starters only. I never was able to get any comb honey from them, except by sheer compulsion. I have hived them for 24 hours, or even more, in the cases only, and then raised them upon a hive; yet they quickly found the place for their home, and this did no good. A few sections perhaps were started, but the rest of their honey went below. They must have positive contraction to the space actually full of brood.

Crowding Frames Together.

I have tried Mr. Pond's plan of crowding frames together, somewhat extensively for the purpose of preventing the hive from becoming choked up with honey. The only advantage I ever gained by it was, that the breeding depth was retained, but it was filled with honey just the same. Taken alone, it was a total failure; but in conjunction with reversible frames of a shallow type, it was a success. The frames should not be deeper than 7 or 7½ inches—surely not more than 8 inches for this purpose.

The same result can be gained with the hanging frame, when placed close by taking the side of a knife and bruising the cappings thoroughly. This will cause the bees to remove the honey in order to repair the combs, when the queen will occupy the combs with brood. I have met with my most perfect success in producing comb honey by the latter process—a gain of

not less than 40 per cent. over any other colony at the time of trial; but it involves double the work.

On the whole, shallow reversible frames promise to be far the best, and I believe that we have not yet half learned to appreciate the reversible frame.

Custer Park, Ills.

WINTERING BEES.

Preparing the Bees for their Long Confinement.

Written for the American Bee Journal
BY REV. STEPHEN ROESE.

The BEE JOURNAL makes its weekly visits with great accuracy, and comes richly laden with its precious contents of valuable instruction and advice, from the bee-keeping fraternity from Maine to California, cultivating, like an electric current, a feeling of sympathy and good-will toward all who love this honest industry and art.

But the summer is now ended, the harvest is past, and the time is now at hand for bee-keepers to be preparing their bees for winter, which is a matter of great importance; for in fall management and winter care lie the bee-keeper's success for the coming season. Bees that winter well in a dry cellar or bee-house with 35°, and not over 40°, of temperature, will come out healthy and strong in the spring, and beginners (and older ones not excepted) in the pleasant and profitable occupation should be very careful, and not allow one colony of bees to go into winter quarters with less than 35 pounds of sealed honey; and to be sure that each hive is placed on the scales, and not guessed at.

September is the best month and time for this preparation, to examine and find out the conditions of each colony. Later, when frosts have injured the honey-flow, and bee-pasture is scarce; where bees will be troublesome and annoy both bees and bee-keeper—while this work of examination and preparation for winter is going on, and often causes a general demoralization of the whole apiary, not a hive should be opened unnecessarily, or left open by neglect; for if one bee is allowed to enter a strange hive, or get a taste of honey not its own, in a short time robbing at wholesale will be the order of the day, and the strongest colonies cannot resist it; and with what fury and terror this warfare is carried on, many bee-keepers, without doubt, have witnessed and experienced!

One who has read of, or has been an eye-witness of the great Battle of

the Wilderness, will be able to form a faint idea of the terrific warfare, when bees have begun robbing in good earnest. I have often wished, on such occasions, that I had never seen a bee.

Preparing the Bees for Winter.

The way I prepare my bees for winter is as follows: I begin early during the extracting season. When shaving off the cappings from the cells that are sealed over, I punch a hole through the frame in the center, 2 inches from the top-bar, for a winter passage, and put away at the same time the best frames of straight combs all sealed over, placing them in vacant Simplicity hives, 2 inches apart, for further use in winter preparations. On finding a colony with frames nearly empty, I take one or more without brood and replace them with full ones set aside for this purpose; and if the colony is strong, I take from it one or two combs with brood, and give them to weak ones, thus making them all equally strong, or as nearly so as I can. But I make it a point to do this work with great despatch, having everything ready and on hand; the smoker filled with dry, rotten elm wood, and also the honey-knife, if needed to cut bits of brace-comb on the outside frames and side-wall of the hive; and also a small chisel or old file to pry loose the frames, if need be. In less than three minutes the work of examination and preparation is completed.

My next work is to contract the hive-entrance according to the strength of the colony, and guard the same closely for several days, until all danger of robbing is over. The partly empty combs thus taken out, I extract, placing them in a Simplicity hive; and toward evening I put the same on a hive of bees having no upper story; during the night the bees will take every particle of honey out and carry it down, and in the morning the combs will be all dry and clean, ready to put away for winter.

I use no enameled sheet for winter covers on the frames; burlap is my favorite cover for winter, or binder twine is still better.

Watching the weather closely, I store all my bees away for winter just before the first hard freezing—before the combs get frosty; after arranging them all in tiers, one above the other, but so as not to rest the upper tier on the lower, taking the cover off from each hive. I spread on the burlap cover, 3 inches of sawdust, which will answer a three-fold object, viz: 1. It will keep the bees warm. 2. It will keep them dry, and absorb the moisture. 3. It will admit air, as it is porous.

The hive-entrance I regulate according to the strength of the colony, and in two weeks I go into the bee-house to see if the entrances are clogged up with dead bees. If so, I have a hook of strong wire, and reach gently into the hive and draw the dead bees out.

If the mercury is at zero, I stop up the ventilator with a bag filled with sawdust, for this purpose, and take the same out when the atmosphere is milder. With this care my bees wintered remarkably well last winter; they came out strong, and I lost, of all I put out in the spring, only 3 colonies by spring dwindling. During the cold weather in May I heated bricks, and placed them, during a cold night, above the frames, to prevent the young brood being chilled, and I shall do likewise in the future.

Improvements in Bee-Keeping.

I think that every intelligent bee-keeper ought to be thankful for modern improvements in bee-keeping, and the light which has dawned upon the times and age in which we live; for since the introduction of the movable comb-frame, by the venerable Father Langstroth, and the Simplicity hive by Mr. A. I. Root, bee-keeping is no longer a task to be dreaded; but it is now a work that is pleasant, easy, entertaining and profitable, and, what is more—honorable. In spite of the "Wiley lie," which was wilfully intended to cast a gloom and dark shadow over so honest a pursuit, in which many intelligent men and women are engaged, the art of bee-keeping is still progressing, prospering and developing more.

Only a fiend and villain could do as Wiley did, wounding the feelings of over 300,000 bee-keepers in this country, and many more in the Old World; and then trying to smooth it over, calling his wicked act a harmless "pleasantry," and complaining that bee-keepers are continually "picking" at him. He may, conscience smitten, take home the truth that he deserves, and he has not heard the last of it yet, for with all his education, wisdom and scientific knowledge, he leaves unclaimed the standing offer of \$1,000 reward offered by a noble defender of this honest enterprise. In this section of country the "Wiley lie" has taken no strong foothold—only once in a while a traveling salesman will tell the merchants what he has seen in the papers, that bee-keepers manufacture comb, honey, and all, without the aid of the bees.

In closing I will say that we are truly living in an age of wonders, considering the progress of science and art during the last 50 years; and since the days of Herr von Berleph and his

associates in Germany, the art of bee-keeping has been wonderfully developing, and every candid reader will agree with the "good book," that in the latter days many shall run to and fro, and knowledge shall be increased, and the wise shall understand.

FLOWER COLORS.

Are Bees Attracted by the Colors of Flowers?

Written for the American Bee Journal
BY MRS. MAHALA B. CHADDOCK.

Among the many good and interesting things in Mr. L. H. Pammel's article on page 633, on "The Pollination and Perforation of Flowers," there is a wrong idea put forth. He takes it from Muller, but also seems to adopt it as his belief. It is in regard to the changes in color of flowers of closely related species. After quoting from Muller, and giving examples of some of the species that show the color-range, he says:

"Slight changes of color must therefore be of great use to an insect; just as changes in color of parts of a flower after pollination are of use to the insect by indicating that its services are no longer needed."

Color is no guide for the insect world. They visit flowers for the nectar and pollen which they contain—not for the good of the flower; and if color is of no account at any time, how can a change in the color of a part of a flower tell an insect that its services are no longer needed?

Bees and other insects work by instinct, and all their labor is for the good of their own kind; they know nothing about "pollination," and a change in the parts of all the flowers in the universe would tell them nothing. Insects cannot reason. If they could, they might alight on a flower, and, if the inside of the petals had turned dark, say, "This flower has already been pollinated. I know by this dark stripe, so I'll not go in, but will go to other flowers where no change in the color has taken place, and then I'll do the work that was intended for me to do. It matters not that I have a thousand empty mouths at home, waiting to be fed. I'm around just now pollenizing flowers, and the babies at home will have to wait until I find a flower that needs me."

But we all know that insects do not reason, but go by an instinct that makes them seize everything that will contribute to their own prosperity. That in working for their own good

the insects do unconsciously pollenize flowers, is true; but that they are conscious of what they do, can never be admitted, unless we admit that they are endowed with reason.

There never was a wilder notion than that bright-colored flowers attract insects. One of my neighbors has masses of zinnias, two long rows reaching from the house down to the road; and as I walk among them I look out for bees. Not a bee is to be seen; but up near the house is an insignificant little bunch of mignonette, with half a dozen bees at work on it. Bees and other insects are attracted by the *scent* of flowers, not by the *color*. Here is the 

Vermont, Ills.

AUTUMN.

Hints About Fall Work in the Apiary.

Written for the Western Plowman
BY C. H. DIBBERN.

As predicted last month, the fall yield of honey has been very fair, and the quality is unusually good. I have never before seen such white honey produced so late in the season. Bee-keepers are now in much better condition than a year ago. Then there were hives that contained not a single pound of honey, and the only thing to do to save the bees, was to buy sugar and make it into syrup and feed them. This required money, work and patience. Now all is changed. The bees are well supplied with honey, in fact many have too much, and some extracting from the brood-chambers will have to be done. Bee-men can keep their money in their pockets, if they have any, and perhaps add to it considerably from sales of honey.

Preparing Honey for Market.

October is usually a busy month, as all the work of removing surplus arrangements, and putting the bees in the best possible condition for winter, should be done now before the weather gets too cold. Then the honey has to be prepared for market. Cases for shipping have to be made, and if any are on hand from previous years, they should be taken apart, and planed so all will look nice and inviting. We should always remember that we cannot have anything too neat about honey—the bees themselves set us a very good example, when they put nectar into snow white waxen cells. Perhaps from this has come the old saying, "Neat as wax."

To the bee-keepers that have honey to sell I want to say a word or two.

Of course you want to get the most money you can out of the crop, which is a very short one at best. If your honey is nice and white, or dark and yellow, be sure and scrape every section clean of propolis, and pack in neat shipping-cases, with clean glass on at least one side. Your name should be on the case, with the kind of honey, weights, etc.

Now do not put nice white comb next to the glass, and dark, poor stuff hid away back of them, as your customers will certainly find it out, and perhaps not buy any more from you. There is no use to try to sell a thing for what it is not, to say nothing of the dishonesty. Some people would call that smart, but such practice will soon be found out, and the man be marked as one to be avoided. It is all well enough to put nice combs next to the glass, but the balance of the case must grade nearly the same.

If you have dark honey, put that into cases by itself, and sell for a few cents less, for just what it is. We are making three grades of ours this year: choice white, heart's-case and buck-wheat, which we expect to sell at a difference of 5 cents per pound between the poorest and best. I have noticed in previous years that some bee-keepers bring in their honey in the cases just as they come off the hives, with the sections all stuck fast, and the propolis still sticking to them, without bottoms, so that every particle of honey leaking out will run on the counter, where it attracts flies, and very often the neighboring bees. I have seen grocers literally driven out of their stores in this way. Is it any wonder that after such experience some grocers will not bother with honey?

Our cases are close fitting, with glass on one side, and a cover that fits perfectly. Before the sections are put in, a neat fitting pan, made of stout wrapping paper, is placed in the bottom to catch and hold every particle of honey that may leak out. Honey in such shape can be handled as easily as sugar. Do not be in too great a hurry to sell. Honey this year should bring 15 to 20 cents per pound for comb, and 10 to 15 cents for extracted.

Honey of Different Colors.

We have noticed one thing this year that struck us as rather odd. Some cases contained as nice white honey as any white clover, while perhaps the very next hive would contain sections stored at the very same time, that were quite dark. This at first puzzled us, but after thinking over the matter, we concluded that bees from certain hives work on one kind of blossoms, while others work on a different kind. I also

noticed that only one kind was usually in a case.

Value of Honey-Plants.

Our honey-plants, with which we have been experimenting, are now done blooming, and we can now form some idea of their value. We are well satisfied with the outcome of our four acres of sweet clover. It kept the bees busy for about a month at a time when there was almost nothing else for them. It is true they did not gather honey fast, but it kept up brood-rearing, and the bees more than held their own, and when the fall blooms came they were ready for it, and how they did work!

The Chapman honey-plant commenced blooming about the same time as sweet clover, and went out of bloom a little sooner. It is undoubtedly very rich in honey, as the bees were on it constantly. Still I do not think it will ever be very extensively cultivated by bee-men, as it requires too much attention the first year. Then, too, it is known to have several enemies that may play sad havoc with it in the future. Others will regard it with disfavor, as it looks so much like thistles. Cattle will not touch it, and on this account we believe it will be valuable to scatter in waste places, about old stone quarries, etc., where other plants could not exist.

Some years ago I got some of Dr. Tinker's golden honey-plant seeds and scattered it far and wide. Now they are growing in many places, and bid fair to add another important source of honey to our field.

We shall save all the seeds this fall that we can use, and send for several other varieties, and do all possible to improve our honey resources. We shall also do what we can to induce farmers to sow Alsike clover.

Brood-Chambers Full of Honey.

In many sections of the West, brood-chambers of hives will be found clogged with honey. Especially is this the case with large hives, or where surplus arrangements are defective. A colony does not need over 40 or 50 pounds of good honey to winter nicely. In fact more is a detriment to them, as they cannot cluster and pack in the combs, on the approach of cold weather, and on this account many bees will become chilled, and lost between cold, solid combs.

A very good plan is to take out the side combs which are usually solid with honey, and extract them, and return empty combs to near the center of hives. It is best to do this before the weather gets too cold, as the bees are then harder to handle, and the honey is more difficult to throw out of the combs.

Brush for Removing Bees.

A brush of some kind is necessary to brush the bees off the combs. We have found nothing better for this purpose than a handful of the stems of any suitable green grass, made into a small wispy broom. Bees do not seem to mind being swept off with grass in a green state, but would become furious if a hair or feather was used. In opening hives and handling combs at this time of year, a good deal of caution is necessary to prevent robbing. Use entrance-blocks where hives have been opened, and do not let bees have access to honey anywhere. Do not put extracted honey into old whisky barrels, on economic grounds, as the honey will be spoiled.

Milan, Ills.

CONVENTION DIRECTORY.

1888	Time and Place of Meeting.
Nov. 3.—	Stark County, at Canton, Ohio. Mark Thomson, Sec., Canton, O.
Nov. 14.—	Alabama State, at Montgomery, Ala. J. M. Jenkins, Wetumpka, Ala.
Nov. 21, 22.—	Pan-Handle, at Wheeling, W. Va. W. L. Kinsey, Sec., Blaine, O.
Dec. —	Michigan State, at Jackson, Mich. H. D. Cutting, Sec., Clinton, Mich.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

SELECTIONS FROM OUR LETTER BOX

Snow.—Mr. S. F. Reed, North Dorchester, N. H., on Oct. 9, 1888, writes:

It is snowing hard here to-day. There are nearly 6 inches of snow on the ground now. A heavy frost killed all vegetation about Sept. 5th or 6th.

The Season of 1888.—Mr. Leslie Stewart, Jefferson, N. Y., on Oct. 15, 1888, writes as follows:

The honey season of 1888 is over, and the bees will now be quiet until the budding spring arrives, when it is hoped that a good season will be in store for us. Certainly we ought to have one then, if we stand the past two poor seasons without flinching. We have now had two very discouraging seasons—in 1887 there was a very short crop, and the crop of 1888 is yet smaller; still we must not complain, for will not this clear our markets of all old and second-class honey, and give a clear market for 1889?

Let us again prepare for the coming season, with light hearts and high hopes. Let us get out a better lot of hives and crates than ever. Let us see that our bees have first-class stores on which to winter. If they are to be wintered out-doors, let us pack them carefully; if in the cellar, let us see that it is clean, dry and warm. We cannot be too particular about such things, and you know we are rather inclined to be a little careless at such times.

To be sure the season has been a poor one, and the honey crop was small. The

prices are not as high as we might expect, yet the demand is good, and we will probably have a great abundance to winter the bees on; and some of us have quite a nice lot to spare, which will go a good ways to pay our actual expenses. My crop for the season is about as follows: Basswood, raspberry and white clover extracted, 45 pounds per colony, and of buckwheat, 65 pounds per colony. Comb honey, 20 pounds per colony; of buckwheat, 50 pounds per colony. While there is not a large yield, yet I am satisfied, and feel sure that it is better than the most of us have done; but it has cost me and my Italians a great deal of hard labor, to say nothing of the expenses.

It has been the poorest season for the rearing of queens ever known to me. I was obliged to have very strong nuclei, and sometimes the cells would become chilled, and the young queens would not hatch out; yet I succeeded in rearing some of the finest queens that I ever saw, when the weather was favorable.

Fall Crop in Georgia.—W. H. Prior, Madison, Ga., on Oct. 10, 1888, writes as follows:

My bees have been gathering honey nicely for the past ten days, there being quite a good flow of honey from the fall flowers, especially from the golden-rod, which is very abundant in this section, and is still in full bloom. Frost generally occurs with us from Oct. 15 to the 20th.

Results of the Season.—J. M. Jacobs, DeWitt, Iowa, on Oct. 17, 1888, says:

I started last spring with 20 colonies of Italian bees, increased them to 45 colonies, and have taken 1,000 pounds of fine fall honey. I sold 500 pounds for 18 cents per pound, in one-pound sections. I produce comb honey, extracting unfilled and uncapped sections. I winter my bees in the cellar, darkened, with the temperature at 40° to 45° above zero. I have the bottom-boards loose, and change them during the winter, so as to remove dead bees and mold, if there should be any. I have been very successful so far. I have a market for 50,000 pounds of honey in one-pound sections.

Bee-Keeping in Nebraska.—Mr. Wm. Stolley, Grand Island, Nebr., on Oct. 13, 1888, writes:

My 30 colonies of bees wintered well in the winter of 1887-88; but owing to my absence from home (in June, July and part of August), and other causes, but 20 colonies were in a condition to gather any surplus when I returned. From them I took 62 pounds of comb honey, and 1,348 pounds of extracted. I had but one colony to produce comb honey in one-pound sections. My system of management is such that I so far have successfully controlled increase to suit myself. This season I have only kept up the number of colonies I had in the spring, and they are all strong, and in good condition now, except 2 colonies that are rather weak in numbers.

My bees have, on an average, 25 pounds of honey for winter stores, and I have 100 well-filled and sealed combs besides, reserved for spring stimulation and feeding. I have superseded all queens over 2 years old, and have now nine queens reared in 1887, and 21 queens reared during this summer. It was owing mostly to old queens that 10 of my colonies became deranged during this summer. All of my bees are in their winter quarters, and well packed now. It is the melilot and alfalfa which, for the last three years, have enabled me to render a good account from central Nebraska.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections $4\frac{1}{2} \times 4\frac{1}{4}$ and $5\frac{1}{4} \times 5\frac{1}{4}$. Price, \$1.00 per 100, or \$8.50 per 1,000.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in *Cheshire's* pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being available, it must be sent by express.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the *Apiary Register* and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 120 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, Ills., is published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$3.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Sweet, or Melilot, Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Cork for Winter Packing.—Its advantages are that it never becomes *musty*, and it is *odorless*. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Exchange.—We will accept Honey and Beeswax in exchange for Bee-Keepers' Supplies in any quantity. Those desiring to make a trade are invited to correspond with us, stating quantity, quality, and price, and the goods they want in exchange.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 10 cents per pound for bag and postage.

We Want 20,000 subscribers. Out of the 300,000 bee-keepers in America, certainly this is not an extravagant desire! It is only one out of every fifteen! We confidently ask those who appreciate the AMERICAN BEE JOURNAL, to show it by sending us one or more new subscribers. We will give them full value for their money.

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality remunerative prices. See list on the second page of this paper.

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1, postpaid.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

Honey and Beeswax Market.

CHICAGO.

HONEY.—New crop arriving slowly, but demand is limited. White clover comb, 17@18c. Extracted, 7@9c.
BEESWAX.—22c.
S. T. FISH & CO., 189 S. Water St.
Sep. 12.

CHICAGO.

HONEY.—For white comb 1-lbs., 18c. Very little inquiry for anything outside of 1-lb., and when it is wanted it is at a lower price. Extracted, the best grades, 7@8c., and some held higher. Offerings are small and demand slow.
BEESWAX.—22c. R. A. BURNETT,
Sep. 12. 161 South Water St.

DENVER.

HONEY.—Colorado, new 1-lb. sections., 13@15c. Extracted, 7@8c.
BEESWAX.—20@23c.
Sep. 7. J. M. CLARK & CO., 1409 Fifteenth St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lbs., 15@17c.; 2-lbs., 14@16c. Fair white 1-lb., 14@16c.; 2-lbs., 13 to 15c. Extracted, white, 7@8c.
BEESWAX.—23@24c.
Sep. 17. THURBER, WHYLAND & CO.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb., 17@18c.; 2-lbs., 13@14c. Fair white 1-lb., 15@16c.; 2-lbs., 12c. Buckwheat 1-lb., 11@12c.; 2-lbs., 10@11c. White extracted, 7@8c.; buckwheat, 5@6c. California extracted, white pure, 7@7½c.; amber, 7½@7c. Demand good and prices firm. New comb honey is arriving quite freely.
BEESWAX.—23@23½c.

HILDRETH BROS. & SEGELKEN,
Oct. 10. 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—White 1-lb. sections, 11@12½c.; 2-lbs., 12½@1c.; amber, 8@10c. Extracted, white, 5½@6c.; light amber, 5¼@5½c.; amber and candied, 4¼@5c. Receipts light and market firm for best qualities.
BEESWAX.—Dull at 19@22½c.
Sep. 22. O. B. SMITH & CO., 423 Front St.

DETROIT.

HONEY.—Best white comb, 17@18c.; dark, 16c.—Extracted, 8@10c. Market bare of all kinds.
BEESWAX.—21@22c.
Sep. 24. M. H. HUNT, Bell Branch, Mich.

CINCINNATI.

HONEY.—We quote extracted at 4½@8c. per lb. Comb honey, 12@16c. Demand slow.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Sep. 18. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—Choice 1-lb. sections, 18c.; dark 1-lb., 14c.; 2-lbs., 16c.; dark, 13c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock fair.
BEESWAX.—None in market.
Sep. 27. HAMBLIN & BEARSS, 514 Walnut St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 17½@18c.; 2-lbs., 14@15c. Fair 1-lb., 14½@15½c.; 2-lbs., 11@12c. Extracted, fancy white clover, 7½@8c. California white in 60-lb. cans, 8c.; light amber, in same cans, 7½c.; amber, 7½c. Buckwheat in kegs and barrels, 5½@6c. Cuban, in barrels and ½-barrels, 65c. per gallon.
Sep. 26. F. G. STROHMEYER & CO., 122 Water St.

BOSTON.

HONEY.—We quote: Best white clover 1-pounds, 16@17c.; best 2-lbs., 15@16c. Extracted, 8c.
BEESWAX.—25 cts. per lb.
Oct. 10. BLAKE & RIPLEY, 57 Chatham Street.

KANSAS CITY.

HONEY.—White 1-lb., 17@18c.; dark, 14@15c.; California white 1-lb., 17c.; dark, 14c. Extracted white 8c.; amber, 7c.
BEESWAX.—None in market.
Oct. 11. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—We quote: Extracted, 4½@5½c. If in cans, 8c. White clover comb, 14@15c. Market is steady and receipts light.
BEESWAX.—21c. for prime.
Sep. 6. D. G. TUTT & CO., Commercial St.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6 cents; light amber, 5½c.; amber, 5¼@5½c. Comb, 1-lbs., 13@14c.; 2-lbs., 10@13c.
BEESWAX.—20@22c.
Sep. 24. SCHACHT & LEMCKE, 122-124 Davis St.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. Oct. 31, 1888. No. 44.

EDITORIAL BUZZINGS.

How doth the little busy bee,
Delight to bark and bite;
It gathers honey all the day
And eats it up at night.

You never hear the bee complain,
Nor hear it weep nor wail;
But if it wish it can unfold
A very painful tail.

The Palmetto Honey of Florida, exhibited at the Columbus, Ohio, Convention, was nearly as palatable as our white clover honey, and Mr. Detwiler wants us to call it by its proper name, and not class it with Southern honey generally. There can be no objection to doing so, and certainly there would be *justice* in it. Let it be known as Palmetto Honey, by all means.

The Canadian Honey-Producer for November is on our desk. It was the first of the monthlies to put in an appearance, and has a fair report of the Columbus convention. Bro. Holtermann is a wide-awake and energetic worker, and deserves great success. He is a rising young man, and some day we hope to announce that he is elected President of the International Bee-Association. He is a "worker-bee" in "the hive of Nature."

Mr. Ivar S. Young writes this to the *British Bee Journal* from Christiania, Norway, on Sept. 28, 1888:

In Norway, last winter was quite serious to us bee-keepers. I suppose that about three-fourths of all the colonies died of cold and hunger, and this summer has only very little bettered us, because the honey-harvest with us in Norway, as well as in England and America, has been scarce nearly everywhere. However, we will not therefore lose heart, but hope for better luck next year.

All in a Row.—At the Columbus convention, after the adjournment, while listening to the songs of the "Glee Club," brother Hutchinson called attention to the fact that if a cannon-ball should strike Brother Root and cross the line of chairs, it would wipe out five or six editors of bee-periodicals—they having unconsciously placed themselves in that position, so as to be near one another and have a "friendly chat" between the songs. We heartily endorse the sentiment of the following concerning it, copied from the last *Gleanings*:

Quite by accident, the editors of the representative bee-papers sat in a line so straight, indeed, that, if a cannon-ball had been fired along that line it would have swept them all down. It was Mr. Hutchinson, we believe, who first called attention to this phalanx of editors. Let's see: There was Holtermann, of the *Canadian Honey-Producer*; Newman, of the *AMERICAN BEE JOURNAL*; Hutchinson, of the *Bee-Keepers' Review*, and your humble servants [A. I. Root and his son Ernest]. This little incident, quite accidental in itself, represents the fraternal feeling that exists among us, we feel sure; and God grant that editors of bee-papers may never be ashamed to sit together and be "kind of decent."

Florida Honey Crop.—Alderman & Roberts, of Wewahitchka, Fla., report their crop of honey for the past season as follows:

Our honey crop has been about 75 pounds per colony. We have taken the honey from about 8,000 hives now. We have 1,000 colonies in Langstroth hives.

Transporting Queens.—Mr. G. M. Doolittle, in *Gleanings*, contends that "queens are not injured so much by transportation in the mails, or by express, as they are by the sudden check in egg production, that results from taking them away from full colonies in which each queen is laying perhaps her weight of eggs each day." This position is very reasonable, and is no doubt correct.

Commenting upon our friendly notice of the exhibit of Mr. A. I. Root at Columbus, he remarks thus: "How gratifying it is that editors of bee-papers, unlike some other pursuits, can say kind things of each other, and not exhibit signs of jealousy." Sure enough. If the editors of the periodicals of an industry cannot be just, reasonable and friendly towards each other, they ought to "get out," and make room for those who will not be such fools as to be jealous. We hate "jealousy." The Bible truly says: "It is as cruel as the grave."

Not Much Honey.—Mrs. L. Harrison, Peoria, Ills., writes: "There have been several frosts in this locality, and thin ice formed one night, yet on Oct. 7 honey came in quite freely during the warm part of the day. Golden-rod and asters are still blooming, also black-heart (*Polygonum Pennsylvanicum*). There is very little honey to be seen in the stores here, and what there is, is badly mixed. It took the bees all the season to fill a few boxes, consequently it is travel-stained."—*O. J. Farmer*.

Bee-Pasturage 8 Miles Away.—Away out in Washington Territory, on Fidalgo Island, there lives a bee-keeper by the name of H. A. March, who also has the only spot of ground in America where canli-flower seeds are matured as a crop. He has acres of them, and sells them to Eastern seedsmen. So says the *Washington Farmer* of the 12th inst. He has also discovered how far his bees go to their pasturage to gather honey. This he did by following with his boat under a line of bees across Padilla Bay. He traced them to where they were gathering honey from the golden-roses on Skagit flats, eight miles distant. He knew they were his, not only because he followed them, but because there were no Italian bees in the county at that time except his.

He also has a dozen poultry houses scattered over his place, at which he breeds special valuable varieties of chickens. He keeps them out of his garden by clipping their wings. Mr. M. is marching along, quite abreast of the times, in that new country so far away. The *BEE JOURNAL* visits the bee-men of that region as well as "islands of the seas," to instill the knowledge of the newest methods and the most profitable management of an apiary.

Autumn in England and its effect on the feeding of bees is thus described in the *British Bee Journal* for Oct. 11, 1888:

With the exception of a few cold days, bee-keepers in the southeastern localities have enjoyed splendid weather for rapidly feeding their bees in anticipation of the long winter on which we are about to enter. Snow, wind-storms, and extremely cold nights, in the north and midland districts, have, we fear, interrupted the feeding process.

The Union.—Mr. J. M. Hambaugh, of Spring, Ills., sent two membership fees for the Union, collected at the Clayton, Ills., Convention, and adds:

We had a splendid time at the Clayton meeting, and will send the report for publication soon. Resolutions were unanimously adopted requesting each member to send their money and names to the editor of the *AMERICAN BEE JOURNAL*, and become members of the Union, in the defense of right.

The Ventilation, by special arrangement, of a bee-depository, is decided to be unnecessary by the leading bee-keepers who have given their views in the *Bee-Keepers' Review* for October. Its editor sums the matter up thus:

Ventilation, simply for the sake of securing fresher or purer air, finds but little support; while the few who plead for special ventilation do so almost entirely upon the ground that they can thereby more readily control the temperature. Some who have been to the expense of furnishing their cellars with sub-earth and special ventilation, have finally abandoned it as not only useless but injurious. If bee-repositories are built sufficiently under ground it does not seem that ventilation would be very much needed for controlling temperature.

In October Days.

From *Vick's Magazine* for October.

I wander down the russet lane
And see the autumn's bonefires burn
Upon the hillside slopes again,
Among the sumac and the fern.

The Oaks have caught October's fire,
And drop their treasures in the grass,
While the still flame creeps high and higher,
Fanned by the warm winds as they pass.

The sky is dim in purple haze;
The spell of dreams is over all,
Unknown, save in the long, still days
When flowers fade and dead leaves fall.

The Constitution of the International Society.

—It was a great disappointment to the Editor of the AMERICAN BEE JOURNAL (who was indisposed and absent much of the time), to learn that the Convention at Chicago, in 1887, did not discuss the merits of the new Constitution and By-Laws he there presented. These documents were "evolved" while on a sick-bed, under considerable difficulty, and were by him acknowledged to be imperfect in many points. The Convention was particularly solicited to discuss, and by its united wisdom improve both the Constitution and By-Laws, and we were surprised that they did not even attempt to do so—but when at Columbus, they adopted the whole, without discussion and without due consideration, we were even more astounded. We desired to offer some amendments, which the intervening time had suggested, and to obtain the views of others upon points which were open to discussion. But it was rushed through by a vote to adopt, in such haste as to show that it was done to get a troublesome thing out of the way as rapidly as possible.

We do not wonder, therefore, that Dr. Miller should seek to discuss it now in the bee-papers (see page 711). That is the next best thing to be done, and we welcome it, even though we had no idea of the Doctor's views on the subject, until his article was received for publication.

Some of the points raised by Dr. Miller "are well taken;" others need discussion, and still others, when explained, will, we think, meet with his unqualified approval, as they now stand. We will review them by numbers, as follows:

1. His first point, suggesting the shorter name, is well taken and should be adopted. The title, "American Bee-Society," is short, expressive and appropriate.

2. In a society, standing at the head of the pursuit of apiculture on the continent of North America, surely *some formality is necessary* in determining who shall be its annual members, and a majority vote by show of hands would occupy but a minute for a dozen of such members. It is probably true that none may ever be voted out—still such a peculiarity may be desired, and the Constitution should give the Society the power to do so.

No such formality is required with delegates from affiliated societies—they are ad-

mitted free without vote, on their credentials.

3. As to the calling of special meetings, something unusual may arise, making it expedient to do so, and then to have the power is a desirable thing.

4. An address by the President is not one of the *new* features, but is no less desirable. Who is more conversant with the items of interest or business matters to bring before the Society, than the President who had charge of it during the intervening year? His address need not be a long one, but should cover the salient points, review the work done, the position attained, and the points deemed desirable by the Society's officers or members, etc.

5. Calling the names of officers, permanent members and delegates, to know who are present, is advisable, even if it does consume a few moments to do so, especially in a representative body. The names of annual members of a former meeting of course are not to be called. Their membership closed with the adjournment. This negatives the Doctor's objection entirely.

6. Giving notice of the regular meetings three months previous is *desirable*, but the law gives the least possible time to have the meeting held lawfully.

7. The items mentioned by Dr. Miller in this division should have received considerable attention, both by the committee, and also by the Convention. They were put into the By-Laws for the purpose of being *discussed* before being adopted. As that was not done, we ask for a general discussion, and will (D. V.) promise to devote our energies at the next meeting to have the whole Constitution and By-Laws amended, perfected, and put into running order.

The Columbus Convention did not appoint the committees required by the Constitution and By-Laws, evidently intending to leave that for the next meeting to do, which should be composed of its officers, life-members and delegates from affiliated societies.

In the meantime, we would recommend every apicultural society in America to elect a delegate to send to the next meeting at Brantford, fully instructed as to the needs and wishes of the local society, and to assist in completing the organization of the International Association.

Buckwheat as a Honey-Plant.

—The editor of the *Canadian Honey Producer*, in his issue for October, reports 10 pounds of honey in a single day by one colony, from buckwheat. The day was showery, so the bees were enabled to work on it from morning till night. Now, friends, what is there in our whole list of plants, that are raised for honey alone, that has given a yield like this? I venture to say, that not one has ever yet given us anything like it. We should like to have friend Haltermann tell us more about it. Was the buckwheat the new Japanese, the silverhull, or the old-fashioned kind?—*Gleanings*.

Horticulture and Apiculture.

—The two legislative halls at Columbus were occupied at the same time by bee keepers and fruit growers. They were friendly organizations, as they ought to be, and the fruit-growers sent a delegation to invite the bee-keepers to their hall to hold a joint session. It was accepted, with thanks. They discussed a subject which was of interest to both societies, and did it in a friendly way, too. This shows that a good, friendly, brotherly spirit is being engendered, and we are glad to see it. We hope that such may obtain all over the country, and general harmony may prevail. The *Orange Judd Farmer* thus mentions the matter in its issue for Oct. 20:

The convention was invited by Secretary Devol, of the Ohio State Horticultural Society, to visit the horticulturists then in session in the same building.

Upon entering the Senate Chamber the horticulturists were discussing the question of fruit fertilization by insects. In this the bee-men joined heartily.

It was decided that the little busy bee was a very useful insect to the fruit-grower in the way of aiding nature in the fertilization of flowers. The consensus of opinion was that "bees seem to 'roar' over the Crescent and Wilson varieties of strawberries in equal numbers." This answers the idea which some people have regarding the value of the perfect and imperfect flowers as honey-producing plants.

The feeling between the fruit-growers and bee-keepers is becoming more friendly every year. They are each beginning to see the necessity of the other for the best results in their respective lines of labor.

Yes, Brother Judd, we hail the omen of a better day, with delight. For this grand result we have labored full many years, and now hope that the peace and harmony may last forever.

Disposing of Honey.—The *American Apiculturist* says that one who has anything to sell must watch his chance and take every advantage of the market, and adds:

I have a brother who carries the mail between Wenham and a summer resort. The idea struck me that it would be a good place to dispose of some of my honey. One day I gave him a package to show the people, and the result was I found quite a sale for honey. He gets 25 cents per pound for it, and I allow 5 cents commission for selling it. You see we both make a good thing out of it, as it requires no extra time or labor to do the selling.

You who have honey for sale should take a sample package when going "to town," or wherever you go, provided the honey can be taken as well as not. In this way you can do your own advertising, and at the same time take orders to fill when going that way again. If there is much passing of teams by your residence, just stick up a "shingle," stating that you have pure honey for sale, and you will be surprised to know how many and how well people love honey.

Do Not Ship Honey to Us without first corresponding with us about it. We have received several undesirable lots without previous notice, or correspondence of any kind.

GLEAMS OF NEWS.

"Manufactured Honey."—In the report of the Columbus Convention on page 695 (middle of the first column), Secretary Hutchinson noticed the fact that the editor of *Gleanings* was "hauled over the coals" for admitting to the market quotations in the number for Oct. 1, the words, "manufactured stock." As we felt sure the matter could be explained, and that it was an oversight in the type-setting, and would be fully ventilated in the next issue of our valued contemporary, we did not refer to it editorially. We now give from *Gleanings* of Oct. 15, the following editorial, which fully explains the whole matter:

As the business for the second evening of the convention at Columbus opened, President Mason gravely announced that some heavy charges had been made against brother A. I. Root. He said he hoped that brother R. would be able to explain matters satisfactorily, but the whole thing looked very dark and suspicious. Thereupon he produced *Gleanings in Bee-Culture* for Oct. 1. Turning to page 748, he with great gravity read the report from St. Louis, from W. B. Westcott & Co., dwelling with much emphasis on the sentence, "Extracted manufactured stock, 4 to 5 cents." Your humble servant asked to be shown where on the pages of *Gleanings* such a sentence occurred. The President handed him a copy, and there was no getting around it. *Gleanings in Bee-Culture*, that has been so active in months past in contradicting slanderous reports of the newspapers, and insisting that, at the present time, very little spurious honey was to be found in any of our markets, has actually been quoting "manufactured honey at 4 to 5 cents a pound," as if it were a regular and reputable article of merchandise. A good deal of sport was indulged in at the expense of the editor of *Gleanings*; but upon his promise to investigate, and make ample apology and correction, he was let off for the time being, and the proceedings of the convention went on. It seems there was a good deal of hurry and rush in many directions just before John, Ernest, and myself got away for three days at the Centennial exhibit. As the market reports are usually not much more than a change of figures from the preceding reports, I believe I skipped them. Ernest did the same, and the compositors, perhaps, did not think why "manufactured stock" should not be all right. I at once wrote to W. B. Westcott & Co. for an explanation, and here is what they say about it:

Dear Sir:—Your favor of the 6th Inst. is at hand, also our postal, sept. 22. What we meant by manufacturers' stock was dark extracted honey that was too dark for table use, and that we sold to manufacturers of crackers, to tobacconists and others, such as head men, etc. We did not mean to convey the idea that the honey is manufactured or adulterated. W. B. WESTCOTT & CO.

St. Louis, Mo., Oct. 8, 1888.

It was my impression, as soon as I saw it, that the report alluded to means the poor honey usually sold for manufacturing purposes as above. In view of the damage, however, that has been done to our industry, I think it behooves us all to be careful how we express ourselves. Had the above item read, "Second quality, dark extracted honey for manufacturing purposes, 4 to 5 cents," all would have been well, and perhaps no great harm has been done as it is. The report was made on a postal card, and the end of the word "manufacturers" ran off the margin, so it was a very difficult matter for the compositor or proof-reader to

decide just what the word was intended to be; but it certainly looks more like "manufactured" than anything else. By making the word terminate with *ers* instead of *ed*, the meaning would be quite different.

The Paris Exposition of 1889.

—Below will be found a circular letter issued by Hon. Norman J. Colman, United States Commissioner of Agriculture, and a supplemental directory note from N. W. McLain, Apicultural Agent.

WASHINGTON, D. C., Oct. 1, 1888.

The Congress of the United States having accepted on the part of this Government, the invitation of the French Republic to take part in an International Exposition to be held in Paris in 1889, has directed the Commissioner of Agriculture, by joint resolution approved May 10 last, to collect and prepare suitable specimens of the agricultural productions of the several States and Territories of the Union for exhibition at said Exposition.

A special division has been organized in this Department for this purpose, and a number of special agents have been appointed by me to collect suitable specimens for exhibition.

Statistics support the assertion that agriculture furnishes four-fifths of our exports, and it is to the interest of all our States and Territories that the United States should be creditably represented by this Department at the great exposition which the French people have organized at Paris, and which will attract countless visitors from all countries of the world. It is therefore needless to dwell upon the importance of the agricultural section of the United States exhibit.

In view of these facts, you are cordially invited to co-operate by every means in your power in the special work assigned to the agents appointed by this Department in this important duty.... This Department would be pleased to hear from you, and to get your views as to the most appropriate products of your section of country, and such as would be most desirable for the purpose indicated. Very respectfully,

NORMAN J. COLMAN,
U. S. Commissioner of Agriculture.

Please address all communications relating to bees, methods and devices used in bee-keeping, bee-forage plants, facts and statistics concerning bee products and methods of marketing, and methods of utilizing honey and wax in the arts and in manufacturing, to N. W. McLain, Apl. Agt. Div. of Ent., Hinsdale, Ills.

We hope that our readers will all feel interested in the effort being made to give to our chosen industry the prominence it deserves among other agricultural pursuits. Let each one determine what he can do to contribute to the success of this undertaking, and then act promptly.

No Honey from Buckwheat.

The Michigan Farmer prints the following concerning an experiment made by D. A. Jones, of Beeton, Ont., in taking 75 colonies of bees to 20 acres of buckwheat:

D. A. Jones, of Beeton, complains that though 75 colonies of bees were moved contiguous to 20 acres of buckwheat, at the opening of its bloom, the bees did not store any honey from it, but rather were compelled to use the stores already in the hives. The soil on which the crop grew was very poor, yet the buckwheat grew well and bloomed abundantly. The bees worked on it, but stored no honey. And he wants to know what the matter was.

At the Lennox Fair, lately held in Ontario, Canada, Mr. Allen Pringle made an exhibit, and this is what the *Napanee Express* says concerning it:

The exhibit of honey by Allen Pringle was quite an attraction, and was excellent for this year. It consisted of both granulated and liquid clover, buckwheat and basswood honey, and was shown chiefly in a dozen different styles of glass holders of various sizes; also styles of crates of sections. These were arranged in tiers one above the other, in square cone shape, being "topped off" by a couple of tin cans of honey. The exhibit was a surprise to many of those who claim to be adepts at bee-keeping. Mr. Pringle has made this industry a special study, and has advanced wonderfully.... Mr. Pringle also exhibited a honey-extractor and four hives of his own get up. The latter were tested last and this year, and Mr. Pringle was delighted with the results. They promise to be quite an aid to bee-keepers.

The awards were as follows in the Honey Department:

Exhibit and quality of comb honey, Allen Pringle, Robt. Metzler and L. Hartman.

Exhibit and quality of extracted honey, Allen Pringle, Robt. Metzler and A. Knight.

Money in Potatoes, by Mr. Joseph Greiner. Price, 25 cents. This is a complete instructor for the potato grower, explaining his new system in 40 lessons. For sale at this office.

A Magnificent Present

For every one who will send us a Club of five new subscribers for 1889, before next January. All the remaining issues of this year free to new subscribers.

**This ATLAS**

contains large scale Maps of every country and civil division upon the face of the Globe.

It is beautifully illustrated with colored diagrams, that show wealth, debt, civil condition of people, chief productions, manufactures and commerce, religious sects, etc., and a superb line of engravings of much historical interest & value, together with many new and desirable features which are expressly gotten up for this work—among which will be found a concise History of each State.

Price, in best English cloth binding (size, closed, 11x14 inches; opened, 22x14 inches), \$4.50.

To any one sending us direct to this office **FIVE NEW Subscribers** for one year, with \$5.00, (renewals not to count) we will present this beautiful Atlas, by mail, postpaid.

We have purchased one of them for our own use, and regard it as a valuable acquisition to our library. It is handsomely bound and contains a fund of very useful knowledge. It contains 192 pages.

THOS. G. NEWMAN & SON,
923 & 925 W. Madison-St., - CHICAGO, ILLS.

QUERIES REPLIES.

Average Yield Per Colony for a Term of Years.

Written for the American Bee Journal

Query 584.—What is an average yield of honey, per colony, for eight or ten years?—Illinois.

Twenty-five pounds.—MRS. L. HARRISON.

From 50 to 85 pounds, according to the location.—DADANT & SON.

In this locality (Michigan) about 30 pounds of comb honey.—H. D. CUTTING.

In my location (Georgia) it would be about 40 pounds.—J. P. H. BROWN.

Fifty pounds of comb honey, or 100 pounds of extracted.—EUGENE SECOR.

The average with me (Louisiana) has not been over 50 pounds.—P. L. VIALLO.

From 35 to 40 pounds in Michigan.—R. L. TAYLOR.

That depends upon the locality and season.—A. B. MASON.

More or less, according to locality. Fifty pounds would be a big average in my own vicinity—Massachusetts.—J. E. POND.

I guess that 75 pounds of comb honey, and 100 pounds or more of extracted. Perhaps that is rather too high.—A. J. COOK.

An average yield with me (Illinois) for such length of time has been about 40 pounds.—C. H. DIBBERN.

I have kept no statistics, and have but little idea; in my location (Indiana) I have got all the way from more than 100 pounds to nothing.—M. MAHIN.

In my location (New York) my average has been about 75 pounds per colony of comb honey, for the past 16 years.—G. M. DOOLITTLE.

I do not suppose that I could tell close enough even in my own location (Michigan) to give you any better idea than you now have.—JAMES HEDDON.

All depends upon the bee-keeper, the kind of bees, the kind of hives, and other appliances, and upon the location; all the way from nothing to 100 pounds per colony.—J. M. SHUCK.

I do not value very highly my reputation as a guesser, but I would not risk it on that. The question is a fair one, and I shall be glad to see the answers.—C. C. MILLER.

If I could forget the past three years I would say 50 pounds in my locality (Kentucky), but I have come to the point that I never expect to see any honey any more.—G. W. DEMAREE.

Much depends on location, and the care taken of the bees. Any estimate would probably be guess-work. In average years each colony should produce at least 75 pounds of extracted, or 40 pounds of comb honey in my locality—Illinois.—J. M. HAMBAUGH.

A "guess" is all that can be expected as an answer to the question. Our guess is about 50 pounds of both comb and extracted honey as an average for ten years, if that average is to include all the bee-keepers of the country. If only the more enlightened about 100 pounds. The specialists will average 25 pounds more.—THE EDITOR.

Removing the Queen to Secure More Surplus Honey.

Written for the American Bee Journal

Query 585.—1. Will removing the queen from a colony three weeks before the honey-harvest, secure more honey in the sections, instead of in the brood-nest, as the bees do after a swarm issues?—Ohio.

I have had no experience in that line.—A. B. MASON.

I think so, if I understand the question.—A. J. COOK.

I have never practiced this method. J. M. HAMBAUGH.

I do not believe it will, I do not understand the latter part of this question.—EUGENE SECOR.

No; if I understand the question, to do so would be disastrous.—R. L. TAYLOR.

In most of such colonies there would be less honey in the sections, and more in the brood-nest.—J. P. H. BROWN.

No. A good queen should be in the hive at all times.—C. H. DIBBERN.

Nothing can be gained by removing the queen, except that swarming may be prevented.—M. MAHIN.

It will secure more honey in the brood-nest, and less honey altogether.—DADANT & SON.

I do not propose to remove any good queen from any colony, unless I see better reasons offered for so doing.—H. D. CUTTING.

My efforts along the line of removal of the queen to secure a good yield of comb honey have all been failures.—G. M. DOOLITTLE.

No. If the queen be removed at the beginning of the harvest, and no queen is allowed to develop, and the honey-yield only lasts about ten days, *yes*; otherwise, *no*. Comb honey secured by this method is almost certain to be badly polluted with pollen, and

later on with the larvæ of the wax-moth. The best work and the cleanest crop can be secured only by having the colony *complete*—a good laying queen, a few drones, and a host of willing workers made cheerful by the perfect organization of their forces.—J. M. SHUCK.

The honey will not be used in rearing brood, and its place will be filled with honey. I would prefer a laying queen for this locality—Illinois.—MRS. L. HARRISON.

I do not think that it will. The question has been discussed somewhat in days past, but with the conclusion that it is unnatural, and therefore valueless.—J. E. POND.

I am not sure that I know what you mean by "as the bees do," but I doubt if removing the queen increases the surplus, unless indirectly by preventing swarming.—C. C. MILLER.

You will always notice that when a colony is queenless, that the bees will always store honey in all the brood-combs below, and it is only when they have a virgin or laying queen that they remove the honey to make room for the laying of the queen.—P. L. VIALLO.

No, sir, not in this locality (Michigan), and I am so positive that the idea is impracticable, if not nonsensical, that I am pleased to go on record as saying that it will never come into general use.—JAMES HEDDON.

I do not have room here to discuss this subject. If the queen is removed as described by you, the bees will store more honey because they will not have so much brood to feed. They will generally fill the brood-combs as the larvæ hatch out, after the fashion of a colony that has cast a swarm, and you will find that the extra consumption of stores necessary to replace the loss in way of bees, owing to the removal of the queen, will be greater than was the gain in honey by reason of the removal of the queen. Try it and report.—G. W. DEMAREE.

We doubt the policy of removing a good queen at any time from a colony of bees. Queenlessness is an abnormal condition, and should not be forced on a colony, except for good and sufficient reasons. It would probably result in having *less* honey in the sections instead of more, and *more* in the brood-nest, where surplus honey should not be tolerated in these days of enlightened methods of storing the surplus honey in neat sections containing virgin comb.—THE EDITOR.

NEW LAWS.

Defective Points in the New Constitution and By-Laws.

Written for the American Bee Journal
BY DR. C. C. MILLER.

At the last meeting of the North American Bee-Keepers' Society, some discussion was had with reference to increasing the usefulness of the Society, and especially with reference to making it representative in character. Some members warmly opposed any attempt at change, because impossible to carry out, and then with singular inconsistency at a later time, jumped to the other extreme and assisted in making such a sweeping change as to revolutionize the whole affair.

At the Chicago convention in 1887, Mr. Thomas G. Newman laid before the Society a carefully-prepared plan for carrying out important changes, evidencing no little amount of unselfish labor in the preparation. Mr. Newman is entitled to a hearty vote of thanks, and the committee appointed to report upon the matter, namely, Prof. A. J. Cook, W. Z. Hutchinson and A. I. Root, deserve a no less hearty vote of—censure, for their neglect to consider and report.

Without in the least detracting from the labors of Mr. Newman, I consider the action of the Society in adopting an entirely new constitution and by-laws, which, it is pretty safe to say, but few of them had read—I consider the action at least hasty. It was probably more than was expected by its framer, for in presenting it at Chicago, he said, "Your committee can easily exclude, revise or make new provisions to suit their own views." Nothing of this kind was done, and it may be pertinent to ask whether the Society were any better prepared to take action at Columbus than at Chicago.

However, it is perhaps well that hasty action was taken, rather than no action at all, and in the columns of the bee-papers is a good place to discuss what changes, if any, should be made; in fact it is entirely in order to discuss the whole matter in all its bearings. I feel sure that friend Newman will not call in question my good intention, even if we should somewhat differ in our views. Indeed, I am confident that he will welcome the most rigid scrutiny.

The most prominent change attempted is that of making the Society representative, and if that intention

can be fully carried out, the new Constitution will be a blessing, even if it makes a less approach to perfection than it now does. But it must be remembered that the Society can only *invite*, not compel representation, and on that account it may be better to discuss the matter here than at the sessions of the convention. My only fear is, that those who are not in connection with the Society, may fail to give to the subject the attention it deserves. And now, if you please, I will consider somewhat in detail the new Constitution and By-Laws, as published on page 695.

Criticisms of the Constitution.

1. The first article reads, "This organization shall be known as 'The International American Bee-Association,' and shall include in its territory all of the United States and Canada." The very pleasant meeting at Toronto is too fresh in my memory to make me feel that the exclusion of Canada would be anything less than a calamity, and the name "International American" was evidently framed with that in view, and on that account is eminently proper. The name is, however, somewhat cumbersome. As "International American" means among the nations of America, and as the nations of America are all American, would it not be equally well to simply call the Society "American Bee-Association," or, still better, "American Bee-Society?"

2. Section 3 of Art. III, requires a majority vote for the reception of each member. Is it necessary to take time for this? In all the history of the Society has there ever been a case in which an applicant would have been voted out?

3. Without being very fully informed on the subject, I doubt the expediency of Art. VII, which says, "Special meetings may be called by the President, Secretary and Treasurer."

4. The last clause of Art. II of the By-Laws makes it the duty of the President, "at the expiration of his term of office, to deliver an address before the Association." Even with so good a President as Dr. Mason, I think the time could be more profitably occupied in discussion, and if the Doctor should be impeached for a violation of this clause, I will try my best to defend him.

5. The fourth by-law requires the Secretary "to call the names of the members of the Association at the opening of each annual meeting." Except for the time taken, this can do no harm, but in a society so migratory in character, it can do little good. Had the roll been called at Columbus, only twelve would have answered.

6. It is also made the duty of the Secretary "to give notice of all regular meetings of the Association in the bee-papers, at least four weeks before the time of such meeting." Would not "at least three months before" be better?

7. According to Art. VIII, a "Honey Company" is to be formed to sell honey. If no thought is given to this before the formation of such "Honey Company" at the Brantford meeting, will it not be a failure? And is not the whole business of honey-selling something so out of the usual line of the Society that it should have been carefully discussed before agreeing to enter upon it at all?

Another item that might well have received some consideration before its hasty adoption, is that of "prizes for honey" in Art. IX, Sec. 2, Sub-Sec. (2) of the By-Laws; and still another is found in Art. XI, relating to giving diplomas to experts in bee-keeping. However well this may work in England where bee-keeping stands on a different basis, and where distances are not so great as in this country, it may well be questioned whether it is desirable or practical in the United States and Canada. Even granting that the committee of three, who are to examine candidates, may make arrangements so that each one of the three may act separately, I doubt if the three members can be so located that there shall not be points of territory one or two thousand miles distant from any or all of them.

Discussing Its Merits.

It may be asked, what good will come of discussing these things now? In reply I may say that it looks to me that when it comes to the matter of carrying out the provisions of the new Constitution and By-Laws, discussion will, almost of necessity, arise, and it may be the better way to look everything squarely in the face, and instead of spending time in the convention, discuss the affair in the columns permitted for our use. It is true that I am talking about what I know very little about, and it is quite possible that I am far from right about some if not all the points mentioned, but others may be just as ignorant as I, and light will hurt none of us.

As I have already intimated, the one thing in the new Constitution making the Society representative, if successfully carried out, over-balances all the defects I have mentioned, if such defects really exist.

WINTER FOOD.

Some Observations on Feeding and Wintering Bees.

Written for the Farm, Field and Stockman
BY S. E. MILLER.

If the fall finds your bees short of a winter supply of honey, feed about a quart of syrup or honey every evening until they have sufficient. If you wish to use syrup, and do not know how to make it, use this recipe: Take about four parts of granulated sugar to one of boiling water, and boil till the sugar is well dissolved. This will all be used up before you get any surplus the next season, so you need have no fear of having your honey mixed with sugar syrup.

If the bees seem backward about taking the feed, give it to them warm, and pour a little down among them, and then make a trail of syrup or honey to the feeder.

While a great part of the bee-keepers, and perhaps the majority of them, are in favor of cellar wintering, and while I have no doubt that it is best further north, I do not believe that it will pay to go to the trouble of cellar wintering in this latitude (Central Missouri). Still, the bee-keepers having the largest apiaries in Montgomery county, practice cellar wintering, and I should not advise those having suitable cellars to leave their bees outside if they believe in wintering bees in the cellar.

My brother and I have wintered our bees out-of-doors for the past three winters with fair success; our apiary, however, is well protected on the northwest, which may have something to do with it, and I should advise all who winter their bees out-of-doors to have some kind of a wind-break to shelter them from the prevailing winds.

In case you have to feed, it should be commenced as early as you can tell whether there will be a honey-flow or not from autumn flowers. If neglected too long, the bees may not be settled down for winter when it sets in.

When through with preparing your bees for winter, you will most likely have a lot of combs to be taken care of through the winter; if containing honey, they should be kept in a dry room, where the temperature never gets much, if any, below freezing. They should be looked after occasionally, if there is much warm weather, to see that the moth does not destroy them. These combs, if containing honey, will come handy in the spring, if you find any of your colonies running short of food.

Montgomery, Mo.

Some Autumnal Api-Thoughts.

Written for the American Bee Journal
BY GEO. W. YORK.

The summer now is ended,
The bee its work has done—
Its hum no more extended
To greet the morning sun.

Its days were full of toiling,
In garnering the stores,
Lest much of it bespoiling
On fields, side hills and shores.

The bee hath hastened ever,
That time may not be lost,
To gather up what never
Should waste at any cost.

And now the winter cometh—
With cold and stormy breeze—
"That tries the souls of men,"
And sometimes those of bees;

But frugal little workers,
With stores of nectar sweet,
Are never like the shirkers,
Who nothing have to eat.

Then quietly they cluster,
Between the combs so snug—
All ready for spring muster
Is every "honey-bug."

Chicago, Ills., Oct. 22, 1888.

PURE BEES.

Parthenogenesis Discussed— Rearing Pure Bees.

Written for the Home and Farm
BY T. E. HANBURG.

This is a subject every apiarist should understand. Without an accurate and thorough knowledge of this theory, the practice of bee-culture cannot be conducted with the skill and judgment necessary to successful results.

This theory as applied to the honey-bee is, that the eggs of a virgin queen will hatch, but that such eggs will only produce drones, and for the eggs of any queen to produce workers or queens, she must be fecundated once in life by a drone.

If this drone is impure or is tainted with black blood, the progeny of such a queen will not be pure Italian bees, and hence, the workers will not be uniformly marked with the three distinct yellow bands which always characterize the pure Italians. Some of these bees, it is true, may have three bands, but others will have only two, and some one, hence they will be pure, mixed bloods or hybrids.

If now a queen should be reared from the egg of such a queen, and even though she mates with a pure Italian drone, her progeny will not be pure. This is the reason that so many commence with Italian bees and after a while they run backwards into hybrids, and should a queen be reared from the egg of this latter queen, the resulting workers will run still further

backwards until they are black bees. It will thus be seen that a contamination, be it ever so slight, will lower the standard of the pure bees.

A theory has been advanced which has a large number of adherents, that an Italian queen will always produce pure drones, no matter with what kind of a drone she has mated. I do not accept this theory, but reject it in part, with all due respect to the opinions of many eminent apiarists. They claim with due force, and that which is true, that the sperm of the male is so managed in the oviduct of the queen that she can impregnate the eggs, or not, as they pass down through the oviduct, and come in contact with the spermatia which contains the male sperm. All eggs thus passing without touching and absorbing some of the male sperm produce drones only, and that the eggs, becoming thus impregnated, marvelous as it is, produce queens or workers, according as they are treated by the bees.

They claim that which is true, that the queen can and does impregnate these eggs at will. Of course, eggs thus passing the oviduct without coming in contact with the spermatia, produce drones only. This theory I do not carry further, and believe in its entirety.

It is a well-known fact that if a pure leghorn pullet mates but once with a black Spanish cock, her chicks ever afterwards will occasionally show a black feather; and by like reasoning and by observation which comes by a long practical experience, I believe it is so with bees.

If those who fully hold to this theory think that the mating of an Italian queen with a black drone, has no effect on her progeny, they must be somewhat in error, for certainly by absorption the queen's blood becomes somewhat contaminated, as the effect of such mating. She may be able to produce pure or nearly pure drones, but the contamination is in her blood all the same, which will show to some extent in her workers, and of course, if an egg from such a queen, which would have produced a worker be so treated that it produces a queen, such a queen will not be a pure Italian, but will be hybrid, and her drones, of course, will partake of this quality.

It is generally conceded that it is rare that an Italian queen will duplicate herself in her daughters. The old queen may produce workers, every one of which will show the three distinct bands, but her daughters, as a rule, will produce bees that vary in this respect. This may be owing to the daughter's mating with a half-blood drone, or it may be owing to the mother or grandmother, etc., hav-

ing been impure. This rule holds good with fowls, as has been stated.

With the mammals it may be claimed by some that impurity is caused by carrying the young in the uterus, and thus the blood of the mother becomes contaminated with the blood of the sire; but with the fowl such cannot be the case, and the impurity, as with a queen-bee, must be caused by absorption of the male sperm. This, of course, is reasoning by analogy, but the presumption is that such reasoning is correct. I therefore leave it for the readers to decide, if a pure Italian queen mates with a black drone, will her drones after such mating be pure?

I have known queens whose progeny would be uniformly marked with the three bands. These bees would be quiet, easily handled, little given to stinging, good nurses, excellent honey gatherers, would cling quietly to their combs while being manipulated, and in every respect were model bees.

I have known a second queen reared from this first queen, and although she undoubtedly mated with a pure Italian drone, her bees would be unevenly marked, given to stinging, and when the hive was opened, would be restless, crawling here and there in the utmost confusion. It might be said that there was a mistake here, and that this queen mated with a black drone, but I do not think this falling off is always to be accounted for in this way. The queen away in the long ago was contaminated, and this contamination shows out occasionally. Of course, when a pure queen mates with a black drone, the resulting bees are hybrids, and they may also be contaminated in the above manner.

It will thus be seen that every bee-keeper who wishes to have pure Italian bees must be vigilant and careful. When he has a queen that produces pure bees, and he rears queens from her, he should see to it that, when she flies out on her wedding tour, no drones are allowed to fly whose mothers are not pure, and whose progeny in every instance shows the marking of pure Italian bees.

It appears from this that those who rear queens should pay careful attention to having pure drones; and by seeing rigidly to it that none but pure drones are allowed to mate with these queens, he can build up impure queens into a state of purity little inferior to those which come from sunny Italy.

I do not tolerate impure queens or drones in my apiary, and he who loves bee-culture, must breed upwards and not downwards. If this course is pursued, he will be amply repaid in many ways. It is also good to occasionally purchase a queen from a distant

breeder with which to cross the blood, and to stop in-breeding.

Carefully note the progeny of every queen, and tolerate those only which are pure, and which show in every bee the three distinct yellow bands. Keep your bees pure, and you will not only be rewarded with large crops of honey, but you will derive a greater pleasure from a calling which is not only honorable and lucrative, but elevating and ennobling.

WINTERING BEES.

Best Age for Bees to Go into Winter Quarters.

Written for the American Bee Journal

BY J. E. POND.

As is well known, I always winter my bees on the summer stands, and for years I have met with practically no loss. This I conclude depends more upon preparation than any other cause, and after repeated experiments I have come to the conclusion that extra-late breeding makes no real difference in results.

For years I had the idea that late-bred bees must winter better than those that were older, but the theory, plausible though it be, is not borne out by the facts; that is to say, I get no better results in wintering from causing the late-breeding, than I do from allowing strong colonies to manage the matter as they please.

Of course there are exceptional cases. If a colony is weak in late summer, from any cause, such as a poor queen, or the queen being crowded out by an extra honey-yield, as may happen at times where the greatest care is used, then I may be obliged to strengthen up my colonies for winter, by forcing the queen to the latest possible point of time; but under ordinary conditions, I find that bees bred as ordinarily done, with no special attempt to force the matter, go through the winter fully as well, and come out in the spring fully as strong, as with forced breeding; and such being the case, I am of the further opinion that too much interference in that direction, at the hands of inexperienced persons, under the instructions as given at the present time, will prove hazardous, and do more harm than good.

I do not think that in the hands of experienced men, late breeding will do any harm, but I fear that those who attempt the matter without knowing just how it should be done, will fail in the work.

Late breeding artificially, is rather against the natural law, and any va-

riation from that law, must be made on certain lines, else failure must ordinarily result; for this reason, I advise those only who have large experience, to attempt the matter on a large scale. Those who have no large experience, should go slow, and gain that experience by working on a colony or two only, until they fully understand the matter.

North Attleboro, Mass.

FALL WORK.

Some Hints about Necessary Seasonable Work.

Written for the Prairie Farmer

BY MRS. L. HARRISON.

Whatever work has to be done with bees should be done before they enter the quiescent state. They should have stores enough to last till flowers bloom, as spring is a poor time to disturb them. Feeding during early spring excites them to an unusual activity, and they fly out, get chilled, and never return. Many a colony, that swarms out in early spring, might be traced to some disturbing cause. I had a nucleus pass a very mild winter on its summer stand. I was so pleased about it, that I began to coddle it, and put frames of honey back of the division-board. It soon began to carry the honey into the brood-nest, became very lively, and in a few days swarmed out, and was destroyed while trying to enter a hive containing a large colony.

"Of all sad words of tongue or pen, the saddest are these, 'It might have been!'" Had I let them alone, they might have built up into a good-sized colony by the time flowers bloomed. Bee-keepers have arrived at the conclusion that the best time to do spring work in the apiary, is to do it in the fall; or rather, anticipate and do all that is necessary, and not disturb them in the least until warm weather has come to stay.

Frost Not Yet Injurious.

There have been several frosts, the first occurring in this locality Sept. 27, but not sufficient to injure grapes or kill tomato-vines in our garden up to date, Oct. 2. The golden-rods and asters appear to be but little injured, and, as the days are quite warm, may continue to yield a little honey.

Death of the Drones.

Bees conclude that the season is over, and that they cannot afford such luxuries as gentlemen of leisure. Father Langstroth kindly gave him a day in court, and ably defended him against his accusers, but his eloquence

was all wasted, for he is persecuted as badly now as ever. It is pitiable to see him walk the plank, with a policeman each side of him as he sings the death-watch.

But the law of the hive is "the greatest good to the greatest number," and must be obeyed by the highest as well as the lowest, queens, drones and workers. He fares no worse than the rest; as soon as the queen becomes infirm or is injured, unfitting her to perform her allotted duties, she is carried out and another reared to fill her place. So also it is with the workers.

It is no use for the drone to plead that he is not to blame for idleness, that he has no bag to carry honey in, for he is told, all the same, that his room is better than his company. He submits with more grace to his fate than do some of the human family, who are now suffering under severe quarantine regulations, to prevent "the pestilence that walketh by noon-day," spreading itself all over this fair land. "The greatest good to the greatest number," is a very good rule to observe, whether in communities of bees or of men.

Removing Surplus Honey.

The sooner surplus honey is taken from the hives the better, for Italian bees are always looking out for No. 1, and will fill up the brood-nest as fast as it is empty. I have been surprised many times to see the difference between black bees and Italians in this respect. After removing boxes filled with surplus honey from the black colonies, I would find that the body of the hive was nearly empty, while the Italians were full—more provident, it seems.

I removed a case of sections lately in this way: I removed the cover and sheets, and blew smoke down through them, driving the bees below, when it was removed, and carried into the honey-house. A few remained, which gathered in a cluster upon the window, and when it was darkened and the door open, flew out. When Dr. Miller removes his cases of sections, he piles one upon the other, until they are five or six high, and places a little tent, made something like an Indian wigwam or tepee, on top. This can be made of mosquito-netting, with rubber elastic in the bottom, to fit nicely around a case, with a hole in the top. Smoke does not issue out of this hole, but bees do. It needs some sort of a frame-work, either of wire or of wood, to hold it up.

Where there is only a small amount of honey secured in close boxes, or those made by nailing sections together, a barrel is a good receptacle to put them in while the bees are leaving

them. It should be covered closely, so as to be dark inside, and have a little hole by which the bees can escape; they will see the light and come out, while robbers will not find it. Sometimes it is well to pry up the cases or boxes one day and leave them until the next. If the night following is cool, the bees will all cluster below, and they can be removed early in the morning, when there are no bees in them.

Peoria, Ills.

BEE-LANGUAGE.

What the Bees have Taught Us —They do Hear.

Written for the American Bee Journal
BY J. O. SHEARMAN.

On page 599, Dr. Miller states that the young queen utters a "shrill cry, pe-e-p, peep, peep," replied to by the young queens in their cells, "quahk, quahk." Now is it possible that as fully developed a bee-master as Dr. Miller, does not know that the queens make the noise with their wings? Such is the case, however. I have seen them do it—a short, quick, vibratory motion; and the hoarser "note" of the queen in the cell is caused by its confined position—though they have room to make the motion all the same.

It seems to me that this alone should settle the question, "Do bees hear?" Why do they make any noise else? What is hearing anyway, but a concussion of the waves of sound upon any sensitive object, whether it be ears or the soft parts of bees *all over them*. We all know that bees are very sensitive, and their sense of sight, smell and taste are more acute than most other animals; and I claim they are equally sensitive to sound. Why, they even have a bee-language, and I know it, for I have learned a part of it by practice—all by notes made by their wings moving in different ways, and with different velocity.

A worker bee can make a noise in the same way that a queen does, but it sounds more like "perrr" to her "peep." Then it is easy to tell just when a swarm starts, even with my back to them, at 10 or 12 feet distance (and often more), and right in a yard full of bees that make a great deal more noise than the swarm does when first starting.

I could give many more instances, such as the change in the note when a queen is given to a queenless colony, even while she is in the cage; also their "call," when bees start for the hive, if they are shaken down in front of it. But what is the use? We all know it.

Further, as to the usual combat when two or more young queens hatch, only the one first recognized by the bees goes on the "war path," as I call it. The rest avoid her, and each other, until they happen to meet, or else are expelled by the bees, or go out with the second swarm, as it sometimes happen with even 3 or 4 young queens. Then in that case the bees "ball" all but the first one, after being hived.

New Richmond, Mich.

QUEEN-REARING.

Effect of the Swarming Impulse on Queen-Rearing.

Read at the Wabash Co., Ind., Convention
BY J. J. MARTIN.

Every bee-keeper knows the importance of having a strong and vigorous queen in order that the colony may be profitable; and in order that we may have good queens, the queen-rearer studies and makes use of all the means possible to bring about the desired result, so that the queen-bee or mother of the colony, may possess as far as possible all the good qualities, such as honey-gathering, gentleness, etc.

It is the general impression with most bee-keepers that the only good queens are those reared under the swarming impulse, which I admit is a correct view in one respect; but I am prepared to say that better queens can be reared by what is termed the "artificial process" by some bee-keepers. Yet it is the natural process after all, with the assistance of the queen-breeder, whose knowledge in this particular line should be of value in proportion, as it is in any other department of the apiary.

The swarming impulse can be brought about without waiting for it naturally, by removing the queen from a strong colony and uniting with this colony young bees from other colonies, until the hive is overflowing with bees; then remove all the eggs and unsealed brood, and give the colony eggs from a selected or imported queen, and the colony will build from 15 to 20 queen-cells. The great advantage gained over natural swarming, is in having the cells built from the eggs you wish them.

In twelve days the cells will be sealed, and can be cut out and placed in the queen-nursery, or in queenless nuclei, to hatch, always selecting the best and most nearly perfect cells. If hatched in the nursery they are introduced to queenless nuclei or colonies, and in five days they fly out to meet the drone.

Here is another point of great advantage—allowing drones to fly only from selected colonies, all others being kept in the hive by the use of perforated zinc, or by the use of the ordinary drone-trap, thus mating the queens with the selected drones, or just those desired. This, I think, makes a gigantic stride, in my estimation.

It is sometimes argued that there is so much danger of queens mating with black drones from a neighboring forest, or from a colony of black bees, kept by some one in the vicinity of the apiary, but I believe it is only a rarity where this occurs, when a large number of drones are present in the apiary; for, from close observation, I am lead to believe that the virgin queen flies but a very short distance until she meets the drone and returns to the hive.

After mating, the queen will usually lay in three days, and if she lays in worker-comb, we may safely conclude that she is properly fertilized. Now, to cull again, take only those which are large and vigorous.

We have queens superior to those reared by the ordinary colony without any assistance. To the average bee-keeper, this is of but little interest, as the rearing of a small number of queens would necessitate the disturbing of one or more of their best colonies, during the very best of the honey-flow. It would prove quite expensive, if only a half dozen or more queens are wanted, as the same colonies would gather more honey during the 25 or 30 days required in hatching and mating the queens, than would buy the same number.

North Manchester, Ind.

CONVENTIONS.

The Importance of Being in Attendance, etc.

Written for *Gleanings in Bee-Culture*
BY PROF. A. J. COOK.

Since returning from the meeting in Columbus, I am more than ever convinced of the value and importance of such gatherings. I have always felt that there could be no mistake in this matter. The common practice of all intelligent societies sustains this position. We say the farmers, as a class, have suffered from isolation and the lack of such associations, and that the Grange was a God-send to the farmer, in that it supplied this long-felt want. Mr. Heddon and I have often argued this matter *in extenso*, both by word of mouth and by letter; and while I have very great respect for Mr. Heddon's ability as a bee-keeper, which is rarely

surpassed, I cannot but believe that in this matter he is wholly wrong. The opinion of the world, as expressed in actions, is with me, and not with him.

There is one serious obstacle in the way of making our meetings in the highest degree satisfactory; that is, the great size of our country. If our association is to warrant calling it North American, we must not limit the meetings to one section of country, nor have we done so. New York, Rochester, Toronto, Cleveland, Detroit, Columbus, Lexington, Cincinnati, Indianapolis, and Chicago, are wide apart. I think it would be well to go to St. Louis, Louisville, Philadelphia,* Pittsburg, Richmond, and New Orleans.

But it has always appeared to me that such meetings were more successful where some one appeared in person, invited the association, and so became in some sense responsible for the success of the meeting. Thus it was that I moved and favored the going to Brantford next year. I feel sure that Mr. Holtermann will spare no pains to make the meeting a success. I should have preferred, had we been invited, to go to St. Louis or Kansas City.

Now, if we thus migrate we cannot expect to have the same persons present each, nor representatives from all sections. It is too expensive. Of course, if State associations would appoint and bear the expenses of delegates, this might be done. But from my observations in other associations, I much doubt the success of any such plan, much as I should like to see it succeed. Yet for all this I still think we can make the meetings representative.

While we may not secure the personal presence of Smith and Jones at each meeting, we can secure their brains, their thought, which, after all, is what we want. I believe most thoroughly that what we need and must secure is such action by our Secretary, in preparation for each meeting, as will call forth in brief, say fifteen minutes, carefully prepared "papers," the best that is known, from the best bee-keepers of the several States. I say, "prepared papers." I mean just that. Then we get mature views, and concise, well-digested pointers. Our best men will do better, when time is taken to carefully prepare themselves.

Thus we shall have a dozen or fifteen just such admirable presentations as Dr. Tinker gave at Columbus. Then we have a representative meeting. We have some facts of real value presented from all sections. We have some topics to hold us in our discussions. Oh! but it did me good to have my dear friend Dr. Mill—but I must

not call names—say to me at Columbus, "I believe you are right in this matter of papers." It is such a comfort to see our friends converted. If I could only get Mr. Heddon out to conventions, I should soon have him on my side as to their importance.

I hope this matter will be fully discussed. I desire that our next meeting be a grand success, and thus a type of the many more to follow it. I believe these meetings may be a great blessing to all, not only to those who attend, but to those who stay at home. I have made some suggestions in the above. Who will speak next?

Agricultural College, Mich.

Mr. A. I. Root, editor of *Gleanings*, remarks as follows on the subject:

Friend Cook, I heartily agree with all you say; and although I myself am much inclined to backslide a little, especially if I do not attend the conventions for a while, I never get home without feeling that I am a wiser and a better man, and with a feeling, too, that I have been fulfilling better the purpose for which God placed me here upon this earth. In other words, I do believe that the man who stays at home hurts himself. The great troubles and trials that beset us through life are often caused by not being acquainted. The uncharitableness, the greed, and selfishness, which we see exhibited are the consequences and outgrowth of staying at home—yes, oftentimes of sticking to business. Of course, there are people who do not stick to their business enough, or, perhaps, not in the right way; but they are exceptions to the general rule. Inasmuch as our good friend, the editor of the AMERICAN BEE JOURNAL, gives a carefully prepared report of all the proceedings of the convention, we have not thought best to take space for it here; but I want to speak a little of the social time we had outside of the regular meetings. . . .

Before our last evening assembly opened, we were informed that the Senate Chamber, which we occupied, must be vacated exactly at 9 o'clock, for another crowd. Yankee-like, we inquired what the next crowd were going to do. The reply was, that a large company of male jubilee singers were to practice on some campaign songs; and when we suggested that the bee-men were fond of music, we received a very cordial invitation to remain. Well, the singing was the grandest and the finest, I believe, I ever heard in all my life. It never dawned upon my simple understanding before, that the human voice unaided is capable of such flights of melody as we had there. These singers, of course, and the audience, were,

as a rule, members of one of the great political parties. Bee-keepers do not all think alike, nor vote alike, and I do not know but I should be a little ashamed of them if they did; but I was happy to hear those who hold different political views from the sentiments of the campaign songs join heartily in the enjoyment of it.

Our talents, abilities, and accomplishments are in different lines. Friend Newman is, perhaps, not so much of a bee-keeper as some of the rest of us; but he has a wonderful gift in the ease and clearness with which he makes himself understood to everybody. President Mason had to be continually telling us to speak louder, while friend Newman could, without doubt, make himself heard and understood to a thousand people. He is perfectly at home and at ease in addressing an audience, while a great many, like myself, feel neither at home, nor exactly at ease, in such a place.

On the Centennial grounds is a great building erected exactly on the plan of a half-sphere—an immense dome, so high and broad that one speaker can easily make himself heard by 12,000 people. Not a stick of timber, nor a pillar, nor even an iron-rod, breaks the space enclosed; and we soon discovered that the acoustic properties of the building are wonderful. A piano and an organ stood there invitingly open; and by a little persuasion Dr. Miller was induced to sit down and sing my favorite hymn, "The Rock that is Higher than I." To my surprise, and perhaps a little to his surprise also, he discovered that his voice would fill the room easily; and before he got through, several came forward and joined in the hymn. Then we had the pieces which we give in this issue, and on page 756 of the last number, and several more joined in the chorus. One friend attracted our attention by his beautiful voice, and Dr. Miller asked him if he was a *bee-man*. He said he was not a *bee-man*, but we found out he was one of the 150 who surprised and delighted us at the campaign meeting the night before; and as we chatted with him we felt that we had found a new brother—yes, a *brother in truth*, although those that sang together represented the politics of at least three of our great political parties. . . .

There are grand enjoyments provided for us, even in this world, in the way of using our eyes and ears and other senses intelligently; and the only way to use them intelligently is to get acquainted—to know by face and to know by reputation; and if we stay at home there is no way in the world by which we can know about and enjoy

in the *right way* these things God has, in his wonderful wisdom and love, provided for us.

*Prof. Cook seems too have forgotten that the sessions of 1873 were held at Louisville; 1874 at Pittsburgh, and 1876 at Philadelphia. In 1885 the International Congress, a similar meeting, was held in New Orleans—taking four out of the six places named, and leaving but St. Louis and Richmond.

The next meeting at Brantford, we feel sure will be the greatest success of the present decade. Mr. Holtermann intends to leave no stone unturned which may be used to advance its interests. Prof. Cook is quite right about having some one interested, on the spot, to manage the matter.

Any meeting not having a full programme of carefully prepared essays, will be more or less of a failure, as Prof. Cook says. The foundation is now laid for making the Society a grand success, and all our energies must be devoted to that object from now until the next meeting at Brantford.

SAFE WINTERING.

Methods of Preparing Bees for Safe Wintering.

Read at the Wabash Co., Ind., Convention
BY AARON SINGER.

This subject is a puzzler. After we read the current literature on the subject of wintering bees, and find all kinds of ways and devices set forth for the successful wintering of our colonies, yet we are at a loss to come to a correct conclusion in this matter, as to which is the best and cheapest way to winter bees successfully. If each bee-keeper were asked separately, as to his ideas of wintering, I doubt very much if any two would agree on all points. So the best that I can do, is to give my ideas on this subject without trying to follow any of our great leaders.

To winter well, colonies should go into quarters strong in bees, as there will be more heat generated when it is necessary by a strong colony than by a weak one. All will agree that a certain amount of animal heat is essential to the vitality of the colony. The question then arises, how can we best pack or prepare our bees so as to retain the greatest possible amount of heat?

Many, perhaps, have observed that colonies having plenty of good stores, winter well in the old-fashioned box-hive. The bees generally glue shut all cracks and crevices near the top with propolis, this being no doubt done to keep the heat from passing off so rapidly. The combs are generally built so as to form a double wall on the outside of the cluster, and in this way the bees form a natural double-walled hive for their own protection against cold. This will lead us to the conclusion that the colony in a movable-frame hive should have more protection around the hive than a single wall affords.

Winter Protection for Hives.

I use something like this, as an additional protection around the outside: Make four sides of a box separately, out of rough lumber, about 10 inches larger each way than the hive, and about 10 inches higher. These separate pieces can then be placed around the hive and nailed at each corner with two nails. The hive is then enclosed in a box with 5 inches of space around the outside.

An entrance must then be left to the hive through this space, which can be made by nailing together two boards about a foot in length, and 8 or 10 inches wide. Put two strips about one-half an inch thick, between the boards near the edges before nailing together, and then you will have a passage-way through the boards one-half an inch in height by nearly the width of the boards. Arrange this so that one end of the opening is against the entrance to the hive, and the other end protruding from the box. This gives the bees a place of ingress and egress.

Then all the space between the hive and box can be filled with sawdust to the top of the box. After this is done, cover the box to keep out rain, and let the bees alone.

These boxes can be taken apart and piled up when not in use, and they will last a long time.

A very good outside protection is to shovel snow all around against the hive; but there is an objection, that this has a tendency to jar the bees and cause uneasiness.

Accumulation of Moisture in Hives.

The accumulation of moisture is one of the drawbacks in wintering. It is advisable that some arrangement be made for it to escape from the cluster, without allowing much of the heat to escape with it. A sack made of some light material, the size of the hive on top, and filled with clover chaff, or some like material, makes an excellent covering for the bees in winter.

This absorbs the moisture arising from the cluster, and at the same time it does not let the heat pass off rapidly.

Good Stores for Winter.

Another very essential thing is plenty of good stores of honey. I would pay but little attention to pollen, for I am not able to say that it does much damage in excess of its good.

It is a question whether it pays to take all the honey from bees and give them a substitute in the form of sugar, as it is quite an additional amount of labor to make the exchange properly.

