I have a simply-made hive in this way: The sides of $\frac{1}{2}$ or $\frac{3}{8}$ inch stuff; ends about 1 inch thick, and the cover simply a flat board, or boards thick or thin cleated with elinch-nails, and to prevent warping and melting of the combs, I put on top the same two thicknesses of rag carpet that I use over the frames for wintering, on top of which a stone or brick is put to prevent the wind blowing the carpet or cover off. It answers a nice purpose, and I cannot think of anything simpler or more convenient.

Making Section-Cases and Rearing Queens.

After trying many styles of section-cases, I am best pleased with T-tin ribs, either loose or fast, but I prefer them fast, and I have used them so for about four seasons. I also use propolis-shields or guards at the top and bottom of the sections, and they come out easily, and are neat and clean.

It will hardly pay the small bee-keeper to rear his queens, except for the knowledge he gains from the operation. I do, however, find it profitable, after my *best* and most valued colonies have sent out a prime swarm, to take from them all queen-cells but the *one* that is largest and best; the others I cage in a hatching-box, or frame, made by nailing screen-wire on one side of a regular frame, dividing the inside into small compartments, and on the back fastening with tack heads, strips of tin to slide in and out as covers. This I then hang in a strong colony, and as the queens hatch, if good and promising, they are used to replace others, to form nuclei, etc.

This is as far as I attempt to control or hinder swarming, and it almost universally prevents after-swarms, gives a supply of good young queens, and leaves both colonies in the best possible condition for profitable work.

The Chick-a-Dees Killing Bees.

When the bees flew freely, about Feb. 1, I for the first time discovered a new (to me) enemy of bees, viz., the chick-a-dees; perhaps 8 or 10 were constantly about and on the watch, and nearly every bee that alighted on the snow, and failed to rise, was, as soon as helpless, pounced upon, carried to a limb near by, and pecked upon at the back, the honey-sac extracted, and then dropped into the snow again. None, however, were taken until they became helpless and unable to rise!

Is this a new enemy, and will the habit be continued in the flying season? or have the birds been forced into it from starvation, caused by the long-continued cold weather and deep snow? Will some one having knowledge of the facts, please answer. As yet I have not that any, since the taking of the old and worn-out bees of course is not an actual loss.

Schaghticoke, N. Y.

A Pocket Dictionary will be presented for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

Your Full Address, plainly written is very essential in order to avoid mistakes.

New Subscribers can obtain the full numbers for 1887 and 1888, for \$1.75, while there are any sets of 1887 left.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one **FREE**, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it *free*, by mail, to any one, for a club of three subscribers and \$3.00.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

Frank Leslie's Popular Monthly for June.—Summer Saunterings in Spanish San Sebastian is a charming bit of descriptive from the pen of Mrs. Frank Leslie, one of the most notable women of the day, equally skillful in the management of a great business and in literary effort, in prose or verse. The description of the famous old frontier town, now becomes a resort of gayety and fashion, is full of characteristic touches. The stories are all bright, attractive, and well written, and the *Popular Monthly* for June gives a most attractive and interesting mass of reading for the pleasant days when travel or a shaded porch invite one to read.

Honey and Beeswax Market.

DETROIT.

HONEY.—Best white in one-pound sections, 15c. Extracted, 9@10c. Large supply and few sales.
BEESWAX.—23@24c.
Apr. 24. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—Prices range from 15@16c. for best one-lb. sections; other grades are slow, at lower prices. Extracted, 7@8c. Light demand, and supply larger than usual at this season of the year.
BEESWAX.—23c.
R. A. BURNETT,
161 South Water St.
May 1.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 14@15c.; fancy 2-lbs, 12c. Lower grades 1@2c. per lb. less. Buckwheat 1-lbs., 10@10½c.; 2-lbs., 9@9½c. Extracted, white, 7@7½c.; dark, 5½@6c.
Mar. 19. F. G. STROHMAYER & CO., 122 Water St.

CHICAGO.

HONEY.—We quote: Fancy white clover 1-lb., 16@17c.; 2-lbs., 15@16c. Dark is slow sale at almost any price. Extracted is scarce, and sells at 7@10c.
BEESWAX.—23c.
Mar. 13. S. T. FISH & CO., 189 S. Water St.

OINCINNATI.

HONEY.—We quote extracted at 4@9c. per lb., for which demand is good. Comb honey, 14@17c.—Demand slow.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Apr. 23. C. F. MUTH & SON, Freeman & Central Av.

MILWAUKEE.

HONEY.—Choice white one-lb. sections, 16@17c.; 2-lbs., 15@16c.; 3-lbs., 14c. Extracted, white in kegs and ¼-barrels, 8 to 8½c.; in tin and pails, 9½@10c.; dark in barrels and kegs, 5@7c. Market fair.
BEESWAX.—22@25c.
Apr. 23. A. V. BISHOP, 142 W. Water St.

DENVER.

HONEY.—Best white 1-lb. sections, 17@19c.; 2-lb. sections, 15@17c. Extracted, 7@10c.
BEESWAX.—20@23c.
Mar. 1. J. M. CLARK & CO., 1409 Fifteenth St.

KANSAS CITY.

HONEY.—We quote: Choice white 2-lb. sections, 17@18c.; dark 2-lbs, 14@15c.; choice white 1-lbs., 18 to 20 cts., dark 1-lbs., 15@16c. White extracted, 7@8c.; dark, 5@6c. Demand is slow. White extracted in drum when in 60-lb. tin cans.
BEESWAX.—21 to 22c.
Mar. 29. HAMBLIN & BEARSS, 514 Walnut St.

BOSTON.

HONEY.—We quote: 1-lb. sections, 16@17c.; 2-lb. sections, 14@16c. Extracted, 6@9c. The market is not very brisk and sales are slow.
BEESWAX.—25 cts. per lb.
Mar. 24. BLAKE & RIPLEY, 57 Chatham Street.

SAN FRANCISCO.

HONEY.—We quote: White to extra, 10@17c.; amber, 9@14c. Extracted, white liquid, 7@7½c.; amber and candied, 8@7c. Market quiet.
BEESWAX.—16@21c.
Mar. 20. SCHIACHT & LEMCKE, 122-124 Davis St.

KANSAS CITY.

HONEY.—We quote: White 1-lbs., glassed, 16@17c.; unglazed, 17@18c.; and dark 1-lbs., glassed, 15c.; unglazed, 16c.; white 2-lbs., glassed, 16c.; unglazed 2-lbs., 17c. California white 2-lbs., 17c. California extracted in 60-lb. cans, 8c. Market quiet and receipts are larger.
BEESWAX.—No. 1, 20c.; No. 2, 18c.
Mar. 19. CLEMONS, CLOON & CO., cor 4th & Walnut.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2.00	3.00	3.50
1,000 Labels.....	3.00	4.00	5.00

Samples mailed free, upon application.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 18 cents per pound for bag and postage.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$3.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Sweet, or Melilot, Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, \$1.00 per 100, or \$8.50 per 1,000.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Advertisements.

SPECIAL OFFER!

To prevent increase, I will sell five lbs. of Italian Bees, with tested queen for \$5.00.
Miss A. M. TAYLOR, Box 77,
21A1t Mulberry Grove, Bond Co., Ill.

FOR SALE.

35 COLONIES of Italian Bees in Langstroth hives made frost-proof. Apply to,
20A2t PETER DIXON, Saginaw, Mich.
Mention the American Bee Journal.

DON'T OVERLOOK THIS. I have quit bee-keeping, and offer 50 Heddon hives (Simplicity frame), 70 upper stories painted two coats white lead, used one season, Heddon Honey-Board, and everything complete for only \$25; also one Foundation Mill (6 loches), new, \$5.20; new Heddon Feeders (largest size), 25 cents each, and a sample hive complete, 50 cents. Satisfaction guaranteed.
E. J. SCOFIELD,
21A1t HANOVER, Rock Co., Wis.

The Bee-Keepers' Review

FOR MAY is now out. Having regained the time lost during his illness, the editor will hereafter take pride in getting out the Review promptly on the 10th of each month. The special topic of the present Number is "Hiving Bees." The review of Mr. Cheshire's work, which was begun in the March No., is finished in the present issue. We have a surplus of the Numbers containing this review, and, so long as they last, these three Numbers will be sent free to all who apply.

Price of the REVIEW, 50 cts. a year.
The Production of Comb Honey,
A neat little Book of 45 pages, price 25 cents. THE REVIEW and this book for 65 cents. Stamps taken, either U. S. or Canadian.
Address, W. Z. HUTCHINSON,
20A1t 613 Wood St., FLINT, MICHIGAN.
Mention the American Bee Journal.

OUR ILLUSTRATED
CATALOGUE
FOR 1888

WILL be mailed free to any one who is not already supplied with it. Send us your address, plainly written, on a Postal Card.
THOS. G. NEWMAN & SON,
923 & 925 W. Madison-St., - CHICAGO, ILLS.

READY TO SHIP.
24 ITALIAN QUEENS, all reared from imported mothers in swarming season. One, untested, \$1.00, 3 for \$2.75. Two-frame nucleus with 2 lbs. of bees and untested queen for \$4.00. Price list free.
J. N. COLWICK,
21A3t Norse, Bosque Co., Texas.
Mention the American Bee Journal.

WANTED,

Beeswax.—We will pay 20 cents per pound, delivered here, for Yellow Beeswax. To avoid mistakes, the name of the shipper should always be on each package.

THOS. G. NEWMAN & SON,
923 & 925 West Madison St., - CHICAGO, ILLS.

Dadants' Foundation Factory, wholesale and retail. See advertisement in another column.

THE NEW HEDDON HIVE

NAILED AND PAINTED.

WE have a FEW of the above hives, all complete, for sale, at \$4.00 each. As we do not handle these hives this year, we cannot fill orders for them in the flat. Those nailed and painted are left from last year's stock.

THOS. G. NEWMAN & SON,
923 & 925 West Madison-St., - CHICAGO, ILLS.

OUR No. 2 One-Piece Sections are the cheapest in use—\$2.60 per M. No. 1 are the best in use—\$3.60. These are 4¼x4¼, of various widths. Address as in cut. 20A4t
Mention the American Bee Journal.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. May 30, 1888. No. 22.

EDITORIAL BUZZINGS.

Ever Learning and exploring the fields of thought, speculation and invention—still the best apiarists have yet much to learn about bee-keeping, and the manipulation of bees, and the marketing of the honey product. Much yet remains to be learned, much to unlearn, and still more to be developed from that which has not yet evolved from the human brain.

Mailing Queen-Bees to Canada.

—Last week we published a letter from the Superintendent of Foreign Mails, announcing that though queen-bees could not now be mailed to Canada, that a modification of the treaty was expected so as to admit them. Dr. S. W. Morrison, of Oxford, Pa., wrote to us on the 24th inst., the following concerning the matter:

I am requested to address a cage with bees to the Superintendent of Foreign Mails for transmission to the Canadian authorities for examination. Permission to send queens by mail to Canada will be surely arranged for within the next week.

Holy Land Bees.—A correspondent writes the following queries for answer in the AMERICAN BEE JOURNAL:

What do you know about "Holy Land bees"? Are they better than the Italians? If so, I want queens. Who rears them for sale? I see none advertised, and why not?

The Holy Land bees are good workers, and are favorites with many bee-keepers. If our memory serves us right, we have advertised them for some breeders. They ought to know enough about business to "keep these matters before the people," especially at the proper season for selling queens. THE AMERICAN BEE JOURNAL is unsurpassed as an advertising medium, and offers advantages possessed by no others.

Cremation.—Mr. L. C. Wemple, of Rogers' Park, Ills., is now traveling in California, and has sent us the following cut from the Los Angeles, Calif., *Tribune* of April 22, 1888. It seems that Mr. Hinde, who was very far behind the spirit of the times, has cremated 500 colonies of bees, sacrificed them to ignorance and superstition. The *Tribune* says:

Mr. Hinde, of Anaheim, who burned up 500 colonies of bees, possessed by himself, because the alleged busy little workers had been engaged in pillaging his neighbor's orchards and vineyards, must be a man made of the same stern stuff as that which went to the mental and physical composition of our Pilgrim fathers. He is honest, certainly, to a fault—for he destroys his own property to save the property of others—but after all I cannot find it in me to commend his act.

He did not think of the bees, you see, who were to suffer a fiery martyrdom for obeying their natural instincts; and yet the bees had rights. They had the right to live out their little span of life, to gather sweets, and to alight upon the flowers, and to flash their wings in baths of sunshine.

Mr. Hinde's bees were probably not consenting parties to their burning, either, and if they had not been so blinded by smoke as to forget all about their possession of a business end, I have no doubt that they would have endeavored to bring the gentleman to a realizing sense of that fact. But it is very doubtful whether they would have been successful even under the most favorable circumstances.

A man of his stony heart and adamant conscience must be the possessor of an epidermis totally impervious to so small a thing as the sting of a bee. And if he was not, a thousand stings would not turn him from what he conceived to be his duty.

Superstition has brought untold woe upon the world, and men of Mr. Hinde's stamp have long been a curse to the world. He is a slave to an erroneous idea. The bees were busily engaged in fertilizing the flowers, increasing the fruit, and proving a blessing to the orchard and its owner, and yet in his blindness, the owner of the bees cremated them, and thus repaid them for their generous labors by instant death.

This is the same piece of superstitious stupidity as that of the bee-keeper who closed the entrances to his bee-hives on Saturday night to prevent them from working on Sunday! Such ignorance is inexcusable in the full blaze of the light of the closing years of the nineteenth century! The fiat of the Almighty is: "Let there be light," and it behooves men and women of the present day to help scatter the light, and banish darkness and superstition from the earth.

Two-Ounce Sections.—We have received a frame containing 20 "two-ounce" sections for honey (that is to hold two-ounces of honey when filled) from Mr. W. Harmer, of Manistee, Mich. The frame came safely by mail, with pieces of foundation in each, and when put on our desk, attracted considerable attention for several days. It now occupies a place in our Museum. These two-ounce honey sections were fully described on page 292. If they can popularize honey by putting it up in 5-cent packages, all will bid them welcome.

That Trembling Disease.—Salt as a cure for the trembling disease in bees has been recommended by several in these columns, and now comes Mr. C. H. Dibbern with the result of a trial in his apiary. He remarks, under date of Milan, Ills., May 23, 1888, as follows:

It seems that some bee-keepers are seriously troubled with what is usually called the trembling disease. I had a colony last fall that was badly affected, and had dwindled away to a mere quart. I had heard salt recommended, and I gave them a sprinkling with salt water on top of the frames, but had little faith in it. The disease has, however, entirely disappeared, and the colony is strong again and hard at work.

A Riddle.—S. M. Keeler, of Chenango Bridge, N. Y., propounds this riddle for explanation:

Concerning the Chapman honey plant, I read in the AMERICAN BEE JOURNAL, page 308, the committee appointed at the Detroit Convention, report that the seed may be scattered in waste places; that it seems to root out all other vegetation and take possession, etc., to commence with, and then closes with this remark: "It does not spread in seeding." Can you, Mr. Editor, solve this riddle?

Oh! "riddle me, riddle me right"—that is *easy to solve!*

That committee was well-"rooted." In fact it consisted of *two Roots* (L. C. Root and A. I. Root), and N. W. McLain. They commenced at "the root of the matter," and at first stated that it was "characteristic" of the plant to "root" out all other vegetation, and take possession of the soil. That is done by the *roots*—not the seed!!

Now at the end of the report they speak of the *seed*, and declare that "as it does not spread in seeding," that the winds do not carry the seed, because it is not provided with balloons for that purpose, and therefore it is not like the Canada thistle, "a pest or noxious weed," and its extirpation is therefore easily accomplished!!

When the "roots" and the "seed" are kept separate, the "riddle" vanishes out of sight!!

The Votes on the location of the next meeting of the North American Bee-Keepers' Society are coming in. Dr. Mason reports that 62 of the 81 votes so far received from the members, are all but one (which is not against it) in favor of the change to Columbus. We felt sure that there was no question but that the vote would show that the members desired the change, under the circumstances.

Now, it should be borne in mind that, as this is a migratory convention, it is not best to decide upon a location a year in advance. It should adjourn subject to the call of the executive committee, who, during the interim, can canvass the claims of the different localities and decide upon the best, all things considered. This would save trouble and annoyance, and would often be of great advantage to the Society, and save members much of the cost of railway transportation. This matter should be thought of when an adjournment is taken at the next meeting.

GLEAMS OF NEWS.

Still they Come.—M. W. Shepherd, of Rochester, O., writes us as follows :

I enclose a clipping from the *Family (Monthly) Visitor*, published in Camden, N. J., for February, 1883, showing how the bogus honey business is carried on—somewhere! Here it is :

The industrious bee will have to be more industrious than ever, now that artificial honey is being made. The comb is manufactured from a white wax, placed in a jar and the syrup poured over it. It is not a very good imitation, and can easily be detected, but it is much cheaper than the real article. Will the dealers raise its price and pass it off as genuine honey ?

Some are determined to push these assertions—and to accommodate them, an inventor is now trying to make comb with cells half an inch deep or more. We have seen some of it, but so far no one has attempted to fill it with honey and seal it over, *a la* Wiley. The same writer adds this :

Also inclosed you will find an article clipped from the *Orchard and Garden*, published in Little Silver, N. J., which I think will answer the person who said the bees had destroyed the grape industry of northern Ohio, the particulars of which were given in the AMERICAN BEE JOURNAL, page 84. The counties mentioned are two of the smallest engaged in grape culture, and if the bees have destroyed the same, what must it have been before the little sinners got in their work. Some people will lie for fun (Wiley for instance), and others will lie because they do not know any better, and between the funny man and the fool the poor little bee will have a hard time of it.

The article in question is written by Geo. H. High, of Ottawa county, O., and in it he completely refutes the lying assertions of the Atlantic, Iowa, *Messenger* (viz., that "the grape-raising industry has been almost entirely killed in Ohio" by the bees). He says :

We have had but few entire failures with the Catawbias here for 17 years. My own vineyard has averaged for that time 3,872 pounds to the acre. No vine responds so quickly to good treatment. More than 60 per cent. of the six or eight thousand acres in this and Erie counties are Catawbias. More than 12,000 vines will be planted in this vicinity this spring.

The *Messenger*, it will be remembered, advised grape-growers to poison bees in their localities, and as an excuse for doing so, lied about the industry in Ohio—proofs of the falsehood is presented above from an extensive grape-grower himself !

Bees are Swarming.—That is the general tune now. The following is a sample of many of the letters now coming in, and is from J. H. Loudon, of Bloomington, Ind., and dated May 21, 1888 :

Bees are just booming. I had a very large swarm yesterday, if it was Sunday, and today I had three more. The hives are running over with bees, the result of keeping them in chaff hives, with a cushion on top, where they keep warm during cold spring nights.

WELCOME APIARY.

The engraving represents "Welcome Apiary" at Bedford, O., which was founded by Mr. J. B. Hains, who, when a mere lad, captured a fugitive swarm of bees which were seeking to assert their independence, while their fellow-citizens on a higher plane of creation were, with perhaps less order and more ardor, with fife and drum and waving banner at the head of their column, parading the streets of their little village, celebrating the 67th anniversary of our National Independence.

The line of march taken by the patriotic citizens and that of the absconding swarm being at right angles, crossed each other, the bees passing over the squad of bare-footed boys who were following in the rear of their elders.

The sweet music of the bees contrasted with the discordant notes of the amateur

graving, as it is across the railroad tracks that are seen in the rear of the house.

The name of the apiary was suggested by the fact that visitors to the apiary were always made *welcome*, and being only 12 miles from Cleveland, on the lines of the Cleveland & Pittsburgh, and Cleveland & Canton Railroads, a large number favor Welcome Apiary with a visit every year.

Funny.—An item is going the rounds of the American papers about the honey product of France, which reads thus :

At Bordeaux, a bee-keeper obtained 1,965 kilos (3,930 pounds) of honey in one season from 71 colonies. He uses the movable frame. At Claixan, in the Pyraenes, there is an apiary of 100 colonies that yields an annual revenue of about 350 frames, but the bees are smothered every fall.

In 1874, the honey and wax product in France was worth 25,000,000 francs ; in 1875 the product was 10,000,000 kilos. of honey,

martial band, and aided perhaps by the visions of sweetness rising before his imagination, caused the boy Hains to give chase to the bees which soon clustered, perhaps having been thrown into disorder by the noise which the boys thought to be the finest of music.

He then procured a dry-goods box and dumped the bees into it. For a few years boxes and salt barrels furnished shelter for their descendants, presenting a motly row, until the invention of the Rev. L. L. Langstroth, which was destined to revolutionize bee-keeping, was brought to his notice, and changed his methods. Although he constructed a house-apiary or bee-house, at quite a considerable expense, he does not recommend it for practical purposes, but very much prefers chaff hives.

This view was taken from the west half of the apiary, which is not shown in this en-

and 25,000,000 kilos. of wax. On Dec. 31, 1885, 1,731,604 colonies of bees were in France.

What an enormous honey crop that bee-keeper of Bordeaux had ! A little over 50 pounds per colony !! Had it been ten times that amount there might have been something to crow over ! What would he think of our Texan's report of 1,200 lbs. from a colony, or a similar amount from 3 or 4 colonies that in Bordeaux it took 71 colonies to gather !

At Claixan it is even a worse report. That honey from a hundred colonies was gathered and deposited in large brood-frames—instead of in the small American sections holding a single pound of delicious honey deposited in virgin combs !

The fact is that France is away behind the times in apiculture—away behind almost every other country in Europe in bee-manipulation and honey production.

Honey Transformation.—Mr. D. Stoler, of Saxton, Pa., sends us the following for explanation. It is taken from the *Grocers' and Cannery's Gazette*. Please notice that the last word in the second line stamps the article as *pure* honey. All the transformation that occurred was the ordinary granulation consequent upon its being exposed to the air after a part of it had been eaten. The article reads thus :

Some weeks since it was our fortune to come into possession of a pound-box of pure honey, with which we had an experience such as to warrant reference to it here. For several days we ate the honey with our lunch until there remained but a thin layer on the bottom about $\frac{1}{4}$ to $\frac{1}{2}$ of an inch in thickness. This we left untouched in the drawer of our desk for some two weeks, when, upon examining, we found a peculiar transformation had taken place. All semblance of the honey structure had disappeared, and in place thereof we discovered a white substance that closely resembled in appearance the crust upon cooled lard, beneath which was a white semi-fluid of about the consistency of condensed milk. It was sweet and palatable, yet no one would judge that it could have been honey. To make inquiries relative to the matter, we called upon a firm which handles a large part of the honey that comes to this market, and from them received a courteous explanation of the phenomenon. Said the one interviewed: "It was what we call 'winter-fed' honey; that is, during the months of winter the bees were fed by a mixture of honey, much sugar and something else the nature of which is kept a secret. From this artificial feed the bees made the honey of which you speak, and which, in its nature, is that of a natural, artificial product.

The explanation given by the honey-dealers simply show their ignorance and stupidity. They ought to have known that bees never *make* honey! They gather it from the flowers, but never *make* it. In order to cover up their ignorance, they invented the silly story of "winter-fed honey," a mixture of sugar and a mysterious "something else!" These fellows had not the ordinary intelligence, or even cheek of the villain of honey, or they would have said that it was glucose. They simply made an exhibition of their ignorance by saying that it was a "mixture of honey, much sugar, and something else, the nature of which is kept a secret." Bah! Such bare-faced lying is deplorable!

Late Spring.—Thos. Stokes, Minesing, Ont., on May 18, 1888, writes :

We are having a cold, windy, late spring. The growth is very slow. The native red plums are not open yet. It snowed enough to make the ground white on May 15, when the mercury went down to 30°. Bees have only gathered honey one day, from golden willow, and not many days were fit for pollen. They are breeding fairly well; those having a good supply of stores have come out strongly. Fully 50 per cent. of the bees in this locality have been lost in the past winter and spring. The honey harvest will be late this year; the sward of clover is splendid.

Bees are now making up for lost time. The wet and cold weather of the past 3 or 4 weeks has passed away, and beautiful sunny weather has come—we hope to stay.

INTERROGATORIES.

Drones Flying Early—Mailing Queens.—Ira N. Lyman, St. Peter, Nebr., on May 19, 1888, writes :

I had only 3 colonies of hybrid-Italian bees wintered in a cellar, and all came out strong, save one that lost its queen, but reared another. Drones were flying from all my hives on April 15. I think that it is the earliest that I ever have seen drones flying in this country from *all* the hives. The spring has been very backward, there being only an occasional day when bees can fly; but they are all doing first-rate, considering the time they have had to fly. Some in this neighborhood have lost a part of their colonies, from being short of food, I think, and bad weather. They were all wintered out-doors. I like wintering bees in a dry cellar the best. The bees have an abundance to work on now, if only the weather was good. Plum blossoms, gooseberries and other plants are in bloom now. Please answer the following :

1. Can an Italian queen be sent by mail safely, and be three days on the way to its destination? 2. If a queen should die on the way, would the sender be likely to send another, or would it not be reasonable to expect one? 3. Would candied honey be sufficient feed to put into the cage to send a queen on a long trip by mail, say three days? 4. Please give a good description of the Albino bees? 5. Where can I get thorough-bred queens and bees, described as thorough-breds, and what is their cost?

1. Yes; it may be in transit for three days or thirty, if sufficiently protected and provisioned.

2. Yes; have the post-master certify to its being received dead, and send it back to the breeder, cage and all, just as it was received, and he will send another. That is what "Safe arrival guaranteed" means.

3. No; do not use candied honey, but make "candy" of sugar and honey, so that it may not soil the mails in transit.

4. Albino bees have white bands.

5. Consult the advertising columns of this paper.

Uniting Colonies, etc.—Henry H. Arnold, Ionia, Mich., on May 15, 1888, writes:

I have 5 colonies of bees in good condition, wintered on the summer stands. I lost 2 small colonies in the cellar, but it became too cold for them. I obtained no surplus honey from my bees last year.

Please answer the following: 1. How do you unite bees or double up colonies? When is the best time to do it? 2. Can we take frames of bees and brood from different hives and place them together, and not have them fight?

1. The best time to unite, weak colonies is upon the eve of the honey harvest. Sprinkle both colonies with sweetened water scented with the essence of peppermint; smoke well, and put them all together in one hive. If you do not wish to select the poorest queen and kill it, leave that matter to the bees to settle. Feed any colony that is short of stores, or unite it with one that has plenty.

2. If they show any signs of fighting, smoke them thoroughly, and that will probably take the "fight" out of them.

Did they Hibernates?—Mr. Malone, Newbern, Iowa, asks for information about a damaged colony of bees which lived in a camp when all the others died:

In the fall of 1885, on Oct. 15, and when the mercury was at 60° at sundown, I put 10 late colonies of bees into a camp, each of which did not have to exceed 4 pounds of honey. When putting the last one in, the little boy let his end of the hive drop; but I got them in, and after they were covered 12 inches deep, I could hear them roaring. On March 1, 1886, I took them out, and all were dead except the one before mentioned, and if it had eaten any honey, I could not detect it.

We may speculate as much as we like, but there are many questions that no one can answer; and it is among the latter to ascertain why the poor damaged colony lived when the others not damaged died; and as to what these bees lived on, we may guess, but could not determine with certainty. They may have gotten some honey from the other hives where the bees had died.

Queenless Colonies—Uniting, etc.—J. W. Smith, Moscow, Vt., on May 21, 1888, writes thus:

I had 6 colonies of bees which came out queenless this spring. I had no queens to give them. I asked an old bee-man what I had better do with them, and he said he would advise me to give them to weak colonies that had queens. I did so, smoking them several times, and in a week's time I had lost my 6 colonies, and the ones I gave them to are weaker to-day than they were in the first place. The combs I have taken out of the hives and put them away for future use. I have fumigated them with sulphur. Will that be objectionable to the bees if hived on those combs in swarming time?

If you had no extra queens, and could not get them, the best thing to do was to unite them with weak colonies. Combs fumigated with sulphur will not be objectionable to the bees.

Death of Dr. Judson.—From Mr. John C. Swaner, Salt Lake City, Utah, we have the intelligence that the most noted bee-keeper in Utah, has just passed over to the "silent majority," and Mr. Swaner remarks as follows concerning him:

Dr. Benjamin Judson died on May 14, 1888. He was interested in bees in England when he was a mere boy, and was, you may say, the first man in Utah who understood the management of bees. He owned, at the time of his death, about 100 colonies. His age was 59. His death resulted from inflammation, caused by hernia—the painful strangulated kind.

They all Say the Same.—Messrs. Charles Dadant & Son, of Hamilton, Ills., who advertise all the time in all the bee-papers, desires to record their experience in these words:

We will say the same as Mr. Hutchinson. Since you asked your readers to say where they saw our advertisement, we get more mentions of the AMERICAN BEE JOURNAL than of any other paper.

QUERIES AND REPLIES.

Hiving Two Swarms that Issued at Once.

Written for the American Bee Journal

Query 546.—I clip the wings of all my queens, and at swarming time I catch the queen as she comes out with the swarm, and cage her; then I wait for the bees to return. Sometimes they will cluster before returning, and at other times they will not. I have about 30 colonies this year, and I expect that sometimes more than one swarm will issue at once. 1. If two or more swarms issue at once, will they, when returning, separate and go to their different hives, or will they all go to one hive? 2. If they all go to one hive, how shall I separate them, so that each queen can have her bees?—S. P.

1. Each swarm will go to its own hive.—MRS. L. HARRISON.

1. Each swarm will return to its own hive.—G. L. TINKER.

1. Sometimes all will go into one hive, but usually they separate for me. Simply take the frames and shake the bees in front of another hive.—A. J. COOK.

1. They will often unite. 2. You cannot do it. But you can give a share of the mixed bees to each queen.—C. C. MILLER.

1. If they are all queenless, they will nearly all go back to their own hive; but it would take a half page to direct you how to separate them if they all go to the same hive.—DADANT & SON.

1. Generally they will. 2. Shake a part of the bees in front of the hive that is deficient. But cage both queens for a day or two. They will stay where they are put.—M. MAHIN.

1. Sometimes they will, and, sometimes they will not. 2. I do not know, and I should not care to be that particular. If they are *made* to fly before they are ready to break up the cluster, and the hives they come from are some distance apart, they will generally return to their own hives.—A. B. MASON.

1. If two or more swarms issue without queens, and unite, they will return to the parent hives; at least I have found such to be the case in my own experience.—J. E. POND.

1. They will go to one hive if they are close together; but if some distance apart, they often separate. 2. Divide them as soon as possible, giving to each queen the same amount of bees.—H. D. CUTTING.

This is the only objection that I have to queens with clipped wings. When they mix up it is a difficult matter to have each queen have her bees; but if you shake the bees near the one that has the less bees, part of them will go back into the proper hive.—P. L. VIALON.

1. As a rule they will return to the parent colony, though often they will become badly mixed, and unevenly divided. 2. In this case, I would prepare as many hives as I had queens, cage the queens, and divide the brood and bees as evenly as possible.—J. M. HAMBAUGH.

1. They will usually return to their respective hives. 2. You will have to divide them as nearly as you can, and then keep each colony confined in a dark room for 24 or 48 hours; otherwise your operation will likely be a failure. Supply food if they have no stores.—J. P. H. BROWN.

1. Usually they will not return to their own hives in perfect order. 2. Such questions are certainly inappropriate for this department. I know this by the number of words required to answer, and the size of the answer sheet provided.—JAMES HEDDON.

1. I think that they generally return to the hive from which they issued. 1. Divide the swarm, giving part of the bees to the other colony. I do not believe that it makes any difference at such a time, whether the bees are returned to the mother queen or not.—EUGENE SECOR.

1. They will almost surely all go together. That is the main objection that I find to clipping queens' wings. It is all right as long as *all queens'* wings are clipped; but when the second swarms come out, is when the fun begins. 2. The only way is to put the bees into two hives, and see that each gets a queen.—C. H. DIBBERN.

1. They will probably all return to one hive. 2. Divide the bees with a tin dipper, while they are clustered on the hive to which they have returned. It will only take a minute to dip them off into a basket and carry them where wanted. If they are uneasy and inclined to fly, sprinkle them with water.—J. M. SIUCK.

1. They will generally separate and return to their own homes, but they sometimes make a great muss of it. 2. You can divide the united swarm, and give to each, one of the queens; but it is the safest way to leave the queens caged for 24 hours, as the mixed swarms will often "ball" the queen.—G. W. DEMAREE.

1. If the swarms unite in the air, they will cluster together or return to one hive. 2. If the swarms unite, you cannot give each queen her own bees, but you can give each, half of the united swarms, which is just as well. If swarms cluster together, place each queen in a separate basket and shake into each basket the proper share of the bees. If they offer to return to one hive when that hive has its share of the bees, quickly remove

it, substitute the other hive, and attract the rest of the bees to it by placing the queen at the entrance. But circumstances and experience must often dictate the course to be pursued.—R. L. TAYLOR.

1. Frequently, both ways; but with a sheet to spread over the hive that is getting the most bees, I have no trouble in getting them divided in each hive about as I desired. 2. You must not let them all go to one hive, but should they get the start of you and do so, keep the queens caged, and after they get settled, dip them up as you would wheat till you get them as you desire them.—G. M. DOOLITTLE.

They may separate and return them to their respective hives, but quite often they will go to one of the hives. If they all go together, give the surplus bees to weaker colonies, carefully caging the queen before doing so.—THE EDITOR.

The Tiering-Up Method with Gallup Frames.

Written for the American Bee Journal

Query 547.—1. Is the tiering-up method, in working for comb honey, as well adapted to so deep a frame as the Gallup, as it is to a shallower frame? 2. Or would better results be obtained with this frame by practicing storing at the sides of the brood-nest, in conjunction with only one tier deep on top? 3. Is the Gallup frame, at the present time, used by many successful apiarists?—New York.

1. I think that it is. 3. I cannot answer.—J. P. H. BROWN.

1. No. 2. No. 3. Not by many—only by a few.—DADANT & SON.

1. Yes. 2. I do not like side-storing. 3. Yes, by many.—H. D. CUTTING.

1. Yes. 2. No. 3. I do not know. My frames are nearly the size and shape of the Gallup.—M. MAHIN.

1. I like the tiering-up method, and I use it in preference to any other. 3. It is used by some of the best.—EUGENE SECOR.

1. Hardly. 2. Side-storing, in conjunction with one tier on top would, I think, be best. 3. I cannot say.—MRS. L. HARRISON.

1. No. 2. Yes. If you can keep the queen out. 3. As to this, I am not posted.—J. M. HAMBAUGH.

The shallow hive is preferable. I would not bother with side-storing, but I would tier up even on a deep-frame hive. 3. Yes.—C. H. DIBBERN.

1. I find no difference. 2. I have not found it so. 3. Yes, by many; but I think not as many, by far, as use the Langstroth frame.—A. J. COOK.

1. Those that use the deep frames think so. 2. Mr. Videto, of North East, Pa., the only one that I know

personally, who practices that method, and who keeps 150 or more colonies, thinks so, and makes a success of it. 3. Yes, quite a number.—A. B. MASON.

1. In an exclusive top-storing hive, a shallower frame is preferable. 2. Many make side-storing a success. 3. Yes.—G. L. TINKER.

Mr. G. M. Doolittle uses the Gallup frames, and he is one of the most successful comb honey producers that we have. He will, no doubt, answer this query, having full experience with such a frame.—P. L. VIALON.

1. Yes; that is to say, tiering-up for the Gallup frame is to tiering-up for the shallower frame, as the Gallup frames for comb honey is to the shallower frame for comb honey. 2. No. 3. Not by many, so far as I know.—R. L. TAYLOR.

1. I judge so. 2. I should say that side-storing was a bad thing, if it were not that Mr. Doolittle practices it. But then you should tier up in either case.—C. C. MILLER.

1. It is the best method over any depth of brood-frames. 2. No, no; do not waste any time in drudging through the side-storing fallacy. 3. No.—JAMES HEDDON.

1. I think that it is better adapted to a shallower frame. 2. I do not think that any gain can be made by side-storing. 3. Not to any great extent. I will say, however, that I speak only from the stand-point of my own locality.—J. E. FOND.

1. It is not so well adapted. 2. I have some bees on frames 12 inches deep, but I have after many experiments abandoned side-storing for the "tiering-up" method. 3. I know of some of the best apiarists and honey producers who use the Gallup frame, but not many.—J. M. SUREK.

1. I think not; but the difference is not so very great, as some think it is. The disadvantage is mostly in the comparatively small surface over the deep frames. 2. "Side-storing" is entirely too much fuss, to be adopted by practical apiarists. 3. Not by many. A few good bee-keepers still use the little bee-gumish looking Gallup hive. There is a great deal in use.—G. W. DEMAREE.

1. Probably not quite, yet there are good points enough about this frame to more than make up for this lack. 2. Better results can be secured with any frame if worked on this plan, and especially is this true of the Gallup frame. 3. Ask Prof. Cook. There are very successful apiarists who use frames of widely different patterns, but the frame most in use in this country, is the Langstroth. However, the size of this has not been kept strictly pure, for there are about as many of

A. I. Root's modification in the country, as there is of the "standard."—G. M. DOOLITTLE.

Tiering up is the most desirable method, and for that the shallower frames are more desirable. Side-storing, it is generally admitted, requires more labor and attention, though many successful apiarists practice it regularly. The Langstroth frame is generally used, and only a very few use Gallup-frame hives.—THE EDITOR.

MAY FLOWERS.

May shall make the world anew
Golden sun and silver dew—
Money minted in the sky—
Shalt the earth's new garments buy.

May shall make the orchard bloom;
And the blossoms' fine perfume
Shall set all the honey-bees
Murmuring among the trees.

May shall make the bud appear
Like a jewel, crystal clear,
'Mid the leaves upon the limb,
Where the robin lifts his hymn.

May shall make the wild flowers tell
Where the shining snowflakes tell;
Just as though each snowflake's heart,
By some secret, magic art,

Were transmuted to a flower
In the sunlight and the shower.
Is there such another, pray,
Wonder-making month as May?
—St. Nicholas.

CORRESPONDENCE.

EVOLUTION.

The History of Evolution in Bee-Culture.

Read at the Progressive Bee-Keepers' Convention
BY GEORGE B. HAGGART.

Science and centuries change. The authority of to-day is but the foundation of discord in another age. The development in any branch is not however lost, the principles serving as retainers until mind-showing defects points out the inmost principles and searches the utmost depths. Grand, may be christened that subject and that science which meets approval so instantly that the adverse and conflicting mind may grasp the true theory, and reconcile all opposition.

Development was made in apiculture in early times, but conjecture had taken the place of fact in leading details, until 1712, when the mathematician of Nice, Maraldi, invented the glass hive, enabling naturalists to study more closely the in-door life of the bees. Then we find Reaumur, Schirach and Huber leading on the science, and later our noted and highly-honored

Langstroth's toil has gained the principles we utilize to-day. In this, as in all other attempts, there is no unparalleled story of the might of these winged-foes when unting their forces against a common enemy.

They have had many a triumph since the day when Moses described how the Amorites, who dwelt in the mountains, came down and chased the Israelites "as the bees do."

Even the great Mohammedan emperor, when attempting to carry off the brazen bull from sacred Mt. Aboo, was attacked by "a legion of wild bees," which could not stand the invasion of their sacred home, and descended in clouds from the mountain heights, put the whole army to flight in the place known to this day as the "Valley of the Bees."

Let us turn back through the ages. Let us turn over eighteen centuries—eighteen leaves. Where is *apis mellifica*? "And his food was locusts and wild honey."

Back another quarter of a century, and we hear those songs which so charmed the ears of the Roman warriors. Allandro Augustus sang to the shepherds and heathen gods who watched the fate of Rome. The words of Virgil, the king of Latin poets, even Publius Virgilius Maro. Three years he toiled, and the results were the "Elogues." Seven years he toiled, and the results were the "Georgics." Eleven years more, and the "Aeneid" appeared. In the "Georgics" he first sings of Husbandry, then of Forestry, third of Cattle, and last of the Culture of Bees. And in the words of Cooper, "In 277 lines of the finest of heathen poetry."

One quarter of a century before the Christian era, the rude apiculture (rude as it must have been) is praised in the Latin tongue—in the noble language of ancient Rome. He proposes the subject, then shows the proper station for the hives, the management of the swarms, and later, the battle between two discordant "kings" of the hive, as it is literally translated, and as the were evidently called in those early times. He gives the diseases as they then understood them, and the remedies that should be applied, in case they raged among the bees. These are his opening words: "Next I will set forth the celestial gift of aerial sweet. Marcenus pray listen to this part of the Georgics. I will sing to you of the admirable spectacle of a little being, of their mighty leaders, of all their kinds in all stations. This is forsooth, a subject small, but the instruction is not low. First, a seat and stand should be sought for the bees, where the opening is not to the winds; for the winds pre-

vent that they should bear home their sweet, nor to the flocks for the frisky lambs break down the flowers, and the heifer straying in the even field will shake off the dew and crush the rising herbs. And it should be away from the spotted lizard and brown toad, from the woodpecker and its home, from the bee-eater and other birds. It should be away from the reach of the cruel swallow, with red feathers at its breast. For all these devastate widely, and each wishes to baste the bees away as a sweet morsel for their merciless young. But some liquid font should be near, some slow running pool surrounded with moss, and near some small stream flowing through the grass. Their court should be shadowed by palms, or by some Olive tree; so that when the kings lead forth the first new swarms, in the spring-time, the younger bees, just appearing from their combs, may play, and the near bank will encourage them to descend from the heat of summer, and cling to the trees, opposite their former home."

These are but 25 lines, and thus the noble poet goes on, in, I think, the grandest description to be found in Latin literature. The bee even as the beast of burden seems to have followed man, both civilized and barbarous, and as Ripley and Dana say, "To have been cultivated from antiquity."

But why indeed should not development be made in the culture of an insect? Why not as much development as in any other organic structure? This simple organization contains at least the essential elements of all great structures. Here are the embryonic wings, mandible, palpi, even mouth, and teeth both scaly and concave, and the trunk carried without the modern artificial "ticket" and "check."

There are qualities peculiar to this insect alone, which seem to adapt it to the nature of man, not only the man of husbandry, but the sage, the philosopher; for there seems to have been no want of interest or research on the subject among the ancients, for the noted Greek philosopher, Aristomachus, is said to have devoted 58 years to this single branch of zoology.

Virgil at present would not help us much in a scientific point of view. We can only see the evolution—the change in culture, and the change in the solid devout science of apiculture. Of course some of his statements are possible more than probable, for he states further on in the Georgics, that a stock of bees can be obtained from the dead carcass of a steer, beaten and crushed into a mass, and then excluded from the air. Even Horace mentions in a sober manner, this little insect in his second Epode.

"Happy the man, in busy schemes unskilled,
Who living simply, like our sires of old,
Tills the few acres, which his father tilled,
Vexed with no thoughts of usury or gold ;

Or in some valley up among the hills,
Watches his wandering herds of lowing kine,
Or fragrant jars of liquid honey fills,
Or shears his silly sheep in sunny shine."

Yet, that golden bee with its triple-striped body, and all those sunny habits coming as it does most probably from an Asiatic stock, and then being carried westward with the change of empires, scattered over all the lands which spot the earth, finds its finest and sweetest home in that land furthest toward the west. Not alone has the bee companions here, but in sunnier climes further south.