Some bee-keepers prepare their bees for winter with no labor or expense, by just letting them stand as they were at the close of the honey season, with all the fixtures and everything on the hives. This is a very cheap way to prepare bees for winter, but the outcome in the spring is expensive to them in losses, besides the remorse of conscience which should come to all such, for cruelty to their living property.

In conclusion I would say, put an absorbent on the hive; leave the entrance open; protect the outside of the hives in some way; see that all colonies are strong in bees and natural stores—and then give them a good letting alone!

Wabash, Ind., Oct. 20, 1888.

Convention Notices.

The Nebraska State Bee-Keepers' Association will convene at Lincoln, Nebr., on Jan. 9, 10 and 11, 1889. J. N. HEATER, Sec.

The Pan-Handle Bee-Keepers' Association will hold its next meeting in the K. of P. Hall on Main St., between 11th & 12th Streets, in Wheeling, W. Va., on Nov. 21 and 22, 1888. All bee-keepers are cordially invited. W. L. KINSEY, Sec.

The Marshall County Bee-Keepers' Association will meet at the Court House in Marshalltown, Iowa, on Friday, Nov. 16, 1888, at 10 a.m. All bee-keepers are cordially invited to meet with us, and bring along anything that they may have that will interest or benefit apiarists. J. W. SANDERS, Sec.

The next regular meeting of the Stark Co. Bee-Keepers' Society will be held in Grange Hall at Canton, Ohio, on Saturday, Nov. 3, 1888, at 10 a.m. Matters of importance to bee-culture will be discussed. Every bee-keeper is requested to be there. MARK THOMPSON, Sec.

The Alabama State Bee-Keepers' Association will meet at 10 a.m. on Wednesday, Nov. 14, 1888, at the office of the Secretary of the State Fair (in the Fair Building), in Montgomery, Ala. Members are urged to attend, and all persons interested in bees and honey are cordially invited. J. M. JENKINS, Sec.

International Bee-Convention.

—The Pamphlet Report of the Columbus, Ohio, Convention is now issued, and copies have been sent to each member, as well as to the Colleges, Agricultural and Horticultural Societies and periodicals devoted to the industry. Copies can be obtained at this office, by mail, postpaid, for 25 cents. This pamphlet contains the new bee-songs and words, as well as a portrait of the President. Bound up with the history of the International Society, and a full report of the Detroit, Indianapolis and Chicago conventions, for 50 cents, postpaid.

CONVENTION DIRECTORY.

- 1888
 Nov. 3.—Stark County, at Canton, Ohio.
 Mark Thompson, Sec., Canton, O.
 Nov. 14.—Alabama State, at Montgomery, Ala.
 J. M. Jenkins, Wetumpka, Ala.
 Nov. 16.—Marshall County, at Marshalltown, Iowa.
 J. W. Sanders, Sec., LeGrand, Iowa.
 Nov. 21, 22.—Pan-Handle, at Wheeling, W. Va.
 W. L. Kinsey, Sec., Blaine, O.
 Dec. —Michigan State, at Jackson, Mich.
 H. D. Cutting, Sec., Clinton, Mich.
 1889.
 Jan. 9-11.—Nebraska State, at Lincoln, Nebr.
 J. N. Heater, Sec., Columbus, Nebr.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

SELECTIONS FROM OUR LETTER BOX

Mammoth Mignonette.—Mr. B. C. Griffith, of Griffith, N. C., on Oct. 18, 1888, says:

I send a part of a plant which please to name through the BEE JOURNAL. It seems to be a good honey-plant; my bees have been on it more or less since the last of May—five months—and it is still in bloom. If it is of value, I would like to know it.

[It is *Reseda grandiflora*, or mammoth mignonette, a good honey-producer.—Ed.]

An Aster.—J. O. Dedman, Harrodsburg, Ky., on Oct. 4, 1888, writes as follows:

Inclosed is a sprig of wild flower. I notice that when the flower I enclose and golden-rod grow together, the bees hardly notice the latter. Can you tell me what it is? No one here can. It made its appearance very lately.

[It is one of the asters (*Aster tradescanti*), all of which are excellent honey-producers.—Ed.]

The Season in Nebraska.—A. E. Maley, of Auburn, Nebr., on Oct. 20, 1888, writes:

The spring of 1888, in this locality, was cold and rainy. The bees only made a living until July, when they began to fill up the hives. Melissa came into bloom in July, and the bees soon found it, but they did not work on it as well as on catnip. Buckwheat and heart's-ease yielded well, and some colonies stored 50 pounds in the sections. Bees are in good condition for winter, with plenty of sealed stores. There are no large apiaries in this part of the country, but there are some men going into the business in earnest. I know a man about 90 miles west of here, who cleared \$1,000 last year, from the sale of bees and honey.

Fall Honey Crop in Iowa.—J. W. Sanders, Le Grand, Iowa, on Oct. 23, 1888, writes:

I have met with a number of bee-keepers here, and all report no surplus honey this season until the latter part of August. Our bees began to work on the fall bloom about Aug. 20, at which time they were strong in workers, young bees and brood; so that if

cold, wet weather had set in, instead of good bee-weather, we would have had a general bee-tamine, for almost all were nearly destitute of honey, either in the surplus or brood-departments. It is seldom we see hives increase in weight as fast as they did from Aug. 25 to Sept. 3. In fact, the harvest continued good up to the first week in October. Previous to this harvest many had fears that they would have to feed their bees in order to have stores for winter. All are now rejoicing that we have plenty of young bees, winter stores, and some surplus. From what I can learn, I think that many got from one-fifth to one-third of a crop, while others have only a good storage for winter. Our white clover for next season looks well, and as all conditions at this time seem to be well for wintering, we hope for a good season next year.

Half a Crop of Honey.—L. Haun, Leavenworth, Kans., on Oct. 11, 1888, says:

We have had scarcely half a crop of surplus honey this year, in this locality, mainly obtained from linden and white clover. The smart-weed and other fall flowers have yielded abundantly for winter supplies.

Honey-Yield in Different Localities.—A. E. Howe, of Okemos, Mich., on Oct. 22, 1888, writes:

Are localities that yield honey in poor years better than those that yield nothing? Or are the localities that yield nothing just as apt to yield honey next year? Bees have done nothing here for two years, and the reason I ask the question is, I would like to move my bees to where I can do the best with them.

[The questions are unanswerable, because there is no rule by which to be guided. A poor locality may yield honey in a generally unfavorable season, by reason of its not being affected by the special cause of disaster in other localities. Almost a barren hillside (a poor place for bee-pasturage generally) may yield honey in its usual quantity, even when the valleys, usually depending on the rich clovers, may yield nothing, by reason of the sward having been killed by frost during the previous winter. We should prefer to risk the places having the best bee-pasturage in selecting a new location, even though they may fail once in a while.—Ed.]

Moving Colonies to New Pasture.—Vet Tucker, Shelby, Ohio, on Oct. 20, 1888, gives the following novel experience:

My apiary is situated in the village of Shelby, where there are 110 colonies of bees. Thinking this field might be overstocked, about Aug. 20 I moved 4 colonies 3 miles into the country, to an unoccupied field, where there was an abundance of buckwheat, asters and golden-rod. The next day after moving I visited them, and found them all right and busy. In a week I visited them again, and they were storing honey in the sections. Two friends were present at this visit, and I gave the bees two filled sections from the center of a crate on one of the colonies, and replaced them with empty sections. At my next visit this crate was filled, and I raised it and put an empty one under it.

A few days ago I brought them home, and upon examining the honey, I found that the above described colony had filled the upper crate with yellow golden-rod honey, except the two sections in the place of those removed. These two and the lower crate contained only white aster honey. Two other colonies had gathered from golden-rod and asters, but it was somewhat mixed. On opening the fourth hive, I found only dark buckwheat honey. In this I was not able to detect even a trace of golden rod or aster honey, while in the other three, the absence of buckwheat was as marked. With me this was a novel experience. How is it with others?

Bee-Keeping in Dakota.—J. O. Hagen, Aberdeen, Dakota, on Oct. 14, 1888, writes:

I purchased 1 colony of bees last spring, and increased them to 2 colonies by dividing. I obtained only 12 pounds of comb honey, but perhaps I would have had more if I had put on the surplus sections before the harvest was over; so I cannot tell how the honey season has been this year. I believe that bees will do well here in Dakota. To day I opened one of the hives to look at the bees, and half a dozen alighted on my hand, and left their stingers there. I picked them off, and now I enclose them in this letter. Please examine them, and tell me through the AMERICAN BEE JOURNAL what kind of bees they are. My wife and I have been troubled all summer by them. She could not come nearer the hive than within 100 feet, and my neighbors have been troubled at their wells, when they were after water.

[Of course the bees were all mashed up and dead in the letter envelope. As some of them have two, and others three bands, of course they are hybrids—but they are fine, large bees, and look like good workers. —ED.]

Good Fall Honey-Flow.—Green R. Shirer, Greene, Iowa, on Oct. 22, 1888, says:

Last year my bees did nothing at all—I did not get one pound of honey, and no swarms. During the winter and spring I lost one-third of them. Bees just made a good living this season up to Aug. 15, when a wonderful honey-flow began, and the hives filled up quite fast. I extracted 600 pounds of very thick and heavy honey, of fine quality. I have besides about 60 pounds of comb honey, and the bees have an abundance for winter. I will begin the winter with 38 colonies, but 4 of them have drone-laying queens. My bees are packed with chaff for winter, on the summer stands, except one colony that I will put into the cellar. White clover is very promising for next year, and I am hoping for a good honey season then.

The Illinois State Fair, etc.—John A. Williamson, Lodge, Ills., on Oct. 15, 1888, writes:

At the State Fair at Olney, I obtained \$47 in premiums. The first four on the list, which I enclose, represents the four blue ribbons—first prizes. I had the only exhibit of honey. There was pretty strong competition on bees, but I obtained all the blue ribbons except one. There is no honey in that part of the State, there being no clover or linden there, and the colonies were so reduced by the time of the fall run that they had no bees to gather the enormous crop that was furnished by heart's-ease, Spanish-needle, and other fall flowers. My own

crop is about one-half of the usual yield; but I got the most of it during August and September. I kept my bees strong by feeding during the summer. My crop is 3,000 pounds from about 80 colonies. My bees are strong, and have too much honey in the brood-chambers, and being cold nights, they fairly crowded the brood-frames.

Honey from Pepperae.—Miss Dema Bennett, Bedford, O., on Oct. 18, 1888, writes:

Through some mistake, I am credited with saying, on page 677, in the "experience meeting" at Columbus, that, "A few had reported getting 100 pounds per colony from pepperae." This amount far exceeds any report I have received from Ohio this year, as being gathered from all sources. I mentioned that Mr. L. G. Reed, of Kenf, O., thought that the dark honey in his locality was gathered from pepperae, instead of honey-dew, as some thought, and I asked if it was possible that the honey-dew mentioned in a good many of the reports, could have been gathered from pepperae. It was a mistake, but perhaps it was my own fault in not speaking so as to be understood, as there was more or less confusion, and I am not used to speaking in public.

Wanted—Colorado Climate.—Mrs. L. Harrison, of Peoria, Ills., propounds the following question:

Who will supply Prof. Cook with the climate of Colorado, to sow with the seed of the Rocky Mountain honey-plant, to fertilize it in order to secure a crop of honey?

[The Professor may perhaps enter into a compact with "the clerk of the weather," to transfer Colorado climate to Michigan next year, or to make some kind of an exchange in the matter. It would be useless for us "ordinary mortals" to attempt such a scheme, but between "celestial officials" and "college professors," there may appear some *media* for such an exchange or transfer. We respectfully refer the question to Prof. Cook.—ED.]

My Experience with Bees.—Isaac Harman, Robinson, Kans., on Oct. 12, 1888, says:

I obtained 2 colonies of bees last spring, transferred them, and I now have 4 colonies in frame hives; besides, one swarm left, as I supposed afterwards, by not getting the queen in the hive. They left the next day. The first swarm stored 28 pounds of honey in the sections, which sold at 20 cents per pound. I think that this country is excellent for bee-keepers, and I look forward with pleasure to the time when I can be the happy owner of an apiary, no preventing Providence.

We Want 20,000 subscribers. Out of the 300,000 bee-keepers in America, certainly this is not an extravagant desire! It is only one out of every fifteen! We confidently ask those who appreciate the AMERICAN BEE JOURNAL, to show it by sending us one or more new subscribers. We will give them full value for their money.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

Honey and Beeswax Market.

CHICAGO.
HONEY.—New crop arriving slowly, but demand is limited. White clover comb, 17@18c. Extracted, 7@9c.
BEESWAX.—22c.
S. T. FISH & CO., 189 S. Water St. Sep. 12.

CHICAGO.
HONEY.—For white comb 1-lbs., 18c. Very little inquiry for anything outside of 1-lbs. and when it is wanted it is at a lower price. Extracted, the best grades, 7@8c., and some held higher. Offerings are small and demand slow.
BEESWAX.—22c.
R. A. BURNETT, 161 South Water St. Sep. 12.

MILWAUKEE.
HONEY.—We quote: Fancy white 1-lbs., 18@20c.; 2-lbs., 16@18c. Good dark 1-lbs., 16@18c.; 2-lbs., 15 to 16c.; fair 1-lbs., 12@14c. Extracted white in kegs and 2-barrels, 8@9c.; amber in same, 7@8c.; in pails and tin, white, 9@9½c.; in barrels and half-barrels, dark, 6@6½c. Market steady and supply ample for the moderate demand, but present values have a tendency to restrict general consumption.
BEESWAX.—22@23c.
A. V. BISHOP, 142 W. Water St. Oct. 25.

DENVER.
HONEY.—Colorado, new 1-lb. sections., 13@15c. Extracted, 7@8c.
BEESWAX.—20@23c.
J. M. CLARK & CO., 1409 Fifteenth St. Sep. 7.

NEW YORK.
HONEY.—We quote: Fancy white 1-lbs., 15@17c.; 2-lbs., 14@16c. Fair white 1-lbs., 14@16c.; 2-lbs., 13 to 15c. Extracted, white, 7½@8c.
BEESWAX.—23½c.
THURBER, WHYLAND & CO. Sep. 17.

NEW YORK.
HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 13@14c. Fair white 1-lbs., 15@16c.; 2-lbs., 12c. Buckwheat 1-lbs., 11@12c.; 2-lbs., 10@11c. White extracted, 7½@8½c.; buckwheat, 5½@6½c.; California extracted, white sage, 7½@7¾c.; amber, 7¼@7½c. Demand good and prices firm. New comb honey is arriving quite freely.
BEESWAX.—23@23½c.
HILDRETH BROS. & SEGELKEN, 28 & 30 W. Broadway, near Duane St. Oct. 10.

SAN FRANCISCO.
HONEY.—White 1-lb. sections, 11@12½c.; 2-lbs., 12½@1c.; amber, 10@11c. Extracted, white, 5½@6c.; light amber, 5¼@5½c.; amber and candied, 4¾@5c. Receipts light and market firm for best qualities.
BEESWAX.—Dull at 19 2½c.
O. B. SMITH & CO., 428 Front St. Sep. 22.

DETROIT.
HONEY.—Best white comb, 17@18c.; dark, 16c.—Extracted, 8@10c. Market bare of all kinds.
BEESWAX.—21@22c.
M. H. HUNT, Bell Branch, Mich. Sep. 24.

CINCINNATI.
HONEY.—We quote extracted at 4½@28c. per lb. Comb honey, 12½@16c. Demand slow, and only for best qualities.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Oct. 24. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.
HONEY.—Choice 1-lb. sections, 18c; dark 1-lbs., 14c.; 2-lbs., 12c.; dark, 13c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock fair.
BEESWAX.—None in market.
Sep. 27. HAMLIN & BEARSS, 514 Walnut St.

NEW YORK.
HONEY.—We quote: Fancy white 1-lb. sections, 17½@18c.; 2-lbs., 14@15c. Fair 1-lbs., 14½@15½c.; 2-lbs., 12@12c. Extracted, fancy white clover, 7½@8½c. California white in 60-lb. cans, 8c.; light amber in same cans, 7½c.; amber, 7¾c. Buckwheat in kegs and barrels, 5½@6c. Cuban, in barrels and ½-barrels, 65c. per gallon.
F. G. STROHMMEYER & CO., 122 Water St. Sep. 26.

BOSTON.
HONEY.—We quote: Best white clover 1-pounds, 17@18c.; best 2-lbs., 16@17c. Extracted, 8@9c. The market is more active, with an upward tendency.
Oct. 25. BLAKE & RIPLEY, 57 Chatham Street.

KANSAS CITY.
HONEY.—White 1-lbs., 17@18c.; dark, 14@15c.; California white 1-lbs., 17c.; dark, 14c. Extracted white 8c.; amber, 7c.
BEESWAX.—None in the market.
Oct. 11. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.
HONEY.—We quote: Extracted in barrels, 5@6c., according to quality; in cans, 7@8c. Comb, 12½@15c. Prices firmer on account of scarcity, though the demand is not great.
BEESWAX.—21c. for prime.
Oct. 17. D. G. TUTT & CO., Commercial St.

SAN FRANCISCO.
HONEY.—We quote: Extracted, white, 6 cents; light amber, 5¾c.; amber, 5¼@5½c. Comb, 1-lbs., 13@14c.; 2-lbs., 10@13c.
BEESWAX.—20@22c.
Sep. 24. SCHACHT & LEMCKE, 122-124 Davis St.

EDITORIAL BUZZINGS.

A little paper and a little ink
Make thousands, perhaps millions, think.

There are over 200 bee-societies in the little State of Germany, with a membership of over 12,000. They evidently believe in "societies" there. Here in America the largest society of bee-keepers we ever had, lacked a good many of 200 members. This is not for a want of bee-keepers either, for we have 300,000 of them in America. But so many of them think that they "know it all," and that there is no need of societies for them. And as to imparting their knowledge to their less-confident or less-informed brethren—they scoff that idea!

Major Shallard, of New South Wales, is now offering in the Sydney papers, a reward of £20 to any one who produces a sample of adulterated honey, put up by him and bearing his name. This no doubt is an offset for some one who is falsely charging him with adulteration. Sometime since the Major exposed some samples of adulterated honey in Sydney, and the counter charge is no doubt a retaliation. We glean these facts from the *Australasian Bee Journal* for October, which is just received.

Sand, instead of bottom-boards, it is said in a recent work on Polish bee-keeping, is recommended and used in that country for bee-hives. It says:

The stands are prepared by raising the earth at each hive 2 or 3 inches above the surrounding level; an inch of clean, dry sand is then placed on top of each elevation and beaten down smooth and firm. Round the outside edges of the mounds some dry chips or moss is placed, and this again covered with earth well stamped to prevent insects burrowing under the hive.

The Dairy Commissioner of New Jersey, Mr. Wm. K. Newton, whose analysts of samples of honey has been doubtfully noticed in our columns several times, wrote thus to the *Bee-Keepers' Magazine* last June:

Your editorial comment on the article in the *British Bee Journal* is correct, as no comb honey was found adulterated. The heading to my article is "Strained Honey," and all the specimens were of that kind. The samples labeled on the cans and jars, "Choice Comb Honey," were merely small pieces of comb floating in a sea of glucose.

We are glad to learn that the Dairy Commissioner of New Jersey has announced that *no comb honey was found adulterated*—that the labels which read "Choice Comb Honey" were a deception, and merely referred to the small pieces of comb honey "floating in a sea of glucose!"

It would have been far better if Mr. Newton had learned something more about honey before attempting to enlighten the world on that subject. His statement in the above extract is:

The heading of my article is "Strained Honey," and all the specimens were of that kind.

But the probabilities are that *none* of the specimens were of that kind, *i. e.*, *strained honey*—that system of breaking up the comb and *straining* the whole through a cloth having passed out of use long ago! The only thing *strained* about the matter is the implied accusation that nearly all the liquid honey on the market is adulterated! That idea is *strained*!! It is untrue in fact, and full of harm to the industry.

Taking Lessons.—A correspondent in New York asks the following question:

Is it necessary for a person who intends to make bee-keeping an exclusive business to serve an apprenticeship with a practical apiarist? If so, what is the best way to do it?

It would be desirable to take lessons in bee-keeping before embarking in the business. The cheapest way is to hire out to some good apiarist for one season, and keep wide awake to take in all you can hold, and be imbued with the theory and practice. Then by the aid of books and a good bee-paper, you ought to succeed. Almost any one having a large apiary would be glad to have your help for a season by corresponding with them in advance with some one near you, would be the cheapest and perhaps the best arrangement to make.

An Introduction to Entomology by John Henry Comstock, professor of entomology and general invertebrate zoology in Cornell University, Ithaca, N. Y. This is the title of a new book. Price \$2.00. Part I of which is on our desk. Prof. Comstock was formerly United States Entomologist. He has spent several years in the production of this excellent work. The part published now includes the grammar of the science, and about half of the systematic part.

This work has been prepared for the use of students in Agricultural Colleges; and for private students; in fact for any one who desires to find out something about our common insects. Especial pains has been taken to describe the species that are of interest to farmers, and to indicate methods of combatting those that are injurious.

A prominent feature of the book is the use of analytical keys to enable the reader to find out the name of the family to which any insect belongs. These have been prepared with great care. Another special feature of the work is the indication of the pronunciation of the scientific names.

No pains or expense have been spared in the preparation of illustrations, or in printing the book. There are many original engravings made especially for the work. The printing was done by the De Vinne Press (the firm that prints the *Century* and the *Saint Nicholas Magazines*), and is excellent throughout.

The Golden-Rod bids fair now to become the National flower of America. It is our choice, and we believe it to be the choice of the bee-keepers of America. The *New York Observer* thus champions its cause:

It is surely high time that the selection of a National flower were made. England has her rose, Scotland her thistle, Ireland her shamrock, France her lily, and why not America have her floral representative also? There is surely no lack of flowers native to the soil from which a choice may be made.

This question has already been discussed to some extent in the horticultural journals, and several nominations have been announced. One journal has come out in favor of the pansy; another has put the trailing arbutus at the head of its ticket, others have declared for the golden-rod and the aster. It is probable that a choice will eventually fall upon some one of these four candidates.

We have decided, after long and careful deliberation, to champion the cause of the golden-rod. It is sturdy; it is independent; it is free. It is not a sectional flower. It knows no east, no west, no north, no south. It is at home everywhere; as happy and radiant when it lifts itself above the sod of a southern plain as when it nods in the breezes of a northern valley.

Neither is it particular in such matters as soil and surroundings. It can accommodate itself to almost any circumstances, and be just as sweet and beautiful in one place as another. In the pasture, in the meadow, on the hill side, by the stream, it is everywhere the same noble and glorious flower; unpretentious and simple in its attire; yet rich and strong in its beauty; modest and unobtrusive in its habits, yet not too shy and retiring. These are not all the reasons for our believing the golden-rod is entitled to the honor of being chosen as the National flower of America; time and space would fail us to recount all the virtues and peculiar qualifications of our candidate. Such as we have given we leave to the consideration of our candid, and, we hope, unprejudiced readers.

We Regret to notice that the misleading table of the Dairy Commissioner of New Jersey is approvingly copied into three bee-papers—one of them in Australia. Such is exceedingly reprehensible.

GLEAMS OF NEWS.

Experiments.—It is understood that Prof. Cook intends to "hatch out" an extensive system of experiments at the Michigan Agricultural College. The money appropriated by Congress in the *Hatch* bill is to be divided among the different States, and some of the Michigan portion will be expended under the personal supervision of Prof. Cook in making experiments. Concerning what he proposes to do, the *Canadian Honey Producer* remarks as follows:

Prof. Cook stated that in 1878 they started to teach bee-keeping at the Agricultural College, Michigan. For sometime very little was done to assist bee-keepers. He urged the claims of bee-keepers, and while those in authority agreed that it was an important matter, the time had passed by without the College being in a position to do anything. His duties were too numerous to enable him to do much. Every year he had gone before the board to fight the matter, but he had been unable to secure any one but an inexperienced hand. A year ago, however, they had decided to build a larger place for bees, and enlarge the department. They had now a good building, and everything in apple-pie order. A few experiments had been conducted. They had tried pollen and not pollen for winter.

Each State was given \$15,000 for experiments, and he had secured a part of this grant for experiments in bee-keeping. So far as he knew there was no other Agricultural Colleges working in this direction, and only one or two States. There were great problems which wanted working out, and he was about to give the plan of work he proposed following, and he desired the friendly criticism of bee-keepers.

He was crossing Syrian and Carniolan bees; the latter were gentle, good comb-honey builders, the former energetic and prolific, and he was receiving encouragement, and thought something could be done which would give good results. In crossing, the objections which found ground with cattle and the like could not be advanced in bees; cattle had strains followed up for generations in the way of milk or beef production, two distinct objects—whilst the objects with bees were less distinct.

With the strain of bees spoken of, he had been experimenting for five years.

He wanted to get a man to work who could spend hour after hour, down close to a hive of bees, closely observing them. That was aim Number 1. *Can I get a better bee?*

He believed next that something could be done in the direction of special planting for bees. There might be nothing in it, but he thought there was. They had a large area in Chapman honey plants and melissa. He was also trying Rocky Mountain bee-plant and pleurisy-root. There might be nothing in it, but it would be better for the country for him to try it, than for bee-keepers to try a little and each fail.

Mexico is so completely an unknown land to most people, that it is well to have a little insight into its history. "Our Neighboring Republic and its Presidents," in *Frank Leslie's Popular Monthly* for December, fully illustrated, gives a connected view and portraits of all who have been at the head of the Mexican Republic from the days of Hidalgo.

Honey at Jewish Feasts.—Mr. Alfred Neighbour, of London, in the *British Bee Journal* for Sept. 13, 1888, gives these items of interest on this subject:

I have often noticed at this season of the year that there has been rather an unusual demand for honey in the combs, the customers for the most part bearing evidence of belonging to the Jewish persuasion. This year there has been no diminution in this respect, and our supplies (being rather limited, owing to the unfavorable weather) have been largely drawn upon—which has led me to make inquiries into the cause of this consumption of honey by the Jewish people, and I find that it is on the occasion of the first day of their new year.

This occurred on Thursday, Sept. 6, being the first of the month—"Tishri, 5649"—and as it is a festival day, also the harvest season when most kinds of produce have been gathered, the new fruit, etc., are partaken of at mealtimes, because the opportunity admits of the *additional blessing* being said before eating the new ripe fruit. *New honey with new apples* makes an excellent *bon bouche*, and is greatly appreciated on the occasion.

My informant tells me that observant Jews, whenever partaking of food, always repeat a certain short blessing of thankfulness, and an additional one when the fruit or produce is the first of the season. Moreover, their festivals are days of gladness as well as of prayer; and in what better way can people display their pleasure and gratitude than by the sober enjoyment of the good things in season, more especially by a community who are the descendants of the inhabitants of "a land flowing with milk and honey?"

Bee-Keeping is taught in schools in Russia. *The Schoolmaster*, an English paper, gives the following under the heading of "A Hint from Russia!":

A new departure in girls' schools is being tried in Russia, countenanced and aided by the State. A lady has opened in a village near Kief a school where girls of the lower classes will be instructed in such branches of *petite culture* as women can profitably attend to, from market-gardening to bee-keeping. The school is to yearly grant an aid of 1,500 roubles. "Rural School Boards in England," says the *St. James' Gazette*, "might perhaps take the idea into serious consideration. The wives and mothers of a future generation of British husbandmen would probably find a practical knowledge of dairy-farming and poultry-keeping even more useful than the arts and sciences they are now encouraged, if not required, to study."

To the latter the *British Bee Journal* appropriately adds: "To this, we would add bee-keeping."

Another Novel Bee-Suit has been tried in Germany, as we notice by an account of it in *Der Bienen-Vater aus Bohmen* (The Bee-Keeper of Bohemia.) It says:

A widow (Theresa Schottel) who kept bees in Mutzig, Alsace-Lorraine, was hauled before the court, by three of her neighbors, to answer charges brought against her bees. The three neighbors claimed that the bees collected on the udder of their cows and goats, that they drew out the milk, that the cows and goats, kicking at the bees, caused the bees to sting the udders, and that the udders became so swollen and painful that the milk could not be drawn. The case was decided in favor of the widow, and the complainants were obliged to pay costs. The Judge declared the charges unfounded.

Benton Queens.—We have the following letter from Australia, asking for its publication. We think Mr. Frank Benton has gone from Munich, and this may account for his non-attention to Major Shallard's letters. We publish it, hoping it will meet Mr. Benton's eye, and be thereby the means of straightening the matter out. We feel sure that there *must* be some reason for the delay of two years, and await developments. Here is the letter of Major Shallard:

GLENBROOK, New South Wales, Aug. 31, 1888. In May, 1886, I sent Mr. Frank Benton, of Munich, Germany, £7 for six queens. He acknowledged receipt of the money, and sent one queen (which arrived dead) in the early part of the following August. Since then I have written him four letters, but can get no reply.

Mr. Benton has had my money now for two years, and I should like to see the queens. I write this in the hope that its publication will compel him to attend to the matter, as he has evidently decided to ignore my letters on the subject.

MAJOR SHALLARD.

Bees Now in Fashion.—Among the "edicts of fashion" just announced, are some very extraordinary and elaborate "fancies." A "fashion" paper says:

The ladies of Turin presented to the bride, Princess Bonaparte, a regular out-and-out "palanquin," or sedan chair of fabulous value, an exact copy of Louis XV style—panels painted by renowned artists, handles of solid gold, and pockets containing a prayer book bound in red velvet edged with gold, a bonbonniere in gold with enameled miniature, lace fan mounted in gold set with pearls, and perfumery case in gold and brilliants.

This same "faire ladye" designed the "embroidere of her bridale mantel," which was a mixture of *bees* and eagles in precious stones.

The latter reminds us of the brooch presented to the Princess Beatrice, by the apirarists of England, consisting of a bee formed in precious stones—elaborate, suggestive and beautiful.

Money in Potatoes, by Mr. Joseph Greiner. Price, 25 cents. This is a complete instructor for the potato grower, explaining his new system in 40 lessons. For sale at this office.

A Wealth of Illustrations of the highest quality adorns the pages of the *American Agriculturist* for November, making it one of the finest and most useful issues of this sterling magazine ever published. The leading article describes the Lakeside farm and herd of Holstein-Friesian cattle and thorough-bred Clydesdale, Hambletonian and French coach horses. The numerous illustrations of famous cattle and horses are reproduced direct from life, without the intervention of mechanical engraving, thus making the pictures so natural and true to life as to really make a new departure in live stock illustration.

Bee-Keeping in Queensland, Australia, is thus described by Mr. D. R. McCannel, of Brisbane, in the *Australasian Bee Journal* :

I may safely say that, whatever was the condition of bee-keeping in Queensland four years ago, it is on the high road to "the most scientific American method" now. "Modern" bee-keeping is practiced by more than one can count on one's fingers, and yet there are not many bee-keepers in Queensland. We formed a Bee-Keepers' Association last August, 1886, at the annual Agricultural Exhibition in Brisbane, which numbers over 30 members. We have monthly meetings, to which some of us travel over 60 miles, when papers are read, new and old methods discussed, and much business arranged. We have induced the National Association to multiply by four their entries for exhibits under Honey, Bees and Bee-Keeping materials; and we appoint one of the judges for the show. Our improvements, to be taken in hand at once, are the commencement of a museum and a library. We intend also to ask the Government to make arrangements for sending bees by post, which is now impossible. So you see we have not "died ere scarcely born."

It has been remarkable that while you were complaining of the drouth, we had our season almost spoiled by wet. We had had a drouth before that for four or five years; and the rain will have done good for the next season. I am not sure how much of our crop, mostly from eucalypti, depends on the rainfall. Clover, of course, fails certainly without rain; but these gum trees of ours do not seem to mind how dry the ground is. Indeed, some varieties never bloomed at all last year, apparently because the rain came when their flowers should have opened.

Now that we can organize our work and observation through the Queensland Bee-Keepers' Association, we hope to be able by and by to present a complete report of the different times of flowering, and the value of our honey trees.

Robbing.—Many inquire as to how to know when bees are robbing, and how to prevent it. The *Rural Canadian* says it knows it in this way :

When robbing is going on in the yard I generally know it without going into the apiary. An occasional stray bee will come into the office where I am writing. The hive attacked is closed with a wire screen, to give ample ventilation. If but few bees have got at it, I manage to kill them with a piece of thin, wide board.

After the bees once become engaged in robbing, they are of no use in the apiary, as they will continue to steal during the rest of their lives, and the sooner they are disposed of the better. If much robbing is going on in the apiary, the thieving colonies should be found and removed to a new location, at least a mile away. By sprinkling flour on the robber bees as they leave the hive being robbed, they can be easily traced to the stand where they belong. I have often broken up a colony which were robbing by blowing tobacco smoke in their hive. When this is done, care must be taken that the other colonies do not turn to and rob the one that has been doing the robbing.

The *American Apiculturist* remarks as follows as to the danger and the remedy :

Care should be taken in season to prevent robbing in the apiary. The most danger is during the first few days after the honey-flow ceases. The bees at once commence to look around for the weak colonies, or any exposed sweets. Keep all honey out of

reach and smell of the bees. Should the bees get into the bee-house, the best plan is to fasten them in. Let out just before it is too dark for them to find the hive. This will do more towards breaking up robbing than any other plan I know of. A few bees will return in the morning, but they will soon become discouraged and give it up.

Buckwheat Honey.—On page 563 Mr. S. J. Youngman asks these questions: "I have observed that the buckwheat bloom yields no nectar in the afternoon in this vicinity. Is this a characteristic of the plant throughout the United States? Are some varieties better than others to yield honey?"

Several have replied already, stating that they never have seen bees working on buckwheat later in the day than noon. Mr. H. M. Seely, on page 629, says: "When we have a hot, damp and cloudy day, it yields nectar all day; all other times only in the morning. It has not yielded very much this season."

Now the editor of the *Canadian Honey Producer* gives a plausible reason for its non-yielding of honey, in these words :

Honey is secured from buckwheat generally until about 10 or 11 o'clock. The reason is that it requires moisture and secures it from the dew. If there is no dew, there will be but little honey in the buckwheat. Again, if we have a cloudy day and light showers, there will be buckwheat honey in the blossoms all day. Such a day we had lately, and one colony gained 10 pounds that day.

Honey at Fairs.—Concerning the awards made by judges at Fairs, Mrs. L. Harrison makes these comments in the *Prairie Farmer* :

State, district and county fairs are great educators of the people, and whether it pays financially or otherwise, bee-keepers should make an exhibit of honey, wax and bees. I am sorry to say it, but I could not make a creditable exhibit this fall—no, not even buy it, in Peoria. Some exhibitors make a great mistake in exhibiting only white honey. Fair exhibits should embrace all the honeys of the locality, from apple bloom to fall flowers, whether it is white, yellow or brown, both in comb and extracted, and in marketable shape.

Committees at Fairs many times have a mistaken idea of what constitutes excellence in honey, wax and supplies. It is not possible for them to be posted on all commodities upon which they must pass judgment. At one of the Illinois State Fairs held at Peoria, a large glass vessel, filled with comb honey, which took the bees two seasons to fill, and was consequently much travel-stained by the bees, was awarded the "blue," while rich, white honey, in good marketable shape, was unnoticed. This dripping, daubing mess was a curiosity, and consequently was awarded the "blue."

The second premium on honey at the same Fair was given to a confectioner's jar of "strained" honey. The second award was to be given to extracted. The lady who exhibited it, said: "It was nice honey when I strained it, and I do not know what makes it so cloudy." There was on exhibition at the same time a gross of nice, white extracted in Muth's honey-jars, tin-foiled and labeled. Honey-dealers or disinterested bee-keepers should be excellent persons to have on an awarding committee of honey.

Candied Comb Honey.—The question is often asked, "What can I do with honey candied in the comb?" Mr. Will M. Kellogg, in the *Bee-Keepers' Magazine*, describes his plan thus :

I had about 20 cases of 6-inch extracting combs that I had to leave for some time for lack of time and storage room, and when I came to extract it, I found it candied solid. It was fine, clean white comb, filled with clover honey, and I hated to lose it. I cut the combs out of the frames, laid one at a time on a clean, smooth board, and cut it up fine with a chopping knife, then placed it in a large tin can over a slow fire, and carefully melted comb, honey and all.

When it was thoroughly melted I set the can to one side until cold; then the wax having risen to the top, I peeled it off of the honey and threw it into the wax extractor; rewarmed and strained the honey, and I had several pounds of nice wax, and over 300 pounds of as fine, thick honey as an expert ever smacked his lips over. So I received over \$50 for my batch of candied comb honey.

Never Strike at a Bee.—A good illustration of the correctness of this advice is shown by Mr. E. S. Arwine, in the *Pacific Farmer*, who gave his experience as follows :

About 38 or 40 years ago, when I was 8 to 10 years old (I have been used to bees from childhood), I held up a leafy bush for the swarm to cluster on, while tin pans, bells, and two sea-shell horns were making the sweet music of bygone days, to induce the bees to cluster. After circling around about the usual time, a prime swarm began to alight on the stem of my bush, on a level with my head; and as the cluster-call sounded, the bees poured in all over my shoulders; then my hat brim dropped down over my face. I dropped my bush, took off my hat and laid it on the bush, and moved out pretty quickly, with a pint or so of bees on my arms and shoulders. I do not think I got a sting, but the swarm clustered on my old hat. Moral: Never strike a bee.

We Want 20,000 subscribers. Out of the 300,000 bee-keepers in America, certainly this is not an extravagant desire! It is only one out of every fifteen! We confidently ask those who appreciate the AMERICAN BEE JOURNAL, to show it by sending us one or more new subscribers. We will give them full value for their money.

Convention Notices.

☞ The Nebraska State Bee-Keepers' Association will convene at Lincoln, Nebr., on Jan. 9, 10 and 11, 1888. J. N. HEATER, Sec.

☞ There will be a meeting of the Susquehanna County Bee-Keepers' Association at the Court House in Montrose, Pa., on Saturday, May 4, 1888, at 10 a. m. H. M. SEELY, Sec.

☞ The Pan-Handle Bee-Keepers' Association will hold its next meeting in the K. of P. Hall on Main St., between 11th & 12th Streets, in Wheeling, W. Va., on Nov. 21 and 22, 1888. All bee-keepers are cordially invited. W. L. KINSEY, Sec.

☞ The Marshall County Bee-Keepers' Association will meet at the Court House in Marshalltown, Iowa, on Friday, Nov. 16, 1888, at 10 a. m. All bee-keepers are cordially invited to meet with us, and bring along anything that they may have that will interest or benefit apiarists. J. W. SANDERS, Sec.

☞ The Alabama State Bee-Keepers' Association will meet at 10 a. m. on Wednesday, Nov. 14, 1888, at the office of the Secretary of the State Fair (in the Fair Building), in Montgomery, Ala. Members are urged to attend, and all persons interested in bees and honey are cordially invited. J. M. JENKINS, Sec.

QUERIES REPLIES.

Moving Bees in the Fall of the Year.

Written for the American Bee Journal

Query 586.—Is it safe and practicable to move bees in the fall, when the frames are filled with honey, either on wagons or shipped on cars?—Minnesota.

Yes, with ordinary care.—H. D. CUTTING.

Yes, but not great distances. The spring is the proper time.—DADANT & SON.

It is not so good, but with proper fastening of the frames it can be done.—G. M. DOOLITTLE.

I move them on a wagon every fall and spring. I moved 184 colonies this fall.—C. C. MILLER.

When the hives contain only old combs, yes. When they contain new combs, no.—M. MAHIN.

With care, it is safe to move them by either conveyance.—MRS. L. HARRISON.

I should dislike to do so after the weather was too cold for the bees to have a good flight.—EUGENE SECOR.

Yes, if you exercise care regarding "jars and junks." In every respect, except the weight of the combs, fall is the best time, provided the bees have a good flight after removal.—JAMES HEDDON.

It is safer to move bees in the fall, if the weather is not too cold, than in summer. Where the necessary precautions are taken, it is always practicable.—P. L. VIALLO.

Much depends. Should the frames be wired, by exercising great care in their preparation, and in driving, they may be successfully moved.—J. M. HAMBAUGH.

That depends upon the size of the frames and on the combs. If frames are large and not wired, and the comb new, they could not be safely moved without extreme care; while with small or medium-sized frames, well wired and full of comb in which brood has been reared for several years, they could be safely moved.—R. L. TAYLOR.

Yes, if carefully done. If the combs are old or wired, they will be less likely to fall out and do damage. If the bees are in movable-frame hives, the frames ought to be fastened.—A. J. COOK.

It can be safely done if care is used. The frames should be securely fastened so that no swing will be allowed. I find it fully as safe to move bees in

the fall as in the summer. Ample ventilation should be given.—J. E. POND.

There is a little more danger attending the shipment of bees when the combs are filled with honey; but if the honey is sealed, and the frames are secured in place so that they cannot jostle about, the hives can be shipped safely either on a car or wagon.—G. W. DEMAREE.

It is both safe and practicable. I have moved and shipped hundreds of colonies with frames filled with honey. If the frames are well propolized they will go short distances by rail or spring-wagon without extra preparation; but if the journey is long, with re-shipments, the combs must be secured with wired sticks, and the frames securely fastened at the top and bottom.—J. P. H. BROWN.

Yes. If on a wagon, a hay-rack is a good bed to put them in. The frames should ride crosswise, as the most "shake" is crosswise. On the cars the frames should ride lengthwise, so as to suffer the least "bump" from the cars. Frames on metal bearings need to be fixed in the hives so that they cannot move in the hive body. Those that have been used in wooden rabbets one season are usually firm enough.—J. M. SHUCK.

The spring is the best time, when there is but little honey in the combs, but they can be moved in the fall, when the combs are properly secured, and it is not too late for the bees to have a good chance to fly afterwards. Old combs are preferable if the distance be a long one.—THE EDITOR.

Hiving Swarms on Full Combs or on Foundation.

Written for the American Bee Journal

Query 587.—Are frames filled with comb better on which to hive new swarms, than frames half filled with foundation?—I. R.

Yes.—M. MAHIN.

Yes.—MRS. L. HARRISON.

My experience says, yes.—G. M. DOOLITTLE.

Yes. I would prefer the combs every time.—J. M. HAMBAUGH.

Sometimes they would be better, but probably not if comb honey is the object.—R. L. TAYLOR.

If it is desired to extract from the brood-frames, yes. If not, no—an immense NO!—J. M. SHUCK.

To a certain extent it would depend upon your method of work. For extracted honey, I want all the filled frames I can get.—H. D. CUTTING.

Yes, undoubtedly, if the combs are worker-combs, and not too old and dirty. Frames half filled with foun-

dation would incite bees to build drone-comb.—DADANT & SON.

I think that I can do better with full combs. Others may do better with half empty frames.—C. C. MILLER.

I prefer to hive swarms on frames filled with comb, alternated with frames filled with foundation.—J. P. H. BROWN.

Yes, in any case if working for extracted honey; and if for comb, yes, if you properly contract the brood-chambers.—JAMES HEDDON.

Yes, but not better than full sheets of foundation on wired frames. Hiving swarms on frames half filled with foundation is not very practicable, unless wire is used.—P. L. VIALLO.

That depends upon the management. For extracted honey, yes, much better. For comb honey I prefer hiving swarms on starters merely. See my last edition of the "Bee-Keepers' Guide," or Hutcheson's book on "The Production of Comb Honey."—A. J. COOK.

That depends. If worked for extracted honey they might be as good, as, if a sudden flow of honey filled the combs and cramped the queen, you could extract. For comb honey, I should just as soon have the latter.—EUGENE SECOR.

It depends altogether upon the time when they are hived. If in the swarming season, I should prefer the foundation; and in any case I should want empty cells enough to give the queen ample room for egg-laying.—J. E. POND.

In my experience, yes. But proper management has much to do with the final outcome. I hive my swarms on empty combs, and put on the surplus cases immediately, if I have queen-excluders to put over the top of the brood-chamber; otherwise I wait until the queen has begun to lay, say two or three days before I put on the cases. In this way my bees indulge their inclination to build combs in the surplus cases.—G. W. DEMAREE.

If it is intended to extract the honey from the brood-frames, good worker combs will be preferable to frames that are only half filled with comb foundation, because the bees may fill the other half with drone comb.—THE EDITOR.

In that case state the old as well as the new address.

CORRESPONDENCE.

AUTUMN.

Now Ceres roams her laden leas
And sounds her golden horn,
To be answered by the harvest bees
And laugh of tasseled corn.

Over the red and yellow leaves
When smiles the silvery morn,
Light she glides to her bearded sheaves,
By berry bush and thorn.

And hills are lost in purple haze,
White trees are talking low
About the mellow autumn days
And nature's afterglow.

COLOR AND BEES.

Instinct and the Color Sense in Bees.

Written for the American Bee Journal
BY PROF. A. J. COOK.

I am sure I am in no wise peculiar among bee-keepers, in my pleasure and admiration in reading Mrs. Chad-dock's articles. Her piquant style and usual good sense, and accuracy, almost always serve up a meal which delights us all. But is she so happy in her article on page 700? She says, "Color is no guide to the insect world." How does she know this?

I believe that color is an almost universal guide to insects. Nay, more; I think that I know it.

It is the almost universal opinion of scientists, that the color of flowers was developed especially to attract insects; this, of course, for the flowers' good. Lubbock's experiments, moreover, prove beyond a doubt, that bees are guided by color. He placed honey on slips of different color. A bee was attracted to the honey on a yellow strip. The bee loaded and left. While away the great statesman changed the place or positions of the slips. The bee soon returned, and to the yellow, though in a changed position. The thing was tried over and over with the same result. I have confirmed the truth by similar experiments.

Bees do visit flowers for the pollen and nectar; but they are attracted to the flower by color and odor, which, I believe, were developed especially to attract the bees, for the good of the flowers.

Mrs. C. says, again, that bees work entirely by instinct. She also says that insects cannot reason. How does she know this? I believe that bees and other insects do reason. I think that they are intelligent, and can learn. I think that I know this. As Mrs. C. says, "We all know that insects do not reason," the burden of proof rests

with her. I know that habit is very strong with insects; I feel equally sure that they *do* reason.

HISTORIC.

Remarks upon the Origin of the Honey-Bee.

Written for the Bee-Keepers' Magazine
BY C. J. ROBINSON.

The date when honey-bees first existed is wholly unknown and past finding out, and their first appearance on the globe has not been explained in history. No indications of the existence of bees have been found in the rocks of the cretaceous period, nor has the fossil remains of bees been discovered in rock or earth deposits of any period.

The busy bee seems to have claimed greater interest from the ancients than they acquired in modern times. It is certain, however, that the great interest taken in bees from the earliest times is reviving among us with no common force since the publications of John M. Weeks, Father Quinby, Mr. King and others. The great interest in bees has arisen chiefly from the marked resemblance which their modes of life seem to bear to those of man. Remove every fanciful theory and enthusiastic reverie, and there still remains an analogy far too curious to be ratified with a passing glance.

On the principle of *nihil humani a me alienum*, this approximation to human nature has ever made the favorites of their masters. And theirs is no hideous mimicry of man's follies and weaknesses, such as we see in the monkey tribe. Their life is a serious matter-of-fact business, a likeness to the best and most rational of our manners and government, set about with motives so apparently identical with our own, that man's pride has only been able to escape from the ignominy of allowing them a portion of his monopolized reason, by assigning them a separate quality under the name of instinct.

It was the equal of Solomon Virgil who said: "The complicated and wonderful economy of bees can be referred to naught else than the direct inspiration of the divine mind." But we, from all that has been said by eminent men, should not forget the real services achieved in this as well as in every other branch of knowledge by the encyclopedist Aristotle, the pupil of him who was distinguished as the "Attic Bee;" or the Life of Aristomachus, devoted to this pursuit, or the enthusiasm of Hyginus; who more

than 1,800 years before the Rev. Mr. Cotton collected all the bee-passages which could be found scattered over the pages of an earlier antiquity.

Varro, Columella, Celsus and Pliny have each given in their contributions to the subject, and some notion may be formed of the minuteness with which they entered upon their researches from a passage in Columella, who, writing of the origin of bees, mentioned that Eucheremus maintained that they were first produced in the island of Coz, though Euthronius asserted they originated in Mount Hymettus and Hicander in Crete. Considering the obscurity of the subject, and the discordant theories of modern times, there is no branch of natural history in which the ancients arrived at so much truth.

Concerning the antiquity of the *Apis Mellifica* family, we are only able to trace its existence through past historical ages. The primitive natives of Egypt did not record what transpired or was known to them. The most ancient memorial matter that is known was chronicled by the priests—*literali*—who engraved certain characters called "hieroglyphics," which indicated certain meanings understood by the priests. It was called *shokia en neter en neter tur*, picture writing, or writing in sacred words. In the Egyptian dialect the picture of a hive bee represented Lower Egypt, restricted to the island in the Nile at its confluence with the Mediterranean Sea, and called by the Greeks the Delta.

This symbolizing of the honey-bee affords us the remotest data of its existence, and points to the whereabouts of their origin or first appearance on earth. I have made research, and have become satisfied that priests of primitive Egypt had knowledge of the birth place of the original progenitors of the honey-bee race equally as certain as the shepherds had of the place called Bethlehem.

With the ancient Egyptians the picture of a queen-bee was the emblem of royalty; this is evidence that Lower Egypt, the Delta, was the sovereign mother country, anterior to all Egypt, becoming one kingdom under Seros-tris. If, as is claimed by eminent historians, Lower Egypt was the cradle of the primitive Israelites who were the uncles of the subsequent mighty nation of Nineveh and Babylon, from whose loins the world is peopled, may we not logically conclude that the original nursery of the hive-bee, though called an *insect*, living in common like men, each one doing his part for the good of all, was in the Eden of the Israelites, where the landscape is a beautiful plain unadorned with "hills and shrubs?"

If we study the monumental records of early times in Egypt, we may reach back to the dawn of beedom. Egyptian rulers seemed to place their chief glory in rearing monuments for posterity. Their temples and pyramids were the grandest in the world, but the obelisks, an Egyptian invention, became the principal ornaments of all countries. On the planes of these stone pillars were inscribed the memorials of antiquity, the only data of earlier times.

According to eminent Egyptologists, the obelisk taken to Rome, standing at St. John Latern, is over 4,200 years old. The obelisk (Cleopatra's Needle) standing in New York city, is inscribed with memorial data in prehistoric times. No interpretations of the inscription, so far as I can discover, relates to bees, yet I believe they are represented. We fail to fully appreciate that we have in the city of New York such a treasure of antiquity—the obelisk. We but faintly realize that Moses and Aaron, Father Abraham, the Prophets, Alexander the Great, and great personages—antique Hebrews, Israelites, Greeks and Romans, and, quite likely, the Divine Redeemer, have stood near this obelisk and read, or tried to decipher the inscription.

In Egypt and everywhere honey-bees in their natural state take up their dwelling in trees, logs, under stones, and in clefts of rocks. The expressions of Moses and of the Psalmist, "Honey out of the rocks," is proof that the habits of the busy bee has ever been identically the same.

The early part of Egyptian monumental history was covered with the arrivals of Abraham and Joseph, and the exodus of the Israelites, and we can only get a glimpse of what was the state of the world at that period from Biblical literature, from which we learn that bee-keeping had ever been a principal branch of their domestic pursuits.

What aliment, if any, Adam subsisted on, before his unfortunate disobedience, we are not informed, but milk and honey is the food first mentioned; hence we are in possession of evidence that honey-bees were coeval with man's appearance on the globe—created with and for his purpose, else God would not have mentioned honey as the food for His chosen people, yea, He furnished honey as a special blessing to His elect.

We find the honey-bee first on the Delta in Egypt, and it is probable that the original nucleus, or the colony Noah put in, multiplied and spread up along the valley of the Nile; also eastward over the Isthmus of Suez into Syria, and along the eastern coast of the sea, and crossed to Cyprus, Greece

and Italy. Wherever people migrated bees were taken, for they were the first domestics on which mankind were dependent for a living.

Like other creatures, bees show different marks; but the difference is not radical—only a divergence within the bounds fixed by the hand of nature. We know of no type, breed or strain of bees that is constant in reproducing, identically, progeny after its progenitors. This fact settles the claim that bees have but one origin common with all of every name and nature. The differences observed comes about by reason of different geographical influence, or by accident—freak or physical nature. Color is not organic in living creatures. Color of epidermis (skin) and its appendages (hairs, roots, etc.) is the creature of accident; dependent not on constitutional element of species, but on the secretive functions of the skin, an aberration more or less common to all creatures—fickle as the color of the clouds.

Presumably the original type has at some remote periods, diverged somewhat, yet identical in attributes which are enduring and constant as are the planets in their respective spheres. I think the Oriental bees, perhaps by reason of congenial climatic influence, were and are more through long periods in rigorous climates. Color seems to be more uniform or fixed, and the type reproduced more closely by the native bees of the country about the Mediterranean than elsewhere. This circumstance indicates that climatic influences incident thereto subject bees to what is called freaks of nature.

In my research I found one item in sacred history that tells of the original home of the honey-bee. The Prophet Isaiah explained to the people that the Lord would punish people for their disobedience by introducing armies into their country and compare the armies swarming among the people like bees swarming among flowers. "The Lord shall hiss (whistle) for the fly (bee) that is in the uttermost part of the rivers (Nile) of Egypt, and for the bee that is in the Land of Assyria." chap. vii: ver. 18. (The words fly and bee mean the same. Rivers refer to the lower branches of the Nile, and "hiss," in the version, means whistle.)

The Prophet illustrated the idea of armies by alluding to a tradition common among the people of the Orient, which was superstitiously believed that the proprietor of an apiary by one hiss or whistle could summon all the bees to the village, and by the same signal conduct them into one bed or field of flowers; that is, the bee-master could, by the signal, call all the bees from

two countries into one locality making the number fearful, and the idea that the Lord's armies compared in hosts with the myriads of bees must strike terror. If the Prophet wrote by dictation of the Omniscient, he could not mistake the locality of the bee, 1st. Rivers of Egypt, 2d. Assyria.

The foregoing is my version of the subject, independent and alone. Perhaps I am one who can never rise into the region of essayist, but formed to plod on the lower levels of thought, unpossessed of the pinions necessary to reach the heights, and cannot realize the mental act by which a man of genius reaches a conception which unravels and illuminates the tangle of centuries of observation.

WINTER REST.

Immediate Work of Preparing Bees for Winter.

Written for the Farm, Field and Stockman

BY S. E. MILLER.

I prefer to have them in shape so as to not have to meddle with them after the honey-flow has ceased, for there is a vast difference between handling bees during honey-flow and after it has ceased. I have had Italians just as gentle as any one could wish just before the frost, which were just the reverse when the honey-flow was cut short by frost. Therefore, if you wish to avoid robbing, stinging and trouble in general, get your bees in shape before frost comes. Of course I would not advise closing the bees up for winter while there is still a chance of procuring surplus honey, but with the present signal service arrangements, we can tell pretty nearly when to look for frost, and thus have our bees in shape for winter, and still not lose more than a few days that might be devoted to the storing of surplus honey, and even if the flow does continue a few days after you have them prepared, they will make room for it somewhere. I must describe

The Chaff Division-Board

or dummy, and the chaff cushion which are two of the great essentials to successful wintering. The division-board is made as follows: Make the frames the same as you use in your hives, only, instead of the ordinary width, make them about an inch and a half wide, and on each side nail boards about $\frac{1}{2}$ of an inch thick, thus forming a complete box, only before nailing on the last side, fill it with dry chaff or chopped straw. Before nailing on sides, however, you should fasten a strip of strong cloth on the

outside of the ends and bottom-bars of the frames, leaving slack enough in the cloth so that when filled with chaff it will bulge out enough to cause the frame to fit snugly against the sides and bottom of the hive.

The chaff cushion is simply a square sack as wide and as long as the inside of your hive, and about 4 to 6 inches thick, filled with chaff. Care should be taken, however, not to fill it too full, for if too full it will assume a rounded form, and not fit down as well on the frames.

With two division-boards and one chaff cushion for each colony, you are ready to go into the apiary. If your hives are two stories high, remove the upper story, and remove from the lower story enough of the frames to admit of a division-board on each side, which will generally be three. Thus, if you are using a ten-frame hive, it will have room for seven frames of brood and honey between them. Place the frames containing the most brood in the center, and those having the least, or none at all, next to the division-boards. Care should be taken to allow the necessary amount of stores, which should be from 20 to 25 pounds of well-ripened honey. Should there not be bees enough in the hive to pretty well crowd seven frames, remove one, two, or three more frames, and move up the division-boards so as to allow no unoccupied space. Should there not be enough bees to cover well four Langstroth frames, or their equivalent, I prefer to unite them with another colony.

Should you have frames containing brood that are not needed in some colonies, you will most likely find a place in another colony where they can be used to advantage. After you have the frames and division-boards arranged as described, place the enameled cloth over the frames, put on the second story, and put in

The Chaff Cushion,

being sure that it fits down well around the sides, then put on the cover, and do not bother them until some warm day in February, when it might not be amiss to peep in and see how they are getting along. I forgot to say that before placing the cloth over the frames, you should lay two sticks about 3 inches apart, crosswise of the frames. The sticks should be an inch or more in thickness.

This will allow the bees access to any frame in the hive by passing over the top.

See that each colony has a young, healthy queen, before putting them away. I should not like to try wintering colonies that have queens over two years old.

The more bees you have in a hive when prepared for winter, the surer you are of success (at least that is my experience), even if some of them are crowded outside for a while. Should your bees not have enough stores to winter on, you had better feed them. Instead of putting on the chaff cushion I would use a feeder in the upper story, turning the enameled cloth back a little at one end, to allow the bees access to the feeder.

CONGLOMERATION.

Written for the American Bee Journal
BY G. B. OLNEY.

May the A. B. J. ever shine
Through all the coming time,
With light and life a-borning,
Like gold and silver—no dreading;
But sure protection to a union
All o'er the land a-roving,
Their legal rights construing
In a mild way, but ruling
Still but deep—no fooling.

Arkadelphia without number
Will only find they've made a blunder,
To attack an industry as old as time;
With grape-culture and Arkadelphia fine,
It's only wasting time—
There's a "Union" just behind.

From over hills and many hollows,
Comes gleaming forth the single dollars,
Shouting aloud in bold, defiant power,
Steep-pointed shells at their dissembling tower.
They fairly conceive why the land is ours,
And all must "get" from the "land of the free"—
No place here for even the honey-bee.
"You're a 'nuisance,'" but your not to blame—
Bright Arkadelphia gave the name.

Oh, how sweet and euphonious is the sound,
Claiming the honey-bee in any town
Is the greatest "nuisance" ever found.
Arkadelphia—your only a name,
A bursting bubble for public fame,
More "artificial comb made of paraffine,"
"Scientific pleasantry" now it is time
To crawl in to your holes, recall the fine,
Quick to hide and get behind.

Olney, Iowa, Oct. 15, 1888.

NIL DESPERANDUM.

The Failure of the Honey Crop in England.

Editorial in the British Bee Journal,
DATED OCT. 18, 1888.

We are right in presuming that the bulk of our readers in Great Britain are amateur bee-keepers, who do not depend upon honey-raising for a livelihood, therefore to the majority, first, a few words of comfort may be fitly addressed now that the season of 1888 is ended.

One of the great recommendations of this pursuit, one of the principal reasons for the growing popularity of our hobby, has been that *it pays*; this has been proved over and over again, the question has only been one of doubt as to whether or not one could, in our fickle climate, devote the whole time to bee-keeping and obtain a living by it. On this point the consensus of opinion is that bee-keeping should be combined with some other occupation, such as fruit or poultry farming; alone it could not be recom-

mended. The occurrence of a disastrous succession of fruit, clover, and heather crops, such as we have experienced this season, but adds weight to the advice we have repeatedly given in these columns in answer to inquirers who have thought of making a business of bee-keeping *per se*. Keeping bees will then pay, because we have more strings than one to our bow, and a single bad honey season does not mean disgust followed by collapse.

"Tis not in mortals to command success,
But we'll do more, Sempronius: we'll deserve it."

So let those with whom our bee-keeping is but an agreeable pastime, a true labor of love, take heart of grace, and, with true British courage, fight the harder the more we seem to be surrounded with difficulties. It is only by such an exhibition of pluck that we can show our so-called love for bees and bee-culture to be a sterling feeling and not an empty sentiment, lasting only so long as the *couleur de rose* of the hobby—only so long as lasts the golden light gleaming through well-filled honey-jars.

Quite a number of proverbial sayings spring into the mind when we urge our readers to have "a patient continuance in well-doing;" this, by the way, being only a more ancient way of telling us that "Everything comes to him who knows how to wait." (We will allow the cynic to get in his jeer edgeway, that "whilst the grass is growing the horse is starving.") We have often found "the darkest—the coldest hour, the one before the dawn;" we have found, too, the mere *effort* to "take arms against a sea or troubles," as Shakespeare tells us, "and by opposing end them." Who has not felt braced up by a firm determination to get comfort out of disaster by sheer force of will? Why, the oldest amongst us—old stagers, the steady coaches whose wheels have placidly revolved with the years in an uneventful round of monotony—the monotony of mere routine, these can remember how many of the happiest passages in life have been developed and perfected when there has been no single gleam of hope on the horizon, all dark and dismal everywhere.

Be sure we may find much pleasure in sympathizing with such of our fraternity as have found the year's transactions a loss, all too keenly to be felt perhaps; we can try to infuse into them a little of the spirit of Mark Tapley, who played "Away with Melancholy" on a one-keyed flute. We recently saw a couple of bee-keepers returning from the moors with a waggon-load of hives, plodding through a drenching rain for eight miles on a black-dark night; one of them wheeled a broken tricycle, and both were as

happy as sand-boys, wet to the skin as they were, bringing home a dozen hives from which they had not taken a single pound of honey during either clover or heather harvest—on the contrary, they had been forced to feed the bees. England is not in danger (not even of a decline in bee-keeping) so long as we have hearts of this mettle in our midst. Truly, nothing can damp such ardor, and a mishap only makes them “thankful it's no worse,” sheer animal nerve carries them through breakers into the smooth waters of contentment.

Our warmest sympathy is offered to those in the trade who have pluckily launched out in the effort to live by combining bee-keeping with the making of appliances used in the craft. These have had blows with a two-edged sword:—their own bees have earned little or nothing, and there has been very little demand for hives, sections, extractors, and other requisites of the bee-garden. It would be, we believe, a recompense to the trade, if those who have the means would, next season, purchase, instead of making for themselves, such articles as they can. The goods are now-a-days very cheap and well made; competition has given us many things at low rates, so that it would pay us in the long run to keep the competitors in the field until brighter days come, as come they must, when they and we may be repaid for the privations and pinches one has to put up with in such a year as 1888.

The Past and Future.

After such a summer (?) as the bees have passed through, it behooves every bee-keeper to see that a disastrous season is not followed by an utter collapse of his army of workers—workers who, unfortunately, have not had the opportunity to store either for their masters or themselves.

Already we hear of many colonies dying of starvation, and not a few skeppists declare their intention of feeding no more, as they have already fed all the summer in the hope of a turn for the better, and now the bees must go to the wall. Of course this is only false economy with sugar at present rates. Take, for instance, a common skep, well stocked with bees, and hardly an ounce of food. Rather than let them perish, suppose we give them 15 pounds of syrup, which, at the outside, will cost not more three shillings. With a fair prospect of wintering, the following season such colony will be worth at least 15 shillings, without counting its swarm, and almost certain crop of honey. Is there any question about feeding being a good investment?

The oldest bee-keepers do not remember such a honeyless season as we

have just experienced, and it is more than probable that the present generation may not see another such. Apiaries of fifty to one hundred colonies have not given a surplus in total of one hundred pounds; skeps have been “taken up” by the score, and not a half-a-dozen pounds of honey have been secured. Many bee-keepers have had to feed through the summer, while it has been the exception to find some favored locality or apiary where the bees have managed to get a living all the time. Such we know of where a small surplus has been given, and some have even stored themselves for winter during the warm spell of weather experienced in September.

The past summer has been remarkable in that not a single honey-glut occurred while the main crops were in bloom. We have, of course, experienced poor seasons, but with the present exception we do not ourselves remember when there was not at least one honey-glut, whatever the prevailing weather may have been.

INFLUENCE.

Written for the American Bee Journal
BY EUGENE SECOR.

When the dark Lethæan waters,
And the silent mists of ages,
O'er our memories thickly gather,
In the stilly realm of Death-land;—
When no more our names shall quiver
On the lips of friend or kindred,
Whether good or whether evil
We have taught by our example,
It shall live—it dieth never.
When decay earth's classic structures,
When their marble pillars molder,
Then the influence we've exerted
On the lives of fellow mortals,
May retain its wonted vigor—
May its proper fruit be yielding.
Forest City, Iowa.

THE SOUTH.

Hints about Seasonable Work in the Fall.

Written for the Southern Cultivator
BY J. M. JENKINS.

This month, in the South, is the proper time to see that all colonies have plenty of stores to take them through the winter. If any are short of honey in the brood-nest, we can probably find others that have more than they need for their own use, and we can take one or more frames from them and give to those that have not enough for winter.

As to how much honey is needed to winter a colony depends upon circumstances, mainly upon the size of the colony. It is best to be on the safe side, and allow them more than enough. I give my bees 20 to 30

pounds per colony. This weight is guessed at by estimating the number of frames full of honey in the brood-nest, and that a full Simplicity brood-frame will average five pounds; if we are short of honey, and have to feed, we can use extracted honey or sugar syrup for this purpose. The latter is easily prepared by pouring boiling water on twice its weight of cheap sugar. It is not necessary to cook it.

In the North, where bees are confined for months, it is necessary to use the best and purest sugar. In the South, where they fly nearly every fair day in the year, they are safe with any food they will eat.

In this locality, and in many others in the South, the “bitter weed” that spoils the milk in the spring, abounds and yields honey from about the first of August until frost, and although the honey is too bitter to eat, it answers admirably for our bees to live on through the winter. As it does not bloom before the beginning of August, we can make it a point to take all the honey from them before it blooms, and let them fill up their brood-frames with this bitter honey.

Many different feeders have been invented, some of which are complicated and costly, but I have found the “Simplicity feeder” sufficient for all purposes—its cost is only five cents. The little wooden butter plates used by retail grocers, are as good as anything, perhaps, and can be had for nearly nothing. To use these feeders we place them in the upper story, after the sections have been removed, directly on the brood-frames; put enough of them in a hive to hold 5 or 10 pounds of feed. Place the feeder in position while empty, and with a sprinkling pot with the sprinkler removed, or a coffee-pot, pour the feed into the feeder, and cover all with the enameled sheet or quilt used for covering the frames. This retains the heat of the hive, and is essential as the bees would not leave their cluster in cool weather to carry the food below.

With an assistant to handle hive covers, it is very little trouble to feed in this way. The best time to feed is after sundown, so as to avoid robbers. Be careful to spill no feed—not a drop—outside or on the hives, or leave any exposed anywhere that a robber may get a taste the following day. Be sure that no hive has a crack or other opening except the entrance that will admit a bee, and the entrance had better be contracted to a small one, especially if the colony be not strong.

Bear in mind that you cannot be too careful while feeding, for if robbing is commenced you may have trouble.

Wetumpka, Ala.

UNITING.

Some Practical Hints about
Uniting Bees.

Written for the *Prairie Farmer*
BY MRS. L. HARRISON.

Bees, that are to be united, should be brought together after they have ceased flying at night, and placed side by side, and on top of each other, and boards placed in front of the entrance, to attract their attention, so that they will take their bearings. When their location is established, they are ready to be united. All but one queen should be removed; if left, they will cause fighting, and all might be destroyed in the fray. Puff a little smoke into the entrance, so that they will load up with honey, and be on their good behavior, and then proceed to business. Take all the combs containing brood and place them together in a hive, and all others in a comb-basket or some other receptacle, where bees cannot get at them to rob.

Place the hive containing the brood-combs as near the center of the location of the united colonies as possible, and pour all the bees together in front of it. This hive has not been the home of any of them, and as they have now none of their own, they will gladly accept it, and unite peaceably. After they have been domiciled a few days, the combs containing honey might be put in the upper story, and a little opening made so that bees could come up and carry it below. When empty, they should be stored away for use another season.

Sometime since, a boy called saying: "I saw a swarm of bees come out of your lot, and I will show you where they are now." I found them clustered in a neighbor's yard, and brought them home, but what to do with them was the question. I had neither frames or comb nor foundation to give them, and I put them into an empty hive; as the seasons ran, they might fail to build comb and store enough honey to last until flowers bloom. I threw flour on them, hoping to catch the queen, as they ran into an empty hive, and take her away, so that the bees would return to their old home, and I could see where the white bees went to, but I failed in the attempt. Then I remembered seeing a hive which contained very few bees, and on opening it, found it queenless. I took out the frames of comb, and gave them (just as they were, containing honey and bee-bread, but no brood) to the swarm. So they commenced housekeeping in a well-furnished house, with plenty of provisions. These combs would soon have

been taken possession of by moths, and before cold weather, have been entirely consumed.

Some persons have a mistaken idea about moths, thinking they destroy colonies of bees; they merely move in when the bees move out, or are too weak to cover or defend their comb. I was very much amused this summer, while watching a swarm enter a hive which contained empty comb, at seeing these gentry fly out in hot haste; they saw that the enemy was too strong for them, and emigrated, leaving their young to be summarily dealt with. In a few moments they followed suit, being taken by the bees from their cradles and rolled off the hive.

Peoria, Ills.

PATENTS.

The Relation to Invention and
Practical Honesty.

Written for the *American Apiculturist*
BY R. L. TAYLOR.

It seems there is a question arising among bee-keepers concerning the propriety of obtaining a patent on any article pertaining to bee-culture. It is broadly asserted that the bee-keepers of this country are now generally of the opinion that it is not best to obtain such patents. I know not on what authority such assertion is made, but I trust it is not true. I am glad to notice that the *Apiculturist* has boldly challenged the statement, and it seems to me the matter is of such great importance practically, as well as morally, that I have thought it worth while to say a word upon the topic.

It appears plain to me that the patent laws are beneficent in their effects to all; to the inventor in protecting him in his right to his own invention, and not less so to others who reap the fruit of his skill and study by reason of the laws furnishing him an incentive to apply his skill and study.

Many are opposed to the granting of patents, but that is not a difficult thing to account for. Some are opposed because they are themselves destitute of mechanical skill, and so imagine that a freedom to use the inventions of others would be the most advantageous thing for them. Others because, through a spirit of general charity, they think, though stumbled, perhaps, at the idea of taking the thought, time and money of the inventor without recompense, that the greatest good to the greatest number would come of a like freedom. Still others are manufacturers of bee-keepers' supplies, and aim to make and keep for sale everything that is largely called for. Naturally enough, such desire

about all the profit that can be obtained, and so would prefer that the inventor have no legal right to any part of it, and either shut him out from all financial benefit, or else only give him credit for a nominal sum to be fixed at the direction of the manufacturer, and accepted as a gift.

But all these overlook the great fact that every party to a transaction taken as a whole must receive a share of the profit, or transactions become infrequent and business suffers. The drive wheels of a locomotive cannot say to the other wheels, give us all the oil, for that would create friction, and locomotion would cease.

It requires time, thought, labor and money to make and perfect an invention, and certainly the laboring inventor is worthy of his hire. And if that is so, should he not have legal protection in his right?

And then comes the dissemination of the invention, and the making plain its functions and advantages. How often when an invention has been patented, and its dissemination begun, does some one rise up and claim that he invented the same thing long before. He did not believe in patents, perhaps, and so seeing no hope of adequate reward, let his invention sleep in secret. The other, having hope of reward, publishes his discovery, and this, so far as the public is concerned, is the chief virtue of an inventor. Without question, the knowledge of articles patented is more likely to be disseminated.

All effort is made through some incentive; and in the struggle for sustenance and competence, there is only one incentive that moves all, and that is the hope of gain. Who will say it is best to take that incentive way?

It is said that patents give an opportunity for the commission of frauds. If that were true, shall we abolish genuine money because it gives an opportunity for counterfeiting?

But it is not the patent of an article that gives the power to perpetuate fraud. That is rather a safeguard, as the fee prerequisite to the use of the invention begets caution and careful examination. Fraud is accomplished through the effort made to disseminate a worthless article. To the simple, the fact that an article is proclaimed as unpatented, smacks of honesty, and they are easily caught by bait, having apparently such an aroma. Thus, through advertising and other active efforts, a certain hive which is very inconvenient in use, and its making very laborious, and which is discarded by almost every bee-keeper having bees in any considerable number, as soon as he gains a little experience, is

now selling to beginners more extensively than perhaps any other hive.

Practically it operates as a fraud to a greater extent than all other bee-keeping articles with patents real or pretended combined. I speak from experience with the hive both prac-

tically and financially. A patent on the hive instead of increasing the injury, would have lessened it very materially. A few dollars' charge for individual rights has a wonderful effect in suggesting caution in the adoption of new devices.

Smokers furnish another case in point. The ones protected by patent are decidedly the best, and the ones heralded as unpatented are the ones to be shunned.

It is also objected that inventions are the work of many minds, and,

therefore, a single person should not be allowed a revenue from them. It is true, no doubt, that inventors draw upon the common fund of knowledge amassed by others, but is he who is acute enough, and studious enough, and devoted enough to combine that knowledge, and make it produce practical results, and is, after that, sufficiently enterprising to bring it to the doors of the multitude, and to persist in explaining it until stubbornness itself shall admit its value, therefore entitled to no credit?

There is much food for thought in this subject, but time and space forbid its further pursuit at present, but let us intelligently consider, that we may get into a proper attitude with reference to it.

Lapeer, Mich.

WHAT ARE WEEDS?

Not botanically, or scientifically, but specifically. Do we always consider this word weed in its broadest sense? What constitutes a weed? Certainly we all know what common weeds are, even though we do not all do our duty in eradicating them, but there is a class of weeds that may be we do not always properly recognize as such.

We may consistently class any plant a weed that cumber the ground to the detriment or destruction of plants that are wanted for useful purposes. Therefore, cultivated plants become weeds when there is a superfluity of them. If there are two or three more cucumber plants in a hill than can successfully grow there, or this much more than is needed, these surplus plants are just as much weeds as barn-grass or thistles.

The point I wish to make, then, is that a plant too much in any place is a

 De bu - sy bee, De bu - sy bee, What vorks ven I'm in bed.

weed, and if we have no other place for it should be removed and put with other weeds. As a general rule, not enough attention is paid to this operation of thinning. It may be carried too far in being done too early, before we know what the insects are going to do, or by taking out too many plants, but as a rule this operation is not carried far enough for the best results.

It is a very important factor in insuring the largest return possible from a given ground, with the least expense. A great economy to fertilizers will result from a strict attention to this matter, and but a small amount of experience is necessary to enable one to see how far to go with it. In thinning out, if we are at work upon a plant that is easily transplanted, always utilize all the plants we can find room for by setting out in places where they molest nothing else.

In thus filling up the nooks and corners, we shall transfer these surplus plants from the category of weeds to the list of useful plants.

Let us pay good attention to this thinning process while we are weeding, and see that we never neglect this important feature in making the most of our ground. We shall all find room for improvement in this regard.—N. E. Farmer.

CONVENTION DIRECTORY.

- 1888 *Time and Place of Meeting.*
 Nov. 14.—Alabama State, at Montgomery, Ala. J. M. Jenkins, Wetumpka, Ala.
 Nov. 16.—Marshall County, at Marshalltown, Iowa. J. W. Sanders, Sec., LeGrand, Iowa.
 Nov. 21, 22.—Pan-Handle, at Wheeling, W. Va. W. L. Kinsey, Sec., Blaine, O.
 Dec. —Michigan State, at Jackson, Mich. H. D. Cutting, Sec., Clinton, Mich.
 1889.
 Jan. 9-11.—Nebraska State, at Lincoln, Nebr. J. N. Heater, Sec., Columbus, Nebr.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Swarming-Box.—John S. Seely, of Oswego, Ills., on Oct. 30, 1888, writes :

The patent swarming-box that was described in the BEE JOURNAL a white ago,

I am inclined to think does not amount to much. I have used it, or all that is useful, as I recollect the description of it, for at least 3 years. I got the idea from the BEE JOURNAL, or some other paper, of the box on the stick, and I added the slide. I take a 16-foot piece 1x2 inches, cut in two, planed and smooth, and put three strips of tin 1-inch wide around both, and nail all to one piece; then bore holes through both a foot apart, and slide up and down to suit the height required, and put in a pin or small bolt. The box is 6 or 7 inches square, and about a foot long, open at the top, and several holes in the sides. I think that I have not cut a limb since I have used it. I generally give the limb a shake or jar with the box, sometimes with a pole. If the bees cluster on the body of a tree or large limb, I put the box under the bees, brush them off, and they will usually soon cluster on it. I have often carried large swarms 8 or 10 rods in and on the box. I have no patent on this, and I think that no one else has a right to.

Good Yield from Italians.—John Blodget, Flag Springs, Mo., on Oct. 27, says:

I commenced the season of 1888 with 9 colonies, 7 strong and 2 weak ones. I increased them, by natural swarming, to 30

strong colonies, all in good condition for wintering, with plenty of good honey, and to spare. I have taken off 1,428 one-pound sections of comb honey, and sold 900 pounds for 16¢ and 15 cents per pound. This was all heart's-ease honey except about 200 pounds of linden, making an average per colony, spring count, of 158½ pounds. I have one new colony that was hived on June 9, on starters 4 inches wide in brood-frames; since that time it has stored 178 one-pound sections of honey. Its queen is a daughter of an imported queen reared artificially, and of last year's rearing. There was no swarming impulse there.

The black bees are a failure so far as this year is concerned. One of my neighbors, who keeps bees only three miles away, told me recently that he had 12 colonies in the Quinby hives, and that all he would get from all of them was only 90 pounds. I feel like hurrahing for the Italians. They are the "coming bees," and have come to stay. I hope, until they drive the black bee, moth and all into the—I do not know where, but I do not know of a place in Missouri bad enough.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for \$1.50.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in *Cheshire's* pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being mailable, it must go by express.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the *Apiary Register* and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

Photographs of Bee-keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 120 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

Hastings' Perfection Feeder.—This excellent Feeder will hold 2 quarts, and the letting down of the feed is regulated by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for \$3.50, and it can be obtained at this office. Postage 10 cents extra.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$3.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Melilot or Sweet Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 10 cents per pound for bag and postage.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Simmins' Non-Swarming System.—We have a few of these books left, and we will club them with the AMERICAN BEE JOURNAL for one year, both postpaid, for \$1.25. The subscription to the BEE JOURNAL can be for next year, this year, or may begin anew at any time.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, \$1.00 per 100, or \$8.50 per 1,000.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

We will Present a Pocket Dictionary for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide the spelling of words, and their meaning.

Cork for Winter Packing.—Its advantages are that it never becomes *musty*, and it is *odorless*. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Good Enough.—Andrews & Lockhart, of Patten's Mills, N. Y., on Oct. 13, 1888, wrote as follows concerning their use of the advertising columns of the AMERICAN BEE JOURNAL:

We got more orders from our advertisement in the AMERICAN BEE JOURNAL than from all the other bee-papers put together. We shall advertise in it again next year.

Honey and Beeswax Market.

CHICAGO.
HONEY.—New crop arriving slowly, but demand is limited. White clover comb, 17@18c. Extracted, 7@8c.
BEE SWAX.—22c.
Sep. 12. S. T. FISH & CO., 189 S. Water St.

CHICAGO.
HONEY.—For white comb 1-lbs., 18c. Very little inquiry for anything outside of 1-lbs., and when it is wanted it is at a lower price. Extracted, the best grades, 7@8c., and some held higher. Offerings are small and demand slow.
BEE SWAX.—22c.
Sep. 12. R. A. BURNETT,
181 South Water St.

MILWAUKEE.
HONEY.—We quote: Fancy white 1-lbs., 18@20c.; 2-lbs., 14@18c. Good dark 1-lbs., 16@18c.; 2-lbs., 15 to 16c.; fair 1-lbs., 12½@14c. Extracted, white, in kegs and ½-barrels, 8½@9c.; amber in same, 7½@8c.; in pails and tin, white, 9@9½c.; 10 barrels and half-barrels, dark, 6@6½c. Market steady and supply ample for the moderate demand, but present values have a tendency to restrict general consumption.
BEE SWAX.—22@23c.
Oct. 25. A. V. BISHOP, 142 W. Water St.

DENVER.
HONEY.—Colorado, new 1-lb. sections., 13@15c. Extracted, 7@8c.
BEE SWAX.—20@23c.
Sep. 7. J. M. CLARK & CO., 1409 Fifteenth St.

NEW YORK.
HONEY.—We quote: Fancy white 1-lbs., 15@17c.; 2-lbs., 14@16c. Fair white 1-lbs., 14@16c.; 2-lbs., 13 to 15c. Extracted, white, 7½@8c.
BEE SWAX.—23½c.
Sep. 17. THURBER, WHYLAND & CO.

NEW YORK.
HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 13@14c. Fair white 1-lbs., 15@16c.; 2-lbs., 12c. Buckwheat 1-lbs., 11@12c.; 2-lbs., 10@11c. White extracted, 7½@8½c.; buckwheat, 5½@6½c.; California extracted, white sugar, 7½@7¾c.; amber, 7¼@7½c. Demand good and prices firm. New comb honey is arriving quite freely.
BEE SWAX.—23@23½c.
OCT. 10. HILDRETH BROS. & SEGELKEN,
28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.
HONEY.—White 1-lb. sections, 11@12½c.; 2-lbs., 12½@1 c.; amber, 8@10c. Extracted, white, 5¼@5c.; light amber, 5¼@5½c.; amber and candied, 4¾@5c. Receipts light and market firm for best qualities.
BEE SWAX.—Dull at 19½@22½c.
Sep. 22. O. B. SMITH & CO., 423 Front St.

DETROIT.
HONEY.—Best white comb, 17@18c.; dark, 16c.—Extracted, 8@10c. Market bare of all kinds.
BEE SWAX.—21@22c.
Sep. 24. M. H. HUNT, Bell Branch, Mich.