Turning to their Asiatic home, have they not changed much in regard to domicile, if not disposition? For Gordon-Cummings, in reference to Indian travel, describes the meeting of bees in the gorge of the Marble Rocks through which the Nerbudda river has worn its course. The homes of the hornets and wild bees are situated on the white marble, in clusters, like swallows nests, far above the surface of the river, on the perpendicular walls of the gorge. Those traveling on the Nerbudda, pass by this point in perfect silence, and many visit the wild rocks by moonlight, both on account of bees and the scenery of the crags under the light of the moon.

Messrs. Armstrong & Buddington were seeking a sight for the Nerbudda bridge at this point, but were warned not to fire a gun or disturb the bees, but were tempted by rock pigeons, and after discharging their guns, and even plunging into the water, they were unable to escape, and surveyor Buddington was drowned. The wild honey furnishes a great part of the eatable product for the wild Ethiopian, and the uncivilized Black of lately explored Africa.

David Livingston mentions in his recent explorations in central Africa, that there exists such a bird as the Cuculus Indicator or Honey-Guide, and his native companions to the number of 113 out of 114 said, that this bird leads invariably to wild bees. By means of this bird he obtained a large quantity of honey while near the African central forest. The wax is a worthless article to the natives. Near Londa, situated in the lonesome forest, native hives are met with, made from natural cavities in Mepaur trees, and set on logs. He even mentions seeing the wild natives laden with from 80 to 100 pounds of honey, but never saw any but log hives. On the banks of the Quango the honey found a market, at sixpence a pound, and the tribute to Sekeluta of the wild Batoka country is paid in jars of native honey.

At a village 16 degrees, 13 minutes, 38 seconds latitude, 32 degrees, 32 minutes longitude, Livingston was presented with a pint of honey by the Ethiopian chiefton's son. This honey seems to be peculiarly adapted to the wants of civilization also, consisting as it does of the sugar, mucilage, and an acid changing of course to a vinous compound when exposed to air, and furnishing all the properties of a good detergent and aperient to the diseased body. However much the true ideas regarding the bee may be misunderstood by all nations in general, the use of its product seems to be universal.

The ancients have fixed their inadequate ideas of the bee with no small praise. The hum of the bee was no more harsh to their ears than to our own. It signified industry, contentment and happiness. Their human nature did not of course expel all of the objections to treatment and contact with them, and even among the Seven Hills of Rome, and in the city of the Greeks, near the birth-place of the blind bard, they received the praise which is due to the minute, as well as the mighty.

Praise which does not sound soft to our ears, for it is the language of the beggar among the seven cities that contend for immortal Homer. Yet the Grecian heart thrilled with the same impulse at its sound that does the American at its translation, for it sang the "Fall of Ilium"—"Fall of Troy," and the "Wrath of Peleus' son."

The characteristics of the bee have changed with eighteen centuries, and in contrast with the song of the poet, and the interest shown only by the wisest of all lands, in those early days, it exists not to be wondered at and admired, not as an industrial curiosity, but as a social insect, assisted only to assist. The help-meet of the flower, even as the sun and rain.

The hum of our social insect sounds now no longer along the woody streams of "Sunny European lands," with the omen of a wild "Hymenoptera," but now it is chattered, even taxed. Thus has the bee been mentioned for good, for better, and for best, lauded for industry, studied for scientific ends, and placed superlative with regard to its sweet. "As sweet as honey and the honey-comb."

Each revolving year adds more to its scientific investigation. Each age to the settlement of fact and explanation of mystery. Failure and loss in our undertakings may bring despondency for the time, but the hope at least that each and all may add something to the understanding of an insect, beneficial both to the flora of the world and the luxuries (the best of the few): yields a present satisfaction, if

not an ample reward for labor bestowed in the pursuit of apiculture.

Bainbridge, O.

LUCK.

A Little Talk with Mr. Old Phogy.

Written for the American Bee Journal
BY L. W. LIGHTY.

How did your bees do last season, Mr. Old Phogy? Not very well.

Did you get any honey? No.

Did the bees get enough honey to winter on? I do not know. If they want to starve themselves, I have no objection.

Did you pack them for winter? No; I concluded that if they would store no honey for me, they must look out for themselves.

How many colonies have you? Ten or twelve. I don't know for certain. I didn't count them for sometime.

What kind of a hive do you use? Dr. Greenhorn's patent moth-proof, double-ventilator, with a non-swarming attachment.

Ah! and has it movable frames, where the combs are built in? No; what would you want to move the combs for?

To examine the condition of the colony, of course!

Oh, my hive has a glass at the side, and I can examine the colony without tearing out the comb.

How do you secure your surplus honey? I did not secure any for some years.

Well, but what preparations had you for the bees to store honey for you? I bored a hole in the top of the box, and put a lozenge box on, but never a bee entered.

Let me sell you some nice, white clover honey, in one-pound sections. Ah! I see you have some of that stuff they manufacture to order, at Chicago, or somewhere out West, and call it "white clover honey." I don't want any of that stuff!

Now, see here, Mr. Old Phogy, you certainly believe a false report. A. I. Root, of Medina, Ohio, who is a reliable man, offered \$1,000 to any person who would point out the exact location of the factory where comb honey is manufactured, but it cannot be found, because there is none! This season honey is scarce and high—why do they not supply the market and make a fortune?

"Oh, well," replied Mr. Old Phogy, "I noticed it in my neighbor's newspaper.

Mulberry, Pa.

OUR SWEETS.

Sources for Obtaining Sweets in the Middle Ages.

Read at the Wisconsin Farmers' Institute
BY MRS. H. HILLS.

The question, from what source do all the teeming populations of ancient times, and of the succeeding middle ages obtain their sweets? becomes one of considerable interest. As possibly affording some clue to the solution of this question, there may be found, it is said, in one of the earliest extant treatises of botany, written in the third century before Christ, an allusion to "honey in reeds;" just as a similar treatise at the present day might contain an allusion to "sugar in bees." The phrase is certainly a very suggestive one, and appears to indicate that the word "honey" at that time was used in much the same sense as is the word sugar with us. More than 2,000 years have passed since the ancient botanist wrote his treatise; and the curious honey-producing reeds, of which he knew so vaguely, have made their way around the globe, and played their part in shaping the civilization of a new hemisphere.

How familiar to our ears have become the accounts in the Bible, of the "land flowing with milk and honey." And now among the old land-marks that are being swept away by the relentless searchings and siftings of the modern student, in both sacred and profane records, we are told that this familiar phrase might perhaps be more properly rendered, "a land flowing with milk and grape-juice." What a startling idea! If mankind progresses in circles or in spirals, we might almost imagine that we, in our day, had just arrived at the very identical point again. Grape-juice, indeed! Let us hasten forward, to the safe ground, where the bee is monarch and queen.

The earliest Semitic and Indian records, Egyptian sculptures and papyri, as well as the poems of Homer, all testify to the early cultivation of bees, by man, for domestic purposes. And their frequent representation in Egyptian hieroglyphics, wherein the bee occurs as the symbol of royalty, clearly shows that their economy, with a monarch at its head, was known. A hive, too, figured on a very ancient tomb at Thebes, is evidence of the early domestication of the bee there, and how early, even historically, it was brought under the special dominion of man.

It was estimated over 300 years ago, by De Montfort, who then wrote a work on bees, in French, that between 500 and 600 authors had preceded him

on the subject of bee-keeping. Most of these books were written in Latin, and are lost to the world, very few having been handed down to us. From remote antiquity the practice has prevailed in Egypt, of collecting great numbers of hives in vessels on the Nile, and transporting them from pasture to pasture according to the succession of flowers in the different districts. A somewhat similar practice prevails on the Rhone in France, and the conveying of bees from place to place, has been usual in Greece, Asia Minor and Persia, from the earliest date.

Strange to say, it is claimed that the honey-bee was not a native of the western continent. We are told that without doubt, there were no honey-bees here until introduced by the Caucasian race. This seems the more strange, as it is said that all the continents and islands on the eastern hemisphere abound with them. It is one more illustration of the inextricable puzzles connected with the geographical distribution of animals.

Mt. Hybla, in Sicily, on account of its great variety of odoriferous flowers and abundance of honey, has been poetically called "the empire of bees," and Hymettus in Attica, is in the same way famous. The German, black or brown bee, is the variety best known, as through all the ages it has been most widely distributed. We find, however, that the Italians were known both to Aristotle and Virgil, who sang of the variegated, golden bee. It is said that the wider distribution of the German bee can only be accounted for by considering the more vigorous, pushing habits of the Germanic races of men: who not only over-ran and infused new life into southern Europe, but have vitalized all Christendom.

Sheboygan Falls, Wis.

CONVENTION.

The Ohio Bee-Keepers of the North Meet and Talk.

Written for the American Bee Journal
BY MISS DEMA BENNETT, Sec.

The semi-annual meeting of the Progressive Bee-Keepers' Association was held at Bainbridge Centre, Ohio, on May 3, 1888, with President J. B. Hains, of Bedford, in the chair.

After the usual order of business was disposed of, it was thought best to open the Question Box. All were given an opportunity to express their opinion on the different subjects, and many did so, but as this report must necessarily be somewhat brief, I will in the main give only a synopsis of the thoughts expressed.

What is the best method of fastening starters in sections? D. M. Allen uses melted wax with a spoon. Warren Pierce prepares a mixture of wax and rosin (two parts of wax to one of rosin) and dips the foundation in it. He thinks that it is not quite as neat, but it sticks better, and can be put in faster than by any other way he has ever tried. In answer to a question by J. D. Haggart, he said that he did not think that the bees drew it out quite as close to the section as when wax only was used. Mrs. O. D. Newcomb uses the Parker foundation fastener. O. J. Post prefers the Parker fastener to any other. J. B. Hains uses the Gray fastener, something like the Parker, only it is run by foot-power. He also described a starter machine made by the Berlin Fruit-Box Company, but which can only be used with wide frames. Henry Bosworth uses a machine which he made himself, similar to the Gray. As the several methods had quite a number of advocates, no agreement was reached, and the next question was taken up.

How few bees can be safely wintered in a hive? J. W. Chalker had 2 quarts of bees; the queen was reared about Sept. 1, 1887; he put them on 4 frames, and they came through all right. Mr. Haggart thinks a small colony put up properly on 4 frames will winter well if they have a good queen, but much depends on the queen. L. H. Brown: Bees enough to cover 5 frames will be best; less than that I would double up. Small colonies do not winter well, as a rule. J. L. Way asked if it was not possible to have too many bees in one hive. He thinks he lost some on that account. In reply Mr. Hains said: Too large colonies in the hive are not best, and do not keep as well either. There are extremes in both directions, and between these lies the "golden mean." Five pounds of bees in a good hive, with good stores, will come out best. It was the sense of the meeting that a medium-sized colony is best, but they would not throw aside a small one.

Does not wintering well, depend largely upon the age of the bees? It was thought to be necessary to have a prolific queen in the hive, and a full complement of young bees.

What is best to use for winter packing? Miss Dema Bennett prefers forest leaves, and gave as reasons therefore, that they are light and dry. They give good ventilation, and are easily cleaned out of the yard, not making as much litter as chaff or straw, and can be taken from the hive with less trouble. Mr. Pierce uses a honey-board frame with cotton-cloth tacked on the under side, and a board covering the top, excepting a space in

the centre of 3 or 4 inches, which is covered with wire-cloth, and this is filled with leaves. Mr. Haggart uses the same kind of a frame filled with cut rye-straw. Voted for forest leaves.

Will bees secure honey enough to keep them from now until clover bloom? Mr. Brown: They consume a large amount of stores in rearing brood; more than they will gather. Mr. Hains: After fruit-bloom many will perish if they are not closely watched. It was voted that bees are not in a condition to do without feeding until clover bloom.

What does W. S. Wait think of the Heddon hive? Mr. Wait: I think that it is a good hive for honey-gathering, but not so good for wintering.

How shall we keep the bees from robbing? The following ways were spoken of: Contract the entrance; throw straw in front of the hive; spray the hive with cold water; fanning, to let the robbers out, and keep the fresh ones from getting in, and after the fanning, put a glass in front of the entrance.

After dinner, which was served in the hall, the meeting was called to order, and an essay was read by Mr. George B. Haggart, of Bainbridge, entitled, "Evolution in Bee-Culture."

An unanimous vote of thanks was tendered to Mr. Haggart for his kindness in preparing and reading the same.

The Question-Box was then reopened.

What is the trouble when bees apparently swarm, and after being hived, return to the old hive, sometimes 3 or 4 times? Answer: The queen remained in the old hive.

What causes the bees to swarm out, in early spring? Answer: Lack of queen, or bees, or stores; diseased bees, and unwholesome hive, or too many frames.

For one having hives and frames well filled with comb, what is the best use that can be made of them? It was thought best to save the best combs, even if they had to buy the bees, but would render the darkest-colored and drone combs into wax. It was also suggested that if the combs could be hung up with a space of an inch or two between them, that the heat would not be sufficient to generate the moth.

What is the best method to pursue with swarms when working for comb honey? Mr. Wait: Contract them to 5 frames, and give starters; but use full sheets of foundation in the sections above. Mr. Pierce: Hive the swarm and put it on the old stand, moving the old colony, and so get all the working bees with the swarm. Mr. Hains: Use either frames of comb or full

sheets of foundation (there should be a frame of eggs or unsealed larvae to hold the bees) in the brood-chamber, which should be contracted; then place the new hive as spoken of by Mr. Pierce, and take off the super from the old hive and put it on the new one. For extracted honey I follow the same plan excepting that I use light-colored brood-combs, or frames filled with foundation in the upper story, and extract when two-thirds of the honey is sealed.

Which are preferable, single or double tier wide frames? Single-tier frames or cases were preferred by the majority.

Does extracted honey ever lose its flavor? It was thought that thin, unripened honey would deteriorate, but that honey well-ripened, sealed before extracting and kept covered after, retained its flavor. This opinion was no doubt partly based on the fact that we had a sample of extracted honey from the apiary of L. H. Brown, for dinner.

Statistical report of the members, as far as received:

Number of colonies Dec. 1, 1887.....	1,306
" " " at present time....	1,143
Total loss	163
Per cent. of loss.....	12

One member losing 51 colonies out of 102. Aside from his report there was a loss of 112 colonies out of 1,204 last fall, and brings the loss down to 9 per cent., which is a fair average; many reporting no loss at all.

In answer to the question, as to the prospect for the honey crop, while many did not give an opinion, one-third of those who did, said "not good," and the other two-thirds, "good." The Secretary read extracts in regard to the Ohio Centennial at Columbus, and urged all to attend who could possibly do so, and also to make exhibits.

Mr. J. R. Reed, now in California, sent personal greetings by the President.

A vote of thanks was given to the "Sons of Temperance" for the use of their Hall; also to the friends in Bainbridge who assisted in entertaining this association. A motion was made and carried, that the executive committee fix the place of the next meeting.

The meeting then adjourned until Thursday, Oct. 4, 1888.

Bedford, Ohio.

A Warning.—Writing from Dakota, Mr. F. H. Canty remarks thus:

I have lost all my bees, 9 swarms, by letting my bee-cellar get below the freezing point. Take warning! or you will be like me, with empty hives, combs and sections, and bees to buy.

COMBINATIONS.

Can we Control our Honey Market by Combining.

Read at the Oneida Co. Bee-Keepers' Convention
BY J. ASPINWALL.

This subject seems to be agitating the minds of many, or I had better say a few, of the prominent bee-men at the present time. It is an important subject, and one worthy of much thought. We may, by combining to control the market, do ourselves some good, but the chances are that we will do ourselves much harm. To assert that we can so control the honey market as to place the price where we please is preposterous, and to my mind so far from possible, under the present condition of things, as to lead me to think that some other motive prompts the promoters to take the step. Let me put the facts more plainly before you: What is it that regulates trade? What is it that causes fluctuations in any business not controlled by a speculative board, as in the case of stocks and grain? I answer it is supply and demand. Coal is controlled, we know, by great combinations who place the price where they please to a certain limit, until some firm drops out, and out-throat prices are the order of the day, to the detriment of all concerned. But is it to be supposed that because this combination owned *all* the coal fields in a certain very large district, that it could put the price of coal to \$10 per ton? No, they could not hold those prices three days before coal would be coming in from the West, South, North and East to fill the markets at such a price as the market will allow. Controlling a market is a preposterous proposition, if we have not *demand* to act as the chief factor.

The honey interest has not the advantages which exist in other industries, such as iron, coal or petroleum; for in the first instance mines and wells can be bought outright and controlled, but who can buy up the flowers of the field, or who can control the flow of nectar? Only He, under whose providential care bee-culture always rests.

Suppose you gentlemen of the Oneida Bee-Keepers' Association were to combine together, and declare that comb honey should be sold by the members for not less than 20 cents per pound for the best quality, and I was an outsider, not belonging to your association. Is there any law to prevent me from bringing my own honey, and as much more as I chose to buy in other parts, and selling the lot right under your very noses at 18 cents a pound? Where would you gentlemen get your

money from to continue your business, if you found buyers loath to pay 20 cents per pound for the same article they could obtain from me at 18 cents? I leave the answer to yourselves.

What would you think of a lot of enthusiasts getting together to control the egg-market, in country towns and elsewhere. How many farmers' wives would they control when it came to the question of selling a dozen eggs to pay for a new shawl, or to buy bread for the children. In this case, the egg-men have an advantage over the honey-man, in that eggs are a far greater necessity than honey, and consequently there is a *constant* demand. Supposing a man depended on honey for a living, and the "combine" of bee-keepers, to whom he belonged, should say the honey market must be 20 cents, and some fellow comes along offering honey at 18 cents in this man's market, and gluts it. Where is the member of the "combine" going to get the bread from? He will go out of the bee-business next year, and the fellow will reap the harvest in a market the first bee-keeper has toiled so many years to create. Combination, you see, was a curse here instead of a blessing.

I offer the following suggestions, not as a solution of the problem, but something towards a solution. I would propose the formation of a honey company headed by some experienced men in the honey business, and the establishing of headquarters in New York city, with branch establishments at the different centres of commerce. This to be a stock company who shall buy honey outright, and not sell on commission, and whose principal work shall be the creation of a market by circulating pamphlets tending to educate people to the numerous uses to which honey can be put, and above all inspiring the minds of the general public with the absolute confidence that when honey is bought from this company and labeled "pure honey," it is "the truth, the whole truth, and nothing but the truth."

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*
- May 31.—Wis. Lake Shore Center, at Kiel, Wis.
Ferd. Zastrow, Sec., Millhome, Wis.
- Aug. 3.—Ionia County, at Ionia, Mich.
H. Smith, Sec., Ionia, Mich.
- Aug. 14.—Colorado State, at Denver, Colo.
J. M. Clark, Sec., Denver, Colo.
- Aug. 27.—Stark County, at Canton, O.
Mark Thomson, Sec., Canton, O.
- Sept. 8.—Susquehanna County, at Montrose, Pa.
H. M. Secley, Sec., Harford, Pa.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

SELECTIONS FROM
OUR LETTER BOX

Early Swarms.—J. M. Hambaugh, of Spring, Ills., on May 21, 1888, writes:

I had a natural swarm of bees to issue May 5—the earliest ever known in this section of country. I have since had two more, notwithstanding the cool, backward weather. With the weather favorable, we expect a big year for honey.

Bees Wintered Fairly Well.—E. W. Councilman, Newark Valley, N. Y., on May 17, 1888, says:

Bees have wintered fairly well in this locality. I have succeeded in carrying through safely 70 colonies out of 79, wintered in the cellar. Five months is a long time to keep bees in confinement. We have had a week of cold, damp weather, and it is still raining to-day. Bees have hardly had a flight during the whole week.

Cold and Cloudy Weather.—C. Thielmann, Thielmanton, Minn., on May 18, 1888, writes:

The rain ceased for about six days, but it is cold and cloudy most of the time. My bees are getting light in stores, as they secured but little the past three weeks; otherwise they are strong and in a healthy condition.

Improperly Caring for Bees.—Dr. E. W. Parker, Larrabee, Iowa, on May 19, 1888, says:

I put 22 colonies of bees into the cellar, and have but 11 now. Two colonies starved, and 9 had the diarrhea, caused by late honey improperly ripened, or rather, not ripened at all; so my loss is entirely my own fault; and I am of the opinion that nine-tenths of the losses where bees are wintered in good cellars is chargeable to the bee-man himself.

Good Prospects for Honey.—D. Dauher, Madison, Wis., on May 17, 1888, says:

The weather is poor for bees—raining all the time. I have 30 colonies alive, 3 starved to death, and 3 I doubled up. The temperature was 42° in the cellar. All looked as if dead when taken out, but they soon were at work. The prospects are good for a big crop. White clover is all alive, and in ten days we will have plenty of fruit-blossoms. I had no honey last year. There has been no trouble to sell any the past winter for 20 cents per pound.

Bee-Keeping in Washington Territory.—Frank McIlvain, Teanaway, Wash. Ter., on May 12, 1888, writes:

On April 27, 1887, I got 2 colonies of bees and put them into Simplicity hives. Bee-keeping is a new industry in this part of the country, mine being the only bees kept here. I had one swarm. For wintering I placed boxes on the outside of the hives, 6 inches larger than the hives, which I filled with chaff. I removed the sections and placed on Hill's device, over this a piece of cloth and filled in with chaff. When I examined them in January, I found that one colony had become damp, the packing wet and moldy, and the bees dead. Another

colony was in the same condition. I removed the packing, placed in dry chaff, and the live one did finely afterward, and began to gather pollen from the willows by March 10. I will not remove the packing until the bees begin to fan the entrances. The first honey-flow will be from vine maple, and it will soon be here.

Queenless Colonies. Swarming, etc.—Wm. H. Graves, Duncan, Ills., on May 14, 1888, writes:

My loss the past winter was one-half—40 colonies out of 80. Short of stores and too many old queens was the cause. By having no swarms last summer, comparatively speaking, I had a great many old queens which would not breed up strong to go into the winter. I never before had so many queenless colonies. April is a bad month for bees, so cold and cloudy. I have been feeding my bees since April 1, every night. I have just hived a rousing natural swarm of Italian bees—from a colony that I had fed strongly every night since the last of March, to get early drones from them. I have received two packages of the Chapman honey-plant seed. I gave one to a beekeeper friend, and planted the other long ago.

White Clover Looks Promising.—N. Staininger, Tipton, Iowa, on May 13, 1888, says:

We have had a great deal of rain here for the past two weeks, and now it has turned very cold. There was ice $\frac{1}{2}$ -inch thick on the water trough. The bees come out, become chilled, and die; and there is a great loss in brood. There is a loss of three-fourths of the bees among the small beekeepers. I have 90 colonies, and the most of them are in pretty good condition. Some have from 6 to 8 frames of brood, and plenty of drones flying now. I moved my apiary from Denison, Iowa, to Tipton, on April 5, without loss. I had put 101 colonies into winter quarters, and took out the same number; 100 colonies were in the cellar, and one colony was packed outside. I sold 7 colonies, and had 4 queenless ones that I doubled up. There was not one comb broken in all of them. White clover looks fine, and I hope we will have a good crop of clover honey.

Prospects for a Good Honey Crop.—H. M. Moyer, Hill Church, Pa., on May 12, 1888, writes:

I have 57 colonies of Italian bees (blacks are not worth keeping here). Last summer I obtained 1,500 pounds of honey (mostly extracted), and 24 pounds of wax. I fed back about 500 pounds of honey. The retail price of extracted honey is 12 cents per pound, and of comb 20 cents. The prospect is for a good honey crop. White clover is our main source here. I commenced this spring with 43 colonies.

Bees in Good Condition.—J. E. Walker, Clarksville, Mo., on May 16, 1888, writes:

I packed 21 colonies of bees on the summer stands late last fall, with 5 inches of sawdust over the frames. They wintered well, and less dead bees were thrown out than I ever saw before. They carried in the first pollen on March 15. I saw drones on April 11. They had a busy and a happy time for two days on apple blossoms. All the 21 colonies are alive to-day, and in good condition. Many bees have died in this part of the country.

Honey-Plants in British Columbia.—Russell Smithers, New Westminster, B. C., on May 14, 1888, writes:

As far north as I am situated, here on the Pacific Coast, my bees were working hard, carrying in pollen from willows, as early as March 7. Eastern bee-keepers may be interested in the fact that skunk cabbage flourishes here as it does there, and bees patronize it just as freely. The prospects for this year are good. White clover will soon be in bloom, and this is our main resource. Can any one suggest the best honey-plant for this climate—one that would flourish on soil that is somewhat gravelly and poor?

Poor Prospect for Honey Crop.—J. G. Nance, Gracey, Ky., on May 20, 1888, writes:

I will give a brief statement of the situation here: The winter loss was very small; not over 5 to 10 per cent. The fruit bloom was very full. The clovers (both white and red) are badly winter-killed; worse, in fact, than I ever saw it before. The osage orange (hedge trees) are now in full bloom, and the bees are at work on them. Cherries are now getting ripe. Apples and peaches are as large as hickory-nuts. Our Congressman sent me some Chapman honey-plant seed, but it has not come up yet. The weather is very dry and cool, and the prospects for a honey crop are very poor.

Fruit Bloom.—Mr. Thos. C. Evans, Brownsville, Minn., on May 19, 1888, reported thus:

I started last spring with 47 colonies of bees, increased them to 77, and obtained 5,000 pounds of comb honey and 500 pounds of extracted. I put them in the cellar on Nov. 9, where they remained 176 days; and excepting 2 colonies which I took out to-day, all are good condition. I lost but 4 colonies. Two were robbed out, and the other 2 were queenless. It is a very late spring, but I look forward for good crops. Fruit trees are just coming into bloom, and white clover looks well.

Late Season.—O. B. Barrows, Marshalltown, Iowa, on May 17, 1888, writes as follows:

Bees wintered well in cellars in this vicinity during the winter of 1886-87. They bred up well for the white clover honey-flow of 1887, which never came, but a four or five days' dash of basswood enabled those that were strong in bees to fill up the brood-chamber for winter; but what few divided their force by swarming, had to be fed, or starve. There was no fall flow of honey, and consequently they lost in weight through September, October, and, in fact, ever since. A colony that I weighed on Sept. 16, had lost 5 pounds by Nov. 19, when I finished putting my bees into the cellar. In the next 70 days, in the cellar, the same colony only lost $2\frac{1}{2}$ pounds, and only 2 or 3 pounds since then.

On April 6, when I put them out, they carried in pollen from corn and oats, ground, freely, until April 22, when they left the corn and oats for natural pollen. April was pleasant and dry until the 26th, and people prophesied another drouth, but suddenly it changed, and commenced to rain on April 26, and it rained some every day for 16 or 17 days, and for the last 22 days there have been but 4 days that bees could fly freely; consequently in building up strong for the honey crop, they are making haste slowly, but possibly they may be in time for the honey crop, for plum trees are just in blos-

som, and apple trees, strawberries and other fruit are not yet in bloom.

My brood-chambers takes frames 12x12 inches. Most of the hives have 10 frames, but 6 or 8 were 8-frame hives, and those 8-frame hives came out without an exception light in stores and weak in bees, while all the 10-frame hives, which were not queenless, were strong in bees, but not quite all heavy with honey. I wintered mine in a light cellar, *a la* Hutchinson. Five windows were not darkened, and the cellar was used for fruit and vegetables, and visited a dozen or more times each day. The thermometer stood at from 34° to 45° above zero. The bees were dry, clean and healthy, very quiet, and in excellent condition, with the exception above spoken of. The losses from all causes in this county will be from $\frac{1}{4}$ to $\frac{1}{2}$ of all put in the cellars.

Bees Wintered in a Cave.—Henry Stark, Plier, Wis., on April 16, 1888, writes:

I commenced the spring of 1887 with 6 colonies (5 brown and 1 Italian). I got 12 natural swarms from that one Italian colony, and 700 pounds of surplus honey. The brown-German colonies gathered 350 pounds each, and each cast one swarm. I put 14 colonies in a cave the forepart of November, and took them out on April 14 and 16, all in fine condition. They all have from 20 to 45 pounds to spare. The rest I wintered on the summer stands, packed in chaff. I pack my bees thus: Twelve inches from the ground, 12 inches of chaff all around the outside, 2 division-boards, 4 inches of chaff between the hive and the division-board, a device $1\frac{1}{2}$ inches high, coffee sacking, one sheep skin with 4 inches of wool on it, and 12 inches of chaff on top. I have never lost a colony in wintering in this way. The year 1887 was the best honey year I ever saw. The temperature in my cave was from 45° to 48° all winter. The bees were in the cave about 163 days, without a flight.

An Apicultural Conundrum.—James McNeill, Hudson, N. Y., on May 18, 1888, writes as follows:

There is a conundrum that I would like to propound to Mr. Doolittle, and it is this: How does he manage to make his 9 Gallup frames furnish all the room needed by "the really good queen, one which will lay from 3,000 to 4,000 eggs a day?" which he speaks of on page 333.

If I have figured correctly, each of his frames of $10\frac{3}{4} \times 10\frac{3}{4}$ inches contain 115 square inches, and with 50 bees to the inch, such a frame would hatch out 5,750 bees, if filled solidly with brood. Taking his lowest estimate of a prolific queen—3,000 eggs per day—it would require 63,000 cells to furnish such a queen with the necessary room, for each cell is occupied for 21 days before it can be used a second time.

Now, according to my figuring, it would require very nearly 11 frames of the size above-mentioned, to furnish 63,000 cells; and when it is remembered that nearly $\frac{1}{2}$ of these cells would be occupied with pollen and honey, I would like Mr. Doolittle to explain why a "really good queen" would not be very much cramped in his 9-frame hive.

[Mr. Doolittle will, no doubt, be pleased to answer the conundrum presented above, at some future time.—Ed.]

A Pocket Dictionary will be presented for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

CLUBBING LIST.

We Club the American Bee Journal for a year, with any of the following papers or books, at the prices quoted in the LAST column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	Club

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Your Full Address, plainly written is very essential in order to avoid mistakes.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 18 cents per pound for bag and postage.

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2 00	3 00	3 50
1,000 Labels.....	3 00	4 00	5 00

✂ Samples mailed free, upon application.

Honey and Beeswax Market.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 13@15c, the same in 2-lbs., 10@11c; buckwheat 1-lbs., 10c, 2-lbs., 9c. Market dull. We are doing all we can to reduce stock, to make room for the new crop.

BEEWAX.—23c.
HILDRETH BROS.,
28 & 30 W. Broadway, near Duane St.

DETROIT.

HONEY.—Best white in 1-pound sections, 14@15c. Extracted, 9@10c. Supply decreasing slowly.

BEEWAX.—23c.
M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—Prices range from 15@16c. for best one-lb. sections; other grades are slow at lower prices. Extracted, 7@8c. Light demand, and supply larger than usual at this season of the year.

BEEWAX.—23c. R. A. BURNETT,
161 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 14@15c; fancy 2-lbs., 12c. Lower grades 10@2c. per lb. less. Buckwheat 1-lbs., 10@10½c.; 2-lbs., 9@9½c. Extracted, white, 7@7½c.; dark, 5½@6c. Market is dull for comb but improving for extracted, of which new from the south is arriving.

BEEWAX.—Scarce, 24@27.
F. G. STROHMEYER & CO., 122 Water St.

CHICAGO.

HONEY.—We quote: Fancy white clover 1-lbs., 18@17c.; 2-lbs., 15@16c. Dark is slow sale at almost any price. Extracted is scarce, and sells at 7@10c.

BEEWAX.—23c.
S. T. FISH & CO., 189 S. Water St.

CINCINNATI.

HONEY.—We quote extracted at 4@9c. per lb., for which demand is good. Comb honey, 14@17c.—Demand slow.

BEEWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
C. F. MUTH & SON, Freeman & Central Av.

MILWAUKEE.

HONEY.—Choice white one-lb. sections, 16@17c.; 2-lbs., 15@16c.; 3-lbs., 14c. Extracted, white in kegs and ½-barrels, 8 to 8½c.; in tin and pails, 9½@10c.; dark in barrels and kegs, 5@7c. Market fair.

BEEWAX.—22@25c.
A. V. BISHOP, 142 W. Water St.

DENVER.

HONEY.—Best white 1-lb. sections, 17@18c.; 2-lb. sections, 15@17c. Extracted, 7@10c.

BEEWAX.—20@23c.
J. M. CLARK & CO., 1409 Fifteenth St.

KANSAS CITY.

HONEY.—We quote: Choice white 2-lb. sections, 17@18c.; dark 2-lbs., 14@15c.; choice white 1-lbs., 16 to 20 cts., dark 1-lbs., 15@16c. White extracted, 7@8c.; dark, 5@6c. Demand is slow. White extracted is firm when in 60-lb. tin cans.

BEEWAX.—21 to 22c.
HAMLIN & BEARSS, 514 Walnut St.

BOSTON.

HONEY.—We quote: 1-lb. sections, 16@17c.; 2-lb. sections, 14@16c. Extracted, 8@9c. The market is not very brisk and sales are slow.

BEEWAX.—25 cts. per lb.
BLAKE & RIPLEY, 57 Chatham Street.

SAN FRANCISCO.

HONEY.—We quote: White to extra, 10@17c.; amber, 8@14c. Extracted, white liquid, 7@7½c.; amber and candied, 8@7c. Market quiet.

BEEWAX.—18@21c.
SCHACHT & LEMCKE, 122-124 Davis St.

KANSAS CITY.

HONEY.—We quote: White 1-lbs., glassed, 16@17c.; unglazed, 17@18c.; and dark 1-lbs., glassed, 15c.; unglazed, 16c.; white 2-lbs., glassed, 16c.; unglazed 2-lbs., 17c. California white 2-lbs., 17c. California extracted in 60-lb. cans, 8c. Market quiet and receipts are larger.

BEEWAX.—No. 1, 20c.; No. 2, 18c.
CLEMONS, CLOON & CO., cor 4th & Walnut.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, \$1.00 per 100, or \$8.50 per 1,000.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

The Bee-Keepers' Review

FOR MAY is now out. Having regained the time lost during his illness, the editor will hereafter take pride in getting out the REVIEW promptly on the 10th of each month.

The special topic of the present Number is "Hiving Bees." The review of Mr. Cheshire's work, which was begun in the March No., is finished in the present issue. We have a surplus of the Numbers containing this review, and, so long as they last, these three Numbers will be sent free to all who apply.

Price of the REVIEW, 50 cts. a year.

The Production of Comb Honey,

A neat little Book of 45 pages, price 25 cents. The REVIEW and this book for 65 cents. Stamps taken, either U. S. or Canadian.

Address, **W. Z. HUTCHINSON,**
20Atf 613 Wood St., FLINT, MICHIGAN.
Mention the American Bee Journal.

Dissolution Notice.

THE partnership heretofore existing between J. M. McCaul, L. S. Hildreth, and H. P. Hildreth, under the firm name of McCaul & Hildreth Bros., expires this day by limitation.

The undersigned will settle all business connected with the late firm of McCaul & Hildreth Bros., and continue the business as manufacturers of Grocers' Specialties, and dealers in Honey, Maple Sugar, Maple Syrup, Imported and Domestic Salad Oils, etc., at 28 and 30 West Broadway, the location formerly occupied by the late firm. A continuance of your patronage is solicited, and all orders will be carefully and promptly filled.

Respectfully, **HILDRETH BROS.**
28 and 30 West Broadway, New York, April 30, 1888. 22Alt

Mention the American Bee Journal.

BEES FOR SALE.

100 colonies of brown German and hybrid Italian bees in Langstroth 8-frame and Simplicity hives, in lots to suit purchaser; also a quantity of wide frames and half-story frames Simplicity size, at a bargain.

Address, **W. L. COGGSHALL,**
22Atf West Groton, Tompkins Co., N. Y.
Mention the American Bee Journal.

SECTION FOLDER.

FOLDING.

FOLDED. (Patent applied for.)

500 every hour. The corners need no moistening. No breaking. Every section square and perfect. Every honey-producer should have a Machine.

Bee-Hives, sections, Cases, Foundation, and all Apianar Supplies.

Queens and Bees for 1888.—It should be borne in mind that we are the Headquarters for the **ALBINO QUEENS.**

Address, **S. VALENTINE & SONS,**
22Alt HAGERSTOWN, Washington Co., MD.
Mention the American Bee Journal.

A FEW TESTED ITALIAN QUEENS, (by return mail) \$1.50. After June 15, \$1.00 each.

GEO. STUCKMAN,
22Alt NAPPANEE, IND.

CARNIOLAN

Gentlest bees known; not surpassed as workers even by the wicked races.

Imported Queens, "A" grade, \$8.00,
Tested, \$4.00; Untested, in April, \$2.00.

QUEENS.

In May, \$1.50; after June 1, \$1.00.
I can accept no more Orders to be filled before June 1st. Send for circular.
S. W. MORRISON, M. D.,
14Etf. Oxford, Chester Co., Pa.

(Patent applied for.)

BEST FOUNDATION FASTENER for Brood-Frames and Sections. Description and Illustration sent free on application.

J. W. BITTENBENDER,
20Etf KNOXVILLE, Marion Co., IOWA.

10 per cent. OFF

ON SECTIONS, from prices given in price-list. We make four grades of **COMB FOUNDATION**—Heavy Brood, Light Brood, Thin & Extra Thin for Sections.

Send for free Price-List and Samples.—Dealers, write for special prices.

Address, **M. H. HUNT,**
Beil Branch, Wayne Co., Mich. (near Detroit).

Hope leads the child to plant the flower,
The man to sow the seed,
Nor leaves fulfillment to her hour,
But prompts again to deed.

Sugar from Honey.—The *Apiculturist* for June contains something on the above subject. Mr. Alley quotes the following suggestions from his periodical for October, 1886:

The National Convention, which meets at Indianapolis this month, should take some action regarding the matter of disposing of surplus honey. We suggest for the consideration of the meeting, that the sum of \$5,000 be collected from the bee-keepers throughout the United States, and paid to the person who will devise some method for converting honey into sugar, similar to granulated sugar. We believe it can and will be done, provided a proper inducement is held out, and a sum sufficient is offered to compensate for the time, trouble and expense of conducting experiments.

The above sum can be raised from the bee-keepers of this country. Small producers might pay \$1, and larger ones as high as \$5 each. We respectfully submit the above suggestions to the convention for its consideration.

Mr. Alley then makes these remarks:

Those present at the convention well know about how much notice was taken of the above suggestion. Well, I have the satisfaction of knowing that the idea was not so very "cranky" after all, as the following extract from a letter will show.

The "extract" referred to is from a letter written by Allen F. Smith, of Plaquemine, La., and is as follows:

I am a practical sugar maker of the sugar cane, and I am under the impression that I can make a very good grade of sugar from honey, which I have been contemplating doing for some time, but have not the means to give the experiment a fair test. Should

the bee-keepers of the United States decide to offer a premium to the one who will put the matter to a practical test, I shall be glad to make the first experiments. I am almost certain that I can succeed; there is nothing difficult about it. We can make sugar from beets and pumpkins, why not from honey? Give me the means to give it a fair trial, and I will produce the sugar from honey.

Then Mr. Alley triumphantly asks: "Well, friends, how is that? There is nothing like being a little in advance of some other people."

If the "advance guard" is sought, we invite friend Alley into our Museum, where he may find a can of sugar made from honey, which has been there for a dozen years. It was made by Mr. T. S. Bull, of Valparaiso, Ind., and by him placed in the Museum. Hundreds upon hundreds have examined it, and pronounced it "all right"—and excellent sugar.

The only thing to discourage the manufacture of sugar from honey is the fact that it does not pay, and never can be made to pay! It costs too much, to place it in competition with cane sugar.

It is, therefore, quite useless to throw away \$5,000 to obtain a method for making it. That idea is not an *advance!* It is away behind; and so far in the rear as to be "out of sight," and apparently forgotten!

The Dark Side.—Mr. S. B. Ryder, of Brandon, Vt., on May 24, 1888, writes us as follows concerning the dark side of apiculture:

The New York *Independent* having printed within a year past several articles tending to show the favorable side of bee-keeping. Another correspondent lays his pen to the task of bringing out the other side. I enclose a slip containing the gist of his matter as printed in the *Springfield Republican*. It is a curiosity.

I was surprised to read, in one of your recent issues, the statement of a correspondent in northern Illinois, that the Chapman honey-plant was liable to winter-kill. My experience with it is limited, but I do not think that I ever lost a plant from that cause, and surely the winters in Vermont are as severe, or more so, than in northern Illinois. The plant makes an early start in the spring, and has every appearance of being a hardy as well as a thrifty thistle.

Here is the selection mentioned in the above letter:

BEE-KEEPING NOT A PROFITABLE RECREATION.—Bee-keeping is usually represented in the papers as a very fascinating and profitable occupation, one well designed for women and amateurs who would gain a living in a truly idyllic way. A veteran apiarist punctures the bubble in this fashion: As near as I have been able to ascertain, extracted honey has sold in California the past few years at 3 and 4 cents a pound; in other parts of the United States from 5 to 8 cents a pound. The tendency of prices is steadily downward. The honey crop of the past year being one of almost universal failure, prices have raised temporarily.

I know of but one way to get a fair price for any considerable quantity of honey, and that is to peddle it personally from house to house. The reader can decide as to whether or not he would like peddling. To send the honey to the commission men of the cities is, generally to throw away the season's work.

As to bees, they are, doubtless, the most unsalable stock known. Put up at a forced sale, I do not think they would bring \$1.00 a hive. I believe that practical bee-men, who have been through the mill, are pretty well agreed that bee-keeping, from beginning to end, requires hard work, business ability, and a patience made of irridium to withstand the losses, ruinous prices, and the many other petty discouragements peculiar to bee-keeping.

The many painful experiences (I refer to stings) of which I have known among those who ignorantly attempted to handle bees, have led me to decide that if I had the law in my hands, I should prohibit all persons from touching bees who had not had sufficient enlightenment to enable them to handle bees with comparative safety.

We are very often accused of publishing only the bright side—of presenting only the pleasant things about the business of keeping bees. In the above, certainly a glimpse of the other side is given, enough to satisfy any one that it is not all sunshine in the pursuit of apiculture.

There are many who should never attempt to keep bees—the shiftless, the lazy, the one who will not read and study the necessities of the business, those who are afraid of stings, those who are nervous and irritable, and those who have no time to attend to the care of the bees. All such should never attempt to keep bees.

Failures come in every avocation. Of no occupation can it be said that it never fails. Bee-keeping is no exception to the general rule—but it is not more liable to failure than others. The manufacturer, the banker and the merchant often have to grapple with financial distress and commercial panics—but, do they forsake the counter, the desk, and the factory, and look for some other business wherein loss and trouble never come? No! indeed, such reverses but stimulate progressive men to further diligence and more dauntless courage!

When the bankers, merchants and farmers set the example, it will be time enough for apiarists to become discouraged and give up the business—but not till then!

The Apiculturist for June is out; came to our desk on the morning of the 1st—on time, as usual. It is filled with good reading matter, and by the use of smaller type and wider columns it is much improved, and will be more economically published than heretofore. We wish it abundant success.

The Statistical Blanks were sent to the United States Statistician some months ago with a long letter of suggestions by Prof. Cook, but nothing has ever been heard from the matter since. This we mention because there have been quite a number of inquiries concerning it, asking what has been done, etc. There is so much "red tape" about everything connected with the Government, that we could expect nothing else. Probably by next year they may get things to running, and may grind out a batch of statistics for us. We shall see.

BUNCH OF WILD FLOWERS.

BY NELLIE CHASE.

In passing through a clover field,
I cull a nosegay, wild and sweet,
Of flowers, wind-sown, at my feet—
Blooming among the meadow grass,
They nestle timid as I pass—
But gay as any lawn could yield.