CINCINNATI.
HONEY.—We quote extracted at 4¼@8c. per lb. Comb honey, 12½@16c. Demand slow, and only for best qualities.
BEE SWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Oct. 24. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.
HONEY.—Choice 1-lb. sections, 18c.; dark 1-lbs., 14c.; 2-lbs., 16c.; dark, 13c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock fair.
BEE SWAX.—None in market.
Sep. 27. HAMBLEN & BEARSS, 514 Walnut St.

NEW YORK.
HONEY.—We quote: Fancy white 1-lb. sections, 17½@18c.; 2-lbs., 14@15c. Fair 1-lbs., 14½@15½c.; 2-lbs., 11@12c. Extracted, fancy white clover, 7½@8½c. California white in 60-lb. cans, 8c.; light amber, in same cans, 7¾c.; amber, 7¾c. Buckwheat in kegs and barrels, 5½@6. Cuban, in barrels and ½-barrels, 45c. per gallon.
Sep. 26. F. G. STROHMAYER & CO., 122 Water St.

BOSTON.
HONEY.—We quote: Best white clover 1-pounds, 17@18c.; best 2-lbs., 16-17c. Extracted, 8@9c. The market is more active, with an upward tendency.
Oct. 25. BLAKE & RIPLEY, 57 Chatham Street.

KANSAS CITY.
HONEY.—White 1-lbs., 17@18c.; dark, 14@15c.; California white 1-lbs., 17c.; dark, 14c. Extracted white 8c.; amber, 7c.
BEE SWAX.—None in the market.
Oct. 11. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.
HONEY.—We quote: Extracted in barrels, 5@6c., according to quality; in cans, 7@8c. Comb, 12½@15c. Prices firmer on account of scarcity, though the demand is not great.
BEE SWAX.—21c. for prime.
Oct. 17. D. G. TUTT & CO., Commercial St.

SAN FRANCISCO.
HONEY.—We quote: Extracted, white, 6 cents; light amber, 5½c.; amber, 5¼@5½c. Comb, 1-lbs., 13@14c.; 2-lbs., 10@13c.
BEE SWAX.—20@22c.
Sep. 24. SCHACHT & LEMCKE, 122-124 Dsvl

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. Nov. 14, 1888. No. 46.

EDITORIAL BUZZINGS.

When things don't go to suit you,
And the world seems upside down,
Don't waste your time in fretting,
But drive away that frown,
Since life is oft perplexing,
It is the wisest plan
To bear all trials bravely,
And smile when'er you can.

Our English Friend, Mr. T. B. Blow, made us a short visit last week. He spent Sunday at Medina, O., and intends to return to England very soon. He was unavoidably delayed in Wisconsin, and now regrets that he has not time to accept the many invitations to call on bee-keepers on his return trip. He is a well-informed apiarist, and has traveled in many countries in the interest of bee-keeping.

New Cook Book.—On our desk is a copy of "Miss Maria Parloa's New Cook Book." It has an elegantly illuminated cover, and is filled with wise, judicious and palatable instruction. By adopting these directions, house-keeping may be made simple, easy and elegant. It will be sent for 30 cents by the publishers, Estes & Lauriat, 301 Washington St., Boston, Mass.

Honey Turning to Sugar.—When we were at the Columbus Convention Dr. A. B. Mason gave us a bottle of honey-sugar for our Museum. It was obtained thus: Let a barrel of honey granulate, and after removing the head of the barrel, scoop out and remove the honey in the centre. After awhile the honey at the sides will drain off the liquid portion and become dry sugar. That is how the doctor obtained this.

Bees in the Museum Zoo.—Geo. A. Wright, Glenwood, Pa., on Oct. 30, 1888, says:

I have just read the item from the Washington, D. C., *Star*, on page 691, and by your foot-notes to the article in question, I see that you believe there is some truth in the statement. Now I happened to be in Washington, D. C., on Oct. 11 and 12 (only three days after the article in question was written) and I spent the best part of two days in the National Museum; I looked the agricultural and "zoo" departments through with great care; made careful inquiry of the Government officials, and none of them had ever seen or heard anything of bees or honey in the National buildings. Had Miller or any one else placed bees on exhibition in the Museum, I should have been quite sure to have found them, for I had bees and honey particularly in mind when looking through the Museum. So just put the reporter down with Wiley, Evans & Co.

We know that Mr. Miller has bees on exhibition, but the *Star* reporter may have got things mixed up some on page 691.

Since the above was in type Mr. J. P. Miller called at this office, and we showed him Mr. Wright's letter. He said he was sorry Mr. Wright did not see the exhibit of bees. They were in the department of live animals, a small building just south of the Smithsonian. Had he gone there it would have been almost impossible to have missed seeing them. They were near the south window, just to the left of the large cage containing the two black bears six months old. If Mr. Wright still doubts Mr. Miller's word, he can write for the facts to Mr. Hornaday, Superintendent of the Department of Live Animals in the Museum at Washington, D. C. Mr. Miller, during the warm weather, exhibits bees in the large cities of America for a living, and he is an adept at it.

Oleomargarine, as a honey adulterant, is a strange thing, but that is what the paper stated, as we quoted from it on page 691. Our friend, A. I. Root, comments thus upon it in *Gleanings* for Nov. 1:

According to the American Bee Journal there are now reports started in the papers that in Holland honey is adulterated with *oleomargarine*. This last is ahead of all other previous false statements. We have heard about glucose, old rags, shoes, etc., being used as material for making spurious honey; but *oleomargarine* is ahead of them all. I wonder if the compositor or editor had not lost his dictionary, and intended to use some other word.

No, friend Root, it was not a typographical error. The writer may have been imbibing or enthusing, but the proof may be found in Mitchell, a. d. Chem. Tech. Versuchsanstalt in Berlin, 1886, page 14. We hope some German apiarist will look it up, and report in the AMERICAN BEE JOURNAL.

The Time for Reading has come, with the long winter evenings. We have a large stock of bee-books, and would like to fill orders for them. To read and post up is the way to succeed in any pursuit—in none is it more important than in bee-keeping.

A Correspondent in the Canadian Bee Journal suggests that the Ontario Bee-Keepers' Association hold a union meeting at Brantford with the next annual session of the International American Bee-Association. Here is what he says:

I see by the last BEE JOURNAL that the North American Bee-Keepers' Association is to meet at Brantford next year. Why not have the Ontario Bee-Keepers' Association meet there with them? I observe that you, Mr. Editor, suggest that the Ontario Bee-Keepers' Association attend in a body, but I go one better, and propose to hold both annual meetings at once. "I may be wrong," as Mr. Pringle says, in the suggestion, but there is no way to find out how little a fellow knows until he comes out and makes himself heard.

We heartily endorse the suggestion. One large and enthusiastic convention is far preferable to two smaller ones.

Bee-Keepers' Union.—After giving a brief *resume* of the annual report of the Manager of the Union, the *Australasian Bee Journal* adds this paragraph, winding up with an expression of good will and desire for its prosperity:

The report gives particulars of several cases the Union has defended on account of its members, and shows how the Union has forced not only the now celebrated Prof. Wiley, but also lawyers, doctors, and ministers to recant all they have said in connection with artificial comb honey. The Union has paid away principally in defending cases against bee-keeping during the year ending June 30, 1888, \$305.45, and the balance in hand on the same date was \$258.27. Long may the Union flourish!

Colorado Climate.—Prof. A. J. Cook writes as follows in reply to Mrs. Harrison's article on page 718:

Let me assure Mrs. Harrison that Colorado climate seems not necessary. I have had a small plat of Rocky Mountain bee-plant for over ten years. It blooms well, and has attracted the bees freely each year. I have just sown eight acres, and shall know what is what next year.

Farmers should keep a regular account book, which will give them a full showing of the transactions of the year, showing the amount of profit or loss in each department, together with all the receipts and disbursements. Our Farmers' Account Book contains 150 large folio pages, with useful information and reference tables at the end. Price \$3.00.

We will *present* it to any one sending us *four new subscribers* for a year, with \$4.00 to pay for them. A little work in the dull winter days will procure this nice present. We send it by mail post-paid. It is handsomely bound.

Last Week we sent bills for those who are in arrears for subscription for a year and more. We hope they will be prompt in sending in this amount together with a dollar for next year.

GLEAMS OF NEWS.

Statistics.—The subjoined summary of information, derived from individual reports given in *Gleanings* for Nov. 1, 1888, will give a correct idea of the present condition of the apian pursuit throughout the United States and Territories :

1. The average price of comb honey throughout the United States is a small fraction over 19 cents per pound. The average for July 1 was 16 cents. The market is improving some, as will be noticed. In some cases it sells as high as 30 cents. In a large number of localities it is sold for 25 cents. In only three or four places does it sell for less than 15 cents.

2. The average price of extracted honey is a fraction over 12 cents per pound. The statistics for July 15 showed 11 cents. There seems to be less fluctuation in the price of extracted than of comb.

3. A trifle over 48 per cent. of honey was secured throughout the United States by the reporters, and probably this percentage represents very nearly the proportionate amount secured by bee-keepers as a whole through the country. This is some better than the report in July, by about 25 per cent.

4. Of those who report in regard to the quality of honey, 66 report good ; 32 fair, and only 8 poor.

5. Of the number who reply in regard to the season, 13 report it to have been good ; 44 fair, and 53 poor. If we put those who report good and those who report fair together, the ratio stands 57 to 53. In other words, in about half the localities the season has been poor ; and in the other half, from fair to good.

6. This season is decidedly better than last ; 66 report better ; 12 about the same, and 27 worse. At this rate we may expect a tolerably good season next year, if the gradations from worse to better mean anything.

7. As to feeding, very little has been done this fall ; of those who report, 80 will not be obliged to feed at all. The remainder, 27, will feed some, but not much.

Comparing this season with the last, we have great reason to be encouraged ; and although the reports given refer to individuals largely, yet in the majority of cases they are representative of the locality. If one man in a certain section of the State has had a poor season, those about him will experience pretty much the same state of affairs. There are occasionally exceptions to this rule, but it generally holds true.

In Auckland, New Zealand, they have mild winters. Mr. O. Poole, in the *Australasian Bee Journal* for Oct. 1, 1888, remarks thus concerning such seasons :

As a proof of the mildness of the past season, I may mention that a small colony of bees have successfully passed the winter months at Devonport on three combs in a glass observatory hive. The queen has for some time been busily laying, and at present they have every appearance of doing well.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

What Becomes of all the Sugar and Honey? asks the *American Agriculturist*, and then answers it in this way :

In the United States the consumption of sugar per head of the population was 29 pounds in 1869 ; 39 in 1879 ; 48 in 1888, and 54 in 1887. In England the consumption of sugar was 32 pounds per head in 1858 ; 41½ in 1858 ; 62 in 1867 ; 62 in 1876. For several countries the consumption is placed as follows :

Great Britain.....	63 pounds.
France	25 "
Germany	18 "
Denmark	33 "
Holland	25 "
Austro-Hungary	15 "
Italy.....	6 "
Spain.....	7 "
United States	54 "
Canada.....	51 "

Australia is put at 86 pounds *per capita*, and Venezuela at 180—a figure that seems incredible. In all countries the average consumption annually increases. Sugar is becoming as much a necessity of life as bread.

Then on the consumption of honey it continues in the following words :

The annual product is about 28,000,000 pounds, or ½ a pound apiece to the population. In 1880, Tennessee made 2,131,000 pounds ; New York, 2,089,000 ; Ohio, 1,627,000 ; North Carolina, 1,591,000 ; Kentucky, 1,500,565, and seven other States—Arkansas, Georgia, Illinois, Iowa, Michigan, Pennsylvania and Virginia—produced more than one million pounds each ; altogether, in the States named, more than half the entire product of the country.

The *Agriculturist* has fallen into an error, consequent upon copying the figures given in the census reports which are manifestly incorrect. The honey product of America is over a hundred millions of pounds, instead of a quarter of that amount.

Cider for Winter Stores.—Several correspondents have inquired whether it would be advisable to attempt to winter bees on stores composed of cider. In reply we commend the following from an exchange :

Bees should not be allowed liberty to cider. All stores from this and decayed fruit are very unhealthy for them during winter as food. Bees will store their combs full of sweet cider if allowed access to it, and in such a case heavy losses are sure to follow during the winter. It well pays each one interested, the apiarist or the manufacturers of cider, to enclose the mills in a building where bees cannot molest them, as it is almost impossible to manufacture cider, when the mills are located close to large apiaries, in the open air.

Combs containing a large amount of cider should be removed, and others of good honey inserted in their stead. If combs of honey are not at hand, it will pay to feed such colonies the full amount of winter provisions, and the combs of cider honey can be used in the spring with no bad effect for spring feeding ; and even if combs of honey are soured to a certain extent, it will do no harm to give it to the bees in warm weather when they are flying daily. But to confine bees without loss during cold weather, it is essential to have a healthy diet on which to confine them.

New Constitution.—Prof. A. J. Cook writes us as follows about the committee who had it in charge last year :

Please allow me to say in reply to the severe strictures of my good friend Dr. Miller in reference to the committee on the new Constitution and By-Laws, that the entire blame rests upon me as chairman. I do not wish my friends Hutchinson and Root to suffer for my delinquency. I have only to say that, owing to a severe press of work the past year, the whole affair utterly escaped my mind. It was like a thunder clap when Dr. Mason called upon me for a report.

I was not present at Columbus, O., when the new Constitution was adopted. As stated in my improptu report, I do not think the new *regime* will be any improvement on the old. I believe the association is a very important organization. I also believe that it will do the most good by continuing its migratory meetings, reaching to all parts of the country, and securing essays for each meeting from representative men from all sections. After this the more informally, and the less machinery, the better. But we shall see. I shall heartily support the new order, and rejoice sincerely in any improvement that results.

One might easily conclude from reading the above that some one had proposed, or that the Constitution had provided that the annual meetings of the Society should be held at one place all the time. Of course they are to be "*migratory*" meetings, reaching to all parts of the country," as heretofore. We agree with the Professor in regard to obtaining essays. The other plan has been "*tried and found wanting.*"

Clear Grit.—As an illustration of this grand quality, Mr. E. S. Arwine gives in the *Pacific Farmer* his experience in living a swarm of bees. He says :

Once upon a time, about 1877 or 1878, I had a swarm cluster about 20 feet up on a tree near my apiary ; and as I could not get at them with a ladder on account of the small limbs, I climbed the tree to get them. I could get nothing to stand on, in reach of the cluster, but two small limbs about as large as a man's thumb, and held on by a limb about 1½ inches in diameter, and about 4 feet from the body of the tree.

The limbs I stood on being on a small fork that terminated in small branches outside of and around the cluster, I had cut the small limbs from around the bees, and was about tying a line to a limb, when the two branches I was standing on broke. The limb I was holding to, by the jerk of my weight coming all on it, bent quickly, striking the cluster, and that precipitated a large part of it on to my bare head, my hat having been knocked off while climbing.

Think of the joy of my situation—hanging by one hand some 18 or 20 feet high, with perhaps a hundred lances busily testing the hardness of my head, and the sticking qualities of my grit, but I did not fall.

I had had a broken thigh once, and I would prefer a thousand bee-stings to one broken leg. I quietly pulled myself on to the body of the tree, climbed down, combed the stings out of my scalp, while my wife picked a dozen or two out of my forehead, face and neck, after which I climbed up again, knocked the cluster into a basket, let them down by a rope, carried them to the hive, and emptied them out. Thus I learned that we could carry bees in an open-topped vessel as well as any way, and with no risk of jarring the cluster off.

BIOGRAPHICAL.

GRAVENHORST.

A Sketch of the Man and His Methods of Work.

Written for *Gleanings in Bee-Culture*
BY L. STACHELHAUSEN.

The name of the German bee-venturer, C. J. H. Gravenhorst (born Sept. 26, 1823), is well known to Americans. The teachers of Germany educate not only the people in the science of reading and writing, but many of them are likewise excellent amateur bee-keepers, silkworm raisers, etc., etc.; so, too, our friend kept bees as long as he acted as teacher.

In 1863, a disease of the ears made it necessary to quit teaching, and from this time he kept bees in the city of Braunschweig, as a specialist, and for the support of his family. Near that city are the wide plains of Lusneburg, with the honey-yielding heath, where bee-keeping has been a profession for centuries. Here the old heath bee-keeper wanders with one hundred or more straw-skeps from one honey-flow to the other until late in the fall; and they are masters in their trade. Here friend Gravenhorst got his first education as bee-keeper.

As the movable comb was more and more used, he used hives after Dzierzon and Berlepsch. He saw the advantages of these hives, but his income was not so large as he wished. In many respects the old straw-skeps were better. So the aim to unite the advantages of movable-frames with the advantages of the straw-skeps caused Gravenhorst to invent his hive, the "bogenstuelper," and he made it public in 1865.

Here I will remark, that Mr. Gravenhorst's hive was the first one in Germany by which any frame could be taken out without removing a number of other ones, as in our Langstroth hive, and Mr. Gravenhorst has always spoken and written for this principle.

As to his originality, his whole management and many things finally adopted here in the United States were known and used by Mr. Gravenhorst first, although in another form. On the other hand, his knowledge of the English language enabled him to study our American methods, and two voyages to England showed to him the progress of apiculture in that country, and he did not fail to use what he learned, of course modified for his contrivances.

For a long time he was the only bee-keeper in Germany who reported in

bee-papers the advance in the United States and England. His experiences are laid down in many articles for bee-papers.

About 1873 Mr. Gravenhorst published the first edition of his book, *Der Praktische Imker (The Practical Bee-Keeper)*. It was merely a pamphlet describing his hive and management. In 1878 the second edition came out, enlarged to a manual for the bee-keeper, and now I have before me the fourth edition, 1887, beautifully illustrated, and much enlarged and improved.

On the first of October, 1883, he started a new bee-paper, *Illustrierte*

C. J. H. Gravenhorst.

Bienenzeitung, by which he gives to his readers the experiences made in his own large apiary, as well as the most important improvements in apiculture in the wide world. This bee-paper is now one of the best, if not the best, in Germany.

In 1884 he was driven away from his home. His neighbors did not like bees, and Mr. Gravenhorst was ordered to remove his. He appealed from court to court, and the German bee-keepers stood nobly by him, helping to pay the expenses; but the lawsuit was lost, and he sold his old home in the city of Braunschweig and moved his bees to Storbeckshof, near the valley of the Elbe.

If we look in his book we will see many engravings which seem strange to us. But if we read the book, and if we know the honey resources of his country, we are bound to say that Mr. Gravenhorst's hive and management are not to be surpassed for his locality. His hive is especially adapted for wandering and for quick handling. Many manipulations are done by hives instead of by frames, the same idea

represented now by Mr. Heddon, but in quite a different way.

The American bee-keeper will be astonished if he sees that Mr. Gravenhorst's hive is turned upside down to take out the frames. This is at first a concession to the custom of the heath bee-keeper; but many advantages are gained thereby. Many times we see all we need by a glimpse from below by lifting the hive only a few inches on one side. If the colony builds some drone-comb here, we have a sure sign that the swarming fever is commencing. The Heddon and similar invertible hives will show us these advantages by and by.

The cover of the hive is tight, and no mat or cloth or quilt is to be removed. This is an advantage, especially in the spring, after a revision has been necessary, because not a bit of the warm air of the hive can escape. The objections against this hive are, that for a short and very good honey-flow it is too small, corresponding to the one story and a half of the Simplicity only. Again, it cannot be enlarged, and thereby is not practicable for comb honey in sections.

In his management we find many things quite different from ours. In conformity to the honey-flow, and the usage of the heath bee-keepers, Mr. Gravenhorst increases his colonies in the spring, and unites again in the fall. He teaches, and has for many years, that swarms should be hived on starters only—an idea which finds advocates now among our best American bee-masters. For this purpose his artificial swarms are quite similar to the natural swarms; and one of his methods of forming artificial swarms is quite similar to Mr. Doolittle's method of forming nuclei. This chapter of his book is very interesting.

Of importance is the chapter on moving bees from one pasturage to another. This is entirely new for the United States, and we could find no better teacher than Mr. Gravenhorst, who for many years has taken his 200 to 600 hives twice every year to another location, and with the best success, too.

In short, Mr. Gravenhorst is original in every respect. His aim is to advance bee-keeping to a pursuit giving a living to the manager, and to systematize the labor. In this respect he has done more than any other bee-keeper in Germany; and we can truly say that Mr. Gravenhorst is now the greatest master in *practical* bee-keeping in Germany. His crops of honey are counted by tons—a rare case in Germany.

One point I wish especially to mention, because he gives a glimpse of the character of the man. Many inven-

tors of hives think that their invention only is good, and that all other hives are impracticable. Not so with Mr. Gravenhorst. He fully perceives the advantages of other hives, and especially of our Langstroth hive, and his judgment was always impartial. In this respect he is far ahead of a few frivolous enviers who criticized his hive and management a short time ago.

In his book he gives descriptions and engravings of different German hives; but we find the Langstroth, Cowan, and the new Heddon hive too. No other German bee-book mentions these or similar hives. The operations and management are described, but he always gives remarks as to how the bee-keeper should proceed with hives of other styles.

Salem, Texas.

QUERIES AND REPLIES.

Using Chloroform to Quiet Ill-Tempered Bees.

Written for the American Bee Journal

Query 588.—1. Would any ill-effects follow the use of chloroform in quieting very ill-natured Cyprians or other bees? 2. Will they revive after being thoroughly paralyzed by its use?—Iowa.

I have never used it.—EUGENE SECOR.

1. No; not unless you go too far. 2. Yes.—H. D. CUTTING.

The use of chloroform is dangerous, either on bees or human beings.—DADANT & SON.

I cannot say; as I have never experimented in that direction.—J. M. HAMBURGH.

A trial will tell you. If you kill them, it would be a "small loss."—G. M. DOOLITTLE.

1. I think not, unless greatly overdone. 2. I think so, but I have never tried it.—C. C. MILLER.

I have had no experience with chloroform, and so I do not know.—C. H. DIBBERN.

1. No. 2. Unless kept too long under the influence of it, they will revive.—P. L. VIALLO.

I have had no experience with either chloroform or Cyprians. *They might do well together.*—J. M. SHUCK.

1. I cannot speak from experience. 2. I think they will, but I have never tried it on a full colony.—MRS. L. HARRISON.

It all depends upon how much they were paralyzed. If I had cross Cyprians, or any kind of cross bees, I

would paralyze them "for keeps."—JAMES HEDDON.

1. I think not. 2. Yes. I have used chloroform on bees until they fell from the combs. All revived, and seemed unharmed. I prefer, however, not to use it. Smoke, I think, is preferable.—A. J. COOK.

1. There will be no ill-effects if you know just when to stop. 2. Yes; but do not give too much. When you must give bees an anæsthetic, smoke them with puff-balls (*Lycoperdon bovista*).—J. P. H. BROWN.

1. I think not. Those who have tested say that there will not. 2. I have never tested it, but I see no reason why they should not; but I do not think its use should be pushed to that extent.—J. E. POND.

1. I have never used chloroform. On general principles I would think that a moderate use might produce no ill-effects. 2. That would depend upon the quantity used.—M. MAHIN.

It would depend entirely upon the strength of the dose. Just enough to "quiet them" would undoubtedly have no permanent ill-effects. Though I should not want to answer for those that were "thoroughly paralyzed."—WILL M. BARNUM.

I never use any severe measures to conquer spiteful bees. If a colony becomes unmanageable, I proceed to change the strain, and get rid of the unmanageable bees in that way. 1. I have never used chloroform to quiet bees, and therefore I do not know about its effects on them. 2. The word "thoroughly" is pretty strong. I would never expect to see bees active again after once being "thoroughly paralyzed."—G. W. DEMAREE.

No ill-effects would follow a moderate dose, but the true way to conquer ill-natured bees is to introduce a new mother of good-natured bees.—THE EDITOR.

Extracting the Honey from the Brood-Nest.

Written for the American Bee Journal

Query 589.—Would it not be a good plan to extract a part of the honey in the brood-chamber to give room for the queen, and still leave plenty of honey for winter stores, even if some feeding in the spring had to be done?—N. S.

No, never.—JAMES HEDDON.

No.—EUGENE SECOR.

No.—M. MAHIN.

No, not as a general rule.—WILL M. BARNUM.

No; she would have plenty of room without making the stores short.—R. L. TAYLOR.

No. Use Hill's device over the frames.—MRS. L. HARRISON.

Yes; but do this before the weather becomes too cold.—C. H. DIBBERN.

I do not do it. Bees properly managed during the honey season will not store too much in the brood-nest.—J. M. SHUCK.

Be very cautious about extracting from the brood-combs, late in the season. We do not believe in it.—DADANT & SON.

Without great care and good judgment it would be a very bad plan.—J. P. H. BROWN.

I never saw a hive too full of honey for safe wintering. The queen needs no more room than any other bee, late in the fall.—G. M. DOOLITTLE.

Should the colony be quite populous they will probably consume stores sufficient to make room for the queen. It might be necessary to extract in the spring.—J. M. HAMBURGH.

If in the fall after the honey flow, I would not extract. I always found that those colonies which had plenty of honey in the brood-chamber to winter on, came out the strongest and in better condition in the spring.—P. L. VIALLO.

I like the combs well filled for winter. I would rather remove combs and have 30 pounds of honey in five Langstroth frames, or eight Gallup frames, than to have the 30 pounds in all the frames.—A. J. COOK.

Unless the hive is very small, it is not necessary, and I would rather have enough in the hive to avoid feeding in the fall or spring.—C. C. MILLER.

I never allow the queen to be crowded in the brood-chamber. The plan that gives her ample room should be adopted. Experience will prove what plan is the best.—J. E. POND.

It would depend upon the size of the hive and several other conditions. I want enough good honey left in the brood-chamber to carry the bees through without feeding in the spring, if possible.—H. D. CUTTING.

While I would prefer to have two or three combs in the middle of the brood-chamber only partly filled from the top-bars downward, as an empty place for the bees to cluster in, at the beginning of winter, I do not think that it is essentially necessary. The queen needs no "room" at this time of the year.—G. W. DEMAREE.

In winter, the queen takes no more room than a worker-bee. There can be no good reason for taking honey away from the bees in the fall, when they have not enough for their use in the spring.—THE EDITOR.

CONVENTION DIRECTORY.

1888
Time and Place of Meeting.
 Nov. 16.—Marshall County, at Marshalltown, Iowa.
 J. W. Sanders, Sec., LeGrand, Iowa.
 Nov. 21, 22.—Pan-Handle, at Wheeling, W. Va.
 W. L. Kinsey, Sec., Blaine, O.
 Dec. —.—Michigan State, at Jackson, Mich.
 H. D. Cutting, Sec., Clinton, Mich.
 1889.
 Jan. 9-11.—Nebraska State, at Lincoln, Nebr.
 J. N. Heater, Sec., Columbus, Nebr.
 May 4.—Susquehanna County, at Montrose, Pa.
 H. M. Seeley, Sec., Harford, Pa.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

CORRESPONDENCE.**APPLE-BLOSSOMS****In the Land of Flowers—Some Questions.**

Written for the American Bee Journal
 BY ALBERT VOUGHT.

Thinking that apple-blossoms on Nov. 1 would be a rarity in the frosty city of Chicago, I enclose a bunch gathered this morning, and I hope that they may not be too much soiled to help make up the bouquet that is to grace your sanetum on the day of arrival. Of course these blossoms will not come to maturity, but the bees are having a fine time gathering pollen and sipping the sweets "just the same." Apple-blossoms two months before Christmas, and again two months after—who says this is not a land of flowers and honey?

I cannot give an accurate account of honey taken and sold this season, so I will not attempt it; however, I feel very much encouraged with the year's experience. If this has been a poor season, I would like to see a good one.

I, too, wish to make a protest. Why make any distinction in nice, clear, bright honey? We have acres and acres of white clover, why class it all as "southern honey," whether gathered in nice one-pound sections, or extracted and cared for according to modern bee-keeping, or in the old-fashioned "bee-gum," and mashed up with brood, dirty comb, etc., and "strained?" I am satisfied that I get as nice honey as that north of the "Mason and Dixon line."

A neighbor said to me one day, "Have you any more of that nice honey? I declare, that which I got was as good, or better, than any I ever ate in New York, while I lived there. It doesn't taste like the honey we get here. Your bees must be trained." I told him that it was only a difference in the way they were handled.

As I am only partially "trained" myself, and depend almost entirely upon the AMERICAN BEE JOURNAL, and as I have no neighbor bee-keepers (no legislation required here), I wish to ask:

1. Do bumble-bees drive away the honey-bees? In my lawn are six or eight honey-loest trees. I noticed during the past two years, almost countless numbers of bumble-bees and other insects on them, but not as many honey-bees as I thought there should be.

2. Is the Russian mulberry a honey-producing tree?

Illawara, La., Oct. 29, 1888.

[I. We do not think generally that bumble-bees have any antipathy to honey-bees. We remember that some 40 years ago a war between these bees was reported in Wales, at the close of which it is said that "heaps of the vanquished covered the ground, some without heads, others minus their wings, and others completely separated into two parts." One person is said to have "scraped together 3 or 4 bushels of dead bees with his foot," as a result of this singular war. This is very unusual, however, for they generally have no trouble with one another.

2. We think not. We never heard of its yielding any honey.—ED.]

SELLING HONEY.**How to Increase the Demand and Maintain Prices.**

Read at the New York Convention
 BY L. C. ROOT.

Those who have carefully read the various bee-papers during the past year, have observed the unusual interest which has been manifested in regard to the disposition of our products at remunerative prices. I have many times expressed the opinion that far too much thought was being given in the direction of producing large quantities of honey, and too little to the better quality and proper disposition of the same. I have so often expressed my views upon this subject, that I shall offer but few suggestions. Enough has been said, and practical plans enough have been offered to entirely revolutionize the system of marketing. To tell the exact truth, we have had too much talk, followed by far too little action. The great needs at present may be briefly stated as follows:

First, to attain to a higher standard in the production of our honey. This will be reached through the great freedom of discussion which is taking place in all our bee-literature. I am a thorough advocate of the "question and answer department" of our papers, where we are enabled to compare the opinions of so many of our best bee-keepers, expressed in so concise and explicit a manner. We should remember that anything tending to educate in the direction of raising the quality of our honey to a higher standard, is exactly in line with creating and strengthening a better market.

Our first aim should be a prime quality, and next complete and perfect finish, so that it shall be attractive and agreeable to handle. All this means proper fall management and winter work; successful wintering, and proper spring management; so that colonies shall be populous, and in condition to store honey rapidly, which aids its neat appearance. In short, it means, all the year round, hard work.

Second, we need to guard and foster most strenuously the fact that our product is a pure and wholesome article of food. In fact, the only commercial sweet, furnished entirely from natural sources, that has undergone no process of manufacture. It is as wholly and truly as natural a production as milk, and has ranked with it in all ages past.

Third. We are now come to the point where we need a reformation. We talk much about "developing a home market," "creating a greater demand for our honey," "making proper exhibits at our fairs," etc., but we fail to practice what we advocate. In my opinion, one of the very greatest needs in the direction of solving the problem, is an entire revolution in our system of marketing. Our wares should be handled in every large and important market, by those who are thoroughly informed in every branch of bee-culture.

It may be urged that by these exhibitions we will induce many not now in the business to embark in it. I think not. I believe the better way is to come right out square and let them see what we are doing. I have made exhibitions at the Saratoga County fairs for a number of years, and have yet to hear of any one starting in the business as the result, but I know that it has been the means of helping hundreds. I may say thousands of pounds of honey, out of the glutted city markets.

I think, perhaps, you will agree with me that for the cause of apiculture, exhibitions at fairs are desirable, but will it pay the persons making them for their time and the necessary expense? We might ask, does bee-

keeping pay? Does my business pay? The answer depends in a great measure on the individuals themselves. It may not pay directly the first year, but if advertising is worth anything, it no doubt will, in the long run.

If your fair managers offer no premiums, make a good display one or two years without, and I think they will then, rather than lose the attractive feature. There is also a great advantage in being the first one to start anything like this.

Now, if these few ideas that I have here advanced will result in increasing the home consumption of our honey, thereby helping to relieve the city markets, I shall feel repaid for all the labor I have given this essay.

Stamford, Conn.

SPRING DWINDLING.

Loss of Bees in the Spring— Fancy Comb Honey.

Written for the American Bee Journal
C. E. WOODWARD.

On page 697, Mr. Doolittle states in his report for 1888, that he is again out at open sea, for the experience of the past spring has taken all of the conceit out of him; and he candidly confesses that he does not know what causes "spring dwindling," or degeneration. Well, let us see.

Mr. Doolittle says in his report that 2 colonies were wintered exactly alike. That may be true, so far as the eye could witness, and yet not be *exactly* alike. You may take two eggs that look just alike, and yet they are not alike; for one may sink in water, and the other may float.

So Mr. Doolittle's bees might not be just alike. One colony might have contained young bees, and the other might have contained old ones that died with old age. A colony of young bees, if well protected in the spring, will not degenerate, at least such is my experience.

Producing Fancy Comb Honey.

If bee-keepers wish to obtain fancy prices they must obtain fancy honey. How can we obtain fancy honey? Simply by using starters in the sections? No, I think not. Fill the sections half full? No, I would not. I would fill the sections full of foundation, and fasten the foundation to each side of the section, not at the top, and leave a bee-space at the bottom; for the bees will take care of that part.

I have tried, and experimented with all the ways, and I like the above way much the best. The sections are filled flush and full at the four sides. All of

my honey sold for 15 and 15½ cents per pound, while others obtained 12½ and 13 cents per pound in the same market. This is the way I obtain fancy honey, and fancy prices.

South Newburg, O.

BEE-WARRIORS.

A Victorious Army Put to Flight by Bees.

Written for Harper's Young People.

The quiet little village of Holzmen-gen, in Transylvania, was in an uproar one bright summer afternoon long ago, for its Saxon inhabitants were fighting for their lives against terrible odds, as they had fought many a time before. The whole slope of the hill on the brow of which it stood was one great crowd of wild-looking men, with dark, fierce faces and white turbans, and strangely fashioned armor—those dreaded Turkish soldiers, the memory of whose fierceness is still preserved in our saying that any man of savage temper is "a regular Turk."

And all this time, while the air was rent with the din of battle, and Death was gapping to devour the village and all within it, a little girl barely ten years old, with long fair hair, and eyes as blue and bright as the sky overhead, was at work in her little garden just behind the village church, as quietly as if no enemy were within a hundred miles of her.

But this was not so strange as it looked. Little Lizzie was the daughter of the sexton who had charge of the church, which, as the largest and safest building in the place, was always used as a hospital in time of war; and the work upon which the little woman was so busy, was the preparing of bandages for the wounded, who were now being brought in thick and fast.

But in the midst of all this uproar and agony and death, the sun shone as brightly as ever, and the trees of the tiny garden rustled in the evening breeze; and around the twelve neat hives that stood ranged in a row, the bees were humming blithely, as they hovered among the flowers; and any one who had shut his ears to the frightful din below might have thought this spot the most peaceful in the world.

And now Lizzie, catching up a whole armful of bandages, hurried away into the church, where she was soon so busy among the wounded men that she hardly noticed that the noise of the battle was growing louder, seeming to roll nearer and nearer every moment.

But suddenly a fearful cry from without made her look up, and through

the nearest window she saw the Germans crowding wildly into the one small gate of the church-yard wall, while behind them the dark Turkish faces and snow-white turbans were eddying like a flood among the houses. The Turks had taken the village, and were coming on to attack the church itself!

Luckily it could only be attacked on one side, for on the other the rock was so steep and slippery that no man alive could have scaled it. So the brave village bailiff, though bleeding from several wounds, ranged his men along the side of the wall that faced the enemy, and encouraged them to stand firm and fight it out to the last.

On came the Turks with hoarse yells of triumph, and in a moment the whole space outside the church-yard wall was a sea of grim faces and flashing steel.

And now the swarming assailants made a third charge, which brought them right up to the foot of the wall that sheltered all who were left of the defenders; and while some thundered upon the gate with axes, others planted ladders against the wall or tried to clamber up it on each other's shoulders.

Another moment and all would have been over; but just then Lizzie, struck with a bright idea (which came to her from an old story that she had heard one winter evening), darted back to her little garden, seized two of the bee-hives, one in each hand, and springing upon the low wall, hurled them among the swarming assailants. Two more instantly followed, and then other two, until the whole dozen hives had been flung down upon the heads of the clambering Turks.

The bees, enraged to madness at being sent whirling through the air so unceremoniously, fell like furies upon the shaven heads and bare arms of the Turkish soldiers, and gave them such a pricking that the Saxon arrows which had been falling so thick among them, seemed a mere nothing in comparison. Every man in the front ranks was literally black with the infuriated insects, which kept stinging the more fiercely the more the bewildered Turks tried to beat them off.

There was no more thought of battle or assault; for who could wield a sword or climb a wall with his head covered with a perfect nose-bag of enraged bees, and every exposed inch of his body smarting as if pierced by a thousand red-hot needles? Away flew the enemy, and away flew the bees after them, while the yells of pain of the discomfited Turks were answered by the uproarious laughter of the triumphant Saxons, who might well laugh to see a whole Turkish army put to flight by the device of one little girl.

Clouds and Sunshine.

BY M. B. OLEASON.

In their onward progress gliding,
Come and go successive years,
Freighted with the joys and sorrows
That beget our smiles and tears.

Borne on rapid, tireless pinions,
Sweep they down through boundless space,
Leaving now a belt of sunshine
And anon a darkened place.

Light has ever foil of shadow,
So does pleasure mate with pain,
And our joy is twin to sadness,
But our loss is linked with gain.

Life's most patient, helpful lessons
Are with wise, unerring care,
Given through trials that beset us,
Or in burdens that we bear.

—Our Rest.

CANADA.**Keeping Bees in the Hive in Unfavorable Weather.***Written for the American Bee Journal*

BY S. T. PETTIT.

The weather here, almost all the time for the last five weeks, has been cool and cloudy, with a considerable amount of rain. I believe that this state of the weather at this time of the year, in this latitude, is better for bees than if it were warm and sunny. When the weather is warm and clear, at this time of the year, bees wear themselves out sucking around cider-mills, and working upon decaying apples in neighboring orchards.

I have thought a good deal over the matter, and tried to devise some cheap and effective scheme or device, whereby bees could be kept comfortable, happy and quiet at home, when surrounding conditions were just right to tempt them abroad to their own destruction. If any one can tell us how to do it, I am persuaded that the majority will vote him a great discoverer and benefactor.

To me it is a painful trial to look on helplessly, and see my bees storing large quantities of "death," in the shape of poor honey-dew, and frequently many colonies perish from this cause. Now would it not be a great boon to us, if we could make them "hibernate" a few hours every day, or whenever we should find it necessary to do so, until the trouble be past?

In my locality the worst kind of honey-dew is brought in only in the forenoon. Again, the time is apparently at hand, when Paris green and other poisons will be largely used upon fruit-trees; and it may be found necessary for the safety of bees, and for best results, to have it done at certain fixed times, or rather, when the blossoms are in a certain stage of advancement; and when this time arrives, the bee-keeper should be notified, who

then should be in a position to keep his bees at home in that quiet state without worry that will do them no harm.

The pertinent question is, who will make the discovery? Who will tell us how to do it? The want is a felt one, and the remedy, I trust, will be forthcoming.

Experiments for Next Season.

The plan upon which I contemplate experimenting next season, is about as follows:

For each hive I will make a box out of wire-cloth, whose length shall be equal to the width of the hive, about 2 inches high and 3 inches wide, with bottom and one side out. Place this upon the alighting-board, and against the front of the hive, so that the bees can come out into this cage, but cannot escape or get out. Then place pieces of ice upon the box or cage, and shade the hive, particularly the front.

The ice will cause a current of cold air to fall constantly upon the alighting-board at the entrance, with frequent drops of ice-water. If the day is very hot, I will elevate the front of the hive so that both the ice-water and the cold air will flow down into the hive.

Now I fancy every bee that may spend a few seconds in this cold apartment, will return and report the day rather cloudy, cool and wet for outdoor operations. What do bee-keepers think about it? I would add that "lots" of ventilation is a great factor in keeping bees quiet in hot days.

Belmont, Ont., Oct. 25, 1888.

BEE AS DOCTORS.**Incidents in the Apiary Occurring this Fall.***Written for the Prairie Farmer*

BY MRS. L. HARRISON.

The weather has been cut off from the best piece lately, and I have enjoyed exceedingly to be out among the rustling, falling, fragrant leaves, bottling up sunshine to uncork during zero-time. I am like the Yankee seeking work who was hired to pound on the side of a log with an axe. In a short time he threw it down in disgust, saying: "I can't do it; I must see the chips fly." When told by a physician that I must walk and drive in the open air a great deal, I said: "I can't do it unless I have some object." He looked at me in disgust, saying: "Isn't health an object enough?" No, it was not. I needed something to do that would cause me to forget self, pains and aches; and

bee-keeping fills the bill. It is good medicine to be taken well-shaken, but not in too large doses.

Doctors prescribe the bee's sting as a remedy for some ailments, and a powerful one it is, too, and they had better let the bee administer it. It can drop it out from its bottle with more precision than it can from the apothecary's. I have no doubt that rheumatism, dropsy and kidney disorders are greatly benefited by working with bees.

I used to tell a little girl, when putting on my shoes for me during winter, that when the weather got warm, and I worked out with the bees and got stung, she would not have to do it any more; and she never did, for I could do it myself.

I was once very favorably impressed with the life-giving qualities of bees. I had been very sick a long time, and was barely able to walk, when I went to a hive containing a large colony of bees, uncovered them and sat down by them, breathing in their effluvia. It had a wonderfully exhilarating, rejuvenating effect upon me. Why, I was "born again." It was during the working season of bees, when they are visiting thousands of flowers and bringing home with them their medicinal virtues.

Fall Work.

This is the time of year when it pays to work in the apiary, and do it well. Promising to do better another year, will not answer. "Now is the accepted time: now is the day of salvation." Come with me, and we will take a look at the apiary. Do you see anything different in that large colony of bees sunning themselves in the portico, from the others? Yes, drones; there are none to be seen elsewhere. How fat and sleek, jolly and contented; happy as a clam. Why have they not been able to walk the plank? The ladies need them no doubt; so tolerate their company. Let us examine them and see if they are not queenless. How heavy this frame is, sealed clear to the bottom!

We will remove each frame and look it over carefully, and see what we can find. Not a bit of brood—but this is not strange. There is little in any of the colonies now; they usually have a little patch, which is a wise provision of nature, against the loss of the queen; for, as long as they have an egg, they can rear another one. But if not, alas! they must perish; they cannot make something from nothing.

See! this explains it—a queen-cell. She has just come out apparently; if it had been long, the bees would have cut it down like an acorn-cup. I do not like to say the queen has hatched, for how can the bee's egg hatch, and

afterwards the queen? If the young queen returns from her bridal-tour in safety, this colony will be all right in the spring. I will now put on this Hill's device and spread on this new muslin sheet, and run this hot flat-iron over the top of the hive, which melts the propolis, and sticks it fast. Now this hive can be carried "up-stairs, down-stairs, and in my lady's chamber," and not a bee get out. I think this is quite important, whether the bees remain in-doors or out.

When they are carried in the cellar, or out, they cannot escape from the top, or during the winter. I have had colonies badly weakened, almost ruined, by creeping up under the muslin into the cap, and perishing. I tear this sheet large enough so that the cap shuts down over it, and when it is on, the bees can be protected with dry leaves or chaff cushions, as preferred.

Hill's Device.

This looks like four half-moon pieces of wood, with a piece of hoop-iron for a back-bone. It makes a little warm nest under the muslin, so that bees can pass from one frame to another after honey, without going down into the cold. When I have not enough to go around, I put on some cobs or sticks. Bee-keepers formerly made holes in the combs, for passages for the bees during winter, but this device obviates it. It is the invention of a successful bee-keeper, of Mount Healthy, O.

I will now put on the device and muslin on this large colony. It pays to use new muslin in the fall, as the the ventilation will be better during the winter. I formerly used duck, but it costs more and is no better. These stiff, propolized ones make good kindling on a cold morning. There is a good deal of wax on them, but it does not pay to boil them up to melt—more game than candle. How the bees boil out in front and on top! I will mark this hive "No. 1." You see that hive over there marked "Extra." That was marked "Extra" last year, and holds good for this; not on account of it being so populous, but because it stored more surplus than others of its size. That is the kind of a colony to rear queens from, and must keep its colors flying.

This one is the last swarm of the season—quite late—and I did not think that it would pay to climb after them, but I did, all the same. I gave it, when hived, six frames of comb, that I took from a hive that had a drone-laying queen which had been unnoticed, until there was scarcely a corporal's guard of workers. The hive is quite heavy; but, I will put these two frames of uncapped honey back of

the division-board, and leave them to carry it in, before I put on the muslin. I will mark it "C," and be sure that it is carried into the cellar.

Bee-Cellars.

Take a look at mine. You see that it is partitioned off from the main cellar, and is under the sitting-room, where a hard-coal fire never goes out, from fall till spring. It has a window hung on hinges, which is protected with wire-gauze, and a sub-earth ventilator. The window is covered with thick green paper, to keep out the light. It has been freshly whitened, and the window and ventilator have been open all summer. The brick floor was thoroughly scrubbed, after the bees were removed in the spring. Peoria, Ills.

IN COUNSEL.

Report of the Union Bee-Keepers' Convention.

Written for the American Bee Journal

BY JOHN G. SMITH.

The Union Bee-Keepers' Society met on Oct. 16, 1888, at the City Hall in Clayton, Ills., the attendance being small, but all who did attend came with knowledge obtained from the store-house of experience (which is acknowledged to be the very best) concerning the habits and instincts of one of man's best friends—the honey-bee.

The convention was called to order with President S. N. Black in the chair, and the minutes of the previous meeting and the Treasurer's report were read and approved. The convention then adjourned until 1:30 p.m.

AFTERNOON SESSION.

President Black called the convention to order, and an essay was read by J. M. Hambaugh, on Hives and Honey Receptacles.

The next topic discussed was,

How to Increase Colonies.

J. G. Smith selects the best colony in early spring, confines the bees to as small a space as they can well occupy, by use of division-boards, and places on top of the frames a bee-feeder. He feeds regularly every 24 hours just what syrup the colony can consume, and no more. As the colony gets strong in numbers, he removes the division-boards and gives empty combs or foundation as required until full colonies are obtained.

"What is the best method to prevent swarming?"

J. G. Smith—Exchange places with those that are about to swarm, with those that are not.

Mr. Spencer—What if your colonies are all strong?

J. G. Smith—The result is the same.

Comb Honey vs. Extracted.

President Black preferred to produce comb honey.

Mr. Spencer—Mr. President, I think the reason that you do not like extracted honey is because you swallow it too soon.

"How can we overcome the prejudice to extracted honey?" Some one answered that it was hard to do.

J. M. Hambaugh showed a sample of extracted honey in a bottle, and could hardly convince any one that it was honey.

Mr. Robbins preferred extracted honey.

President Black knew of no parties in this place that adulterated honey, but believed that it was done in large cities.

J. G. Smith had been trying to overcome the prejudice against extracted honey. He had taken some nice comb honey, extracted it before a customer's own eyes, and the customer thought that the action of the extractor changed the flavor, or gives the honey a taste that he did not like.

The convention then adjourned until 7:30 p.m.

The convention was called to order at 7:30 p.m., with President Black in the chair. A general talk was indulged in for about two hours, after which the meeting adjourned till 9:30 a.m. the next day.

SECOND DAY.

The convention was called to order at 9:30 a.m., with President Black in the chair, when the following subject was discussed:

Handling Comb and Extracted Honey.

J. M. Hambaugh had worse luck with comb honey than with extracted.

W. T. F. Petty favored the production of comb honey. He uses a frame holding 4 one-pound sections each, and places as many of these frames over the brood-chamber as is convenient, with a case surrounding the frames.

President Black—Do you practice tiering up?

Mr. Petty—Yes.

President Black—How much foundation do you use in each section?

Mr. Petty—Three-fourth inch pieces as starters.

President Black—How do you fasten the foundation in the sections?

Mr. Petty—I use a Parker foundation fastener. I do not think that it

is necessary to invert either hives or sections in order to get them filled completely.

J. G. Smith remarked as follows on, "What constitutes a normal colony of bees?"

The subject is a lengthy one, but I will try to give a short synopsis of it. The word "normal," as I understand it, means perfect, complete. A normal colony of bees consists first of a good, prolific queen, a suitable hive, nice, straight combs, eggs and larval bees in all stages, and hatching brood, and mature workers and drones. I cannot give here a full synopsis, as the describing of the many changes and different duties that each class of bees have to perform, would consume too much valuable time.

"How long does it take to rear a queen?"

T. S. Wallace had reared queens in eleven days, from the egg, and considered it a sufficient length of time.

J. M. Hambaugh claimed 14 to 16 days.

How to Re-Queen Colonies?

Mr. T. S. Wallace gives queen-cells to the colony.

President Black first shakes all the bees of the colony in front of the hive, then drops a fertile queen in their midst. He had been very successful in this way.

Mr. Howard Ogle cages a selected queen, removes the rejected one, places the former queen in a cage on a comb as near the spot as possible to where the rejected queen was; closes the hive, lets the bees liberate the caged queen, and examines the hives 48 hours later, when he removes the cage. He had been generally successful in this way.

How to Unite Colonies.

Mr. D. E. Robbins places one hive on top of the other, first removing the bottom-board of the hive to be placed on top, then puts the two hives together. He pays no attention to the queens (this should be done late in the evening), but lets them remain in that condition for three days, then shakes all together, when the job is complete.

J. G. Smith does the same as Mr. Robbins, except that 24 hours was the time required.

How to Winter Bees.

Mr. David W. McDaniel preferred a cellar, with slight upper ventilation in each hive.

J. M. Hambaugh prefers the same as Mr. McDaniel.

Mr. Daniel Shank, a nurseryman of Clayton, preferred lower ventilation.

Mr. T. S. Wallace winters his bees in a cellar, and favors lower ventilation. He cuts holes in the bottom-

boards, and covers them with wire-gauze.

"When should bees be put into winter quarters?"

J. M. Hambaugh puts his bees in about Nov. 20, and takes them out sometime in April.

The convention then adjourned till 1 p.m., when the afternoon session opened with President Black in the chair, and the discussion continued as follows, on

Swarming and Bee-Pasturage.

President Black thought that pure races of bees would not swarm as much as the mixed races.

"What is best to plant or sow for bee-pasturage?"

Mr. Shank exhibited a raspberry-cane, and a bottle of raspberries in salt brine. They were of the new German variety, which he thought could hardly be excelled as a honey-plant. The canes are self-supporting and very hardy; the fruit is very large, and excellent in flavor. Every bee-keeper, as well as others, ought to grow them.

President Black sows buckwheat and Alsike clover. He found the latter to be good bee-pasturage.

J. M. Hambaugh had some experience with Alsike clover, but wished to try it another season before reporting as to its value as a honey-plant.

Mr. Petty thought that melilot or sweet clover was very good, if not the best pasture for bees.

"What is the proper space between brood-frames from center to center of the top-bars?"

Mr. Petty—One and one-third inches.

Mr. Robbins—One and one-half inches.

President Black—One and one-third inches is about right.

The Rev. Mr. Pears was present, and on motion he was unanimously made an honorary member of the Society. Mr. Pears then thanked the Society for their courtesies.

It was then noted that the name of this Society be changed to the "Central Illinois Bee-Keepers' Union."

The following resolution was then passed unanimously:

Resolved, That we tender our sincere thanks to the landlord, T. H. Brents, and to the resident members of this Society for their kindness and hospitality during our sojourn among them.

The election of officers for next year being in order, resulted as follows: President, Howard Ogle; Vice-President, W. T. F. Petty; Secretary, Jos. M. Hambaugh; Treasurer, J. G. Smith.

The officers will act as a committee on programme for the next meeting.

Mt. Sterling, Brown county, Ill., was then chosen as the next place of the annual meeting, the date of the

meeting to be decided by the President of this Society.

On motion of J. M. Hambaugh, Pres. S. N. Black said: "I recommend the members of this Society to join the National Bee-Keepers' Union, at their earliest opportunity."

The convention then adjourned meet next year at Mt. Sterling, Ills.

JOHN G. SMITH, *Sec. pro tem.*

NEW LAWS

Of the International American Bee-Association.

Written for the American Bee Journal

BY R. F. HOLTERMANN.

It was with feelings of pleasure that I found Dr. Miller's criticisms of our Society, on page 711. There were several points that I thought might be changed to advantage, but when President Mason brought the matter up so (to me) unexpectedly, it took my breath away; all the time I knew there were, some points, in my estimation, objectionable. Now kindly bear with me, and I will state them.

Article I. Strike out the word "American," and you have the name. Let me say that I cannot see any reason why we should not have an association truly international. Who dares to say that we in America have nothing to learn from Germany, Britain, France, Norway, Sweden, and other countries, and that they have nothing to learn from us, or from one another? If this is the case (and we know that there are men there of means, and who desire to advance bee-keeping), why, then, have we not reason to expect that they shall join us in convention? We may make a special effort to have such a meeting, say once in five years. Yet, let it be *international*, and let them understand that our doors are always open to them, and they have a right to meet us on equal footing.

Some may say, "Have we not papers published in the interests of bee-keepers, and we can have an interchange of all valuable ideas?" Let me say that that is impossible. He who thinks that he may remain at home, and read the report of a convention, and profit equally with the one who has attended, is greatly mistaken. Reports are not verbatim. Every reporter—it may even be unconsciously—gives prominence to what he thinks is of importance, and what he may consider correct, however mistaken he may be. You have then, to a great extent, to think as he does, and to see as he sees. Even were you to read a report verbatim, you would not share equally in advantage, for the very tones used

in expression alter the meaning of the words. For this reason, and to secure a mutual interchange of thought between countries, it is proposed, and we hope to succeed next year, in having the grandest bee-keepers' convention ever held, in which representatives from several European countries will take part—a convention from which every one can go home not only benefited, but *enriched*.

Article III. What about life members? Are we going to make figure heads of them? We do not allow them to vote, hold office, etc., unless they give us another \$1.00 each year. This is *wrong*, and should be corrected, or the life membership clause struck out.

Article VI. The time is to be fixed at the previous meeting. Is this wise, or had the executive better decide this as circumstances may direct.

Article VIII of the BY-LAWS is optional, hence it is not objectionable, although it will probably never be made use of. Dr. Miller is wrong; he says *is* to be formed.

In Article IX., Clause 2, I agree with Dr. Miller. Five dollars is the affiliation fee; the local society gets two silver medals and a free membership. If these can be had for \$5.00, all right; otherwise our funds will not allow it. And that reminds me that members should send on their membership fees for the new year, as funds are low, and a great deal of work requiring funds has to be done during the coming year.

Article XI is of no use to us. I agree with Dr. Miller.

Article XII is very good, but remember, send on those annual fees. We are out of funds, and the association is already indebted to me for postage, etc.

Article XIII, Clause 2, is very good. Let us stick to that.

In closing, let me say that I agree with Dr. Miller, and I am sure we all feel that a vote of thanks was, and is, due Mr. Newman for the great trouble he has taken in this matter, more especially as he was quite sick at the time.

Brantford, Ont.

EXTRACTING.

Constructing a Simple, Home-Made Honey Extractor.

Written for the Practical Farmer.

The production of comb honey, with amateur bee-keepers, is a difficult matter, especially to those having a few hives, and who prefer obtaining their honey to increasing their colonies. To read the number of articles

written upon the subject in bee-periodicals and apicultural newspapers, it would seem that even apiarists with a large number of colonies have considerable trouble in getting the bees to work freely in the section boxes. Various plans have been suggested, the principal and probably the only certain one being the contraction of the brood-chamber to five frames, thereby compelling the bees during a honey flow to deposit it in the surplus chamber.

Now this may be a very good plan, and it certainly can be readily carried out by the party who makes bee-culture a business, and can sit down, pump in hand, ready to throw a wet blanket on a swarm endeavoring to get up and dust, or get in as unhandy a place on a tree as possible; but the bee-keeper in a small way, who has other things to attend to, is vexed when he comes home and finds that the honey he saw in the sections a week before is now safely stored in the honey-sacs of the missing swarm. Why, we may ask, should the bee-keeper run such a risk to obtain comb honey? It is no purer than extracted honey, neither is it so easy to partake of, unless you eat the wax, which certainly was never intended for food.

Mr. Lemuel Stout, of Philadelphia, after five years of bee-keeping, with from 3 to 5 colonies, had very little success in getting comb honey in the surplus department. There was plenty elsewhere, but unobtainable without destroying the comb, and then the product was only strained honey, an article not relished by any one who knows how it is obtained.

Mr. Stout had decided to get rid of his bees except a little pet colony in a hive about 8 inches square. The last week in June, 1888, there were about 40 pounds of honey nicely capped over in his hives, which, if he had an extractor, he could recover, but it certainly would not pay him to purchase an article that he might not want to use six hours annually. He thought it strange that among the 300,000 beekeepers in the United States, no one of the number had devised some simple contrivance that would answer the purpose—an instrument that any one could make with very little trouble and expense.

If centrifugal motion would throw the honey from the comb in the standard extractors, it would do the same if the comb was put in a suitable shaped can and placed upon the edge of a horizontal revolving wheel. This, if secured to a vertical shaft about 6 feet long, might be operated by pulling a stout cord, say 10 feet long, around it.

Accordingly he took an old hoe-handle pointed at one end for his up-

right shaft. On this he fixed a discarded front wheel of a carriage. The pointed end of the shaft rested in a small countersunk hole made in a block of wood nailed to the floor, while the upper end revolved in a hole bored through a block fastened to a joist overhead. Round the hub of the wheel which extended downward, the cord was wound, by pulling on which strongly the wheel revolved, and with so much velocity that by the momentum acquired, the cord after being unwound, was wound up again ready when drawn upon to impart to the wheel an equal velocity in the contrary direction.

The tin-can used is deep enough to receive one of the hive frames, standing on end. It is nearly diamond-shaped in its cross section, and is securely closed by a tin lid. When in place it stands erect on the upper side of the felloe of the horizontal wheel, where its lower end is secured between wire uprights. Its upper end is embraced by strong wires attached to and extending from the shaft.

His instrument was first tried last 4th of July, when Mr. Stout uncapped the combs, introduced frames and combs, and extracted over 40 pounds of nice, clear honey, the combs being free from injury.

BEE-KEEPING

Considered as a Pursuit for Farmers.

Written for the Maryland Farmer
BY THE EDITOR.

The progress of this pursuit since our boyhood days is something wonderful, and even now it is quite evident that still greater progress is in store for the bee-keeper of the future. Men, women and children are now in the business of skillful bee-keeping, and the honey production of the country is becoming of vast magnitude.

The Bright Side.

That bee-keeping has a bright side is a fact which every one realizes. At the farmer's home it speaks of the delicious sweets gathered from the flowers, and reaped and enjoyed with the smallest degree of labor and care. All day long, while the farmer is toiling in the fields, these industrious providers are gathering the very nectar of the crops for his delight, and for the health and happiness of his household.

The Dark Side.

But it has a dark side, also. Not so heavy in the farmer's home, as when the bee-keeper, who has made this the

one great business of the year, meets with a failure of the honey crop, and after a season's labor, places all on the losing side of his ledger. This is indeed a dark side. But with the farmer, the only dark side is the slight additional labor, and the natural dread of stings; with the study necessary to make his venture a success.

Smoke.

Among the protections perhaps none is actually superior to smoke—a good smoker skilfully used will often prove a great blessing, and without injuring the bees, will enable the operator to handle them to his entire satisfaction. It is very true that in time of swarming but little danger may be apprehended as a general thing from bees, unless some accident should happen; for they are then too busy about important things of their own to trouble any one else. Yet the greatest care should be taken to move in the most moderate, cool and quiet way in their midst. We used to think that certain ones—when we have seen them taking up swarms in their naked hands, and pouring them into a prepared hive—were proof against bee-stings, or were almost supernaturally protected. But we have learned that such persons were protected only by a perfect self-possession and fearlessness, which bee-keepers must cultivate, and if possible acquire. Meanwhile, we do not advise any one to run the risk of arousing an angry colony and suffering when by a little forethought and care he can have all needed protection.

Planting for Bees.

The whole domain of nature, rich in flowers, is the treasury from which bees gather their sweets; but it should be the aim of bee-keepers to help out the supply by especial care. It is true that bees cannot generally reach the honey in the red clover; but in white clover and Alsike they find a good supply, and of the best quality. Some have planted large fields of buckwheat for their bees; but it does not give as rich a supply, nor as attractive a produce in the market as the others. Mignonette is also cultivated for the bees; and every year new plants are brought to notice and extolled highly. All the blossoms of the forest and the field are placed under tribute by the bees, and no farmer can go amiss in keeping a few colonies.

Last Year's Discouragement.

In many parts of the country last year was a great failure among those who depended upon bees and honey for their yearly income; but this was only a temporary check to the industry which is liable to befall in the prosecution of any single department

belonging to the farm. It may not again occur in many years to come, and is no reason for neglecting the important duty of gathering so great a crop as that which every farm will yield, if bees are kept.

Helping the Bees.

A great success is in the various methods of helping the bees in their work. So great has been the improvements during the past few years, that much of the work which took up the precious time of the bees may be done now by machinery, and the actual work of gathering the honey be left to occupy the bees more continuously. By means of the uncapping knife and the extractor, the honey is taken from the sheets of comb, and the comb replaced for the bees to fill again, saving thus the long time necessary in building new combs.

Again, comb foundation for either brood-cells or honey surplus is made, and the work of the bees is thus directed to the best profit of the bee-keeper. This wax foundation is one of the greatest and best inventions connected with bee-keeping. It enables us to have straight combs of honey, in whatever sized frames we may desire, and the market is supplied with the beautiful one-pound sections which so attract the purchaser. It gives us also most perfect control of honey or brood production.

MELISSA HONEY.

Yield of 60 Pounds Per Colony from Melissa.

Written for the American Bee Journal
BY A. C. TYRREL.

FRIEND NEWMAN:—I have sent you a sample of melissa honey, which I think you will pronounce excellent. You will notice that the honey is amber colored, but that does not in the least detract from its good qualities.

You will also observe that it is very thick, notwithstanding the jar in which it has been kept since the middle of October, was tightly sealed. The plants from which the honey was gathered are rich in nectar, as well as pollen, and grew on very weedy ground, the seed being sown broadcast, and the ground harrowed over but twice, consequently having to take their chances with weeds of the rank-est growth.

The yield exceeded my most sanguine expectations, and the facts will warrant the assertion that melissa is entitled to rank *first* as a honey-plant. From two acres my bees stored 1,500 pounds of as fine honey as I ever saw.

The comb is as white as from any honey-producing plants, I believe.

I am so well pleased with the results of my experiments with the above-named plants since 1881, that I will plant 4 or 5 acres next season. Your unbiased opinion as to the quality, etc., of the honey sent, will greatly oblige, as I wish to refute by solid facts and statements the oft-reiterated assertion that, "it does not pay to raise plants for honey alone." That theory—it is not a fact—published for so many years in some of the leading bee-papers, has discouraged apiarists in experimenting with various honey-plants, and planting for honey, to their detriment, and in consequence a protracted wail of "blasted hopes and no honey; bees dying of starvation; not a pound of honey in my hives, etc." has gone forth from nearly every hamlet in the country.

I forgot to say that at the commencement of blooming of melissa, the hives were empty, but before the close of the season, they were all filled, and some colonies had stored 60 pounds of surplus—a pretty fair showing for an "off year."

Madison, Nebr., Nov. 1, 1888.

[This is certainly a very excellent showing on the practicability of planting for honey. We have never doubted the judiciousness of the advice to plant for honey, and do not think that we ever shall decide adversely to it.

The experiments to be made by Prof. Cook, will be interesting to us all.

The honey said to have been sent to us by Mr. Tyrrel has not yet come to hand. When it does come, we will cheerfully give our opinion of it.—ED.]

Convention Notices.

☞ The Nebraska State Bee-Keepers' Association will convene at Lincoln, Nebr., on Jan. 9, 10 and 11, 1889.
J. N. HEATER, Sec.

☞ There will be a meeting of the Susquehanna County Bee-Keepers' Association at the Court House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a. m.
H. M. SEELEY, Sec.

☞ The Pan-Handle Bee-Keepers' Association will hold its next meeting in the K. of P. Hall, on Main St., between 11th & 12th Streets, in Wheeling, W. Va., on Nov. 21 and 22, 1888. All bee-keepers are cordially invited.
W. L. KINSEY, Sec.

☞ The Marshall County Bee-Keepers' Association will meet at the Court House in Marshalltown, Iowa, on Friday, Nov. 16, 1888, at 10 a. m. All bee-keepers are cordially invited to meet with us, and bring along anything that they may have that will interest or benefit apiarists.
J. W. SANDELS, Sec.

☞ The twentieth annual convention of the New York State Bee-Keepers' Association will be held in the City Hall, Syracuse, N. Y., on Dec. 11, 12 and 13, 1888.
G. H. KNICKERBOCKER, Sec.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

SELECTIONS FROM OUR LETTER BOX

Fall Crop of Honey.—G. M. Whitford, Arlington, Nebr., on Nov. 4, 1888, wrote as follows:

The season, in this locality, was very unfavorable to the production of honey. Wet weather and cool nights prevented the secretion of nectar in the flowers until the last part of August and the first part of September, when we had a short spell of warm weather; then for about three weeks the bees worked with energy until the honey flow was checked by the dry weather. My yield from 10 colonies is 236 pounds of comb honey, and 66 pounds of extracted honey. The greater part of the comb honey has been sold for 18 and 20 cents per pound for choice well-filled sections, and 15 cents for the imperfect ones. Extracted honey is selling at 15 cents per pound.

Good Yield of Honey.—L. E. Traphagan, Ellery Center, N. Y., on Oct. 30, 1888, writes:

On June 17 a swarm of bees issued that weighed 8 pounds. I have taken 75 pounds of honey from it, and they have 65 pounds by weight now. On June 29 I transferred a colony of old bees to a new hive, and they have 50 pounds of honey now, and I have taken off 20 pounds in sections. I think that they have done very well. This is my first year with bees. I get a great deal of excellent information in the BEE JOURNAL, and all bee-keepers should read it.

A Fraud.—Alderman & Roberts, of Wewabitchka, Fla., write as follows:

Noticing the address of Joseph McCaul in the AMERICAN BEE JOURNAL, stating that he had opened up bee-keepers' headquarters on Duane Street, N. Y., and as we had previously sold honey quite largely to the firm of McCaul & Hildreth Brothers, we shipped him 4 barrels and 10 kegs of honey to sell on commission. He received the honey and sold it to Strohmeier & Co., but never answered any of our letters. If any readers of the AMERICAN BEE JOURNAL know where he can be found, we would like to hear from them.

[We wrote a letter to Mr. McCaul as soon as the above came to hand, demanding that he make proper returns for the honey at once, but the letter was returned to us unopened, by the New York Post-office, marked, "Removed—present address unknown." This is evidently another addition to the list of swindlers.—Ed.]

Experience of an Aged Bee-Man.—James Jaggard, Rosefield, Ills., on Oct. 20, 1888, writes:

My bees did well considering the season, the colonies averaging 40 pounds. The old colonies did not store much surplus honey. I did not feed one pound of sugar. I have 38 colonies on the summer stands, with the brood-frames full of honey. I have ceased farming, and will devote what little time I have to bee-keeping. I am in the 83rd year of my age, hale, hearty and well. Bee-keeping is my delight, and their stings do not hurt me half a minute after being stung. I think that I have the best location for an

apiary that is in this part of the country. I live on the banks of the Kickapoo creek, and there are hundreds of acres of flat land which abound in flowers of almost every kind. One queer feature is, that there is an abundance of Spanish-needle and golden-rod which the bees did not touch. There is a clearing of 30 acres joining my land, grown full of thistles; the bees worked on them for six weeks, and the honey was as light in color as white clover honey. I sold it all to the stores in Peoria for 15 cents per pound.

Bee-Keeping in Georgia.—R. H. Campbell, Madison, Ga., on Nov. 2, 1888, writes:

The season is mild, and the Italians have been booming and roaring on a plant that I have not as yet learned the name of. A brother bee-keeper in Mississippi calls it "bitter-weed," but this is not bitter-weed, as cows eat it, and it does not affect the milk. It is a species of buckwheat, as the bloom is white and very profuse. It yields honey abundantly, and we have it every fall when there is plenty of rain through September. I think that the plant is one of the asters. It abounds everywhere over the whole country in this section. I have sent a specimen to Prof. Cook, and will see what he says about it. The bees do not notice golden-rod while this is in bloom. The honey is excellent.

I have one or two A B C scholars here, and one says that his bees have gathered more honey this fall than they did in the spring. That is accounted for by his bees not being in proper condition at the time of the honey-flow. There have been three heavy honey-flows this year, viz: the first of May, the first two weeks of August, and from Oct. 15 until now. My 90 colonies of Italians are in excellent condition for winter.

I received a fine lot of imported queens from Italy in September, that were five weeks in coming by express. In two of the cages every bee was dead except the queens, which shows that they were very hardy. They had plenty of stores, and I cannot see why the workers did not live, unless they were all old bees, and no doubt that was the case. In the lot of eight queens, five came through safely. I have drones still flying in my apiary. We had one slight frost on Oct. 10, but it did no damage. Black bees and hybrids have done poorly, and the moths have played havoc with some.

International Bee-Convention.

—The Pamphlet Report of the Columbus, Ohio, Convention is now issued, and copies have been sent to each member, as well as to the Colleges, Agricultural and Horticultural Societies and periodicals devoted to the industry. Copies can be obtained at this office, by mail, postpaid, for 25 cents. This pamphlet contains the new bee-songs and words, as well as a portrait of the President. Bound up with the history of the International Society, and a full report of the Detroit, Indianapolis and Chicago conventions, for 50 cents, postpaid.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for \$1.50.

Do Not Fail to get up a club and send it with your renewal for next year.

Honey and Beeswax Market.

CHICAGO.

HONEY.—New crop arriving slowly, but demand is limited. White clover comb, 17@18c. Extracted, 7@9c.

BEEWAX.—22c.

Sep. 12. S. T. FISH & CO., 189 S. Water St.

CHICAGO.

HONEY.—For white comb 1-lbs., 18c. Very little inquiry for anything outside of 1-lb., and when it is wanted it is at a lower price. Extracted, the best grades, 7@8c., and some held higher. Offerings are small and demand slow.

BEEWAX.—22c.

R. A. BURNETT,
161 South Water St.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lbs., 18@20c.; 2-lbs., 16@18c. Good dark 1-lbs., 16@18c.; 2-lbs., 15 to 16c.; fair 1-lbs., 12½@14c. Extracted, white, in kegs and ½-barrels, 8½@9c.; amber in same, 7½@8c.; in pails and tin, white, 9@9½c.; in barrels and half-barrels, dark, 6@6½c. Market steady and supply ample for the moderate demand, but present values have a tendency to restrict general consumption.

BEEWAX.—22@23c.

Oct. 25. A. V. BISHOP, 142 W. Water St.

DENVER.

HONEY.—Colorado, new 1-lb. sections, 13@15c.

Extracted, 7@8c.

BEEWAX.—20@23c.

Sep. 7. J. M. CLARK & CO., 1409 Fifteenth St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lbs., 15@17c.; 2-lbs., 14@16c. Fair white 1-lbs., 14@16c.; 2-lbs., 13 to 15c. Extracted, white, 7½@8c.

BEEWAX.—23½c.

Sep. 17. THURBER, WHYLAND & CO.

NEW YORK.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 15@16c. Fair white 1-lbs., 15@16c.; 2-lbs., 12c. Buckwheat 1-lbs., 11@12c.; 2-lbs., 10@11c. White extracted, 7½@8½c.; buckwheat, 5½@6½c.; California extracted, white sage, 7½@7¾c.; amber, 7¼@7½c. Demand good and prices firm. New comb honey is arriving quite freely.

BEEWAX.—23@23½c.

Oct. 10. HILDRETH BROS. & SEGELEN,
28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—White 1-lb. sections, 11@12½c.; 2-lbs., 12½@1c. amber, 8@10c. Extracted, white, 5¼@6c.; light amber, 5¼@5½c.; amber and candied, 4¼@5c. Receipts light and market firm for best qualities.

BEEWAX.—Dull at 19@22½c.

Sep. 22. O. B. SMITH & CO., 423 Front St.

DETROIT.

HONEY.—Best white comb, 17@18c.; dark, 16c.—

Extracted, 8@10c. Market bare of all kinds.

BEEWAX.—21@22c.

Sep. 24. M. H. HUNT, Bell Branch, Mich.

CINCINNATI.

HONEY.—We quote extracted at 4¼@8c. per lb. Comb honey, 12½@16c. Demand slow, and only for best qualities.

BEEWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.

Oct. 24. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—Choice 1-lb. sections, 18c.; dark 1-lbs., 14c.; 2-lbs., 18c.; dark, 13c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock fair.

BEEWAX.—None in market.

Sep. 27. HAMBLIN & BEARSS, 514 Walnut St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 17½@18c.; 2-lbs., 14@15c. Fair 1-lbs., 14½@15½c.; 2-lbs., 11@12c. Extracted, fancy white clover, 7½@8½c.

California white in 60-lb. cans, 8c.; light amber in same cans, 7½c.; amber, 7½c. Buckwheat in kegs and barrels, 5½@6c. Cuban, in barrels and ½-barrels, 65c. per gallon.

Sep. 26. F. G. STROHMEYER & CO., 122 Water St.

BOSTON.

HONEY.—We quote: Best white clover 1-pounda, 17@18c.; best 2-lbs., 16@17c. Extracted, 8@9c. The market is more active, with an upward tendency.

Oct. 25. BLAKE & RIPLEY, 57 Cbatham Street.

KANSAS CITY.

HONEY.—White 1-lbs. 17@18c.; dark, 14@15c.; California white 1-lbs., 17c.; dark, 14c. Extracted white 8c.; amber, 7c.

BEEWAX.—None in the market.

Oct. 11. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—We quote: Extracted in barrels, 5@6c., according to quality; in cans, 7@8c. Comb, 12½@15c. Prices firmer on account of scarcity, though the demand is not great.

BEEWAX.—21c. for prime.

Oct. 17. D. G. TUTT & CO., Commercial St.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6 cents; light amber, 5¼c.; amber, 5¼@5½c. Comb, 1-lbs., 13@14c.; 2-lbs., 10@13c.

BEEWAX.—20@22c.

Sep. 24. SCHACHT & LEMCKE, 122-124 Davi

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. Nov. 21, 1888. No. 47.

EDITORIAL BUZZINGS.

He who plants a tree Plants a hope.

Rootlets up through fibers blindly grope ;
Leaves unfold into horizons free.
So man's life must climb
From the clouds of time
Unto heaven's sublime.
Canst thou prophesy, thou little tree,
What the glory of thy boughs shall be?
—Exchange.

That Melissa Honey mentioned by Mr. A. C. Tyrrel, on page 749 of our last issue, came to hand a few days ago, after that JOURNAL was printed. It is of excellent quality, thick body, and pleasant to the palate; though amber-colored, it will be found good for table and other uses. It has rather a pungent taste, which is more pleasant than otherwise.

Mr. Ivar S. Young, who visited the apiarists of America last year, has published some very disparaging and untruthful things about Americans. The head-master of the Grammar School in Christiania makes an apology for Mr. Young in these words, as published in the *Canadian Bee Journal* for Nov. 7:

Mr. Young... is very warm-blooded, and therefore at times rash and unconsiderate, and says things that had better be left untold.

True: and now let us hope that a sense of honor will lead him to correct the many erroneous things he has already said. We have written to him, pointing them out, and given him a chance to set himself right in the matter, as publicly as the misstatements were made. If he does so, Americans will forgive and forget. If not, they will know the measure of the man and the clothes which best suit him.

The Review of the new edition of "Cook's Manual of the Apiary," by the editor of the *British Bee Journal*, which may be found on pages 760 to 762 of this JOURNAL, is a very complete, fair and thorough criticism. While in general it meets our approval, there are some matters which are still open to discussion. Many are not ready to adopt the view that "honey is digested nectar," nor is the question, "Do bees hear?" settled to the satisfaction of some of our best-informed apiarists. But the matter, as discussed in the Manual and by the reviewer, is well worth careful study and investigation.

The reviewer makes repeated comparisons between Prof. Cook's Manual and the work by Mr. Frank Cheshire, and points out the superiority of the Manual in many respects. It is to be regretted that typographically comparisons result the other way. Mr. Cheshire's magnificent work is printed in the highest style of the art, on beautiful paper, and the illustrations are superb. It is a disappointment not to be able to truthfully say as much of Prof. Cook's Manual. The exceedingly fine illustration on page 46 of Mr. Cheshire's work is a marvel of beauty and excellence; in contrast, those on pages 306 and 307 of Prof. Cook's book are so badly printed as to be almost indistinguishable—caused by the inferior quality of ink and paper, and worse press work.

Giving credit for the illustrations is mentioned by the reviewer as commendable, and so it is, but unfortunately the Professor has therein made thirteen mistakes. This is a matter of but little importance, but it might be corrected in future editions.

Take it all in all, Americans have cause for pride in the many excellencies of the new edition of Prof. Cook's Manual.

Mr. George K. Hubbard, an apiarist of La Grange, Ind., has taken unto himself a wife. The pleasant ceremony occurred on the 8th inst. The bride was Miss Josie L. Spires, of Tiffin, O., a teacher in the public schools. The BEE JOURNAL extends congratulations, and wishes for them unbounded happiness and lots of honey.

Wooden Comb.—An exchange says that Mr. Aspinwall has, this summer, used wooden combs; that is, we presume, a mid-rib of thin wood, with the combs built on each side in the brood-chamber. It adds:

If the wintering of his bees in this comb is as successful as the summer experience, it will prove quite an innovation in bee-keeping. After making, these wooden combs are treated in hot wax, and are readily accepted by the bees, while the treatment prevents any effects of moisture on them.

The Date on the wrapper label of your paper indicates the end of the month to which you have paid. If that is past, please send us a dollar to carry the date another year ahead.

Fun for the Boys.—This time it is made by one of the "girls"—Mrs. Lucinda Harrison, in the *Prairie Farmer*. She is always saying something original and amusing. Here is her latest dose:

OBITUARY.—Died at Columbus, O., Oct. 4, 1888, the North American Bee Keepers' Society, aged 19 years and 1 day. Services held at Representative Hall at the State House. Dr. Thomas G. Newman, of Chicago, officiating; Dr. C. C. Miller, leader of music; pall-bearers, Dr. Mason, Dr. Besse, Dr. Tinker, Prof. Cook, Sec. Hutchinson and R. F. Holtermann.

The heir to this inheritance is known as "The International American Bee-Association," and includes in its territory "all of the United States and Canada." I cannot see why the heir does not inherit the whole estate. Perhaps it is reserved for minor heirs. I thought North America extended from Behring Strait to the Isthmus of Darien. It is not stated what disease the parent died of, but I inter it was a dose of too much doctor, as there were many in attendance.

That is the unkindest cut of all, especially after dubbing the editor of the BEE JOURNAL as "Doctor!" "Died of too much doctor." It is a pity that Mrs. Harrison was not there to soothe its last moments, and administer consolation.

But it is the old proclamation: "The King is dead! Long live the King." The same announcement of death is also one of life. One succeeds the other instant. The "North American" is dead, but the "International" lives, and by many reforms and improvements expects to merit and obtain the fealty and devotion before given to the one it has now succeeded.

Let us **all pull together** for success, and heed the moral of the following bridal story:

An eccentric bride-groom requested his bride to accompany him into the garden a day or two after the wedding. He then threw a line over the roof of their cottage. Giving his wife one end of it, he retreated to the other side, and exclaimed, "Pull the line!"

She pulled it, at his request, as far as she could. He cried, "Pull it over!"

"I can't," she replied.
"Pull with all your might!" shouted the whimsical husband.

But in vain were all the efforts of the bride to pull over the line so long as the husband held on to the opposite end. But when he came round, and they both pulled at one end, it came over with great ease.

"There," said he, as the line fell from the roof, "see how hard and ineffectual was our labor when we pulled in opposition to each other, but how easy and pleasant it is when we both pull together. If we oppose each other, it will be hard work; if we act together, it will be pleasant to live. Let us therefore *always pull together.*"

Moss for Winter Packing.—According to *Tidskrift for Biskjotsel*, moss is very often used in Norway for winter packing, and it is spoken of as very excellent. They let it dry, when it is green, and in this state it will better absorb the moisture from the brood-chamber than anything else. It never becomes musty, but is called to life again by the moisture, and will be as green and fresh as ever.

GLEAMS OF NEWS.

Hunting Bees in Australia.

The following very interesting account of bee-hunting in Australia, is from an exchange:

The wild bee of Australia differs little in size or appearance from our common horse-fly, and is stingless. Most of the trees in that country are hollow, and it is in the cavities of the branches that the bees deposit their honey, at a considerable distance from the ground. It is of an aromatic taste, and chiefly gathered from the leaves and blossoms of the different trees that clothe the whole country, from the summits of the mountains to the sea-shore, with the exception of occasional plains, which are of rare occurrence. By the aborigines of Australia this honey is regarded as a great luxury, and it is very interesting to note with what sagacity they contrive to indulge their taste for it—searching it out with infallible eye-sight, and with amazing delicacy of touch. Their method of finding these natural hives, which are not numerous, is curious, not only from the fact that the most minute observation, and the most delicate manipulations must have been required to enable the inventor of it to succeed, but also because it displays a knowledge of the natural history of an insect, such as I can venture to say, a large portion of the civilized world does not possess.

From the absence in many parts of the bush of Australia of flowers, the little native bee may be seen busily working on the bark of the trees, and unlike the bee of this country, which is ever on the move from flower to flower, it seems to be unconscious of danger. This may arise from the vastness of the solitude in Australia, which are seldom or ever disturbed, except by a passing tribe, or by its own wild denizens, which are far from numerous. The bee is therefore easily approached, and the bright, clear atmosphere of the climate is peculiarly favorable to the pursuit.

A party of two or three natives, armed with a tomahawk, sally forth into the bush, having previously provided themselves with soft white down from the breast of some bird, which is very light in texture, and at the same time very bluffy. With that wonderful quickness of sight which practice has rendered perfect, they descry the little brownish, leaden colored insect on the bark, and rolling up an end of the down feather to the finest possible point between their fingers, they dip it in the gummy substance, which a peculiar sort of herb exudes when the stem is broken, they cautiously approach the bee, and with great delicacy of touch place the gummed point under the hind legs of the bee. It at once adheres. Then comes the result for which all this preparation had been made. The bee, feeling the additional weight, fancies he has done his task, and is laden with honey, and flies off from the tree on his homeward journey, at not a great distance from the ground. The small white feather is now all that can be discerned, and the hunt at once commences.

Running on a foot amid broken branches and stony ground, requires, one would think, the aid of one's eyesight; but with the native Australians it is not so. Without for a moment taking their eyes off the object, they follow it, sometimes the distance of half a mile, and rarely, if ever, fail in marking the very branch where they saw the little bit of white-down disappear at the entrance of the hive. Here there is a halt, the prize is found, and they sit down to regain their breath, before ascending the tree, and to light a pipe, to which old and young, men, women and children, are extremely partial.

When the rest and smoke are over, with one arm round the tree, and the tomahawk in the other, the blackman notches in the bark, and placing the big toe in the notches of this hastily constructed stair, ascends till he comes to where the branches commence. Then putting the handle of the tomahawk between his teeth, he climbs with the ease and agility of a monkey, until he reaches the branch where last he saw the white-down disappear. He then carefully sounds the branches with the back of his tomahawk, till the dull sound as distinct from the hollow sound, tells him where the bees are. A hole is then cut, and he puts his hand in and takes the honey out. If alone, the savage eats of the honey until he can eat no more, and leaves the rest. But if others are with him, he cuts a square piece of bark, and after having his part as a reward for his exertion, brings down a mass of honey and comb mixed up together, which, though not inviting, is greedily devoured by his partners below.

Bee-Association for Maryland.

—An enthusiastic correspondent of the State of Maryland, writes as follows on the subject:

I wish to call attention to the fact that there is not in our State (Maryland) a bee-keepers' association, although it embraces three of the largest supply depots in the country, and therefore suggests a goodly number of bee-keepers. Among the "Editorial Buzzings" of the AMERICAN BEE JOURNAL of Nov. 7, in an article about the number of bee-societies in America compared with those in Germany, it states as a reason for their scarcity in America, that our bee-keepers "think that they know it all, and there is no need of societies for them. And as for imparting their knowledge to their less confident or less informed brethren—they scoff that idea!" Now shall we not try to remedy this, and add one more to the number of American bee-societies? Can we not organize an association that will call together the bee-keepers of Maryland, and the surrounding country? Or shall we always remain "in short-arm'd ignorance?"

Certainly you can organize a society. Just issue a "call" for a meeting, organize an association, and there is no reason why you cannot have one of the best societies in America.

Here is a hint: If you act at once, you may be the first to affiliate with the "International American;" and that would be quite a "feather in your cap," for the "International" is taking everywhere, and will become the "central sun" of apiculture in America in a very short time.

Act quickly! Strike out for success! Be enthusiastic! These are the watch-words which bring success, everytime.

Ants.—A bee-keeper in Norway, Mr. P. A. Larsen, recommends as a remedy against ants, the use of the intestines of fish. He puts some of it into the nest, and he insists that the ants are always chased away, if this remedy is applied once or twice.

Another gentleman, Mr. C. Omberg, recommends the use of powdered lime. He puts some of it around the hives with the same good effect.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

Food Adulteration was discussed at the annual meeting of the National Board of Trade at Chicago, last week, when considering the advisability of asking Congress to pass a law against adulterated lard. Among other things the preamble sets forth that "such adulteration of lard has grown to be a National scandal, and has seriously damaged the good name of American lard, both in this country and abroad."

The following resolution was, after considerable discussion, carried:

Resolved, That the National Board of Trade recommends to the Congress of the United States the enactment of such laws and regulations as will compel all refiners and dealers to brand all adulterated lard, "Compound lard," or with some brand such as will plainly distinguish the pure from the impure article, in order that the consumers at home and abroad may know the one from the other.

This is all very well, but why not by law condemn all other food adulterations? Almost everything used for food and medicine by man is adulterated, and all should be protected by law from the ill-advised and health-destroying sophistications. If we mistake not, a bill was prepared, and is now pending before Congress, which covers not only the adulteration of food, but also the compounded articles of food.

Every honest man should not only favor and endorse such action by Congress as would compel men to be honest with food of all kinds, including honey; but they should work for the enforcement of such a law to the letter, as well as the spirit thereof.

The low prices of honey have fortunately driven adulterators of that article to the wall. But if the prices advance again, they may revive their nefarious business.

A law against all adulterations is needed, and it should be speedily passed by Congress, and rigidly enforced in every part of the United States of America.

The Honey Season in Norway.

—An editorial in *Tidskrift for Biskjotsel* for October, says: "This season has for us bee-keepers been a dull one, and the previous winter was still worse. A worse failure in the honey crop will scarcely be heard of. Many colonies had to be fed in the midst of the summer, and many of them starved to death. But now we have a good flow from heather, and we hope that the bees have gathered enough for winter use."

Regarding the heather honey, it is said, in another editorial, that it must be extracted *every day*, because if it is left with the bees until it is capped over, it is impossible to get it out of the cells.

We will Present a Pocket Dictionary for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide the spelling of words, and their meaning.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for \$1.50.

Women and Bees.

'Tis a fact that can never be questioned,
However absurd it may sound,
That 'twixt women and bees a resemblance
Most wonderful is to be found.

They have both of them "combs," that is certain,
And in energy neither are lax;
And though honey to both is delicious,
They are both now and then in a "wax."

A wife full of cares economic
Is most like an industrious bee;
And the waist of a wasp on a lady
Is something delightful to see.—*Jud.*

Rapid and Tireless Work.—Concerning the work performed by bees and wasps, Susan Power, in *Vick's Magazine*, writes as follows:

Early as a man of science may be, Sir John Lubbock entering his study a few minutes after four in the morning, found a wasp already at work on the honey set out of the window. Bees and wasps suck all the honey from flowers and sweets they can carry, fly back to the hive, store it, and come back directly for another supply.

The wasp in question kept at work without a moment's rest until 7:46 in the evening, making a day of sixteen hours. The bee began at 5:45 in the morning, and also left off earlier than the wasp. Each visit from the honey to the hive took about six minutes, and it made ten visits an hour, and a hundred in the day. The wasp made sixty visits between 4:13 in the morning and 6 minutes past 12 at noon, for Sir John timed them all, and gives a table exact to the minute of each return to the honey on the sill.

Sir wasp must have strayed to visit flowers sometimes, or to have a flight by the way, for his time varies from five to ten and 20 minutes between visits, which were kept up till dusk. This was in autumn. In summer they make overtime, and work late in the long English twilights, which are clear till after 9 o'clock.

In fine weather, bees often visit more than 20 flowers in a minute, and so carefully do they economize the sunny hours that if they find one nectary dry in a flower they do not waste time to examine others on the same plant. Mr. Darwin watched certain flowers carefully, and found that each one was visited by bees at least thirty times in a day. In large clover fields, or plains of wild flowers, every one is visited in the course of a day. Mr. Darwin carefully examined a large number of flowers in such fields, and found that every single one had been visited by bees. There is something very pretty in the thought of this tireless, faithful industry of insects, and of two of the most learned men in Great Britain spending whole summer days in the fields with great faithfulness watching the flower industry.

What use in it, you ask, with true modern disregard of any pursuit which does not return its per cent. of interest within the week? Only to find out more of the uses flowers and insects have for each other, that flowers were made to attract and feed bees that they in turn might carry the pollen which fertilizes and secures the seed of plants. Without this careful searching work of the bees in the clover fields and orchards, our field and fruit trees would die out in time.

The Time for Reading has come, with the long winter evenings. We have a large stock of bee-books, and would like to fill orders for them. To read and post up is the way to succeed in any pursuit—in none is it more important than in bee-keeping.

A New Implement for bee-keepers has just been brought out by the W. F. and John Barnes Co. It is a combined scroll saw and a circular saw. Each machine is perfect, neither being impaired by the other. The two machines can be put in one, ready for use either way, in one minute, and each will do its work with absolute success. This combination of uses doubles the value of the machine, at less cost than they can be furnished separately. The capacity of the scroll saw is exactly the same as that of scroll saw No. 7, the warranty as to what that will do applying equally to this. For light ripping, cutting to length, cutting joints, drawer and box work, etc., the circular saw of the combined machine is invaluable. In short, for general use, no more profitable investment can be made by any bee-keeper, or almost any wood worker, than this combined machine with its different combinations and attachments.

Combined Scroll and Circular Saw.

The circular saw, while remaining on its mandrel, can be taken at once out of the way when the scroll saw is to be used. The mandrel is set in its bearing in such a manner as to enable the operator to take the whole (mandrel and saw) from the machine in an instant.

All varieties of joint work can be done truly and rapidly. The table can be handily adjusted up or down by a cam, to allow any desired depth of cut being made by the saws or cutter tools. The circular saws are 6 inches in diameter, and reach 1 5/8 inches above the saw-table. A 7 or 8 inch saw can be used if desired.

Emery wheels, in size up to 1 inch face by 6 inches diameter, can be used to good advantage on this machine.

Those who make their own hives or surplus arrangements will find it an invaluable aid. Its price is \$50, and it can be obtained at this office.

Do Not Fail to get up a club and send it with your renewal for next year.

Conventions as aids to progressive bee-culture, is thus set forth in the *Canadian Farmers' Advocate* for November:

Perhaps there is nothing, aside from periodicals, which so benefits a pursuit as the meeting in convention of those interested in that pursuit. Points which require solution may be discussed, or an idea secured, which leads to an entirely new and valuable train of thought. Amongst bee-keepers these conventions are very general, and the most important of them all is the North American Bee-Keepers' Association. Its last meeting was held Oct. 3, 4 and 5, at Columbus, O. Although the season has been a very poor one for bee-keepers, the attendance was very fair, and embraced four authors of standard works in apiculture.

A new departure was made in the way of a programme. There were but few essays, and a programme committee selected topics for discussion for each session, with a leader for the topic. Whilst many and lengthy essays should be avoided, a medium might be advantageous; and short ones interspersed with lengthy discussions, would bring out and concentrate discussion. Many topics of interest were brought up, and the sessions thoroughly enjoyable.

Brantford, Canada, was selected for the next place of meeting; and as this is only the second time in twenty years that the society will meet in Canada, a very large attendance is expected. Mr. R. F. Holtermann, of that place, is the Secretary.

Let us hope that the next meeting will be a right-royal one, inasmuch as it is to be held in the Dominion of Royalty.

Frank Leslie's Sunday Magazine for December closes the twenty-fourth semi-annual volume. It is filled, as usual, with the most entertaining matter in prose and poetry, fiction and fact. A Christmas anthem, entitled, "Unto Us a Child is Born," composed by Mr. C. Wenhams Smith, organist of Plymouth Church, Brooklyn, occupies three pages, and is a brilliant piece of music. A sermon by Dr. Talmage, on "The Veil of Modesty," appeals strongly to American women.

Convention Notices.

☞ The Nebraska State Bee-Keepers' Association will convene at Lincoln, Nebr., on Jan. 9, 10 and 11, 1889. J. N. HEATER, Sec.

☞ There will be a meeting of the Susquehanna County Bee-Keepers' Association at the Court House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a.m. H. M. SEELEY, Sec.

☞ The Pan-Handle Bee-Keepers' Association will hold its next meeting in the K. of P. Hall on Main St., between 11th & 12th Streets, in Wheeling, W. Va., on Nov. 21 and 22, 1888. All bee-keepers are cordially invited. W. L. KINSEY, Sec.

☞ The twentieth annual convention of the New York State Bee-Keepers' Association will be held in the City Hall, Syracuse, N. Y., on Dec. 11, 12 and 13, 1888. G. H. KNICKERBOCKER, Sec.

☞ The 23rd annual meeting of the Michigan Bee-Keepers' Association will be held in the Council Room at Jackson, Mich., on Dec. 12 and 13, 1888. Greatly reduced rates have been secured at the Iurd House, also at the Commercial House (near the Michigan Central depot) at \$1.50 and \$1.00 per day. A programme is being prepared and excellent essays are already promised. Any bee-keeper having anything new and useful, and finding it impossible to be present, can send it by Express to Jackson, in care of the Secretary, who will place it on exhibition and return it as per orders. Please to come and bring your bee-keeping friends with you. H. D. CUTTING, Sec.

The Indian Summer.*Written for the Home and Farm*

BY A. F. BROWNE.

The sunlight, in a warm and mellow tide
Upon this Indian summer day descends;
Earth, sky, and all the view of waters wide
In silent and harmonious beauty blends.

Along the southward slopes, the aftergrass
Still shows the emerald shade of summer time;
With lingering pace a troop of zephyrs pass,
And oft repeat a verse of mystic rhyme.

The vapor ships that slowly cross the sky
Are smooth and fleecy, like the clouds of June,
And only trees that leafless meet my eye
Remind me earth has passed from Nature's noon.

QUERIES AND REPLIES.**Depositing Eggs in the Royal Cells.***Written for the American Bee Journal*

Query 590.—How nearly complete is the royal cell when the queen deposits the egg in it?—S.

About one-third, as to the length.—
G. M. DOOLITTLE.

I do not know.—J. M. HAMBAUGH.

Usually it is in the early stages.—
MRS. L. HARRISON.

When it is about in the shape of the cup of a small acorn.—M. MAHIN.

Just when they are about the size of a small acorn-cup.—P. L. VIALLO.

Only just started, or in the "acorn-cup" stage.—JAMES HEDDON.

Probably about one-half completed.—
C. H. DIBBERN.

It is only advanced to a cup-shaped appearance.—J. P. H. BROWN.

I have seen some barely begun, and others almost large enough to seal over.—C. C. MILLER.

It is like an acorn-cup, $\frac{1}{4}$ to $\frac{3}{8}$ of an inch deep.—R. L. TAYLOR.

I do not remember just now of having seen a queen deposit an egg in the royal cell. You will generally find an egg in the cell when about one-third formed.—H. D. CUTTING.

The royal cell is frequently made around an egg that has been placed in a worker-cell, and I have known the egg to be placed in the royal cell when more than half completed.—A. B. MASON.

It varies much; often in a shallow cup; sometimes in a nearly completed cell.—A. J. COOK.

It depends upon circumstances. I have known the egg to be deposited in

the incipient cup from which the cell is built. The question is mooted.—J. E. POND.

As a swarm sometimes issues before queen-cells are started, it is plain that they are *sometimes* far from complete. I think that the queen does not always deposit the egg in a royal cell.—
EUGENE SECOR.

I have seen this done only once. I held the comb in my hands, I saw the cell prior to the queen's visit, and saw it at the time of visit and afterwards. She undoubtedly laid in it at the time. The cell was about $\frac{1}{2}$ an inch deep. A very fine queen was developed in the usual time from this queen-cell.—J. M. SHUCK.

The queen does not deposit the egg in the royal cell. The workers select a common worker-cell (with a larva from one to two days old); enlarge the cell—perhaps at the expense of three or four adjoining cells—and literally "float" the larva in royal jelly, which is simply partly-digested honey and pollen. The worker-egg, under this treatment will, in 16 days, hatch out into a perfect queen.—WILL M. BARNUM.

I have often seen eggs "standing on end" in the usual way, in queen-cells no deeper than an ordinary acorn-cup. According to my observations none but old or otherwise condemned queens ever lay eggs in queen-cells; and in these cases most likely they are forced to do it by the worker bees. Laying workers and exhausted queens, and sometimes drone-laying queens will lay eggs in queen-cells. But when strong young queens swarm, they usually go out before any cells have been started.—G. W. DEMAREE.

The egg will generally be found in the royal cell when it is from one-fourth to one-third of its length—but sometimes when it is nearer complete.—
THE EDITOR.

Does it Injure a Queen to Sting Her Rival?*Written for the American Bee Journal*

Query 591.—Is a queen injured by stinging her rival?—Illinois.

No.—P. L. VIALLO.

No.—R. L. TAYLOR.

Not usually.—DADANT & SON.

I think not.—H. D. CUTTING.

Not in the least.—M. MAHIN.

Yes, probably.—MRS. L. HARRISON.

I think not.—J. M. HAMBAUGH.

I think not.—A. B. MASON.

Probably never.—C. C. MILLER.

I think not, but I do not know for certain.—C. H. DIBBERN.

Usually not; but possibly she may be sometimes.—A. J. COOK.

No, sir; but she is by her rival stinging her.—J. E. POND.

I do not know, but I think not.—
JAMES HEDDON.

Gracious! I don't know.—J. M. SHUCK.

I think not. Still I should prefer that a good queen should never combat with another queen.—G. M. DOOLITTLE.

I have met with cases where I concluded that they had been injured in this manner.—J. P. H. BROWN.

No; not as I have ever been able to observe—and I have made some observations in this direction.—WILL M. BARNUM.

I never supposed that the constitution of a mule was impaired by the sudden contact of his hind feet with some soft spot on the driver. No.—
EUGENE SECOR.

To say that the surviving queen is never injured in her conflict with her rival, may be putting it too strong, but as a rule she is not injured in the least. I know of one case in which the contest between two queens proved fatal to both combatants; which case seems to prove that there are exceptions to the general rule.—G. W. DEMAREE.

Generally she is not injured, but an injury may occur in some cases.—
THE EDITOR.

CLUBBING LIST.

We Club the American Bee Journal for a year, with any of the following papers or books, at the prices quoted in the LAST column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	Club
The American Bee Journal	1 00	...
and Gleasons in Bee-Culture	2 00	1 75
Bee-Keepers' Magazine	1 50	1 40
Bee-Keepers' Guide	1 50	1 40
Bee-Keepers' Review	1 50	1 40
The Apiculturist	1 75	1 65
Canadian Bee Journal	2 00	1 80
Canadian Honey Producer	1 40	1 30
The 8 above-named papers	5 65	5 00
and Cook's Manual	2 25	2 00
Bees and Honey (Newman)	2 00	1 75
Binder for Am. Bee Journal	1 60	1 50
Dzierzon's Bee-Book (cloth)	3 00	2 00
Reed's A B C of Bee-Culture	2 25	2 10
Farmer's Account Book	4 00	2 20
Western World Guide	1 50	1 30
Heddon's book, "Success"	1 50	1 40
A Year Among the Bees	1 75	1 50

How to Propagate Fruit	1 50	1 25
History of National Society	1 50	1 25

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

CORRESPONDENCE.

CENTENNIAL.

The Premiums Awarded at the Columbus Exposition.

Written for the American Bee Journal
BY DR. A. B. MASON.

I have been so busy since getting home from Columbus, O., that it has seemed impossible to write, and send a list of premiums awarded in the Bee and Honey Department of the Centennial Exposition at Columbus, but I will take the time this morning, 2 a.m. I want to give you an article on the Exposition and the Bee and Honey Department, but I shall have to do that some other time.

Mr. Elias Cole, of Ashley, O., was awarded first premium on a foundation mill, samples of foundation for brood-chamber and surplus, and wax extractor; second premium on display of extracted honey, and third on a colony of bees, display of beeswax, display of queens, and bee-hive.

Dr. G. L. Tinker, of New Philadelphia, O., was awarded first premium on a colony of bees, bee-hive, exhibition bee-hive, arrangement for securing surplus, sections and supplies; and third on the best race of bees.

Dr. H. Besse, of Delaware, O., was awarded first premium on a smoker (Bingham's); second on beeswax, foundation mill, sections and supplies; and third premium on display of comb honey, sample of comb honey, honey extractor (Muth's), and wax extractor.

Mr. C. E. Jones, of Delaware, O., was awarded second premium on display of comb honey, colony of bees, race of bees, display of queens, extractor (Root's), wax-extractor, smoker, and arrangement for securing surplus; and third premium on a sample of extracted honey.

Mr. Aaron Goodrich—a gentleman over 75 years old—of Worthington, O., was awarded third premium on a display of comb honey and a display of beeswax; second on a sample of honey-vinegar, and third premium on a display of extracted honey.

Mrs. Mason, who has a larger apiary than I have, was awarded first premium on a display of extracted honey, sample of extracted honey, sample of comb honey, race of bees, honey-cake, honey-cookies, honey-jumbles, and honey-candies; and second premium on honey-plants.

E. E. Mason was awarded first on foundation made on the grounds, for brood-chamber and surplus; second

on sample of comb honey and honey-candy; third on honey-plants.

If I am last on the list, and did not get as many premiums as I might have had if there had not been so much competition, I was not "left out in the cold" entirely. I was awarded first premium on a display of honey-plants, honey-vinegar, display of queens, foundation press, and honey extractor; and second on sample of extracted honey, foundation for brood-chamber and surplus, made on the ground; bee-hive and exhibition bee-hive; and third on supplies.

If I had the time, and did not have the "fear of the editor's waste-basket" before me, I should like to write somewhat in detail of the Bee and Honey Department and the exhibits, exhibitors, and some of those who visited our building during the Exposition, and it may not be wholly uninteresting to say something of our display, etc.

A building 36x60 feet was put up purposely for the apiarian department, and was well filled with everything relating to the apiary.

There were thirteen exhibitors, but only eight competed for premiums, as will be seen by the above list of awards.

A. I. Root sent a whole earload of appliances, and his display included almost everything from a queen-cage to machinery for making sections. It is perfectly useless to attempt to enumerate them, and he had two men there all the time to look after and explain everything about which a question might be asked, and to run the four new machines for making one-piece V-grooved sections. Mr. Root did not compete for premiums. His exhibit, without the machinery, occupied a space of 8x40 feet, and the section machinery occupied a space of 12x15 feet in machinery hall, and attracted a great deal of attention from the thousands and thousands of visitors, during the seven weeks of the Exposition.

Too much could not be said in praise of the gentlemanly conduct and ways of the five different gentlemen Mr. Root had at different times at the Exposition, and it seems but natural to mention Mr. Warner and Mr. Will Turner, who were the first on the grounds to put up the machinery and get things in running order. Then came Mr. Whipple, and Mr. Turner went home. Then these were relieved, and Mr. Art Pulsifer came and took charge of the machinery, and Mr. Will Weed relieved Mr. Whipple. It was a pleasure to make the acquaintance of these men, and to have their company.

Mr. Aaron Goodrich, of Worthington, O., who keeps bees, as he said, "just for the fun of the thing," occu-

ried a space 20 feet long by 7 feet wide, and exhibited comb and extracted honey, honey-vinegar, and beeswax, which was displayed on shelves that extended up 9 feet. Mr. Goodrich lives about nine miles north of the Exposition grounds, and having rather poor health, his family and friends objected to his making an exhibit, but his whole soul was in the business, and he wanted to help show the world what could be done in exhibiting the progress of bee-keeping in Ohio. He came from home to the grounds every Monday morning, bringing his "provender" (as he called it) and bedding with him, and staid in the building every night until Saturday, when he would go home to spend Sunday with his family.

The first four weeks Mr. Goodrich gained in flesh a pound a week, and the next three weeks two pounds a week, and before the Exposition was over he got so that from eating just enough to keep "soul and body together," he could, to use his own words, "eat a good square meal, and take his rations regularly."

I could tell of a good many interesting things about "Uncle Aaron," as everybody calls him, and so did we exhibitors, but it takes up valuable space; but the pleasure he enjoyed, and his partial restoration to health, more than paid him for all trouble and expense.

At some future time I will try to write about the other exhibits, exhibitors, etc., if acceptable; but time forbids more at present.

Auburndale, O., Nov. 12, 1888.

BUCKWHEAT.

Keeping a Record of each Colony in the Apiary.

Written for the American Bee Journal
BY LESLIE STEWART.

It seems rather queer to me that such bee-keepers as Messrs. G. M. Doolittle, D. A. Jones, etc., should not have found buckwheat a valuable honey-plant, while with me here in New York, it has not failed to give a goodly amount of surplus in the last seven years. In fact, I am beginning to put more confidence in it for a large amount of surplus than any honey-producing plant we have in this locality. To be sure, it has not quite so fine a flavor as white clover or basswood, nor so light colored, and must of course sell for a little less per pound.

I sell the extracted buckwheat honey at 2 cents per pound less than white clover or basswood honey; yet I find

that to my home customers I sell 5 pounds of buckwheat honey to 1 pound of clover or basswood extracted honey.

Buckwheat began to bloom about Aug. 3, this year, and it made lively times for the bees during the following ten days. I had up to this time extracted 50 pounds per colony, on an average, through my entire apiary, while my best colony stored in ten days (from Aug. 3 to Aug. 13) 78 pounds of extracted honey; the second best, 74 pounds, and the third 71 pounds; please remember that this was all surplus, and not one drop taken from the brood-chambers. This honey was well ripened and very nice.

At the above time I had grand hopes of a large crop from this source, and boasted that I would extract over 100 pounds per colony of choice buckwheat honey. But, alas, a cold rain set in, and has kept at it pretty much ever since. Yet my best colony succeeded in storing 109 pounds; second best, 107 pounds; third best, 103 pounds of buckwheat extracted honey. But my entire apiary averaged only 65 pounds, after seeing that all that had been run for extracted honey had enough to carry them until another season.

The above will show that buckwheat is not such a bad honey-plant in some sections, at least in a poor season.

The following report tells how it has done as compared with other honey-plants during the last three years:

In 1886: Extracted white clover, 20 pounds; basswood, 76 pounds; buckwheat, 69 pounds. Of comb honey, no complete sections of white clover; basswood, 52 sections; buckwheat, 48 sections.

In 1887: Extracted white clover, none; basswood, 82 pounds; buckwheat, 68 pounds. Of comb honey, no white clover; basswood, 61 pounds; buckwheat, 50 pounds.

In 1888: Extracted white clover, 25 pounds; basswood, 20 pounds; buckwheat, 65 pounds. Of comb honey, no complete sections; basswood, 20 sections; buckwheat, 50 sections. In the case of comb honey, the number of complete sections are counted.

I keep a careful record of each colony on a small slate, and when I extract, the date of extracting is put down with number of pounds extracted, and the quality of the honey. While with comb honey, an account is kept of the number of complete sections taken off, with the quality of the honey stated.

In the fall I go carefully over the entire apiary, and see that each colony has a goodly supply of winter stores. If one should be found short of stores, it is immediately fed, and the amount deducted from its year's record on the

slate. For instance, colony No. 26 was worked for extracted honey, and the record on the slate is as follows: "Extracted honey, 20 pounds of white clover, 50 pounds of basswood, and 89 pounds of buckwheat—total 159 pounds. I was obliged to feed 10 pounds back for winter stores, leaving a total of 149 pounds as the record for the season."

Now during the month of September, the little slates are all gathered in, and their records with the number of the hive is carefully recorded in a large book for the purpose; and the next spring, should I want a choice breeding queen, I go to the book and select the best colony there indicated, which does not take long.

By the above plan it will be seen that my record is taken after the bees have been given a sufficient supply on which to winter. My bees are all wintered on natural stores. I never have fed a pound of anything else. I positively think that if all the beekeepers would follow my plan in this respect, we would have less honey to clog our large markets, and get a better price for the honey.

Jefferson, N. Y., Nov. 5, 1888.

COOK'S BOOK.

Criticism of the New Edition of Cook's Manual.

Review from the *British Bee Journal*
BY THE EDITOR.

We are pleased to welcome this the thirteenth edition and fifteenth thousand of Prof. Cook's Manual, which first made its appearance as a modest pamphlet in 1876. So much was this at that time appreciated that it sold rapidly, and Prof. Cook has from time to time enlarged it, until it has grown to contain nearly 450 pages. In the present edition there are 110 added pages, and 31 illustrations; and it has been in a great measure re-written, to bring it up to the knowledge of the present day.

Not only has the practical part been brought up to the present time, but also the first part—treating of the natural history of the honey-bee—has had full justice done to it; for the works of Schiemenz, Schonfeld and others, have been mentioned, and the reader is made acquainted not only with the progress made in the science connected with bees, but also with the names of those to whom we are indebted for the discoveries.

Just fancy any one writing about Parthenogenesis, and not mentioning that to Dzierzon we owe its discovery in connection with bees, made in 1835,

and published by him in 1842; yet hard as it is possible to believe it, an author has recently done so, and only mentions Dzierzon casually in connection with the introduction of the Italian bee in 1853, which enabled him to *prove* his discovery to be true, yet never once is he mentioned as the discoverer. This is the way many books are made! So conscientious is Prof. Cook in acknowledging where he gets his information, and giving due credit, that in the preface he even mentions where every woodcut is taken from; and this is in striking contrast to the ways of compilers of the present day, who copy right and left without even so much as alluding to those from whose works they copy.....

In Chapter II. the anatomy and physiology of insects, and the honey-bee in particular, are treated. Here we find many new illustrations, and much fresh matter. Describing the antennæ, he agrees with those who, like Leydig, Erichson, Hauser, and others, consider these the organs of smell, and tell us that "while Erichson first discovered the pits in the antennæ, Burmeister discovered the sensitive nerve-ending hairs at their bottom, and Leydig the perforated pegs or tooth-like hairs.

Further, he says, "We may state, then, that the antennal organ of smell consists of a free or sunken hair-like body, which opens by a pore or canal to a many-nucleated ganglionic nerve. We thus understand how the bee finds the nectar, the fly the meat, and the drone and other male insects their mates."

That the antennæ are organs of smell are generally admitted, but some have from time to time endeavored to show that they also contain the organs of hearing. Taking this view, we find Dr. Braxton Hicks, Graber, and Mayer, but the evidence they bring forward is not sufficient to satisfy scientists that these depressions are really organs of audition. This also is our view, and is the one taken by Prof. Cook, for he says, "Mr. Cheshire speaks of small pits in the antennæ, which he regards as organs of hearing. He gives, however, no proof of this, and the pits that he describes are not at all ear-like in their structure. Dr. Packard says that there is no proof that any insects except crickets and locusts have real organs of hearing. He here refers to the ear-like organs situated on the sides of the body of these insects. Dr. C. S. Minot, in reviewing Graber's work, says that it has not been demonstrated that even these tympanal organs are auditory, and adds that all attempts to demonstrate the existence of an auditory organ in insects have failed. That in-

sects are conscious of vibrations, which with us cause sound, I think no observing person can doubt. . . . Every apiarist has noticed the effect of various sounds made by the bees upon their comrades of the hive, and how contagious is the sharp note of anger, the low hum of fear, and the pleasant tone of a new swarm as they commence to enter their new home. Now, whether insects take note of their vibrations as we recognize pitch, or whether they just distinguish the tremor, I think no one knows. There is some reason to believe that their delicate touch-organs may enable them to discriminate between vibrations even more acutely than can we by the use of our ears. A slight jar will quickly awaken a colony of hybrids, while a loud noise will pass unnoticed. If insects can appreciate with great delicacy the different vibratory conditions of the air by an excessive development of the sense of touch, then undoubtedly the antennæ may be great aids. Dr. Clemens thought that insects could only detect atmospheric vibrations. So, too, thought Linneus and Brunet. From our present knowledge this view seems the most reasonable one, for nothing answering in the least to ears, structurally, has yet been discovered."

We are ourselves inclined to the same view, and do not see any reason why bees should not be sensible to vibrations which produce no effect upon us. Our ear is so fashioned that it is sensible to vibrations reaching at the outside to 38,000 in a second. The sensation of red is produced when 470 millions of millions of vibrations enter the eye in a similar time. But between these two numbers vibrations produce on us only the sensation of heat, for we have no special organs adapted to them. There is, therefore, no reason why bees should not be sensible to vibrations even with their touch-organs which do not affect us.

We have examined the antennæ repeatedly with the microscope, both superficially and section by section; and although using instruments second to none in efficiency, we have failed to trace any connection between the organs described by Graber and Mayer and an auditory apparatus. The title of Graber's work above referred to, is *Über neue oboestruartige Sinnesorgane der Insecten, 1878*; and Mayer's, *Sopra certi organi di senso nelle Antenne dei Ditteri, 1878*.

In describing the compound eyes, Prof. Cook gives illustrations from Gegenbower, but we think they do not give such a good idea of the structure of the eye as those of Grenacher, copied by Cheshire, and introduced on Plate IV. of his book. We have a

very beautiful, unique microscopic section of the eye, showing the disposition of the rods, and the decussating nerve fibrils, corroborating Grenacher's views, and showing the accuracy of his drawings. When we were staying at the College, we showed this preparation to the students of Prof. Cook's class, and they were astonished at the beauty of the structure of this organ.

Prof. Cook does not hold the view of a mosaic vision, which, he says, "is now abandoned," but thinks the philosophy of sight in insects is rather like that of higher animals, except thousands of eyes instead of two are used as one. Although their sense of color is very keen, our author believes "more has been made of this matter of color than truth will warrant." We think so, too, and believe that the experiments of Sir John Lubbock go to prove, not that bees prefer one color to another, but that they can be accustomed to recognize a certain color.

There is much worthy of study in this part of the chapter which refers to organs common to most insects, but we have not the space to go through them as carefully as we would wish, or as the work deserves. The second part of the chapter refers more particularly to the honey-bee. Referring to food given to queens and drones, he says Schiemenz and Schonfeld are unquestionably correct in the belief that they are fed by the workers the same food that the larvæ are fed, and reasons from the fact that, as he finds the queen lays over 3,000 eggs a day weighing 3,900 grams, while she herself only weighs 2,299 grams, for her to be in a position to lay nearly double her weight daily can only be possible because she is fed with highly nutritious food, which was wholly digested for her. Schonfeld found that the queen, like the drones, will soon die if shut away from the workers by a double wire cage, even though they have access to honey.

One of the most interesting paragraphs in this chapter is that referring to the glandular organs, which we find very well explained both as regards their structure and functions. Ramdohr, in 1811, discovered a pair of salivary glands in the thorax, and two other pairs were discovered by Meckel in 1846. These have been fully described by Siebold. Their functions are well known. Still Cheshire says on page 72, "and yet dense ignorance respecting them is common to the present day, even such an accomplished German apiculturist as Berlepsch failing to mention them." Had Cheshire looked at page 136 of *Die Biene*, by Berlepsch, he would have found that not only does this distin-

guished German mention them, but that he also describes their functions. Schiemenz goes into the matter very carefully, and in an elaborate monograph, beautifully illustrated, he endeavors to show that they produce a secretion which is the food of the larvæ and queens. This view has been proved to be incorrect, and Schonfeld has fully demonstrated that the food of the larvæ is, as Dufour first pointed out, digested by the workers. Moreover, any doubt as to this being the case has been removed by the experiments of Dr. A. de Planta, who shows that the chyle food of the queen, drone and worker larvæ varies. Prof. Cook explains this very clearly, and then goes on to treat of the honey-stomach with its four-lipped mouth, and shows how the bee can either feed herself or store honey at will.

We ourselves do not believe that the glands supply the larval food exclusively, although we think that secretion from these is added to the chyle food given them. Also, why do the queen and drones have glands? for if they get food as a secretion they do not want them.

This is how Prof. Cook sums up the matter: "Before leaving the subject, it seems well to remark that it would appear that the old view of Dufour, so ably advocated by Pastor Schonfeld, is, despite the arguments and researches of Schiemenz, the correct one. The queen, drone and larvæ do not get this food as a secretion—a sort of milk—but it is rather the digested pollen or chyle modified, as the bees desire, by varying their own food. In addition to this albuminous food the queen and drones also take much honey; thus they need the glands which furnish the ferment that changes cane to reducible sugar, and they have them. If all honey were fully digested, then the drones and queen would not need any glands at all. The fact that the pollen that the larvæ do get is partially digested is further proof that this is chyme, or partially digested pollen."

The legs of bees, with their antennæ—cleaners, claws, spines, and beautiful pulvilli, are fully described and illustrated, as are also the mouth parts and sting. He does not believe that the poison is dropped into the cells to preserve the honey according to Dr. Mullenhoff's theory, but thinks the formic acid in honey doubtless comes from the honey-stomach of the bee.

Chapter III. is devoted to swarming and natural methods of increase. Alluding to the piping of queens, he agrees with Landois that this is a true voice made in the cells, and even also by a queen whose wings are cut off.

He says it is usually asserted that bees do no gathering on the day they swarm previous to leaving the hive, but that is not true. Mr. Doolittle thinks they are just as active as on other days. The reason for clustering of the swarm, he says, is, no doubt, to give the queen a rest before her long flight.

Speaking of honey, he says it is "digested nectar." This nectar contains much water, though the amount is very variable—a mixture of several kinds of sugar and a small amount of nitrogenous matter in the form of pollen. Nectar is peculiar in the large amount of sucrose or cane sugar which it contains. Often there is nearly or quite as much of this as of all the other sugars. We cannot, therefore, give the composition of honey; it will be as various as the flowers from which it is gathered. "Again, the thoroughness of the digestion will affect the composition of honey." He thinks it likely that incomplete digestion and the possible variation in nectar make the determination by the analyst either by use of the polariscope or chemical reagents a matter of doubt. He goes very fully into the action of honey under the polariscope, and shows that too much reliance should not be placed on this test. He finds the specific gravity varies from 1.40 to 1.50. Honey will generally granulate when the temperature is reduced below 70°. Some honey seems to remain liquid indefinitely. Granulated honey is almost certainly pure.

In speaking of honey-comb he says, "The late Prof. J. Wyman demonstrated that an exact hexagonal cell does not exist. He also showed that the size varies, so that in a distance of ten worker-cells there may be a variation of one cell in diameter, and this in natural, not distorted cells." "This variation of one-fifth of an inch in ten cells is extreme, but a variation of one-tenth of an inch is common." We have ourselves carried out a large series of measurements which fully confirm this, and we hope soon to be able to publish the results. He says, as we have also maintained, that bees change from worker to drone cells, not by any system, but simply by enlarging and contracting. The transition cells are usually of four rows, although sometimes there are two or as many as eight."

Prof. Cook says, "An English writer criticises Langstroth's representation of these irregular cells, and adds that the angles can never be less than 100°. This is far from the truth, as I have found many cells where an angle was considerably less than this." We have also got a large number of impressions

taken direct from the comb showing that Langstroth is right. Some combs which we last year exhibited at the *Conversazione* of the British Bee-Keepers' Association had several rows of perfectly square cells which would represent angles of 90°.

Referring to the number of cells to the square inch, he says, "A recent English author, after stating the diameter of the cells, adds, 'The statement, many times made, that 25 and 16 of these respectively is erroneous, as they are not square.' He says these are 28 13-15 and 18 178-375. After many counts he thinks he should have used his eyes rather than his mathematics, for he finds worker-cells per square inch vary from 25 to 29, and drone-cells from 17 to 19 per square inch. Our English author seems quite to have ignored the fact that because of this great variation, and for convenience of calculation, the above figures were adopted as an average."

A very interesting paragraph on pollen and propolis concludes the first part of the work, which occupies 163 pages. It is not rambling and spun out like the writings of some authors, but is concise, clear, and contains all of any value to the bee-keeper. It is also written in a Christian spirit towards those from whom the author differs.

The second part is practical, and is devoted to the management of the apiary. Here the principal hives, appliances, and various methods in use in America are described very fully and illustrated. In this part there is also much new matter added, making it very complete. The Langstroth and Heddon hives have full justice done them, as well as other hives in use in America. Our English bee-keepers will find much useful information, although some of the appliances and methods may not be suited to this country.

All Prof. Cook says as to the management of hives for surplus is as useful for us as for our American friends, but we do not encounter the same difficulties in wintering as they do, therefore we do not need to take the same measures for the protection of our bees. Our methods of open driving and transferring are also simpler than theirs. The chapters following are full of practical information, and from them much may be learned. Honey-plants are treated more completely than in any other work; diseases and enemies of bees, with what is known about them, have also proper attention.

Prof. Cook is the leading scientific authority on all that concerns bees in America, and, as most of our readers know, is a pleasant writer. Being

Professor of Entomology at the State Agricultural College in Michigan, he has the opportunity of testing methods and appliances at the experimental apiary attached to the College, some of the advantages of this being apparent in the book before us. Unlike a recent author, who not only jealously withholds the names of many of the inventors or advocates of particular methods, but in many cases claims them as his own, thinking, no doubt, that he is the man, and that wisdom will perish with him, Prof. Cook is scrupulously particular in giving names. This is as it should be, and we think it shows a much more noble spirit to give glory unto whom it is due than to rob those entitled to it. Altogether the work is a great improvement on the former editions, and is one that no bee-keeper should be without. . . .

BEGINNING.

A Woman's Experience in Keeping Bees.

Written for the American Bee Journal
BY MRS. EMILY CASBON.

You do not know how much pleasure it gives me to read the AMERICAN BEE JOURNAL. I do not set myself up as an example for any one, but I have had a little *actual* experience, and if it will be a benefit to any bee-keepers, they are welcome to it.

In the fall of 1886 I bought a colony of bees. They were in a box-hive nailed securely with a glass in front, and a wooden door on hinges. By the way, the bee-man, of whom I bought them, assured me that it was the very best now made. I had been taking the BEE JOURNAL, consequently I had read of the Langstroth, and knew better.

It was late in October, and the bees did not have stores enough. I fed them some old honey I had, but not sufficient. My feeder was a very common arrangement, being a pie-pan with wire netting arranged like the shape of the pan. I propped it out of the honey just enough to let the bees eat and not get into it. Being a new hand at the business, I did not think to warm the honey, so they would not take it.

I babied those bees worse than any batch of bread I ever made, and I have made a great deal. On Nov. 14, I put those bees into the cellar, having first tacked wire netting over the entrance to keep them in. I visited them every day or two, to ascertain their condition. I cleaned off the bottom-board every little while, and there were lots of dead bees.

Finally one bright February day I took them out and gave them a flight. How they did enjoy it; from 11 a.m. until after 3 p.m. they hummed and buzzed around.

March came, and the combs were getting moldy, and I took my bees out into the yard. I had a large dry-goods box, with one side off. I put the hive on a soap-box in the larger box, and packed all around with clean pine shavings (I took what came first), then I spread an old floor oil-cloth over the front, and let it down in cold, chilly weather, raising it in warm, bright days. I do not think that this colony had one dozen workers. When they began to work in the spring I fed sugar syrup to hasten the brood, and the result was that by the fall I had a hive full of bees and honey, besides some surplus.

This section southwest of Valparaiso is especially adapted for bees, as there are many acres of asters, golden-rod and Spanish-needle, besides other plants. I should like to obtain some bees on shares, as I want to start a new apiary. There are no bees within miles of here, as most of the farmers are engaged in agricultural pursuits, and do not want to bother with them.

I love to work with them. They never sting me, and I have always handled them without gloves, and sometimes without a veil.

Valparaiso, Ind.

WINTER.

Speculation as to What Kind of a One it will Be, etc.

Written for the *Western Plowman*
BY C. H. DIBBERN.

The season is now over, and the story of 1888, as far as the bee-keeping interests are concerned, is now told. The general result over the United States and Canada is not very satisfactory, although some very good yields are reported. The general average is perhaps a one-fourth crop, but the bees are in much better condition than a year ago. The prospects for another year are also very much better, as the young white clover plants got a good start, and if we have a reasonable amount of snow during the winter, a good crop next year is almost a sure thing. This being assured, we should do now, before steady freezing weather sets in, everything possible to place the bees in the best condition to withstand the rigors of the coming winter.

Do not be caught by the idea that we will have a moderate winter. The only safe way is to expect a severe

winter every season in the northern States. There is still a great difference between bee-keepers as to in and out-door wintering; but this question has long since been settled in favor of cellar wintering. It takes but five minutes to carry a hive to the cellar, where, if the condition of the colony is all right, they are almost certain to go through the winter in good condition.

On the other hand, it takes much longer to pack them on the summer stands, and requires a great deal of material, such as boxes, lumber, chaff, straw or leaves, and this again has to be disposed of in the spring. This is much more labor than carrying in and out of the cellar, and then one can never feel very safe about the bees when they become buried under the snow, and the mercury persists in dodging far below zero. At such times one can go into his bee-cellar, and hear the gentle hum of contentment from the hives, and feel assured that it is all right, and go to bed and sleep soundly.

Now as to the time of putting the bees into winter quarters, there is some difference of opinion. It is not best to do so too early, nor will it do to wait too long. We once knew an apiary of 340 colonies to be lost, by leaving them out too long, waiting for a favorable time, which never came, to put them away. The bees ought to be allowed to fly as late as possible, as their confinement will be long enough anyway, and on the other hand they should be removed before ice forms on the combs.

It is not always easy to determine just the right time to do this, and one must study the season, whether it is likely to be early or late. Our rule of late years has been to commence storing the hives as soon after the 20th of November as the bees have had a nice day for a flight. Our practice is to carry in 30 or 40 hives at a time, and the same in carrying them out, as otherwise it gets to be tiresome work, especially if the hives are heavy with honey, as they are this year. It is well to put them 5 or 6 inches from the bottom of the cellar, by placing pieces of scantling under them, or bricks answer the purpose nicely if at hand. Of course we know that some bee-keepers are so situated that they cannot winter in-doors, on account of a low location or having no suitable place. As our numerous experiments in out-door wintering have never been very satisfactory, we will recommend such to study the methods of bee-keepers who have met with better success in this matter.

The Time to Sell Honey.

This is the month in which the honey crop should be closed out. If

that is not possible, make it a point to do so before Christmas, as after that time it is usually dull and harder to sell. All the comb honey should be overhauled and scraped of propolis as soon after it comes off the hives, as time can be spared. It should then be graded, and crated in neat, new cases, weighed and marked. All extracting must be finished up early this month, as the honey is hard to remove from the combs in cold weather, and the combs are liable to break.

Apicultural Contemplation.

As we are writing these "notes," and look through the open window at the apiary, the white, blue, red and yellow hives among the trees, whose green and yellow leaves are now fast falling this October afternoon, we cannot help thinking what a pretty scene it is! What a study, pleasure, profit—yes, and it is hard work, too! We have other large interests in the commercial world, but there is nothing we would rather do than to keep bees, and that is what we expect to do in our declining years. Work becomes a pleasure and a study when one learns from nature as we go along. To discover new principles, new methods, and new facts one's own self, is like exploring some unknown country, interesting, fascinating, but never satisfied. Something new and unknown, that appears to be hidden just beyond the distant hills, is ever leading onward and upward.

Extracting Honey from Brood-Frames

Lately we have extracted considerable honey from outside brood-combs, which with us are solid with very nice honey, and replacing the empty combs near the center of the hives. This is particular work, and requires judgment and tact, otherwise the robber bees would soon have possession of the apiary. It is easy enough to take the combs away from the bees, but when the combs from which most of the honey has been extracted, are returned, it causes great excitement, and soon attracts the robbers. We found that about the only time we could do this kind of work was late in the afternoon, about an hour or two before dark. By having a number of empty combs they could be exchanged for full ones, and the confusion would all be over before morning. With wire screen doors and windows, the extracting can be done any time during the day. Some of this honey was put up in pint, quart, and half gallon Mason jars. We found that by exposing these to the sun for a week or two, the color of the honey became much lighter, and the quality was also much improved.

Milan, Ills.

THE CELLAR.

Ingenious Harness Used for Carrying Bee-Hives.

Written for *Gleanings in Bee-Culture*
BY G. M. DOOLITTLE.

I am asked to give an article on the above subject; and as the asker puts his query in the shape of several questions, I think it best to answer them by number, in the order they are put.

First, he says, "I should like to know how I can place the bees in the cellar without disturbing them." This is nearly an impossibility, as far as not arousing them at all is concerned, for bees are sensitive to the least movement of their home, and, no matter how still it may be done, if done times enough the result always is a restless colony. But, practically speaking, bees can be set in the cellar without disturbance, or, in other words, not be disturbed enough so that it is noticeable, or to do any harm. In fact, I am not sure that a disturbance, so great as to cause them to come out all over the front of the hive after they are in the cellar, does any harm, yet I prefer not to so disturb them.

I have two ways of carrying the bees to the cellar: one of which is, to get a strap of the harness-maker, or otherwise, long enough to go over my shoulders, and reach the cleat that goes around the top of the hive, or the hand-holes, if cleats are not used, so that the hive may be held up in about the position that it would naturally be when carried in the hands. Now get two large snaps, such as are used on the breast-straps of heavy harness, and have them sowed, one on each end of the strap. After this is done, take out the tongues, or snap part, of each, and file the projecting hook part of the snaps to a sharp point, when your strap is ready. On going to the hive, throw the strap over the shoulders, and, on stooping down, hitch the sharp points of the snaps into the cleats, or hand-holes, of the hive, and straighten up, thus lifting the hive by the shoulders, instead of the arms. With the hands, keep the hive away from the body, and thus you can carry it as still as you please.

The other way, and the best one for all not physically strong, is to get a spring wheelbarrow, and on this place a sawdust cushion, such as is used over the hives in winter; or, in the absence of this, put on several thicknesses of old carpet, or horse-blankets, and on this set the hive, when it can be wheeled right into the cellar, if the cellar is built as it should be, or to the cellar-door, in any event. In this way no serious disturbance should be

caused, if set on and off the wheelbarrow as they should be.

Secondly, he says, "I want to raise them an inch off the bottom-board." This is as it should be, only, instead of an inch, I prefer that the distance be 2 inches, or, better still, the whole height of the hive. By this, I mean to let the bottom edges of one hive rest on the top edges of two other hives, so that there is an open space, the size of a hive, under each hive except the bottom ones.

To explain more fully: I first carry into the cellar some bottom-boards, placing them on the cellar bottom nearly as far apart as the width of a hive. On these bottom-boards I place a 2-inch rim, and on these rims I place the first tier of hives, which leaves the hives a little too close for a hive to stand between them. Now, in setting in the next tier, they are set on the other hives, so as to come over this space between the hives below, they resting on the edges of the hives below, as I said at first, the next tier setting over the empty spaces between the last, and so on until the top of the cellar is reached. To keep the dead bees, etc., from soiling the cushions and hives below, newspapers are spread over them before the next tier is set on top. I believe this is something similar to the way friend Boardman winters his bees. In any event, I like the plan very much.

When to Carry Bees into the Cellar.

Thirdly he asks, "Is it best to carry them in in the daytime or after dark?" As to this matter, I do not know that it makes any difference with the bees. The only thing to be considered is the convenience of the operator, and the prospect of what the weather will be on the following day. I have frequently carried in my bees on a moonlight evening, when I feared it might rain the next morning, for I consider it a great disadvantage to have the hives set in the cellar when dry. At other times I have risen at 4 o'clock in the morning and set the bees in before daylight, getting them in just as it was commencing to rain; still, the most of the setting-in has been done by daylight, thus having the advantage as far as seeing is concerned.

Fourthly he asks, "Should the weather be cold or warm, when the bees are set in?" I used to think that the weather should be cold, in order that the bees need not fly out of the hive if they were disturbed, fearing that they would disturb easier in warm weather than in cold; but after an experience of the past five years, I now say, set them in when the outside air is nearly or of the same temperature of that in the cellar, if possible, and

never when the hives are full of frost, and frozen down, if it can be avoided.

Where hives are frozen down to the bottom-boards, and the outsides of them covered with snow and ice, it is the worst time possible to carry them in; while getting them in at such a time without disturbing them is out of the question, for each hive will come up from the bottom-board with such a shock that all the bees in the hive are at once aroused. The proper temperature in which to set them in is from 35° to 50°; but as this cannot always be obtained, from 30° to 35° will do very well.

In closing, I will say that the time of year in which to set bees in the cellar is from Oct. 25 to Nov. 20, according to latitude, and not in December, as used to be advocated.

Borodino, N. Y.

KENTUCKY.

Some of the Good Results of the Past Season.

Written for the *American Bee Journal*
BY GEO. W. MORRIS.

My report for the past season is as follows:

My 11 colonies of Italian bees wintered without loss. They bred up early, and began to swarm early in May, but I checked swarming as much as possible by extracting. All the surplus obtained in June was honey-dew, amounting to 500 pounds. This honey is dark, and not very well flavored. Bees ceased to gather it about June 20.

With the exception of the clovers, sunflowers, and some other bloom, all of which was very scarce, bees had no forage until the asters commenced to bloom, about Sept. 20, when they rallied and gave me a surplus of 400 pounds of as pretty white honey as I ever saw.

My apiary has produced the following results this season: Four hundred pounds of white honey, at 12½ cents, \$50; 500 pounds of honey-dew honey at 10 cents, \$50; for queens, \$18; and for 6 swarms, \$12, making a total of \$130.

This is the second season that the asters have given much surplus in this locality, last season being the first. I have been noticing it for about six years, and it is increasing very rapidly, and bids fair to outstrip all other pasturage for bees, especially as fall pasturage, and for extracted honey, because bees can gather and store honey when it is too cool to build comb.

I believe it would pay me to cultivate sunflowers by the acre, and have them bloom in August and September,

in order to keep my bees built up strong for the fall crop. I planted one row of them in the garden this season, and the bees worked on them at least four weeks, as busily as ever they worked on Alsike clover in this locality. If any know of a better substitute for bee-pasturage than the above plant, I would be glad to hear from them through the BEE JOURNAL.

The prospect now for white clover is much better than it was one year ago in this locality. My bees paid me better than any yet heard from in this State the past season.

Cornishville, Ky., Nov. 1, 1888.

CARNIOLANS.

The Value of Carniolan Bees— They are Not Robbers.

Written for the American Bee Journal
BY S. W. MORRISON, M. D.

For the introduction of Carniolan bees into this country, Mr. Benton deserves the gratitude of all bee-keepers. As having the largest experience in the United States with Carniolans, I am entitled to express my opinion of them at this time, the close of the third summer with 50 colonies.

The most notable new trait about them is, their freedom from the disposition to "rob," or their vigilance in guarding their hives. With 200 nuclei colonies, daily exposure of their combs, and a poor honey season, it is remarkable that I have not had a single colony robbed. Such freedom from robbing never happened to me when I had Italians.

I am still convinced that Carniolans are better honey-gatherers than Italians, Cyprians or Syrians; and as for gentleness, I have little use for smokers, and many colonies can be handled with the same impunity as if they were so many flies.

In the issue for Nov. 7 is published a complaint against Mr. Frank Benton, which is certainly unjust. Mr. Benton may see the article, or he may not. Many will read it who will not see the reply he makes to correct it, and thus a wrong is done him which he can never correct. I have had probably more business transactions with Mr. Benton during the past five years than any other person in the United States, and I can vouch for his honesty and promptness.

Mr. Benton left Munich in the spring of 1887, I think, and spent the winter of 1887-88 in Laibach, Province of Carniola, Austria, because he could not afford to incur the expense of the return to Munich. His last letter to me was dated at Laibach, Sept. 29; in

it he stated that he expected to spend the winter elsewhere, but did not give me his address. Registered letters only will be forwarded to him. It is fair to suppose that Major Shallard's letters never reached Mr. Benton.

Oxford, Pa.

[No injury to Mr. Benton was intended by the publication of the complaint—just the reverse, it gives him a chance to fix the matter up. The fact of his moving after Sept. 29, 1888, has no relation to the previous fact that Major Shallard has been writing him for over two years, and can get nothing but an acknowledgement for the money sent. We sent him a marked copy of the JOURNAL containing the article, and we hope that he will be able to fully explain the cause of the delay. Publishing the matter will be a benefit to him, then.

Since the above was in type, we notice an article on Carniolan queens in the *British Bee Journal*, written by Mr. Benton, and dated at Laibach, Oct. 19, 1888, nearly a month later than the date given by Dr. Morrison. He will probably receive the marked copy we mailed to him.—ED.]

BEEES AND ODORS.

Robbing Stopped by the Use of Musk and Peppermint.

Written for the Country Gentleman
BY A COUNTRY PARSON.

Twenty-five years ago I began bee-keeping with a row of hives, all painted alike, and placed close together, say 12 inches apart. This likeness and nearness of hives, together with my work and fussing, soon brought on the calamity—robbing right and left, stealing, fighting and killing, until some of the hives were empty, and the ground covered with dead bees. I rushed to my library, and then tried the plans prescribed as infallible remedies—tied them up in sheets; deluged them with water; buried them in loose straw; smashed the robbers' combs; put them to sleep with chloroform; shifted positions of hives. But they still fought and robbed, and killed like little demons.

Then I sat down to study out a remedy, or to see the end of the Killenny-cat process. I soon found the difficulty to be in this—that the robbed bees could not distinguish between the friends in their own family and their enemies from other families. I

could tell which were robbers from their hesitating flight about the entrance of the doomed hive. The home bees came in like an arrow from a bow. The robbers hesitated, backed and filled, and seemed watching for a chance to get in. But of this sign the home guard seemed to take no notice. From this I concluded that they did not discriminate by sight.

In this way I went on to eliminate the different senses from their method of discrimination, until at last I reached the conclusion that the sense of smell was their chief, if not their only dependence.

But to return to our robbers. The guards are on duty at the entrance of the hive. The robber lands on the alighting-board. He either steals in unobserved, or is challenged. If he has been in the hive often enough to have acquired the right odor, he is admitted as a friend. If the scent is not clear, he is doubted, and there is hesitation. If he brings a brand-new and strange odor, he is "bounced," and a fight begins that generally ends in the death of the bouncer or bounced.

This suggested the remedy. I took some musk, wrapped it loosely in muslin and covered the package with wire-netting, for fear the bees might eat it and get poisoned, or tear it to pieces and carry it out of the hive. This little package, about 1 inch long and $\frac{1}{2}$ inch in diameter, I dropped in the midst of the combs of the *robbed* hive.

The next step was to get a contrasting and strong odor for the robber hive. I selected essence of peppermint, diluted an ounce of it with a pint of milk-warm water, borrowed my wife's in-door plant sprinkler, uncovered the robbing hives, and gave them a dash of their perfumery.

It is not easy to laugh alone, but I did laugh out long and loud when I saw the result. The musk guards waited in alert expectancy. A peppermint robber began to buzz around, but the musk fellow detected its presence, and followed every motion of the peppermint adversary, by turning his belligerent front, when the robber was at least 12 inches distant. And when he would venture within 2 or 3 inches of the vigilant musker, the guard would fairly leap at him and catch him "on the wing." There was no room for fight, and no killing. The alien peppermint robber would flee with the cowardice of his profession.

It is no exaggeration to say that within five minutes the whole thing was stopped, and for good. The remedy is effective, and can be applied with little trouble, and not more than two minutes of time.

Staten Island, N. Y.

CONVENTION DIRECTORY.

- 1888 *Time and Place of Meeting.*
 Nov. 21, 22.—Pan-Handle, at Wheeling, W. Va.
 W. L. Kinsey, Sec., Blaine, O.
 Dec. 11-13.—New York State, at Syracuse, N. Y.
 G. H. Knickerbocker, Sec., Pine Plains, N. Y.
 Dec. 12, 13.—Michigan State, at Jackson, Mich.
 H. D. Cutting, Sec., Clinton, Mich.
 1889.
 Jan. 9-11.—Nebraska State, at Lincoln, Nebr.
 J. N. Heater, Sec., Columbus, Nebr.
 May 4.—Susquehanna County, at Montrose, Pa.
 H. M. Seeley, Sec., Harford, Pa.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Bees in Winter Quarters.—J. W. Tefft, Collamer, N. Y., on Oct. 30, 1888, writes as follows:

For once I have been fortunate. I had my bees all packed for winter on the summer stands by Oct. 1. Had I not done so, I do not think I could have done it by this time, for nothing seems to come but rain. The temperature has for the past thirty days been as low as 28°, and only on three days has it been up to 60°, and then only between the hours of 12 and 3. I have not seen a bee flying except on three days when it was 60°. We have nothing to do but saw wood and keep out of the mud, which is "too sott to walk upon, and too thin to swim in," which makes it very inconvenient to navigate.

Small Increase, etc.—John Moller, Fremont, Nebr., on Nov. 12, 1888, writes:

I have had a very small increase in colonies during the past summer, and not much honey until the fall gathering. I have obtained 2,000 pounds from 50 colonies.

Southern Aster Honey.—W. H. Prior, Madison, Ga., on Nov. 12, 1888, writes as follows:

I send a wild flower and stem of the same (I think an aster), which has proved to be by far the best honey-producer as to both quantity and quality that we have had during the entire year. It made its appearance here some 20 years ago, and has been spreading gradually until this year, and to use an old and familiar expression, "The whole face of the earth was covered with it." In fact it was everywhere, along the road side, in every old field, and could be seen everywhere except on land that was in cultivation. It is commonly known as "The last flower of summer," or "Farewell summer." It began opening about Oct. 10 this year, and has continued up to the present time.

We had our first frost this morning, giving us a very late fall. This flower came up all among the golden-rod, and towered above it with beautiful white flowers. As soon as it began opening, the bees left the golden-rod and began working on it. I have one colony, and by no means a full colony, that has stored, with only starters, 20 pounds of nice comb honey in pound sections, since Oct. 12. My 18 colonies averaged 20 pounds of honey per colony in October. Had I expected the honey-flow, I could have secured 25 pounds per colony, just as easily. We

had a rain of more than a week beginning about Oct. 20, that cut us short about one-third of a crop.

I began bee-keeping last spring with 5 weak colonies of black bees in box-hives: now I have 18 colonies of Italian bees in movable frame hives (having bought 12 queens and reared 6), with plenty of honey for winter, besides 25 pounds of comb honey extra per colony, spring count. How will that do for a beginner?

Thinking that it would be something of a novelty for the editor, away up in Chicago, to eat honey gathered from flowers in the month of November, as well as for him to see a good quality of Southern honey, I have sent him by express a pound section that was taken from the hive on Saturday, Nov. 10, just finished by the bees. This was gathered from the white flower mentioned above. I will ask the editor to tell me what he thinks of the honey, and to name the flower.

[The flower is from an *Aster tradescanti*, sometimes called the "Michaelmas daisy," and produces excellent honey of light amber color, and fine flavor. The sample of honey came, all mashed up, with about an ounce of honey on the paper, the comb being all drained dry. This shows what care is taken of small packages by the express companies.—ED.]

Results of the Season.—S. Burton, Eureka, Ills., on Nov. 12, 1888, writes:

I commenced with 14 colonies of bees last spring, 10 colonies being strong, and 4 weak. I had 18 swarms, 4 of which went to the woods, leaving me 14 new colonies. I bought 4 colonies, so I now have 32. All are packed on the summer stands with a shed over them facing the east and south, packed with straw behind and between them; with sticks across the frames, burlap over the sticks, a cushion of leaves on top of that, and then the hive-cover. My crop of honey was gathered after Aug. 20. I got about 300 pounds of surplus in one-pound sections, and the bees have their hives well filled for winter. I am getting the bee-fever. I want to have 100 colonies of bees as soon as I can, as I am the only one that has any bees to amount to anything here.

Getting Rid of Ants.—Byron Benton, Bronson, Mich., on Nov. 13, 1888, writes as follows:

My way of getting rid of ants in bee-hives is to kill what I can, and then place green catnip over the brood where the ants gather, which I find drives them away effectually. There must be a great loss of bees here this winter among such bee-men that have not fed their bees.

The Michigan Convention.—President Geo. E. Hilton, of Fremont, Mich., writes as follows concerning the coming meeting of the State Convention:

The Michigan State Bee-Keepers' Association hold their next annual meeting at Jackson, Mich., on Dec. 12 and 13, 1888. While the season has been far from encouraging, we want to give a cordial invitation to all within reach of the association, to favor us with their presence; and I can assure all, that we will have subjects for discussion that will be encouraging, for Michigan is not going to lose her record of holding the "Convention of the Continent," and we expect to send all home with "Nil desperandum" as their motto.

Money and Beeswax Market.

CHICAGO.
HONEY.—We quote: White clover 1-lbs., 18@19c.; 2-lbs., 16@17c. Good dark 1-lbs., 15@16c.; 2-lbs., 13@14c. Buckwheat 1-lbs., 14@15c.; 2-lbs., 12@12½c.—Extracted, 7@9c., depending upon quality and style of package. Receipts increasing, but demand still limited. Stock is not selling as freely this season as a year ago.

BEEWAX.—22c.
 Nov. 13. S. T. FISH & CO., 189 S. Water St.

CHICAGO.
HONEY.—For white comb 1-lbs., 18c. Very little inquiry for anything outside of 1-lb., and when it is wanted it is at a lower price. Extracted, the best grades, 7@8c., and some held higher. Offerings are small and demand slow.

BEEWAX.—22c. R. A. BURNETT,
 161 South Water St.

MILWAUKEE.
HONEY.—We quote: Fancy white 1-lbs., 18@20c.; 2-lbs., 16@18c. Good dark 1-lbs., 16@18c.; 2-lbs., 15 to 16c.; Fair 1-lbs., 12½@14c. Extracted, white, in kegs and ½-barrels, 8½@9c.; amber in same, 7½@8c.; in pails and tin, white, 9@9½c.; in barrels and half-barrels, dark, 6@6½c. Market steady and supply ample for the moderate demand, but present value have a tendency to restrict general consumption.

BEEWAX.—22@23c.
 Oct. 25. A. V. BISHOP, 142 W. Water St.

NEW YORK.
HONEY.—We quote: Fancy white 1-lbs., 15@17c.; 2-lbs., 14@16c. Fair white 1-lbs., 14@16c.; 2-lbs., 13 to 15c. Extracted, white, 7½@8c.
BEEWAX.—23½c.
 Sep. 17. THURBER, WHYLAND & CO

NEW YORK.
HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 13@14c. Fair white 1-lbs., 15@16c.; 2-lbs., 12c. Buckwheat 1-lbs., 11@12c.; 2-lbs., 10@11c. White extracted, 7½@8½c.; buckwheat, 5½@6½c.; California extracted, white sage, 7½@7¾c.; amber, 7¼@7½c. Demand good and prices firm. New comb honey is arriving quite freely.

BEEWAX.—23@23½c.
 Oct. 10. HILDRETH BROS. & SEGELKEN,
 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.
HONEY.—White 1-lb. sections, 11@12½c.; 2-lbs., 12½@1 c.; amber, 8@10c. Extracted, white, 5½@6c.; light amber, 3½@5½c.; amber and candied, 4½@5c. Receipts light and market firm for best qualities.
BEEWAX.—Dull at 19@22½c.
 Sep. 22. O. B. SMITH & CO., 423 Front St.

DETROIT.
HONEY.—Best white comb, 17@18c.; dark, 16c.—Extracted, 8@10c. Market bare of all kinds.
BEEWAX.—21@22c.
 Sep. 24. M. H. HUNT, Bell Branch, Mich.

CINCINNATI.
HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 16c. Demand slow.
BEEWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
 Nov. 12. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.
HONEY.—Choice 1-lb. sections, 18c.; dark 1-lbs., 14c.; 2-lbs., 15c.; dark, 13c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock fair.
BEEWAX.—None in market.
 Sep. 27. HAMBLIN & BEARSS, 514 Walnut St.

NEW YORK.
HONEY.—We quote: Fancy white 1-lb. sections, 17½@18c.; 2-lbs., 14@15c. Fair 1-lbs., 14½@15½c.; 2-lbs., 11@12c. Extracted, fancy white clover, 7½@½c. California white in 60-lb. cans, 8c.; light amber (in same cans), 7½c.; amber, 7½c. Buckwheat in kegs and barrels, 5½@6c. Cuban, in barrels and ¼-barrels, 65c. per gallon.
 Sep. 26. F. G. STROHMMEYER & CO., 122 Water St.

BOSTON.
HONEY.—We quote: Best white clover 1-pounds, 17@18c.; best 2-lbs., 16@17c. Extracted, 6@9c. The receipts are very light, and honey sells fairly well.
 Nov. 12. BLAKE & RIPLEY, 57 Chatham Street.

KANSAS CITY.
HONEY.—White 1-lbs., 17@18c.; dark, 14@15c.; California white 1-lbs., 17c.; dark, 14c. Extracted white 8c.; amber, 7c.
BEEWAX.—None in the market.
 Oct. 11. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.
HONEY.—We quote: Extracted in barrels, 5@6c., according to quality; in cans, 7@8c. Comb, 12½@15c. Prices firmer on account of scarcity, though the demand is not great.
BEEWAX.—21c., or prime.
 Oct. 17. D. G. TUTT & CO., Commercial St.

SAN FRANCISCO.
HONEY.—We quote: Extracted, white, 6½ cents; light amber, 6@6½c.; amber, 5½c. Comb, white 1-lbs., 13@14c.; 2-lbs., 13c. Light amber 1-lb., 12@13c.; 2-lbs., 11@12c. Demand very active for extracted, and fair for comb honey.
BEEWAX.—20@21c.
 Nov. 6. SCHACHT & LEMCKE, 122-124 Davis St.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. Nov. 28, 1888. No. 48.

EDITORIAL BUZZINGS.

To Kiss her cheek! as honey fine
The bee from rose or eglantine
Doth sip, so I from dimple cute
Would taste of love's delicious wine!
What could a knight (or bee) compute
Dearer than such delight divine?

Pure ammonia is a good remedy for bee-stings.

We Regret to learn that Mr. John G. Smith, Secretary of the Central Illinois Bee-Keepers' Society, met with an accident on his way home from the Clayton Convention. While on the train between Bluff City and Barry, a cinder lodged in his eye, which caused him severe pain for several days. Since then he has been indisposed from the results of a severe cold in the head. His many friends will be sorry to learn these particulars of his illness, and with us will no doubt offer him their sympathy.

A Correspondent in central New York writes us concerning the complaint against Mr. McCaul, published on page 750, and states that he is still doing business at 122 Water Street, New York. We have written to him, at that address, calling for a settlement for the Florida honey, and await a reply. Our correspondent adds: "Mr. McCaul has sold hundreds of dollars worth of honey for me, and always rendered an accurate account, at good prices." If he will do the same for the Florida honey, and satisfactorily explain the cause of the delay in remitting for it, after having sold it for cash long ago, Alderman & Roberts will no doubt be very glad to state the fact as publicly as they made the complaint.

Why was Mr. Doolittle Not There?—That question is often asked about bee-conventions, but it has never been publicly answered. We have known the reason for some years, and when Mr. Doolittle's name was mentioned for President of the International at Columbus, we suggested that Mr. Doolittle was not a member, and was therefore not eligible. We did this to have his name dropped, and still not give the *real* reason. Then one enthusiastic member paid the dues for his friend Mr. Doolittle, so as to make him eligible to the office. This made it necessary to take another tack, for we had never felt authorized to state the true reason. The result was that Dr. Mason was re-elected.

Then our friend Doolittle wrote to us asking why his name appeared among the members, when he had not paid any dues. We replied with the above facts, and this is his reply:

FRIEND NEWMAN:—Your letter regarding to how I came to be a member of the North American Bee-Keepers' Association is at hand. Thanks to that friend who so kindly paid my membership fee, but I am sincerely glad that I was not made President. If anything of the kind ever again comes up where you are, please say for me that I cannot accept the office on any account. I have a heart trouble that excitement makes much worse, and being away from home at conventions, etc., puts me in such a condition that I am wholly unfitted to assume any office, or take any comfort in the proceedings of a convention. For this reason I have staid at home, of late.

G. M. DOOLITTLE.

As the above question is so often asked, we take the liberty of publishing friend Doolittle's letter, without his knowledge or consent, just to reply to the many similar inquiries to the one at the head of this article, which are so frequently propounded. We know of no one more worthy of the honor of being President of the "International," and so stated at the convention, but his wishes should be consulted. In the higher sense we know his "heart is right," even if physically he has a "heart trouble"—which has not been generally known till this announcement.

Gone to California.—Our friend A. J. Root has taken his departure for California, going by way of New Orleans, for a six weeks' sojourn. *Gleanings* for Nov. 15, says that he left on the 12th inst., and then it adds:

He has worked long and hard at his post; and while some of us at home will have to work a little harder, perhaps, in his absence, it is a pleasure to us to think that he has now arrived at that point in life when he can take this change and rest, which he so richly deserves. He will furnish notes of travel by the way, besides telling of that great bee-country—California—a country whose resources seem boundless, and about which we bee-keepers of the East know comparatively little.

The Appeal in the lawsuit against Z. A. Clark, of Arkadelphia, Ark., was to be called for Monday, the 26th inst. In our next issue we hope to be able to record some good news concerning it.

Governmental Statistics.—At the late meeting of the National Board of Trade, a resolution was presented recommending the "discontinuance of monthly crop bulletins by the department of agriculture, as their only effect had been to disturb the world's markets without giving any reliable information." One of the members remarked as follows:

The statistician of the department has been continually representing the annual produce of grain in this country as enormously in excess of what it was. The report of last year was so ambiguous in its language that nobody could understand it, particularly that part concerning the wheat crop. The Secretary of the Chicago Board of Trade endeavored to ascertain what this meant, and had made frequent interrogations. The statistician, for instance, represented in his returns that the spring wheat crop last June was 13 bushels to the acre.

Now, the average produce per acre was 12 bushels. The fact was that the spring wheat crop was more than a month late last year, and was far behind the average. A farmer in Indiana reads the reports of the statistician, and makes up his mind that there is a big crop in the country, and that he will sell all he has got. He finds out, when it is too late, that the crop is meager, and that he has lost heavily. The returns of last year, prepared in the month of December, showed a produce of 11,000,000 bushels in excess of the later and perfected returns prepared three months afterward. The result of the whole thing was encouragement for the operations of English bears, and injurious to American agriculture.

After some discussion a substitute resolution was adopted, which provides for the establishment of reporting agencies throughout the country, which will collect and furnish to the bureau all the necessary information regarding the crops of the country, and provides several other improvements in the machinery of the department.

This is similar to the work undertaken by apiarists, after waiting some time for the governmental reports through the statistician, on bee and honey statistics.

The National Bee-Keepers' Union fiscal year has heretofore ended on June 30. Sometime since it was proposed to have it end with the calendar year. It was submitted to vote, and every vote so far received is of the same tenor as the following from Mr. H. K. Staley, Pleasant Ridge, Ohio:

At the request of the Manager of the Bee-Keepers' Union, for the members to vote on the proposed change for the paying of the annual dues from June to January, I vote in the positive, or in other words, I favor the change.

If any one wants to vote in the negative, please let it come at once; if none are received by Dec. 10, the motion will be declared to be carried, and the change made accordingly, by consent.

This change will make the time for paying dues and voting for officers come on Jan. 1, and blanks will be sent out on Dec. 15, for that object—unless somebody votes against the change.

GLEAMS OF NEWS.

Preparing Bees for Winter.

Mrs. L. Harrison describes some of her experiences while preparing her bees for winter, in the *Prairie Farmer*. She says that she found the bees in fine condition, the colonies being very populous, with a sufficiency of sealed honey for winter stores. She then adds :

Although the weather is fine and warm for working out-of-doors, it would have been better to have fixed them up earlier, for as long as they can gather honey they are easily handled ; but when there is none to gather, they are on the war-path with the least provocation. Bees act very differently on a cold day than on a warm one, when smoke is blown upon them. On a warm day, when smoke is blown upon them, they rush down among the combs and fill their sacs with honey, when they are as good-natured as a fat alderman after dinner ; but when it is cold, they rush into the smoke and right into the fire, if they can gain access to it, and perish.

This is one reason why bees are so cross when there is no honey in the fields. Let a hive be opened on these mild, warm days, when bees are on the wing, and robbers will soon appear. Their clarion note soon arouses the colony, which will be on the defensive, and stinging everything within reach. The dog will be off with a roll and a howl, biting and scratching ; the cat will dart up a tree with her tail as large as a rolling-pin, while the chickens scratch their combs with their feet, and seek shelter under weeds and bushes. To avoid this I open and fix up colonies in the early morning, before there are any bees flying, and if I am very careful not to jar or knock the hive, I can get through with quite a number without the use of smoke, or robbing induced.

There has been but a small amount of surplus honey secured this year, but what has been secured is in good condition. Some years there is a little honey scattered through many sections—little patches of sealed honey not larger than a dollar in the center of some—but, this year, whatever they undertook, they finished up in good shape. Those sections last year that had little patches of honey in them, were uncapped, extracted, and stored away for use this year. Now we find that they have been put to good use.

The Same Old Queen. more than 40 years old ! This is what the old Californian, Wall, tells about the age of a queen-bee. The *Napa Register* gives this laughable account of the old "Forty-niner :

Many are familiar with Mr. Wall's extraordinary feat, in 1849, of driving (according to his statement) a swarm of bees across the plains. A day or two since, as one of our business men was coming down town, he happened to discover a huge bee quietly resting on Wall's shoulder, as preparations were being made to sprinkle the Court House lawn. "Say, Wall, what are you going to do with that bee on your shoulder ?"

Wall was startled for a moment, but, recovering his usual composure, spoke with gravity, carrying convictions of untarnishable truth. "I'll tell you. That bee is the queen of the swarm that I drove across the plains. She has been hunting me for years, and knew me the moment I call her name. You see, she is getting a little gray, but I know her on sight. She piloted the swarm, and I used to feed her from my own molasses can. That bee is the last of her race, and I shall take care of her in her old age.

I tell you, John, that bee brings up many reminiscences of that memorable trip. Several times that swarm stood by me in an hour of peril. They could scent an Indian several miles away, and they got to really enjoy an Indian attack. The fact is, they understood tactics as well as the best trained soldiers. When the queen sounded an alarm, every bee was under arms, ready for fight. First a skirmish line was thrown out, and you could see more or less uneasiness among the redskins as one and another would claw about his ears, eyes, or nose, but when the order to 'charge' was sounded, and the bee-battalions began to move in 'double-quick,' a rout and stampede always followed. It is a fact, John. Those bees fought all of my battles across the plains, and this is my 'old queen' sure enough."

Do Not Sell all the honey you have. Keep what is necessary for use in the family. Mr. C. H. Dibbern tells some of his experience in this connection in the *Western Plowman* in these words :

I have no patience with that class of bee-keepers who think they cannot afford to eat honey and supply it on their tables. I well remember when I was a boy, working out during vacation, how carefully I attended a few colonies of bees in the old way ; how I hived them, and put on the boxes, for the owner, who was afraid of them ; how anxiously I watched the white combs through the little piece of glass as they neared completion ; how finally the eventful time came, and one evening I removed the boxes (we knew nothing about sections then) from the hives. I left the boxes near the hives over night, so that the bees could run back during the night, which was the common practice then. As there were still some bees in them next morning, they were removed to the cellar, leaving the door slightly open, so that the bees could find their way out.

Like a boy, I had been anticipating the "good time coming" when we would be feasting on honey. I waited patiently for some days after this, for the appearance on the table of the beautiful comb honey, but none came. Finally I ventured to ask what had become of the honey, when I was informed that it had all been taken to town and sold ; that they could not afford to eat honey when they could get 15 cents per pound for it. I said nothing, but thought a great deal for a long time ; in fact, I have not got over it yet, although I have produced carloads of honey since.

DARK OR FALL HONEY.—Late honey, which is usually dark, or in some localities of a golden color, should be sold, whether extracted or in the comb, for just what it is. If you have any "honey-dew" or poor trash, do not try and work it off by hiding it in the middle of the cases, and exposing only nice white combs. Such practice may be sharp, but it is dishonest, nevertheless, and it will be sure to react on the guilty bee-keeper. Such usually find their home market "played out," and have to resort to shipping.

PARTLY-FILLED SECTIONS.—Partly-filled sections should be extracted before it gets very cold, as the honey soon gets too thick to run freely. I used to consider these empty combs of great value for use the next season, but nice comb foundation has changed all this. I now cut out all combs that have been extracted, and melt them up by placing them in a large dish-pan over a pot of boiling water. When all is melted, let it cool, and you will have a nice cake of wax, and some very nice honey.

USE NO SOILED SECTIONS.—Burn up all sections that are not nice and clean. It is poor economy to have nice white honey stored in old dirty boxes. If we wish to hold our customers for our honey, we must always have it in the best possible condition.

Colors and Bees.—In *Viek's Magazine* for October we find the following on flower colors and their visitors, the bees :

All through creation appears a consideration, a taking thought for the pleasures of slight beings, very moving and comforting to see. Not a wood-tick or red spider, or hard working bee but is meant to be happy as well as useful, and while we take the world with a sublime conceit of its being all for us, we find that certain pleasures were designed peculiarly for insignificant beings on whom we do not waste a thought.

If the flowers are dyed in every warm, enticing hue, it is not for us alone, but to draw the honey-seeking insects which have a fine eye for color.

To test this power in bees, Sir John Lubbock tried a pretty experiment, placing some honey on a slip of glass laid on blue paper outside his study window, and when a bee had made several journeys and become used to the color, laying an orange slip with honey in its place, and the blue further away. The bee came back, finding the honey in the same spot, but it preferred the blue color, and pausing a moment darted for the blue paper.

The Cause of Failure of the honey crop for 1888 is thus stated in the *Michigan Farmer* for last week :

The Central Michigan Bee-Keepers' Association ascribed the cause of the failure in the honey crop to the following reasons : The bees have been remarkably free from all disorders. The trouble lay in the failure of nature to properly perform her duty. The chalice of flowers, from which the bees collect the sweet semi-fluid substance contained but little nectar. A close observer states that the absence of this substance was due to the atmosphere and the direction of the winds. North, northeast, and east winds are very destructive to the honey-flow, and during the past season almost continued winds from these directions prevailed, together with a dry, harsh atmosphere. The best flow of honey is secured by a southwest wind, and a west wind is the next most favorable. A damp, warm, balmy atmosphere is essential to successful bee-culture.

A Living Mouse smothered in honey is a great delicacy in China, as appears from the following item in an exchange :

If you were a Chinese girl, remarked a Celestial nobleman belonging to the Chinese mission, and wanted to give some one a great delicacy, you would get two young baby mice, blind and unable to crawl, and place them before your guest alive on a plate. He would dip each living morsel in a dish of honey and envelop it in a sugary shroud before popping it into his mouth. The dying squeak of the poor little atom is the sauce piquante of this favorite dish in China.

Magnificent Increase.—Mr. John Kentch, Tioga, Pa., writes to *Gleanings* that he has obtained 278 bushels of Japanese buckwheat seed from 2 pounds of seed in two seasons. He says :

One year ago last spring I bought 2 pounds of Japanese buckwheat, which I sowed on July 5, 1887, from which I harvested 8 bushels and one peck of good buckwheat. On July 3 of this year, I sowed 4 bushels of it on $\frac{6}{8}$ acres of ground. It promised to be a big yield, but the frost of Sept. 6 and 7 cut it short. I cut it right away after the frost, and set it up. I threshed it Oct. 11, and got 278 bushels of good, clean buckwheat.