Feathery sprays of elder bloom,
And daisies bright as stars of gold,
With milkweed's pink and orange mold,
A head of rye, a head of wheat,
Some clover blossoms pink and sweet,
I choose to deck my study room.

In passing through this life of ours,
We find our dulllest days alight
With blessings hidden half from sight.
Among the weeds of toil and strife,
Are loving deeds that brighten life,
Scattered along our path like flowers.

—Selected.

GLEAMS OF NEWS.**Bees and Honey in Canada.**

The following is the report of the Ontario Bureau of Industries issued by the Ontario Department of Agriculture, dated at Toronto, May 15, 1888. Its statistical information will be read with interest:

It was evident when the bees were placed in winter quarters that the season would be very trying to them. The flow of honey had ceased unusually early in the summer, and so had breeding, and as a consequence stores were light in the hives, and the occupants were chiefly old bees, lacking the vitality to stand a long period of winter seclusion.

Losses are reported as general, ranging from 5 to 75 per cent., and it may be assumed that about one-fourth of the colonies entering the winter died before the time came for their spring flight.

The counties of Huron, Bruce and Simcoe seem to have suffered most heavily in the matter of winter losses. In many instances the bees died of actual starvation, owing to the scanty supply of summer honey; and to poorly ventilated cellars are also ascribed a cause of loss, although several experienced apiarists express themselves as puzzled to account for the mortality in certain cases. Many of the surviving colonies were weak from long confinement in their winter repositories, and the cold and backward spring thinned them out in several districts. Complaints were also made of losses from diarrhea and spring dwindling.

Where specially well fed and cared for during the winter, the honey-makers came out as a rule very lively, and are now busily engaged carrying early pollen.

No mention is made of foul brood from any quarter.

An effort was made during the past winter, at the suggestion of the Bee-Keepers' Association, to procure statistics of the industry, and 3,000 schedules were sent out to apiarists in the province. Returns were received from 651 persons, sufficiently complete for tabulation, the aggregates of which showed that 19,015 hives were put into winter quarters in 1886, and 23,828 in 1888. The season of 1887 opened with 14,613, showing a decrease of 4,402 during the winter; but as sales were not reported, it is not likely that the whole decrease was due to mortality. The increase by colonies last year was 19,863, making an aggregate of 25,476 hives for the season.

These gave a product of 112,477 pounds of comb honey, 499,093 pounds of extracted

honey, and 6,686 pounds of wax, valued at \$67,237, or an average of \$103.28 for each proprietor.

Full returns for the province would doubtless show that the industry is one of very considerable importance, but a practical difficulty in the way of procuring statistics is the lack of a complete list of apiarists.

Seasonable Hints.—Mrs. L. Harrison, in last week's *Pratier Farmer*, gives the following on the present outlook for a honey crop, and management of weak colonies:

Though the outlook is at present unfavorable, all bee-keepers should keep their dishes right side up to catch the shower if it falls. I have seen the ground white with bloom, and yet the bees took no notice of the blossoms. If, however, the electrical conditions should be just right, and nature's laboratory in good running order, there may yet be a fair harvest. In some favored localities, basswood may yield a large supply of a fine quality of honey.

I used to practice taking from strong colonies to build up the weaker, but I believe it is poor policy, for men or bees. Strong colonies are the ones which pay the rent. Some bee-keepers take brood from the weaker to aid the stronger during an approaching flow of nectar. These small colonies reduced to a nucleus, can be built up after the rush of business is over, and I think much more honey will be secured in this way than by taking from the stronger to strengthen the weaker. There is no profit in weak colonies, barely able to support themselves—living merely from hand to mouth.

Last season the bees were all ready to move; queen-cells capped, and their haversacks packed for the journey, when the honey failed. Now bees are wiser than some people who set up house-keeping with no income. When there are no supplies coming in, they stay where there is a well-stored larder, and are content not to increase their family very much, and when worst comes to worst, drive out all non-producers (those that they had so carefully nursed only a short time before), even casting out undeveloped brood. When I saw this state of affairs, I began to cast around to see what to do with the combs not used. I was tired of fighting moths, so I concluded that all the strong colonies could easily spare two combs of honey, brood and bees, and put two of these empty ones in their place. I put these frames of brood and bees into a hive until it was full, alternating them; they were so mixed they did not fight. I had no extra queens, so I let them rear their own. As the season turned out, I should not have had any surplus, and the strong colonies were not injured; and the combs were preserved.

Planting for Honey.—Upon this subject Mr. W. Z. Hutchinson writes an article for the *Country Gentleman* for last week. He takes the ground that "to be of any value there must be acres and acres of bloom." Hence there should be acres and acres planted, for we cannot expect honey unless there are honey-producing blossoms in profusion. He closes the article thus:

It must not be forgotten that cultivated plants on rich land often yield honey much more abundantly than those growing wild, or upon a poor soil. As not many could afford to devote tillable land to the cultivation of a crop without reasonable expectations of securing at least \$15 per acre for the use of the land, for labor and seed, it is evident that planting for honey could not be

indulged in unless 500 or 600 pounds of—not simply honey, but of surplus honey, could be secured, per acre.

As this amount of honey is worth at least \$75, some may wonder why such a large yield would be needed to make the planting remunerative. The reason is this: Four-fifths of the cost of honey is represented by interest on bees and fixtures, rent on land, and by labor, the latter item being much the largest; hence, if the surplus be increased by planting, this increase is not clear profit by any means. It is true that there are farm crops, such as Alsike clover and buckwheat, that will produce honey, but it is seldom that it would pay a farmer to make very much change in his farming routine simply that his bees might have access to a few acres of Alsike or buckwheat. The latter seldom yields honey in paying quantities oftener than once in four or five years.

All things considered, there is probably no plant that can be raised in this latitude with better prospects of receiving a crop of honey as a free gift than Alsike clover. In soils adapted to its growth, such as moist land or gravelly loams, Alsike is a profitable crop for farmers to grow. I have just returned from a visit to Ionia county, Mich., where I found that Alsike was grown to the exclusion of red clover. The Alsike is not "heaved" by the action of the frost in spring, as is red clover; hence I found many farmers using it for pasture. When thus treated it becomes of great value to the bee-keeper, as there is a profusion of blossoms throughout the whole season. In ordinary seasons Alsike furnishes no after-math, as does red clover; in wet seasons it does. When cut for seed, if not allowed to stand too long, the clover, after being threshed, is equal to timothy for hay. For sowing in waste places, there is probably nothing better than sweet clover. It will spread and take care of itself, and the honey is of light color and good flavor.

Let all remember, however, that small "patches" of honey plants are of no account; that a few often may even be a detriment, as the honey furnished would be so small in amount as only to invite to brood-rearing, and no surplus would result. To be of any value there must be acres and acres of bloom.

Albino Bees.—Mr. Thomas A. Anderson, of Big Springs, Mo., on May 29, 1888, writes as follows:

On page 259, third column of the *BEE JOURNAL* for April 18, 1888, in your answer to Mr. Barker's question, you say "Albino bees have white bands instead of yellow." Is this correct? If so, we are sadly misinformed, and we have bees from Maryland's best breeders.

Mr. Barber asked, "Are there any bees that look like the Italians, but that are white instead of yellow?" We briefly answered, "Yes; Albino bees have white bands 'instead of yellow,'" quoting the last three words of the question.

Our intention was to simply inform Mr. Barber that there were such bees as Albinos, and not to *critically* describe them. Had this been our aim, we should have said that the white bands were additional to the usual yellow ones—though in different strains of these bees, the number of yellow bands vary, as do the shades of color in the yellow; some being rich orange, and others pale yellow, almost white. Those bred in our apiary here, some years ago, had three yellow and two white bands all distinct and plain to be seen.

INTERROGATORIES.

Fumigating Honey.—Mr. J. Smith Head, of Park Place, Ark., on May 23, 1888, writes :

The weather throughout this section of country has been dry and cool, but the bees are doing well. So far I have averaged about 18 pounds per colony. I started here this season with 80 colonies, mostly in Langstroth hives; they have increased to one hundred.

1. Is it best to fumigate my section honey before shipping? 2. Can I fumigate it sufficiently in a tight room with sulphur by having the sections scattered promiscuously around on the shelves and places?

1. Yes, by all means. 2. It would be better to pile up the sections of honey. In order to make this very plain, we will let Mr. Doolittle describe how he does it. He says: "We build a platform on either side of our honey-room of scantling, about 16 inches high, and on this we place the boxes, so that the fumes from burning sulphur can enter each box; in about two weeks we fumigate, by burning $\frac{1}{4}$ of a pound of sulphur for every 200 cubic feet in the room. We take coals from the stove and put them in an old kettle, so as not to get anything on fire; pour on the sulphur and push it under the pile of honey, and shut up the room. Watch through the window, and in 15 minutes after the last fly or bee that chances to be in the room has died, open the door and let out the smoke, for if it stands too long, the smoke may settle on the combs and give them a greenish hue. As there may be a few eggs that have not yet hatched, we fumigate again in about 10 days, after which the honey will be free from moths, if you do not let millers into the room."

Chapman Honey-Plant Seed.—A. D. Buckley, of Weston, Tex., on May 26, 1888, writes as follows concerning it:

In reply to the question in the BEE JOURNAL I would say that I wrote to the Department at Washington for some of the above seed several weeks ago, and I am now informed in reply that they had no more of the seed left—all had been sent out. I am sorry, for I would have been glad to receive some to try in the Sunny South of Texas. I have 90 colonies of bees, and have had 8 swarms. The prospects for increase and honey are very good. I have from 4 to 6 acres of sweet clover; it grows from 4 to 6 feet high here.

Now that no more seed is to be given away by the Department, we happen to have a little left, and can supply those desiring to test its value as a honey plant in their localities. For prices see page 381. As we have but a few pounds it will be necessary to order at once, to get some of it.

Bee-Keeping was known to the ancients. Canaan was a "land flowing with milk and honey." The Perstans, Grecians, and Romans used honey extensively as an article of food, and in preparing their food.

BIOGRAPHICAL.

MR. J. B. HAINS.

The following is a biographical sketch of Mr. Hains, furnished by Miss Dema Bennett, of Bedford, O., and it will be read with interest:

The parents of Mr. J. B. Hains came from Vermont to the Western Reserve when this part of the country was a trackless wilderness, and his father, Rev. N. C. Hains, who was a Methodist minister, organized the first church in this place.

The subject of this sketch was born June 13, 1833, and the deed to the homestead, where he has always lived, was made on that day.

He has been interested in bee-keeping ever since the first swarm which he hived on July 4, 1844, and the bees in his apiary are in direct line of that first swarm. Mr. Hains early adopted the movable frame,

Mr. J. B. HAINS.

and prefers the Langstroth frame to any other. He also carefully tested the different races of bees, finally choosing the Italian to the exclusion of all others.

Being desirous of establishing apiculture on a better basis, he transferred the bees in this locality from box-hives to movable combs, and Italianized them at the same time. Both Mr. and Mrs. Hains devoted the entire summers of 1878 and 1879 to transferring and caring for the bees within a radius of 10 miles, when the box-hive became a thing of the past, as far as this locality is concerned.

By furnishing the hives and doing the work for one season, he acquired ownership of one-half of the bees, which aggregated more than could be profitably managed in one locality, and which he divided into six apiaries, at convenient distances from home, making seven apiaries in all.

The out-apiaries are managed by assistants, and run principally for comb honey, while his home apiary of 100 colonies is devoted to the rearing of queens, nuclei, and the production of extracted honey.

He experimented with regard to comb foundation before it was successfully made, purchased and used it on its first appearance regardless of expense, and when the

price was reduced to 75 cents per pound for a very poor article, 4 feet to the pound, he purchased it in large quantities, and used full sheets in all of his frames.

Mr. Hains was engaged in the hardware business for many years, but as the bee-keeping interest developed so rapidly, it became necessary to abandon one pursuit or the other, but his preference for apiculture, combined with his thorough knowledge of the business, induced him to give up the former about two years ago, since which he devotes his entire time to apiculture, except in winter, which he employs in other interests.

Mr. Hains is President of the Progressive Bee-Keepers' Association, and has always been ready to give to others the benefit of his experience.

Being a practical mechanic as well as an apiarist, he has constructed a good many implements for use in the apiary, but has never patented any of them, and a few of them can be seen by looking in the Museum at the office of the AMERICAN BEE JOURNAL.

As I have intimated before, Mrs. Hains is a practical bee-keeper also, which fact, no doubt, has helped to make the management of bees a success at Welcome Apiary. They put 109 colonies into winter quarters, which came through with a loss of but one.

Nashua, Iowa, Convention.—H.

L. Rouse, of Ionia, Iowa, the Secretary, sends this condensed report of the meeting:

The Nashua Bee-Keepers' Association met in the Council Rooms at Nashua, Iowa, on May 19, 1888, as per adjournment on Feb. 18, 1888. Owing to the bad condition of the roads, and the busy time of the year, very few members were present. The past winter and spring has been very disastrous to the interests of bee-keeping in this locality. As near as could be estimated from the meager reports, the loss has been fully 50 per cent. A good many colonies have spring dwindled. Some have reported cases of laying workers. One method suggested to get rid of laying workers was this: Set a new hive in the place of the old one; put in a comb containing brood in all stages, then shake the bees on the ground, and let them hunt their home.

After some discussion of various topics connected with bee-keeping, the meeting adjourned.

The season is very backward here for this time of the year. Scarcely any corn has been planted yet. Dandelions are just in bloom. Fruit bloom will quickly follow. There has been but very few days up to May 16, that bees could work to advantage, and as a result brood-rearing has advanced slowly. I had several cases this spring where the old bees died off faster than the young bees hatched out, and the colony vanished like a dream. There seems to be a general complaint among bee-keepers this spring about finding more queenless colonies than common. We have had an abundance of rain. The prospect for white clover is quite good. I have received a package of the Chapman honey-plant seed; planted it in April, but it has not come up very well yet.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

QUERIES AND REPLIES.

Is Newly-Made Foundation More Acceptable than when Older?

Written for the American Bee Journal

Query 548.—1. Will foundation one or two years old be drawn out by the bees as quickly and satisfactorily as newly-made foundation? 2. If not, is there any process by which it can be renewed so as to make it as good as newly-made foundation? 3. Will it pay to use old foundation?—Indiana.

1. My experience says it will. 3. Just as well new.—G. M. DOOLITTLE.

1. Yes. 2. Steaming it slightly will soften it. 3. Yes, undoubtedly, if not dirty.—DADANT & SON.

1. No. 2. Put it in hot water. 3. Yes, I use it without doing anything to it.—C. C. MILLER.

1. Yes, nearly. 2. It is claimed that softening foundation with warm water makes it "good as new." 3. Yes.—R. L. TAYLOR.

2. If softened by dipping in warm water before using, it will work satisfactorily. 3. Yes.—A. B. MASON.

1. Yes. 2. Dip it in warm water, or place it in the sun for a few moments. 3. Yes. H. D. CUTTING.

1. Not quite. 2. Steam it. 3. Yes, if not too old.—J. M. HAMBAUGH.

1. There is little if any difference. This is answer enough for all the questions.—JAMES HEDDON.

If old foundation is placed in hot water for a few minutes it will become just as good as new, and the bees will work it out just as well.—P. L. VIALLO.

1. I have observed very little difference. 2. If heated until quite soft, either by dipping it in hot water, or by exposing it to a temperature of 100° or more, it will be as good as new.—M. MAHIN.

1. Yes, if your foundation is all right in the first place. 3. Yes. I have used foundation two years old, and could see no difference between it and that freshly made.—MRS. L. HARRISON.

Old foundation becomes hard by atmospheric influence, but can be "annealed," so to speak, by exposing it to a warm sun sufficient to soften it.—J. P. H. BROWN.

Yes, if softened, I think it will. I always use foundation. If the colony is not very strong, I warm the foundation so as to have it soft.—A. J. COOK.

1. That depends much upon how it has been kept. If allowed to freeze, it becomes hard, and is worked out by the bees slowly. But if kept in a warm room it remains soft and pliable, and I doubt if age injures it, if it is put in a tight box with papers between the ayers.—G. L. TINKER.

1. There is but little difference. 2. It can be dipped in warm water to freshen it, but I do not think it is necessary, as the bees clustering on it will render it pliable. 3. Yes.—C. H. DIBBERN.

1. If the wax is not injured in the manufacture of foundation, age does not affect it. 2. The heat of the hive will "renew it," all that is necessary. 3. Yes, it will. I prefer new foundation because it is apt to be cleaner than old.—J. M. SHUCK.

1. If it has been kept closely packed in a box it is as good as any, but if it has been exposed to the air it becomes dry and hard. 2. If the foundation has become dry and hard it can be renewed by soaking it in warm water, sweetened with honey. 3. It pays me.—G. W. DEMAREE.

1. I have found no trouble in using it. 2. Warming it slightly is said to improve it, but I have not found any material difference in so doing. 3. It certainly does with myself.—J. E. POND.

1. I cannot say from verified experiment, but have used more or less of it, thinking (whether true or not, I cannot say) that when the temperature is right for working wax it would be utilized just the same.—E. SECOR.

1. Yes; if it has been properly kept in a box, it will be just as good as that just made. 2. If it has been exposed to the air, and become hard, dipping it in hot water or placing it in the sun will soften it. 3. Yes.—THE EDITOR.

Purity of Drones from a Mismatched Queen.

Written for the American Bee Journal

Query 549.—1. If the drone progeny of a pure Italian queen that has mated with a pure drone of the German variety, is as pure as its mother, why is not the agamic progeny of a pure Italian queen as capable of performing the functions of the male in fecundation, as one from a fecundated queen? 2. Will the drones of a pure black queen, that has mated with a pure Italian drone, display evidence of Italian lineage or markings?—L.

1. It is. 2. No.—DADANT & SON.

1. They are. 2. No.—JAMES HEDDON.

Please ask "the Professor."—H. D. CUTTING.

1. Oh, dear! I wish I knew. 2. Yes.—A. B. MASON.

1. Give me something easier. 2. No.—MRS. L. HARRISON.

I will leave this for expert queen-breeders to answer.—C. H. DIBBERN.

1. That is the question, Why are they not? Who knows? 2. I think not.—J. M. HAMBAUGH.

I suppose it is as capable if reared under as favorable circumstances. 2. No.—R. L. TAYLOR.

1. I think that it is. Do you know that it is not? 2. They do not in our apiary.—A. J. COOK.

1. Send 15 cents to the editor of the AMERICAN BEE JOURNAL, and he will send you "Dzierzon's Theory." 2. I never could detect any.—P. L. VIALLO.

1. Such progeny is, if developed under as favorable conditions as the drones of a fecundated queen. 2. I have never found any such display.—J. P. H. BROWN.

1. Has it been fully proven that what you assume to be true in the latter part of your subjunctive proposition is true? 2. I do not know from actual observation.—EUGENE SECOR.

I have not had experience enough along that line to entitle me to any decided opinions. I think, however, that drones from a mismatched queen are not exactly pure.—G. M. DOOLITTLE.

All that is known of this matter has been pretty thoroughly discussed in the books and bee-papers. I have nothing new, startling, or even plausible to add to what has already been iterated and reiterated.—J. M. SHUCK.

1. Isn't she? 2. I would like to look in your face before answering. If you are common every-day folks, I answer "no;" if you are not a bee-keeper but a theorist, I answer "certainly."—C. C. MILLER.

This question opens up a subject too immense to be treated satisfactorily in this department. Read "Dzierzon's Theory," and judge for yourself. Any answer will only be theoretical, and I differ from many in my views upon the question.—J. E. POND.

1. I believe the drone progeny of a virgin queen or of a laying worker reared in drone cells as capable of fecundating queens as any other drones. Any egg from a laying worker will produce as large and perfect a drone as one from a fecundated queen, if it has the same treatment. 2. No.—M. MAHIN.

All that I have been able to demonstrate by practical experiments results in this conclusion, to my mind, viz: 1. Virgin queens produce drones without the agency of the male. I have demonstrated this by repeated experiments. 2. Drones that are the progeny of a virgin queen, are impotent, and not capable of propagation. The peculiarity of the spring seasons in my locality has given me the opportunity to test this matter, and drones of virgin queens have failed to mate with the young queens in every case under my observation.—G. W. DEMAREE.

1. That is a pertinent question bearing on the Dzierzon theory. If the mating drone affects or changes the habits and instincts of the queen, as

we know, it would certainly be remarkable if her drone progeny was not also affected, and if their virility is affected, they cannot be pure. Many experiments have proved that the drones of agamic queens do not possess virility. 2. No; but their subsequent progeny will.—G. L. TINKER.

These questions involve propositions and theories too profound for ordinary persons. When the most learned professors disagree on such theories, what can be settled by the mere "conclusions" of those who have not made it a life-work to study the anatomy and physiology of bees? The whole thing is but speculation. But to answer the question: 1. I think it is, if properly developed. 2. No, so far as I have been able to observe and form an opinion.—THE EDITOR.

JUNE ROSES.

O, sing of the roses,
The beautiful roses,
Adorning the warm, pulsing bosom of June,
Exult in their sweetness,
Extol their completeness,
And only lament they must perish so soon.
Then sing of the roses,
The beautiful roses,
Or scentless, or filling the air with perfume,
They lessen our sadness,
They bring to us gladness,
These roses that gem the fond bosom of June.
—Vick's Magazine for June.

CORRESPONDENCE.

EXPERIMENTS.

Showing of what Nature's Bee-Hives Consist.

Written for the American Bee Journal
BY G. M. DOOLITTLE.

By the replies to Query 525, I see it is supposed that either a fool asked it, or else some one had a practical object in view. Well, in answering it I see but one idea of the querist, and that was to get at facts.

Since answering it, I have been conducting some experiments, as I had also before, and I have arrived at the conclusion that much of the teachings of the past have been erroneous—in part, at least.

We have been taught that the bees heat a hive on the same plan that a fire in a stove heats a house. In which case, all know that the room where the fire is, is the warmest at the top.