"Moisture and its relation to wintering bees," is the special subject matter of the last issue of the *Bee-Keepers' Review*. The editor sums it up thus:

The burden of the testimony is that moisture plays but an unimportant part in the wintering of bees, except as it relates to temperature. But little moisture is required to saturate cold air; that is, it will absorb but little moisture, the point when it will receive no more being soon reached. As the temperature rises, the absorbing capacity of the air increases. When air of a high temperature, at that of our bodies, or nearly that, is saturated, or nearly so, with moisture, the exhalations from the lungs and skin are taken up but slowly; we are oppressed, and say the weather is "muggy." This explains why we feel better on bright, clear days. Heating air increases its power of absorption, hence we enjoy a fire upon a damp day. If the air of a cellar is dry, it will be readily seen that the temperature may be allowed to go much lower. In other words, a cold, dry atmosphere, or a warm, damp one, may be about equal, so far as effects are concerned. We fear this point has not been sufficiently considered. We have had many reports of the successful wintering of bees at such and such a degree of temperature, but nothing is said as to the degree of saturation.

We wish bee-keepers would use a wet-bulb thermometer in their cellars; it would not be the work of half an hour to arrange one; then let the degree of saturation be given with that of the temperature, and we will have something approaching accuracy. We say "approaching accuracy," because the strength of the colonies and the manner in which they are protected, have a bearing. A populous, well-protected colony can warm up the inside of the hive, expelling the moisture and increasing the absorbing capacity of the enclosed air. Building a fire in a room on a damp day is the same in principle.

While it is true that moisture may be brought into the cellar with air from the outside, we do not think this is the case in the freezing cold of winter. Frozen air, if the expression is allowable, has a very low point of saturation. That is, it will hold but very little moisture; and when it is brought into the higher temperature of the cellar its capacity for absorption is greatly increased—it is ready to receive water instead of giving it out. When the outside air comes into a cellar and deposits moisture upon the objects therein, it is evident that the incoming air is warm and moisture laden—warmer than the cellar and its contents. Mold in bee-repositories is usually looked upon as something undesirable, and we will admit that its appearance is far from pleasant, but we must not forget that, in a certain sense, it is a plant—the child of warmth and moisture—and that the conditions necessary for its development may not be injurious to the bees—*may* be more beneficial than a condition under which mold does not develop, one of moisture and cold.

A very damp cellar ought to be warm enough for the development of mold. But the cellar need not be damp. It can be made both warm and dry. These matters of temperature and moisture are under our control. Either by fires, or by going into the earth, preferably the latter, we can secure the proper temperature; and by the use of lime to absorb the moisture, a dry atmosphere can be secured. Certainly, it is not much trouble to keep unslacked lime in the cellar. While it is evident that moisture in ordinary cellars is not injurious, provided the temperature is high enough, it is a great comfort to know that there is nothing to fear from a dry atmosphere; that we can indulge our fancy, if you choose to call it that, for dry, sweet-smelling, moldless cellars, and know that the results will at least be harmless.

First Premium.—In the report of premiums awarded at the Centennial Exposition at Columbus, O., a typographical error occurred, concerning which Dr. Mason writes as follows:

On page 759 is a big blunder, either of mine or the printer, and we are always ready to blame the printer. If it had been in regard to myself, I should have said nothing, but when an old man, that every one who knows him regards with esteem, and took so much pains to help make our State Centennial honey exhibit such a success, is the sufferer, then I want to do all I can to correct the mistake.

In the sixth paragraph, in mentioning the premiums awarded Mr. Aaron Goodrich, it says he "was awarded third premium on a display of comb honey and a display of beeswax." It should read **first premium** on both. He had a fine display of comb honey, and I never saw a nicer display of beeswax at a fair or exposition.

It was an oversight of the printer, and we gladly make the correction to do justice to our aged friend Goodrich, for it was a magnificent display, indeed.

A Portrait of Mr. George E. Hilton will look down over the Paris Exposition next year. The *Fremont, Mich., Indicator* for Nov. 15, 1888, contains the following item about it:

Among the many attractions at the Paris Exposition of 1889, will be an enlarged picture of Geo. E. Hilton's Red, White and Blue Apiary. The work is done by a new process, in the Department of Agriculture at Washington, and at Government expense. Also a crate of honey gathered from the famous willow herb (*Ephitobium angustifolium*). The picture will be exquisitely framed, and the honey exhibited in a black walnut case, after the pattern of George's shipping cases, and made by himself. At the close of the Exposition they will be placed in the Museum at Washington.

Mr. Hilton spent some money for engraving, but it has paid him well. His portrait, and his apiary, too, have been published in nearly all the bee-periodicals of the world. He is well advertised.

A Correspondent from British Columbia makes the following inquires about sweet clover:

1. Will sweet clover blossom when it is grazed with stock the same as white? 2. What quantity of seed is required per acre? 3. When is the best time to sow it?

We reply as follows: 1. As it does not bloom until the second season, it will do no harm if it is grazed by cattle during the first season.

2. Six pounds to the acre is about the right quantity to sow.

3. It can be sown at any time, even on the snow in winter. It is excellent for waste places, commons, etc.

At Rest.—Dr. C. C. Miller's mother died at his residence a few days ago, after an illness of nine months. It is a relief to know that her long illness is now over, and that she is released from her sufferings, even though it does sever the dearest of human ties—the most sacred of all earthly affections. Peace to her dust.

It is Refreshing to get a report stating that the past season was the best in twelve years. That is the interesting news given in the following from Mr. H. A. Schultz, of Clontarf, Ont. He says:

This has been a very good season for honey with me, in fact the best in my 12 years of bee-keeping. I am greatly pleased with my crop this year. A few more good seasons like the past one, and I think that I shall be able to say that my bees have paid me back the money I have expended for them, and on their account. To-day we are having a fall of snow, and I am moving my 45 colonies into the bee-house. The past three days were nice and warm, and the bees had a grand final flight before being put into winter quarters. This is the first time that I can put my bees away on full natural stores; in previous years I had to feed considerable sugar syrup.

A Key to the Families of Insects, by Noble M. Eberhart, B.S., Ph.D. This is the name of an 8-page pamphlet issued by the Popular Publishing Co., at Chicago Lawn, Ills. This Key is the only one of the kind published, and consequently of more value to entomologists than if it was only one of several. Although the matter does not occupy much space, from its nature it is readily seen that years have been spent in its preparation.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

The 23rd annual meeting of the Michigan State Bee-Keepers' Association will be held in the Council Room at Jackson, Mich., on Dec. 12 and 13, 1888. Greatly reduced rates have been secured at the Hurd House, also at the Commercial House (near the Michigan Central depot) at \$1.50 and \$1.00 per day. A programme is being prepared and excellent essays are already promised. Any bee-keeper having anything new and useful, and finding it impossible to be present, can send it by Express to on exhibition and return it as per orders. Please to come and bring your bee-keeping friends with you.
H. D. CUTTING, Sec

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the *American Bee Journal* must be sent with each order for another paper or book:

QUERIES AND REPLIES.

Spacing Frames in the Brood-Nest.

Written for the American Bee Journal

Query 592.—1. What is the proper or best distance apart to space frames in the hive? I use the Van Deuseo metal corners, and my hives take 8 frames spaced $\frac{1}{2}$ an inch apart. 2. Would not 9 frames in the same space be better? 3. If so, why? If not, why not? The queen will only deposit eggs in cells 7-16 deep. I think that the Van Deuseo corners are a little too wide, as the bees are apt to build the cells too deep for eggs, and fill them with honey, thus preventing the queen from depositing eggs in them.—S.

Seven-eighths inch top-bars are the usual width. I prefer to space brood-frames $1\frac{1}{2}$ inches apart from center to center.—JAMES HEDDON.

1. I use $1\frac{1}{2}$ inches from center to center of the frames. 2. I have no experience with the Van Deuseo hive.—G. M. DOOLITTLE.

I have usually used frames $1\frac{1}{2}$ inches from center to center. That satisfies me. I think that a slight variation does no harm.—A. J. COOK.

The distance from the center of one top-bar to the centre of the other should be nearly 1 7-16 inches.—J. P. H. BROWN.

Space your frames just 1 7-16 inches from center to center, and you will be about right for all practical purposes.—H. D. CUTTING.

From center to center brood-frames should be about $1\frac{3}{8}$ inches apart. I have usually spaced them $1\frac{1}{2}$, but that is wider than necessary.—M. MAHIN.

1. I space $1\frac{1}{2}$ inches from center to center. I am not authority on questions 2 and 3.—J. M. HAMBAUGH.

1. Eight frames to the foot are what I generally use, but I have used nine. I prefer eight, as it gives more room for the bees, and they are more convenient to handle.—A. B. MASON.

1. One and three-eighths inches or a little less, from center to center. 2. That depends upon the size of your hive. Give each frame from $1\frac{1}{4}$ to $1\frac{3}{8}$ inches from center to center.—R. L. TAYLOR.

As I do not use the metal corners spoken of, and therefore cannot appreciate your difficulty, and as you seem to have reasoned out the matter pretty well, I will not advise.—EUGENE SECOR.

In questions of this kind you should give dimensions of the hive, etc., as many do not know anything about the Van Deuseo corners. Frames should be a little less than $1\frac{1}{4}$ inches from center to center; ten frames in a space of $14\frac{1}{4}$ inches is about right.—P. L. VIALON.

1. One and a half inches from center to center. 2. I think not. 3. The queen always has the comb well stocked with eggs and brood before the honey-flow causes the bees to enlarge the combs.—MRS. L. HARRISON.

I use $1\frac{3}{8}$ inches from center to center space of brood-combs. As you do not give the size of your hives, I am unable to answer your other questions.—C. H. DIBBERN.

1. I prefer $1\frac{3}{8}$ inches for my brood-combs. 2. I would think so. 3. Because the combs are kept straight by reason of there being no surplus room to bulge them out of shape. After looking more carefully at your questions, you leave me in the dark when you say that your frames are $\frac{1}{2}$ inch apart. The proper way is to measure from center to center of the frames.—G. W. DEMAREE.

1. I am not sure. Perhaps $1\frac{3}{8}$ inches from center to center. 2. I am inclined to think it would. 3. Because with only 8 frames the space is $1\frac{1}{2}$ inches, which, I think, is too much. I take it that your top-bars are one inch wide. If not, that changes the whole affair.—C. C. MILLER.

1. Usually $1\frac{1}{2}$ inches from center to center. 2. I think nearer spacing would be better. 3. The reasons, therefore, would require more space than can be given here—in fact they would form the text or basis of a long article.—J. E. POND.

1. Three-eighths of an inch; in other words, just the width of your forefinger. 2. Yes. 3. Because the $\frac{1}{2}$ inch is too wide, and the additional frame would decrease the distance. Bees are quite liable to build comb in spaces any larger than $\frac{3}{8}$ of an inch.—WILL M. BARNUM.

1. One and a half inches from center to center. 2. No. 3. Because your combs would be too crowded, and would be gnawed down by the bees wherever there would be too little room. Also, because less bees can cluster between the combs, and they do not keep up the heat so well, etc.—DADANT & SON.

Eight frames to the foot for winter, and nine frames to the foot for summer. Frames closely spaced are more suitable for brood, and less suitable for storage, because of the thinness of the combs; and there is less spare room also when closely spaced than in the old way. This close spacing, as a principle, is known as "the J. E. Pond method," and is quite valuable.—J. M. SHUCK.

1. About $1\frac{1}{8}$ inches from center to center is the best distance to space brood-frames, but some use them wider apart, and others even narrower,

varying all the way from $1\frac{1}{4}$ to $1\frac{1}{2}$ inches. Those who use "Van Deuseo metal corners" for frames are best qualified to criticise them. Perhaps you are right in your deductions.—THE EDITOR.

Planting Trees for Honey and as Wind-Breaks.

Written for the American Bee Journal

Query 593.—I have 4 or 5 acres that I wish to plant to forest trees. 1. What variety (or varieties) would be the most valuable and hardy? 2. Will the basswood (or linden) grow from cuttings? or what time should the seed be planted, or will they grow from the seed? I want to plant most of the trees next spring, and would like to plant trees that would produce honey as well as make a wind-break and shade.—Iowa.

1. Basswood. Plant small trees.—JAMES HEDDON.

I would recommend basswood. It is best to propagate it from the seed.—J. P. H. BROWN.

I know nothing at all, practically, of the matter.—J. E. POND.

I have had no experience in this line.—H. D. CUTTING.

This can be better answered by some one in your State.—P. L. VIALON.

Black locust and honey locust, or linden and box-elder.—MRS. L. HARRISON.

I should prefer basswood, and would get the young trees at some nursery. I think that cuttings of basswood would grow.—G. M. DOOLITTLE.

Linden, and tulip if they do well, from seeds. Plant in the fall or spring. The trees grow rapidly, and are beautiful.—A. J. COOK.

1. Linden, if you want honey. 2. We need light upon raising linden from seed. You would probably better buy young trees. I do not believe that they will grow from cuttings in open ground.—C. C. MILLER.

I would plant the linden, and a few soft maples. I am not authority on how to get the plants started.—J. M. HAMBAUGH.

1. I would plant black walnut. 2. I do not know, never having tried it. Plant the seed in the fall. For a shade and honey-tree plant basswood (or linden).—A. B. MASON.

If I were to plant for the value of the timber, I should plant black walnut; for honey, basswood is the best for your State. I do not know whether they will grow from cuttings, but they will grow from seed. I do not know the best time or manner of planting.—C. H. DIBBERN.

1. Where fence-posts are used, black locust is very valuable. It grows very rapidly, and lasts equal to red cedar.

2. Basswood seed will grow. Plant as soon as gathered, and keep the ground moist with a light covering of leaves. Plant seeds in nursery rows, and transplant when large enough. Locust, basswood and soft maple would answer your purpose.—R. L. TAYLOR.

Honey-locust (*Gleditsia triacanthus*) yields an abundant flow of honey, and can be propagated from the seed. Also poplar (sometimes called tulip-tree) is a good honey-yielder. But for general use, the basswood cannot be beat. The best way would be to get small trees from the woods. Cuttings would be far preferable to seed.—WILL M. BARNUM.

1. Basswood, locust, soft maple, and perhaps tulip trees. 2. No! Take roots from places where the trees have been grubbed out and have sprouted up again. So far as our experience goes not one seed of basswood in twenty will grow. For wind-breaks, etc., all things considered, we would use first, maple; second, locust; and third, basswood.—DADANT & SON.

1. For your purpose I would recommend basswood, and next to that, the *Lindodendron tulipifera*, commonly called in this country "poplar." 2. Basswood can be grown from cuttings, but I think that success could only be secured on a large scale by using a hot-house. 3. They will grow from the seed, and the seed should be planted in the late summer or early fall.—M. MAHIN.

1. Iowa is a large State—200 miles across north and south. What would do well in the southern part might not in the northern—instance catalpa. For an ornamental tree few excel linden, but in planting I would not confine myself to one variety. While you like honey, your posterity may like walnuts and butternuts. The lumber from the latter will be four times as valuable. Linden is best raised from the seed gathered in fall. They can be bought cheaply from some nurseries. This question needs more space.—EUGENE SECOR.

Plant the beautiful American linden. I would not bother with seeds or cuttings, but go to the forest and get the young trees. They transplant readily, but the young trees must be protected from stock. Nearly all four-footed animals like to browse on the mucilaginous twigs and bark, and I have even seen bipeds of the *genus homo* doing the same.—J. M. SHUCK.

Your locality must be taken into consideration when deciding your questions. In my locality I would plant the black locust, as it is an extra honey-producer, a rapid grower, and is valuable for fence-posts. A five-acre lot worth \$40 per acre here, if

planted in black locust, in my locality, would be worth \$250 per acre in 15 years from the time it was planted. Perhaps the linden would prosper best in your locality. It will not pay to raise forest trees from cuttings.—G. W. DEMAREE.

If you want honey, transplant young linden trees (basswood) in the spring, from the woods. They grow readily if sufficient moisture is provided. To grow from the seed is less satisfactory. The poplar (or tulip), black and honey locusts, soft maples, etc., are hardy, easily grown, and are very desirable for shade, wind-breaks, and the honey they produce.—THE EDITOR.

CORRESPONDENCE.

THANKSGIVING.

Written for *St. Nicholas Magazine*
BY GRACE WINTHROP.

The sunflowers in the garden
Are bending limp and low.
Two cornstalks, brown and withered,
Stand rustling in a row.
"We were so fine," they murmured,
"A little while ago!"

The sky is gray and gloom
Without the sunshine's glow.
There is no smiling anywhere
Unless—Oh, glad some show!
Twelve plump and golden pumpkins
All beaming in a row!

They say, "Why so despairing?
We're always here, you know,
At this unpleasant season
Expressly sent to show
The need of glad Thanksgiving,
In spite of frost and snow."

ITALIAN BEES.

Putting on Sections—Symptoms of Foul Brood.

Written for the *American Bee Journal*
BY G. M. DOOLITTLE.

A subscriber to the AMERICAN BEE JOURNAL wishes me to give a description of the Italian bee. While this would seem almost unnecessary at this late day, yet I will try to comply with the request in a sort of a general way.

This bee belongs to one of the yellow varieties, to which also belong the Cyprian and Syrian. The Italians are very quiet and gentle, in their purity, while the other two varieties named are very cross and vindictive. Italians were imported to this country about 1860, while the other two were not brought to our shores until about

1880. So far nearly all apiarists agree in placing the Italian bee at the head of all others, both as to ease of manipulation, beauty, and honey-gathering qualities.

As comb-builders the Italians are not quite as good as the black or German bee, neither do they use as much wax in capping their surplus honey, which causes it to have a little darker, or watery, appearance. They cling very tenaciously to their combs, while the black bees often fall off or run about in a frightened way, making it a nuisance to handle them, especially if a little too much smoke is used. The tenacity of the Italians makes the handling of the hives and combs very pleasant, but when we wish to get them off the combs for extracting the honey, or for any purpose, it is quite a job.

However, the main point of superiority of the Italian bee is in its honey-gathering qualities. If there is any honey to be had, they are away to the fields after it, and will toil incessantly all day for a very little, while the black bees will not work at all unless honey can be gathered quite freely. Italian bees will labor faithfully all day long for only "pennies," while the German bee must have the "dollars" or it will not work. To illustrate:

In the spring of 1872 the writer had 15 colonies of black bees, and 3 Italian colonies. As an experiment, a 14-quart pail full of maple sap was placed in shallow dishes after adding about 2 pounds of sugar, so as to make a very thin sweet. With honey, the bees were started to work near this sap, and as long as the honey lasted they came in about the proportion named above—15 of the dark, and 3 of the yellow bees. As soon as the honey was gone, they took to the sap, but in a few minutes the black bees began to stop coming, so that in an hour none but Italian bees were carrying the thin sweet. These bees worked until they carried all the sap home, and had it evaporated down to the consistency of honey, while the black bees thought it not worthy of their notice.

When to Put on Sections.

From the various letters which I get, asking when sections should be put on the hives, it would seem that there was a lack of knowledge on the part of some along this line.

In the forepart of the season a little care is required, for if put on too early they will greatly retard brood-rearing, owing to the cool nights which are liable to occur at the time, during which the bees are obliged to economize heat as much as possible. At this season of the year it is not best to put them on until the hive is filled

with bees and brood, so that they can take possession of the sections at once, and if cold nights do come, the bees will crowd down into the hive below, so as to protect the brood.

Again, there is no use of putting on sections until the bees are getting honey, for they not only tend to discourage brood-rearing, but the bees, having nothing else to do, will often cut down the foundation starters, and plaster propolis or bee-glue over them so as to make the labor of the apiarist much more than it otherwise would be.

The proper time to put on sections is when the hive is filled with bees and brood, and the bees are getting honey enough so that little bits of comb are being built about the tops of the frames. At such times the cells of comb will be lengthened along the tops of the frames, which is so pleasing to the eyes of the experienced bee-keeper, thus showing that the bees are getting honey, and are ready for the surplus department.

Symptoms and Cure of Foul Brood.

Another subscriber wishes to know the symptoms and cure of foul brood. When a colony has this dreaded disease, a few of the larvæ die soon after the bees seal the cells containing them. The cappings to the cells soon have a sunken appearance, with a pin-hole in the centre of each. Upon opening the cells the larvæ is found stretched at full length in the cells, and have a brown appearance, while all healthy larvæ or pupæ are white. If touched, this dead brood is of a salvy, ropy nature, and gives off an offensive smell.

From the first few cells the disease spreads rapidly until the combs become a putrifying mass, generally during the first season, and nearly always during the second, which stench at this stage, if allowed to get so far, can be smelled a rod or two from the hive. A few of the larvæ mature into bees, the population of the hive decreases until it becomes an easy prey to robbers, when the honey is taken off by these robber bees, only to carry the seeds of the malady to the robbers' hive, for the disease to spread through the honey, and all else coming in contact with it.

The cure is to drive out all of the bees from the affected hive, and keep them shut up in an empty box until they are nearly starved, so that they will have digested all of the diseased honey. They should then be hived and fed in a new, clean hive, when they are clear from the disease. If in the honey season, a swarm issues from a foul-broody hive, it is not necessary to put them through the starving process; simply hive them in an entirely empty hive, the same as you would a

healthy swarm, and as far as my experience goes, they will always be healthy thereafter, unless they contract it again by getting diseased honey from some other hive.

Great care should be taken that no bees get at the contents of the old hive before the combs are rendered into wax, and the honey and hive sealed. Other cures have been recommended, but most of them are ineffectual, except in the hands of an expert.

Borodino, N. Y.

ODOR OR COLOR.

Which is it that Attracts the Bees to the Flower?

Written for the American Bee Journal

BY MRS. MAHALA B. CHADDOCK.

Prof. Cook asks how I know that color is no guide to bees. I answer, I know it because I am a reasoning being. If I were an insect I should know it by instinct. I *know* that bees are guided by odor, and I think that I can prove it, even to Prof. Cook's scientific mind.

Most of the nectar-bearing plants that I am acquainted with are inconspicuous in color, but strong in odor. Is there anything bright or showy in a field of white clover? Anybody with eyes in his head must answer "No." Do not the bees always find the white clover blossoms? A thousand voices answer "Yes." Well, then, color does not attract bees to white clover, but odor does. It seems to me that this is incontrovertible.

The blossoms of the linden are yellow, but there is a sort of white membrane near the clusters of flowers that makes many people think that the blossoms are white. A silver-leaved maple appears, when the wind is stirring, as much like a flowering tree as the linden does when full of bloom. Can the bees see the blossoms on the linden and pick them out from other forest trees? No, they cannot! They smell them, and go for them. Can any body doubt this? Can Prof. Cook doubt it?

Then there are the raspberries, the catnip, the sweet clover, and ground-ivy, all inconspicuous flowers, but flowers that are never neglected by the bees when they contain nectar. And is there on all the earth a more insignificant flower than the smart-weed? It grows mostly in corn-fields, and never reaches to the tops of the stalks; the flowers are a pale pink in color, and so small that at any considerable distance up in the air they must be practically invisible. Are the smart-weeds ever neglected by the bees? Never. Why, if it were possible to

stretch a curtain over the entire field, and nail it to the fence all around, the bees would go in through the rails and gather the nectar all the same. Can Prof. Cook doubt this?

I think that I have proved my statement, but I will prove it in another way. When you feed bees out-of-doors, put some honey in a plate of rye flower, for instance. Is it a yellow color, or *any* color, that attracts the bees to it? The rye flower is a whitish gray—one of the most inconspicuous colors—but Prof. Cook knows that the bees will go to it. How can they find it except by the odor?

When old bee-hunters go out to "line" bees, what do they take to attract the bees—some bright-colored yellow flowers fastened in a bouquet on a pole? Not at all; they take some foul smelling stuff in a vessel, and the bees come to it because they smell it. Can any one dispute this point? I think not.

If the slops from the bed-rooms are emptied on the grass at certain seasons of the year, the bees will work on that spot. There are no flowers of any kind, only green grass and *odor*. Can this be disputed? When bees go to cess-pools, do they go for bright colors? Everybody knows better—they go because they smell something that they want. There can be no question of color about it.

I think that I have covered every point, so far. Prof. Cook says: "It is almost the universal opinion of scientists, that the color of flowers was developed especially to attract insects: this of course for the flowers' good." If this is so, then it only goes to show that scientists are almost universally wrong. Bees visit flowers for the honey and pollen they contain, not for the good of the flowers. To believe otherwise, is witchcraft. A bee can know no more of what is good for flowers, than a hog knows of the prices of pork in a daily newspaper.

If color is given to flowers to attract insects, why do not bees work on flowers that have no nectar or pollen? Why do not bees work on zinnias and dahlias, and peonys? Nothing could be much brighter, but they contain no honey or pollen, and the bees pass them by. So if Nature gave color to flowers to insure their fertilization, she made a big mistake. She would better have endowed all her flowers with nectar or pollen. If insects do by chance alight on a brilliantly colored flower containing no honey or pollen, they do not stay; they do not go in and out, and handle the stamens, as it is necessary they should do, in order to fertilize the flowers.

The Professor asks how I know that insects do not reason. I know it in

this way: All reasoning animals study out ways to better their surroundings. This is the *insignia royal* of reason. Well, bees do just the same things over and over that they did thousands of years ago. They live in hollow trees, and hang suspended on limbs now, when in a wild state, just as they did then; and build in the crevices of rocks just as they did in Bible times. Why, if bees had been endowed with reason, there would be no free man on the earth to-day. Armed as they are with a deadly weapon—a weapon that will kill a horse or a man as surely as a bullet—they would be marching us around with a guard of bees on every side, and telling up *pointedly* what to do, and how to do it—to improve their houses, to train up their young, and to prepare their dainty dinners.

Vermont, Ills.

BEE LIFE.

The Length of the Term of Bee Life Considered.

Written for the *Journal of Horticulture*
BY A LANARKSHIRE BEE-KEEPER.

Notwithstanding all that has been written upon the natural term of bee life, there is still much misconception regarding the limit. From the fact that many articles have been written on preserving the life of bees, is proof that their management is by many but imperfectly understood, and that many bees die at an early age through ignorance on the part of the owner. There is no time throughout the whole year that the apiarist is justified in pursuing a course that is likely to shorten bee life. Where profit is expected it should be the aim at all times of the bee-master to prolong it.

Although care to prolong bee life is necessary at all times, yet during autumn a little extra attention is absolutely necessary before we can reasonably expect our favorites to tide over the winter months successfully, and obviate the untimely deaths we read so much about. That bee life can both be prolonged or cut short there is no doubt, and the bee-keeper has the control of that to a great extent, as can be witnessed by comparing results under different managements.

I have expressed my views strongly as to what constitutes the best preserving hive, the first principle in apiculture. I have also shown that the short term of bee life, as set down by modern writers, is misleading; in short, the six-weeks theory cannot be supported by any evidence. However

desirable the youthful element may be in the hive at certain seasons, it is positively injurious at others. It is a fact well known that bees, on or about the fifth day of their existence, if the weather is warm, fly out and void their excreta, which, if delayed beyond a reasonable time, they become restless and cold, communicating the restlessness to the adult bees; and the young ones, unable to fly, either leave the hive to die outside, or are chilled to death inside. Young bees cannot endure the same length of confinement, if they have never had an airing, as adult bees, and are often the direct cause of the entire loss of the colony that bred them.

Late feeding is a mistake, and many a bad result has arisen therefrom. Late breeding we cannot always prevent, but it should not be encouraged. It has always been our object to be in possession of bees that neither require feeding nor coddling. Some years since, and for years in succession, a cotemporary advised feeding in October, and we know something of the evil that beset those who took that ill-timed advice.

Bees, as a rule, cease breeding with the decline of the honey season, which usually occurs about the end of August, except in the case of those having young fertile queens, which, unless fed, will not breed beyond the autumnal equinox, but will sometimes begin again soon after the shortest day. When this is the case, and a mild February follows, there will be a chance for the young and tender bees to get an airing. Then all may go well; but should the weather be unfavorable and protracted, so as to prevent the flight of the young bees, the colony may succumb to the influence of the evil. But, happily, early breeding is not so fatal or injurious to bees as late breeding.

I have for some time past been paying particular attention to colonies with late-bred bees, not for the purpose of getting information, but to be enabled to give that to others from accurate observations. Since Nov. 10, the last day bees carried pollen for this year, I have collected all the dead bees from several hives, having taken the precaution that none should be carried off by the birds, by netting the front of the hive. I collected the ejected dead, and found, as I fully expected, not more than 10 per cent. of adult bees out of more than ten thousand. These I laid down near a hive, and in less than an hour the sparrows and titmice had carried every one away. My reason for mentioning the alacrity the bees displayed is to impress bee-keepers that, though their hives may show signs of dead bees, they may be

actually dwindling rapidly through some autumnal mismanagement.

The foregoing will, perhaps, impress the beginner with the evils of late feeding and breeding, and convey to him the cause of dwindling. This is sometimes aggravated by uncalled-for molestations, and a superabundance of cloth coverings, which often cause internal damp and disease in the bees. Thus, by excess, they aggravate evils that sensible bee-keepers would obviate by using, in moderation, the proper quantity of a suitable material, which helps greatly to prolong the life of bees.

PROTECTION.

Legislation for the Protection of the Rights of Bee-Keepers.

Written for the *American Bee Journal*

BY DR. C. C. MILLER.

I have been sometimes amused, sometimes unmoved, and sometimes pained at the inevitable misconception and misrepresentation that generally occur whenever my views as to legislation for bee-keepers are mentioned. Do I express myself so indistinctly on this subject that I cannot be understood? Quite frequently the misrepresentation is in attributing to me views that I never held. I clip the following from the *Western Plowman*:

For some years a discussion has been going on in the bee-papers as to bee-keepers buying the "honey rights" of their respective districts, to the exclusion of all others, by paying a small rent to the owners of the land on which the bees are supposed to forage. Dr. C. C. Miller, of Marengo, Ills., is at the head of such a proposition, and seriously proposes to have a law enacted to that effect. Lately some others have come to his assistance, and they seem to seriously think that some such law should be passed, and would be of practical advantage to both bee-keepers and land owners. How such a question can be seriously considered, and why it should be urged by bee-keepers is astonishing. Such a law ought to be entitled, "An act for the extermination of bee-keeping," as that would be the inevitable result if it could be enforced. Bee-keepers have certainty expenses, and difficulties enough now, without adding new burdens, especially if self-imposed. But let us look at the justice of the proposition.

Bees have been kept for thousands of years, and their rights to go and gather the nectar from forests and fields have never been questioned. Such rights have never been deeded in fee simple to any land owner, and consequently they do not own them, and have nothing to rent or sell. But even admitting that they had a right to the honey produced, and which would go to loss but for the bee-keeper, then in order to protect such property they would be compelled to build a legal fence which would of course be such a fence as no well-behaved bee could get over. That this cannot be done is very evident. Then such a proposition is contrary to public policy. The bee-keeping industry interest is now worth more than \$25,000 annually. Many a poor man, and woman too, are now able to

make a good living in this pursuit, for themselves and families, without injuring any one, that would otherwise, perhaps, become charges on the community. Then, too, would not such a law be a step in the direction of trusts, favoring a few at the expense of the many? But it is almost nonsense to talk of this matter, only to show its absurdity. It will be many a day before any such law will be passed in this country.

The above is from the pen of Mr. C. H. Dibbern, for whom I have much respect as conducting a department in the *Western Plowman*, of Moline, characterized, so far as I have had opportunity to judge, by fairness and good sense. Mr. Dibbern and I have had no bitter quarrel, and so far as I know, nothing but kindly feelings exist between us, and why he should misrepresent my views, and hold me up to the ridicule of his readers, is something that I can understand no more than I can understand the many previous cases of misrepresentation.

Whether the proposition to buy "the 'home rights' of their respective districts by paying a small rent," etc., be a wise proposition or not, I will not stop to discuss, but certainly I have no recollection of advocating such a proposition, or proposing "to have a law enacted to that effect." Indeed I have said very little as to the particular means of attaining the end, the only point I have insisted upon being that there should be some way in which a bee-keeper might be secure from interference in a certain territory, without specifying how such a security should be obtained, or whether it should be secured for one colony or a thousand.

Mr. Dibbern says, "Lately some others have come to his assistance," and I am glad to believe that their number is not small, and I feel confident that when Mr. Dibbern gives the matter the thought it deserves, he will come to my way of thinking.

Mr. D. says: "Bees have been kept for thousands of years, and their rights to go, and gather the nectar from forests and fields have never been questioned." Softly! Has Mr. D. forgotten the cases of S. I. Freeborn, of Ithaca, Wis., Z. A. Clark, of Arkadelphia, Ark., and others? On account of the absence of laws for the protection of bee-keepers, more than one has been obliged to give up his bees or move.

Has Bro. Dibbern forgotten the existence of the Bee-Keepers' Union, born of the necessity for organized effort to withstand the assaults of ignorance and malice, just because proper legislation is lacking? What would be said of a "Farmers' Union" combined to resist the attempts that might be made to drive a farmer from the cultivation of his land? No such thing is needed, for the law is sufficient to

protect each farmer on his territory. be that a rod or a mile. Something in the same line is needed that the bee-keeper may be protected, whether he may have one colony or a hundred.

As the matter now stands, Mr. Dibbern may awaken some fine morning to find that his apiary, "the white, blue, red and yellow hives among the trees," upon which he looks so lovingly, may no longer be continued, on account of legislation from a lower power that was made possible by the apathy of bee-keepers in failing to secure from the State the legislation that might be had for the asking. Or he may find, as others have done, that within a few rods of his, another apiary may be planted, thus spoiling the chances for both; and then Mr. D. might think it a very fine thing if he could stand on the same footing as a farmer, in possession of his territory.

The fact that "such a fence as no well-behaved bee could get over" cannot be built, cuts no figure in the case. Fences are not built to confine fish within certain limits, and yet fishing limits are defined within which no outsider dare intrude.

Does Mr. D. think that the laws protecting farmers ought to be entitled "An act to exterminate farming?" Does he think such laws "a step in the direction of trusts?" Would it be an improvement to throw all lands open in common that each man could settle down anywhere at his own sweet will?

Now please remember, friend Dibbern, I ask nothing more for the bee-keeper than for the farmer, and I have no more desire to drive out of the business "many a poor man and woman who are now able to make a good living in this pursuit," than I have to drive them out of farming.

Marengo, Ills.

ASIATIC BEES.

Where the Caucasian Bees Came From.

Written for the American Bee Journal
BY J. W. TEFFT.

It will be seen at the extreme eastern end of the Black Sea in Central Asia, there stretches eastward the range of Caucasus mountains to the Caspian Sea. The great Russian railroad now building into the heart of Asia is at last a fact, and travelers can now go from St. Petersburg almost to the boundary line of the Chinese Empire in twelve days. From St. Petersburg the new line runs through Moscow, Womnesh, Rostoo and Valkavas; here the route is barred by the Cau-

casus range, over which the line is not yet completed, and one has to take a camel caravan to travel 18 hours over a pass of 8,000 feet high, 2,000 feet higher than St. Gothard.

With scenery twice as wild as that of Switzerland, the Caucasus will be a great summer resort in the near future. Over the pass we come to the rich valley of the Oxus, the Mississippi of Central Asia, now opened up, having no outlet save by caravan. The resources of this territory are all kinds of minerals and agricultural, and all undeveloped. The effect on civilization, of the new railroad line, can better be imagined than described. Considering the fact, the great mechanical advances, and the higher civilization of the nineteenth century will now be carried into this barbaric Asia. Its effect upon school geographies is not even to be surmised.

In referring to Webster, he defines Caucasian thus: "Any one belonging to the Indo-European race, and the white races originating near Mount Caucasus." These mountains stretch from longitude 40° to 50° east, and latitude 46° to 50° north, about the same latitude as the State of Maine, 47°, being several degrees north of Syria, Cyprus or Italy, the homes of the Syrian, Cyprian and Italian bees. Thus it will be seen that the Caucasian bees came from a cold climate.

Peculiarities of the Caucasian Bees.

Now whatever may be the individual or class merit of the Caucasian bees, they take the lead in all points save one, and that is swarming. They are remarkably gentle, seldom stinging, yet they can sting when abused.

In manipulation I never use smoke, as that arouses them to anger. The only time I use smoke is when closing up the hive, to drive them away to prevent bruising.

These bees cling to the combs firmly when the frames of combs are handled. As honey gatherers they are as good as the best. Their cappings are equal to that of the blacks, being very white and thick. The bee-glue or propolis is not half as sticky as that of the blacks or Italians. They gather immense quantities of pollen. The queens are remarkably prolific, and colonies swarm once a week, if left to their own management.

They build more queen-cells than any other race of bees. The brace-combs seem to be made of dark wax, a kind of mud color, which is objectionable when cappings are stuck to the separators. They are extra hardy, and stand our cold, bleak winters splendidly.

Their color is of a dark copper hue, or fine orange like—not so light a

color nor as handsome to my eye as the Cyprians, but tending towards that splendid species. They are large bees, yet long and slim. Their wings are long, and will carry a big load. They work when Cyprians and blacks are idle, and are out earlier in the morning, and fly later in the evening. They gathered honey right along during the drouth of 1886 and 1887, when the blacks, Cyprians and Italians gathered none, but used up all unsealed honey in the sections, and then nearly starved.

They not only stand the heat, dryness and cold better, but against robbers, insects, moth-millers and fungus they have no equal; and when properly understood and managed, they will gather as much honey as any bees, but they require another system of management.

They are amazingly interesting as a race; not for their superior hardiness against cold and drouth, but for the fact that they introduce a distinctly new strain of blood, one which by crossing with those we already have, is likely to give us very superior bees.

The four years that I have been experimenting with the Caucasian bees, I have learned something. The first swarm I was at my wit's end to understand rightly. At that time I would have willingly given \$50 had I never seen them. They gave me much trouble by their continuous swarming, which was decidedly disagreeable and annoying. I transferred them to reversible frames, and with a determination to conquer, and also to study their habits and requirements, and by domestication to civilize them so that they would stay at home, I soon found the prime cause to be in the queen, resulting from her extraordinary prolificness. The minor cause was pollen.

The queens want more room than any race of bees that I ever owned. The peculiar device I have adopted in my management of them was that I gave the queens more room without inserting extra combs, and with the help of the device I solved the puzzle, and now I have them under control.

Securing Hardiness in Bees.

For 31 years I have been trying in vain to discover one type of bees that I could rear successfully in northern central New York; and one of the most discouraging things to contend with, has been the difficult character of hardiness. Indeed, I think if it were not for this unsurmountable difficulty, we have bees hardy enough to successfully breed much further north. Without hardy bees there cannot be a great success in honey-production; and to my thinking, it is this weakness which has prevented my succeeding

with the almost hardy bees, such as the Cyprian, Italian and blacks, and their crosses. They are all fine honey-gatherers, but they fail during our severe winters.

It seems reasonable, and it may be of some wisdom, that with the Cyprian bee from the South, and the Caucasian bee from the North (or any other first-class race of bees)—if we could cross them with this most hardy bee, and could rear them successfully, we would have the "American bee;" and by crossing and judicious selection, we could retain the quiet, gentle disposition and hardiness of the Caucasian, and thus remedy the terror—stings.

A cross of the Cyprians, and this the hardiest and gentlest of all bees, might confer upon the former those better qualities, gentleness and hardiness, which are generally needed; and by commingling the several different natures, we will have an exquisite beauty—the American honey-bee, not now found in any one type.

But our triumph will not then be completed. We must, and can, produce an American bee vastly superior to any now known. There is no question of the certainty of such results. We want first-class bees, and in order to get them, we must have *first-class parentage*.

From the fact that all bees are more or less mongrels of many degrees of crossing, and various relatives will crop out in a multitude of disappointments, yet our past success is a guaranty for the future, that out of many, some will be good.

I trust that some enthusiastic apiarist may be sufficiently interested in the matter to make these crosses. This can only be done by those who are so situated as to be able to breed all kinds, which we of the bleak, cold North are unable to do.

Collamer, N. Y.

COLORADO.

Report of the Colorado State Bee-Keepers' Society.

Written for the Colorado Farmer

BY J. M. CLARK.

An adjourned meeting of the Colorado State Bee-Keepers' Association met in Denver, at the Chamber of Commerce, at 10:30 a.m., on Nov. 13, 1888, with President Milleson in the chair.

Secretary Clark read the minutes of the last meeting, which were approved.

Chairman Rhodes, of the committee on foul brood, desired to confer with the other members of the committee, and report in the afternoon.

Secretary Clark reported that he had received communications from Delta and Montrose, from parties desiring to form an association auxiliary to the State society. He also read a letter from C. E. Carroll, of Liberty, Rio Grande county, stating that he had had several colonies in the San Luis valley, but the experiment had not been a success.

President Milleson urged that the Society be incorporated, so that they could get their reports printed in connection with the Horticultural Society report, etc. V. De Vinney agreed with the President, and moved that the Secretary be authorized to take immediate steps towards incorporation under the State laws, which was carried.

Foul Brood and its Cure.

V. De Vinney thought that for quite awhile his bees had no foul brood. He was appointed executor for an estate, and brought the bees (which had originally come from the East) to his apiary three years ago. He did not understand foul brood then. He found white spots and a slight odor, but not such as books had led him to believe. His own bees had robbed them as they grew feeble. Sixty colonies got this foul brood. Bee-Keepers should not wait until the combs get bad, but as soon as they find white spots and a slight odor, they should look out. He cut out the bad places and washed the frames with salicylic acid as the bee-books direct. He saved some, as it looked good, but gained nothing, as much afterward proved bad, and other foul brood was placed where he had cut it out. He had been over five years in getting this foul brood, so he did not think that it was as bad in Colorado as elsewhere.

Mr. De Vinney's belief is that this is nothing but a mold or mildew, no worse than other mildew, and if cut out early no harm would result. Where he used salicylic acid last spring he had found an improvement. It is generally said that when the comb is flattened, it is an evidence of foul brood. This is not true, for it may be even. The depression is caused by bees pressing against it in warm weather. He saw such depressed combs, took them out and examined them under a magnifying glass, when he saw them move, showing that there was life.

Bees will store honey when there is foul brood. To tell if clear comb is affected with foul brood, tip it to an angle of 90°, when you see the "mummy." Do not look at them flat, as they will appear all right, since the bees will clean them out when they can, but the "mummy" part is too sticky.

Mr. Davis—To what extent has foul brood been scattered?

Mr. Knight—My bees had it in Littleton.

Mr. Devinney—The bees had it in Morrison, but none up near Central City. It is in North Denver and Ralston creek.

Thos. Crisman lives on the upper end of the Ralston, and had heard of none west of Arrada.

J. W. Bacon said that there was none in the neighborhood of Longmont.

Mr. Hurlburt feared that many bees had the foul brood, as it was in the unsealed as well as the sealed honey, although the bee-books taught differently.

Mr. De Vinney corroborated Mr. Hurlburt's statement, as did also Rev. R. H. Rhodes.

Prof. Cheshire's book on foul brood was highly endorsed.

Mr. De Vinney said that science never discovered a gold mine, but it could tabulate experience. He had read much, but stated facts regardless of reading. As a big fire will destroy the whole earth while a little will not, so a little mildew amounts to little, but much will ruin.

Mr. Lofb had foul brood introduced into his apiary through some old comb. As soon as he found the punctures, he read bee-books, and put all the bees into an empty hive, and smoked the hive with sulphur. He used sulphur to a great extent when in the nursery business in Missouri. It destroys all fungus. It kills fungus also in the human system. He gave the bees new combs, and that was the last he saw of it.

Mrs. Graves, of Clear creek, found a great deal of foul brood. Mrs. Rhodes advised her to get medicine which she gave in syrup, and some queens were now laying, and they are thrifty.

Mr. Rhodes said that he had followed strictly the teachings of Prof. Cheshire's book, and the bees are now so lively that they act like bees in the spring.

Mrs. Graves said that she poured this medicated syrup over the broken combs. She used only a very little of the best of the poor comb in feeding.

Mrs. Rhodes' bees had had the foul brood all summer. Now she has some strong colonies, but has taken out 150 frames with foul brood. Mr. Rhodes dug a big hole in which she buried the frames and honey. She intends to experiment in feeding the best of the frames of honey to the bees.

Mrs. Everett had not found foul brood among her bees, which are lively, and come out each fine day.

They have averaged 95 pounds per colony, and 5 swarms.

Mrs. Bacon said that her bees had averaged 150 pounds to the hive in extracting, but only 50 pounds of comb honey. This is not fair, as the bees were weak.

After a little discussion several new members joined, and the convention adjourned until 1:30 p.m., when Mr. Rhodes, of the committee on foul brood, consisting of H. Knight, Wm. Davis and J. M. Clark, with himself, made a report, showing that the disease was spreading very rapidly, that it was clearly defined, and they besought all Colorado bee-keepers to aid them in suppressing it; urged the appointment of a committee to petition the Legislature to pass a protective law, and to see that it is enforced. They recommended Cheshire's work on foul brood, and requested the members to forward to the Secretary all information pertaining to the subject.

The report was considered in parts, and with a few slight verbal changes, the entire report was adopted.

"At what season is the best honey gathered?"

H. Knight—The first about June.

Secretary Clark agreed that this was so, whether gathered from alfalfa or other flowers. Early honey has a white comb, as well as a better flavor.

Mr. Carlzen found that early honey is less gummy.

Secretary Clark said early honey would keep the best.

Mrs. Rhodes said that some tastes preferred the late honey.

Mr. Rhodes said that a Pennsylvanian, accustomed to buckwheat honey, would think our worst honey better than his best.

Secretary Clark thought that late flowers were yellow, and those of spring, white.

Mr. Knight wanted to know why late honey always granulates. Mr. Rhodes said that it was a question of locality; his did in the spring.

Secretary Clark said that alfalfa honey would candy, also rosin-weed honey, when extracted.

Mr. De Vinney said that raspberries would be in bloom about June 5, before alfalfa. His bees worked on willow, and he wanted to know about the quality of the honey. Answer—Mr. Root gives it as a honey-plant.

Mr. Rhodes offered the following resolution which was carried unanimously by the convention:

Resolved, That a committee of three be appointed whose duty it shall be to search out fraudulent honey, and dealers in the same, and work in the Legislature to secure laws to check such dishonest attempts to injure the honey industry of Colorado.

"Will the queen deposit eggs in cells that have contained foul brood?" Mr. De Vinney said that they would when crowded.

Keeping Honey from Candying.

"What method is best to keep comb honey in winter from candying?"

Secretary Clark favored a temperature like that in which it was stored. If we can keep it in the same conditions as regards light and heat, as in the hive, we can keep it longer; but honey stored in some conditions, nothing can keep it from candying. Rosin-weed honey would sometimes candy in 48 hours.

"Is foul brood an epidemic, or is it a contagion?"

Mr. Rhodes thought that we must treat it as a clearly defined disease. The remedies recommended have acted as checks, and he thinks next year will demonstrate. This year he began too late, when brood-rearing had ceased. In Colorado it can be checked easier than elsewhere. Stringent legislation is necessary; at the last meeting one member objected to a penalty. In Michigan the law is \$100; he had made it \$50. When a man refuses to destroy his bees he should be punished. He took Mr. Davis to see a man who had lost all of his colonies but nine, and they were diseased. The committee had asked him to destroy the bees, offering to give him a new start. He would not destroy them, and they are living now. He believed that they had given the disease to Mr. Graves' bees.

Mr. Carlzen said that we ought to have a foul brood law like that in Minnesota concerning mustard seed—if they would not clean it, the county would and charge them for it.

Best Race of Bees.

"Which race of bees are the best honey-gatherers?"

Mr. Davis thought that cross-bred bees stored as good honey as any.

Secretary Clark and Mrs. Rhodes thought that the Italians were the best.

Mr. De Vinney saw no difference in regard to honey-gathering. Blacks had done as well as his nearly pure Italians.

President Milleson said that certain races, whether pure-blooded or hybrid, did better than others. The rule is to adopt the best races, and breed from them to secure a particular strain. This is as important in bee-culture as in cattle-breeding. His experience is that if bees will not sting and fight in defense of their honey, they have very little to spare.

Mr. Bacon thought that this theory would prove the blacks better than the Italians, but he did not believe this.

President Milleson said that hybrids were considered the best by many bee-keepers.

"Which section is the best, the one-piece or the four-piece?"

Secretary Clark preferred the four-piece section, although it took more time to form them than the one-piece. If well put together, the one-piece will do well.

Mr. De Vinney said that the one-piece sections had to be soaked, and if too wet, there was trouble; sometimes they would split in two.

Secretary Clark said that it was hard to crate honey if the one-piece section did not make a perfect square.

Mr. Hurlburt said that too much water was bad; he moistened the inside with a sponge, but did not touch the groove. He would take ten or more and wet them crosswise.

Secretary Clark laid them down, and wet them on the backs, rather than the grooved side; as that swells and the other side does not, there is no danger of breaking.

Prevention of Robbing.

"What is the best way to prevent bees from robbing?"

Mr. Bacon noticed a small swarm, two weeks ago, that had done nothing, and for days they waited on the outside. He thought that they were waiting for others to rob them, and then join them.

President Milleson thought that he would investigate; there must be some reason; it may have been foul brood.

Secretary Clark said that the best way was to narrow the entrance so that only one bee could enter at a time; another method was to make each colony strong.

Mr. Davis was bothered two years ago. If he covered the hive, it stopped the robbing, but the bees could not find their way back. He found an effective way. He opened the hive and let them come in, then killed them with sulphur; in a short time he opened it again, and when filled he gave them another smoking. He killed about 3 colonies, mostly his neighbor's.

Mrs. Rhodes found that if syrup was placed in crocks on the ground, away from the hives, it prevented robbing.

Mr. Knight always narrowed his hive-entrances, and had no trouble.

President Milleson said that bees were like men, if you allowed a man to get some money that he did not earn, he will always seek some way to get other money that he has not earned; and bees will get honey without work if they can.

The Colorado Honey-Yield.

"What is the aggregate yield of honey in Colorado for 1888?" was not

answered, as the Secretary said that he was getting honey all the time. The members were directed to report to him by the January meeting. Dr. Shaw urged them to be careful, as their figures were valuable, and none such had ever been collected. The Secretary said that if all would help him, he could get up a column of figures that would astonish our legislators. He would send circulars to every apiarist, but his experience in the Horticultural Society convinced him that not one in ten would report.

Mr. Rhodes had found new bee-men in Boulder county, who had started with 20 colonies; they now had 22, and 1,000 pounds of honey. Wherever he went he tried to get statistics. Dr. Shaw favored personal visitation.

It appears that there is a difference in the tendency of different samples of honey to candy. What is the cause of such a tendency?"

Secretary Clark said that the difference was in the flowers and seasons.

Mr. Pratt said that he had resolved to build a bee-house the next day. Mr. De Vinney said that bees often struck each other in a bee-house, if they were too crowded. Mr. Knight had found that height made no difference; a house 9 feet from the ground did as well as those lower.

Mr. De Vinney said that the Legislative committee should get to work now; they should go to our member of the House and urge the cause; then go to the Speaker of the House, and get him to put this man on the committee.

Stephen R. Pratt, R. H. Rhodes and Henry Knight were appointed committee on Legislation. Messrs. Clark, De Vinney and Hurlburt were appointed a committee on fraudulent honey.

Mr. Pratt said that he would like to have members address him thus: "Box 2804, Denver, Colo.," and state what legislation they desired.

On motion the executive committee was ordered to draw up a programme for the annual meeting on the third Monday in January, 1889. The convention then adjourned until that date.

J. M. CLARK, Sec.

SWARMING.

Experiments for Controlling the Swarming Fever.

Written for the American Bee Journal

BY DR. A. E. SMITH.

I carried on some experiments last summer to prevent swarming, and as far as the colonies were concerned, they did not swarm, but produced 140 pounds of comb honey each.

The plan is as follows: I watched the colony closely. Just when I thought they would commence building queen-cells, I opened the hive, took out two frames of brood, shook off most of the bees, looking sharply that I did not have the queen, and put in their places two frames full of foundation. I then replaced the section-cases.

In one week they began to show symptoms of swarming (as I thought), and I removed one frame, and put in its place a frame full of foundation (I use the 10-frame Simplicity hive). In the last removal, I changed the outside for the center frames, putting the four center ones to the outside.

At the first removal I also took out the fourth ones from the outside. In the last removal, I took an outside frame, but the one with the foundation went in the same place that one of the first did.

As I could not experiment on a large scale, and some apiarists may know something of this method, I would ask them, "About what proportion of colonies will it prevent from swarming?" This seems to be enlarging the brood-nest, but it makes no difference what it is, *that* is the way to get the honey.

This was done while I was putting on or taking off section-cases, so it will be seen how much labor it took with those colonies, and the removal.

I should say that at the second removal, and the change of inside for outside frames, I like to uncap as much honey as I think the bees will take care of, and *up* it goes.

This, to me, looked the most feasible in my "well-digested plan," for the production of comb honey, and it was a perfect success. I use a modification of the T-super, and "tier up," filling the sections full of foundation, and never forgetting to praise the Italians.

If in another year I could succeed in a large majority of cases, in preventing swarming, that would be well, but I was afraid of an accident, etc. Any information will be thankfully received, and for this purpose I wish to submit it to the correspondents of the AMERICAN BEE JOURNAL.

Darlington, Wis.

Convention Notices.

The Nebraska State Bee-Keepers' Association will convene at Lincoln, Nebr., on Jan. 9, 10 and 11, 1889. J. N. HEATER, Sec.

The annual meeting of the Ontario Bee-Keepers' Association will be held at Owen Sound, Ont., on Jan. 8 and 9, 1889. W. COCSE, Sec.

There will be a meeting of the Susquehanna County Bee-Keepers' Association at the Court House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a.m. H. M. SEELEY, Sec.

The twentieth annual convention of the New York State Bee-Keepers' Association will be held in the City Hall, Syracuse, N. Y., on Dec. 11, 12 and 13, 1888. G. H. KNICKERBOCKER, Sec.

CONVENTION DIRECTORY.

- 1888 *Time and Place of Meeting.*
 Dec. 11-13.—New York State, at Syracuse, N. Y.
 G. H. Knickerbocker, Sec., Pine Plains, N. Y.
 Dec. 12, 13.—Michigan State, at Jackson, Mich.
 H. D. Cutting, Sec., Clinton, Mich.
 1889,
 Jan. 8, 9.—Ontario, at Owen Sound, Ont.
 W. Couse, Sec., Streetsville, Ont.
 Jan. 9-11.—Nebraska State, at Lincoln, Nebr.
 J. N. Heater, Sec., Columbus, Nebr.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM
OUR LETTER BOX

Fair Report for 1888.—Mr. Wm. Crouley, Redwood Falls, Nebr., writes:

My report for 1888 is fair. I have obtained something over 3,000 pounds of honey from 48 colonies, spring count, and increased them to 84 colonies and several nuclei. I will send a detailed report of the season when I have more time.

Bees in Good Condition.—Theo. Johnson, Fairbury, Nebr., on Nov. 17, says:

Bees in southern Nebraska only produced about one-fourth as much surplus as usual, but they are all in excellent condition for winter. The honey is of a fine quality, and nearly all in the market.

Feeding Bees for Winter.—Mr. Lemuel Stout, Philadelphia, Pa., Nov. 17, 1888, writes:

I have never lost a colony of bees in wintering. I use the "Hill device" on the summer stands. I have carried the hives one at a time into the kitchen, as late as the middle of November, the colonies having sugar stores of 12 pounds of sugar to 6 pints of boiling water, with no acid, and no further cooking after the water is added. Furthermore, about once a week, on a sunny day, I take the covers off of the hives, raise the cotton, open the muslin door, and take a peep in. Some of them cluster on the muslin, and some down among the frames. I do not recollect ever seeing published how fast they will take food. I placed 18 pounds of syrup in a long tin vessel, on one of my hives, at 3 o'clock in the afternoon, and at 6 o'clock the next morning they were running over the bottom of the vessel, averaging 1 1-5 pounds per hour.

Smoking Bees, etc.—T. F. Kinsel, Shiloh, O., on Nov. 19, 1888, writes:

In reading the article on "Bee-Keeping," on page 748, I was particularly attracted by the part of it relative to "smoke." The remarks, if heeded, may be worth the price of the AMERICAN BEE JOURNAL for a year. I have often heard men remark, "Bees won't sting me." It is not true. Bees, at times, without smoke or something to subdue them, will sting the oldest bee-master in the world, if jarred or irritated. When men "never get stung," they, perhaps, only go among bees to handle swarms, or when honey is coming in freely, when there is really but little danger unless an accident occurs. Let such men hive swarms when they have become mixed up in the air, or have been fighting—such bees sometimes become savage, and are dangerous to handle

even with a good smoker. I never use a veil or gloves, yet a good smoker I consider indispensable, especially when doing the last extracting, or preparing the bees for the cellar.

The season here has not been a good one for surplus honey, though the brood-chambers are well filled with bees, and honey enough for winter use.

Shaking Bee-Disease—Mignonette.—Frank Waring, Philipsburg, Pa., on Nov. 19, 1888, writes:

Last spring I had 2 colonies of bees which I thought had symptoms of the "shaking disease." Their queens had been reared from one which I had bought. I had read, in the BEE JOURNAL, of people curing the shaking disease by pouring salt brine over the frames. I thought that I would try feeding salt brine in the open air; so I procured a small trough, put salt and water into it, and placed it near the hives, but not a bee was seen on it until after one night, when it rained hard, overflowing the trough; the next morning the bees were busy, and continued working on it for weeks. I filled it up with water, and added salt to suit their taste. All signs of the shaking disease disappeared before fall.

This fall my sister had one small plot of dwarf mignonette, one of mammoth mignonette, and one of Alsike clover, in bloom at the same time, the first crop of Alsike having been cut off when in bloom. When the small mignonette had 20 or 30 bees on it, the mammoth would have about half as many, and the Alsike clover would have 2 or 3 bees on it. If we had plenty of that small mignonette it would keep bees from robbing late in the fall, when the frost has killed more tender plants.

A Magnificent Present

For every one who will send us a Club of five new subscribers for 1889, before next January. All the remaining issues of this year free to new subscribers.

Price, in best English cloth binding (size, closed, 11x14 inches; opened, 22x14 inches), \$4.50.

To any one sending us, direct to this office, **FIVE NEW Subscribers** for one year, with \$5.00, (renewals not to count) we will present this beautiful Atlas, by mail, postpaid.

We have purchased one of them for our own use, and regard it as a valuable acquisition to our library. It is handsomely bound and contains a fund of very useful knowledge. It contains 192 pages.

THOS. G. NEWMAN & SON,
 923 & 925 W. Madison-St., - CHICAGO, ILLS.

Honey and Beeswax Market.

CHICAGO.

HONEY.—We quote: White clover 1-lbs., 18@19c.; 2-lbs., 16@17c. Good dark 1-lbs., 15@16c.; 2-lbs., 13@14c. Buckwheat 1-lbs., 14@15c.; 2-lbs., 12@13c.—Extracted, 7@9c. depending upon quality and style of package. Receipts increasing, but demand still limited. Stock is not selling as freely this season as a year ago.

BEESWAX.—22c.
 Nov. 13. S. T. FISH & CO., 189 S. Water St.

CHICAGO.

HONEY.—It is selling fairly well at 18c. for best 1-lbs.; very fancy lots have sold at 20c. Dark and yellow comb sells slowly at 13@16c. Extracted, 7@9c. according to quality and style of package. The stock of best comb honey is light.

BEESWAX.—22c.
 Nov. 22. K. A. BURNETT,
 161 South Water St.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lbs., 18@20c.; 2-lbs., 16@18c. Good dark 1-lbs., 16@18c.; 2-lbs., 15 to 16c.; fair 1-lbs., 12@14c. Extracted, white, in kegs and ½-barrels, 8@9c.; amber in same, 7@8c.; in pails and tin, white, 9@9½c.; in barrels and half-barrels, dark, 6@6½c. Market steady and supply ample for the moderate demand, but present values have a tendency to restrict general consumption.

BEESWAX.—22@23½c.
 Oct. 25. A. V. BISHOP, 142 W. Water St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lbs., 15@17c. 2-lbs., 14@16c. Fair white 1-lbs., 14@16c.; 2-lbs., 13 to 15c. Extracted, white, 7½@8c.

BEESWAX.—23½c.
 Sep. 17. THURBER, WHYLAND & CO

NEW YORK.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 13@14c. Fair white 1-lbs., 15@16c.; 2-lbs., 12c. Buckwheat 1-lbs., 11@12c.; 2-lbs., 10@11c. White extracted, 7@8½c.; buckwheat, 5½@6½c.; California extracted, white sugar, 7½@7¾c.; amber, 7¼@7½c. Demand good and prices firm. New comb honey is arriving quite freely.

BEESWAX.—23@23½c.
 Oct. 10. HILDRETH BROS. & SEGELKEN,
 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—White 1-lb. sections, 12@12½c.; 2-lbs., 12@14c.; amber, 8@10c. Extracted, white, 6½@6¾c.; light amber, 6c.; amber and candied, 5¼@5½c. For comb honey the demand is light; for extracted it is good, and market firm.

BEESWAX.—Dull at 18@22c.
 Nov. 15. O. B. SMITH & CO., 423 Front St.

DETROIT.

HONEY.—Best white 1-lbs., 17@18c. Supply is better. Extracted, 8@9c. Sales slow.

BEESWAX.—22@23c.
 Nov. 17. M. H. HUNT, Bell Branch, Mich.

CINCINNATI.

HONEY.—We quote extracted at 5 7/8c. per lb. Best white comb honey, 16c. Demand slow.

BEESWAX.—Demand is good—20@22c. per lb. for good in choice yellow, on arrival.
 Nov. 12. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—Choice 1-lb. sections, 18c; dark 1-lbs., 14c.; 2-lbs., 13c.; dark 1½. White extracted in 80-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock fair.

BEESWAX.—None in market.
 Sep. 27. HAMBLIN & BEARNS, 514 Walnut St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 17½@18c.; 2-lbs., 14@15c. Fair 1-lbs., 14½@15½c.; 2-lbs., 11@12c. Extracted, fancy white clover, 7½@8½c.; California white in 60-lb. cans, 8c.; light amber, in same cans, 7½c.; amber, 7½c. Buckwheat in kegs and barrels, 5½@6c. Cuban, in barrels and ½-barrels, 65c. per gallon.

Sep. 26. F. G. STROHMMEYER & CO., 122 Water St.

BOSTON.

HONEY.—We quote: Best white clover 1-pounds, 17@18c.; best 2-lbs., 16@17c. Extracted, 8@9c. The receipts are very light, and honey sells fairly well.

Nov. 12. BLAKE & RIPLEY, 57 Chatham Street.

KANSAS CITY.

HONEY.—White 1-lbs., 17c.; fair, 14c.; California white 1-lbs., 17c.; 2-lbs., 15c. Extracted white California, 7½c.; amber, 7c.

BEESWAX.—None in the market.
 Nov. 22. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—We quote: Extracted in barrels, 5@6c., according to quality; in cans, 7@8c. Comb, 12½@15c. Prices firmer on account of scarcity, though the demand is not great.

BEESWAX.—21c. for orange.
 Oct. 17. D. G. TUTT & CO., Commercial St.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6½ cents; light amber, 6@6½c.; amber, 5½c. Comb, white 1-lbs., 13@14c.; 2-lbs., 13c. Light amber 1-lbs., 12@13c.; 2-lbs., 11@12c. Demand very active for extracted, and fair for comb honey.

BEESWAX.—20@21c.
 Nov. 6. SCHACHT & LEMCKE, 122-124 Davis St.

EDITORIAL BUZZINGS.

Patience, O mortal, Patience yet awhile!
How long soe'er thy evils here, the gates
Of glory do but wait to open wide
For him who waits!

Typhoid Fever, says the *Canadian Bee Journal*, has laid low two of the children of Mr. G. A. Deadman, of Brussels, Ont. He and the entire household were stricken with the fever, but they have recovered. Our sympathy is with our brother in his affliction.

The Langstroth Fund has had quite a boost, by a contribution from our English brethren amounting to about \$12. This was forwarded by Mr. Thos. Wm. Cowan to Dr. C. C. Miller, and by the latter sent to Mr. Langstroth. The following letter of acknowledgement is published in the *British Bee Journal* for Nov. 15, 1888, which has just come to hand:

MY DEAR MR. COWAN:—Yours of the 5th inst., with 23l 5s. 6d. for the Langstroth Fund, is received. It is not necessary that I should offer any words of thanks to you and your countrymen for your aid in this worthy work, for the reward comes with the doing; yet I would do violence to my own feelings did I not express to you my deep feeling of gratitude that God has prompted you to this act. I am sure I know the bee-keepers of America well enough to say that I am speaking for them when I say, "Thank you, thank you." Surely such things bring us nearer together. The ocean is not quite so wide as it was. The bond of friendly feeling between the two countries grows stronger each day; and if I were ever to stray so far from these "western wilds" as to find myself on "Albion's green isle," I am quite certain I could sing "God Save the Queen!" as heartily as any of you.

Most cordially yours,

C. C. MILLER.

Marengo, Ills., Oct. 24, 1888.

Our British Friends are having a fierce fight in the *British Bee Journal* over Carniolan queens and bees. The combatants are Mr. Simmins, Mr. Benton, Mr. Blow and "Amateur Expert." The editor and sub-editor of the *British Bee Journal* also take a hand in the controversy—Mr. Blow's last article being written from Wisconsin. After one of these articles by "Amateur Expert," in the issue for Nov. 15, he remarks as follows concerning the annual convention at Columbus, O., and our article on European adulterated honey, in the *AMERICAN BEE JOURNAL* for Oct. 24, 1888, on page 691:

Now let us cross "the pond." While we are stinging each other in this fashion, our friends over yonder have been holding a big convention at Columbus, Ohio. Mr. E. Secor, the bee-men's *Lauricate*, has composed two "bee-poems," and Dr. Miller has set them to music; consequently, they sing these hymns in the meetings as Cronwell's "Ironsides" sang when on the march. We shall have to get a piano at Jermy Street for the "Annual," so that we too may have a harmony. Would it not be a strong inducement for more to attend? You will find the music and words in *Gleanings* and the *AMERICAN BEE JOURNAL*.

Talking about the *AMERICAN BEE JOURNAL*, reminds me friend Newman has been giving us a poke in the ribs over *adulteration*. He finds "C. Lyle patented a mixture in England (patent No. 8863) of grape sugar, fruit sugar, and glucose (dextrose, levulose, and glucose), with the addition of fruit essence, and thinks this compound is equal to any natural honey." Mr. Newman wishes to know what we know about it, or if it is only a "joke," as "adulterated beehives" in America, that we are so fond of talking about, are only a joke. Perhaps Mr. Hooker will look up the patent when he next goes to the Patent Office. As to the stuff, I do not know if any is made from Lyle's prescription, but I do know that all our grocers sell what they call "honey syrup," at five-pence per pound. It is light-colored, like clover honey, does not granulate, is evidently flavored with some essence, and is presentable both to the eye and the palate. I cannot find that any one buys it for "honey" but perfectly understands it is a manufactured article, consequently no harm is done; and that is altogether a different matter from the bogus honey put up by purveyors and sold as the product of the bee at more than double price.

Honey Jumbles.—When at the Columbus convention we purchased a package of the honey jumbles which were being sold in the building devoted to the bee and honey exhibit, by a young man in charge of A. I. Root's exhibit. They were nice. This is a description of them from *Gleanings*:

One of our men sold in a few days seven barrels of these honey cakes, and could have sold a good many more had he been able to get them from the factory before the Exposition closed. At one time he sold two barrels in about twelve hours. Now, the particular point about this lot of jumbles that made them sell, is, that they were a year old, and yet they were just as nice to eat as the day they were baked, and not one of the great crowd took a single exception to them. This is the great point in using honey for making jumbles. You can keep them just as long as you choose, and they do not get dry and hard, like cakes made of sugar or molasses. Possibly under some circumstances they may dry up; but by placing the barrel in the cellar, or anywhere else where it is a little damp, they will very

soon become soft and delicious, and yet there is no danger of mold or anything of the sort.

A B C of Bee-Culture.—The 37th thousand of this excellent book by A. I. Root, of Medina, O., is now published, and a copy of it is on our desk.

The book has been thoroughly revised, and brought down to the present day. Our ever-changing pursuit demands these revisions every year or two, in order to keep abreast of the times. The book now contains 400 large double-column pages of closely printed matter, and over 300 engravings; many of which are executed in the best style of the art. Generally speaking, the printing is also done very creditably, though some of the engravings are not up to the mark in the matter of press work. About 50 new engravings have been made for this edition, and about 50 pages of entirely new matter have been added to the body of the work in addition to the other new matter under various headings, to take the place of the discarded matter.

At the end of the book we discover 16 pages devoted to biographical sketches of some of our prominent apiarists, accompanied with illustrations. These are mostly from the fertile pen of Dr. C. C. Miller, of Marengo, Ills., who has given in a condensed form biographies which are very interesting.

The author of the book gives the following concerning it in *Gleanings in Bee-Culture* for November:

In 1880 we employed G. M. Doolittle to carefully read the A B C and point out such faults and add such suggestions as his large experience might dictate. His comments have been found to be so valuable that we thought best to employ a no less practical and extensive bee-keeper, Dr. C. C. Miller, to perform the same task on the present edition. He did so, adding his comments, or suggestions, to the latter portion of the work. The experience of two such *every-day* bee-keepers, confirmatory, in the majority of cases, on various topics brought up in the A B C book, will be found to be exceedingly valuable to the reader....

Nothing but that which is known to be *thoroughly practical* has been admitted to its pages. In other words, every subject has been treated from a dollar and cent point of view. Strict attention to this particular, more than to anything else, has given the A B C enormous sales. Although we have added greatly to the value of the book, as well as to its cost, the price will be the same as heretofore—\$1.25 in cloth; \$1.00 in paper, postpaid.

This book and Prof. Cook's are well worth the prices at which they are published, and we cannot do better than to advise every apiarist to get *both* and study them well. Prof. Cook's is more full and valuable on the anatomy and physiology of bees, while Mr. Root gives interesting details about all the implements used in the apiary, and how to make them. Much of the new matter in the latter is in reference to hive-making, comb honey, comb foundation, swarming and rearing queens.

We are well pleased with these new books for 1888, and specially recommend them both to the craft in general.

GLEAMS OF NEWS.

Paris Exposition.—It will be seen from the following circular letter of the Representative of the United States Department of Agriculture that the work of preparing the collection for the exhibit of this Department alone is no small undertaking. An idea of the collection in the aggregate can be imagined when we remember that agriculture is only one of the nine groups, into which the exhibit of the United States is divided:

By joint resolution approved May 10, 1888, Congress formally accepted the invitation of the French Republic to take part in the Paris Universal Exposition of 1889, and made an appropriation to defray the expenses incident to the collection and installation of the American exhibit. It was provided that a commissioner general, and an assistant commissioner general should be appointed to frame rules and regulations for the undertaking, and, under the direction of the Secretary of State, to control the expenditures to which it might give rise; and that as assistants to the Commissioner General, nine scientific experts, to be assigned to the nine groups into which the French authorities have divided the Exposition, should be appointed by the President. It was furthermore made the duty of the Commissioner of Agriculture to collect and prepare suitable specimens of the agricultural productions of the several States and territories.

In accordance with the provisions of this resolution of Congress, arrangements have been duly made between Gen. William B. Franklin, Commissioner General, and Norman J. Colman, Commissioner of Agriculture, for preparing that part of the exhibit for which the latter is responsible.

The undersigned, having been appointed by the President as one of the assistants to the Commissioner General, and assigned to Group VIII (agricultural products), has also been designated by the Commissioner of Agriculture as his representative to prepare the agricultural exhibit, and a board has been formed in the Department of Agriculture, consisting of the undersigned, Mr. William Saunders, Mr. O. D. La Dow, Mr. M. Trimble, and Dr. D. E. Salmon, to consider and decide upon all questions relating to the agriculture exhibit.

A sub-division of the work into various branches has been made, to facilitate the collecting and preparing of material for the exhibit, and special agents have been assigned as follows:

1. Grains—Mr. George William Hill, of St. Paul, Minn.
2. Citrous and other Fruits—Mr. H. E. Van Deman, of the Department of Agriculture, Washington.
3. Cotton and Fibres—Col. Jas. R. Biford, of Duck Hill, Miss., and Mr. Charles Richards Dodge, of Boston, Mass.
4. Viticulture—Mr. B. F. Clayton, of New York, and Mr. George Husmann, of Napa City, Calif.
5. Tobacco and Peanuts—Mr. Alexander McDonald, of Lynchburg, Va.
6. Agricultural Education and Experiment Stations—Prof. W. O. Atwater, of this Department.
7. Vegetables, including Hops and Cranberries—Mr. M. G. Kern, of St. Louis, Mo.

8. Entomology, including Apiculture and Silk-Culture—The undersigned, Mr. N. W. McLain, of Hinsdale, Ills., and Mr. Philip Walker, of this Department.

9. Forestry—Prof. B. E. Fernow, of this Department, and Mr. M. G. Kern, of St. Louis, Mo.

10. Sorghum and other Sugar Plants—Prof. H. W. Wiley, of this Department.

11. Grasses and Forage Plants—Dr. Geo. Vasey, of this Department.

12. Meat Products.—Dr. D. E. Salmon, of this Department.

In addition to the foregoing divisions of the exhibit the heads of Divisions of the Department of Agriculture have been called upon to make contributions and their several specialties as follows:

Methods of collecting and of sending out seeds—Mr. W. M. King.

Mammals and birds injurious or beneficial to agriculture—Dr. C. Hart Merriam.

Illustrations of the principal fungus diseases of agricultural products—Prof. B. T. Galloway.

Illustrations of the methods of discriminating between adulterated and pure food products by microscopic methods—Dr. Thomas Taylor.

General Agricultural Statistics—Dr. J. R. Dodge.

The attention of all who intend or wish to become contributors to the agricultural exhibit, is called to the necessity of putting themselves into communication with this office, either directly by mail, or through the special agents who are already in the field. The time remaining, though ample, if exhibitors are prompt in making their purposes known, is yet so short as to leave little margin for delay.

It is intended, as far as practicable, to show not only the varied products of the country by samples, but also by means of photographs and models, the methods and processes of cultivating, harvesting and preparing for the market.

While it is the purpose of the Commissioner to make the display one that will be creditable to the country at large, yet the advantages to follow from the spread of information, among foreign peoples, as to the great variety and unrivaled qualities of American agricultural productions, are designed to accrue directly to individuals and associations who may contribute of their products to the enterprise. The name and locality of the exhibitor will be plainly affixed to every exhibit, and will appear, as well, in the official catalogues of the Exposition.

Materials contributed in bulk will be placed in suitable receptacles for display, at this office, and all exhibits will be transported to Paris, cared for, and returned free of cost to the exhibitor.

Organizations desiring to prepare, at their own expense, more elaborate exhibits of the products of a given locality, should communicate at once the extent of floor or wall space they desire.

All materials designed for the Agricultural exhibit must be in Washington not later than the middle of January, 1889, and must be carefully addressed to the undersigned and marked, as must all letters, *Paris Exposition.* C. V. RILEY,

Representative.

Ancient Foolishness.—The following very quaint extract was taken out of a book entitled, "Speculum Mundi; or A Glasse Representing the Face of the World," written by John Swan, M. A., 1835, by T. Bonner Chambers, F. L. S., and sent to the *British Bee Journal* for publication. It exhibits the ignorance about bees 250 years ago:

BEEES.—These be those winged workmen, which whether their profit or admiration be greater, I am scarce able to say. For they do not only busily bestirre themselves to gather hooy, which is very usefull in the life of man; but they do work it up in most strange manner, and keep it in their waxen cells so rarely built that all the men which the world affords are not able to do the like. Neither is this all: for they live so, as they may be true patterns of needfull government, keeping themselves under the subjection of a king, and order of laws. They may well be likewise said to have the sovereignty and pre-eminence above all others of this kinde, because the rest come farre short of their perfections.

It is a creature having foure wings, and bloudesse, the onely crafts-master of honey. Their eyes are somewhat of a horny substance, hid deep in their bodies, as is also their stings; which when they lose they die:

Vitam in vulnere pronunt:

because their sting and entrails come away together. They want neither tongue nor teeth, and out of their short feet or stumps, there grow forth as it were two fingers, wherein they carry a little stone, for the poysing their bodies in stormy, windie, tempestuous weather; it being a great means to keep them from blowing away and losing their homes.

Neither can it be denied but that by nature they are much different: for some are more domestical and tame, and others again are altogether wilde, uplandish, and agrestial. Those former are much delighted with the familiar friendship, custome, and company of men; but the other can in no wise brook or endure them, and therefore they keep their trade of honey-making in old trees, caves, and such like other holes.

As for their breathing, I do not believe it; howbeit they may pant, move, or stirre (as the heart or brain doth), and by transpiration be comforted and made lively: for they be much refreshed by the aire which passeth through their divided places, inso-much that they alwayes use great diligence and care to preserve them from being stopped: for as soon as they be stopped in those passages, they die; as we see if at any time they chance to fall into oyl, or the like liquour, which may stop their pores.

Some make three kings amongst them, differing in colour, as black, red, and divers coloured; but perhaps there is rather one king in a companie, the other like kings may be esteemed as viceroyes. In their breeding, they actually couple together, after which they lay eggs, setting upon them for the space of five and fourtie dayes; then do they hatch their young ones, which at the first come forth much like to white worms, except the king, who only is said to be hatched with wings. And sometimes there is a kinde of bee bred out of putrefaction, as authors write. A rotten horse breedeth wasps; a dead calf bees, if the west wind blow; from an asse proceed humble-bees; of a mule, hornets, etc. And whether the bees in Samson's dead lion were bred anywhere else, no man knoweth.

There will be a meeting of the Susquehanna County Bee-Keepers' Association at the Court House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a. m. H. M. SEELEY, Sec.

QUERIES AND REPLIES.

Two Colonies in One Hive in the Spring.

Written for the American Bee Journal

Query 594.—The hives I use take 10 and 12 Langstroth frames, and the hive-entrances are 7 or 8 inches long. Would it be a good idea, in the early spring, to put one of the division-boards in the centre of the hive, thus making two divisions, using the 10 or 12 frame—5 or 6 frames in each division, and put in two queens, one in each apartment, and arrange an entrance-slide in the center of the entrance, so as to make two entrances; and when they have bred up strong, to remove one of the queens, take the division-board from the center, and put the brood from the two divisions in the centre, and take away the entrance-slide?—New York.

It looks practicable, if you have the queens.—MRS. L. HARRISON.

I have found such an arrangement to work nicely.—A. B. MASON.

In early spring, one good queen can lay more eggs than the bees can care for.—G. M. DOOLITTLE.

This would answer all right experimentally; but *practically*—"it never would do."—WILL M. BARNUM.

I think that the plan is too cumbersome to pay.—M. MAHIN.

I have had but little experience in this line. It looks well, but does not "pan out" all right.—H. D. CUTTING.

No. One queen, if good, will lay all the eggs the whole colony can take care of in the spring.—R. L. TAYLOR.

Your plan will work, but I would arrange the entrances at opposite sides of the hive.—J. M. HANBAUGH.

Your plan has some plausibility about it, but practically I fear in the end there would be little gained.—J. P. H. BROWN.

Theoretically the plan is all right. There is a quicker and cheaper way to get what honey a field affords.—JAMES HEDDON.

I always practice contraction in the spring, though I only keep one colony in each hive. Dr. Miller puts 2 colonies in each hive in winter, I think, and likes it.—A. J. COOK.

I should prefer to keep the bees all together, rather than to attempt to split them up. One queen is sufficient in the spring.—J. E. POND.

No; that is not practical. It looks better in theory than in practice. A good queen, after a good wintering, will fill your 12 Langstroth frames with brood.—DADANT & SON.

No doubt but your plan will work well, but it occurs to me—where would you get *two* queens for each hive in the early spring? I find it no easy matter to furnish all my colonies with one good queen each, in the early spring.—G. W. DEMAREE.

That would undoubtedly work all right if one liked so much *fussing*; but I should prefer smaller hives and less manipulating of the frames.—EUGENE SECOR.

This may work well, but if a colony is strong enough to make two 5-frame nuclei, I would prefer to contract it to its capacity, and let one queen do the business.—P. L. VIALLO.

Everything will work nicely until you come to separate them. Then, if not careful, you will give one queen all the flying force. With the plan given in "A Year Among the Bees," I have no trouble in letting each queen keep her own bees.—C. C. MILLER.

This plan might work very well, but I do not see where you would get your extra queens so early, unless you practice doubling up. I have experimented some on this line, but I have not yet decided whether it is of any advantage. Give it a trial and report in the AMERICAN BEE JOURNAL.—C. H. DIBBERN.

No, do not do it. If a good queen cannot fully occupy the hive before the honey-yield, the hive is too large, that is all. If the queen cannot populate a hive of the proper size, get a new queen. The bee-keeper should work his bees in wholesale lots, and avoid puttering.—J. M. SHUCK.

We can see no advantage in the plan proposed, for one good queen will lay all the eggs required, and all that can be taken care of. The fuss and extra labor would not pay, especially if the apiarist has anything else to do; and the *separation* in the spring may cause more trouble than you expect. Besides, to obtain the extra queen required when dividing, and to profitably employ them after uniting, will be a problem to solve.—THE EDITOR.

Frames for Producing Extracted Honey.

Written for the American Bee Journal

Query 595.—When working for extracted honey, and the tiering-up system is practiced, suppose the bee-keeper uses the Langstroth brood-frame, would it not be more desirable, and would not more honey be secured by using frames $\frac{1}{2}$ the depth; or if that is thought to be too shallow, say 6 or 7 inches deep, and the same length as the Langstroth frame, instead of using the frames in the upper story the full depth of the Langstroth frame?—New York.

I think not.—WILL M. BARNUM.

I believe it would.—EUGENE SECOR.

I prefer a uniform frame above and below.—J. M. HANBAUGH.

I think not, judging from my own experience.—MRS. L. HARRISON.

I use full-depth frames for extracting.—G. M. DOOLITTLE.

I think not. I believe that we cannot afford two sizes of frames.—A. J. COOK.

I prefer a shallow frame for top-storing for extracted honey.—J. P. H. BROWN.