Following out this thought, Mr. Dadant, on page 247, tells us that "the bees will be enabled to warm about 6 inches in depth since the warmth always rises," and by a process of reasoning, arrives at the conclusion that a broad flat-topped hive is not as good for bees in early spring as a tall, narrow one would be.

Again, on page 107 we find Mr. Heddon adopting the same line of reasoning, to prove that by putting one empty brood-case of his new hive under one already filled with brood, that brood is in "the warmest part of the hive." Now, if Mr. Heddon is correct in this part of the matter, he is certainly incorrect in his reply to the above query, for bees are most active in the early spring where the heat is the greatest; yet he answers, "At the bottom, usually." On page 107, he tells us that "the direction which the queen naturally breeds," is "downward," which goes to prove that his reply to the query was right, and his conclusions on page 107 wrong.

Without trying to decide for these gentlemen which are right, or trying to reconcile Mr. Heddon's statements, I will give some of the things I have found out by my experiments, and leave the reader to follow out the "pointers," and arrive at his own conclusions.

A few years ago Mr. Betsinger was at my house, and he asked the same question that the querist asked on page 182. I replied to it as did most of those answering the query, that the bees were the most active at the top of the cluster, but Mr. Betsinger said I was wrong.

Accordingly, to prove my position, the next morning, while there was still a frost on the ground, I carefully lifted the quilt from over the cluster of a fair colony of bees, and found that they were very quiet, stirring but little more than they would have done had I so looked at them in mid-winter. I now carefully put back the quilt, and raised the hive at the bottom, and much to my surprise I found them at this point ready to resent an intrusion, flying out at the least disturbance. Thinking that I had aroused them, by first lifting the quilt, I went to another hive and raised this from the bottom first, when I found them just as lively there as the others had been, and upon lowering the hive and raising the quilt, they were in the same sluggish state at the top that those were in the first hive.

Without dwelling longer, except to state that hundreds of trials have resulted the same as the first, I am led to believe that the warmest part of the hive, as we reason from our fire-heated rooms, has little if anything to do with our bees. While the hive may help a little along the line of keeping the bees warm, yet the main reason for a hive is to protect the bees from the storms of wind, rain and snow which our climate is subject to, for bees cannot stand cold of any amount while wet.

Bees are natives of a warm climate, and in their native home they frequently do not seek any hive at all.

but build their combs on the limb of a tree, or on the under side of some flat surface, in which case the bees themselves form the hive, properly speaking.

To illustrate: If we have a natural swarm of bees in a large box, and closely watch them work, we find that they suspend themselves from the top in a compact form, appearing like an inverted cone, which, to all appearances, is nearly motionless, so that it will appear as if the bees were idle, while the fact is, that these apparently idle bees are really the hive proper, and inside of this, active work is going on, building comb, etc. This is easily seen by passing a wire suddenly through the cluster horizontally, and letting the lower half drop.

Outside this living hive or crust of bees, the temperature is often not more than 50°, while just inside they are working wax nicely with from 90° to 95° of heat, as I have found by several carefully conducted experiments with a self-registering thermometer. As the combs grow, this crust of bees expand until they touch the hive, when it gives away at that point to a large extent, letting the hive there form the crust, but were the hive not there the crust of bees would still hold their position, so that, as I said before, the hive helps a little, but this only in the heat of summer, where a hive of the size of 2,000 cubic inches is used; for as fall comes on, the bees contract and form the crust, or "nature's hive" again, thus to remain until the next summer, unless the hive is contracted by man.

But more closely to the point: In 1874 I had a colony of just 82 bees, and the queen by actual count, on the 1st day of June, which was the remnant of a once populous colony. These few bees I decided to leave without help to see what they could do. They had a few cells of brood in the center of one side of two combs, as they were not strong enough to enclose one comb. On cool mornings it was a curious sight to peer down through that range between the combs which they occupied, and see the points of their abdomens all turned in an outward direction, and closely packed together, so as to keep up the necessary 85° to 90° of heat for brood-rearing, yet they did it through day after day of weather too cool for bees to fly, while at night it was nearly freezing several times.

Well, not to dwell longer on this point, they increased their brood, so that by July they had brood in three combs, while so far they did not touch the hive at any point, and, as I firmly believe, kept the heat all in the cluster, and not in the top of the hive. They increased to a fine colony in the last

half of August, and gave me about 5 pounds of box-honey, besides enough to winter on, all made from the outcome of that little handful of bees, in the centre of a hive, only contracted to five combs at the time they were the smallest, if I remember correctly.

Any one can prove the correctness of the foregoing by placing their hand on the quilts over different hives on a cool morning in May. Where the cluster comes up so as to break the crust of bees on the quilt, it will feel quite warm at that point, but all around this place the quilt will be cold; which certainly proves that the heat is not all in the top of the hive, but kept by the bees in the cluster.

If the above is correct, then the only contraction that amounts to anything is that close contraction that forces the bees to touch the hive at all points.

Borodino, N. Y.

DRONES.

Objects and Work of Queens, Workers and Drones.

Written for the American Bee Journal
BY E. GERRY.

Bees are divided into three classes. Each has a special duty to perform. They are created and constituted to be happy, and enjoy the labor allotted to them.

The absence of either class would ruin the colony. The queen is the mother, and produces the eggs from which all the bees are hatched. She is especially adapted to fill the place she occupies, and is so organized that she is able to produce either male or female. If she desires to lay an egg that will produce a male, she will deposit the egg in a large cell (drone-cell); if a female, she will lay the egg in a small cell (worker-cell). The sex depends upon the size of the cell in which she deposits the egg, if she has been properly matured, or has not become barren or injured.

There is another class of females that have become dwarfed in size by being allowed to remain in a small cell insufficient for the growth of a perfect female, consequently the genitive organs become contracted, and the desire for copulation destroyed; hence they never mature, and are rendered imperfect. Their nature and desires are changed, thus their duties are different from a perfect female or queen. This is a wise freak in the development of the female. The larvæ, when not more than a day or two old, is taken from the small cell and placed in a large cell made for the queen, and supplied with a kind of food to produce a fully developed female or queen,

while the dwarfed female or worker bee is allowed to remain in the small cell; otherwise they would all be queens, and deadly enemies to each other, and would be destroyed; but as it is now arranged, their desire is to gather stores for the support of the colony, and they are friends.

The third class is the male bee (or drone), from the peculiar adaptation of his duty. He was created with a lazy, indolent disposition, that he might be contented to remain in the hive, to generate the animal heat, to hatch the larvæ, and dry down the nectar (gathered by the workers) to honey. Had he the same industrious disposition of the workers there would be none to remain in the hive, and the consequence would be there would be no young bees hatched, and the nectar would sour, and the whole colony go to ruin. Is this a good reason why the drones should be left alone to the entire management of the bees? It is wrong, in my opinion, to interfere with the drones only for breeding purposes. If we wish to rear queens from the choicest colonies of bees, we should remove the best queen from a prosperous colony, and start another colony with her, and then the bees from which the queen was taken, will at once rear several queen-cells; and the queens should all be properly cared for. When the young queens have hatched it is better to shut in all the drones except those from your best colony, which would give a better chance for the young queens to be mated with choice select drones, and after the queens are mated, let the drones fly as usual.

Where there are more drones than workers, it is evident that the queen has been injured, or is about to become barren. The bees understand when they have no need for the drones, and will dispose of them in due time.

Lummi, Wash. Ter.

LEARNING.

The Experience of a Beginner in Bee-Keeping.

Read at the Rockford, Ills., Convention
BY MR. HERRICK.

The experience of a beginner in bee-keeping is a succession of surprises. For in this, more than in any other avocation, does he find that the reality is almost the opposite to what he anticipated.

For example, he watches an experienced apiarist go into the top of a tall tree, and cut off a limb on which is clustered a swarm of bees, and carry it safely to the ground, and hive the

bees. He thinks that it is a very simple and easy thing to do; and so it is. But a few days later, when he essays to hive a swarm that he finds on one of his apple trees, and he becomes the chief actor instead of the spectator standing at a safe distance, the thing appears very different to him. He sees from a different standpoint. On the topmost round of the ladder, balancing himself with his knee against a limb, both arms extended, holding the limb on which the bees are clustered, with one hand, and sawing it off with the other, his muscles quivering, the sweat pouring down his face, the bees buzzing inconveniently near his eyes, what wonder if, on attempting to go down the ladder, his eyes fixed on the cluster of bees, he makes a mis-step, and, "Jack-and-Jill" fashion, "tumbles down and cracks his crown," and the bees come buzzing after.

Then, again, he watches an experienced bee-keeper open up a hive, take out the frames and look them over, cutting out a queen-cell here and a patch of drone-comb there, and he thinks the old man's slow and deliberate movements are due to the infirmities of age; and he goes home full of conceit of what he can do with his bees, and how much more quickly he can do it. But after several attempts he begins to learn that old adage, "the more haste, the less speed." I do not know of anything that will knock the conceit out of a man quicker than to find himself face to face with a colony of excited bees; compelled to move very deliberately while the bees are doing just the opposite, and having it all their own way with him. I know how it is, for I have been there myself.

And here let me say to my young bee-keeping friends, pay no attention to what old bee-keepers say about never using gloves or a veil when manipulating bees. I do not doubt their word in the least, for a good, honest, old bee-keeper is like little George Washington, he cannot tell a lie. But all the same I know it is perfectly safe to wear gloves and a veil. If you are at all nervous, as most young bee-keepers will be, these articles will reassure you; and in any case will prevent many a sting. I do not, on any account, wish to intimate that you would care for a few stings, but, you know, it kills the bee.

But there are many experiences about bee-keeping that are really pleasant. It is pleasant to watch them in early spring, and learn their ways and methods. Later on it is pleasant to supply them with needed surplus storage. It is also pleasant, during the honey flow, to note, from day to day, the increase of honey in

the sections. It is pleasant to take off large amounts of honey from each hive and sell it for a good round price. And I presume all will agree that it is pleasant to eat it, providing you do not eat too much at a time. In fact, when you and the bees become good friends, it is all pleasant.

But the writer has to acknowledge that he has not progressed so far as that yet. His bees are the black variety, and do not seem inclined to cultivate the acquaintance of any one "not in their set." And here I am led to say that bee-keeping calls for a great deal of patience, of perseverance, and of earnest study, as well as close watchfulness, for there is no telling when they will not do some absurd thing or other.

The first summer that I kept bees, I hived a swarm on frames filled with foundation, and they seemed satisfied, and went to work. In a short time the hive was filled with honey and brood. And then came the *strange* part of it. They suddenly left the new hive and went back to the parent hive. They were soon driven out, and they clustered on the limb of a tree. I put them back into their own hive, but they were soon out again. I then put them into another new hive, when they were satisfied and went to work. Now I have not the slightest idea what caused those bees to desert their hive. Perhaps some of the older bee-keepers present can tell us why it was.

While speaking of my own experience, it might not be out of place to mention the experience of the past season. In the spring 14 colonies came out of the cellar in fine condition. Plans were made for extending the business by natural increase and by purchase; and 40 new hives were made, also 50 surplus cases, 3,000 sections, 50 pounds of foundation purchased, and a large stock of enthusiasm and hopeful anticipation was on hand.

Result: Three new colonies, one by increase and one by purchase, all of which had to be nursed all summer to keep them alive. One pound and 6 ounces of very dark surplus honey, probably put in the boxes for sale because not fit for home consumption, and even that taken in exchange for 140 pounds of sugar fed to them to give them a ghost of a chance to live through the winter. It being then a "glorious uncertainty" whether any would live through, to thank me for my efforts in their behalf.

But the one who is really determined to make a success of bee-keeping, will not allow such an experience as that of last season to cool his enthusiasm. Rather, he will make it a useful lesson. And he will go on, with a level head,

learning all he can about bees. He will take at least one first-class bee-paper, and thus get the experience and observations of eminent apiarists. Then, too, he will study his own bees. He will have an observation hive, and will spend his leisure moments watching them in their varied work. Thus verifying the experience of others, and making it his own as well. He need not be afraid of exhausting the subject. Many very intelligent men have made it their life study, and yet, all of them combined, have been unable, as yet, to learn one-half of what there is to know.

For myself, after two years' study, I am amazed at the little I have learned, and the much there is yet to learn. Aside from the petty annoyances attending the handling of bees, it is a delightful study; and the more one learns, the more eager is he to learn still more.

DWINDLING.

How the Bees have Wintered— Spring Dwindling, etc.

Written for the American Bee Journal
BY J. M. HANBAUGH.

In the latter part of September, 1887, I prepared 65 colonies of bees in large Dadant hives for wintering on the summer stands, as follows: Each hive was carried into a bee-tight room, and where there was not fully 30 pounds of honey in the hive, combs filled with honey from other colonies were given, keeping the combs with brood in them to the centre as near as possible, removing all surplus combs from the sides, and inserting a division-board on each side. I then placed $\frac{3}{4}$ of an inch strips crosswise over the tops of the brood-frames, over which I spread burlap sacking. The intervening space between the division-boards and the sides of the hive was then packed with dry hard-maple leaves, and the lid filled full of the same. This, you will perceive, is a very simple and inexpensive preparation.

Out of the 65 colonies all came through the winter but two; one of which fell into a thief's hands, who stole the two center combs, leaving the poor bees exposed, and of course they died. The 63 colonies are now in excellent condition, generally speaking. Tally one more for the large hives as a success for out-door wintering.

I prepared 95 colonies at home for cellar wintering by simply preparing them with, as I supposed, an abundance of natural stores, weighing each hive, and giving from 20 to 40 pounds of honey, net, to each colony. From Nov. 19 to 21, they were put into the

cellar. In consequence of showing diarrhetic symptoms, I placed them upon the summer stands on March 1. Every colony was alive at that time, but they spring dwindled, until at present I can boast of but 81 colonies—a loss of 14.

Another notable feature is the finding of 7 queenless colonies. While out of the 63 colonies at the Vandeventer apiary, only two were found to be queenless. At the time of placing the bees upon the summer stands, the consumption of honey was very little, but they drew heavily upon their stores during the spring, and quite a number had to be fed.

Mr. Heddon says on page 267, that his tabulated report "gives sufficient reply to the criticisms of Messrs. Hambaugh and Dadant on page 199," and that "those reports settle the question of its merits, etc." Mr. Newman has clearly shown our failings wherein he states, "Our hives are like our wives and babies—each of us think ours the best." If this be true, what does the table amount to, and how are we to get at the superiority of one hive over another, only in the actual work done in the field. A speed-horse must not be declared the winner until he has actually run the race, and gained it by honest work. So with bee-hives, when any disinterested parties will show the actual work of the small hives of any pattern to exceed financially those of large ones, we will cease to exalt the virtues of the large hives, and adopt the small, be they of the single or divisible brood-chamber pattern. We want the hive that will produce the *most money*.

Spring, Ills., May 21, 1888.

NEBRASKA.

The Bee-Pasturage of the State, and the Time of Blooming.

Written for the American Bee Journal
BY GEO. GALE.

While Nebraska is deficient in the chief honey-plants of the States further east, such as white clover, basswood, etc., we have in the southeastern portion of the State an abundance of plants in their season, producing a moderate, and sometimes an abundant flow of nectar throughout the whole season.

We are, of course, subject to drouth the same as other countries, but not more so than the States east of the Mississippi; but as we are not dependent upon one or two species for our honey crop, it must be a very poor season indeed if we suffer an entire failure. The two seasons of 1886 and 1887 were the poorest seasons for bees

known since bees have been kept here. During these two seasons bees kept within a mile or so of the streams, have made a living and some increase, and in some instances some surplus has been secured, while those out on the prairie, distant from timber, fared very badly; many colonies, even of Italians, starving to death during the summer.

The following list of honey-plants of southeastern Nebraska is made by me, after a residence here of nearly 30 years, and a pretty thorough study of the botany of the district. I have omitted some species that are abundant in the bluffs of the Missouri river, and are common in the States eastward, but are rare or absent in other parts of Nebraska. This list includes very few plants except natives, as very little has been done by way of planting for the bees. This list furnishes a continuous succession of bloom (in favorable seasons) from the last of March until frost or stormy weather closes the season in October.

The first pollen is gathered from soft maple (*Acer rubra*), followed closely by white elm, red elm, cottonwood, several species of willow, box-elder, white ash, gooseberry, wild plum (*Prunus chicasa*), dandelion (in some places), apple and cherry, choke-cherry, burr-oak, hickory (*Carya amara*), black and red raspberry, wild grapes (*Vitis cordifolia*), black locust (in a few places), and honey locust.

This brings us up to the first of June in average seasons. Very few of these, perhaps, furnish much nectar except the gooseberries and other bloom (in favorable seasons), but all produce pollen in great abundance; and if the weather is favorable for it, and the bees have plenty of honey in their hives, they build up very rapidly, and are now ready to swarm, or have already commenced. From now on we may expect some surplus, provided the bees do not over-swarm, and now is the time to put on the surplus cases to prevent it.

The honey-locust ought to, and in favorable seasons will furnish some surplus. So will the hackberry, Virginian-creeper (*Ampelopsis quinquefolia*), and a small species of willow that blooms about this time, on which the bees work for several days to the neglect of everything else.

Sumac (*Rhus glabra*), common milkweed, pleurisy-root or butterfly weed, and later several other species of *Asclepias* furnish nectar in great abundance. In some seasons of good quality, in others not so good. There is so little white clover away from the Missouri river that the bees scarcely notice it, and as a source of honey it amounts to very little. Catnip, mother-

wort, buckberry (*Symphoricarpos*), and some seasons partridge-pea (*Cassia Chamærista*) all bloom now, and later, two species of wild cucumber bloom for a long time, and all yield surplus of excellent quality, and in great abundance.

About the last of July or first of August, the plant incorrectly named heart's-ease begins to bloom. This plant (which is a *Polygonum*, while heart's-ease is a violet) is in some seasons the principal source of our surplus honey, and in others it is scarcely visited by the bees. It grows in all open waste places, in stubble fields after harvest, and particularly luxuriant in neglected corn fields. This plant may fairly be considered our best honey plant, and as it always comes whether wanted or not, and blooms at the same time, and yields honey under the same conditions of weather that buckwheat does, and yields a much better quality of honey than buckwheat. It does not pay to sow buckwheat, as it is too uncertain a crop to sow for the grain.

Of fall flowers yielding honey we have several species of asters. One with purple flowers must yield considerable honey, as it is much frequented by the bees from September until severe frost. These, with a species of *Eupatorium*, and one of *Coreopsis* are all the species of *Compositae* that I think are used to any great extent by the bees. The golden-rods that are so highly prized in some localities are scarcely visited by the bees, and the same may be said of the many species of sun-flowers that brighten our landscapes through the autumn months.

The species that I have mentioned comprise the bulk of the honey-plants of southeastern Nebraska, though I have omitted some that in some localities and in some seasons undoubtedly yield some honey. In some instances the plants themselves do not occur in sufficient numbers to be of economic importance, while in others though plentiful, they are little sought by the bees.

Of all the great wealth and variety of bloom that covers and beautifies our wild prairies from May until November, including at least 15 species of *Leguminosae*, and more than that number of *Compositae*, not one, so far as I have been able to discover after years of close observation, are of any value as honey-plants. Our honey-producing plants grow in and around the margins of the timber, on the streams, or in the sloughs for short distances from timber, and in fields and waste places on farms. There is one plant growing in patches about the margins of the timber, and in sloughs near the creeks, that as a honey-producer prob-

ably surpasses any other plant in this portion of Nebraska, but on account of its peculiar habit of blooming, it is of very little value as a source of honey. The plant I refer to is *Glauca biennis*, of the evening primrose family. It blooms from the latter part of August until hard frost, and blooms in the evening after the bees have all gone home, and the flowers wither and dry up in the morning usually before it is warm enough for the bees to fly. The flowers secrete nectar in great abundance; sufficient in some observed instances to flow down the stiles and hang in drops on the stigmas.

As some of the readers of the AMERICAN BEE JOURNAL may contemplate a removal to Nebraska, I will add a few words on bee-keeping in Nebraska. There are very few large apiaries here, though quite a large number of persons keep a few colonies—from one to a dozen, and a few as high as 30 or 40—but I do not think that large apiaries would be profitable except possibly on the Missouri river, where there is plenty of white clover and some basswood.

I think that the country might be very easily overstocked, as nearly all the honey must be gathered along the streams. The high winds which prevail here through a great part of the honey season greatly interferes with the gathering of honey, and must at times totally prevent long flights in search of stores. While as I have said large apiaries might not be profitable, a few colonies in connection with some other business, and properly cared for, might pay well for the trouble. All kinds of hives are used here, though I know but one man that uses the old box-hive, and he never gets any surplus honey, but depends for his supply of honey on some of his colonies dying out in the winter, leaving him a legacy of dirty honey mixed with bee-bread and moth larvæ.

Artificial pasturage for bees has not yet been provided to any great extent. Some few have sown a little white and Alsike clovers. The Alsike has not so far proved a success, and the white clover is disliked for pasture on account of its causing horses to slobber, and is thought to be too insignificant for a meadow-grass, still the bee-keepers are sowing some, and it is spreading, and will be plenty in time; but neither white nor Alsike clover if cut for hay, will be of much value for honey.

Some have sown mustard, catnip and motherwort in waste places, with much satisfaction, but it is doubtful if it will pay to use good farm land for any crop that is only good for honey. My opinion is that if any plant will pay for good land, catnip and motherwort

will. It will seed itself after the first sowing, and is in bloom from July until frost, and during this time no day passes when the bees can work but that they work on it, whatever other plants may bloom at the same time; but as to the quality of the honey I cannot say, as we have never had it unmixed, but I hope it is better than the white sage honey of California, which I do not like.

Adams, Nebr.

TRULY GREAT.

A Visit from the Father of Practical Apiculture.

Written for the *American Bee Journal*
BY JAMES HRDDON.

I cannot convey to the minds of my brother bee-keepers the enjoyment which my family and myself experienced from the four weeks visit with Father Langstroth, which I shall always remember as an honor, and with the greatest pleasure.