This will give you more frames to manipulate; hence extra labor and no more surplus.—P. L. VIALLO.

The shallow frames are better if you do not mind having two kinds of frames.—C. C. MILLER.

We decidedly prefer frames 6 inches deep, after having tried different kinds side by side for years.—DADANT & SON.

Many of our most successful bee-keepers use a 5-inch frame, Langstroth length, with the best results.—H. D. CUTTING.

I have used half Langstroth depth frames for extracting over 15 years, and I prefer them to full-depth frames.—JAMES HEDDON.

I think that no more honey would be gathered by using shallow frames in such a case, and their use might, or might not, be more desirable, according to the other circumstances.—R. L. TAYLOR.

For extracted honey I prefer a frame not more than 6 inches deep in the clear. Those that I use are $5\frac{1}{2}$ inches, and they seem to be just right.—M. MAHIN.

This is a question on which there has been considerable discussion. I prefer the regular Langstroth frame. I think that the question is a local one, and wholly a matter of individual preference.—J. E. POND.

I think that good results could be secured with frames $\frac{1}{2}$ the depth of the Langstroth frames. I prefer a frame 7 inches deep, but about 4 inches longer than the Langstroth, and would use these to tier up for extracted honey.—C. H. DIBBERN.

For shallow supers, I make them just right to hold a frame that will just take in a $4\frac{1}{4} \times 4\frac{1}{4}$ -inch section; so if I want to use sections, I put in brood-frames. When the bees require more room than is furnished by the shallow super, I remove it and put a full story in its place, using the Langstroth frame, and place the shallow super, if not completed, on a weaker colony.—A. B. MASON.

According to my experience, extending through eight or ten years, I would say yes, if the shallow frames are properly adjusted in cases suitable to the tiering-up system. I would not advise frames more than 6 inches deep. I make mine a fraction less than 5 inches deep, so that 2 frames will go in the extractor made for the standard Langstroth frame. When the season

is very good, I use the standard size of supers interchangeably with the shallow cases, on the strongest colonies.—G. W. DEMAREE.

The honey-yield never depends upon the kind of hive, nor the shape of the frame. Flowers yield honey, if any is gathered; bees are the gatherers, and the combs are the vessels to hold the honey. We may get more honey in a marketable shape by some method than we may by another, but if the flowers yield, and the colonies are strong, and storage room is abundant, a "log gnm" will hold as much as the finest hive in the world, of the same capacity. (Give me credit for priority on this statement. I think that I have a "moral right" to it.)—J. M. SHUCK.

Economy would probably decide this question in the negative. Two sizes of frames are not only undesirable, but unnecessarily troublesome and laborious in the manipulations of the apiary.—THE EDITOR.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the *American Bee Journal* must be sent with each order for another paper or book:

Convention Notices.

☞ The Nebraska State Bee-Keepers' Association will convene at Lincoln, Nebr., on Jan. 9, 10 and 11, 1889. J. N. HEATER, Sec.

☞ The annual meeting of the Ontario Bee-Keepers' Association will be held at Owen Sound, Ont., on Jan. 8 and 9, 1889. W. COUSE, Sec.

☞ The twentieth annual convention of the New York State Bee-Keepers' Association will be held in the City Hall, Syracuse, N. Y., on Dec. 11, 12 and 13, 1888. G. H. KNICKERBOCKER, Sec.

☞ The 23rd annual meeting of the Michigan State Bee-Keepers' Association will be held in the Council Room at Jackson, Mich., on Dec. 12 and 13, 1888. Greatly reduced rates have been secured at the Huron House, also at the Commercial House (near the Michigan Central depot) at \$1.50 and \$1.00 per day. A programme is being prepared and excellent essays are already promised. Any bee-keeper having anything new and useful, and finding it impossible to be present, can send it by Express to Jackson in care of the Secretary who will place it on exhibition and return it as per orders. Please to come and bring your bee-keeping friends with you. H. D. CUTTING, Sec.

CORRESPONDENCE.

HONEY-BEES.

Ancient Apicultural History and Literature.

Written for the *American Bee Journal*
BY HENRY K. STALEY.

Bees have been known to man since the highest antiquity, then living in trees, caves, box-hives, or the conical straw-skeps and other rude habitations prepared by the ancients. That they existed long before the Christian era, we have the Bible as our testimony. Who has not heard of the "land flowing with milk and honey?" or of Samson, how that, when he went down to Timnath, to view his girl, he came upon a young, stalwart lion, which he rent with his hands? or, how that, after a time, when he went to take her to wife, turning aside to the vineyard, he found the carcass of the dead lion inhabited by a populous swarm of busy bees, from whose ossiferous domicile he partook of the honey and ate, also offering some to his parents?

And growing out of this came that mighty riddle of riddles, which he put forth at the marriage feast, completely dumb-founding the would-be expounders, viz: "Out of the eater came forth meat, and out of the strong came forth sweetness." A beautiful thought this is indeed, how that out of a lion's carcass could come that sweet, delicious honey, which the bees can gather from the reddest clover tops to the whitest buckwheat blossoms. No wonder it tempted Samson, for what boy or girl, when buckwheat cakes are in season, does not desire the smooth-healing honey for a covering?

It was on this riddle that Samson declared, that if within the seven days of the feast they could declare it unto him, then he would donate them 30 sheets and 30 changes of garments; but if then they could not expound it, he then was to receive the same from them. At first not being able to accomplish the desideratum, they got his wife to entice her husband to tell her the riddle, and she to them; and having plowed with his heifer (as he appelted her), until she nearly wore the life out of him, he, the man, who at his death, to be avenged of the Philistines, pulled down the pillars of a temple, thus killing more men at his death than in his lifetime; he, the man, with the new jaw-bone of an ass slew a thousand living souls, and carried off the huge doors of the gate of Gaza, bar and all, had to submit to that delicate creature—woman. And

as a sequel of this riddle, emanating from the bee, were 30 men slain at Ashkelon by Samson, to purvey goods for those who had wrongfully won the guerdon of the riddle.

This was not the end of that slight affair; for, the Philistines having burned Samson's wife, enraged him the more, so that he took 500 foxes, and, turning them tail to tail, put a fire-brand between to tails, and let them go into the standing corn of the Philistines. Thus we can see, as "great oaks from little acorns grow," terrible results from meager things may follow, as it does from those dirty and abominable apicultural lies circulated throughout the country. And I think that that carcass ought to have the praise of being the first frame hive, and possibly of giving the idea of movable-frame hives to men.

Honey as an Ancient Food.

Honey was held in great esteem by the ancients. Jacob, when he sent his sons down into Egypt, had honey as one of the gifts for the Governor. I wonder if he thought it would soften the temper of Pharaoh, or curb his tongue and ire; for you know how sweet it tastes.

The diet of John the Baptist in the wilderness was locust and wild honey; and Solomon said: "Hast thou found honey? Eat so much as is sufficient for thee, lest thou be filled therewith and vomit it;" and also, "It is not good to eat too much honey; so for men to search their own glory is not glory."

Not long after this Virgil sung of them in his *Georgics*, and especially in that renowned poem, the *Æneid*, when he compared them with the enthusiastic Tyrians, thus:

"Quidvis apes aetate nova per florea rara,
Exeret sub sole labor, cum gentis adultos
Educat letos, aut cum li gentia mella
Stipant et dulci discedunt nectare cellas.
Aut onera accipiunt venientum aut agmine facto,
Tervet opus, redolentque thyme tragantia mella."

Even this great Italian poet had to stop and muse upon these insignificant insects, which albeit they do come into close consanguinity with the dreaded tape-worm, yet they are one of God's grandest pieces of mechanism among the animal creation—microcosms in themselves.

The bee has two antennæ jointed in about twenty places. Do they not in this peculiarity resemble the tape-worm, that dreaded visitor of people? The antennæ, like the yards of a ship, seem to be the directors of the bee, for it is supposed through them that the bee is directed to the sweet-smelling flowers, or skips to the blooming orchards, and sips the balmy nectar. The antennæ are the objects of touch,

and are supposed to be the objects of smell and hearing.

The Bee's Eyes and Pollen-Baskets.

Each bee has two eyes, compound, which are composed of numerous smaller eyes, having a hexagonal shape. Prof. Frank R. Cheshire, of England, by use of the microscope, counted 6,300 of these smaller eyes on one side of a worker-bee; 4,920 in a queen, the mother of this; and in one of her sons, the tremendous number of 13,090. Think of it, one girl, by a stamp of her dainty foot, can kill an insect with more eyes than the horrible Argus had!

There are also found, on the upper part of the head, three simple eyes called "ocelli." The bee has three pair of legs, compactly located in the thorax; on the hinder pair of legs are little hairs which form the pollen-baskets.

Value of Bees in Pollenizing Blossoms.

The bees go forth and gather the pollen from the stamens of the flowers, carrying it from blossom to blossom, thus fertilizing the bloom. The bee is one of man's greatest benefactors, because it fertilizes the blossoms, thus producing fruit. To show how necessary they are for this purpose, let me quote a few examples:

First: When the spring is too cold for the bees to come out, gardeners who raise early cucumbers in hot-beds often have to transfer the pollen from blossom to blossom with tiny spoons, whereas, if the spring was warm, and the hot-beds uncovered so that the bees could get at the bloom, there would be no need of this.

Second: Red clover was introduced into Australia, and although it grew nicely, no seed of much account could be garnered, because of the imperfect impregnation without the bumble-bee. The trouble with the ordinary honey-bees is the shortness of their proboscis, that is, they cannot reach down far enough into the corollas of the red clover to fertilize them well. So nests of bumble-bees were exported over the briny deep, and with their presence came the much-desired clover seed.

Yes, truly, everything has its purposes and various functions to perform. A nest of bumble-bees in a man's clover patch—if red—providing he is raising it for seed, may be worth about \$25, or \$50, to him. But woe unto the bumble-bees when the juveniles come forth armed with broom-sticks, tea-kettles of hot water, tin-pans, bells, shingles, clubs, etc., to bombard their domicile, and lay it in ruins by *vis et armis*, although a few are rendered *hors de combat*, and go home bawling

to mamma for arnica, or lemon and salt, as an antidote.

Treating a Horse Stung by Bees.

Let me say right here, if any person should be so unfortunate as to have a swarm of angry bees alight on a sweaty horse—for they detest them when in this condition—quickly smoke off the bees, throw a blanket over the raging animal, give him a dose of laudanum, and rub him down with baking-soda, and this, if the case is a bad one, may be depended upon as almost the only cure.

Bee-Stings and Rheumatism.

A swarm of bees may contain from 5,000 to 30,000, or even as high as 45,000 bees, having one queen, a few drones, and the rest workers; so a person can see if 10,000 bees should ply their swell-producing pins, it would be enough to make a horse crazy or a man a maniac. Its effects were illustrated in that article, "A Victorious Army Put to Flight by Bees," written for *Harper's Young People*, where victory and success were turned into bedlam by the stings of bees.

One thing which they say bee-stings are good for, I must not fail to mention, and that is rheumatism. If you are in any way troubled with such in your lower limbs, procure a pair of trousers with broad legs, not forgetting to have strings ready to tie them at the bottom, so that the bees cannot crawl out. Having obtained a bottleful of honey-bees, run them up the leg of your pantaloons, and being sure you have tied the pants at the bottom, uncork the bottle from the inside of your pocket.

Now all is ready to excite the medicine and cure the rheumatism. The way to set the stingers in operation is to start and run a race with some friend, and no matter how hard they bite, persevere and they say it is a cure. This may be a "scientific pleasantry," but there is no school like the school of experience, you know.

How the Bee Gathers Pollen.

To return to the pollen-baskets: The bee gathers the farina with its tongue and the hairs of its legs and body; then by means of its tongue and legs it moulds the pollen into little balls. These balls are then taken up by the front pair of legs, transferred to the second pair, and then with the middle ones it is packed away into the pollen-baskets on the hinder ones, until it often hangs over like hay does on a wagon. Having reached its home, the pollen is deposited in a cell; then using its head as a battering-ram, the farina is compressed into the bottom of the cell.

The toad is one of the bee's deadliest enemies. In the evening it comes around to the hive and, watching its chance, it springs into the air, at the same time giving its oyster-shaped mouth a funny motion, and Mr. Bee is gone. The toad will thus catch lots of them, and grow fat off of the sweet convivium.

A Colony's Care for its Queen.

The queen is the mother-bee of the colony. She is treated with the greatest respect and affection by the bees. A circle of bees constantly environ her, or else a retinue follow after, offering her their sincere affections, either by gently caressing her with their antennæ, or feeding her with honey from time to time. If they are deprived of her, the whole colony is thrown into a state of the most intense excitement, either rushing over the combs or flying a short distance from the hive in search of their beloved mother, soon returning to join the excited throng.

Finally becoming cognizant of their terrible misfortune, the bees return to their home, and with sorrowful tones reveal their deep sense of so deplorable a calamity. All business is suspended—just as when a great human king or queen dies—and if another queen is not soon introduced, or eggs supplied from which they can rear one the colony soon perishes, wasting away in numbers, and becoming too careless to repel the ravages of the devastating bee-moth.

What scene could more minutely or pathetically describe the death of a queen or king among men, than this of a colony of bees when deprived of their mother? Upon the announcement of the death, the people rush forth from their houses, business is suspended, they gather together in motly crowds and discuss the situation, showing by their lethargic forces, hypochondriacal ways and sobbing tears the depth of their loss.

The Workers and Drones.

The workers are the neuters, or the bees that gather honey. In them lies the strength of the colony, being sometimes from 10,000 to 30,000 strong. They visit either flowers that are foul-odored, or those of a sweet, aromatic flavor, sipping up the soothing nectar, diving down into the chalice of the lily as well as the corolla of the common white clovers.

Up to about the first ten days of their lives they are the house-keepers, sweeping up the floor with their slender limbs, or propolizing the cracks to keep out the whistling wind. This propolis is gathered from flowers and

trees, delightfully described by Evans, thus :

"With merry hum the willow's copse they scale,
The Fir's dark pyramid, or Poplar pale ;
Scoop from the Alder's leaf its oozy food,
Or strip the chestnut's resin-coated bud ;
Skim the light tear that tips Narcissus' ray,
Around the holly-hocks bear fragrance play ;
That forms a fretwork for the future comb,
Caulk every chink, where rushing winds may roar,
And seal their circling ramparts to the floor."

The drone bees are the males of the hive, and, like many people, are inveterate loungers. They have no stinger, the shortness of their proboscis disqualifies them for gathering honey, their thighs are destitute of baskets for holding bee-bread, and no pouches are found on the abdomen for secreting wax.

Like the Indian to the squaw, the drones live off of the workers until those little creatures find there is no further use for the gormandizing drone, when they seize him by the neck or any other part of the body, pull him out, sting him to death, and hurling him over the alighting-board, Mr. Drone is *non est*.

Dr. Evans very appropriately describes drones thus :

"Their short proboscis sips
No luscious nectar from the wild thyme's lips,
From the lime's leaves no amber drops they steal,
Nor bear their grooveless thighs the foodful meal ;
On other's toil in pampered leisure thrive
They, lazy fathers, of the industrious hive."

Thus we see many peculiarities of people are found in the bee. There are the wild bees as there are the wild people ; the cultivated bees as there are cultivated people ; the queens with their royal retinues, the robbers plying their nefarious tricks, idle loungers, etc. So Shakespeare, recognizing this, said :

"So work the honey-bees,
Creatures that by a rule in Nature teach
The art of order to a peopled kingdom.
They have a king and officers of sorts,
Where some like magistrates, correct at home,
Others like soldiers, armed in their stings,
Make boot upon the summer's velvet buds ;
Which pillage they with merry march bring home
To the tent-royal of their emperor,
Who, busied in his majesty, surveys
The singing masons building roofs of gold ;
The civil citizens kneading up the honey ;
The poor mechanic porters crowding in
Their heavy burdens at his mansion gate ;
The sad-eyed justice, with his surly hum,
Delivering o'er to executors fate
The lazying, yawning drone."

Pleasant Ridge, Ohio.

BEE-WORK.

Methods and Implements Used in the Apiary.

Written for the American Bee Journal

BY G. P. HACHENBERG, M. D.

In my article on page 519, I advocated the superiority of a simplicity bee-smoker, but neglected to mention the kind of fuel I use with it. It is an excellent smoker with rotten wood, but the best fuel to give the best results is corn-stalks cut up in short pieces. The way I do is to fill the can

with cut corn-stalks, with a few chips of wood to hold the fire.

I ignite it with a little kerosene oil, and afterwards modify the blaze with the metallic fan. Soon a smoldering fire is established, and the smoker is fit for use. It will do any bee-man good, that has any faith in smoke for the subjugation of bees, to see the gushing volume of smoke coming from that can—not in short intervals, as in the ordinary bellows-smoker, but in a ceaseless, continued flow sufficient to last for any ordinary work on a hive.

There is another important item in the use of this smoker. A wire rack

1. Handle. 2. Place to hold the smoker. 3. Hooks to hold it.

Rack for Holding the Smoker.

is used to hold the can, so that the upper edge is level with the top of the hive. This rack, illustrated here, with its hooks, usually is adjusted, leaving the hive on the lee side.

Holding the Comb when Extracting.

Another subject that may demand an explanation is the management of

1, 1. Two lids of equal size, made of light galvanized wire-netting. 2, 2. The outside bound by tin. 3, 3. A wire to hold the lids together, and likewise serve as a hinge between the two. The two stems (3) are about an inch apart and connected. Where inside cloth of the wire is used, different hinges must be used, such as 4, to be placed at 5.

Comb Supporter for Extracting.

natural comb in the process of capping and extracting, so as to keep them from going to pieces. I mean comb not supported by wire, or made on foundation. To meet the difficulty I made a pair of wire-netting clasps to receive the comb in a way to give sup-

port to both sides, both in capping as well as extracting.

The illustration will show how this comb supporter is made.

Although I am the originator of this implement, I have good reason to be very proud of it ; for it is a good thing in an apiary. With it I meet with no vexations by injuring in the least the frailest comb. There is another use to which it can be applied. Slip it into a tin frame with a close bottom, This gives a receptacle for cappings, which in a minute can be thoroughly drained of its honey by the extractor.

Reversing Combs in Extracting.

Allow me here to suggest an improvement that could be made, in the extractor itself. In this age of lightning haste, it is a tedious operation to handle a comb twice, or oftener, in passing it through the extractor. To do good work a comb should go through a double process of extracting. This, however, is not always done for want of time. But if the drum of the extractor was a little larger in diameter, and the comb worked on pivots, so as to reverse the sides, simply by reversing the action of the crank, extracting honey could be greatly expedited. Such an extractor could be easily made, and would be cheap almost at any price.

Rendering of Beeswax.

I have tried different methods of rendering wax, and some that cost me a good deal of money. I must humbly confess that this wax business has been the "sand in my bread." Finally I made a sun wax-extractor, and was pleased with the purity of the wax it afforded me. But for an extensive apiary it is a process too slow and uncertain. The fault with a sun-extractor is that the solar heat may be sufficient to melt away surface wax, but it lacks penetration (as wax is a poor conductor of heat), and unfortunately a heavy body of it will not melt away before the rays of the sun, as would a cake of ice. And another defect is the loss of heat by conduction.

To meet in a measure the above difficulties, I took a good-sized store-box and knocked out two connecting sides of it ; these I covered with two glass windows. Inside of this box I placed a large hotel tin-tray, that I happened to have, with a sufficient incline for the melted wax to run of. The wax enclosed was exposed to the direct rays of the sun, and as it melted (by a process too slow for me) it was received in a tin basin.

To improve things I placed a kerosene lamp, burning rather low, within the large vacant space of the box—not to heat the tray as much as to com-

pensate for the loss of solar heat by conduction. By this operation I increased the flow of wax a hundred fold—and it was as free from impurities as if the sun alone had done the work.

The advent of cold weather put a stop to these operations, leaving me several hundred pounds of wax unrendered. I dumped the whole into a large water tank heated by a furnace. After the mass was all melted down, cooled, and rid of the substrata impurities, I remelted it in dry heat with a high temperature, leaving the melted wax to run through a close wire strainer into hot water.

Fastening Frames in the Hive.

In my article on page 519, I spoke of fastening the comb frames from the inside of the hive to keep them in place; but since then I have much improved on that plan, and now I fasten them from the outside with wire nails about $1\frac{3}{4}$ inches long, leaving the head end of the nail exposed nearly half an inch. In the inside the nails are forced into a groove of the upper cross piece of the frame, that is made for the narrow strip to hold the foundation or starter. The holes in the hive to receive the nails are made large enough so that they can be pushed or forced in with but little resistance.

I am now reconstructing all of my upper stories in that way, as I go along in exchanging combs in extracting. With a tin gauge the holes are always made true to their place, and made with rapidity. This arrangement will always give us nice, uniform combs, and save time and comb in capping and extracting, etc.

Exposed Honey and Robbing.

Will honey exposed in an apiary cause robbing and a demoralization of the bees? I paid considerable attention to this subject, and finally came to the conclusion that honey can be exposed with impunity under peculiar circumstances.

Perhaps it may shock some people to tell them that I often feed back refuse honey to the bees in the open air, such as extracted cappings, unwashed honey-vessels, etc. But I only do this under a healthy government of my apiary, under the assurance that all my hives are well supplied with honey, and this refuse honey is never exposed near a hive. A hungry dog is always a thief.

But mark this precaution: When I pile up three or four stories of extracted comb over a hive that has storage for honey, to have them cleaned out, I always lessen the entrance of the hive. This is to prevent robbing. Now in this there is no contradiction.

The fact is, you may expose a barrel of honey in the woods away from any apiary, and bees will take it away, but molest none of their neighboring hives on that account.

In a good honey season, when bees are busy gathering honey from flowers, such an exposure of refuse honey will not attract them, unless it may be a few smooth-back, lazy bees that wear themselves out in the friction of stealing. At one time, in the honey season, I placed a piece of comb full of honey near the entrance of a hive. In a week I removed it, and found the honey still in the comb.

It is true that I have had honey exposed, and it appeared that the robbers made a raid on several hives at the same time; but after an investigation I found that the cause was not as much in the honey that was exposed, as in some defect in the unfortunate colonies that were assailed, as being queenless, weak, that were already in a starving condition, or molested by moth, etc.

It is a good rule, as soon as a hive is raided by robbers, not only to lessen the outlet, but see what is wrong with the hive itself. A healthy colony of bees is always respected. I had one colony the past summer that had not much more than a handful of bees. All summer long it struggled for existence and for an increase. But the colony was healthy and well organized, and notwithstanding its rich neighbors, it was by them never molested in the least. But let any morbid influence be brought to bear on that little colony, the robbers by some intuition will soon find it out, and in less than an hour clean it out entirely.

Defenders and Fighters of a Colony.

There is another interesting subject in connection with the bees, that has recently attracted my attention and that is, which are the defenders and fighters of a colony? Are they a distinct class of bees assigned for that function, or are all workers warriors when the occasion demands it?

I am inclined to believe that each colony has a standing army full of fight and viciousness. This army in some hives is very numerous, in others of a very limited number. It is this that gives temper to a colony. I have some that are so vicious that it is with the greatest difficulty that anything can be done with them; others so docile and harmless that they hardly show any resistance in handling.

But what made me in particular think that the fighters of a colony are a distinct class, was the way the bees conducted themselves that happen to get inside of my honey-house, where the extracting is done. Those that

follow me in, on the warpath, would buzz around me, and often sting me even two days after their captivity; but those that got in simply for plunder, were harmless, and manifested no resistance by any handling, except they should be accidentally pressed by the fingers. These two classes I repeatedly held as prisoners for several days, in order to watch their actions in regard to this matter. I do not know that there is any physical difference between them, as I never made a microscopic examination of the two; but I might do so in some future time.

That the stinger in the worker is conclusive that it is a fighting bee, does not make it so; otherwise the queen would be as belligerent as some of the rest. In defending a hive it appears that the drones mix up some in the melee, but only as a set of noisy bull-dozers.

Austin, Texas.

MOISTURE.

Its Effects on Bees in Cellars Easily Avoided.

Written for the Bee-Keepers' Review
BY R. L. TAYLOR.

So far as I have been able to discover, there is nothing that would lead me to suppose that moisture affects the welfare of bees in any respect differently from the manner in which it operates upon the well-being of the larger animals. The problem involved in "Moisture" seems to me not to be a difficult one if we remember two facts, viz: that heat expels moisture; and that moisture furnishes an excellent medium for the escape of heat. So, it is evident that, in the discussion of this question, these two elements must be taken as independent; that is, what might be an injurious amount of moisture in one case might be perfectly harmless in another, owing to the existence of a higher temperature.

And it is plain that this matter of heat presents two aspects, viz: the internal heat, so to speak, of the clustered colony, and the temperature of the surrounding atmosphere. Each should be taken as complementary of the other—the higher the one, the lower the other may be permitted to be. The well-fed, fat and vigorous ox throws off the moisture left on his sleek hide by a shower, in clouds of vapor, even in a low temperature; while an ox of low vitality, ill-fed and lean, in the same temperature would remain wet and shivering; but if the temperature were sufficiently raised he would throw off the moisture equally as well

as did the other in the lower temperature.

We must recognize the same distinction between strong, healthy colonies of bees and those weak in numbers and vitality. While I say this, I do not think there is anything to fear from the moisture of any ordinary atmosphere. There is no danger from moisture in the dampest of cellars, only it will not answer to arrange the hives and their trappings so as to collect the moisture. If there is much moisture, the temperature must be under control and kept well up; and the hives so arranged as to favor the expulsion of the moisture. All that is necessary in order to guard against any ill-effects, even from a saturated atmosphere, is well-fed colonies of fair strength, in well ventilated hives, kept in a temperature of from 45° to 50°.

A cellar can scarcely be so dry that moisture will not drip down the inside of the hive if the temperature be low; and while this indicates too little warmth, it is not necessarily injurious. The important point is to keep the moisture out of the cluster; hence it follows that the fact that the moisture is so great that mold gathers on the comb is not in itself any proof that the conditions are unfavorable to the well-being of the bees.

Having had considerable experience with both damp and dry cellars, I am firm in the belief that there is nothing to fear from the effects of any atmospheric moisture, if one only bears in mind the principles above hinted at—providing the conditions indicated which will enable the bees to drive that moisture away from the cluster.

Lapeer, Mich.

LESSONS.

Some Lessons Taught by the Past Season.

Written for the Country Gentleman
BY PROF. A. J. COOK.

The past season has been the most discouraging one for bee-keepers in the memory of man. This seems to be true, not of one State only, or even of one country alone. Every State in our country, Canada, England, Germany—in fact all Europe—are chanting the same dirge. It would be interesting to know just the cause of this universal honey drouth. It is probable that the cause is not one-and-the-same in all the localities. In the North and Northwest of the United States, it is plainly, two; yes, even three, successive seasons of unparalleled drouth. Such continuous drouth not only dries up the nectar-fountains of the flowers,

but it also kills or dwarfs the very plants that bear the flowers.

No Adulteration.

Discouraging as has been this drouth of nectar, and consequent ill-success of honey-producers, the season has not been without its valuable lessons. One of the most baneful influences that has worked against bee-keepers for several years, is the quite general impression that honey is largely adulterated. Many like honey, and would use it, except for this wide-spread fear—bugbear, I may say—of adulteration.

The truth is that comb honey has never been adulterated, and extracted honey never by the producers. Some years ago when honey was very high-priced, extracted honey was widely adulterated. Now it is so low-priced that such adulteration does not pay, and so is discontinued. It was hard to convince people of this truth. The past two seasons of scarcity, however, have shown that this cry is wholly baseless. I have made a very careful investigation, and I feel quite sure that honey is not at present adulterated even by dealers. In showing that this accusation is false, the past seasons have conferred a very substantial benefit on the bee-keeping industry.

Bee-Keeping as a Pursuit.

Another lesson is that bee-keeping serves best as a supplementary pursuit, and not as an exclusive business. I know of farmers who have, in past seasons, secured hundreds of dollars from bees, and yet carried on their regular business with no special difficulty. In several cases, and for several successive years, the proceeds of the apiary have exceeded those of a good farm.

For physicians and ministers, bee-keeping serves even better than for farmers. Here it not only supplements the earnings, but gives exercise that often conserves the health. In every case the bee-keeping breaks the routine, and so serves as a recreation. Indeed, few industries afford more pleasure to, or awaken more studious interest in, those who wisely engage in it, than does bee-keeping.

While the past two years are very discouraging to the bee-keeping specialist who has all his "industrial eggs" in one basket, they are not at all so to the person who has other means of support. While he has secured little or no returns, he has been to very little expense, and he knows that he has a good net spread to "catch the game" when it comes. While, then, two such unfortunate seasons are severely trying to those whose only means of support are tied up in bees, they are only disappointing, not disas-

trous, to him who has apiculture as only one of the excellent strings to his industrial bow.

The past season then pronounces with emphasis that bee-keeping is not for the specialist, but for him who would add to other pursuits one that combines profit with pleasure, and, if his life is sedentary, with wholesome recreation as well. While bee-keeping has done well for the specialist, it serves better as a supplemental pursuit.

Migratory Bee-Keeping.

The third lesson of the season to the bee-keeper is the importance of honey-plants, hitherto not sufficiently appreciated. Mr. R. L. Taylor, of Lapeer county, Mich., a large and successful bee-keeper, secured only enough honey for his bees, while neighboring bee-keepers, near a large marsh, secured a remunerative harvest. So moving bees a short distance, in such years, may transform what would otherwise prove to be a failure and discouragement, into gratifying success. Henceforth bee-keepers will be on the lookout to discover how, by migratory bee-keeping, they may bridge over the disaster occasioned by unpropitious seasons.

New Honey Sources.

Again, it has been discovered this year that other than generally recognized sources of honey may come to the rescue in such years. Thus the cucumber plantations in certain parts of Illinois have not only paid the growers a good profit, but have furnished nectar, so that the bees have gathered a good harvest. Bee-keepers thus learn that it may pay a double profit to secure a pickle factory in their neighborhoods.

In Illinois, Iowa, Nebraska, etc., a large crop of honey—fine honey—has been secured from *Polygonum*, *P. pennsylvanicum*, which grows spontaneously in the corn-fields. This plant belongs to the same family as do buckwheat and smart-weed. The flowers, however, are a very bright pink, and the leaves and stems have not the pungent character that is possessed by those of the smart-weed. It grows, too, on upland, and not in low places. The bee-keepers all over the country call this heart's-ease. This certainly is a very appropriate name, and may well be transferred from pansies to this *polygonum* in all our botanies.

Special Planting for Bees.

The fact that some plants furnish nectar, even if the seasons are dry and unproductive, makes it important to test the matter of special planting for bees. Is it possible to cultivate a plant that will keep the bees busy, independent of the weather? If so,

how many acres would be required to supply 100 colonies of bees? These are questions that I have undertaken to solve, under the auspices of our Experimental Station.

I have just sowed eight acres of *Cleome integrifolia*, or the famous Rocky Mountain bee-plant. This beautiful flower blossoms from early August till frost. In Colorado it grows on the dry fields with no irrigation. It furnishes there much excellent honey. I have grown it here for several years in small beds, and find that bees are always working upon the flowers in their season. I have hope that it will prove a great blessing to bee-keepers.

I am also trying three other promising plants, and expect to show that it will pay, or else that it will not, in which latter case I will save private expenditure in similar experiments.

Agricultural College, Mich.

MARKETING.

Hives and Surplus Comb Honey Receptacles.

Read at the Central Ills. Convention
BY JOS. M. HAMBAUGH.

The hive we want is the one that will bring us the most honey, and the one easiest manipulated for the rapid storing of honey in its most marketable form.

There is, however, some prime factors to be understood for the obtaining of the necessary force to reap the very first results, for without a strong force of bees at the time of bloom, and when the elements yield up the precious nectar, our efforts will come to naught. Then I maintain now, as in the past, that we must cater to the needs of the queen as regards her power of reproduction, in order to obtain the very best results numerically from our colonies, which is a prime factor in obtaining an abundant harvest of honey; and any device, whereby the queen is hindered in rapid depositing of eggs in the proper season, is a detriment to the apiarist, and costs him many pounds of honey.

The hives, to be non-swarming, must be capable of expanding, to meet the needs of an extensive army of workers, and at the same time we should be able to quickly contract them to any small-sized nucleus; by this means we have increase practically at our command, if we will be awake and attend to the bees in their season.

As the markets call for honey in comb form, in one and two pound sections, of course our receptacles must be put up to accommodate this size of

package, and if we can persuade our bees to build the sections marketably without separators, I would advocate their abolishment; but this is a debatable question, and one not fully settled in my own mind.

The Prevention of Increase.

There is another question of more vital importance to the apiarist than the use, or non-use, of separators, in working for comb honey, and one which we believe to be more difficult of solution, viz: the prevention of increase, and how to induce the bees to work in the sections. A practical method that will solve this problem, will be a boon to the apiarist, and we will listen with interest to all arguments in that direction.

It has always appeared to me that combs the size of one pound sections were contrary to the laws governing the household economy of the bee; and when they occupy them it is with reluctance, and only under force of circumstances; their brood-chamber must be filled to its utmost capacity, with brood, pollen and honey, and then only for pastime will they cluster in the sections, and gradually deposit a small amount of honey therein, until sufficient "steam" is raised to engender the swarming fever, when out go the bees, and the sections are left as empty and void of workers as a church-house garret.

It is the swarming nuisance that is a menace to the comb-honey producer, and any surplus receptacle that will overcome this difficulty, will be a boon to the bee-man, as well as to the consumer.

I also believe that a skeleton break-joint or zinc honey-board used in the center of the hive is a detriment to the progress of the bees, more or less, and should be excluded. In manipulating for extracted honey, the case is quite different. Combs put up more in accordance with their natural instincts, can be placed above the brood-chamber, and with little or no ceremony they are quickly occupied, and the apiarist can expand the size of the surplus department to accommodate the size of the colony, by adding more combs and cases; and the force and attention of the bees being turned to honey-gathering, the swarming impulse is almost wholly overcome.

To sum up: 1. Let us see that the hives and combs are put up in a way that will give the queen a chance to develop her strength. 2. See that the surplus receptacles are arranged so that they can be accommodated to the needs of the colony, be it strong or weak, and abolish as much as possible all complicated features. Let all frames, hives and surplus receptacles

be made by a pattern, and use no other throughout the entire yard. Let all hive-stands, bodies, covers, brood-frames, etc., be interchangeable with any hive in the yard, and you will be prepared to combine pleasure with profit in your bee-keeping.

Spring, Ills.

BEE-CELLAR.

When and How to Put Bees into Bee-Cellars.

Written for the Prairie Farmer
BY MRS. L. HARRISON.

What is the best time to put bees in the cellar? October, November or December? Surely, you have me now, and I can only say, I don't know. I used to be as wise as an owl on this subject, and recommended putting them in late, thinking that there is generally a warm spell in the forepart of December, and that it would be better for the bees to have a cleansing flight during this time, before they retired for their long rest. They clean house during this mild spell, and carry out many dead bees, and I thought that they would die in the cellar, and had better be left out-of-doors. These bees that die might live much longer in the cellar, and might or might not be a benefit. If there are plenty of bees without them, then there would be no profit in feeding them longer.

A successful bee-keeper of northern Vermont told me that he always housed his bees when dampness gathered on the glass of his observing-hive. Now a thoughtful person will readily see that the right condition for housing bees will not occur in central Illinois at the same time as in Michigan, Vermont, or Iowa. I am now of the opinion that the best time to house bees in any locality, is when they hibernate, or in other words, are compactly clustered. Reports favored the putting of bees away as soon as October, at the late convention, but in this county, up to date (Nov. 15), there have been but few days when the bees were not upon the wing.

The Best Time to Move Bees.

It is during daylight, of course; "for the night cometh, when no man can work." In the morning, when the person who carries them is fresh, and has nerves steady—that is the best time of all.

Hives should be dry, and the entrances closed; then any person of sufficient strength can carry them without fear. Most inexperienced persons are afraid of bees, and if the live-entrances are open, and the hive in tran-

sit be jarred or knocked against something, the bees would rush out, and the person carrying them drop the hive, when the consequences would be very serious.

Should a cold day or a warm one be chosen for moving bees to the cellar? The night previous to moving them, I would leave the cellar open, so that the temperature would be nearly like that out-doors—a temperature of 35° would do very well. The temperature being the same, would help to keep the bees quiet. On a cold day, combs break easily, and on a warm day bees would be restless and want to fly.

When hives are covered with ice and snow, it is a poor time to handle them—unpleasant for both the bees and operator. When the bees are all carried in, leave the cellar open and the hive-entrances shut until the next morning, when they can be opened, as the bees will then be quiet, and the cellar closed and darkened.

Some bee-keepers claim that light in a cellar does no harm, but I prefer it to be dark; darkness has a quieting effect on all animated nature, and bees are no exception. It is true that no one has ever found them sleeping very soundly, but they do not leave their hive so much in darkness as in light.

Advantages of Cellar-Wintering.

One big item is the saving of stores. It is also a saving of hives, as they are protected from the elements for 5 or 6 months of the year, but the greatest good is in keeping the inmates in good health. The last 5 years we have wintered half of our bees in the cellar, and would put in more if there was room.

One winter there were as many colonies in number lost in the cellar as there were out-of-doors, but this was in their favor. Parties who came to purchase colonies in the spring, invariably chose those that had passed the winter in the cellar, as they could see at a glance that they were the most populous.

There has been a great deal said by bee-keepers about lugging hives in and out of the cellar, in comparison with chaff hives, and leaving them upon the summer stands. Two laboring men will carry 50 colonies into our cellar in less than half a day; it has no outside door, but they are taken through a window.

Peoria, Ills.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

AN AUTUMN SECRET.

Written for the *Etna*
BY J. K. LUDLUM.

I stand at the gate in the garden
And gaze o'er the level field,
Yellow and ripe in the sunlight,
That perfect harvest will yield.

Down from the broad *maple* branches
The leaves are fluttering slow,
Touched by the brilliant tipt brushes
Of elves that set them aglow.

A perfumed south wind comes stealing
And whispers among the leaves,
Then like a mischievous truant
Slips on to the ripe wheat sheaves.

The *asters* are royal purple,
And stand in kingly array,
Gallant and tall at the roadside,
Like guards of the autumn day.

They challenge the wind in passing,
But soft, he whispers a word
And all the guards bow before him
As soon as the word they heard.

And I 'neath the *maple* shadows
Behind the old garden gate—
I heard the message delivered,
And bold it inviolate.

And lo, my heart is a-kinde
With strong, and burning desire;
I glance at the branches o'er me
A-gleam with the magic fire.

Next day to the gate in the garden
Over the frost-sprent sod
I pass as a loyal subject
To welcome queen *golden-rod*.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*
Dec. 11-13.—New York State, at Syracuse, N. Y.
G. H. Knickerbocker, Sec., Pine Plains, N. Y.
Dec. 12, 13.—Michigan State, at Jackson, Mich.
H. D. Cutting, Sec., Clinton, Mich.
1889.
Jan. 8, 9.—Ontario, at Owen Sound, Ont.
W. Couse, Sec., Streetsville, Ont.
Jan. 9-11.—Nebraska State, at Lincoln, Nebr.
J. N. Heater, Sec., Columbus, Nebr.
May 4.—Susquehanna County, at Montrose, Pa.
H. M. Seeley, Sec., Harford, Pa.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Uniting Colonies, etc.—D. E. Robbins, Payson, Ills., on Nov. 19, 1888, writes:

In the report of the Union Bee-Keepers' Convention on page 747, I am said to use for uniting colonies a method that is hardly what I intended, through some misunderstanding. We were discussing the prevention of increase, and after several plans had been given, I remarked that the method of preventing increase by uniting colonies had not been touched. Having last summer a number of colonies with mismatched queens, and not wishing so many colonies, I removed the poor queens, and in one, two, or three days thereafter, I united the queenless colonies with the weaker of those hav-

ing pure queens, in some instances by alternating the combs of the colonies, and in other cases by placing the hive containing no queen, on top of the other. (I use the Simplicity hive.) This I did at any time of the day when most convenient; but it was during a good honey-flow, and in every instance proved a perfect success. Some discussion followed as to the danger to the queen, and some advised always caging the queen; then I remarked that I paid no attention to that. This proved profitable under the circumstances, as the two weak ones united made a first-class colony, and gave much more surplus than both would if kept separate. The best united colony gave 170 pounds of extracted honey; the best yield from a single queen was 150 pounds, which weighed over 12 pounds per gallon.

Bees did Fairly Well.—Wm. Shier, Marlette, Mich., on Nov. 22, 1888, says:

I commenced last spring with 15 colonies in a rather indifferent condition. I lost half of my bees in wintering, consequently the surviving ones were quite weak. However they did fairly well, having increased to 31 good colonies, and produced 1,100 pounds of fine comb honey in one-pound sections. I winter my bees on the summer stands, in chaff hives.

Well Supplied with Winter Stores.—J. M. Young, Rock Bluffs, Nebr., on Nov. 23, 1888, writes:

Bees throughout this section of the country are well supplied with stores sufficient to last them until honey comes again in the spring. My apiary of 60 colonies has been in charge of other parties a portion of the past summer. My attention being called away on other business the most of the time, hence the bees have not received the care and attention that they should have had, and only a part of a crop of honey has been obtained, and that being comb honey. From this time on I expect to be with the bees, and give them my personal attention. But few swarms have been obtained by bee-keepers throughout this neighborhood. Comb honey is selling for from 18 to 20 cents per pound. There is not much extracted honey on the market; it is selling at from 12 to 15 cents per pound.

Bees in a Raging Storm.—Henry Alley, Wenham, Mass., on Nov. 26, 1888, writes:

For the last 24 hours a terrible storm of wind, rain and snow has raged. My bees have suffered some from the water, as it was impossible to keep the caps on all the hives.

Photography and Bee-Keeping.—Geo. A. Walrath, Norwood, N. Y., on Nov. 12, 1888, writes:

How would it do to combine bee-keeping with photography? I live in a town of about 1,600 population, and have a good photographic business, but I find time to look after my bees, which is a recreation as well as a profit. I began in the spring of 1887, with 5 colonies, which I increased to 13, and bought 10 colonies more in box-hives, in the fall. This season I started with 24 colonies, increased them to 33, and purchased 20 colonies more this fall, at \$2.50 per colony. In Simplicity hives, which makes me 53 colonies now. I got only about 500 pounds of comb honey this season, and 8 swarms from 24 colonies, spring count. This is the poorest season that I ever knew

in St. Lawrence county. White clover yielded no nectar, and buckwheat was cut by the frost on Sept. 1; since then there has not been a drop of honey, and it has been cold and raining about 20 days out of the month. As a result, I have not been able to look through the hives and prepare the bees for winter. I think that some of them will have to subsist on candy. I introduced 3 Carniolan queens in August; the first one was introduced by taking as many frames of sealed brood as would fill a hive, without any bees adhering, and keeping in the house with the queen confined until the brood had mostly hatched, when it was put out, a full colony of bees.

[Photography and bee-culture are admirably adapted to go together, as you have no doubt discovered experimentally.—ED.]

Silver Lining—Pure Honey.—J. C. Armstrong, Bromley, Iowa, on Nov. 27, 1888, writes:

"All is well that ends well." I am able to give a little better report for my bees from that given on page 515. Then, apparently, the best part of the honey season was past, and many of our bees were on the point of starvation. They remained in that condition until about the middle of August, when the long-looked-for "silver-lining" came; when for nearly a month, I think, I never saw hives fill up so fast before. Some of my best colonies filled up one set of sections, and were crowded for room before I was aware of it. Unfortunately a light frost came on the night of Sept. 12, followed by cool weather, which checked the honey-flow, after which they did not more than hold their own. My bees have ample stores for winter, and, like all others, I am looking for a good honey season next year.

While I have the subject of honey, I wish to ask the readers of the AMERICAN BEE JOURNAL a question for information (and no one needs it worse). We have, for some length of time, read through the papers a great deal about pure and adulterated honey. In such reading I have mentally asked the question, "What is pure honey?" Prof. Cook says that it is "digested nectar." All right; but is not the nectar of one flower different from that of another? The nectar from white clover is different from that of buckwheat, both in color and flavor; hence there must be ingredients in the one not found in the other. A person analyzing different samples of honey, as has been done to show up the dishonesty of bee-keepers, and having the common idea that bees *make* honey instead of gathering it from the flowers, and taking white clover honey as pure honey, would pronounce buckwheat honey adulterated. Hence the question, what is pure honey?

Ready for the Winter.—W. V. Bosworth, Jr., Clockville, N. Y., on Nov. 23, 1888, says:

I have 60 colonies in good condition for winter in chaff hives, and, like all bee-keepers that have had their eye-teeth cut, and have learned by experience that one head does not carry all the knowledge there is in bee-keeping, I hope to have the same number next spring.

The Time for Reading has come, with the long winter evenings. We have a large stock of bee-books, and would like to fill orders for them. To read and post up is the way to succeed in any pursuit—in none is it more important than in bee-keeping.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in *Cheshire's* pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being available, it must go by express.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one **FREE**, if you will send us 3 new yearly subscriptions for the **BEE JOURNAL**.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the *Apiary Register* and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 120 representative apiarists, and a printed sketch of each one, will be sent with the **BEE JOURNAL** for one year for \$1.75; or we will present it *free*, by mail, to any one, for a club of three subscribers and \$3.00.

The National Bee-Keepers' Union fiscal year has heretofore ended on June 30. Sometime since it was proposed to have it end with the calendar year. It was submitted to vote, and every vote so far received is of the same tenor as the following from Mr. H. K. Staley, Pleasant Ridge, Ohio:

At the request of the Manager of the Bee-Keepers' Union, for the members to vote on the proposed change for the paying of the annual dues from June to January, I vote in the positive, or in other words, I favor the change.

If any one wants to vote in the negative, please let it come at once; if none are received by Dec. 10, the motion will be declared to be carried, and the change made accordingly, by consent.

This change will make the time for paying dues and voting for officers come on Jan. 1, and blanks will be sent out on Dec. 15, for that object—unless somebody votes against the change.

International Bee-Convention.—The Pamphlet Report of the Columbus, Ohio, Convention is now issued, and copies have been sent to each member, as well as to the Colleges, Agricultural and Horticultural Societies and periodicals devoted to the industry. Copies can be obtained at this office, by mail, postpaid, for 25 cents. This pamphlet contains the new bee-songs and words, as well as a portrait of the President. Bound up with the history of the International Society, and a full report of the Detroit, Indianapolis and Chicago conventions, for 50 cents, postpaid.

Good Enough.—Andrews & Lockhart, of Patten's Mills, N. Y., on Oct. 13, 1888, wrote as follows concerning their use of the advertising columns of the **AMERICAN BEE JOURNAL**:

We got more orders from our advertisement in the **AMERICAN BEE JOURNAL** than from all the other bee-papers put together. We shall advertise in it again next year.

We Supply Chapman Honey-Plant **SEED** at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, \$1.00 per 100, or \$8.50 per 1,000.

The Date on the wrapper label of your paper indicates the end of the month to which you have paid. If that is past, please send us a dollar to carry the date another year ahead.

Do Not Fail to get up a club and send it with your renewal for next year.

Hastings' Perfection Feeder.—This excellent Feeder will hold 2 quarts, and the letting down of the feed is regulated by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for \$3.50, and it can be obtained at this office. Postage 10 cents extra.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2 00	3 00	3 50
1,000 Labels.....	3 00	4 00	5 00

▲ Samples mailed free, upon application.

Simmins' Non-Swarming System.—We have a few of these books left, and we will club them with the AMERICAN BEE JOURNAL for one year, both postpaid, for \$1.35. The subscription to the BEE JOURNAL can be for next year, this year, or may begin anew at any time.

Cork for Winter Packing.—Its advantages are that it never becomes *musty*, and it is *odorless*. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Mellilot or Sweet Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 10 cents per pound for bag and postage.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

We will Present a Pocket Dictionary for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide the spelling of words, and their meaning.

Do Not Ship Honey to Us without first corresponding with us about it. We have received several undesirable lots without previous notice, or correspondence of any kind.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

Honey and Beeswax Market.

CHICAGO.

HONEY.—We quote: White clover 1-lb., 18@19c.; 2-lb., 16@17c. Good dark 1-lb., 15@16c.; 2-lb., 13@14c. Buckwheat 1-lb., 14@15c.; 2-lb., 12@12½c. — Extracted, 7@9c., depending upon quality and style of package. Receipts increasing, but demand still limited. Stock is not selling as freely this season as a year ago.
BEEFWAX.—22c.
Nov. 13. S. T. FISH & CO., 189 S. Water St.

CHICAGO.

HONEY.—It is selling fairly well at 18c. for best 1-lb. very fancy lots have sold at 20c. Dark and yellow comb aells slowly at 13@16c. Extracted, 7@9c., according to quality and style of package. The stock of best comb honey is light.
BEEFWAX.—22c.
Nov. 22. K. A. BURNETT, 161 South Water St.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lb., 18@20c.; 2-lb., 16@18c. Good dark 1-lb., 16@18c.; 2-lb., 15@16c.; fair 1-lb., 12½@14c. Extracted, white, in kegs and ½-barrels, 8½@9c.; amber in same, 7½@8c.; in barrels, dark, 6@8½c. Market steady and supply ample for the moderate demand, but present values have a tendency to restrict general consumption.
BEEFWAX.—22@23c.
Oct. 25. A. V. BISHOP, 142 W. Water St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb., 15@17c.; 2-lb., 14@16c. Fair white 1-lb., 14@16c.; 2-lb., 13@15c. Extracted, white, 7½@8c.
BEEFWAX.—23½c.
Sep. 17. THURBER, WHYLAND & CO

NEW YORK.

HONEY.—We quote: Fancy white 1-lb., 16@17c.; 2-lb., 13@14c. Fair white 1-lb., 14@15c.; 2-lb., 11 to 12c. Buckwheat 1-lb., 11@12c.; 2-lb., 10c. White extracted, 8@9c.; buckwheat, 6@7c. Demand good for white 1-lb. and buckwheat 1 and 2 lbs., of which the stock is light. Good stock of white 2-lb., with but little demand.
BEEFWAX.—22½@24c.
Nov. 24. HILDETHI BROS. & SEGELKEN, 23 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—White 1-lb. sections, 12@12½c.; 2-lb., 12@14c.; amber, 8@10c. Extracted, white, 6½@6¾c.; light amber, 6c.; amber and candied, 5¼@5½c. For comb honey the demand is light; for extracted it is good, and market firm.
BEEFWAX.—Dull at 18@22c.
Nov. 15. O. B. SMITH & CO., 423 Front St.

DETROIT.

HONEY.—Best white 1-lb., 17@18c. Supply is better. Extracted, 8@9c. Sales slow.
BEEFWAX.—22@23c.
Nov. 17. M. H. HUNT, Bell Branch, Mich.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 16c. Demand slow.
BEEFWAX.—Demand in good—20@22c. per lb. for good to choice yellow, on arrival.
Nov. 12. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—Choice 1-lb. sections, 18c.; dark 1-lb., 14c.; 2-lb., 12c.; dark, 13c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock fair.
BEEFWAX.—None in market.
Sep. 27. HAMBLIN & BEARSS, 514 Walnut St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 17½@18c.; 2-lb., 14@15c. Fair 1-lb., 14½@15½c.; 2-lb., 11@12c. Extracted, fancy white clover, 7½@8½c. California white in 60-lb. cans, 8c.; light amber in same cans, 7½c.; amber, 7½c. Buckwheat in kegs and barrels, 5½@6c. Cuban, in barrels and ½-barrels, 65c. per gallon.
F. G. STROHMEYER & CO., 122 Water St.
Sep. 26.

BOSTON.

HONEY.—We quote: Best white clover 1-pound, 17@18c.; best 2-lb., 16@17c. Extracted, 6@9c. The receipts are very light, and honey sells fairly well.
Nov. 12. BLAKE & RIPLEY, 57 Chatham Street.

KANSAS CITY.

HONEY.—White 1-lb., 17c.; fair, 14c.; California white 1-lb., 17c.; 2-lb., 15c. Extracted white California, 7½c.; amber, 7c.
BEEFWAX.—None in the market.
Nov. 22. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—We quote: Extracted in barrels, 5@6c. according to quality; in cans, 7@8c. Comb, 12½@15c. Prices firmer on account of scarcity, though the demand is not great.
BEEFWAX.—21c. for prime.
Oct. 17. D. G. TUTT & CO., Commercial St.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6½ cents; light amber, 6@6½c.; amber, 5½c. Comb, white 1-lb., 13@14c.; 2-lb., 13c. Light amber 1-lb., 11@13c.; 2-lb., 11@12c. Demand very active for extracted, and fair for comb honey.
BEEFWAX.—20@21c.
Nov. 6. SCHACHT & LEMCKE, 122-124 Davis St.

Advertisements.

A Magnificent Present

For every one who will send us a Club of five new subscribers for 1889, before next January. All the remaining issues of this year *free* to new subscribers.

This ATLAS

contains large scale Maps of every country and civil division upon the face of the Globe.

It is beautifully illustrated with colored diagrams, that show wealth, debt, civil condition of people, chief productions, manufactures and commerce, religious sects, etc., and a superb line of engravings of much historical interest & value, together with many new and desirable features which are expressly gotten up for this work—among which will be found a concise History of each State.

Price, in best English cloth binding (each, closed 11x14 inches; opened, 22x14 inches), \$4.50.

➔ To any one sending us, direct to this office, **FIVE NEW Subscribers** for one year, with \$5.00, (renewals not to count) we will *present* this beautiful Atlas, by mail, postpaid.

We have purchased one of them for our own use, and regard it as a valuable acquisition to our library. It is handsomely bound and contains a fund of very useful knowledge. It contains 192 pages.

THOS. G. NEWMAN & SON,
923 & 925 W. Madison-St., - CHICAGO, ILLS.

We have some **ELEGANT RIBBON BADGES**, having a rosette and gold Bee, for bee-keepers' use at Fairs, Conventions, etc. Price 50 cents each, by mail, postpaid.

THOS. G. NEWMAN & SON,
923 & 925 W. Madison St., - CHICAGO, ILL.

BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN,
Editor of the American Bee Journal.

It contains 220 profusely illustrated pages is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey-bee, and at the same time produce the most honey in its best and most attractive condition. Bound in cloth, \$1.00, postpaid.

➔ A Liberal Discount to Dealers, by the Dozen or Hundred.

THOS. G. NEWMAN & SON,
923 & 925 West Madison St., CHICAGO, ILL.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. Dec. 12, 1888. No. 50.

EDITORIAL BUZZINGS.

One Day at a time!
It's a wholesome rhyme!
A good one to live by,
A day at a time.

We have received the first number of the "Queen Breeders' Journal," dated January, 1889. It is to be issued monthly at 50 cents a year, at Marlboro, Mass. It contains 16 pages, and is nicely printed.

Candy for Winter Feeding—Mr. Fulkenson, of Wayne Co., Pa., desires us to give in the AMERICAN BEE JOURNAL a receipt for making candy to feed bees on the top of frames in winter. Here it is:

Use four parts of coffee A sugar, and one part of water; simmer until it becomes quite hard, on being cooled; mould it into frames of one-inch thickness, and lay it on the top of the frames, using sticks underneath $\frac{1}{2}$ -inch square, to give the bees free access to it, and the heat of the hive will keep it warm, and soften it.

As the Cold Weather approaches every kind-hearted man who owns a horse will provide his animal with a comfortable blanket, both for stable wear and for covering when hitched out-of-doors. Nor is it a matter of kindness of heart alone, but is really a matter of economy with the owner of the horse. An animal which is kept comfortably blanketed will keep in good condition and come out in the spring in better condition for hard work, on less feed than one that is afforded none but its natural protection. The cost of the blanket will be more than saved in the feed, besides adding to the physical comfort and appearance of the beast.

The Canadians, it seems, are preparing for a monster convention at Brantford next fall, in connection with the meeting of the International there. The *Honey Producer* for December remarks as follows:

The *Canadian Bee Journal* makes a very happy suggestion, and one which reflects much credit upon it, in speaking of the International American Bee-Association meeting at Brantford next year, it says:

"Next year the meeting being in Brantford, we trust that some arrangement may be made to secure a good crowd. Let the Ontario Bee-Keepers' Association and all county societies make it a point to attend in a body. . . . Our suggestions may be premature, but beginning in time is half the battle."

What an excellent idea if all the county associations, and we believe there are seven alone affiliated with the Ontario, besides a number of others—and the Ontario and the Quebec can arrange to meet in a body at Brantford. They alone would have one of the very best conventions ever held; if we add to this the bee-keepers of the United States, and as it is proposed, representatives from several European countries, we shall certainly have the best meeting bee-keepers have ever held, and we can assure the editors of the *Canadian Bee Journal* and all others a most hearty welcome to Brantford.

We should like to see such a convention held, and think that the suggestions are "good and timely." We support the motion enthusiastically.

Revised Langstroth.—On page 814 will be seen the announcement that the new and revised edition of the book of the Rev. L. L. Langstroth will appear next week. It will show the progress of thirty years, and will be very interesting. It is somewhat strange, and certainly a coincidence, that in the year of three 8's (1888) there should appear new editions of three of the standard books on apiculture—the other two being by Prof. Cook and Mr. A. I. Root. The revised Langstroth is published by Ch. Dadant & Son, whose long experience in practical apiculture abundantly qualifies them for the work of revision. As soon as the book comes to hand we will give further notice and review. It can be obtained at this office as soon as issued from the press.

To Delinquents.—After January 1, 1889, we shall discontinue sending the AMERICAN BEE JOURNAL to those who have not responded to the bills we sent out a few weeks ago.

This does not mean that we shall try to deprive any one of the pleasure of reading the BEE JOURNAL who really desire its continuance, but find it difficult to pay now. Such can get a short extension of time by asking for it. We should be sorry to lose any subscriber who wishes to have its weekly visits continued, but do not want any to continue to take it who do not think they are getting the full worth of their money.

We hope each one will endeavor to send us one or more new subscribers when they renew. We want at least ten thousand subscribers for 1889.

Maryland, My Maryland.—John B. Reed, Owing's Mills, Md., on Dec. 3, 1888, writes us as follows concerning an article on page 756, on the institution of a Bee-Keepers' Society in Maryland:

I lately met with a correspondent of the AMERICAN BEE JOURNAL who was very enthusiastic about the organization of a bee-keepers' association for Maryland. He showed me an article that he wrote on that subject, which I think is very good; but I do not think there has been enough of bee-literature distributed in our State to start one very soon. If you would make an appeal to some of our large bee-keepers, and some of the neighboring States would lend a helping hand, we might in time organize such a body; if only very small at first it would very likely increase. There are a good many who would keep bees if they had some one to attend to them. If there were men going about doing such work that were endorsed by some association, it would increase the number of apiarists. Do you not think that it would be well to agitate this matter?

Will the bee-keepers in the surrounding country correspond with Mr. Reed, so that there may be a good working society instituted in Maryland, as we suggested in an editorial on page 756? It requires some one to lead, and considerable energy to get the bee-keepers together, and then the thing can easily be done. Enough enthusiasm can be kindled at such a meeting to make a society a success. We repeat what we before said: Act quickly! Strike out for success! Be enthusiastic! These are the watch-words which bring success, every-time.

Indian Summer seems to have "slipped a cog" this year. The beautiful weather which usually comes in October, and which we are wont to call "Indian summer," arrived this year about the middle of November, and is still here. In fact we can truthfully say that though not quite as warm, still "December is as pleasant as May," in all that makes it enjoyable. Our friends in the country have good roads, and with bracing atmosphere, clear skies, and a lack of snow in the West, the season is delightful. In the East they are having lots of snow, and storms have been too plenty, while no snow is the rule all through the West.

The Michigan Bee-Keepers meet in convention on Wednesday (the date of this paper), and hold a two-days session. This is the 23rd annual convention of this State Association. It is one of the oldest and best societies of bee-keepers in America, and this meeting will no doubt be a very interesting one. We shall have a report of the proceedings in due time.

In Australia there is a great complaint of drouth, which seems to have extended all over that continent, New Zealand and the islands adjacent. It is much of the same state of affairs as existed in North America in 1887, the results of which are yet being felt quite extensively.

GLEAMS OF NEWS.

World's Congress of Bee-Keepers.—The idea grows, day by day. Mr. J. W. Tefft now gets enthusiastic, and says that the coming meeting at Brantford, Ont., should be a World's Congress of bee-keepers; that it should select as a permanent location Niagara Falls for holding its sessions. He asks to have the following "Notice" submitted for the consideration of bee-keepers, and a prophecy of the future:

The World's Congress of bee-keepers will hold its first council at Brantford, Ont. Now is the time for local conventions to elect delegates, etc., giving four days of high thinking in apiculture. Bee-keepers of culture and of earnest thought should not fail to attend the sessions of the World's Bee-Keepers' Congress, to be held at Brantford, Ontario, Canada, on — date — Tuesday, Wednesday, Thursday and Friday, —, 1889.

The old reliable AMERICAN BEE JOURNAL has already dwelt upon the character and purposes of this Congress. It is simply a gathering for the liberal discussion of what is best in bee-culture for men and women; and also for finding out in which direction true progress lies; in what measures the greatest good will result. The Congress seeks to be simply a little advance guard of bee-keeping civilization, blazing away for general advance.

We apprehend a marked effort at the coming Congress of bee-keepers to be practical. To point out some steps which may actually be taken, and what practical good may follow. Messrs. Allen Pringle and L. C. Root are expected to share in the discussions, as they are conspicuous among the educators, as exponents.

Dr. A. Stanley Hancock, of Buffalo, N. Y., will give his experience in reversible frames, all-purpose bee-hives, ventilation, etc.

Thomas G. Newman will probably indicate in a measure the character and purposes of the four days' celebration.

Dr. Tinker on the new sections open on all sides.

The question of the race and type of bees, by Prof. A. J. Cook.

Tobacco, humbugs, and scientific bee-keeping by A. J. Root.

A welcome address by R. F. Holtermann is sure to be earnest and suggestive.

We submit the above by request, but it is too early yet to get up a programme for the Congress.

We are glad to notice the general waking-up to the importance of having a good convention, and hail with delight the indications of a monster meeting, which shall be noted for the sacrificing of selfish motives and designs, and for the unanimity of those present—all working for the general good—while making plans for the advancement and prosperity of the pursuit. That is a hopeful sign—a good omen!

Money in Potatoes, by Mr. Joseph Greiner. Price, 25 cents, postpaid. This is a complete instructor for the practical potato-grower, and explains the author's new system in 40 interesting lessons. It is for sale at this office.

Odor and Color.—On page 776 Mrs. Chaddock avers that she knows that "odor is a guide to bees" in search of honey. This was in reply to Prof. Cook, who claims that "the color of flowers" was the attraction to the bees. Now, in *Gleanings* for December, on page 926, Prof. Cook makes these additional remarks on the subject:

Do you remember what ludicrous blunders Agassiz made when he attempted to write of bees? He was a master in science, yet the humblest bee-keeper in the land could have taught even Agassiz very much.

The point I wish to make is: If we wish to learn of bees and their work, we go to a bee-man; so when we wish to learn as to the nature, growth, development, and general economy of plants, we will, if wise, go to a first-class botanist. W. E. Gladstone is a marvelous man, but I would give a thousand times as much for Dr. Beal's opinion on an intricate matter connected with plants as I would for Gladstone's.

Now for my point: All our botanists believe that odor and color in flowers are developed peculiarities. They have been evolved for the good of the plant. The method by which they aid the plants is by attracting insects. We positively know that insects by cross-fertilizing the flowers of the same species do immense good to the plants. This often changes sterility to maximum productiveness, and almost always increases the productiveness many fold. Of course, as bees are so much more numerous in early spring than any and all other sweet-loving insects, they are the chief agents in this good work.

We may say, then, that the rich coloration and penetrating odors of flowers are their distress signals. Bees see the colors or smell the odors, and so are attracted, to the mutual benefit of both parties. We see, then, why many showy flowers, like cardinal bloom, and the Rocky Mountain or Colorado cleome attract bees and other insects without odor. Other inconspicuous flowers, like mignonette, are very fragrant, and so attract insects by scent, not gaudy coloration. Still others, like the phlox, are both showy and fragrant.

Again, are not our bees governed by reason? It is sometimes said, that bees are wholly ruled by instinct. I do not think so. A red clover field is rich in clover, and delightful with fragrance. Yet the honey-bee generally passes it by. A less fragrant and more feebly adorned white clover field at the same time rings with the hum of bees. Why the difference? The bees have learned by experience that they receive no benefit from red clover. Indeed, the very fact that they are attracted by color argues that they are reasoning from former experience. Bees are, in a sense, botanists.

A Good Christmas Present for an apiarian friend or relative would be one of the *new* books on apiculture, or even a year's subscription to the AMERICAN BEE JOURNAL. See list of books on page 815 of this issue, and select what you desire. If sent for at once, there will be plenty of time to get either the book or subscription receipt in time for Christmas.

Now is the time to sell the honey. The holidays are at hand, and the best prices rule about that time.

Well did Pythagoras put it when he said, "Rest satisfied with doing well, and leave others to talk of you as they please."

Button-Ball Honey.—Mr. S. A. Shuck, of Liverpool, Ills., gives the following particulars concerning this honey-producer, in *Gleanings*:

There are thousands of acres of it in the marshes of this, the Illinois river bottom. I have lived in this place five years, but we got no button-ball honey until last season. It bloomed about three weeks, and gave us (wife, children and I) something over a ton from this source.

This season it bloomed six weeks, and we have taken off the hives about 2,000 pounds, all button-ball honey. There is about a ton on the hives, and the greater part of that is button-ball.

The cause of its failure in previous years was ice breaking it down during the winter; and its continuing so long in bloom this season was caused by the water. When it commenced to bloom it was standing in water up to its "chin." The water commenced going down; and as the water continued to fall, new shoots put forth, and new buds kept coming, so that there was considerable button-ball bloom yet last week.

We obtained nearly three tons of honey last season from 93 colonies in the spring, and went into winter quarters with 114 colonies. We commenced last spring with about 108 colonies; and while we have not a big crop, we have a fair yield. Our neighbors got almost nothing last season, and a little less so far this season.

Among the ancient "Irish Signs and Omens" enumerated by an exchange, we notice the following as directions or enchantments to attract wild bees:

Gather fox-glove, raspberry leaves, wild marjoram, mint, camomile, and valerian, mix with butter made on Monday, on which day the herbs should also be gathered. Boil with honey, and rub the vessel into which the bees should go, with the mixture. Place it in a tree, and the bees will come.

In our day they sound very strange among matter-of-fact people.

☛ The National Bee-Keepers'

Union fiscal year has heretofore ended on June 30. Sometime since it was proposed to have it end with the calendar year. It was submitted to vote, and every vote, so far received, is in favor of the change, except one which suggests that "January is always settlement month, and funds scarce." As the dues are not delinquent for six months, that objection is nullified. The change is therefore declared carried by consent.

This change will make the time for paying dues and voting for officers come on Jan. 1, and blanks will be sent out on Dec. 15, for that object.

To Our Subscribers.—Send to F. P. Shumway, Jr., Boston, Mass., for a free sample copy of the *Cottage Hearth*, a beautiful illustrated magazine, and so realize what an EXTRAORDINARY OFFER we are making when we propose to send both the *Cottage Hearth* and the AMERICAN BEE JOURNAL for a full year for only \$1.50, when the price of the *Cottage Hearth* alone is \$1.50 a year, thus giving you two standard publications at the price of one.

DREARY WINTER.

Alas! all flowerless are the vales;
We feel the breath of Arctic gales.

All silent are the honey-bees,
And gaunt and leafless are the trees.

The daisies to the zephyrs nod
No more—dear I is the golden-rod.

No fire-flies in the alders gleam;
No more the swallows skim the stream.

The grass is withered on the lawn;
No more the song-bird greets the dawn.

The merry crickets chirp no more;
The weather-strips are on the door.

Now come bleak winds with drizzling showers,
And 'neath the eaves the sparrow cowers.

The glory of the autumn's past,
And dreary winter's coming fast.

The dreary winter with its snow,
And days of "eight and ten below."

QUERIES AND REPLIES.**Placing the Section-Case for Comb Honey.**

Written for the American Bee Journal

Query 596.—When comb honey is desired, can any more honey be obtained by placing the section-case crosswise over the frames, than by using it lengthwise; that is, running with the frames, or from front to rear?—New York.

No.—C. C. MILLER.

No.—MRS. L. HARRISON.

I think not.—J. M. HAMBAUGH.

I think not.—M. MAHIN.

No, certainly not.—R. L. TAYLOR.

No. No more, and no less.—EUGENE SECOR.

No. What kind of a hive do you have?—WILL M. BARNUM.

No; and there are serious objections to such a practice.—JAMES HEDDON.

I can see no difference in favor of either plan.—G. M. DOOLITTLE.

We do not think that it makes any difference as to quantity.—DADANT & SON.

Having never tried them crosswise, I do not know.—A. B. MASON.

I prefer them to run crosswise, but practically I do not think it makes any difference.—J. P. H. BROWN.

I think not. I have them both ways, and I see no difference in the amount of honey secured.—A. J. COOK.

I do not think that there can be, and I see no good reason why it should.—J. E. POND.

I can see no difference as far as honey is concerned. I prefer the sections to run with the frames.—H. D. CUTTING.

No, never. Besides it is wrong anyway. Run sections the same as the frames, and the hive need be level or

true one way. Run the sections crosswise, and the hive must be level both ways. Double trouble without a single advantage.—J. M. SHUCK.

I do not think that it makes much difference, but putting the sections lengthwise is generally preferred.—P. L. VIALLO.

It makes no difference, but as hives are generally tilted forward to shed water, it is best to place the sections running from front to rear. The hives must be kept plumb sidewise, when comb either in brood-frames or sections is being built.—C. H. DIBBERN.

I have used cases largely in both ways, and as to quantity of honey I have failed to see any difference in favor of either way. I make my cases so that the sections run with the brood-frames, in order that the hives may be "tipped" forward slightly so as to drain the alighting-board of any water that may get there.—G. W. DEMAREE.

Oh, no! No good reason is presented why it should make any difference in the quantity of honey obtained, so far as we can discover. There are reasons for having the combs parallel with the brood-frames, other than a quantity of honey.—THE EDITOR.

Separate Section-Cases, or Wide Frames?

Written for the American Bee Journal

Query 597.—Can more honey be obtained by using separate cases (that is, those with sections) than by using wide frames with sections?—E.

No, I think not.—R. L. TAYLOR.

No more honey, but less work.—C. C. MILLER.

I never use wide frames. Place all sections in cases.—J. P. H. BROWN.

I think not, but it is more convenient to use separate cases.—A. B. MASON.

Not according to my experience.—P. L. VIALLO.

I think so, and in better shape usually.—MRS. L. HARRISON.

There is no difference as to quantity; it is only a matter of convenience to the bee-keeper.—C. H. DIBBERN.

I have never made a practical test, but I believe the difference would not be very marked.—J. M. HAMBAUGH.

The wide-frame plan will give as much honey as any plan so far known.—G. M. DOOLITTLE.

I do not know as I understand your question fairly. But I am satisfied that I can get more honey with the

section-case than with wide frames.—WILL M. BARNUM.

I see no reason why. It is simply for convenience that we use crates or cases, in lieu of wide frames.—A. J. COOK.

It depends upon circumstances. There are advocates of both plans. Probably but little difference will be found.—J. E. POND.

I use separate cases, also sections in wide frames, and I can see no difference with the same race of bees and colonies of the same strength.—H. D. CUTTING.

One plan will secure just as much honey as the other, other things being equal. It is altogether a question of cheapness and convenience. I began with wide frames, but I have discarded them.—M. MAHIN.

Perhaps not, but the latter method would involve the most work, I think. In a large apiary the question is not simply quantity, but maximum quantity with minimum labor.—EUGENE SECOR.

Cases for surplus honey of half-depth offer advantages that those of full-depth do not; for the reason that a small amount of storage-room is offered at one time, and heat is economized. The "case" system has almost superseded the wide-frame system, and will eventually "push it to the wall." Very much of this popularity is due to the old Heddon case.—J. M. SHUCK.

I have tried both the wide-frame and the case system, and I conclude that if the apiarist is possessed of genius, and is indifferent to what is by some people called "fuss" in the bee-business, there need be but little difference in the quantity of comb honey realized. But for my part I am not fond enough of "fuss" to be found fussing with such impracticable traps as wide frames.—G. W. DEMAREE.

In all probability the difference in quantity is very little, if any. Convenience and economy of labor and material are the only things which are claimed for section-cases for surplus honey, which are now superseding the wide frames very rapidly.—THE EDITOR.

The Time for Reading has come, with the long winter evenings. We have a large stock of bee-books, and would like to fill orders for them. To read and post up is the way to succeed in any pursuit—in none is it more important than in bee-keeping.

The annual meeting of the Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association will be held in the Supervisors Room of the Court House at Rockford, Ill., on Jan. 15 and 16, 1889. D. A. FULLER, Sec.

CORRESPONDENCE.

REMINISCENCES.

A Record of a Woman's Work Among the Bees.

Written for the American Bee Journal
BY S. B. ATWATER.

The season has been a disastrous one to me. There was one continual drouth from the beginning to the end of the season. I kept my bees alive by feeding honey.

Death of Mrs. S. B. Atwater.

But on Dec. 12, 1887, my dear wife passed to the "summer land." As a consequence of this death in the family, the bees also died.

If it were known how many years I have been reading the AMERICAN BEE JOURNAL, the reader would no doubt exclaim, "Can any man read modern bee-culture to so little purpose, that that old superstition still clings to him?" I have read modern bee-culture quite extensively, and still what I have said I believe to be true. My wife also had studied the books, and read the papers until she became well versed in what is known of the nature and habits of the honey-bee, and an adept in the management of an apiary.

We worked our apiary at first altogether for extracted honey; and in building up by dividing, by forming nuclei and other methods of increasing the original stock, she had considerable experience. In this work she often made discoveries by her observations, and came to conclusions that months afterwards, and sometime years afterward, she saw confirmed by the observations of others, and recorded in the bee books and papers.

Bees Devouring their Eggs.

One of these observations I recall now, made several years ago. She had strengthened a nucleus by giving it frames of brood from a strong colony. When these frames were put in, she noticed one frame filled with eggs that were not hatched. In two days afterward the cells in this frame were empty—the bees had evidently devoured the eggs. The same was noticed every time that eggs were put into the hives where there were but few bees, and those bees young.

On another occasion after we had divided some strong colonies, leaving about the same quantity of bees and brood in each of the two hives, she noticed that but few bees were flying the next day in front of the hives that

had been moved to a new location. On noticing these bees closely, she saw that they would walk out of the entrance a little way on the alighting-board, and then return to the hive without taking wing. She came to the conclusion that the old bees—the honey-gatherers and water-carriers that had been once in these hives—had flown out in the early morning, and when they had obtained their loads, had gone back to the hive on the old stand instead of coming back to the new place; and that the bees in the hives on the new stands were all young bees, and not old enough to fly. She sprinkled some water on the edge of the alighting-board, and was delighted to see how eagerly the young bees crowded out and drank it.

In a few days, as she watched these hives, she saw that the young bees were beginning to fly, and hunt new watering-places. And then again, when she had the good fortune to catch a stray swarm, that had struck out to find a new habitation, and had it nicely hived, she thought it was not one new colony that we then most wanted, but two or three. So she lifted two or three frames from the newly-hived swarm with their clusters of bees, and put them in a new hive with plenty of frames of brood from hives that could well spare them in June; and two or three more frames were lifted from the hive containing the new swarm, and placed in still another hive, which was filled up by frames of brood drawn from strong colonies. These hives were each placed in a new location, and as the division was made before the newly-hived swarm had had time to mark its location, each part staid with the brood that was given it.

In this experiment there was no complaint about the bees eating fresh eggs in comb that was put in the hive, nor was there any necessity for sprinkling water on the alighting-board for the young bees to early in. This division of the new swarm was so satisfactory, that in after years, when we desired to increase, we waited for a natural swarm and then divided it according to its strength.

These and many other things she discovered which afterward she saw confirmed by the writings of others. Some experiments that she tried in the management of bees did not work out as well as she expected they would, but even in failures there were lessons that were learned. In trying different plans of management, she found which were the best. As an illustration, she put the extra story of empty comb below the bees instead of above, as is usual, but the experiment was not a success.

Those colonies which had their extra stories of empty comb placed above them gathered more honey than those did whose condition was reversed. I have written this much to show that my wife was a thinker and an experimenter. She had read that it is natural for bees to store honey over their brood, and she believed it after she had tried to make them store it below.

Bee-Stings and Smoke.

I cannot tell you all the discoveries she made in one short letter, but I will relate one more: She noticed that sometimes when we pinched a bee and induced it to resent the provocation by a sting, that other bees would be excited by the scent given out by the stinging bee; and perhaps a half dozen other bees, that up to that moment had been well-behaved, would instantly take the warpath and rush right to the spot already stung, and do their best to sting it some more. At such times she used the smoker, turning on a blast of smoke to take away the scent of the bee-sting. It was but a short time till she discovered that smoke was an antidote for the poison of the bee-sting.

We have tried many things, but nothing gives so much relief as smoke blown from the bee-smoker for a few moments on the place stung. This fact has been mentioned in the BEE JOURNAL, but for the benefit of new subscribers it ought to be repeated every three months. Those who try the experiment for the first time will soon learn to lose as little time as possible after being stung, before beginning to puff the smoke on the sting. I never saw any man who could do as much work, and do it as intelligently in handling bees, as my wife could.

The Philosophy.

I will now return to the philosophy—not the superstition—that connects the death of my wife with the death of the bees the same winter. She and I had always worked together in preparing our bees for winter. My wife was taken sick just about the time we expected to go to work to prepare the bees for winter, and she was not able to help. My whole time and thoughts were engrossed in caring for my wife. The bees were neglected, and stood out through the rigorous winter without any packing. They are dead now, but there would have been but little profit in them this summer had they lived. The white clover was killed by the drouth one year ago. It came up from the seed, and if we have a good winter, this will be a good location for bees next year.

Viola, Ills.

PEACHES.

Sound Fruit is Never Attacked by the Bees.

Written for the Farm Life.

The matter has come up a great many times in regard to bees and peaches, and perhaps more this present season than heretofore. A few days ago a neighbor told me that our bees had taken complete possession of his peach orchard. They were "cleaning the fruit right off the trees, and would not let anybody go near the trees." I told him they were eating the decayed peaches, and no others. He would not believe me until I took him down to our fruit-house and showed him several baskets of sweet cling-stone peaches. These sweet cling-stones are the first that ripen, and this year they began rotting, a great part of them, before they got mellow enough to eat. I have taken considerable time and pains to look into the whole matter, and I think I understand it.

I thought of a neighbor about two bushels of these peaches, and I immediately sorted out all decayed and mellow ones. Before I got through, the bees were busy on the decayed ones, and where the skin was bruised they rapidly enlarged the opening and soon finished the peach. For two or three hours not a bee was to be found on those that had been sorted out as perfect. By noon, however, knots of bees were gathered in different parts of almost every basket.

I sorted them again, and found little white spots, indicating that rot had commenced since I went over them in the morning, and whenever the bees found these indications that decay had commenced on a small spot, they pushed their tongues into it, and rapidly made the opening larger. I then placed a part of the peaches indoors, where the bees could not get at them. In about three hours' time, as before, quite a number of the peaches showed decayed spots. Some had commenced to get mellow, but the greater part of them commenced to rot before getting mellow at all.

Well, wherever they were left out-of-doors the bees found out what was going on, and kept going over the peaches, waiting for a soft spot to appear. Before these soft spots appeared, a whitish down always indicated where rot was going to commence. The appearance was something like mildew.

Good peaches, however, that became mellow before this rotting commenced, were never attacked or injured by the bees at all. If, after the peaches get

mellow, they are tumbled around in the baskets so as to bruise the skin, they will be attacked by the bees. They will also, within 24 hours, as a rule, commence to decay if the bees do not get at them.

Now, friends, I think you have the truth of the whole matter. The bees do not injure sound peaches. They will, however, get through the skin at once when this process of decay commences, and it will start out through the basket of peaches in just a few hours—that is, if you sort out every decayed peach, and every one that shows any symptoms of decay, at nine o'clock in the morning, during hot, rainy weather, by noon you will find a good many that have commenced to rot—enough so that the bees will get at them. In a few hours more, the peach will sometimes be too rotten for sale or use.

Now, I do not know whether this kind of rot always occurs with these sweet cling-stones or not. I have noticed it several seasons, but I never saw it so bad as this season. It commences when the peach is nearly ripe, and it may attack fruit before it is mellow, or after it is mellow, or not at all. It is not the same kind of rot that spoils fruit when it rots from over-ripeness. If you get a remedy for the rot, you will also have a remedy for the bees; and this kind of rot is certainly a very serious matter to fruit-growers.

Now, then, there is one other trouble: When your fruit gets bruised so as to break the skin, the bees will rapidly take out the inside. People who handle fruit, however, greatly magnify the effects; and my neighbor was greatly surprised to see me pick out peaches and push the bees away with my finger, in order to show him the white mold which is the forerunner, or harbinger, of the rot on every peach where the bees had found an opening. He could hardly believe me when I told him they did not chase his people out of the orchard.

Now, I wish the whole matter might be fully understood, and I wish our agricultural papers would copy the facts I have here given. There is some trouble with bees and fruit, I am well aware; but the trouble is not so great as fruit-men often imagine; and I am sure it will be very much less expense to arrange the damages in an amicable way, rather than to attempt to right the matter by going to law.

Let the bee-keeper and the fruit-raiser both look into the matter, and talk it over in a friendly way. I proposed gathering the fruit, or paying the damages; but my neighbor finally declared that there were not sound peaches enough there in the first place

to be worth talking about. He knew many of them were rotting, even before they were ripe; but he did not know the bees were at work on the trees, only on those that had begun to rot.

Another thing: The bees would pay no attention to these peaches, even the sweet ones, were it a season when honey could be found in the fields. With us, however, the bees seldom find honey enough to keep them busy at the time when peaches begin to ripen.

October, 1888.

[When the whole facts are known, the bees will be fully exonerated from the charge of attacking sound fruit, as is so well demonstrated in the foregoing article from that excellent agricultural periodical called the *Farm Life*, published at Rochester, N. Y.—Ed.]

UNITING.

Use of Chloroform in Handling Bees.

Written for the American Bee Journal

BY C. E. WOODWARD.

On page 742 some one asks if any ill-effects would follow the use of chloroform in quieting bees, or introducing queens. As I have never seen any method for its use in the apiary, from our leading apiarists, I will give the method I use for uniting colonies and introducing queens.

In the first place, we must take into consideration the powerful liquid we are to use. Chloroform is a colorless, volatile liquid, and is very powerful for man or beast, and should not be allowed in the hands of any child.

Get the chloroform and three sponges, and saturate one of the sponges with the liquid; dampen a sponge with water, and put the sponge into the bee-smoker; then put in the sponge saturated with the chloroform, and then put in the third sponge. Be sure that you have the sponge saturated with the chloroform between the two sponges dampened with water. This will hold the strength of the chloroform.

Wet a cloth with water and cover over the frames of the hive that is to be manipulated, and cover the hive up again. Now take the smoker and give the bees two puffs of the chloroform. Then go to the next hive and operate on it as before. If you are uniting bees, then go back to the first hive and give them two puffs more. By this time the bees will be "silly,"

and the queens may be allowed to run in, and all will be right.

The bees may also be united with perfect satisfaction, and without loss. No consumption of honey is needed, no sweet solution is wanted, and the perfumes of cremated wood is uncalled for. The time is fast approaching when the old 48-hour-method will become obsolete.

South Newbury, Ohio.

HONEY-BEES.

Apicultural Literature and Facts About Bees.

Written for the American Bee Journal
BY HENRY K. STALEY.

Among the bees still holds good that law of the stronger preying upon the weaker. The thought rendered in poetry is as follows :

Big fleas have little fleas to bite 'em,
And little fleas have lesser fleas, ad infinitum.

So, when we look into the animal kingdom on this nether world, we find the lion preying upon the jackal, the wolf upon the lamb, etc.; but, of course, there are exceptions to the general rule.

The Robbers Among the Bees.

The bee in its formation, life and idiosyncrasies is a good deal like man, as I mentioned on page 792. That is, in a case of continuous drouth, and when honey-bearing plants cease to pour forth their nectar, the bee, like man when he is out of employment and becomes down-hearted, will often resort to robbing. But this robbing may be easily remedied, by so changing the hives, that, the robbers instead of bringing honey to their own hive, will be taking it from their own alveary to the other. This will often neutralize the affair, but sometimes it will not. Then you had better try the odor plan (*i. e.*) putting one kind of odor (as peppermint) in one hive, and another kind (as musk) in the other; and, then, the bees of the various hives being able to distinguish themselves from one another, you will soon see the truth in that old saying, "*Über dem Sturme ist Ruhe*"—After the tempest is sunshine.

No one who has not seen this wholesale robbing among bees, can hardly comprehend how the little sealaws dart through the air from one hive to the other, the robbers bearing home their little load of pilfered sweets, shaking themselves at the entrance of their own hive to inform their co-laborers, when the air is soon filled with a maddened, angry swarm of bees, ready to sting the first person

that comes in sight, on the least provocation, while over the alighting-board of the robber hive may be seen the pilferers falling thick and fast.

Virgil's description of a *pugna* between two colonies of bees, applies very well to this robbing incident. It is as follows :

"As soon, therefore, as they find the spring serene, and the fields of air open, forth they rush from their gates; they join battle: buzzing sounds arise in the sky aloft: mingled they cluster in a mighty round, and fall headlong: hail rains not thicker from the air, nor such quantities of acorns from the shaken oak. The kings themselves admit the hosts, distinguished by their wings, exert mighty souls in little bodies, obstinately determined not to yield till the dread victor has compelled either these or those to turn their backs in flight. These commotions of their minds, and this so mighty fray, checked by the throw of a little dust will cease."

The above, of course, is the embellished language of the poet, and adorned by his imagination to look plausible to the illiterate; but in practicable experience he will find the difficulties are greater than he expected. We may exclaim with Bobbie Burns, when bees are on the pilfering rampage, and

Bizz out wi' langry fyke, (bustle)
When plundering herds assaul their byke (hive).

that for the nonce, it is enough for a literate apiarist to manage them, let alone an illiterate one.

For 21 days of its life (the worker-bee)—16 days for the queen, and 24 for the drone—it lives what may be termed an aquatic life; and from the hatching of the egg it passes through great changes, until it finally emerges from the cell a perfect bee, when its life may be said to be that of the aerial type; for then, it soon acquires the power to use its wings, feet and other organs.

It devotes about the first ten days of its aerial life to cleaning cells—preparatory to receive the eggs or honey—or taking care of bees just emerging, etc., like children learn to perform the work in a cuisine and household duties.

At 12 or 14 days of age the bee commences to labor in the fields, and passes its prime at about six weeks in the working season, when mild—or it may be only 30 days, during a strong honey-flow—when it steadily begins to go into decline. So, like us, it is only a few short days from the time they had their first after-birth frolic, when

Sporting with quick glance,
Show to the sun their waved coats dropt with gold,

to the time when, with torn wings and haggard limbs, they wearily draw

themselves away from the busy swarm of population, to some remote place to die in. Hence when the peculiarities of the bee are brought *vis-a-vis* with the peculiarities of the human race, does it not seem that we are very closely allied to the family of the *Apis Mellifica*?

Ataxy, when the hive is in a healthy condition, finds no place among the bees. Everything must be in apple-pie order. If there are some that get mad, and throw they will do what they please *sans souci*, they are soon ousted out or treated to a reprimand. One thing very queer about them is, the utter *nonchalance* they have for infirm members of their family.

It is a well known fact, that some people who are too lazy to work in the winter-time, through their influence with the trustee in their township, get a permit to enter the county infirmary palming off valetudinarianism on him. Of course, with this permit, they gain an entrance into the infirmary, and feast there, through the winter at the expense of the county, leaving again

When that Aprile with his show'ers swoote
The drouth of Marche has perced to the roote,

to seek employment. We find no such thing in the bee-hive, because they believe in the adage that says, he who does not labor shall not eat.

Those bees that are sick, bruised, or in some way rendered infirm, are hustled out and thrown overboard. This resembles the way Sparta did with her infirm children. Every newly-born babe was taken, according to the Law of Lycurgus, before a committee of aged men, who gave the decision upon his right to live. If puny or sickly, into a ravine they slung him to die; but, if he seemed likely to be strong, he was accepted as one of the sons of Sparta, and had one nine-thousandth part of the public lands given to him.

So also with the bees, they allow no cripples among them, and will even tear down an inchoate queen if one of her limbs is in some way injured. They have no time to bother with the infirm; life is too short, and the honey-flow too uncertain and pusillanimous to be bothered with them. Like the Spartans of old at the pass of Thermopylae, they have a mighty work to accomplish with small numbers, and in a short time; and, therefore, they have no time to bother with the infirm when the honey-flow is thundering rapidly pass their threshold.

The type of a man's life for nine months is aquatic, and during that interval of time he assumes many different but eorrelated forms; and is it not so with the bee? The egg hatches, and the larva grows, in what may be termed a *parvum fretum* (little sea) of

liquid food, which it gradually, through many distinct forms, uses up, going through the various forms of larva, pupa (where it spins its cocoon, which serves as a velvet bed for its immature body to bounce about in, and also to guard against jars, as well as apicultural eruptions indulged in by illiterate bee-men), to the imago state where it assumes the real form of the bee. During this time—*mirabile dictu*—the pabulum in the cell seems to change directly into the body of the bee, and if any offal escapes, it must be in the form of gaseous vapors.

At the birth of a child his life becomes aerial; he soon, through nourishment from his mother's bosom, acquires the power to use his limbs with energy; to expand his lungs with the atmospheric air, and squall, and many other doings I need *not mention* to those blest with little children. How wonderfully similar to the bee in its peculiarities is man! No wonder that great poet, Green, wrote this lovely little passage:

To the mind's ear, and inward silence,
There silence speaks, and shade gives light;
While insects from the threshold preach,
And minds disposed to musing teach;

Proud of strong limbs and painted hues,
They perish by the slightest bruise;
Or maladies begin within
Destroy more slow life's frail machine:

From maggot-youth thro' change of state,
They feel like us, the turns of fate,
Some born to creep have lived to fly,
And chang'd earth's cells for dwellings high;

And some that did their six wings keep,
Before they died, been forced to creep.
They politics, like ours, profess;
The greater prey upon the less.

Some strain on foot huge loads to bring,
Some toil incessant on the wing;
Nor from their vigorous schemes desist
Till death; and then they are never mist.

Some frolic, toil, marry, increase,
Are sick and well, have war and peace;
And broke with age in half a day,
Yield to successors, and away.

Yes, truly, Green saw and understood the bee in the way the poet, Gray, meant the following lines, thus:

To contemplation's sober eye
Such is the race of man.

The quotation from Green's "Grotto," I consider one of the gems of bee-literature, worthy of being learned by every bee-loving person, notwithstanding the apicultural effusions of Shakespeare, or the embellished sayings in Virgil's Fourth Georgics, to the contrary; for where in all the realm of bee-literature will you find a poem containing so great a maximum of thought in so small a number of words, which at the same time may be construed to apply to the human race so minutely?

Are we not proud of brawny arms and sparkling eyes, rubicund cheeks and dainty hands? Yet, is not a slight cut or bruise able to produce *telenus*, when Death, with his reaping scythe, claims us as his own? Although many are the panaceas that have been

recommended and tried to cure consumption, it, like foul brood, may emanate from the mother, so that no remedy may be able to cure it. If the parents are consumptive, we know that the child may, in all probability, be made the possessor of what may be termed hereditary consumption; and we know also, that a healthy person without the slightest blemish of hereditary consumption, may contract that awful disease through the neglect of a cold.

So also there is hereditary foul brood, emanating from the queen-bee, the germs of which are supposed to exist in the eggs themselves, and also the foul brood that grasps a healthy colony being conveyed to it by bees from other infected colonies; or the germs may be wafted through the air, or it is supposed that the bacilli may exist in the newly-gathered pollen, and thus find its way into the rank and file of the bee-hive.

The following lines of Pope, in his "Essay on Man," seem to apply directly to hereditary consumption in man, and may be construed to apply to hereditary foul brood in bees, thus:

As man perhaps, the moment of his breath,
Receives the lurking principle of death;
The young disease, that must subdue at length,
Grows with his growth, and strengthens with his strength.

Returning to Green's sayings, we can easily construe the distich,

Some born to creep, have lived to fly,
And chang'd earth's cells for dwellings high,

to apply to man. Yes, some men who were born in penury, like Lincoln, Grant and Garfield, changed their humble abodes for dwellings high, ascending step by step to the top of the ladder of Renown, until at its summit they stood environed with the Nimbus of fame, and the Aureola of glory; while some, born with "silver spoons in their mouth," before they died have been forced to beg from door to door. Nor do we from our vigorous schemes desist till death, and then we are missed very little, for the world still gyrates on its axis, our orb still circles round the sun, seed-time and harvest come and go, and the busy populations of the earth still fill up the combs of prosperity with the rich productions of our globe, while we go into oblivion and glide down the river of Forgetfulness. Truly our "life is but a sheet of paper white, where on each one may write his word or two, and then comes night;" or we can exclaim with Gray:

Poor moralist! and what are thou?
A solitary fly!
Thy joys no glittering female meets,
No hive hast thou of hoarded sweets,

No painted plumage to display;
On hasty wings thy youth is down;
Thy sun is set, thy spring is gone—
We frolic while 'tis May.

Pleasant Ridge, Ohio.

NECTAR.

Honey is Not Made, but Gathered from Flowers.

Written for the *Prairie Farmer*

BY MRS. L. HARRISON.

In an old book that my father used to read from as I stood by his knee, are these words: "My son, eat thou honey, because it is good." Yes, indeed, "it is good;" not only for the young, but the old, decrepit, and middle-aged. It gives warmth to the system, arouses nervous energy, and gives vigor to the vital functions.

After the closing of the North American Bee-Keepers' Convention during the fall of 1880, a number of bee-keepers, myself among the number, called at the home of General Withers. We walked through and admired that beautiful palace, with its many stained windows, perfect ventilation, and hard-finished interior, furnished with every convenience, for the comfort and health of the horses, which were to be its inmates. In the course of conversation this genial gentleman said the horses had paid for their home, and among other things, that his father, who lived to be a very old man, always ate a little honey every day.

People have said to me: "I thought honey was all the same; that bees made it, and you bee-keepers call it basswood, clover honey, etc." It is true, that all that the bees collect and store in their combs is honey, whether it is the product of the leaves or bark of trees, honey-dew or sweet juice oozing from corn-stalks, wheat-stubble, or distilled in the corollas of beautiful flowers.

Bee-masters now endeavor to keep the different kinds of honey as distinct as possible, and they do it in this way: All the honey gathered in the North and the West, up to the time of the blooming of white clover, is used in brood-rearing. There may be exceptions to this, in the vicinity of large apple orchards, but in this locality there are but few trees, and what there are, are crab apples.

During some seasons, very large colonies, at near the close of fruit-bloom, will have their combs built out white with new wax, and the bees rich in wax, so much so that the scales are visible with the naked eye, and occasionally a swarm issues. These are the right conditions for colonies to be in when surplus boxes are to be put on; but instead of putting them on we remove two or three frames of brood and honey, as the circumstances may favor, and fill their places with empty comb.

I do this because I know that honey from this source is of short duration, and it is better to remove this brood and honey, and give it to weak colonies, so that they may all be strong, at the advent of white clover.

Apple honey is dark, but has a rose flavor which is agreeable, but bees are not strong enough when it blooms, to store any amount of surplus, as it requires so much to support brood-rearing at this time of the year.

Raspberry honey is fine, but there is not enough of it in this locality to yield much surplus, and at about the same time wild cherry blooms, which secretes bitter honey. Some seasons, locusts and dandelions are rich in nectar, and it is much better to have these honeys *made into bees*, than mixed up in surplus.

White Clover Honey.

When the spring flows of nectar are passed, and the apiary has been managed intelligently, every colony will be ready for business, with its hive full to over-flowing with workers, anxious for the fray. Where there are acres upon acres of white clover, with millions of blossoms, and the electrical conditions are favorable for the secretion of nectar, comb will be built so rapidly to store the flood coming in, that it will be so delicate as to be almost imperceptible, as it melts away in the mouth. When there are millions of nectar-bearing blossoms of white clover, there is no need for bees to roam among other flowers to get honey to mix with clover.

It is evident that white clover honey is simply the nectar secreted in the blossoms, gathered and evaporated by bees. I have eaten the white sage honey of California, the orange of Florida, yet I have never seen the white clover of the North excelled in delicacy of flavor—a real ambrosia, fit food for gods.

Basswood Honey.

This is a fine white honey, with a flavor peculiarly its own. In this locality, there is little of this honey to be had in its purity, as it blooms before the close of the white clover, and usually lasts only for a day or so. In northern latitudes the bloom lasts for three weeks, and the trees are very plentiful. More honey has been gathered in one day from this source, than from any other.

About twenty years ago a bee-keeper in this vicinity knowing the reputation of these trees, erected a monument to his memory, by planting them largely, and in order to prolong the season of bloom, planted both the American and European varieties. His planting was a success, as far as the trees are concerned, for they grew finely, but he

did not take into consideration the difference of soil and climate, and they are a partial failure as to honey. In this dry, sandy soil, the bloom all opens at once, and the bees hold high carnival while it lasts, for a day or so.

Granulated Honey.

At the National Bee-Convention at Detroit, there was on exhibition a square block of extracted, granulated, basswood honey. I was requested by the owner to sample it, and I never enjoyed eating any kind of confectionery as I did this magnificent sweet. The honey had been stored in a barrel, and, when it was used, it was taken out from one side, and a part left standing, which drained and hardened. A block was cut out from the dry side, and how nicely it sliced off.

Some persons have a mistaken idea, with reference to the granulation of honey. When it granulates in cold weather, as it runs out of the comb, they jump to the conclusion that the bees have been fed sugar, when it is an evidence of its purity.

Adulteration of Honey.

"Good morning: I called to see if I could buy some bees' honey. The doctor told me not to buy it at the store, but to get it where bees were kept, as there was so much manufactured stuff in the market."

"Come into the honey-house. Now what kind of honey do you want? Here is comb honey in sections, and there is extracted honey."

"The doctor told me to be sure and get bees' honey in the comb, and render it out myself."

"Now suppose I take this knife and cut off the cells and put it into that tin can which I call an extractor, turn the crank, and throw out the honey, would not that do?"

"No; the doctor said I must render it out myself. What do you charge for that white honey?"

"Twenty-five cents a pound."

"Twenty-five cents per pound? Why, I bought as nice honey three years ago as that for 'a bit,' and some for ten cents. What has become of all the honey? Then there was piles of it in the stores?"

"There has been a failure in the honey crop for several years. I want to make a bargain with you. When the doctor calls again, find out where I can buy some manufactured honey, for there is a man in Ohio who offers five hundred dollars for a sample. I'll go snooks with you, as the children say, and we'll make some money. Now my good woman, don't you suppose that if comb honey could be manufactured, at the price it now brings, the stores would be full of it?"

Peoria, Ills.

VALUE OF COMBS.

Practicability of Saving them for Several Years' Operation.

Written for the American Bee Journal

BY A. E. MALEY.

MR. NEWMAN:—I send you the following article which I found in our county paper, and think it worthy a place in the AMERICAN BEE JOURNAL. It is as follows:

It has long been a question with bee-keepers whether honey-combs could not be used for repeated filling, thus saving much time to the busy insect. A correspondent of the German-town *Telegraph* considers the question as completely settled, for he has thoroughly tested the experiment in his own apiary. He says: A beehive should contain about 1,800 or 2,000 cubic inches in the brood-chamber, which will require 1½ pounds of comb to fill it (if properly arranged as the bees will do), this being a fact as every one knows anything can testify. It requires at least 25 pounds of liquid, sweet or honey as the case may be, to make the 1½ pounds of comb, which it also requires at least 15 days' time for a good colony of bees to gather and secrete into wax in order to build the combs from, which is to supply the brood-chamber. It is also a fact, not successfully controverted, that a good colony of bees, say 20,000 strong, will gather at least 8 or 10 pounds of honey in a day if the honey season is a good one. We have often had them gather double that amount in a day.

At first thought, those who think but little about the true value of combs can hardly believe that it takes 25 pounds of honey for the bees to produce a pound and a quarter of comb, yet this statement is true, and any one who can figure will find that bees will store at least 100 pounds of nice honey in a season in combs given them to start with, and not compel them to use up the best and most valuable honey for making their combs.

We have often contended, and are still of the opinion that the best honey is gathered about the time that fruit blossoms come out, and especially when the white clover and other earliest blossoms are in full vigor, which is usually the time our bees here in the North do their swarming.

They are too often placed in an empty hive or gum to build new combs and shift for themselves, or, as it is usually called "luck," while we are very sure the old sinner "luck" has for many years been a failure.

As before stated, the first honey is our best, and in order to procure the

best we must save our combs from colonies that may have died, or in some other way left their hive, which is done too often by spring dwindling. These combs are truly valuable to the bee-keeper, and can be turned to good account by saving them for another year's operation. Do not melt them up for wax, for surely there is but little pay in the wax to the producer at 20 or 23 cents per pound, while the combs in many instances can be turned to good account by giving them to the bees, which will soon fill them with the best of all sweets—that of honey—which you can with very little expense extract and return the combs to the bees for refilling, and thus make a saving of at least 100 pounds of nice extracted honey worth, as a rule, 15 cents per pound.

"We know whereof we speak when we state that in the year 1882 we took from one colony of Cyprian bees 718 pounds of nicely extracted honey, which netted us 20 cents per pound; this we could not have done had we not saved our best combs and used them as before stated, saving both time and honey in the early part of the season, giving the bees the full benefit of a splendid honey harvest. Again let me say, look well to your bees, and they in return will richly repay you for all the trouble you may be at in their care. Time in bee-keeping may be as valuable as in any other calling on earth, and he who will heed its demands must expect to make slow progress."

Auburn, Nebr.

[We doubt the value of the advice to save empty combs for use during the succeeding season. It would be better to melt them up and use comb foundation, especially when the price of the latter is so reasonable as it is at the present time. The trouble of preserving combs from the ravages of moths would then be averted, which to the careless or inexperienced is something to think of.—ED.]

CANADA.

The Bee-Men of Norfolk Meet and Talk.

Written for the Norfolk Reformer.

The Norfolk Bee-Keepers' Association met at Dean's Hotel, on Sept. 1, 1888. The Vice-President, L. W. Kitchen, opened the meeting.

Mr. Rider reported very few swarms, no light honey, all dark, with an average of about 20 pounds of comb honey per colony.

Mr. Murphy reports no early honey. From 10 colonies in the spring he had extracted 500 pounds, and increased to 15 colonies.

Mr. McInlay gave his report. He had 115 colonies in the spring, increased to 200 colonies, and had 4,500 pounds of honey. He had worked on the tiering-up system this season, which was generally thought best for a year of this kind.

Mr. Kitchen reported very little early brood, and no clover honey. He had 6 colonies in the spring, increased to 8, and had taken 140 pounds of honey.

R. S. Gage reported an average yield of honey, but no increase.

C. W. Culver gave this report: From 13 colonies in the spring he increased to 23, and had taken 400 pounds of honey, gathered from the Japanese buckwheat. The winter stores are all buckwheat honey this year.

Rag-weed, motherwort, and golden-rod were spoken of as good honey plants this year. It was decided to give a special prize of \$10 at the Union Exhibition for the best and neatest display of honey and apiarian fixtures, the largest amount not necessary to win.

The next meeting will be held in Delhi, on Dec. 2.

THE QUEEN.

Lessons in Government from the Bee-Hive.

Written for the American Bee Journal

BY G. P. HACHENBERG, M. D.

Perhaps there is nothing in nature that has excited my admiration more than to watch and study the government of a thrifty colony of bees under the influence of the queen. The laws of political economy as instituted by man, surely could not improve it. Did nature here give us a representation of a government as it should be? If so, what a reflection on democracy?

When in the service as surgeon in the United States army in the far Northwest, I greatly astonished an Indian chief by telling him that the most powerful nation of the world was governed by a woman. He thought "such a nation was no good." Let me state here what I told him, that no King ever did as well as Queen Victoria.

Here comes to our mind what is the nature of that psychological influence of woman that is gifted to rule? It may not suit us men always to accede this gift to her, but nevertheless she has it, and it soon would manifest itself if physically she held the relation to man that working bees do to the

drones. Her primitive power to govern is manifested over her children.

No man can do justice to a child as a good woman can. And when she is called to a higher sphere of government, as her latent powers are brought into requisition, they develop into an irresistible force and influence. What woman ever took the military field that did not control every soldier heart and hand? It may be admitted that her force of reasoning and her power of execution may not be equal to man *ceteris paribus*; but her intuition of what is proper, armed with her own quick manner of reasoning, is not apt to run riot with false premises, such as characterizes so often the mental operations of man. Of course I only speak here of the best of women, and the general run of men in power, and not the woman that has been crushed by misfortune, perhaps through the bad habits and viciousness of her parents, husband and brothers or sons.

I have no doubt we have some women in this country, if any one of them could be made President of the United States, *with an able cabinet of men*, would glorify this country perhaps more than any President did since the days of Washington. With such a President and such a cabinet, their sexes would form hardly a factor in the party, except such as exist between father and daughter, son and mother, or rather between the bee-queen and her workers. The affiliation would be close, but exceedingly deferential and respectful, such as could not exist with any ruling power made up of one sex.

Nature evidently has made the female a ruling power—to rule in love, peace, and harmony. The male in all departments of animal life is by nature selfish, cruel, and exceedingly belligerent. In this there is no exception in man—and only where he soars over his own sex, he is a gentleman, a Christian, and a true scholar.

Austin, Texas.

Convention Notices.

☞ The Nebraska State Bee-Keepers' Association will convene at Lincoln, Nebr., on Jan. 9, 10 and 11, 1889. J. N. HEATER, Sec.

☞ The annual meeting of the Ontario Bee-Keepers' Association will be held at Owen Sound, Ont., on Jan. 8 and 9, 1889. W. COUSE, Sec.

☞ The twentieth annual convention of the New York State Bee-Keepers' Association will be held in the City Hall, Syracuse, N. Y., on Dec. 11, 12 and 13, 1888. G. H. KNICKERBOCKER, Sec.

☞ The 23rd annual meeting of the Michigan State Bee-Keepers' Association will be held in the Council Room at Jackson, Mich., on Dec. 12 and 13, 1888. Greatly reduced rates have been secured at the Huron House, also at the Commercial House (near the Michigan Central depot) at \$1.50 and \$1.00 per day. A programme is being prepared and excellent essays are already promised. Any bee-keeper having anything new and useful, and finding it impossible to be present, can send it by Express to Jackson, in care of the Secretary, who will place it on exhibition and return it as per orders. Please to come and bring your bee-keeping friends with you. H. D. CUTTING, Sec.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*Dec. 11-13.—New York State, at Syracuse, N. Y.
G. H. Knickerbocker, Sec., Pine Plains, N. Y.Dec. 12, 13.—Michigan State, at Jackson, Mich.
H. D. Cutting, Sec., Clinton, Mich.1889.
Jan. 8, 9.—Ontario, at Owen Sound, Ont.
W. Couse, Sec., Streetsville, Ont.Jan. 9-11.—Nebraska State, at Lincoln, Nebr.
J. N. Heater, Sec., Columbus, Nebr.May 4.—Susquehanna County, at Montrose, Pa.
H. M. Seeley, Sec., Harford, Pa.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM
OUR LETTER BOX

Results of the Season.—R. L. Tucker, Nevada, Mo., on Dec. 1, 1888, writes:

I commenced the season with 75 colonies, having lost 11 last winter. I doubled up the weak ones in the spring, and obtained about 4,000 pounds of choice clover and lucifer honey, of which 600 pounds was put in one-poun sections. I am now out of the bee-business, but I do not think that I will get much rest until I get back into it again.

Sugar Syrup Granulating, etc.

—G. H. Ashby, Albion, N. Y., on Nov. 27, 1888, writes:

I have noticed lately a good deal of complaint about sugar syrup granulating in the comb after teeding, and I think that I can see the main trouble. Those giving directions for making such syrup invariably say, take so many parts of granulated sugar, and so many of water. I have not seen the kind of water mentioned. Now soft water should always be used, and if not more than brought to a boil, it will not granulate, unless it is made too rich with sugar. I use two parts of sugar to one part of water, and never had it granulate. If hard water is used, acid must be added to correspond with the hardness of the water. Any confectioner can tell one all about it. Some do not need these instructions, but I am satisfied by reports that a good many do.

The honey season was very poor here, being about 20 per cent. of an average crop. Bees have had but few flights since Sept. 20, and gathered nothing since that time, although there was lots of bloom. It will make seven months' subsistence on less than the average amount of stores. All will depend upon the weather of early spring.

Bee-Literature and Bee-Work.

—Jas. W. Tefft, of Collamer, N. Y., writes as follows:

The AMERICAN BEE JOURNAL comes so regularly, and is freighted with the best about bees and honey. It is a remarkably clean paper, and is doing the bee-keepers of the world an inestimable amount of good. Its valuable opinions cause us all to think, and stimulate self-respect among bee-keepers. It is noted for the heavy paper on which it is printed, the artistic taste displayed in its illustrations, and the typographical work in general. To read and study it is to acquire a thorough knowledge of bee-keeping not readily obtained in any other way. It also illustrates the fact that

honey producing is one of the noblest pursuits.

There are two kinds of men in the world—those who care for bee-keeping, and those who do not; the latter class have no sympathy for the enthusiasm of the former, and are at a loss to see how the former can think that working in wet weather, on an empty stomach, long hours in cramped positions, and no end of bodily discomfort and hard work, can compensate for a few miserable pounds of honey! Nor can a true bee-keeper tell, but he simply knows that they do.

Originality in Bee-Keeping.—C. D. Battey, Peterboro, N. Y., on Dec. 3, 1888, says:

I have been a constant reader of the BEE JOURNAL for nearly a year, and I find it very interesting and instructive, although this is my thirtieth year in bee-keeping. I commenced when at the age of 8 years, and have been constantly in the business ever since. I have tried a large number of hives, plans, etc., in that time, but I have discarded them all, and I use hives and fixtures, and, I may say, a process of my own of managing bees. But I have always found that the more a man reads and studies, the more perfect will be his own theorizing. I have also built a house for wintering bees, above the surface of the ground. It is entirely different from what most bee-men advocate, but it was a perfect success last winter, and I now have 125 colonies peacefully at rest within its sawdust walls.

Spraying Orchard Bloom, etc.

—Dr. I. W. Warner, Elba, N. Y., on Dec. 3, 1888, writes:

1. Will you tell me through the AMERICAN BEE JOURNAL what effect, if any, spraying an orchard in full bloom with Paris green or London purple will have on the bees or honey? This has been a poor year for the bees and for me. I have 50 colonies. 2. Is there much honey stored in the State of Maryland? Is the central portion of the State a good bee-country?

[1. The spraying should be done just as the blossoms have fallen in May, and before the worms have entered the fruit. Then as there is nothing to attract the bees, it will not be detrimental to them or the honey.

2. Maryland is a good honey-producing locality, but we cannot determine the comparative value of different parts of the State. Will Dr. W. G. Phelps, of Galena, Md., kindly answer that question in the BEE JOURNAL?—ED.]

Wintering Bees Out-Doors.—Dr.

P. W. Schmidt, Ottawa Station, Mich., on Nov. 29, 1888, writes:

About one year ago I had the misfortune in the going of the railroad train, to have my left arm and a hip bone broken, from which I suffer badly yet, by the way of rheumatism, as I am 72 years old, and recovery is slow. I have 12 colonies of bees well packed on the summer stands in good sheds, as I think as much of my bees as some people think of a fine horse. They want to be protected as well as a horse. I did not get much honey this year, and the reason is, I am always gone away from home amongst the sick and afflicted, so I have to trust the bees to an ignorant man, and all know that if we have to look through another man's "specs," we can see but little. I have had over 20 swarms,

but through neglect I lost all but 3 of them. I got some honey, but not any to sell—200 pounds, that is all I obtained. My bees are in good condition, I think. I do not believe in any other way of wintering. I have kept bees all my life, but "out-door wintering of bees, well packed in straw," is my motto.

Heart's-Ease Honey.—Mr. E. T. Flanagan, Belleville, Ills., on Nov. 30, 1888, wrote as follows:

I did not get 100 pounds of honey during the summer from 160 strong colonies. In the fall they gathered enough to winter on from heart's-ease or smart-weed. The prospects are excellent for a tip-top crop from white clover next season.

Sneeze-Weed Honey, etc.—Mr. U. Stephenson, Gladstone, Ills., on Nov. 28, 1888, writes:

My bees did nothing until the fall honey-flow. I am situated near the confluence of the Henderson river or creek and the Mississippi, and fall flowers are abundant, such as golden-rod, asters, Spanish-needles and the sneeze-weed (*Helenium autumnale*), which I consider as good, and with me the surest producer of any of the above-named flowers. I have often wondered that this honey-plant was never mentioned by our modern writers. The honey is similar in appearance to the golden-rod honey, and I have had good judges pronounce it flavored with golden rod when I know there was none in it. I thought that I would call your attention to sneeze-wort, or "sneeze-weed," as I call it. I put 108 colonies into a good, warm, dry cellar or cave, on Nov. 26. A great many of which were so heavy that I am afraid they were too full.

A Magnificent Present

For every one who will send us a Club of five new subscribers for 1889, before next January. All the remaining issues of this year free to new subscribers.

**This ATLAS**

contains large scale Maps of every country and civil division upon the face of the Globe.

It is beautifully illustrated with colored diagrams, that show wealth, debt, civil condition of people, chief productions, manufactures and commerce, religious sects, etc., and a superb line of engravings of much historical interest & value, together with many new and desirable features which are expressly gotten up for this work—among which will be found a concise History of each State.

Price, in best English cloth binding (size, closed, 11x14 inches; opened, 22x14 inches), \$4.50.

To any one sending us, direct to this office, **FIVE NEW Subscribers** for one year, with \$5.00, (renewals not to count) we will present this beautiful Atlas, by mail, postpaid.

We have purchased one of them for our own use, and regard it as a valuable acquisition to our library. It is handsomely bound and contains a fund of very useful knowledge. It contains 192 pages.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in *Cheshire's* pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being mailable, it must go by express.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

A Home Market for honey can be made by judiciously distributing the pamphlets, "*Honey as Food and Medicine.*" Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the *Apiary Register* and begin to use it. The prices are as follows:

- For 50 colonies (120 pages)..... \$1 00
- " 100 colonies (220 pages)..... 1 25
- " 200 colonies (420 pages)..... 1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 120 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the LAST column. The regular price of both is given in the first column. One year's subscription for the *American Bee Journal* must be sent with each order for another paper or book:

International Bee-Convention.

—The Pamphlet Report of the Columbus, Ohio, Convention is now issued, and copies have been sent to each member, as well as to the Colleges, Agricultural and Horticultural Societies and periodicals devoted to the industry. Copies can be obtained at this office, by mail, postpaid, for 25 cents. This pamphlet contains the new bee-songs and words, as well as a portrait of the President. Bound up with the history of the International Society, and a full report of the Detroit, Indianapolis and Chicago conventions, for 50 cents, postpaid.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, \$1.00 per 100, or \$8.50 per 1,000.

The Date on the wrapper label of your paper indicates the end of the month to which you have paid. If that is past, please send us a dollar to carry the date another year ahead.

Do Not Fail to get up a club and send it with your renewal for next year.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 10 cents per pound for bag and postage.

Honey and Beeswax Market.

CHICAGO.
HONEY.—We quote: White clover 1-lbs., 18@19c.; 2-lbs., 16@17c. Good dark 1-lbs., 15@16c.; 2-lbs., 13@14c. Buckwheat 1-lbs., 14@15c.; 2-lbs., 12@12½c.—Extracted, 7@9c., depending upon quality and style of package. Receipts increasing, but demand still limited. Stock is not selling as freely this season as a year ago.

Sep. 17. THURBER, WHYLAND & CO

NEW YORK.
HONEY.—We quote: Fancy white 1-lbs., 16@17c.; 2-lbs., 13@14c. Fair white 1-lbs., 14@15c.; 2-lbs., 11 to 12c. Buckwheat 1-lbs., 11@12c.; 2-lbs., 10c. White extracted, 8@9c.; buckwheat, 6@7c. Demand good for white 1-lbs. and buckwheat 1 and 2 lbs., of which the stock is light. Good stock of white 2-lbs., with but little demand.
BEESWAX.—22½@24c.
Nov. 24. HILDRETH BROS. & SEGELKEN,
23 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.
HONEY.—White 1-lb. sections, 12@12½c.; 2-lbs., 12@14c.; amber, 8@10c. Extracted, white, 6½@7½c.; light amber, 6c.; amber and candied, 5½@5¾c. For comb honey the demand is light; for extracted it is good, and market firm.
BEESWAX.—Dull at 18@22c.
Nov. 15. O. B. SMITH & CO., 423 Front St.

DETROIT.
HONEY.—Best white 1-lbs., 17@18c. Supply is better. Extracted, 8@9c. Sales slow.
BEESWAX.—22@23c.
Nov. 17. M. H. HUNT, Bell Branch, Mich.

CINCINNATI.
HONEY.—We quote extracted at 5½c. per lb. Best white comb honey, 16c. Demand slow.
BEESWAX.—Demand is good—20@22c. per lb. for comb and choice yellow. On arrival.
Nov. 12. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.
HONEY.—Choice 1-lb. sections, 18c.; dark 1-lbs., 14c.; 2-lbs., 16c.; dark, 13c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock fair.
BEESWAX.—None in market.
Sep. 27. HAMBLIN & BEAR, 88, 514 Walnut St.

NEW YORK.
HONEY.—We quote: Fancy white 1-lb. sections, 17½@18c.; 2-lbs., 14@15c. Fair 1-lbs., 14½@15½c.; 2-lbs., 11@12c. Extracted, fancy white clover, 7½@8½c.; California white in 60-lb. cans, 8c.; light amber, in same cans, 7½c.; amber, 7½c. Buckwheat in kegs and barrels, 5½@6c. Cuban, in barrels and ½-barrels, 65c. per gallon.
Sep. 26. F. G. STROHMAYER & CO., 122 Water St.

BOSTON.
HONEY.—We quote: Best white clover 1-pounds, 17@18c.; best 2-lbs., 16@17c. Extracted, 8@9c. The receipts are very light, and honey sells fairly well.
Nov. 12. BLAKE & RIPLEY, 57 Chatham Street.

KANSAS CITY.
HONEY.—White 1-lbs., 17c.; fair, 14c.; California white 1-lbs., 17c.; 2-lbs., 15c. Extracted white California, 7½c.; amber, 7c.
BEESWAX.—None in market.
Nov. 22. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.
HONEY.—We quote: Extracted in barrels, 5@6c. according to quality; in cans, 7@8c. Comb, 12½@15c. Prices firmer on account of scarcity, though the demand is not great.
BEESWAX.—21c. for prime.
Oct. 17. D. G. TUTT & CO., Commercial St.

SAN FRANCISCO.
HONEY.—We quote: Extracted, white, 6½ cents; light amber, 6@6½c.; amber, 5½c. Comb, white 1-lbs., 13@14c.; 2-lbs., 13c. Light amber 1-lbs., 12@13c.; 2-lbs., 11@12c. Demand very active for extracted, and fair for comb honey.
BEESWAX.—24@26c.
Nov. 6. SCHACHT & LEMCKE, 122-124 Davis St.

To Every Lover of Good Reading :

DEAR FRIEND :—Mr. Will C. Turner, the well known Publisher and Managing Editor of the CITY AND COUNTRY, that excellent 16-page monthly magazine published at Columbus, O., has recently made an offer in connection with his publication which should certainly be accepted by you. CITY AND COUNTRY has been regularly published at the rate of \$1.00 per year, for the past seven years. Mr. Turner is anxious to increase his already large circulation within the next three months to 50,000 regular subscribers more.

To accomplish this purpose, believing that every subscriber will, at the expiration of their subscription, renew, he has devised the following plan :

Every person desiring to become a subscriber to CITY AND COUNTRY, which, by the way, contains each year four to five continued stories, thirty to forty illustrations in each issue, and a large amount of interesting reading—especially so to the ladies—is requested to carefully and plainly write out two complete copies of this letter, and sign your name at the bottom after the word "Per". These copies must then be mailed by you to two of your friends or acquaintances in some other town or locality, who are thereby requested to do just as you have done, viz : Write two copies and send to two of their friends, and so the work will go on and on. After mailing the two copies, the original letter which you copy from, together with a slip of writing paper, cut the size of a postal card, with your address plainly written on one side, and the addresses of the two to whom you have sent the copies on the other side, and 25 cents in silver or postage stamps must be enclosed in a letter and mailed to Will C. Turner, Columbus, O. On the receipt of these you will be placed on the subscription list for one year, the copy for the present month will be promptly mailed, and also, which is the greatest reason why you should accept this offer, five complete novels in pamphlet form will be sent you by mail, postpaid, which would regularly cost one dollar each if bound in cloth. Do not let the opportunity pass, as Mr. Turner only proposes to let this offer stand for a short time. True, it requires some time and work to copy all this twice, but you will be most handsomely rewarded for it.

[Signed,] WILL C. TURNER.

Per

EXTRACTED HONEY FOR SALE.

WE have a Large Quantity of CHOICE EXTRACTED HONEY for Sale, in kegs holding about 220 pounds each, which we will deliver on board the cars at 10 cents per pound for the WHITE, and 9 cents per pound for the AMBER COLORED. Orders are Solicited. Address,

MOISTURE.

IF you would know the effects of moisture in bee-cellars, how injury to the bees from its presence may be avoided, or how to have dry cellars, read the November Number of the BEE-KEEPERS' REVIEW. It gives upon these points the views and experiences of Jas. Heddon, H. R. Boardman, Dr. C. C. Miller, J. H. Martin, Eugene Secor, O. O. Poppleton, R. L. Taylor, Prof. A. J. Cook, and S. Corneil. Besides this, there are the usual lively, wide-awake, pointed editorials upon current topics; also appropriate extracts pertaining to the special topic under discussion. The Dec. No. will discuss "Sections and their Adjustment on the Hives."

Price of the REVIEW, 50 cents a year. Sample free. Back Numbers can be furnished.

The REVIEW and "THE PRODUCTION OF COMB HONEY," for 65 cts.

Address, W. Z. HUTCHINSON,
45EtF 613 Wood St., FLINT, MICHIGAN.

Free. ONE YEAR. Free.

WE have made arrangements with the publishers of the COTTAGE HEARTH, of Boston, Mass., to offer the AMERICAN BEE JOURNAL as a free premium, with their Magazine for the year 1889, and we now give to all our readers the benefit of this arrangement.

THE COTTAGE HEARTH

Is a well-known Family Magazine now in its 14th year, and is a favorite wherever it has been introduced. It has each month Music, Floral and Health Departments, Latest Fancy Work, Sabbath Reading, Demorest's Patterns, Approved Receipts, Household Hints, and Prize Puzzles for Children.

This beautifully illustrated Monthly is a large 34-page, elegantly printed Magazine, and has attained a large circulation solely on its merits as a family magazine. Its

Price, \$1.50 per Year,

is very low for such a desirable home magazine, but we will send both **The Cottage Hearth** and the **AMERICAN BEE JOURNAL** to any one who sends us \$1.50—just the price of one of these standard publications.

Sample Copies sent free on application to F. P. Shumway, Jr., Boston, Mass.

THOS. G. NEWMAN & SON,
923 & 925 West Madison-Street, - CHICAGO, ILLS.

We have some ELEGANT RIBBON BADGES, having a rosette and gold Bee, for bee-keepers' use at Fairs, Conventions, etc. Price 50 cents each, by mail, postpaid.

THOS. G. NEWMAN & SON,
923 & 925 W. Madison St., - CHICAGO, ILL.

THE FLORAL INSTRUCTOR.

A Beautiful monthly magazine, especially designed for amateur cultivators, will be sent a whole year, on trial, for only 20c. in silver or stamps. Mention this paper in replying.

EDITORIAL BUZZINGS.

Peal, Christmas Bells, peal loud and deep !
Ring out a merry Christmas chime
Till darkened eyes forbear to weep,
And hard hearts glow with love divine.
In rippling music die away
With ringing laughter, glad and gay,
Till rich and full the dark night swells
With Christmas lights and Christmas bells.

Now is the time to sell the honey. The holidays are at hand, and the best prices rule about that time.

Do not send to us for sample copies of any other papers. Send for such to the publishers of the papers you want.

The Pleasantest Things in the world are pleasant thoughts, and the great art in life is to have as many of them as possible.—*Bovee*.

Do Not Forget to send a dollar for a membership fee to the National Bee-Keepers' Union for 1889. It merits your approval, and needs your assistance.

The Ontario bee-keepers will meet in convention at Owen Sound on Jan. 8 and 9, 1889, at 2 p.m. For particulars about fares, etc., write to the Secretary, Mr. W. Couse, at Streetsville, Ont. Let there be a general rally, and profitable sessions will be the result.

Chin Protection.—A correspondent says that his bee-veil does not protect his chin. The "new bee-veil," having ribs of steel, fully protects not only the chin, but the whole head and face. It can be obtained at this office for a dollar, postpaid. It is the best protection ever invented.

Artificial Humbug.—S. Whan, of Venango Co., Pa., writes as follows to *Gleanings*, and which was published in the December number :

I fear your card in regard to false statements in the honey business will not prove effectual in all cases, as I met a man a few days ago who claimed he had talked with a man a few days previously who had eaten manufactured or artificial eggs in Chicago, and they could not be told from the genuine egg, except when attempting to beat the yolk and white together for pastries, as they would not mix. He also stated that the man had eaten artificial comb honey. After talking with him for some time I left him, in some doubt.

The editor follows this item with these remarks :

We had thought the story about manufactured eggs was too big for anybody to believe ; and yet there seems to be some old fogies and reporters who still persist in repeating it. Before us lies a clipping entitled, "What Next ?" It was taken from the *Pittsburgh Dispatch*. This clipping goes on to tell, in very plausible language, how eggs are manufactured, and how the same cannot be detected from the genuine. It is simply a rehash of the same old story. Why do not these chaps get up something new ? Manufactured live chickens or artificial strawberries would make good material for another yarn. This clipping has been copied in other papers, and will continue to be copied, probably, as long as anybody can be made to believe it. If such stories must be repeated, we sincerely hope that these "wily" reporters will take in the whole fruit realm, and go so far that even the old fogies will shake their heads in doubt.

If there is anything bad or vile—anything marvelous or prodigious—it seems to find a base for proof in Chicago.

The "impudent" and "ignorant" repeaters of falsehoods—the malicious vendors of "scientific pleasantries"—the venal and corrupt reporters of slanders about an honest and honorable pursuit, all pretend to find proof of their villainies in Chicago. Why is this ? There is but one excuse, the city is large enough in which to hide, when attempting to trace their calumnies to the supposed source.

When cornered, one of these "detestable villains" lately averred that the manufactory for "paraffine combs filled with glucose and capped by machinery made for that purpose" was located at the "honey shop on Madison street, near Oakley street"—meaning the office of the AMERICAN BEE JOURNAL. He loudly claimed to have there "seen the process and machinery at work." But when pressed to go and show the place, by one who knew that the BEE JOURNAL was fighting such diabolical lies, he was pressed for time, and could not throw away time to prove what he *knew* existed, and had seen at work.

Artificial eggs, artificial comb honey, and the like, are only talked about for the purpose of *deceiving* the public and injuring the sale of useful articles of food. The one is as reasonable as the other, and *both* are impossible—creations of the fertile brains of newspaper reporters who write for the dollars they obtain for "spicy" but lying "articles," "interviews" which never oc-

curred, and "fancy sketches" of things about which they are entirely ignorant.

Yes, Brother Root, the truth will never serve such fellows—they live on falsehoods and grow fat on carrion !

Mr. J. W. Bittenbender, when sending us a dollar for a year's subscription, makes this remark : "With pleasure I send you this dollar for subscription to the AMERICAN BEE JOURNAL ; for it is the *best investment* a bee-keeper can make." It certainly is the *best investment* a bee-keeper can make, to subscribe for a good periodical devoted to the pursuit in which he is engaged. He needs to keep abreast of the times, and he cannot afford not to do so. He needs to be fully posted as to the crop of honey, the state of the market, and the price of the product. The only way to successfully do this is to take an interest in a good bee-paper. By the investment of a single dollar in the AMERICAN BEE JOURNAL, he will get 52 dividends—one every week. If he does not make this small investment, he stands in his own light !

Reader, do not fail to send a dollar and get those 52 dividends for 1889.

The Rev. L. L. Langstroth has again recovered (at least partially) from his severe indisposition, lasting for some months, which caused a great weakness of body, although it did not induce the distressing despondency of former periods of illness. As usual, he has not been able to use his pen during the intervening months covered by his indisposition. He writes us that he begins "to feel that the worst is now over." We hope it is, and that he may now be able to enjoy the remaining years of a noble life, and when the summons comes to enter eternal life, he may receive a hearty welcome at the portals of Glory, and become one of "the living stones" in the Temple of Heaven, where no *discordant voice* of censure or bitterness will ever be heard, and all experience will be perfect bliss, and all expressions will be perfect praise, and "love divine will ennoble every heart, and hallelujahs exalted employ every tongue."

Foul Brood (so-called) is said to be cured by the use of dried thyme, in Switzerland. The *Bee-Keepers' Record* for December remarks as follows :

According to a newspaper cutting just sent us, a Swiss bee-keeper cured foul brood with thyme. This common herb was dried, put into an ordinary smoker, set alight, and the smoke injected plentifully into the hive at the entrance. After doing this eight evenings, he found the larvae, which had died from the disease, quite dry, and the new brood in a perfect, healthy condition. He continued the fumigation another eight days, which ended in a complete cure of the disease.

Roaches.—Gum camphor will speedily clear the house of cockroaches.

GLEAMS OF NEWS.

Bees in Winter.—The *American Agriculturist* for December contains the following directions for the care of bees in winter, from the pen of Mr. W. Z. Hutchinson. It contains many valuable hints about bees in winter quarters. He says:

There are various methods of preparing bees for winter so that no subsequent care is needed. One is to place the hives above the snow line, packing them in chaff, leaves, sawdust, or fine hay, with a rim two inches wide under each hive. When prepared in this manner the entrance cannot be clogged by snow or dead bees. Should a warm day occur, the bees can enjoy a flight.

Another method is to bury bees in a pit or "clamp," where, of course, no attention can be given. Bees stored in a properly arranged cellar or repository require no attention except to see that they are undisturbed by rats or mice, and that the temperature and ventilation are correct. An effective way of getting rid of mice or rats in a cellar is to poison them with equal parts of arsenic, flour and sugar. The temperature should be kept at about 45° during the early part of the winter.

After the bees have commenced brood-rearing, say in February, a higher temperature is beneficial, and it may be gradually raised to about 55°. Authorities differ in regard to ventilation; but pure air in the cellar can do no harm, and there is no better method of supplying it than through tiles laid below the frost line.

An abundance of stores should be left in the hive, as it would probably be better to allow a few colonies to starve than to disturb all the hives by examining them to learn if any needed feeding. Should it be discovered, however, that a colony is short of stores, and there are no combs of honey to give it, candy made of granulated sugar may be fed.

Hives, as usually prepared for winter, are often partially buried in snow. This does no harm, but may be beneficial, until a warm day comes and the bees wish to fly, when the snow must be shoveled away from the entrance, or the cover removed, and the bees be allowed to take their "purifying flight" from the top of the hive.

Hives standing in the open air should be protected against the intrusion of mice. Have the entrance only $\frac{1}{4}$ of an inch high, and protected with tin.

Skunks sometimes scratch at the entrance of a hive; the bees come out to learn the cause of the disturbance, and are caught. A box-trap set for the skunk is the best preventive. The animal never discharges its weapon while in a box-trap.

When bees are buried in a pit, a sandy hill-side should be selected as the site, and a tile drain put underneath. When these precautions have been neglected, care should be taken that no water stands upon the surface around the pit.

A California Pun.—"Say, Gran'pa, wh'd'ye spouse was the cause of the yell Charley gave when he passed the bee-hives just now?"

"Give it up, Johnny."

"Why, bee-cause, of course."—*San Francisco Examiner.*

Your Full Address, plainly written, is very essential in order to avoid mistakes.

Five-Cent Packages of Comb Honey.—Mr. W. Harmer, of Manistee, Mich., who got up the two-ounce packages of honey in the comb, reports that he has made another improvement in the plan of getting them for the market. He says:

The improvement is in the production of the two ounce sections without inserting comb foundation in them, when finished there is no center piece or mid-rib, but one continuous cell capped on both ends.

Foundation is used, but it is removed before the honey is quite finished, and the same sheets of foundation can be used over and over again. I consider this a great improvement, as it produces a more delicate article with less trouble. This is true economy, and you will agree with me, is in the right direction to work.

I do not think this would be an improvement for the larger sections, for the mid-rib gives support for shipping, and we get more honey for the amount of wax than we would in a small section that was only $\frac{1}{8}$ of an inch thick.

Of course there is no patent on this, but I think it will be a great help to those who produce honey in the two-ounce sections, as the trouble of putting in the foundation has been mentioned as an objection to them.

Christmas Weather Proverbs are not new, but may be interesting reading to some, who may fancy speculating upon the coming year and its prospects. They are as follows:

A warm Christmas, a cold Easter.
A light Christmas, a heavy sheaf.
A green Christmas, a white Easter.
A green Christmas, a fat cemetery.
A wind on Christmas day, trees will bring much fruit.

If Christmas finds a bridge, he'll break it; if he finds none, he'll make one.

If ice will bear a man before Christmas, it will not bear a man afterward.

The shepherd would rather see his wife enter the stable on Christmas day than the sun.

If the sun shines through the apple-tree on Christmas day, there will be an abundant crop the following year.

Bee and Pigeon Race.—On page 692 we gave an absurd item from the London *Sporting News* on the above race, said to be had in Germany. The *Bee-Keepers' Record* has been tracing it out, and gives the following explanation of it:

Referring to the absurd paragraph which went the round of the British press, describing what was called a "Bee Race," we are enabled, through the courtesy of a gentleman conversant with the German language, to give a correct version of the affair as described in the German papers. It appears the race actually took place, and was for *one mile*, not "*one hour*." The bees were dusted well with flour before being started, consequently they were *white*, hence the mistake as to the "white drones" referred to as returning first to the hive. Finally the eight working bees preceded the ten pigeons by one *second*, not "a length," as stated.

The Time for Reading has come, with the long winter evenings. We have a large stock of bee-books, and would like to fill orders for them. To read and post up is the way to succeed in any pursuit—in none is it more important than in bee-keeping.

The January Number of Frank Leslie's Sunday Magazine, coming before the holidays, very properly and pleasantly devotes some of its pages to Christmas scenes, stories and poems. Beginning with a beautiful poem by G. A. Davis, entitled, "Under the Mistletoe, A. D. 1187," we have discussions of the "Significance of Christmas," "Christmas Customs and Festivities," "Christmas Street Music," and "Christmas at Mount Vernon," a poem by Etta W. Pierce. There are also an article, "From Bethlehem to Calvary," with four full-page pictures of actual scenes in the Holy Land from recent photographs, a very interesting article on "The Legend of the Holy Grail," and a caustic one on "The Firm of Push & Pull," by Dr. Talmage. This number is the first of a new volume, and affords a favorable time to subscribe to the magazine.

To Our Subscribers.—Send to F. P. Shumway, Jr., Boston, Mass., for a free sample copy of the *Cottage Hearth*, a beautiful illustrated magazine, and so realize what an EXTRAORDINARY OFFER we are making when we propose to send both the *Cottage Hearth* and the AMERICAN BEE JOURNAL for a full year for only \$1.50, when the price of the *Cottage Hearth* alone is \$1.50 a year, thus giving you two standard publications at the price of one.

While we are now getting ready for the rigors of winter, the Australian bee-keepers are preparing for their honey season. From the last *Australasian Bee Journal* (Oct. 1) we learn that the season has opened up unusually early. Swarming has already commenced, and the prospects are bright. Who knows but this is simply a forerunner of what we may expect when our spring comes? Certainly such a state of affairs will be very acceptable. Our world is so large, that we sometimes think that the whole of it is going into winter quarters. It is refreshing to hear the notes of spring, even though from a far country.—*Gleanings.*

To Delinquents.—After January 1, 1889, we shall discontinue sending the AMERICAN BEE JOURNAL to those who have not responded to the bills we sent out a few weeks ago.

This does not mean that we shall try to deprive any one of the pleasure of reading the BEE JOURNAL who really desires its continuance, but finds it difficult to pay now. Such can get a short extension of time by asking for it. We should be sorry to lose any subscriber who wishes to have its weekly visits continued, but do not want any to continue to take it who do not think they are getting the full worth of their money.

We hope each one will endeavor to send us one or more new subscribers when they renew. We want at least ten thousand subscribers for 1889.

QUERIES AND REPLIES.

Securing Clean Sections of Comb Honey.

Written for the American Bee Journal

Query 598.—Is there any method by which honey can be secured in sections so clean as not to need scraping?—S.

No.—M. MAHIN.

I have found none.—MRS. L. HARRISON.

I do not know of any.—A. B. MASON.

Not that I know of.—J. M. HAMBROUGH.

None that I am aware of.—J. E. POND.

I think not, that would satisfy me.—C. C. MILLER.

There is no practical way of securing it so clean that it will not be the better of some scraping.—R. L. TAYLOR.

By using wide frames properly made, the sections will need very little scraping.—G. M. DOOLITTLE.

Yes, by using crates so arranged that the entrance to the sections is the only part exposed to the bees.—J. P. H. BROWN.

By using clamps—the Manum, Foster or Heddon—there will be but little propolis. But the principal requirement is to take off the sections as soon as sealed.—DADANT & SON.

Yes. I believe there has lately been invented a section-case by somebody, that pretends to accomplish this feat (?).—WILL M. BARNUM.

I do not think that there is. It makes no difference what kind of crate, or how tight you put the sections together, there is always a little scraping to be done.—P. L. VIALON.

Yes. The "two-part super" with wooden partitions and section shields will do it, if care is used in filling the super.—J. M. SHUCK.

No, not invariably; but with a slatted honey-board we get very nearly there. But the bee-spaces must be just right.—A. J. COOK.

Not all, at all times of the year, and in all localities. There are places where, at times, no propolis is gathered by the bees, and when honey is stored and finished then and there, no matter what style of case you use, no scraping is needed.—JAMES HEDDON.

No, not if you want to put your honey on the market in first-class condition, and that is the only condition you should put up honey for market.—H. D. CUTTING.

Mr. Shuck's method very nearly accomplishes it, but there is more work in putting up the cases. I shall be glad to know of one that will leave the sections so clean that they need no scraping, and yet can be manipulated rapidly.—EUGENE SECOR.

No, there is no method that is practicable in a large apiary, that will entirely exclude propolis. I use a section-case adapted to the tiering system, and I only have to clean the edges of the sections. Bees will *spew* propolis between the edges of the sections, no matter how closely they join together.—G. W. DEMAREE.

No. There will always be some propolis in the corners and edges of the sections. No system is perfect where the bees are allowed to come in contact with the outside of the sections. Carniolan bees use very little propolis, and sections filled by them need but little scraping.—C. H. DIBBERN.

Perhaps no method will prevent *all* propolis, but it can be reduced to a minimum by the use of section protectors of the same size and shape of the bottom-bars of sections, then the edges alone are exposed. To take away the honey as soon as capped will prevent much discoloration. But in all methods the edges of the sections should be scraped.—THE EDITOR.

Sawdust for Protection Around the Hives.

Written for the American Bee Journal

Query 599.—I can get all the sawdust I want by hauling it 300 yards. Will it pay me to haul it and put it around three sides of my hives on the summer stands, placing none in front, for winter protection?—Kentucky.

Not if you put it on loose.—DADANT & SON.

For myself, I should consider it of no value whatever.—J. E. POND.

I think it would. It would in this latitude, if kept dry.—R. L. TAYLOR.

I have had no experience. In some locations it might pay.—C. C. MILLER.

Yes, if dry, with the extra precaution of a good covering.—J. M. HAMBROUGH.

I would not advise sawdust in the apiary, since I had it to get on fire by sparks from the smoker.—P. L. VIALON.

I should think it would, and by fixing the entrance the sawdust could be used in front also.—A. B. MASON.

I am in doubt on the subject. If dry, and kept dry, it might be all right.—EUGENE SECOR.

I think not. In Kentucky no packing is necessary. A few inches of saw-

dust over the brood-nest, with ventilation above it, would be an advantage.—M. MAHIN.

It would be a great help if the sawdust is protected and kept dry.—H. D. CUTTING.

It is doubtful, unless the sawdust is dry, and can be kept so. Chaff hives would be much more preferable.—G. M. DOOLITTLE.

No. It absorbs moisture, and promotes the decay of the hives. It will pay to place it around the hives to keep weeds down.—J. P. H. BROWN.

In your latitude I do not believe that it would pay to do this. Try a few and determine for yourself.—C. H. DIBBERN.

In a Northern latitude it doubtless would, if covered so as to keep the sawdust dry. In Kentucky I should think that it would not pay.—MRS. L. HARRISON.

I am satisfied that it would pay me, though it would have to be packed down well. Why not put it in front of the hive also, laying a thin board before the live-entrance?—WILL M. BARNUM.

I do not know just what sort of a climate you have, but I think that it will pay you to do as you say. I would put the sawdust between the hive and an outer case, and keep it dry at all times.—JAMES HEDDON.

It makes it very easy to find a queen, to have sawdust all over the ground, but there is always danger from fire. I have tried all the ways, and I settle down on a close, smoothly-cut lawn.—A. J. COOK.

It will pay well if intelligent and faithful treatment follows through the seasons. If the bees are to be "let alone" during the gathering season, and no profit derived, any expense whatever is so much lost.—J. M. SHUCK.

I think not; our winters in Kentucky are usually attended with a great deal of wet weather, rain and melting snow, and your bank of sawdust would become a wet heap about your hives, well calculated to rot the under part of your hives without doing any good. Here in Kentucky, plenty of stores and some warm quilts over the tops of the frames have proven ample protection to my bees. Give me a hive full of honey, and I will show you rousing colonies in the spring, no matter if the winter "howls."—G. W. DEMAREE.

In your latitude it would hardly pay, we think; especially if not kept dry and well packed down. If you try it for a few hives, you can better judge of its utility.—THE EDITOR.

CORRESPONDENCE.

NEBRASKA.

The Apiarian Exhibit at the State Fair.

Written for the American Bee Journal
BY J. N. HEATER.

I have sent a picture of the building erected by the Nebraska State Fair Association expressly for the bee and honey exhibit. The building is 20x30 feet, with a bee-yard 20x24 feet. The interior of the building is arranged with tables on one side for the, honey exhibit, on the other side for imple-

Upon looking at the picture, one would no doubt ask who the parties are, standing in front of the building. The one at the corner with heavy side-whiskers is the Superintendent of the Bee and Honey Department of the State Fair, Mr. E. Whitcomb, Friend, Nebr., and to whom every bee-keeper and lover of honey in this State is indebted perhaps more than to any other person, for securing permanent quarters, and so neat and convenient a building on the grounds of the Nebraska State Fair Association. When the bee-keepers in convention last winter recommended Mr. Whitcomb to be appointed superintendent of this department, we requested him to endeavor to secure for us a permanent location, and, if possible, a build-

a snow-bank, as we have often been advised to do, in our bee-papers and elsewhere. I know that there are some who seem to have success in that way, but with me, whenever I have tried it, either by purposely doing so, or by getting caught with a deep snow-bank over a part of my bees when I did not expect to be so caught, the result has always been one of disastrous wintering. Why this should be so I do not know.

All seems to go well for a short time, say three or four weeks, when the bees get uneasy and begin breeding, which brings on bee-diarrhea, resulting in the soiling of the hive and combs, and finally death ensues. If any of them get through to spring, they are taken with spring dwindling, so as to be nearly worthless as colonies for storing honey. What causes such a state of affairs, I do not know, unless it is because the bees get too warm; for I always find the snow all thawed away from the hive, enough so that a small dog or cat could go all around it at the bottom, with no frost in the ground.

As my hives are only three inches off the ground, that may have something to do with the matter; and I would here ask those who are successful in wintering bees under snow, to tell us how much above the ground they have their hives when under the snow.

To illustrate the condition I always find my bees in, when I have tried to winter them under snow, and to show that I am not the only one who cannot succeed by this plan, I will quote a little from an article found on page 409 of the AMERICAN BEE JOURNAL for 1885, written by L. H. Scudder, of New Boston, Ills. He says:

"Fifty colonies left on the summer stands were in Langstroth hives in a row along the east side of a hedge, and about four inches from the ground. Soon after winter set in, the snow drifted until it was level with the top of the hedge, thus completely burying the bees under a snow-drift from 3 to 5 feet deep. It looked like cold comfort for the 'little busy bees,' but as I had frequently heard that plan of wintering recommended, I concluded to let them alone; however, after allowing them to remain in that condition for some three or four weeks, I thought I would see how they were doing, and accordingly I opened up a trench in front of 16 hives, and found the bees all alive, and apparently in good condition.

"By this time I was tired of shoveling snow, and being satisfied that I could not improve their condition, I quit work, leaving 34 colonies under the snow unmolested until March 1, when it commenced thawing. I then

House for the Apiarian Exhibit at the Nebraska State Fair.

ments with an elevated platform the full length of the implement tables, for exhibitors to stand upon and explain their wares.

A high, tight board-fence is at the rear of the building; this is the bee-yard, which is entered from the building through double sliding-doors, the inner one covered with wire-netting. There is also wire-screen windows all the way around the fence, which permit persons to see inside the enclosure with safety. The fence is 8 feet high, which compels the bees to fly high in the air when going to and from the hives, passing over the heads of the people.

The State Fair Association have, we think, been very liberal with us in putting up so neat a building for our use, and they still further promise to revise and enlarge the premium list, and make the bee and honey show a permanent feature of our future fairs.

ing, not thinking that any one would be able to accomplish so much in our interest.

The middle gentleman is Mr. M. L. Trester, of Lincoln, the President of the Nebraska State Bee-Keepers' Association, and the modest fellow standing in the door is the writer, your humble servant.

Columbus, Nebr.

UNDER THE SNOW.

The Wintering of Bees Under the Snow, etc.

Written for the American Bee Journal
BY G. M. DOOLITTLE.

As winter has again put in its appearance, and the time of snow is at hand, I thought it best to write a word of caution about wintering bees under

opened them up, and found but few living, and all in a miserable condition. They all had been breeding, some having five or six frames of brood. It took but a glance to see that diarrhea had done its work effectually. Of this lot of 34, 6 are now living, and from the 16 from which the snow was removed, 10 are living."

In the above case it will be seen that Mr. Scudder's bees were 4 inches off the ground, yet his experience was almost exactly the same as mine has been for the past 15 years, whenever I let any of my bees get drifted under.

I would advise all those who have not had experience in the matter, not to let many of their colonies get drifted under snow until they are sure that they will winter well that way.

The Best Kind of Hives.

From the many letters which I get, asking how much more honey the writers would be likely to get if they were to change the hives they were now using for such and such hives, it would seem that there was an impression in the minds of some that the *hive* produced the honey, to a certain extent at least, rather than the bees. Now this is not true. Bees will store as much honey in one hive as in another, or in a nail-keg, for that matter, provided they have at all times as much room as they need. All that any hive can claim over the nail-keg is, the ease that it gives in manipulation, and the facilities it possesses for giving us the product of the bees in the most marketable shape. It is the bees, not hives, which produce honey.

With a hive which is easy of manipulation, we can get the bees in time to collect the harvest of honey which, God in his providence causes the flowers to secrete at certain periods of the year; while if the nail-keg is used, or some unwieldy hive, we have little if any control of the matter of getting the bees at just the right time for the harvest.

With the nail-keg, we could cut the honey out of the top of it, to a certain extent, and so supply ourselves with the product of the bees, which, perhaps, would be better than no honey at all; but no one who retails honey at the present time would give half as much for it, as they would for honey in the nice sections of the present day.

If any one has to the number of 25 colonies of bees in any of the good, movable-frame hives of to-day, I do not believe that there is enough advantage to be gained by changing them to a hive of another pattern to pay for the cost of changing; nor do I believe that the labor of manipulation will be lessened with the new hive to any extent proportionate to the cost

which will be required. Any of the new theories of the day can be accomplished with any of the half-dozen good hives we have in the different apiaries of our land, and any of the different surplus arrangements can be fitted to any of these hives.

This idea of frequent changes in the apiary, as regards hives, fixtures, etc., is damaging to our pursuit. The old adage, that "A rolling stone gathers no moss," is as true here as anywhere. He who thinks that it is necessary to pay out half of the income from the apiary every year in the changing of fixtures, so that he may be up with the times, is certainly laboring under a mental abnormality. If any one has the necessary resources, so that he can go into all of the new-fangled arrangements as they come up, without injury to his family or those about him, he has a perfect right to do so; but the impression that seems to obtain, that all must do this, is not right, and the sooner it is frowned upon, the better for the world, and the better for our pursuit.

Borodino, N. Y.

CHLOROFORM

As a Prevention of Increase— Introducing Queens, etc.

Written for the Canadian Honey Producer
BY W. H. KIRBY.

During the past season many articles have appeared in the various bee-papers, written by some of the most extensive and most experienced bee-keepers of the day, on the important subject, "The prevention of increase in working for comb honey." The sum and substance of all that has been written is to give plenty of room to a colony to prevent them getting the the swarming fever, and the vigorous use of the extractor to deprive them of the swarming fever after they once get it.

In my opinion, prevention is better than the cure, by a long odds. This extracting of nice sealed honey out of the brood-nest (which makes the best of winter stores) is something I could not tolerate, to say nothing about the extra work for nothing, when a much easier and simpler method will do.

The swarming fever appears to be, and is, the great trouble to get over when the bees once get it. The best, the easiest, the quickest, and the cheapest way to cure that fever is by the use of chloroform, given to them by the smoker, just at dark when the bees are nearly all in the hive—to be given to them until they lie like dead bees upon the combs, or until not a

bee will fly when the honey-board is taken off and the hive kicked.

Two years ago last June I treated a colony just as I have described. They had their first queen-cell capped, and would have swarmed the next day. The morning after drugging they went to the fields as usual, apparently none the worse for the dose. Upon examining them in the evening, 24 hours after the drugging, the queen-cell was still intact. Forty-eight hours after drugging, I examined them again, and found the cell still intact, and no further progress had been made on any of the other queen-cells.

They had one case of sections on. I then took away all finished sections, and filled up again with sections containing full sheets of foundation. Seventy-two hours after drugging, I examined them again, and found the cell torn to pieces. About a week after this I gave them another case of sections; there was a steady, moderate yield from the raspberry during this time. This colony gave me about 50 pounds of nice finished sections that season.

The above experiment convinces me that chloroform is the specific.

When a swarm issues, put it back, take away all finished sections, and fill up again, and give room enough for all the bees to work; then give them a good drugging in the evening. Before morning they will get rid of the effects of the drug, and will have forgotten, or given up all notion of swarming, and go to the fields to gather nectar and pollen as usual the next day. I find chloroform very useful in the apiary.

In introducing queens not a queen need be lost. Also in the uniting of colonies, not a bee will be lost from fighting excepting one of the queens. Also in moving bees about the apiary, set them anywhere, and in the evening give them a dose. In the morning they will be seen marking their location as they fly out, and will return to it, they having forgotten all about the old one. I suppose ether would do as well as chloroform, although I have never used it.

In all cases the drugging should be to a stupor, except in introducing queens in a honey flow, when very little or none is needed. Objections may be taken to the use of anaesthetics in the apiary, on the ground of their being injurious to the bees. My observation has been very close, and so far I have not been able to detect any difference. Twelve hours after a colony has been drugged, they will be as brisk as ever. As a proof of this, take a queenless colony in the fall that is being robbed by wholesale, no defense being made at all; drug in a

queen in the evening, and in the morning watch and see how the inmates will shoot up off the alighting-board at the robbers as they appear.

The foregoing remarks are from my own observation and experience. My theory for the prevention of increase in working for comb honey originated with myself (never having seen any thing written on the subject).

I only tested it on one colony; but I have no doubt but what chloroform will prove effectual every time if properly used. I do not need to prevent increase as yet, because I am working up an apiary from a small beginning, but if the time ever comes that I shall need to, chloroform is what I shall use to accomplish my purpose.

Oshawa, Ont.

BEE-NOTES.

Items of Interest about California Bee-Keeping.

Written for the American Bee Journal
BY S. L. WATKINS.

Bees have ceased working for the season, as all kinds of bloom have ended. The foliage of the surrounding forests has begun to exhibit the hues and tints of autumn. The birds have gone further south for the winter. The air is no longer gladdened by the sound of myriads of insect wings.

Bees Ready for the Winter.

The honey-bees are now housed up for winter, and every three or four days they go out for a flight, and circle around for a while, but soon return to the hive. The breeding season has now passed, although some colonies with extra prolific queens have a few square inches of brood. All careful apiarists have prepared everything for winter, covering each hive with a roof to shed winter rains and snow, and giving colonies that are in need of stores, sufficient to winter on, etc. Bee-keepers can now take a few days' rest preparatory to getting ready for another season's work.

Races of Bees vs. Location.

It has been proved conclusively that the Italian bee is superior to the black or brown bee, for honey-gathering in most locations. Having three different apiaries located twelve miles apart, respectively, I have a good chance for observation and study on this subject. I find that at an elevation of 4,000 feet and upwards, the black bee equals the Italian, or any of the yellow races; while at an elevation of 1,000 to 4,000 feet, the yellow races do the best.

Crossing Italians and Carniolans.

I find that a cross between the Italians and Carniolans give the best results when working for comb honey at any of the apiaries. A few miles make a great change in bee-locations. For instance, if it is a very wet and rainy season, the foot-hill apiary will do the best, and if it be a dry season, the mountain apiaries do the best. Such has been my experience the last few years.

At the mountain apiaries there is continual bloom from the middle of February to November, keeping the bees busy the entire season. In the foot-hill region the honey season ends in July. I was always bothered a great deal by robber bees in the latter location. After the honey season ends, and the hot weather comes on, bees dwindle down rapidly. I lost several colonies of Italian hybrids and black bees the past season. They would not protect themselves against robber bees. The Carniolan bees did not participate in the robbing, and not a single colony of them was robbed. They are second to none in defending their hives against robber bees. In the mountains I have no trouble whatever with robbing.

Placerville, Calif., Dec. 4, 1888.

ITALY.

A Visit to the Queen-Breeders of Italy.

Written for the British Bee Journal
BY T. B. BLOW, F.L.S.

The many controversies which have arisen during the past with respect to the merits or demerits of the Italian bees, induced me, in the interests of British bee-keeping, to pay a visit to the north of Italy, to study them in their native habitats, and to come to some decision as to their qualities as compared with other races, and more especially with the English bees.

Those who have carefully noted the published accounts of the Italian bees from their first introduction will remember the surprising successes that were years ago achieved; and I could call to mind several who have kept Italians for many years, and still hold that they are far ahead of the blacks. The Americans, too, quite upheld this opinion, and hold it strongly still.

Carefully considering these facts, I was led to think that the root of the evil, and the reason of the many grievous complaints that have lately been made, might lie in the inferiority of the queens imported during the last few years. Those who years ago went in strongly for Italians (and have suc-

ceeded), usually kept in stock by breeding from the best, rather than by constantly importing queens. And the same method obtains in America, where most of the Italians are home-reared—not imported—and I think it will be admitted on all sides, that, as far as scientific queen-rearing is concerned, the Americans stand at the head of the world, though the successful persons in England, that I allude to, are individually equal.

To get the best results we ought, undoubtedly, to import the finest queens, and then to rear the best from them here, keeping up the stock with occasional importations, perhaps. In this way we can perpetuate the best features of the race, and at the same time get bees that are perfectly acclimatized. For it is an admitted fact, that the bees, the immediate progeny of imported queens, are far more liable to disease—especially diarrhea—than are the progeny of a home-reared Italian. And, with the facilities which modern bee-keepers have, there is not the least difficulty in getting the home-reared queens purely mated, and thus practically keeping our strain pure, if absolute purity is desirable.

The complaints made by those dissatisfied with Italians are: 1. They do not winter well. 2. As honey-producers they do not equal the English bee. 3. That they are very vicious and unmanageable. 4. And lastly, some have asserted that a very virulent form of foul brood has been introduced by them. From an examination (extending over a considerable time) of many apiaries, I have come to the conclusion that most of the evil repute that has fallen upon Italians has been brought about by the inferior queens sent. In some cases the breeders know nothing about their business, and procured the cheap queens which are sent so freely in the autumn, by going around and collecting them from the colonies condemned by the country people to be taken up for the honey; they get these and the bees for about a franc each.

By this system many queens would be quite old and worn out, others unfertilized, and therefore drone-breeders; and in a district where foul brood occurred, of course the disease would go with the queens, and disastrous results would follow by its introduction into the apiary of the unsuspecting British bee-keeper. I have in my mind's eye one case of a well-known cottage bee-keeper, whose apiary was utterly ruined by the introduction of foul brood by Italian queens. This system of getting queens from condemned bees, I saw in full swing in many cases (in one case by the servants of a well-known exporter); the

time of year being most favorable for this practice, and I certainly saw several fine examples of foul-broody combs.

In other apiaries no trouble seemed to be taken with the quality of the queens, such as selecting the best queens to rear progeny from, nor was any attention paid to the rearing of drones from suitable colonies. These great considerations were quite neglected; the great point seeming to be, the largest number of queens in the shortest possible time, and with the least trouble; and, as far as I can judge, many were sent off without it being definitely known that they were fertilized, and I feel sure that some such queens arrive in England, and are here fertilized, as, in the course of my experience as an expert, I have had shown to me many colonies of bees that I was assured were the progeny of an imported queen, but were certainly hybrids.

My visits to apiaries extended over the country between Bellinzona and Montselice; this embraced the mountainous district of the northern Italian lakes, and the plains of Lombardy, and again the hilly country around Bologna.

I may say at once that I certainly prefer the bees from the mountains, as they seem much more vigorous and hardy; and the results in the way of honey-gathering, as far as I could get at the facts, were certainly far better. The bees from these hilly parts would, too, be better suited for our climate. The number of apiaries visited was large, yet I can count upon my fingers of one hand all those who knew anything about their business; and if those who took a real pride in the production of their queens, and who use really scientific means to insure the best results, then the number would certainly be less than five.

I shall describe the apiaries of the best of these, and their methods; but before doing so, will give the conclusions which I have come to with regard to Italians: That, excepting perhaps Caruiolans, there are no better bees than Italians if care is taken to get the best queens from a breeder of recognized merit.

That the bees of the mountains are hardy, vigorous workers, great honey-gatherers, prolific, and certainly gentle, and in their own country not given to robbing much.

That to get the best results from Italian bees, we must get a good strain to start with, and then, by careful selection, rear our own queens, and be constantly on the look-out for those having the most desirable characteristics, and to propagate from them only.

I can name one very striking case in my own country, where all these points

have had most careful attention given to them, and with the result that the bee-keeper is not only the best in the country, but one of the best in England, as far as results go; and practical results (the largest amount of honey, of the highest possible quality, got with the least expenditure of labor on the part of the bee-keeper), are what we require in this age of keen competition.

The first apiary which I visited belonged to Jean Pometta, and was on the hills above Gudo, near Bellinzona. He had promised to meet me at Bellinzona station; but on account of the breakdown of the telegraph wires, owing to a heavy fall of snow, he failed to be there. However, it was not much trouble to find him. Everybody whom I asked was able to direct me to the man who had a lot of bees; and after a most picturesque walk of two or three miles I arrived at his home, in the midst of vineyards, and with a waterfall close by, which would have made the fortune of any man in England who possessed it.

He was from home; not having got my telegram he did not expect me. I had a chance, therefore, of looking at his apiary at my leisure, and without any interruption, which is an advantage. His father (a venerable old man) received me in a very hospitable manner, and, as Mr. Pometta is a vineyard-owner as well as a queen-breeder, I was able to see all the vintage operation in full swing. I may say that he takes pride in his wine products as well as in his bees; and he showed me with great interest an ancient-looking, squat flagon of Aqua Vitæ, very old, of his own distilling, that had taken the gold medal at Zurich.

I found an immense number of colonies of bees, many of them in bar-frame hives with straw sides; the majority of them on the Italian plan, opening at the back, and iron tongs being used to remove the combs. There were, too, a large number of nucleus hives, with bar-frames lifting out in the ordinary way. The bees were the leather-colored strain, not the bright colored bees such as I saw later on in Lombardy. To show their energy, I may mention that Mr. Pometta told me that they are usually at work at six in the morning, and that on one or two occasions he actually saw them work by very bright moonlight. We have heard this same story from the Americans, and I fear every one has doubted it.

On Mr. Pometta's return we looked through many colonies, and I had explained to me his whole system of queen-rearing.

The system used of rearing queens depends upon the time of the year. In

the early spring (when loss of heat must be much guarded against) a colony is taken, and, by means of three dummies, is divided into four nuclei, the hive being made with four entrances for this purpose. In this way five queens are secured from one colony, and though the system is a somewhat wasteful one, yet it answers, as the price obtained for queens in early spring is comparatively high. Another plan is to preserve a large number of small colonies with young queens in the autumn. In the spring two or three of these can be united, and one strong colony formed, and the surplus queens sold.

As the season advances, the nucleus hives are used; each nucleus being large enough to be again divided into two. By this plan better queens can be reared, and in good quantity too. The bars of these are of just such a size that two will fit into the large bars of the Italian hives. This, of course, is of great service to the queen-rearer in many ways, such as making up nuclei for queen fertilization, and afterwards for strengthening such with hatching brood.

SEASON OF 1888.

Report of a Summer's Work with the Bees.

Written for the American Bee Journal
BY GEO. W. STEPHENS.

I caught the "bee-fever" away back in the '70's, and have never been cured. I once owned a number of colonies, but about eight years ago, during a long and severe winter, when so many bees were lost all over the country, they took sick and died of that most fatal disease, neglect.

I began again last spring with 2 colonies of black bees—one in a Langstroth hive, and the other in an American hive. I transferred them by driving, to a hive that is used by a prominent apiarist of this State, but which has not yet been named. The hive is of about the capacity of a cracker-box in length, breadth and thickness.

The spring was cold and rainy, and the conditions were such that the spring blossoms yielded no nectar, and my bees gathered no honey until about July 4; in fact, by that time they had consumed all of their winter stores, and although I had fed them some, there was not at that time a pound of honey in either hive. The same could be said of all the bees in the neighborhood. I kept my bees in the same yard with Mr. Hawk's 20 colonies, which were worked on shares

by Mr. Wheeler, and we helped each other occasionally in manipulation, etc.

Cross Bees and their Stings.

The bees were pretty cross from the time they were put out in the spring until basswood bloomed, and we were the victims of a good many stings. I think I received about thirty stings during the summer, and Mr. Wheeler's average was somewhat higher, he being a large man and not a very swift dodger. My greatest trouble was, that the bees persisted in crawling up my pants' legs; contrary to the good advice in the books, however, I invariably made a quick motion about that time and escaped a sting—the bee generally died, and—Mr. Wheeler laughed. I find that is one great fault with the black bees; upon lifting a comb, if the weather be a little cool, they will scatter like a flock of sheep, alight upon the ground, and then crawl up one's pants' legs.

But for all the bees were so cross during the spring and early summer, I can truthfully say that I never once while handling them, put on a pair of gloves. Gloves are awkward and clumsy things to handle bees with; they are hard to get on and off, and in many ways hinder the movements of the operator; and besides, an angry bee can easily sting through a pair of dog-skin gloves, as I saw them do repeatedly last summer. I just used my last winter's mittens; they were thick and heavy, having been built for cold weather, and no bee could make its presence felt through them.