I may say that prior to this time, and owing perhaps to his ill-health, I had had but little correspondence with him, always considering it a duty never to write to him except in answer to his letters. I had met him once in Detroit and in Chicago amid the rush and confusion of conventions, but knew so little of his character, that I believe what I am about to say will be interesting to the thousands of bee-keepers who have reaped rich rewards from his life work.

Nearing 80 years of age, and not in the enjoyment of very robust physical health, I was astonished to find his mental powers as young and vigorous as those of a man of middle age. Indeed, it was a rare treat to converse upon our favorite topic with the man whose clear, practical mind had transformed bee-owning into commercial honey-producing. Together we traversed the past in the field of apiculture, and never was I more interested and edified than in listening to his description of the early days of practical apiculture in this country, as well as to his trials in the introduction and defense of his own invention.

Twice while here he preached in the Congregational church, and I think I may safely say that many years have passed since our city has been honored with such beneficent and well-delivered sermons. His voice is round, full and melodious, fully equal to four times the capacity of any church in the city, and this, together with his impressive manner and kind, moral utterances, caused many wet eyes in his large audiences, and created very much

favorable comment among our church-going people.

His perfectly honest, sincere and kindly spirit sheds rays of sunshine over every household he enters, and while all regret his departure when the time for leaving comes, they rejoice in the effects of his presence while with them.

Thus I found him whom we bee-keepers have learned to love, and regard as our benefactor, a very exceptional and great man, entirely outside of his greatness as an apicultural inventor. I thank him for what he has written regarding my late invention; not for the facts which he has stated, for these were compelled convictions, but for the labor and pains which he took in gathering in and publishing to the public the important truths which his article contains, but I feel it my duty to make clear the fact that my own invention, and my knowledge of bee-culture which led to it, never could have been, but for his own of 37 years ago.

Before we can learn the conditions of the interior of a hive by outward symptoms, we must be able to dissect its interior, comparing these outward symptoms with its internal conditions. Father Langstroth's hive was the first ever constructed which made it practicable for the honey-producer to do this. Now we have learned to almost instantly determine internal conditions by outward symptoms, and this and the invention of comb foundation, giving us uniform combs, led to the first functional improvement of any importance in hives which has been made since Father Langstroth's, in 1851. The improvements which have been made have all been in the nature of detail mechanical construction; new and improved clothing for the better carrying out of the construction of Father Langstroth's great invention.

Dowagiac, Mich.

BEGINNERS.

A Few Seasonable Hints to the Inexperienced.

Written for the *Prairie Farmer*
BY MRS. L. HARRISON.

It is poor policy for beginners to purchase bees in boxes and barrels, as transferring is not the best kind of work for a novice. Better buy a good colony or two, not more, of Italians in a movable-frame hive. The Langstroth frame is to be preferred for this reason, that two-thirds of the scientific bee-keepers use this frame, and bees sell better in hives where this frame is used. Every hive in an apiary should

be exactly alike, so that every cover, frame, etc., can be mixed up and all fit when put together. Better choose a hive first, and not get a half a dozen different ones to see which is preferable.

Bees can be shipped long distances on the cars without injury, if packed correctly. I obtained my first lot of bees from Wisconsin, and the bottom-bars of the frames were placed in a board □□□ notched so that they not strike against each other. If the frames of a hive have not been removed this spring, this is not necessary, as they are fastened securely with propolis. Bees in transit need air, which can be admitted through wire-gauze, nailed over their fly entrance.

Persons who only do work by halves should never fix up bees for transportation, either by rail or wagon, for disaster will certainly follow. Bees that were sent off by a prominent bee-keeper were three weeks knocking about on the cars before reaching their destination, and arrived in good condition. In this case several thicknesses of woolen blanket were wrung out of water and spread over the frames. This served to keep them cool, and to furnish water. Bees should be fastened in their hives, when they are all in, or those loose in the air may follow and be very annoying. A man who moved his bees sixty miles in the cars, and traveled with them, told me that every time the train stopped a bee would fly in that appeared to follow them all the way. And when hives are moved in wagons these loose bees might follow and sting the horses. Night is the best time to fasten up a hive, as bees leave very early when the weather is warm.

When I ship bees I cut wire gauze and fit it into the entrance of an empty hive, by putting in the gauze and driving in a piece of wood which fits exactly. This gauze is then of the fit, and can be quickly slipped over the fly entrance and fastened along the edges by placing little strips of wood over them, and nailing. New muslin is spread over the frames, and a perforated board nailed on. The perforations serve to admit air, and to help to keep them cool.

Success in bee-culture is attained only by the faithful performance of many little items. Some persons never have any "luck" with bees, why? One year the moths destroyed them, and another season the swarms left while the hives were being made ready, washed with apple-tree leaves and salt. A person who expects to make a success in bee-culture must study their lessons well, learn the habits of these industrious insects and their wants, and supply them. Last year the honey crop was an almost

complete failure, owing to the severe drouth, and many colonies at present have not a day's ration ahead. Let there be a long continued cold storm, and bees in this condition must starve. Their owner must know their condition, and this is one of the good things of the movable-frame hive. Bees consume stores very fast in the spring, because of their rearing so much brood. Scientists tell us that an insect in its larvæ state consumes more food than during the remainder of its life. If a colony is short of honey, the best way to supply it is to remove as quietly as possible an empty frame, and insert a full one in its place. Where no frames of honey are obtainable, feed syrup made of any kind of sugar when bees are flying. Little wooden butter dishes make good feeders, as bees cling to their sides and never drown as they do in glass or earthenware, unless filled with cut straw or shavings. This spring I fed a lazy man's way—tied cheese cloth over large pans of syrup, and fed in the open air. When the syrup was lowered so that the bees could not reach it, I push the muslin down upon the surface so they could.

Peoria, Ills.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*
 Aug. 3. Ionia County, at Ionia, Mich.
 H. Smith, Sec., Ionia, Mich.
 Aug. 14.—Colorado State, at Denver, Colo.
 J. M. Clark, Sec., Denver, Colo.
 Aug. 27.—Stark County, at Canton, O.
 Mark Thomson, Sec., Canton, O.
 Sept. 8.—Susquehanna County, at Montrose, Pa.
 H. M. Seelye, Sec., Harford, Pa.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

Very Promising Prospects.—E. Liston, of Virgil City, Md., on May 25, 1888, writes :

Bees are just booming from honey-dew. The perstimons will be in bloom in a few days. The weather is warm and showery. The prospects were never more promising. It makes us all feel happy to hear the music they make; particularly so after having a total failure last year.

Bees Working on Early Raspberries.—Daniel Shank, Clayton, Ills., on May 24, 1888, writes :

While not extensively in bee-culture, yet I make it a side-issue. I have 16 colonies in box-hives. I have bought Langstroth-Simplicity hives for my swarms. I have read the AMERICAN BEE JOURNAL for two years, and I like it very much. I was on my farm yesterday, and found the rasp-

berries blooming; that is the early kind. I have fruited the Shaffer colossal for three years, and find them grand for fruit and honey, as they bloom later than any other raspberry. Every bee-keeper should add this berry to his stock. My bees are gathering honey fast now. White clover is scarce, owing to the drouth of last summer.

Quantities of Brood Chilled.—

Leslie Stewart, of Jefferson, N. Y., on May 25, 1888, writes :

The weather here is fair at present, but we have had about 3 weeks of wet and cold weather, which has given bees a bad setback, especially the weak ones. It has chilled quite a large quantity of brood, especially in colonies have young Italian queens, as such had more brood than they could cover. I do not think that more than two-thirds of the bees in this section will be able to store any surplus this season. Fruit will be in full bloom in about one week. I find that a colony having a young Italian queen will build up one-third faster than one of the same strength having a black one.

Queen-Bees to Canada.—S. W.

Morrison, M. D., of Oxford, Pa., on May 28, 1888, writes as follows :

At the request of the Superintendent of Foreign Mails I have sent two cages containing queens and their attendants "for transmission to the postal authorities of Canada," that they may "see the method of packing bees for transmission through their mails." If satisfactory they will be forwarded to Seaforth, Ont., and queens will be again allowed in the mails. I am confident that the matter will be arranged within the next week, so that queen-bees can again cross the lines in the mails.

Chick-a-Dees Eating Bees.—

Martha Smith, of Monroe, Wis., writes as follows on the above subject :

In regard to the chick-a-dees eating bees I will say that it is no uncommon thing here for them to eat dead ones in the manner described by Mr. Evans in this week's BEE JOURNAL. They will eat all they can find on the snow, and will alight on the porticos of the hives and get all at the entrances. Starvation does not cause them to do it, for they act just as bad when there is meat hanging on a tree near the hives. I have never seen them kill a bee, but they annoy them in summer. A chick-a-dee built her nest near the hives, and the bees would chase her from the hives to her nest.

Prospects now Good.—Mr. D. M.

Stoler, Saxton, Pa., on May 28, 1888, writes :

The last three weeks have been exceedingly wet and cool, so that the bees could not work half of the time. The prospects are now good for a prosperous season. The loss in this section during the winter was about 50 per cent.; principally in old-style hives. I wintered my bees on the summer stands, with Hill's device over the frames, with mats and loose wool packing. I put supers on three days ago, when I found the combs well filled with brood and honey.

Bees in Dakota.—Andrew Craig, of

Empire, Dakota, on May 21, 1888, writes as follows :

The spring here is unusually backward—cool with too much wind for bees to do well. They gathered no pollen from elms, as is usual; the weather being too cool and

windy at the time of its bloom. Cottonwood began to bloom, but was "nipped in the bud" by frost. We have had several frosts in May. On May 16 it snowed without freezing, and on the 17th there was frost and ice 1/2 of an inch thick. It is warmer now, and raining too much for farmers to get in their corn. I put into winter quarters 3 colonies, and all came through, but one was very weak, and was robbed to death by one of the others that was very populous. Had the weather been warmer, so that there would have been nectar to gather, no robbing would have occurred. Mine are the only bees I can hear of in this part of the territory.

Salt.—O. B. Barrows, of Marshalltown,

Iowa, writes the following on the uses of salt for bees and berries :

Several years ago the Iowa State Horticultural Society recommended the use of salt for strawberries. I tried it once only. I also tried N. W. McLain's receipt for the stimulation of spring breeding, viz: "Half a pint of dairy salt to 10 pounds of sugar," and I do not think I will ever try it again. Who else has tried it? How do they like it? My bees thought it a good thing to let alone.

Dandelions and Fruit Bloom.—

Francis M. Merritt, Andrew, Iowa, on May 30, 1888, wrote thus :

In my article on page 341, I am made to say that the white clover was just blooming. This is a mistake of the printer, for I wrote it "booming" instead of blooming, as the white clover is not in bloom yet. We are passing through a grand harvest of dandelion and fruit bloom. Bees are increasing rapidly.

CLUBBING LIST.

We Club the American Bee Journal for a year, with any of the following papers or books, at the prices quoted in the LAST column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	Club
The American Bee Journal	1 00	...
and Gleanings in Bee-Culture	2 00	1 75
Bee-Keepers' Magazine	1 50	1 40
Bee-Keepers' Guide	1 50	1 40
Bee-Keepers' Review	1 50	1 40
The Apiculturist	1 75	1 60
Canadian Bee Journal	2 00	1 80
Canadian Honey Producer	1 40	1 30
The 8 above-named papers	5 65	5 00

CONVENTION NOTICE.

The Hardin County Bee-Keepers' Association will meet at the Court House in Eldora, Iowa, on the second Saturday in each month, at noon (12 o'clock), until further notice.
 J. W. BUCHANAN, Sec.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near our post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2.00	3.00	3.50
1,000 Labels.....	3.00	4.00	5.00

✓ Samples mailed free, upon application.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Your Full Address, plainly written is very essential in order to avoid mistakes.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 18 cents per pound for bag and postage.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Cork for Winter Packing.—Its advantages are that it never becomes *musty*, and it is *odorless*. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Sweet, or Melilot, Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

New Subscribers can obtain the full numbers for 1887 and 1888, for \$1.75, while there are any sets of 1887 left.

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, \$1.00 per 100, or \$3.50 per 1,000.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Honey and Beeswax Market.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 13@15c.; the same in 2-lbs., 10@11c.; buckwheat 1-lbs., 10c.; 2-lbs., 9c. Market dull. We are doing all we can to reduce stock, to make room for the new crop.

BEESWAX.—26c.

HILDRETH BROS.,

May 21. 28 & 30 W. Broadway, near Duane St.

DETROIT.

HONEY.—Best white in 1-pound sections, 14@15c. Extracted, 9@10c. Supply decreasing slowly.

BEESWAX.—23c.

May 21. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—Prices range from 15@16c. for best one-lb. sections; other grades are slow, at lower prices. Extracted, 7@8c. Light demand, and supply larger than usual at this season of the year.

BEESWAX.—23c.

R. A. BURNETT,

May 1. 161 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 14@15c.; fancy 2-lbs., 12c. Lower grades 1@2c. per lb. less. Buckwheat 1-lbs., 10@10½c.; 2-lbs., 9@9½c. Extracted, white, 7@7½c.; dark, 5½@6c. Market is dull for comb but improving for extracted, of which new from the south is arriving.

BEESWAX.—Scarce, 24@27.

May 21. F. G. STROHMEYER & CO., 122 Water St.

CHICAGO.

HONEY.—We quote: Fancy white clover 1-lbs., 16@17c.; 2-lbs., 15@16c. Dark is slow sale at almost any price. Extracted is scarce, and sells at 7@10c.

BEESWAX.—23c.

Mar. 13. S. T. FISH & CO., 189 S. Water St.

CINCINNATI.

HONEY.—We quote extracted at 4@9c. per lb., for which demand is good. Comb honey, 14@17c.—Demand slow.

BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.

Apr. 23. C. F. MUTH & SON, Freeman & Central Av.

MILWAUKEE.

HONEY.—Choice white one-lb. sections, 16@17c.; 2-lbs., 15@16c.; 3-lbs., 14c. Extracted, white in kegs and ½-barrels, 8 to 8½c.; in tin and pails, 9½@10c.; dark in barrels and kegs, 5@7c. Market fair.

BEESWAX.—22@25c.

Apr. 23. A. V. BISHOP, 142 W. Water St.

DENVER.

HONEY.—Best white 1-lb. sections, 17@19c.; 2-lb. sections, 15@17c. Extracted, 7@10c.

BEESWAX.—20@23c.

Mar. 1. J. M. CLARK & CO., 1409 Fifteenth St.

KANSAS CITY.

HONEY.—We quote: Choice white 2-lb. sections, 17@18c.; dark 2-lbs., 14@15c.; choice white 1-lbs., 13 to 20 cts.; dark 1-lbs., 15@16c. White extracted, 7@8c.; dark, 5@6c. Demand is slow. White extracted is firm when in 60-lb. tin cans.

BEESWAX.—21 to 22c.

Mar. 29. HAMBLIN & BEARSS, 514 Walnut St.

BOSTON.

HONEY.—We quote: 1-lb. sections, 16@17c.; 2-lb. sections, 14@16c. Extracted, 8@9c. The market is not very brisk and sales are slow.

BEESWAX.—25 cts. per lb.

Mar 24. BLAKE & RIPLEY, 57 Cbatham Street.

SAN FRANCISCO.

HONEY.—We quote for new extracted 6@4½c., as to color and quality. New comb honey 14@10c., as to quality. Arrivals are still small, and demand of a jobbing nature.

BEESWAX.—Scarce, 20@24c.

June 2. SCHACHT & LEMCKE, 122-124 Davis St.

KANSAS CITY.

HONEY.—We quote: White 1-lbs., glassed, 16@17c.; unglassed, 17@18c.; and dark 1-lbs., glassed, 15c. unglassed, 16c.; white 2-lbs., glassed, 16c.; unglassed 2-lbs., 17c. California white 2-lbs., 17c. California extracted in 60-lb. cans, 8c. Market quiet and receipts are larger.

BEESWAX.—No. 1, 20c.; No. 2, 18c.

Mar. 19. CLEMONS, CLOON & CO., cor 4th & Walnut.

We have some ELEGANT RIBBON BADGES, having a rosette and gold Bee, for bee-keepers' use at Fairs, Conventions, etc. Price 50 cents each, by mail, postpaid.

THOS. G. NEWMAN & SON,

923 & 925 West Madison-Street, - CHICAGO, ILLS

TESTED ITALIAN QUEENS, \$1 each; untested, 75 cents each; 3 for \$2; 12 or more 65 cents each. 75 cents per pound for bees. Albino queens same price.
23A1f **I. R. GOOD**, Nappanee, Ind.
Mention the American Bee Journal.

EXTRA THIN FOUNDATION 40 cts. per pound—job lot—12 square feet to the pound. Write quick to
OLIVER FOSTER,
23A1t MOUNT VERNON, IOWA.
Mention the American Bee Journal.

ALBINO QUEENS. I will furnish pure queens of this gentle and beautiful race of bees in this season at the following prices: Warranted queen, \$1.00; tested, \$1.50.
23A1t **JOS. MOSER**,
FESTINA, Winneshiek Co., Iowa.
Mention the American Bee Journal.

THE OLD AND RELIABLE KNICKERBOCKER BEE-FARM
(ESTABLISHED 1880.)
It will **PAY** you to send for our Circular and Price List of Bees and Queens before ordering elsewhere. Address,
GEO. H. KNICKERBOCKER,
23D2t (Box 41) PINE PLAINS,
Duchess Co., N. Y.
Mention the American Bee Journal.

Canadian Hardy-Working Stock!
NEW BLOOD!
HAVING secured queens from three of our most successful honey-producers (J. B. Hall, S. T. Pettit and Martin Emigh), I am prepared to furnish queens from the above strains, at the following prices: Virgins, 50 cents; untested, \$1.00; tested, \$2.00; selected, \$3.00. Three at one time, deduct 10 per cent. Six at one time, 20 per cent. In ordering, mention which strain you prefer. The last named are pure Italians. The first two, almost pure Italians—all carefully selected for desirable qualities. Sent post-paid. Until postal difficulties between Canada and United States cease, I have arranged to express queens every 10 days to Detroit, from which place they will be sent by mail to American customers. Orders booked in rotation. No queens mailed until July 1 at the above prices.
Address, **R. F. HOLTERRMANN**,
23A8t Ed. Canadian Honey Producer,
BRANFORD, Ont., Canada.
Mention the American Bee Journal.

The Bee-Keepers' Review
FOR MAY is now out. Having regained the time lost during his illness, the editor will hereafter take pride in getting out the REVIEW promptly on the 10th of each month. The special topic of the present Number is "Hiving Bees." The review of Mr. Cheshire's work, which was begun in the March No., is finished in the present issue. We have a surplus of the Numbers containing this review, and, so long as they last, these three Numbers will be sent free to all who apply.
Price of the REVIEW, 50 cts. a year.
The Production of Comb Honey,
A neat little Book of 45 pages, price 25 cents. The REVIEW and this book for 65 cents. Stamps taken, either U. S. or Canadian.
Address, **W. Z. HUTCHINSON**,
20A1f 613 Wood St., FLINT, MICHIGAN.
Mention the American Bee Journal.

NEW ONE-POUND HONEY PAIL

THIS new size of our Tapering Honey Pails is of uniform design with the other sizes, having the top edge turned over, and has a ball or handle, making it very convenient to carry. It is well-made and, when filled with honey, makes a novel and attractive small package, that can be sold for 20 cents or less. Many consumers will buy, in order to give the children a handsome toy pail. Price, 75 cents per dozen, or \$5.00 per 100.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. June 13, 1888. No. 24.

EDITORIAL BUZZINGS.

Beautiful billows of blossoms,
Rolling o'er orchard trees,
Pink and white foamy the blossoms,
Floating away in June breeze.
Would I might rest here forever,
Bathed in these apple-bloom seas.
Here 'mid the wealth of the orchard,
In silence, save sound of the bees.

The Honey Crop of California is said to be large, and the product is of the very best quality.

Spring Dwindling has been very severe among the bees. The Saginaw, Mich., *Courier* remarks that Mr. John Rey was unfortunate enough to lose 116 colonies by spring dwindling. He is not discouraged, however, and proposes to purchase enough to replenish the hives.

Sweet Clover.—A correspondent in *Gleanings* has the following to say about sweet clover :

I have raised it four years with good results. The first year I had about three-fourths of an acre, and 10 colonies of bees. In the latter part of June the sweet clover came into bloom, and soon the bees found it. In a week more it was a regular hum in the patch from 9 o'clock until dark. It was the only patch for miles around, and there was scarcely anything else yielding honey at that time, so that the neighbors' bees had time to help take care of the honey in the sweet clover, and they did. My uncle lives two and a half miles in a bee-line from here, and had about 25 colonies; and such a stir there was among them for this little patch! Why, we just had a strong bee-line from here to Uncle Abraham's.

New Subscribers can obtain the full numbers for 1887 and 1888, for \$1.75, while there are any sets of 1887 left.

The Wiley Lie in England.—Again we have to remind our British cotemporary that it is doing American bee-keepers a great injustice in asserting that comb honey is adulterated here. It is untrue, and the British *Bee Journal* ought to know that. He quotes a report by "the dairy commissioner of New Jersey," on the purity of "strained honey," which shows that it is itself a fraudulent statement in the fact that three samples mentioned near the top of the list are "comb honey," and not extracted, erroneously and ignorantly called "strained" by the doughty "commissioner!"

These slips were distributed at the New York convention last winter, and we will here quote what our friend A. I. Root, who was present, says about it in *Gleanings* for June 1, 1888 :

At the Bee-Keepers' Convention in Utica, N. Y., last winter, one of Thurber, Whyland & Co.'s men was very busy in distributing circulars to the bee-men. He had a great pile of them, and evidently made it his business to spread them broadcast. These slips of paper gave an analysis of honey which was made, as was stated, by the dairy commissioner of New Jersey. We do not know who this dairy commissioner is, nor how good an authority he is; but when I first glanced over the circular, I felt a little troubled to see that it contained a list of names of good and responsible firms who were accused of selling adulterated honey. In fact, almost every sample of honey that was examined, according to that report, was adulterated, with the exception of a few samples from private farmers or bee-keepers, with one other exception. This exception is Thurber, Whyland & Co.