When basswood bloomed, about July 4, the bees filled their brood-chambers in about a week; then basswood ceased, and we got no more honey until the latter part of August and September, when the golden-rod, asters and heart's-ease bloomed. Then the sections began to fill up, and in the fall we took off some of the nicest "digested nectar" that ever was gathered, averaging about 40 pounds of comb honey to the colony, spring count, in one-pound sections.

It is a very fine quality of honey, heavy, fine flavored, and not dark in color. But the bees got all the basswood honey in their brood-chambers, and as I had no extractor, and did not care to bother with strained honey, I put into the cellar, on Nov. 27, 2 strong colonies with about 75 pounds of honey each, and a couple of weaker colonies, built up from nuclei, with about 25 pounds each. I expect by "this method" to get the basswood honey next season "in this section."

My bees did not swarm during the season, and Mr. Wheeler had but 2 or 3 swarms from his 20 colonies. I Italianized one colony, and next season I

will keep none but Italian bees. All the bee-keepers around here that I have talked with, are going to Italianize their bees. Most of them have blacks and hybrids, and one man has "high bred" in "Longtrough hives." He can take out a "sash" of honey whenever he wants it.

Denison, Iowa, Dec. 3, 1888.

MAPLES.

What do the Bees Gather from the Hard Maples?

Written for *Gleanings in Bee-Culture*
BY MAHALA B. CHADDOCK.

How much honey do bees get from the hard maple? We have them in our dooryard, and they were in bloom last spring for two weeks, and the bees fairly roared about them. I watched them at work, and it seemed to me that they did not stay long enough at one blossom to suck nectar from it, but just rolled and tumbled the stamens about as though they were hunting for something that they never seemed to find; then on the wing a moment, twisting their legs together in a most frantic way, then to another cluster, and the same hurrying-securrying motions.

They worked on the maples only when the days were warm. On coolish days they flew away somewhere and came back—some of them with a differently-colored pollen on their legs, but the most of them with nothing on them. They came to the well for water, and it seemed to me that, if pollen was all that they got from the maples, they might as well be working away at them.

I see, in examining the stamens of different flowers, that there is a white, sticky substance on the most of them, wound carelessly around the pollen-grains, something as an ear of corn might look after being thrust through a thin spider-web. Now, is this sticky substance propolis? and do the bees get some of it out of flowers if they want it? If this sticky substance is propolis, it would be easy to see why bees gather pollen better on warm days than on coolish ones.

This substance is very tenacious. A thread of it will lift half the pollen on one stamen—a thread that is invisible to the naked eye. I killed a few bees as they attempted to enter the hives. Only one of them had honey in the honey-sac, and I am inclined to think that it was old honey that the bee had carried from the hive. But finding no honey in the bees would not prove that the maple-blossoms contained no honey. They might yield enough to make the pollen stick together, and

still the bees have none to carry home in her sac. So with what I have investigated as to whether maple-blossoms yield nectar, I have concluded that I do not know. Is the nectar ever in the stamens? It seems to me that the tube, or cup, that all flowers have, is the place for the nectar.

I like to look at flowers under the magnifier. The most dull and insignificant flowers are then gorgeous and beautiful. The currant, gooseberry, sassafras and maple are all interesting. But the most delicate and beautiful of all that I have seen is the cherry. The petals look as if one could almost see through them, while the many stamens spread every way.

Nature seems to be very free with her stamens, placing them not only where they are needed, but also where they are not needed. I find that the maple-blossom has eight (or seven) stamens protruding from its bell-shaped flower. No more are to be seen anywhere; but in some days—a week perhaps—when the wings are half grown, if we turn down the husk that was once the flower, we find six more stamens, with anthers bigger and more full of pollen than any of the eight that protruded from the flower. These six stamens are useless. No bee, no insect of any kind can get to them to carry the pollen away, and the seed in the seed-pod is much too far along to need pollen.

Vermont, Ills.

EXPERIMENTS.

When to Put Bees into the Cellar, etc.

Written for the *American Bee Journal*
BY A. C. WALDRON.

An experience of two years makes me more enthusiastic than ever in my chosen pursuit, having gone beyond my own expectations. I started with 2 colonies, increased them to 8, lost one, bought 5 more last spring, and now I have 58 colonies, all in good condition, so far as I know. Perhaps I ought to say that I bought 3 Italian queens during the time of working for increase. I have had no large yield of honey, although that has been satisfactory. My bees are now in the cellar, with the exception of one colony, which is on the summer stand, in a single-walled hive.

I am experimenting a little in regard to the time to put bees into the cellar, and also in regard to ventilating the hives in the cellar. I weighed nearly all of my hives on Sept. 21, and on Nov. 14 to 16 I put them into the cellar, weighing them again. The loss

was from 1 to 10 pounds, or an average of about 7 pounds. One colony had gained one pound. I expect to weigh them again in the spring, and give the results.

In using full sheets of foundation in the brood-chamber, I find it difficult to keep them from warping, even in wired frames. I have been more successful with starters of thin foundation. I also prefer starters in sections.

In what little experience I have had with cellar-wintering of bees, I think that we have more to fear from a too low temperature than from a too high one, unless the cellar is very dry. My experience would say that from 42° to 50° is better than lower. One thing I do know, and that is, that moisture enough to cause water to gather on the hive-cover, is not good.

Buffalo, Minn., Dec. 11, 1888.

SPRING WORK.

Manipulating Bees in the Spring of the Year.

Written for the Canadian Honey Producer
BY G. W. DEMAREE.

It is well to know how to winter bees successfully, how to obtain increase of bees in the way of stocking up the apiary, etc. But if the apiarist lacks the necessary knowledge and experience in spring management of his bees, he will discover after awhile that the chances for the best results have been slipping through his willing fingers, and from under his faulty judgment without his knowing the true cause of his partial failures.

One of the important things to learn is, that what suits some other locality may not suit yours. This matter of "locality" is one of the things upon which no apiarist can depend on some one else who occupies some other locality, for definite information as to what is best for his particular case. Hence it is essentially necessary that each apiarist for himself, should study every feature of his own environments, his climate, honey-producing flowers, at what time in the season they blossom, how long they continue to yield nectar, etc.

Let me illustrate here: Some years ago when I was just beginning to see the necessity of this sort of knowledge, I left home on Monday morning early in May. I had been with my bees almost daily for two weeks past, and they were living from "hand to mouth," just barely getting enough honey from late blooming trees, etc., to keep from actual want; in fact I was compelled to feed some of the weaker colonies. I attended court

that week, and did not see my bees until the following Saturday morning. The first hive I opened was one that I had been feeding, and did not have one pound of stores when I left home just five days before. I found it full of honey from top to bottom, I hastened to another hive, and to another, not willing to believe my own eyes, every hive in the apiary was jammed full of honey, and I never knew how much I lost by not being on hand to furnish what room the best colonies needed. The black locust had come into bloom, and poured out nectar as free as water, outstripping the famous linden before Kentucky was denuded of her wonderful forests. How necessary then it is to be thoroughly posted in regard to these matters.

Perhaps I have mentioned this incident before, whether or not, it is to the point here. Some years ago a neighbor of mine took up bee-keeping, and on one occasion he met the writer and said, "It is about time to put on the surplus boxes, is it not?" *The surplus boxes!* I replied, why, sir, I have taken a large honey crop, and the harvest is about over. You can put them on, but you have lost this year. He was perfectly astonished.

Spring Work in the Apiary.

If the bees have stores to last them until the blossoms begin to open in the spring, they should be left undisturbed till they begin to gather pollen. Any warm day thereafter, each colony should be examined, and all upward ventilation should be closed. To accomplish this I spread some newspapers between the quilts, and cover warmly above the brood department. All very weak colonies are contracted on but few frames, and they are made as comfortable as possible. If the colonies have plenty of stores, stimulative feeding is not resorted to, as I have received but very little benefit from my experiments in that direction. But if the bees are scarce of stores, they will not breed up rapidly without some feeding.

After giving the matter a fair trial, no "spreading of brood" is practiced in my apiary. It is a positive injury to a colony of bees to break the nest early in the spring, as advised by some writers on bee-culture. When colonies have been contracted on less than a full set of combs, the combs are restored to the bees as fast as they need them, but they are placed at the sides next to the brood, not between combs of brood as practiced by some apiarists. I am now speaking of the early spring. When warm weather has come in earnest, the empty combs may be placed between the combs of brood without doing any harm.

Approaching the Honey Harvest.

I keep a close watch over my bees, and supply them with food if any of the colonies run short by reason of rapid breeding. When I discover that a colony has begun to lengthen the cells near the tops of the brood-combs, giving them the "gilt-edge" appearance so pleasing to the eyes of the apiarist, being the first real sign of the approaching honey harvest, I proceed at once to adjust the surplus cases on the hives, and as others are ready the surplus cases are put on, till the whole apiary is equipped for the campaign. As soon as the surplus cases are about two-thirds filled with honey, they are raised, and an empty case is adjusted under each one of them. Usually the top case will be ready to "take" by the time the lower one is two-thirds full; if not, a third case is used.

Tiering Up.

After this I proceed cautiously, so as not to carry the "tiering up system" too far, and thereby have too many unfinished sections at the close of the honey harvest. To guard against this, as soon as the facts appear that the main flow of nectar is past, I begin to tier downward, that is, I begin to concentrate the work in the surplus cases by sorting out such sections as have been advanced most, and grouping them together in fewer section cases, in order to have them finished up instead of permitting the bees to neglect the partly filled sections and start new work to be left unfinished at the close of the honey harvest. By this management not many unfinished sections are left on hand at the close of the season.

Chistiansburg, Ky.

Convention Notices.

The Nebraska State Bee-Keepers' Association will convene at Lincoln, Nebr., on Jan. 9, 10 and 11, 1889.
J. N. HEATER, Sec.

The annual meeting of the Ontario Bee-Keepers' Association will be held at Owen Sound, Ont., on Jan. 8 and 9, 1889.
W. COUSE, Sec.

There will be a meeting of the Susquehanna County Bee-Keepers' Association at the Court House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a. m.
H. M. SEELEY, Sec.

The annual convention of the Vermont State Bee-Keepers' Association will be held in the Court House at Middlebury, Vt., on Tuesday, Jan. 15, 1889.
MARCIA A. DOUGLAS, Sec.

The annual meeting of the Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association will be held in the Supervisors' Room of the Court House at Rockford, Ills., on Jan. 15 and 16, 1889.
D. A. FULLER, Sec.

Money in Potatoes, by Mr. Joseph Greiner. Price, 40 cents, postpaid. This is a complete instructor for the practical potato-grower, and explains the author's new system in 40 interesting lessons. It is for sale at this office.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*
 Dec. 29.—Brant, at Brantford, Ont.
 K. F. Holtermann, Sec., Brantford, Ont.
 1889.
 Jan. 8, 9.—Ontario, at Owen Sound, Ont.
 W. Couse, Sec., Streetsville, Ont.
 Jan. 9-11.—Nebraska State, at Lincoln, Nebr.
 J. N. Heater, Sec., Columbus, Nebr.
 Jan. 15.—Vermont State, at Middlebury, Vt.
 Marcia A. Douglas, Sec., Shoreham, Vt.
 Jan. 15, 16.—N. W. Ill. & S. W. Wis., at Rockford, Ills.
 D. A. Fuller, Sec., Cherry Valley, Ills.
 May 4.—Susquehanna County, at Montrose, Pa.
 H. M. Seelye, Sec., Harford, Pa.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

 SELECTIONS FROM
 OUR LETTER BOX

Report for the Season.—Mr. R. J. Mathews, Riverton, Miss., on Dec. 4, 1888, writes :

The past season was worse for me than the one previous, but I did tolerably well, taking the bad season into consideration. I commenced the season of 1888 with 20 colonies, increased them to 29, and secured 1,269 pounds of comb honey in one-pound sections ; 786 pounds of extracted honey, and 26 pounds of beeswax. All the colonies have plenty of stores for winter.

Successful Bee-Keeping, etc.—Ezra J. Cronkleton, Dunlap, Iowa, on Dec. 7, 1888, writes :

My bees did very well the past season, considering that it was such a poor one. From 40 colonies I obtained 2,500 pounds of comb honey in one-pound sections, an average of 70 pounds per colony. It is the lightest crop that I have had in the five seasons that I have been engaged in the business. My increase was 10 colonies. My bees are all tucked away in the cellar, the hives full of stores, and not in debt to me a cent. I do not remember of ever losing a colony of bees in wintering, and have had no spring dwindling—in fact the word "success" expresses my situation ever since I embarked in the bee-business. Honey is selling readily here at 18 cents per one-pound section. The weather is fine here, with no snow yet. Corn is all gathered, and the crop is immense.

Poor Yield of Honey.—S. M. Cox, Angola, Ind., on Dec. 7, 1888, says :

One year ago I had about 85 colonies of bees, about 30 of which failed to winter, mostly from lack of stores. During the winter I moved to Angola, a distance of about 12 miles, and about June 1, I moved 24 colonies, with the loss of one. I left the rest on the farm, and let them out on shares. I got less than 50 pounds of surplus honey, and a good many of the colonies will starve this winter, although there were several fields of Alsike clover, and considerable basswood near them. The bees that I brought here stored about 300 pounds of surplus comb honey, and cast 10 swarms. I have 26 colonies in the cellar now, the rest being on the summer stands. I think that we will have more white clover next season than we had this year.

Honey Jumbles—Fall Honey-Flow.—O. P. Miller, Glendon, Iowa, on Dec. 5, 1888, writes :

I notice on page 787, an account of a young man selling seven barrels of honey jumbles at the Columbus Exposition. I would be pleased to have a recipe for making them published in the BEE JOURNAL. People here think that honey is not worth anything to cook with. The honey season in this vicinity was very poor until the very last. About the time we thought the "jig was up," the bees commenced work, and in 16 days they stored 62 pounds of surplus honey to the colony. One of the strongest colonies in this time stored a little over 100 pounds of surplus honey in three weeks. I practice the tiering-up system with full-sized Langstroth frames, for other reasons aside from the production of honey.

[Just show your neighbors who think that honey is not good for cooking, copies of "Honey as Food and Medicine." Perhaps Bro. Root will supply the formula for making the honey-jumbles.—Ed.]

No Fall Honey Crop.—R. B. Woodward, M. D., Somerset, O., on Dec. 10, 1888, writes :

My bees wintered last winter without loss. I had 15 colonies to begin with ; one queen would not lay on account of old age, and one died from an unknown cause, which left me 13 colonies. From these I secured 400 pounds of honey, about one-half being comb honey. I had to put back in unextracted frames 100 pounds, and had to feed about 50 pounds of sugar for winter purposes, leaving about 250 pounds net, of surplus honey from 13 colonies. I increased them to 18 colonies, which are now in good condition on the summer stands, and wintering well thus far. My bees gathered nothing after August, yet the fields were yellow with golden rod, and waste land was full of asters ; but it was too wet and cold. My best colony produced 36 pounds of extracted apple-bloom honey, which was very good.

Bees in Good Condition.—L. B. Graves, Ninereh, Ind., on Dec. 10, 1888, says :

The honey season has not been good for three years. Last spring I had 5 colonies which I increased to 7, and took about 150 pounds of comb honey. All are in good condition for winter. My best colony produced 48 pounds of honey, besides about 15 pounds in two boxes not finished. Some of my neighbors got about the same as I did, while three miles east and north they got no honey, and had to feed their bees for winter. I can speak for only a few, as I am not posted very far from home.

Predicts Successful Wintering.—Mr. J. W. Bittenbender, Knoxville, Iowa, on Dec. 11, 1888, writes :

Bees in this locality are all in their winter depositories, with plenty of good, ripe honey to winter on, and, as far as I can tell, I predict that of all colonies properly prepared, 95 per cent. will winter ; and as far as I can ascertain from my correspondence, bees are all in good condition in Iowa, Nebraska, Missouri and Kansas. The outlook seems to indicate a good season for 1889. White clover never was in better condition at this date. We have had but very little cold weather, no snow on the ground, and farmers are plowing yet.

Honey and Beeswax Market.

CHICAGO.
HONEY.—We quote : White clover 1-lbs., 18@19c.; 2-lbs., 16@17c. Good dark 1-lbs., 15@16c.; 2-lbs., 13@14c. Buckwheat 1-lbs., 14@15c.; 2-lbs., 12@13c.—Extracted, 7@9c. Depending upon quality and style of package. Receipts increasing, but demand still limited. Stock is not selling as freely this season as a year ago.

BEEWAX.—22c. T. FISH & CO., 189 S. Water St. Nov. 13.

CHICAGO.
HONEY.—It is selling fairly well at 18c. for best 1-lbs.; very fancy lots have sold at 20c. Dark and yellow comb sells slowly at 13@16c. Extracted, 7@9c., according to quality and style of package. The stock of best comb honey is light.

BEEWAX.—22c. K. A. BURNETT, 161 South Water St. Nov. 22.

MILWAUKEE.
HONEY.—We quote : Fancy white 1-lbs., 18@20c.; 2-lbs., 16@18c. Good dark 1-lbs., 16@18c.; 2-lbs., 15@16c.; fair 1-lbs., 12½@14c. Extracted, white, in kegs and ½-barrels, 8½@9c.; amber in same, 7½@8c.; in pails and tin, white, 9@9½c.; in barrels and half-barrels, dark, 6@6½c. Market steady and supply ample for the moderate demand, but present values have a tendency to restrict general consumption.

BEEWAX.—22@23c. A. V. BISHOP, 142 W. Water St. Oct. 25.

NEW YORK.
HONEY.—We quote : Fancy white 1-lbs., 15@17c. 2-lbs., 14@16c. Fair white 1-lbs., 14@16c.; 2-lbs., 13 to 15c. Extracted, white, 7½@8c.

BEEWAX.—23½c. THURBER, WHYLAND & CO Sep. 17.

NEW YORK.
HONEY.—We quote : Fancy white 1-lbs., 16@17c.; 2-lbs., 13@14c. Fair white 1-lbs., 14@15c.; 2-lbs., 11 to 12c. Buckwheat 1-lbs., 11@12c.; 2-lbs., 10c. White extracted, 8@9c.; buckwheat, 6@7c. Demand good for white 1-lbs. and buckwheat at 1 and 2 lbs., of which the stock is light. Good stock of white 2-lbs., with but little demand.

BEEWAX.—22½@24c. HILDRETH BROS. & SEGELKEN, Nov. 24. 23 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.
HONEY.—White 1-lb. sections, 12@12½c.; 2-lbs., 12@14c.; amber, 8@10c. Extracted, white, 6½@6¾c.; light amber, 6c.; amber and candied, 5½@5¾c. For comb honey the demand is light ; for extracted it is good, and market firm.

BEEWAX.—Dull at 18@22c. O. B. SMITH & CO., 423 Front St. Nov. 15.

DETROIT.
HONEY.—Best white 1-lbs., 16@18c. Supply is not large, but equal to the demand.

BEEWAX.—22@23c. M. H. HUNT, Bell Branch, Mich. Dec. 12.

CINCINNATI.
HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 16c. Demand slow.

BEEWAX.—Demand is good—20@22c. per lb. for good to choice yellow on arrival. Nov. 12. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.
HONEY.—Choice 1-lb. sections, 18c.; dark 1-lbs., 14c.; 2-lbs., 16c.; dark, 13c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock fair.

BEEWAX.—None in market. HAMBLIN & BEARSS, 514 Walnut St. Sep. 27.

NEW YORK.
HONEY.—We quote : Fancy white 1-lb. sections, 17½@18c.; 2-lbs., 15@16c. 1-lbs., 14½@15½c.; 2-lbs., 11@12c. Extracted, fancy white clover, 7½@8c. California white in 60-lb. cans, 8c.; light amber, in same cans, 7¾c.; amber, 7½c. Buckwheat in kegs and barrels, 5½@6. Cuban, in barrels and ½-barrels, 65c. per gallon.

Sep. 26. F. G. STROHMAYER & CO., 122 Water St.

BOSTON.
HONEY.—We quote : Best white clover 1-pounds, 17@18c.; best 2-lbs., 16@17c. Extracted, 8@9c. The sales are good, and indications are that all the honey in the country will be sold by Feb. 1.

Dec. 12. BLAKE & RIPLEY, 57 Chatham Street.

KANSAS CITY.
HONEY.—White 1-lbs., 16@17c.; fair, 14@15c.; California white 2-lbs., 14@15c.; amber 2-lbs., 12@13c.—Extracted, white California, 7½c.; amber, 7c.

BEEWAX.—None in the market. Dec. 11. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.
HONEY.—We quote : Liquid extracted in barrels, 5@6c. According to quality ; in cans, 7@8c. Comb, 12½@15c. Prices firmer on account of scarcity, though the demand is not great.

BEEWAX.—21c. for prime. D. G. TUTT & CO., Commercial St. Oct. 17.

SAN FRANCISCO.
HONEY.—We quote : Extracted, white, 6½ cents; light amber, 6@6½c.; amber, 5½c. Comb, white 1-lbs., 13@14c.; 2-lbs., 13c. Light amber 1-lbs., 12@13c.; 2-lbs., 11@12c. Demand very active for extracted, and fair for comb honey.

BEEWAX.—20@21c. SCHACHT & LEMCKE, 122-124 Davis St. Nov. 6.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in *Cheshire's* pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being mailable, it must go by express.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the *Apiary Register* and begin to use it. The prices are as follows:

- For 50 colonies (120 pages).....\$1 00
- " 100 colonies (220 pages)..... 1 25
- " 200 colonies (420 pages)..... 1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 120 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the LAST column. The regular price of both is given in the first column. One year's subscription for the *American Bee Journal* must be sent with each order for another paper or book:

	Price of both.	Club

International Bee-Convention.

—The Pamphlet Report of the Columbus, Ohio, Convention is now issued, and copies have been sent to each member, as well as to the Colleges, Agricultural and Horticultural Societies and periodicals devoted to the industry. Copies can be obtained at this office, by mail, postpaid, for 25 cents. This pamphlet contains the new bee-songs and words, as well as a portrait of the President. Bound up with the history of the International Society, and a full report of the Detroit, Indianapolis and Chicago conventions, for 50 cents, postpaid.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, \$1.00 per 100, or \$3.50 per 1,000.

The Date on the wrapper label of your paper indicates the end of the month to which you have paid. If that is past, please send us a dollar to carry the date another year ahead.

Honey.—We have for sale a quantity of Extracted Honey in kegs holding about 220 pounds each, which we are selling, free on board the cars, at 8 cents per pound for Amber and 9 cents per pound for White.

New Subscribers can obtain the full numbers for 1888 and 1889 for \$1.80, if application be made at once, before all the sets of 1888 are gone.

In order to pay you for getting new subscribers to send with your renewal, we make you this offer. For each yearly subscriber, with \$1.00, you may order 25 cents worth of any books or supplies that we have for sale—as a premium.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

We will Present a Pocket Dictionary for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide the spelling of words, and their meaning.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for \$1.50.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2.00	3.00	3.50
1,000 Labels.....	3.00	4.00	5.00

✶ Samples mailed free, upon application.

Simmins' Non-Swarming System.—We have a few of these books left, and we will club them with the AMERICAN BEE JOURNAL for one year, both postpaid, for \$1.25. The subscription to the BEE JOURNAL can be for next year, this year, or may begin anew at any time.

Cork for Winter Packing.—Its advantages are that it never becomes musty, and it is odorless. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Melilot or Sweet Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Hastings' Perfection Feeder.—This excellent Feeder will hold 2 quarts, and the letting down of the feed is regulated by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for \$3.50, and it can be obtained at this office. Postage 10 cents extra.

To Every Lover of Good Reading :

DEAR FRIEND :—Mr. Will C. Turner, the well known Publisher and Managing Editor of the CITY AND COUNTRY, that excellent 16-page monthly magazine published at Columbus, O., has recently made an offer in connection with his publication which should certainly be accepted by you. CITY AND COUNTRY has been regularly published at the rate of \$1.00 per year, for the past seven years. Mr. Turner is anxious to increase his already large circulation within the next three months to 50,000 regular subscribers more,

To accomplish this purpose, believing that every subscriber will, at the expiration of their subscription, renew for one year, he has devised the following plan :

Every person desiring to become a subscriber to CITY AND COUNTRY, which, by the way, contains each year four to five continued stories, thirty to forty illustrations in each issue, and a large amount of interesting reading—especially so to the ladies—is requested to carefully and plainly write out two complete copies of this letter, and sign your name at the bottom after the word "Per". These copies must then be mailed by you to two of your friends or acquaintances in some other town or locality, who are thereby requested to do just as you have done, viz : Write two copies and send to two of their friends, and so the work will go on and on. After mailing the two copies, the original letter which you copy from, together with a slip of writing paper, cut the size of a postal card, with your address plainly written on one side, and the addresses of the two to whom you have sent the copies on the other side, and TEN CENTS IN SILVER must be enclosed in a letter and mailed to Will C. Turner, Columbus, O. On the receipt of these you will be placed on the subscription list for 3 months, the copy for the present month will be promptly mailed, and also, which is the greatest reason why you should accept this offer, five complete novels in pamphlet form will be sent you by mail, postpaid, which would regularly cost one dollar each if bound in cloth. Do not let the opportunity pass, as Mr. Turner only proposes to let this offer stand for a short time. True, it requires some time and work to copy all this twice, but you will be most handsomely rewarded for it.

[Signed,] WILL C. TURNER.

1889.

Free. ONE YEAR. Free.

WE have made arrangements with the publishers of the COTTAGE HEARTH, of Boston, Mass., to offer the AMERICAN BEE JOURNAL as a free premium, with their Magazine for the year 1889, and we now give to all our readers the benefit of this arrangement.

THE COTTAGE HEARTH

Is a well-known Family Magazine now in its 14th year, and is a favorite wherever it has been introduced. It has each month Music, Floral and Health Departments, Latest Fancy Work, Sabbath Reading, Demorest's Patterns, Approved Receipts, Household Hints, and Prize Puzzles for Children.

This beautifully illustrated Monthly is a large 34-page, elegantly printed Magazine, and has attained a large circulation solely on its merits as a family magazine. Its

Price, \$1.50 per Year,

is very low for such a desirable home magazine, but we will send both The Cottage Hearth and the AMERICAN BEE JOURNAL to any one who sends us \$1.50—just the price of one of these standard publications.

Sample Copies sent free on application to F. P. Shumway, Jr., Boston, Mass.

EDITORIAL BUZZINGS.

We Wish all of our readers, both young and old, a prosperous and
"HAPPY NEW YEAR."

Christmas has come and gone. Of all holidays this is the most welcome, because it is ushered in with friendship's pleasant gifts, and ends with the pronouncement of blessings on all. Its observance for so many hundreds of years has given it a character which appeals to all to promote the joy and happiness of kindred and friends.

This week is the time for joyous parties and gladsome greetings. Let every day be bright and beautiful, and we hope all hearts will rejoice and be glad! *A Happy New Year* to all our readers.

Accept Our Thanks for the patronage of the past, and we cordially invite all our readers to retain their places in the BEE JOURNAL family for 1889.

A Complete Index is presented this week, not only to the subjects discussed during the year, but also to the names of correspondents. The latter one comprises nearly all of the best and most thoroughly successful apiarists of the present age.

A Favorable Word from any of our readers, who speak from experience, has more weight with their friends than anything we might say. Every one of our readers can lend us a helping hand, in this way, without much trouble, and at the same time help to scatter apicultural knowledge and promote the welfare of our pursuit.

Another Tirade of Abuse finds a place in an Eastern publication, from the pen of C. J. Robinson. This time the invectives are aimed at our old and honored friend—the Rev. L. L. Langstroth, who it seems, some eight years ago, wrote an article correcting some mistakes made by Mr. R. in an article on the first importation of Italian bees.

As usual the comments of Mr. Langstroth were a mere statement of facts, without the slightest unkind remark. This exasperated Mr. Robinson, and he has, at every opportunity, dipped his pen in gall and hurled forth abuse at the devoted head of our esteemed friend Langstroth.

It is to be regretted that any paper—much less a bee-periodical—could be found that would publish an article which contained such epithets applied to such a good man as Mr. Langstroth. Here are some of them: "Robber," an "outrage," "foul," "land-pirate," "rob a dead man," "robbed so ruthlessly," etc., winding up with the following:

Mr. Langstroth's motto, on paper, has been: "Give honor to whom honor is due," but he has signally failed to practice what he has preached.

No excuse can be given for such vile charges. The insignificant matter of who was the first to import Italian bees is hardly worth discussion, much less the maligning of a man of such prominence and character as Mr. Langstroth.

It only shows the tendency of the times, to follow with a dagger the greatest and best men of the age, and exhibits the perversity of shallow minds. To such we would recommend the study of the following noble thought and language of the great Rufus Choate, which is worthy of being enshrined in the hearts of all high-minded Americans. "National Hatred" was the topic of one of his orations. In it he said:

No, sir, we are above all this. Let the Highland clansman, half-naked, half-civilized, half-blinded by the peat-smoke of his cavern, have the hereditary enemy and his hereditary enmity, and keep the keen, deep and precious hatred, set on fire of evil, alive if he can.

Let the North American Indian have his, and hand it down from father to son, by heaven knows what symbols of alligators and rattlesnakes and war clubs, smeared with vermilion and entwined with scarlet.

Let such a country as Poland, cloven to the earth, the armed heel on the radiant forehead, her body dead, her soul incapable to die—let her remember the wrongs of days long past.

Let the lost and wandering tribes of Israel remember theirs—the manliness and the sympathy of the world may allow or pardon this to them.

But shall America, young, free and prosperous, just setting out on the highway of heaven, decorating and cheering the elevated sphere she just begins to move in, glittering like the morning star, full of life and joy—shall she be supposed to be polluting and corroding her noble and happy heart by moping over old stories of stamp act and tea tax, and the firing of the Leopard on the Chesapeake in the time of peace?

Every true man—every high-minded American will join in saying, "No, Sir;

we are above all this" mud-throwing! There shall be no maligning of the men we delight to honor! No abuse of our honored and honorable fathers in apiculture! No polluting of their garments with the slime of invective, railing or abuse!

The Twenty-Fourth Volume of the AMERICAN BEE JOURNAL ends with this number, making another valuable "book of reference" for the apicultural world. Its record, character and usefulness in the past is its GUARANTEE for the future. As heretofore it will lose no opportunity to further the interests of boney-producers by booming the product and faithfully defending the pursuit of apiculture on every occasion requiring it. For Fifteen Years we have labored to publish a bee-periodical which should be a credit to the pursuit, and a medium of communication between the bee-keepers of America and the world generally. How well that task has been done we leave our readers to say. At first it was a monthly containing about the same amount of reading matter as is now issued weekly. Then the price of subscription for the monthly was two dollars; now the weekly is issued at one dollar—four times as much matter for one-half the price.

In order to be of the greatest advantage to our pursuit, we must have the largest constituency of wide-awake, progressive apiarists, and we request that if our patrons think we have labored for their interest in the past, that they will give us "the vote of confidence" in the shape of continued exertions for the prosperity of the AMERICAN BEE JOURNAL.

It is only fair to expect you to work for the BEE JOURNAL'S interest, for it is working for your interest every day in the year.

Do Not Forget to send a dollar for a membership fee to the National Bee-Keepers' Union for 1889. It merits your approval, and needs your assistance.

By Using the Binder made expressly for this BEE JOURNAL, all can have them bound and ready for reference and examination every day in the year. Price 60 cents, postpaid. Subscription for one year and the binder for \$1.50.

Do not send to us for sample copies of any of our papers. Send for such to the publishers of the papers you want.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM
OUR LETTER BOX

A Woman's Work.—Mrs. S. E. Sherman, Salado, Texas, on Dec. 10, 1888, writes as follows:

Last spring my apiary consisted of 40 good colonies of Italian and hybrid bees. I increased them to 60 colonies, and obtained from them 6,000 pounds of honey—mostly extracted. How does that do for a woman?

[It is first rate. You must have had a good season down in Texas.—ED.]

Scanty Surplus.—J. W. Vandervoort, Belleville, Ont., on Dec. 13, 1888, writes:

The last two years have been very poor seasons for apiarists. There was but very little surplus honey, and exceedingly small increase of bees. We hope for something better next year.

Fair Season's Report.—Mr. Albert Schumacher, New Alsace, Ind., on Dec. 13, 1888, writes thus about his bees:

Last spring I had 20 colonies of bees left out of 24 put into winter quarters in the fall previous (6 being blacks, 8 hybrids, and 6 young colonies from swarms of the previous year.) I have put 24 colonies away into winter quarters this fall, all being packed in a bee-house, and all are in good condition with plenty of honey, and I hope they will go through the winter safely, and come out strong next spring. My honey crop for the past season was 370 pounds of comb honey, and 200 pounds of extracted. I value the BEE JOURNAL very highly, and can hardly wait from one number to another, so anxious am I to read its very interesting articles.

Honey from Wild-Rice.—C. P. Hewett, of Kingston, Wis., writes as follows:

I have never seen anything published in relation to wild-rice honey, in the AMERICAN BEE JOURNAL. It is the finest flavored honey that I ever saw. It has medical properties that no other honey possesses. My wife has been using it for the last six months, and now she is cutting a fine set of teeth, at the age of 58 years. There is so much "doctor" connected with the bee-fraternity. How is this? I shall work 100

colonies for rice honey next season, and we may expect to see every lady here with bright, shining teeth, grown from the use of wild-rice honey. If any one disputes the above statement, he can write to the postmaster here, or to H. Qalkman, the dentist, who has extracted teeth for my wife.

Theory and Practice.—Mr. J. W. Tefft, of Collamer, N. Y., sends the following argument on the theory and practice of apiculture:

If the theory of the theoretical bee-man is true theory, and if the practice of the practical bee-man is correct practice, then the theory and the practice will fit each other, line for line and dot for dot.

The practical man becomes a theoretical man when he begins to give his reasons for doing as he does. If a person learns the laws of nature which relate to bee-mechanics from books or lectures, and then applies these laws to practice, and makes no mistakes in this application, he stands equally face to face with the man who begins at the practical end, and works up until he learns the same laws. They start at opposite ends of the same path, but both get there, all the same.

Wild Cucumber Honey, etc.—Geo. W. Hanson, of Chapman, Kans., on Dec. 10, 1888, writes:

I commenced last spring with one colony, which swarmed on May 19, 22 and 25. I bought 5 nuclei, and one of them swarmed on July 23 and 29. The others swarmed twice each, and I have now 15 colonies. I fed 4 of the last swarms. I lost one queen, but united a weak colony with the queenless one. I had no trouble in uniting. I have learned many valuable lessons from the BEE JOURNAL the past season, and still desire to learn more. My bees did not work on wild sunflowers as they did on the tame ones; but about Aug. 10 I noticed them taking a northeast course in nearly a perfect swarm; I traced them nearly one-half of a mile, and found them working on a large patch of wild cucumbers. They work on it as strong as they do on buckwheat, and all day long. It blossomed four or five weeks. I examined some of the flowers, and could see the nectar in the blossoms, and it tasted very sweet. I intend to put some of it under cultivation next year. It grows on low land, and I hope that I can give a fuller report of it next year. I have my bees in the cellar now, and they are doing well. With this letter I send a few seeds of what is called "wild cucumber."

[Thanks for the seed. We will plant them next spring.—ED.]

To Delinquents.—After January 1, 1889, we shall discontinue sending the AMERICAN BEE JOURNAL to those who have not responded to the bills we sent out a few weeks ago.

This does not mean that we shall try to deprive any one of the pleasure of reading the BEE JOURNAL who really desires its continuance, but finds it difficult to pay now. Such can get a short extension of time by asking for it. We should be sorry to lose any subscriber who wishes to have its weekly visits continued, but do not want any to continue to take it who do not think they are getting the full worth of their money.

A Magnificent Present

For every one who will send us a Club of five new subscribers for 1889, before next January. All the remaining issues of this year free to new subscribers.

This ATLAS

contains large scale Maps of every country and civil division upon the face of the Globe.

It is beautifully illustrated with colored diagrams, that show wealth, debt, civil condition of people, chief productions, manufactures and commerce, religious sects, etc., and a superb line of engravings of much historical interest & value, together with many new and desirable features which are greatly to be gotten up for this work—among which will be found a concise History of each State.

Price, in best English cloth binding (size, closed, 11x14 inches; opened, 22x14 inches), \$4.50.

To any one sending us, direct to this office, **FIVE NEW Subscribers** for one year, with \$5.00, (renewals not to count) we will present this beautiful Atlas, by mail, postpaid.

We have purchased one of them for our own use, and regard it as a valuable acquisition to our library. It is handsomely bound and contains a fund of very useful knowledge. It contains 192 pages.

THOS. G. NEWMAN & SON,
923 & 925 W. Madison-St., - CHICAGO, ILLS.

Mark It.—We have received several local newspapers from our subscribers, in which no item was marked. Please do not forget to mark any paragraph you wish us to read, when sending local papers to this office. We have no time to read thirty or forty columns of matter in order to find a few lines that may be of interest to us or the pursuit. Mark it, either blue, black or red, with pencil or ink, as may be most convenient—but be sure to mark it.

To Our Subscribers.—Send to F. P. Shumway, Jr., Boston, Mass., for a free sample copy of the *Cottage Hearth*, a beautiful illustrated magazine, and so realize what an EXTRAORDINARY OFFER we are making when we propose to send both the *Cottage Hearth* and the AMERICAN BEE JOURNAL for a full year for only \$1.50, when the price of the *Cottage Hearth* alone is \$1.50 a year, thus giving you two standard publications at the price of one.

The Time for Reading has come, with the long winter evenings. We have a large stock of bee-books, and would like to fill orders for them. To read and post up is the way to succeed in any pursuit—in none is it more important than in bee-keeping.

Do Not Fail to get up a club and send it with your renewal for next year.

QUERIES AND REPLIES.

Wired Frames of Foundation for Straight Combs.

Written for the American Bee Journal

Query 600.—1. Are there any objections to very thick foundation? 2. Which is the better, wired frames or wired foundation? or are both used together? 3. Are wired frames a certain guaranty against all warping or sagging? 4. Where can I get reliable and detailed instructions for wiring frames, and putting in foundation? I have spent about \$60 in foundation, and I do not believe that I have one perfectly straight comb. The foundation was a little over four sheets to the pound; the frames were 17½ by 8½ inches, inside measure, and the hives were well shaded. I would like to have combs as straight as if they were sawed out.—B. C.

Let the bees build their combs *à la* Hutchinson, and thus avoid all expense and bother.—G. M. DOOLITTLE.

1. Yes, the cost. 2. I prefer wired frames. 3. Yes, if properly used. 4. In our standard bee-books. I have now used wired frames for several years, and all my frames are true and straight.—A. J. COOK.

1. Yes. 2. Wired frames. 3. No. 4. Attend some bee-convention and call up the question, or write to some well known authority.—H. D. CUTTING.

1. Yes, very thick foundation is too heavy for any purpose. 2. Foundation in wired frames. 3. I think so, if properly made and properly used.—EUGENE SECOR.

1. Not for brood-combs, except the cost for so much wax. 2. Wire the frames, and then press on the foundation. 3. Yes, if properly put up. 3. In the back numbers of the BEE JOURNAL. I think you had the very best foundation to get straight combs from, but you must have handled it badly.—JAMES HEDDON.

1. No, only it may be an unnecessary expenditure of wax. 2. I do not use either. 3. While a remedy, the bees object to them. 4. In most of the bee-books. Perfectly straight combs can always be obtained if the bee-keeper will give an eye to the drawing-out of the foundation by the bees.—J. P. H. BROWN.

1. It should not be too thick. 2. I prefer wired frames. 3. I have never had any warping or sagging with them. 4. Instruction has been given in different bee books and papers.—C. C. MILLER.

1. Not for brood, except its cost. 2. Either. Most people wire the foundation too much. 3. Yes, three wires

horizontally, or four perpendicularly. 4. We do not know that any special instructions are needed, though there is probably some fault in your method. We never have any trouble. Our combs are all as straight as boards.—DADANT & SON.

1. Not for the brood-chamber, except the expense of wax. 2. Wired frames are the better, because the frames are also strengthened. Either way is sufficient. 3. Yes, if the wire and foundation are good, and the work properly done. 4. In any good work on bee-keeping, or in back numbers of the bee-papers.—R. L. TAYLOR.

1. No objection except the extra expense. 2. I prefer wired frames. 3. If properly wired and filled, they are. 4. The late published manuals on bee-keeping explain fully.—J. M. SHUCK.

1. There is no objection to very thick foundation for brood-combs, except the cost. 2. Wired frames are the best, and if rightly used there is no trouble in getting combs "straight as a board."—C. H. DIBBERN.

1. I know of no objection to heavy foundation for the brood-chamber. 2. Wired foundation. 3. No. One must use some judgment and skill in putting foundation in the frames. 4. In the bee-papers.—MRS. L. HARRISON.

1. I prefer foundation about six sheets to the pound (Langstroth size). 2. I have never used wired foundation, having used only the wired frames. 3. Yes, with me. 4. Get a sample wired frame. Almost all dealers have instructions for that purpose.—P. L. VIALLO.

1. I think there are. Very thick foundation is a waste of capital, besides the combs are not so nice, in my estimation. 2. I would prefer wires in the frame. But I have my combs drawn out in the upper story of the hive, and use the finished combs to hive swarms on, and by this management I dispense with wire altogether. 3. Yes, if the work is properly done. But I do not like wire in combs. 4. You ought to find the information in any good work on bee-culture.—G. W. DEMAREE.

I have but little experience with foundation in the brood-nest. 1. There are no objections to quite thick foundation, except the waste of wax. 2. I have never used wired foundation or wired frames. I have straight combs without either. 3. I do not know. 4. In any of the books on bee-culture.—M. MAHIN.

1. Yes. About 5 or 6 feet to the pound suits me best, and is very nearly the same weight as comb built by the bees; and more wax or weight is a waste. 2. I make my own foundation

on a Given press, so I prefer and use wired frames. 3. Yes, if properly done. 4. I do not know, unless you ask some one to write out instructions to be published, or write to some one who is posted, for instructions.—A. B. MASON.

I use Dadant's heavy foundation, 5 feet to the pound. If you will wire your frames horizontally, four or five strands to the frame, use full sheets of foundation, and space your frames 1½ inches from center to center, you will realize but little inconvenience; at least that has been my experience with thousands of combs. Chas. Dadant & Son are about as good reference as I can give you, for detailed instructions.—J. M. HANBAUGH.

1. Yes, the expense of wax; eight sheets to the pound, one foot square, is thick enough for the brood-chamber. 2. Wired frames, by all means. 3. Not in all cases; so a little judgment must be used. 4. In any practical work on bee-keeping, or in the old files of the AMERICAN BEE JOURNAL. No set instructions on this point alone can be given that will be of much value. Study the whole subject thoroughly.—J. E. POND.

1. For sections, yes. For the brood-chamber it should not be less than 7 square feet to the pound. 2. Wired frames. 3. Yes. 4. Look in Prof. Cook's Manual, last edition, pages 314 to 316. Your foundation was entirely too thick; you should have used not less than 12 sheets to the pound for sections. If your combs are badly bulged out, place them upon a table or some other level surface; place a level board upon the comb and press it firmly down into the frame. This plan works well with me.—WILL M. BARNUM.

1. Yes; its cost, principally. 2. Wired frames filled with comb foundation. 3. Probably so, if carefully made and used. 4. In the standard bee-books and bee-periodicals. The fault must have been in management, for the foundation was all right.—THE EDITOR.

Convention Notices.

☞ The Nebraska State Bee-Keepers' Association will convene at Lincoln, Nebr., on Jan. 9, 10 and 11, 1889. J. N. HEATER, Sec.

☞ The annual meeting of the Ontario Bee-Keepers' Association will be held at Owen Sound, Ont., on Jan. 8 and 9, 1889. W. COUSE, Sec.

☞ The annual convention of the Vermont State Bee-Keepers' Association will be held in the Court House at Middlebury, Vt., on Tuesday, Jan. 15, 1889. MARCIA A. DOUGLAS, Sec.

☞ The annual meeting of the Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association will be held in the Supervisors' Room of the Court House at Rockford, Ills., on Jan. 15 and 16, 1889. D. A. FULLER, Sec.

☞ There will be a meeting of the Susquehanna County Bee-Keepers' Association at the Court House in Montrose, Pa., on Saturday, May 4, 1889, at 10 a.m. H. M. SEELEY, Sec.

THE DYING YEAR.

The New Year comes, and on her wings doth bear
A holy fragrance, like the breath of prayer;
Footsteps of angels follow in her trace,
Witnessing the Old Year's death in holy peace.

The stream is calmest when it nears the tide,
And flowers are sweetest at the eventide,
And birds most musical at close of day,
And saints divinest when they pass away.

Morning is lovely—but a holier charm
Lies folded close in evening's robe of balm;
And weary men must ever love her best,
For Morning calls to toil, but Night to rest.

All things are hushed before her, as she throws
O'er earth and sky her mantle of repose;
There is a calm, a beauty and a power,
That morning knows not, in the evening hour.

"Until the evening" we must weep and toil,
Plow life's stern furrow, dig the weedy soil,
Tread with sad feet our rough and thorny way,
And bear the heat and burden of the day.

So when our sun is setting, we may glide
Like Old Year's evening, down the dying tide;
And leave behind us as we pass away
Sweet, starry twilight round our sleeping clay!

CORRESPONDENCE.

COLORS AND BEES.

Are Bees Attracted by the Color of Flowers?

Written for the American Bee Journal
BY PROF. L. H. PAMMEL.

On page 700 Mrs. Mahala B. Chad-dock takes objection to the statement that changes in color of flowers, after they have been pollinated, and the secretion of nectar has ceased, is developed for the apparent purpose of indicating to insects, that their services are no longer needed, thereby saving them much waste of time in probing such flowers.

In many flowers, the fertility depends upon the insects which visit them. The more frequent the visits of insects, the greater the fertility. So that color as a guide is not only advantageous to insects which visit flowers, but the plant in return is capable of producing more and better seeds, thus giving it a better chance in the battle of life.

That odor is important in attracting insects, is an established fact, which no one disputes. Most naturalists agree that color is an important factor, in attracting insects to flowers, and that they have done much to develop the colors in flowers.

In nearly all of the brightly colored flowers, pollination is effected by insects, as in mints, larkspurs, columbines, honey-suckles, salvia, etc., but in the inconspicuous flowers of the hazel, walnut, oak, grasses and sedges, it is done by the wind.

Will Mrs. Chaddock please explain why the sunflower should have developed the large, conspicuous ray-flowers surrounding the head; the vermilion red tracts surrounding the flowers of poinsettia; the bright red corollas of bee-balm, or the rose purple corolla of the dragon-head, and numerous other cases which might be mentioned? Have the colors and forms of flowers been developed merely to gratify and please our senses?

The simple statement that insects are attracted "by scent and not color" has little weight. Experimentally it has been shown by Sir John Lubbock, in "Ants, Bees and Wasps," chapter X, page 274; and by Hermann Muller, in "Versuche ueber die Farbenliebhabe-rei der Honig-biene," Kosmas, No. 10, Vol. XII, page 273, that bees possess an acute color sense, readily distinguishing such colors as blue, green, orange, red, white and yellow. It does not follow from this, that insects reason because colors are discerned, any more than a bee uses reason to construct its cells.

BUCKWHEAT.

The Japanese Variety—Its Seed, Flower and Honey.

Written for Gleanings in Bee Culture
BY PROF. A. J. COOK.

As you requested, I send my conclusions after raising a crop of Japanese buckwheat. I thought at the time, that \$3.00 per bushel was a good deal to pay for seed; but now after raising the crop I do not regret that I paid it. I sowed one-half early in June, and the remainder late in the same month. Thus the field was in blossom a long time.

When the blossoms first opened, the bees visited them freely, though upon close observation it was found that the bees ceased gathering from these flowers sometime before the flowers faded.

Common report hath it, that bees will not work after noonday on the flowers of common buckwheat. This was not true this season on the Japanese variety; bees were on the flowers at all times of the day. But what astonished us all was the prolificness of this buckwheat, and the great size of the berry. All who saw it said they never saw its equal.

I sowed it on the site of an old brick-kiln—solid clay soil with almost no humus, and yet I had a fairly good crop. I took two bushels to mill, that we might test the flour. The miller said he never saw so little waste in buckwheat, nor such enormous kernels. Of course the little waste would follow from the large size of the kernel. We have tested the flour in griddle-cakes with maple syrup, and pronounce it A No. 1.

Dr. Beal says he believes that this is our common buckwheat, *Fagopyrum esculentum*. As buckwheat is a native of North Asia, this is quite likely true; but one has only to see the two side by side, to be convinced that this Japanese is a distinct and well-marked variety.

Let me suggest reasons why farmers (especially bee-keeping farmers) should sow buckwheat as a part of their crop rotation. First, it is sown late in June, and the comparative leisure after planting gives opportunity to prepare the ground. Secondly, it is an excellent crop to precede corn on land that is infested with wire-worms. It seems to starve out these terribly destructive grubs. Again, it is a profitable crop, often paying as well or better than does wheat. It also gives us the basis of our buckwheat cakes, which, with maple syrup, will tempt the most capricious appetite. Lastly, buckwheat furnishes oftentimes abundant nectar for the bees when all else fails.

OVER-PRODUCTION.

Over-Stocking and Legislation for Bee-Keepers Considered.

Written for the American Bee Journal
BY J. W. TEFFT.

Many very interesting articles have appeared in the AMERICAN BEE JOURNAL concerning over-production and legislation for bee-keepers, but they do not hit the mark, I think, or at least do not strike it in the centre, and make a convincing argument. There is no such thing as apianian over-stocking or over-production! The trouble lies in marketing the product. Impenunious honey-producers create an unfortunate depression of prices by selling honey at any figures that may be offered! We might legislate until doom's-day to cure this evil, and accomplish nothing.

Many are fitted by nature and experience to manage large apiaries, and their tact, judgment and knowledge of human nature enable them to succeed, where others ignominiously fail! They use discretion, and only in cases

of absolute necessity will they lower prices or give an additional discount to secure a sale. Other considerations will be brought into play by them. A sale of honey at good prices will be considered more of an achievement than a heavy order actually bought by a special inducement in cut-rates! It is an old adage that, any one can sell honey at cut-rates.

If an inexperienced honey-producer, or one of limited resources, has the power to name lower prices when necessary, he is likely to think that every time he meets a buyer, that emergency confronts him. If the buyer is indifferent (and they generally are), or is well supplied with honey, or prefers to wait a week or two before deciding what to do, that honey-producer weakens, and straightway the lever, a cut-price, is pulled, and the power of that mighty influence is brought to bear, and its effects are felt from one end of the country to the other.

Again, if the cut is deep enough, or if this is what the buyer has been playing for, a sale is effected, and the sacrificing seller is happy—a great deal happier than his partner, wife or principal. Such a salesman is able to make matters very uncomfortable for his competitors all over the continent.

This is the true feature of the situation, and it is worth looking into by those who are anxious to improve the condition of the honey trade, through weak salesmen, commission men or jealous competitors.

Just look at the following figures for comb honey, as quoted in the several markets named:

Chicago, Ills	18@19c.
Milwaukee, Wis.....	18@20c.
New York, N. Y.....	16@18c.
Detroit, Mich.....	17@18c.
Kansas City, Mo.....	18c.
Boston, Mass.....	17@18c.
St. Louis, Mo.....	14@15c.
Syracuse, N. Y.....	10@13c.

Syracuse is the home markets of Messrs. Doolittle, House, Salisbury, Betsinger, Parks, Ross, Bailey and others. From appearances something is wrong there. From 10 to 13 cents is one-third less than any other market. Collamer, N. Y.

[Perhaps some of the honey-producers named above will in reply state some cause for the apparent discrepancy in prices between New York, Boston and Syracuse. Is it not possible that the quotations in the latter market are for extracted honey? The difference is so great as to seem to be almost unaccountable, if it is intended to represent the true market prices for honey in the comb.—ED.]

THE QUEEN.

Lessons in Government from the Bee-Hive.

Written for the American Bee Journal
BY G. M. ALVES.

Under the above heading, on page 811 of the BEE JOURNAL for Dec. 12, an article from Dr. G. P. Hachenberg is published, wherein he *assumes* that the government of a colony of bees is performed by the queen, and following argues at some length the wisdom of female government.

To enter into a discussion of the latter subject, is probably out of place in a JOURNAL devoted exclusively to bee-culture, but it surely is proper to point out the error of his first assumption.

We may say with positiveness, that modern scientific bee-keeping has thoroughly dissipated the old myth of a monarchy in the hive. Wherever modern observations have been scientifically accurate, they have furnished no reasons for concluding that the queen does little else in the economy of the hive, than the producing of the eggs, and in the light of these facts it would be much preferable to call her the mother, rather than the queen.

That the above is true, is not a subject for discussion, but of citation, and those who question, are properly referred to our modern bee-literature. Henderson, Ky.

[Dr. Hachenberg was evidently intent upon paying a deserved compliment to the women who are "gifted to rule" among the nations of earth.

Mr. Alves says in the foregoing article that the Doctor "*assumes* that the government of a colony of bees is performed by the queen." What the Doctor did say was this:

Perhaps there is nothing in nature that has excited my admiration more, than to watch and study the government of a thrifty colony of bees *under the influence* of the queen. The laws of political economy as instituted by man, surely could not improve it.

He admired the government of the colony of bees *under the influence* of the queen. We all know that in the *absence* of the queen, the bees are uneasy, and "the government" is not so much to be admired as it is with her presence, and soothing *influence*, and in all probability this was the controlling thought of Dr. Hachenberg, when writing the article in question.

He evidently knows well enough that the so-called "queen" is but the "egg-layer"—the mother—but for the compliment to our mothers, wives, and sisters, he uses the term *queen*, and charms us all into reverence and loving devotion. This thought is *justified*, perhaps, by the closing paragraph of the Doctor, which is as follows:

Nature evidently has made the female a ruling power—to rule in love, peace and harmony. The male in all departments of animal life is by nature selfish, cruel, and exceedingly belligerent. In this there is no exception in man—and only where he soars over his own sex, he is a gentleman, a Christian, and a true scholar.

As long as she can "rule in love, peace and harmony," every true man will gracefully submit, and yield to her the palm!—ED.]

HONEY-PLANTS,

And the Time Each Bloomed the Past Season.

Written for the American Bee Journal
BY W. H. SHANER.

I started the bees to carry flour early last March, and the colonies that carried it the fastest bred up the most rapidly. On March 27 they brought in the first natural pollen, and work on the flour ceased. On April 15 the maples bloomed, but the weather was wet and cold, and the bees lost nearly all of it.

Peaches bloomed on April 30, pears on May 3, and apples on May 4, and lasted 14 days. The weather was pretty fair, and the bees bred up very fast. On May 17 we had a very heavy frost.

Crab-apples bloomed on May 24, and locust and raspberries on May 30, and the bees worked so lively that I put the sections on, which they occupied, and in five days the combs were half drawn. The bloom then failed, and work in the sections ceased.

Alsike and red clover came into blossom on June 10, but the bees worked more on the red clover than on the Alsike. We had no white clover this year. A neighbor, who lives a mile from me, told me that he had a notion to get a net and catch a lot of my bees, where they crossed a high hill to get to his red clover field. He saw one of the big Italians catch a black bee, and fly away with it. But I had the pleasure of seeing a nice lot of sections filled with red clover honey, which is dark, but very good.

Linden bloomed on July 12, and lasted twelve days. These trees are scarce here, so the bees did not have a "boom." Golden-rod bloomed on July 26, and the bees got some surplus from it, which is very nice, and fully up to the white clover honey.

Buckwheat bloomed on Aug. 5, and the bees gathered enough from it to give some of them the swarming fever, but no surplus. Asters were in bloom on Aug. 20. They are like the buckwheat where the sun strikes it—the bees only work on them in the forenoon.

Last spring I bought 5 colonies of bees from a man near Cincinnati, O., and I told him to ship them by freight about the close of apple bloom. They were shipped on May 7, and arrived on May 17 in good condition, and not a comb broken. In 23 days No. 1 swarmed, in 24 days No. 2 swarmed, and they were all at work in the sections. They were shipped in two-story Langstroth hives, a notched strip being put in the bottom to hold the frames, which were nailed at each end. Each hive was fastened together with cleats, and a 1½-inch hole was in the side and in the end of the hive, covered with wire-cloth. A hole was also bored through the front of the hive, under the portico (which is very important), and wire-cloth nailed over the portico. Bees packed in this way are good for a shipment of ten days or two weeks. The queens all kept laying on the way, but the bees capped no brood.

The past season was a very poor one. I got 500 pounds of honey from 19 colonies, and increased them to 37. I fed 250 pounds of honey for winter stores.

On Nov. 22 I carried 29 colonies into the cellar; they are very quiet at a temperature of 48°, Fahr. Eight colonies are packed in chaff, on the summer stands.

Leechburg, Pa., Dec. 10, 1888.

MOVING BEES.

When to Buy and Move Colonies of Bees.

Written for the *Prairie Farmer*

BY MRS. L. HARRISON.

A subscriber wants to know which is the best time of the year to purchase bees—fall or spring; and if they can be moved at any other time of the year, except when there is snow on the ground, so that they can be moved upon a sled.

If bees are purchased in the fall, there cannot possibly be any profit in the investment, except they can be sold at an advance, until the following

summer, and the risks are large. Veterans, who have grown old in the service, often lose many colonies during the winter. The seasons are so variable, and we have not the gift of knowing whether the coming winter will be very cold, moderate or mild; if we had, we could advise more wisely.

I have seen bees die during the winter when the conditions were favorable for their living. When I took out the combs and examined everything connected with the hive carefully, I could not see any cause for their death. I simply knew that the bees were dead. Perhaps if there had been a coroner's jury, the verdict would have been, "heart disease."

When a colony of bees that belongs to a person who owns many colonies dies, the loss is trifling, for he can, another season, use the hive and comb. But when a person purchases colonies in the fall, and they perish during the winter, he may lose his combs by the moths, before he can procure swarms to put into the hives. Occasionally, colonies are sold at sales for not more than the honey and hives are worth; then it would be safe enough to invest.

In the spring, a good, strong colony of bees promises to be a good investment. I have never seen a season but that, during some period of it, bees laid up stores for winter. It is true that a crop of honey cannot be depended on every season, in most localities. Last year and this, were partial failures, owing to the severe drouth. Agriculturists and horticulturists have losses and failures in crops; pigs and chickens die of cholera; apples fail; while corn, wheat, oats and potatoes are not always sure. On the average, taking one year with another, three crops of honey out of five can be depended upon.

Moving Bees.

Bee-keepers of "ye olden time," who used the gum, or box-hive, thought that the only time to move bees was during good sledding; but this is a mistake, for they can be moved, with care, almost any time during the year.

There are several points in favor of moving bees upon the snow, where they are wintered out-of-doors. They can be lifted carefully and taken many miles, when the sleighing is good, with so little jar that they will not find out that they are moved at all.

A bee-keeper told me that when he started in the business he purchased a colony in a box-hive and moved them home in cold weather in a wagon over rough roads. The bees were shaken from the combs into a pile in the bottom of the hive. Many of them were numbed with cold and perished, for they could not crawl back where their stores were.

Beginners in bee-culture have got into more scrapes in moving bees, than in any other part of the business. Many persons do things by halves, and when told that they must fasten up the hives so that no bees can get out, they will stick a wisp of hay into the entrance, saying, "I guess that will do; and I will stuff some more around the hives when they are in the wagon," and lift them in.

I have known of a serious accident by the second story of a hive being knocked off through the jolting of a wagon over a rough road. A few nails, wisely driven, would have saved much loss.

There is another difficulty in moving bees, even in December. They may be moved safely, and all go well until the first warm day when they are on the wing, when they will return to the place where their hive stood, unless it has been moved more than a mile.

Late one fall we moved hives together so as to protect them, and the first warm day I noticed bees flying where hives had been. The night following there was a light snow, and the next day I gathered up handfuls of benumbed bees that could not find their hive. When bees go to work, they run out and fly, apparently taking no note of their surroundings.

A new swarm always takes its bearings, and returns to the same place; if it only remains a few hours after hiving, and is moved after sunset, many will return to the place where the swarm was hived.

When bees are moved in the spring, they are not so apt to return; it appears natural for them to mark their locality, with the advent of a new season. When hives are moved, it is well to put hay or grass against the entrance, or a board, so that they cannot run out and fly as they usually do. When they bump their heads, they will look for a reason, take notice of their surroundings, and return to the same place.

Tenant farmers usually move about the first of March, and many of them have a few bees—if they are not in hives of the latest fashion. March and April are very trying months on winged stock, and it is best that they be kept as quiet as possible. As the roads are usually rough and full of chuck-holes at this time of the year, it would be well to move their bees in advance, the last of winter, on the snow if possible. They should be protected from winds, and from the inroads of stock, and then not be afraid of using straw and corn-fodder liberally. It would be better for the owner to do this moving at his leisure, than when crowded with moving, seeding, etc., and much better for the bees,

as they will be at home, having marked their location, at the time of their first spring flight.

Peoria, Ills.

THE UNION.

Fourth Report of its Work, by the General Manager.

The General Manager congratulates the members of the NATIONAL BEE-KEEPERS' UNION upon the fact that so far NOT ONE case, which the Union has deemed it proper to defend, has been decided against the Union—its successful banner still waves triumphantly over the members, and makes the "Bond of Union" still stronger than ever. Every well-wisher, as well as member, will, no doubt, add—

Long may it, in triumph, be waved,
Until every bee-keeper sees
His rights defended and saved,
As well as the lives of his bees!

It is a well-known fact—one firmly established in the minds of all, that "in Union there is strength;" and a union of bee-keepers to defend our pursuit from the unjust attacks of ignorant or prejudiced persons, is not only desirable, but very necessary to our well-being and general prosperity.

For this purpose, and for it alone, does the National Bee-keepers' Union exist—to throw a safe-guard around the pursuit, as well as its devotees. It does not seek a quarrel, but when one is forced upon any of its members, it sets up a "Defense" by its very existence and record. *Never yet* has it suffered a defeat. While that is a record to be proud of, it is also a *warning* to ignorant and jealous enemies to beware how they trifle with the pursuit of apiculture, and to keep their *hands off* of the interests of its devotees. It warns them that the bee-keepers, as well as the bees, have a sting, with which to torture their enemies!

The Union not only seeks to obtain decisions from the highest courts of America, but also to have on record these decisions to be quoted as precedents in all the courts of law, and by all the lawyers who practice therein.

The "Rich" Lawsuit.

In the lawsuit in New York, mentioned in our last report, the Judge stated that there were no *precedents* to guide the decision, and hence he ruled adversely to the bees, as did one in Canada, likening an apiary to a pig-sty or a manure pit. Now we are beginning to record decisions—to provide precedents!

This suit is still pending, the Union having engaged attorneys, and guaranteed the expense of the appeal from

the rulings of the Judge, who likened an apiary to "pig-sty or slaughter house"—the jury, being bound by his instructions, awarded damages of *six cents*. The costs and attorney fees amounted to nearly \$500, and the appeal will cost about as much more—thus \$1,000 will have to be paid when the decision is made, by one side or the other.

The Arkadelphia Suit.

Our last report was issued just previous to the trial of this case. Mr. Z. A. Clark's case, who was put into jail at Arkadelphia, Ark., for maintaining his apiary in the suburbs of that city, came on and was tried before the Circuit Court. The case was tried on the "clean-cut" law question, viz: That the "city ordinance was illegal and void." The **victory** in this case is **for the Union**, the Circuit Court deciding that the city ordinance was *illegal and void*—that the **keeping of bees was NOT A NUISANCE!!**

When the prosecution realized that bee-keepers had an organized body for defending the pursuit against the malicious attacks of the ignorant and the prejudiced, it *weakened*—it tried "to hedge"—was willing to dismiss all the cases against Mr. Clark on a pretended informality in his bonds!

The city has decided to appeal the case to the Supreme Court. This is very fortunate, for we want a decision from the *highest* court to declare that bee-keeping is *not a nuisance!* The Union has paid the full fees, and it will be ably defended by Judge Williams, the most successful attorney in Arkansas.

Mr. Clark writes this concerning the case, dated Aug. 7, 1888:

Everybody in our little city, white and black, are rejoicing, but the anti-bee-council and their followers.

I had 25 witnesses summoned in defense of the Union, by whom I would have proved that the bees were not a nuisance; in fact, I never knew of a team or teamster being stung while passing my premises.

When the case came on, the City Attorney began to show weakness by trying to turn us out of court, on a motion to dismiss all the cases against me, on the informality of my bonds, stating that my bond was not sufficient, but Judge Hearn over-ruled the motion.

When my attorneys, Judges S. W. Williams, Witherspoon, Murray, and McMullan made a motion to dismiss the case against me upon the *voidness* of the ordinance, Judge Williams made an able speech in defense of bee-keepers, in which he showed that he knew something about bees himself.

After which, Judge Hearn stated to the attorneys that he had lived a long time in Arkadelphia, and that bees had been kept here all the time, and that he had not heard any complaint until this case came up—and that the keeping of bees *per se* was not a nuisance.

He said that the case would go to the Supreme Court, no matter in which way it was decided, but stated he wanted to be

found on the *right* side, when decided in the Supreme Court.

He then sustained our motion to dismiss the case, and declared the ordinance void. The City Attorney then gave notice of an appeal. Hence, we go up higher, amid the cry of "victory" and "hallelujahs."

This shows what brothers can do when banded together, with a Captain like Thomas G. Newman, to direct our battles against ignorance and the prejudicial whims of an ignorant populace. Z. A. CLARK.

Mr. A. R. Nisbet, a bee-keeper of Dobyville, Ark., writes as follows concerning the trial:

I wish all the members of the National Bee-keepers' Union, and in fact all the bee-keepers of America, could have been with us during the fight at Arkadelphia on the 4th inst. It would have made them all feel good to have heard Judge S. W. Williams read section after section of law, in Mr. Clark's favor, showing that a man's right to hold property is paramount to all legislative power; and any attempt to take away such right is unconstitutional. He certainly made an able defense, proving to all present that he was equal to the task before him.

The Bee-keepers have constitutional *rights* which they should defend—and cannot be just to themselves and their successors in the business if they do not defend them!

High Indorsement.

The following resolution was passed by a unanimous vote at the International Bee-Association last September:

Resolved, That it is the sense of this Society that the National Bee-keepers' Union has been productive of good, and deserves the hearty, moral and financial support of all bee-keepers, and that the General Manager deserves and receives the hearty gratitude of this Association for his very earnest, efficient and disinterested services.

Honey Production.

In addition to the many sensational stories about "manufactured comb honey," the daily papers last August published an article which stated that the St. Louis Society of Microscopists had examined several hundreds of samples of honey, and found the majority of them adulterated. Knowing that this was untrue, I wrote to the editor of the *Journal of Agriculture*, the paper to which the matter was credited, and he has given this explanation:

The facts are as follows: John C. Falk, a practical druggist and active member of the St. Louis Microscopic Society, examined about a score of specimens of honey obtained from dealers in St. Louis. He found pollen in some, and detected its absence in others, but he did not discover an evidence of adulteration in any. Those without pollen appeared to be otherwise pure. He took a few specimens to a meeting of the society, and incidentally mentioned the facts recited. A reporter of a daily paper was present and heard his remarks. Some members informally examined specimens, but expressed no unfavorable opinion of them. That was all there was to it.

The next day that daily paper had an article which purported to be an account of the investigation of the subject of honey by the society. The editor of this department never saw the report, never wrote anything

concerning the alleged microscopic examination of honey, but the editor of another department of the *Journal* read it, and deeming it an item in which honey producers would be interested, he reduced it to a short paragraph, handed it to the printer, and it was put in type without this editor's knowledge.

The truth brought out by the Union shows just the opposite of the reported sensation. The editor of the *Journal of Agriculture* adds:

The real facts show how imaginative a reporter may be, and further show that an expert microscopist has been unable to detect an evidence of adulteration in any one of the twenty specimens of honey indiscriminately collected in St. Louis, all of which is to the credit of honey producers, and of retail dealers in St. Louis. We are gratified at so pleasant an outcome to the matter, which had its origin in a grievous misstatement of facts on the part of a reporter.

Just for a moment consider the facts in the case: A "druggist" examined a score of samples of honey, but did not find any adulterated! This he stated at a meeting of microscopists. The sensational-scribbler reported that the St. Louis Society of Microscopists examined several hundreds of samples, and found the majority of them adulterated! Could lying be more premeditated and pernicious?

Election of Officers.

At the last election all the old officers were re-elected by over 100 majority. While the General Manager would have been pleased to have seen a new set of officers elected—just to exhibit an interest in the organization—still he would also say that the President and Vice-Presidents have all worked so harmoniously for the general welfare, that it would be next to impossible to find those who would have done better, and we presume that the members of the Union concluded that they could not any better show their appreciation of what has been accomplished in the past, than by re-electing them.

Change of Time for Paying Dues.

It was suggested by several members that the time for paying dues should be changed from July to January, when members would not be too busy to give it attention, and also to take some time to get others to join—July being the most hurrying time of the year. Mr. E. France, when urging the change, said: "I am willing to pay another dollar on Jan. 1, if the time can be changed." This was submitted to the members through the AMERICAN BEE JOURNAL, and all were asked to send a Postal Card who voted against the change. Only three votes against it being received, after repeated notices, the motion was declared to be carried, and the time is accordingly changed.

Financial Statement.

From July to Dec. 1888.

Balance as per last report.....	\$258.27
Received from 239 members at \$1.00	239.00
Donations received.....	97
	\$498.24
Paid Judge Williams, attorney	\$150.00
Postage, printing, stationery, etc.....	68.86
	\$218.86
Balance cash on hand Dec. 15, 1888.....	\$279.38

LIABILITIES.—On the Rich lawsuit the costs are about \$1,000, which must be paid as soon as the judgment is rendered, and for which bonds have been given, if the judgment is adverse. The costs on the Arkadelphia case cannot at present be determined.

Concluding Remarks.

Away across the Oceans the Union has been applauded, not only in Europe, but also in Australia. The Editor of the *Australasian Bee Journal*, after giving a resume of the last report of the General Manager, adds: "Long may the Union flourish."

What the Union has done in the past is a guarantee for the future. It may not always triumph over prejudice, envy and ignorance, but it will defend the pursuit, and uphold the right. It is for bee-keepers to say whether it deserves both their moral and financial support or not. If it does, they should render both in unstinted measure. It is to the interest of every individual engaged in the pursuit of bee-culture to do so.

Do the members ever think of what a **power** there is in an organized defense? and what a powerful defense it is, when those engaged in a pursuit combine and employ the very best legal talent which can be had—and plenty of it—and planting their feet squarely upon the constitution of Freemen—in this "Land of the Free and Home of the Brave"—they demand the rights guaranteed to every "honest son of toil" by that *magna charta* of American liberty and independence—the Constitution of the United States!!!

It is not only the **privilege** of aristocrats to belong to such a "Union" for defense—but it is a **high honor**. Like the Royal Hazzards of history, the Union has never been beaten! **Victory** has perched upon its banner in every contest so far undertaken in the defense of the rights of its members! This is, of course, attributable to the care exercised in canvassing the cases before deciding to defend them; to make sure that they are **RIGHT** before going ahead with them! For if not **right**, it would be better to be beaten than to be victorious.

In submitting this my Fourth Report, I desire to say, as before, that I have done to my utmost all that I could for the success of the Union, and am both ready and willing to give place to my successor as soon as elected.

T. G. NEWMAN, *General Manager*.

Honey and Beeswax Market.

CHICAGO.

HONEY.—We quote: White clover 1-lb., 18@19c.; 2-lbs., 16@17c. Good dark 1-lb., 15@16c.; 2-lbs., 13@14c. Buckwheat 1-lb., 14@15c.; 2-lbs., 12@12½c. Extracted, 7@9c. depending upon quality and style of package. Receipts increasing, but demand still limited. Stock is not selling as freely this season as a year ago.

BEE SWAX.—22c.

Nov. 13. B. T. FISH & CO., 189 S. Water St.

CHICAGO.

HONEY.—It is selling fairly well at 18c for best 1-lb. very fancy lots have sold at 18c. Dark and yellow comb sells slowly at 13@16c. Extracted, 7@9c., according to quality and style of package. The stock of best comb honey is light.

BEE SWAX.—22c. R. A. BURNETT, 161 South Water St.

MILWAUKEE.

HONEY.—We quote: Fancy white 1-lb., 18@20c.; 2-lbs., 16@18c. Good dark 1-lb., 16@18c.; 2-lbs., 15@16c.; fair 1-lb., 12½@14c. Extracted, white, in kegs and ½-barrels, 8½@9c.; amber in same, 7½@8c. in pails and tin, white, 9@9½c.; in barrels and half-barrels, dark, 6@6½c. Market steady and supply ample for the moderate demand, but present values have a tendency to restrict general consumption.

BEE SWAX.—22@23c.

Oct. 25. A. V. BISHOP, 142 W. Water St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb., 15@17c. 2-lbs., 14@16c. Fair white 1-lb., 14@16c.; 2-lbs., 11 to 15c. Extracted, white, 7½@8c.

BEE SWAX.—23½c.

Sep. 17. THURBER, WHYLAND & CO

NEW YORK.

HONEY.—We quote: Fancy white 1-lb., 16@17c.; 2-lbs., 13@14c. Fair white 1-lb., 14@15c.; 2-lbs., 11 to 12c. Buckwheat 1-lb., 11@12c.; 2-lbs., 10c. White extracted, 8@8c.; amber, 7@7c. Demand good for white 1-lb., and buckwheat 1 and 2 lbs., of which the stock is light. Good stock of white 2-lbs., with but little demand.

BEE SWAX.—22½@24c.

Nov. 24. HILDRETH BROS. & SEGELKEN, 23 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—White 1-lb. sections, 12@12½c.; 2-lbs., 12@14c.; amber, 8@10c. Extracted, white, 6½@6¾c.; light amber, 6c.; amber and candied, 5¼@5½c. For comb honey the demand is light; for extracted it is good, and market firm.

BEE SWAX.—Dull at 19@22c.

Nov. 15. O. B. SMITH & CO., 423 Front St.

DETROIT.

HONEY.—Best white 1-lb., 16@18c. Supply is not large, but equal to the demand.

BEE SWAX.—22@23c.

Dec. 12. M. H. HUNT, Bell Branch, Mich.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb. Best white comb honey, 12¼@16c. Demand slow.

BEE SWAX.—Demand is good—20@22c. per lb. for good in choice yellow, on arrival.

Dec. 17. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—Choice 1-lb. sections, 18c.; dark 1-lb., 14c.; 2-lb., 16c.; dark, 13c. White extracted in 60-lb. cases, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices steady, and stock fair.

BEE SWAX.—None to market.

Sep. 27. HAMBLIN & BEARSS, 514 Walnut St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 17½@18c.; 2-lbs., 14@15c. Fair 1-lb., 14½@15½c.; 2-lbs., 11@12c. Extracted, fancy white clover, 7½@8c. California white in 60-lb. cans, 8c.; light amber in same cans, 7½c.; amber, 7½c. Buckwheat in kegs and barrels, 5½@6. Cuban, in barrels and ½-barrels, 65c. per gallon.

Sep. 26. F. G. STROHMEYER & CO., 122 Water St.

BOSTON.

HONEY.—We quote: Best white clover 1-ponds, 17@18c.; best 2-lbs., 16@17c. Extracted, 6@9c. The sales are good, and indications are that all the honey in the country will be sold by Feb. 1.

Dec. 12. BLAKE & RIPLEY, 57 Chatham Street.

KANSAS CITY.

HONEY.—White 1-lb., 16@17c.; fair, 14@15c.; California white 2-lbs., 14@15c.; amber 2-lbs., 12@13c.—Extracted, white California, 7½c.; amber, 7c.

BEE SWAX.—None to the market.

Dec. 11. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—We quote: Extracted in barrels, 5@6c. according to quality; in cans, 7@8c. Comb, 12½@15c. Prices firmer on account of scarcity, though the demand is not great.

BEE SWAX.—21c. for prime.

Oct. 17. D. G. TUTT & CO., Commercial St.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 6½ cents; light amber, 6@6½c.; amber, 5½c. Comb, white 1-lb., 13@14c.; 2-lbs., 13c. Light amber 1-lb., 11@13c.; 2-lbs., 11@12c. Demand very active for extracted, and fair for comb honey.

BEE SWAX.—20@21c.

Nov. 6. SCHACHT & LEMCKE, 122-124 Davis St.

INDEX TO VOL. XXIV.

Packing bees, 278.....Ran, 11—Seabright, 45, 165—Kleinow, 61—Styer, 109—Bartow, 203—Buchanan, 328.....Gehring, 550
Paints, 235.....Stockwell, 9—Bachly, 405
Paris exposition, 692, 709.....Riley, 788
Parthenogenesis.....Hamburg, 712
Partly-filled sections, 51, 138.....Theilmann, 25—Stewart, 57.....Hohnadel, 125
PASTURAGE FOR BEES, 88, 682, 707, 747.....
Chaddock, 392—Jackson, 440.....Green, 535
Alfalfa, 68, 245—Willis, 8—Westover, 41—Math-Rassnussen, 183—Jarvis, 285.....Thielmann, 339
Alsike clover, 613.....Baldrick, 10, 41, 132—Lindie, 53—Bates, 155—Campbell, 17—Morris, 274, 169—Hicks, 284—Stanford, 300—Secor, 313, 476—Stokes, 540—Hutchinson, 548.....Bunch, 684
Apple-bloom.....Damarin, 389
Asters.....Pickett, 61—Cushman, 569—Rose, 629—Deadman, 717.....Prior, 766
Basswood, 451, 564.....Read, 11, 217—Lee, 44
Bee, 14, 235.....Barton, 476.....Belling, 572
Blooming curiosity.....Bell, 620
Buck-bush.....Prime, 156
Buckwheat, 708, 709, 725.....Becker, 476—Youngman, 563—Rogers, 604—Miller, 615—Seelye, 629—Moyer, 629—Park, 629—Bunch, 684
Bulbous-crown.....Stewart, 759
Bumble-bee, 804.....794
Chapman honey-plant, 1, 0, 308.....Secor, 313—Highbarger, 325, 468—Keeler, 355—Buckley, 373—Barton, 419—Carlee, 444—Kirkpatrick, 508—Green, 535—Bacon, 596.....Chapman, 620
Cone flower.....Todd, 579
Corn.....Baking, 469
Cove's physics.....Dibbern, 540—Waterman, 572
Dandelion.....Merritt, 380
Eucalyptus.....Pryal, 164
Figwort—Waterman, 572—Harrison, 644—Russell, 649
Fay-leather.....McDaniel, 620
Golden-rod, 723.....Pickett, 61—Cushman, 569—Bates (poem), 614.....Cook, 629
Gardens.....Cook, 649
Heart's-ease.....Martin, 588—Haskins, 624.....Flanagan, 812
Hedge-hyssop.....Coleman, 620
Honey-lucist.....597
Japanese buckwheat.....Kentch, 772—Cook, 838
Lucerne.....Webster, 676
Mellilot.....Bates, 115
Melissa, 735.....Tyrell, 749
Mignonette.....Griffith, 717—Waring, 782
Mustard.....Prior, 405
Palmetto.....810
Peppercorn.....Hone, 317
Poison-ivy.....Becker, 476—Heddon, 643
Poison-ivy.....347
Raspberries, Harmer, 13—Newman, 28—Shabb, 380
Red clover.....Fritz, 93
Skunk-cabbage.....Doellittle, 300
Sneeze-weed.....Shelby, 812
Sourwood.....Humbaugh, 684
Sweet clover, 115, 387, 773.....Davis, 27—Billing, 44—Hone, 317—Dibbern, 535—Waterman, 572—Park, 629
Verbena.....Todd, 579
Winter leaf.....Cory, 405
White clover.....Heed, 11—Doudna, 71—Coffey, 641—Pleming (poem), 343—Bittenbender, 389—Burton, 419.....Miller, 615
Wild basil.....Carlee, 540
Wild cucumber.....Hanson, 834
Wild rice.....Hewatt, 836
Patents and inventions.....Taylor, 731
Pearl honey.....68
Peculiar queen and colony.....Kellou, 656
Rawlins, 341.....Beall, 133
Photography and bee-keeping.....Walrath, 796
Placing colonies close together.....492
Haven, 292.....Barrows, 492
Planting for honey 749.....Ridenour, 298—Hutchinson, 372.....Cook, 794
Planting trees, 296.....Pohl, 547—Gehring, 551—Demaree, 568—Prior, 545.....Miller, 615
Pleasurs and difficulties of bee-keeping.....91
Points in breeding bees.....Duff, 131
Poisoning bees, 457.....Lattner, 40
Bombarder, 84.....Shington, 139
Pollen as food for bees.....Doellittle, 22—Cook, 264
Pollen in the sections.....Heddon, 395
Pollination and perforation of flowers.....Staley, 791
Postal reform.....176
Poultry and bees.....Cates, 123—Coffey, 629
Preparing bees for winter.....Bates, 75—Abbot, 536—Hill, 612—Rose, 698—Singer, 716—Miller, 728—Harrison, 772.....Hutchinson, 820
Preparing feed for bees.....Dibbern, 232
Preparing honey for market.....Dibbern, 70
Preservation of apples.....Park, 7
Preventing stings.....Wildier, 467

Prevention of increase, 91, 198, 246, 394, 406..... Jones, 407 — Elwood, 427 — Dibbern, 794 — Woodward, 608 — Smith, 781 — Humbaugh, 795
 Prodiak—that didn't return (poem)..... Secor, 544
 Progeny of unfertilized queens..... Groff, 665
 Prolific queens..... 309
 Properly attending to bees..... McDonald, 229
 Protecting in Michigan..... Clark, 696
 Protective of honey bees..... 85
 Pure bees are best..... 581
 Pure honey..... Armstrong, 797
 Pure Italian bees..... Campbell, 572
 Purely-mated queens..... 454
 Putting bees into cellars, 20..... Lyman, 170—
 Doolittle, 170—Harrison, 795—Waldron, 826
 Putting bees into winter quarters..... 679
 Putting bees out of cellars, 681..... Pierce, 203
 Atwater, 264—Le Ferre, 389..... Davenport, 325
 Putting sections on the hives..... Doolittle, 775
 Puzzling colony..... Mathews, 28

Quality of winter bee-food..... Pierce, 647
 Queen-cages..... Tucker, 172
 Queen-cells that do not hatch..... 598