Now, the singular part of the whole thing is, that samples Nos. 57, 58 and 60 were *comb* honey, and not *strained* honey, although the heading in small capitals, at the top of the list, says "strained honey."

Friend Cowan takes the matter up, and reflects somewhat on American honey, especially the fact that the American comb honey in our markets is, at least some of it, adulterated.

The *Bee-Keepers' Magazine* also indorses the paper, and makes some severe reflections on firms that we believe to be good and honorable men.

I am exceedingly glad to know that the Thurbers, who so recently put up honey with corn syrup in it, to keep it from candying, have reformed to such an extent as this circular indicates, but I do not believe that everybody else has gone into the adulterating business.

We have instances on record before, where some sort of a chemist has pronounced absolutely pure honey, gathered from the flowers by honest bees belonging to an honest bee-keeper, adulterated.

Who can give us some further information in regard to this dairy commissioner of New Jersey, and this statement given by the *American Grocer*, presenting such a disgraceful showing of the bee-keeping industry of the United States?

I thoroughly indorse all that the *British Bee Journal* has to say in regard to Hoge; and the whole matter looks very much as if Hoge still had hold of the crank. But we beg our English cousins to remember that the American people are not all Hoges, by any means.

The editor of the *British Bee Journal* copied the report of this "commissioner" from the *Bee-Keepers' Magazine*, and it is but just to say that no other bee-periodical in America has ever given publicity to it.

It was sent to the AMERICAN BEE JOURNAL, but being convinced of its unreliability we refused to publish it. Here is what our British cotemporary says by way of introduction :

We have long been aware that American dealers adulterated honey, but we must confess that we were not prepared for the revelation made in the "Bee-Keepers' Magazine" for April. It appears that the Dairy Commissioner of New Jersey has had honey purchased in different towns in the State, and has had it analyzed. Out of *thirty-one* samples of honey put up by packing-houses, only *six* were found to be pure! We reprint the list furnished by our cotemporary, and commend it to the careful study of every bee-keeper.

After enumerating some of the lots analyzed, it again says :

Where does this adulterated comb honey come from? Not from respectable bee-keepers, of that we are quite sure. We have the authority of Mr. Shippen Wallace, Ph.D., for the fact that this comb honey is adulterated, and it is therefore produced. How? That is the secret. Shall we also be told that this is a WILEY LIE, or is there any other explanation than that adulterated comb honey is manufactured on some of the adulterating farms by feeding bees? We are glad to notice that not a single sample of honey purchased of bee-keepers was adulterated. Further comment is unnecessary.

All we can say to our British friends is, that they have been again "taken in," not by a "clergyman" this time, but by a so-called "Professor." We positively deny the soft impeachment. It has no foundation except in the Wiley LIE, when any one says that comb honey is adulterated! That wilful liar is responsible for all this clap-trap nonsense!

Foolish Abbreviations.—Many still persist in using abbreviations when writing to this office. One lately wrote a letter and enclosed money, addressing it to "A. B. J., Chicago." It is a wonder that it ever got to us, and probably many others similarly addressed have been lost. Who among the general public knows what "A. B. J." stands for? They may puzzle their brains over it, and finally conclude that it was intended to indicate "a bright judge," "a big jewel," "a bouncing jockey," "a brown jug," or "a bad jest!!" And perhaps the latter would be the most appropriate cognomen for the cabalistic and unintelligible letters!

We would call the special attention of those who wish to have their letters reach us, to section 574 of the "Postal Laws and Regulations," which reads as follows, and is commended to the consideration of all interested :

Letters and packages addressed to fictitious persons and firms, to initials or to no particular person or firm, unless directed to be delivered at a designated place, such as a post-office box, street or number, or to the care of a certain person or firm within the delivery of the post-office, are undeliverable, and must be sent to the Dead Letter Office unless the envelope contains the card of the sender, or a request to return, in which case the letters or packages must be returned accordingly.

GLEAMS OF NEWS.

The Union and the Wiley Lie.

Mr. G. M. Doolittle, of Borodino, N. Y., Vice President of the Bee-Keepers' Union, sends us the following item, and his remarks, and the subsequent correspondence between himself and a new champion of Wiley's diabolical "scientific pleasantry."

Mr. Doolittle says: "The following is a copy of an item which I wrote for the *Rural Home*, which appeared in the issue of that paper for May 5, 1888:

Here is an item which is going the rounds of the papers. Mr. Root, of Ohio, has a standing offer of \$1,000 for a sample of manufactured honey in the comb. This should have a good effect on our industry, and will do much to counteract the story told by Prof. Wiley, of the United States Government fame, who told as a "scientific pleasantry" the story, that there was lots of honey on the market, selling as genuine comb honey, which was nothing more than manufactured stuff, the combs being made of paraffine, and the honey they contained being of glucose. From the latter, imaginary places sprang up in Chicago, New York, and elsewhere, where comb honey was turned out by the ton, all working well until the past poor season, when honey went from a drug on the market, at the low price of 10 to 12 cents per pound, to a scarcity, scarcely obtainable at the high figure of from 20 to 25 cents. This effectually squelched the Wiley lie, and caused the papers to notice the offer of Mr. Root, which was made several years ago.

A Virginian takes exceptions to the above item, and wrote to the *Rural Home* as follows about it:

AMHERST, Va., May 4, 1888.

EDITOR RURAL HOME:—In May 5th *Rural* I notice under "Bee Notes," that Mr. Root, of Ohio, has a standing offer of \$1,000 for a sample of manufactured honey in the comb, and the further statement is added by Mr. Doolittle, "This should have a good effect on our industry, and will do much to counteract the story told by Prof. Wiley, of United States Government fame, etc."

Then Mr. D. says, because honey was so high last year, "the Wiley lie was squelched." Now, Mr. Editor, if you will open your columns to a fair, open, and honest ventilation of the question, I will show who the little niggers are in this wood pile.

I deny that any "responsible" man has ever made such an offer, and more, I dare any one to make one like it. One of the largest dealers in glucose and syrups, told me four years ago, that the apiarists of Pennsylvania, New Jersey and New York States were then buying large quantities of it. What for? Why, to feed the cows, of course. I will wager \$1,000 that the Wiley lie is true, as to the adulteration of comb honey. Come on saints and sinners, "Barkis is willin'."—W. M. EVANS.

This bold and bombastic letter was answered as follows by Mr. Doolittle:

BORODINO, N. Y., May 16, 1888.

W. M. EVANS.—Dear Sir:—Your letter to the *Rural Home*, regarding the adulteration of honey, has been forwarded to me, and I have this day written to the Manager of the Bee-Keepers' Union (a society to protect our interests), and to Mr. Root, who will doubtless give you a chance to prove

your position, or lose the \$1,000 you wager. The story told you four years ago by a glucose dealer, will do to tell, but may lack of proof on investigation. Yours truly,—G. M. DOOLITTLE.

Promptly Mr. A. I. Root, who is also a Vice-President of the National Bee-Keepers' Union, wrote to Mr. Evans, informing that doubter that A. I. Root was a real living man, and not an imaginary phantom! that he made the offer of \$1,000 for proof "that honey-comb is made, filled with glucose, and sealed up by a machine made for that purpose!" that he lived at Medina, Ohio! that his responsibilities in commercial circles could easily be ascertained from Bradstreet's Agency, and enclosing his "business card!"

Mr. Evans was nonplused. He wrote to Prof. Wiley to help him out of the difficulty, and here is Prof. Wiley's reply:

WASHINGTON, D. C., May 29, 1888.

W. M. EVANS.—Dear Sir:—In regard to the matter of artificial combs of which you wrote me under date of 25th inst., permit me to make the following statement: About eight years ago a very intimate friend of mine, an eminent chemist, Dr. E. J. Hallock, now deceased, told me that in Boston, where he then resided, there had been constructed a full outfit of machinery for the manufacture of artificial comb. He stated further, that this comb was filled with glucose or artificial honey and sold for the pure article. On the basis of this testimony I made a statement in an article I wrote for the *Popular Science Monthly* to the effect that such artificial comb and honey were made.

At the time, I repeated this statement more in the light of a pleasantry than as a commercial reality, for I did not believe that it was possible commercially to imitate the comb, although I did not doubt at the time that attempts had been made in this direction. It is, however, quite a common custom to make an artificial base for the comb, and bee-keepers do not deny that this is done. Some persons, in a malicious spirit, have constantly circulated this statement of mine for the purpose of injuring me professionally, and their failure to do so has only made their persecutions more bitter.

Since Dr. Hallock is dead, I have no evidence except my own statement to offer in regard to the accuracy of the report. It is possible that Dr. Hallock may have been misinformed in regard to the matter, but he was perfectly honest in making the statement to me, and I was perfectly sincere in repeating it. Respectfully,

H. W. WILEY, Chemist.

In the foregoing letter Prof. Wiley makes this astonishing confession: "At the time, I repeated this statement more in the light of a pleasantry than as a commercial reality, for I did not believe that it was POSSIBLE commercially to imitate the comb."

Therefore, he "knowingly, wilfully and maliciously" lied out of whole cloth just to cause a sensation, and to injure an honest pursuit, for the paltry pay which the *Popular Science Monthly* gave him for the article!!!

It is astonishing that any man could make such a bare-faced confession without blushing for the infamy it exhibited!

To lie for the filthy lucre it brings is bad enough, but when he permits that lie to be copied all over the world, and to be used to injure an honest business, without making

the least endeavor to arrest its evil effect by an honest contradiction—the crime is doubled!

Without the least compunction of conscience he wrote "the statement" as to the manufacture of comb honey when he "did not believe that it was possible commercially to imitate the comb"! Infamous!!!

As is usual in such cases, a liar will add to the number of his crimes to hide his meanness. So Wiley winds up his letter by asserting another falsehood, thus: "I was perfectly sincere in repeating it." Could a man be sincere in repeating what he knew to be a falsehood?

He knew it to be impossible "to imitate the comb," and yet (over six years ago, and never tried to contradict it) he wrote this sentence:

"In commercial honey, which is entirely free from bee mediation, the comb is made of paraffine, and filled with pure glucose by appropriate machinery."

Now he wants us to believe that he "was perfectly sincere" in the assertion.

The attempt to justify himself because bee-keepers use comb foundation (that is sheets of pure beeswax, with corrugations corresponding to the base of the cells) is as mean as it is futile.

To take the pure beeswax from the bees, melt it, and thereby take out its dirt and impurities, and give it to the bees again for use at just the time they need it, is no excuse for lying about "making the combs of paraffine and filling them with glucose!"

After receiving the above letter from Prof. Wiley, and getting no proof from it to sustain his bombast, Mr. Evans wrote as follows to Mr. Root:

AMHERST, Va., May 31, 1888.

MR. A. I. ROOT.—Dear Sir:—This letter settles the fact as to Wiley's statement, but it does not refute the fact that Doolittle, in his note to the *Rural Home*, so worded his reference to your \$1,000 offer, as to mislead the minds of the readers as to the real facts. If he had published the \$1,000 reward, and the 4 or 5 lines following (or 2 lines), then no one would have been deceived.

I made the statement two years ago in the *Rural Home*, that comb honey was being adulterated by feeding the bees mixtures, which is a fraud upon the public. Will you open the columns of *Gleanings* for a ventilation of this matter? And will you advocate the formation of anti-adulteration bands?

I mean that the facts shall be known, and shall use the public press freely. An adulterated religion, which uses the essence of hell (fermented wines), and calls it "the blood of Jesus," is one cause of the universal prevalence of adultery, and the adulteration of most everything we eat, drink, wear, and use; and I think it is about time this hell-disease was crushed, but it cannot be done by "wind religion," but only by work for God and humanity. More Golden Rule lived, and less praying and preaching will do it. Prayer in action is the kind needed now—wind is too cheap!—W. M. EVANS.

The last paragraph shows that Mr. Evans is a "crank" of the worst type.

He threatened and blustered. He asserted most positively that there was no such person as A. I. Root! that no responsible man

ever made an offer of \$1,000 for a sample of manufactured honey in the comb! and *dared* an one to make such an offer! He also would "wager \$1,000 that the Wiley lie is true!" and tauntingly added, "Come on saints and sinners, Barkis is willin'."

It shows that it was all bombast and bluff, for as soon as Mr. Doolittle referred the matter to the Bee-Keepers' Union, he wrote to Prof. Wiley, begging for even some slight proof of that *old lie*!

When confronted by our co-laborer, Mr. A. I. Root, who is also Vice-President of the National Bee-Keepers' Union—who also assured him of his *real existence!* and proved that he was no *imaginary* individual, or a financially worthless being—then the *noble patriot* tries to back down; but to show some slight degree of fighting qualities, he proposes to "fight a woodenman, in the shape of adulterated honey!"

He blamed Mr. Doolittle for not doing the very thing that he did do—and in every-way shows that he was frustrated—beaten at every turn—and his vaunting is trailed in the dirt before his very eyes!

Such insolent braggarts must be taught to make sure of their proofs before vauntingly parading them in the face of the intelligent public. The National Bee-Keepers' Union exists to teach the impudent, in a fearless manner, that Truth shall triumph, even though such a "Goliath" shall defiantly and tauntingly say: "Come on, saints and sinners, 'Barkis is willin'."

Audacity cannot win, especially when the National Bee-Keepers' Union lifts up a standard, and defends the pursuit.

Lawyers, doctors and ministers have been caught repeating the diabolical Wiley lie, and even the unknown and unheard-of Virginian essays to repeat it! But all have come to grief before the Union's triumphant banner of truth!

He Forgot.—An exchange tells the following story. It will raise a laugh, and that is as good as a dose of medicine. It says:

A forgetful man's wife sent him to a drug store for some honey. He forgot the name, but remembered how it was made, and had a painful memory of having come in contact with the fire department of the honey-maker, so he asked the druggist for "some swate oil, made by a vicious little baste with a hot fut." The man of drugs, not comprehending the man, called his wife to aid him in interpreting the words of the son of Erin. In the call he addressed her as "Honey." "That's what I mane," said Patrick. "Honey is the thing. That's what I call me own darlin' Bridget, and I am mad at meself for not thinkin' of me own Honey as a kind of reminder like of what I was after buyin'."

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*
 Aug. 3. Ionia County, at Ionia, Mich.
 H. Smith, Sec., Ionia, Mich.
 Aug. 14.—Colorado State, at Denver, Colo.
 J. M. Clark, Sec., Denver, Colo.
 Aug. 27.—Stark County, at Canton, O.
 Mark Thomson, Sec., Canton, O.
 Sept. 8.—Susquehanna County, at Montrose, Pa.
 H. M. Seelye, Sec., Harford, Pa.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

SELECTIONS FROM OUR LETTER BOX

White Clover.—C. V. Lindley, of Sylvania, Ind., on June 4, 1888, asks the following question:

Will you answer through the BEE JOURNAL the following question, for the benefit of the bee-men in Parke county: Will white clover bloom the first year from the seed? The old clover was about all killed out last winter, but the young clover is coming up.

[It will bloom the first year from the seed. It is late this year on account of the backwardness of the season, or it would be in bloom now.—Ed.]

Hold your Breath.—L. Hammer-schmidt, Amana, Iowa, writes on June 8, 1888, as follows:

In the *Scientific American* for June 2, 1888, I find this statement: "If you hold a bee by the legs, between two fingers, and not let her sting on the fleshy part of your finger's point, as long as you hold your breath, the sting will not penetrate the skin." I have tried this, and found it to be correct; even more, I have put my hand between two combs full of bees; have taken a hand-full of bees, and when I sweep off the bees from a comb, as long as I can hold my breath, they will not sting. Will some others of the fraternity try this and report?

Putting Bees Out of Cellars.—Julius Le Fevre, of Pottsdam, N. Y., writes as follows on the above subject:

I started the spring of 1887 with 3 colonies of hybrid bees. I increased them to 7, and obtained from them 100 pounds of comb honey. I put them in the cellar on Nov. 27; the temperature ranging in my cellar from 30° to 35° all winter, from Dec. 25 until about March 15. They wintered well, although many of the bees died from March 15 until I put them out on April 27, at 1 p.m. It was a very hot day, being 85° in the shade. I do not think that it is a good plan to put bees out when it is so hot, for this reason, that some of the colonies will swarm out. Three colonies of nine swarmed out before they marked their locations, and became badly mixed up. They went to one of my neighbor's and alighted, and clustered on a small tree, and they remained there for some time. When I came home (about 5 o'clock) they were gone; so I lost them. Well, I think that this will learn me a good lesson, by experience. The morning is the best time to put bees out, when it is cooler

than 85° in the shade. I received two packages of the Chapman honey-plant seed in March. I planted the seed on April 1, and it is doing well. The AMERICAN BEE JOURNAL is just what every bee-keeper needs to read, and post up on bee-keeping. I should feel lost without it.

Not Much Honey from Apple Bloom.—A. Damarin, of Mason City, Ills., on June 8, 1888, writes:

I had 6 colonies of bees on the summer stands. I lost 3, and the others are straggling. It was too cold during apple bloom for bees to get much honey. White clover is beginning to bloom, what little there is left. I do not look for much honey this season. Nearly everybody has given up bee-keeping around here, on account of last year's failure. I shall keep on trying.

White Clover in Bloom.—J. W. Bittenbender, of Knoxville, Iowa, on June 8, 1888, writes:

Bees are swarming, but are gathering very little honey. White clover is in bloom, but the weather is too cool; the wind is mostly in the north and northwest. The nights are very cool for this time of the year. Unless the weather will soon change, the honey crop will be short.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the *American Bee Journal* must be sent with each order for another paper or book:

	Price of both.	Club

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

QUERIES AND REPLIES.

Enforced Queenlessness of a Colony During a Honey-Flow.

Written for the American Bee Journal

Query 550.—1. Does it pay to remove the queen from a colony of bees during a good honey-flow? 2. If so, what do you do with the queen?—Minn.

No.—J. P. H. BROWN.

No.—DADANT & SON.

1. No.—MRS. L. HARRISON.

1. No.—A. B. MASON.

1. No.—J. M. HAMBAUGH.

1. I have never tried it.—EUGENE SECOR.

1. No; I think it is better to contract the brood-chamber.—R. L. TAYLOR.

I am of the opinion that such a removal will not pay, all things considered.—G. M. DOOLITTLE.

No; just the reverse pays; contract the brood-chamber.—JAMES HEDDON.

1. No. 2. As it does not pay to remove her, leave her where she is.—M. MAHIN.

1. No, not for me. 2. Leave her where she belongs.—H. D. CUTTING.

I do not think it pays to remove the queen from a colony at any time.—P. L. VIALLO.

1. In a short honey flow it may, but not otherwise. 2. She may be preserved in a small nucleus if desirable.—G. L. TINKER.

If ever I want a good queen in the hive, it is during a good honey flow. It pays to have one there at all times.—C. H. DIBBERN.

1. It is a disputed point. 2. If you take her away, she can be kept in a nucleus, or a new colony can be formed.—C. C. MILLER.

I think not. Some excellent apiarists practice this, and like the plan. The queen is kept hard by, usually in a nucleus, often above the old hive, ready to put back at the close of the season.—A. J. COOK.

1. It will depend upon the locality. It will not pay with myself. 2. As I do not remove the queens, I leave it to the ingenuity of those who do, to suggest an answer.—J. E. POND.

1. It has not realized for me. 2. The queen, while trying the the experiment, may be given a comb of brood and adhering bees, and one or two empty combs, and kept in a nucleus hive until the experiment is concluded, and may then be restored to her colony.—G. W. DEMAREE.

1. It does not, most certainly. A colony without a queen is in an unorganized state, and if storing honey all sorts of results may be looked for. Laying workers often make their appearance, and pollen will be distributed throughout the surplus department as well as the brood-nest. If you do not breed bees you will breed moths. 2. I would not do it.—J. M. SHUCK.

It is unnatural to have a colony without a queen at any time, and we very much doubt the utility of any management which requires such a thing as taking her away, even in a good honey flow. Especially is it undesirable for the inexperienced to attempt such a procedure.—THE EDITOR.

Bee-Spaces at the Ends of the Frames, and on Top.

Written for the American Bee Journal

Query 551.—1. Are the bee-spaces at the ends of frames, in such hives as the Langstroth, of any benefit, except to keep the bees from sticking the frames to the inside of the hive? 2. Is a bee-space over the frames sufficient for all purposes?—Bee-Keeper.

1. Yes. 2. No.—A. B. MASON.

1. No. 2. Yes.—A. J. COOK.

Yes, to keep from crushing the bees in handling.—DADANT & SON.

1. Practically, no. 2. Yes, and practically an absolute necessity.—JAMES HEDDON.

A bee-space is worse than none inside of a brood-chamber, except where movable frames are used.—G. M. DOOLITTLE.

No benefit except to keep from "sticking." Not absolutely necessary. J. P. H. BROWN.

1. They are not. 2. For all purposes except that mentioned above.—M. MAHIN.

Yes, bees should have access to their combs from all sides, as well as the top.—J. M. HAMBAUGH.

I think not; but I believe the spaces can be afforded for the convenience of the bee-keeper.—G. L. TINKER.

1. For no other benefit. 2. Yes; but in hot weather a cap or protection from the hot sun must be used.—P. L. VIALLO.

The spaces at the ends of the frames furnish a passage-way for the bees, but the space above the frames is sufficient.—R. L. TAYLOR.

1. I suppose that to be the reason of so making them. 2. In summer, yes; in winter, no.—EUGENE SECOR.

1. They are a great help in rapid work. 2. One space is good, but for comb honey two spaces is better.—H. D. CUTTING.

1. Yes, they afford a passage for the bees at times, in hot weather for a current of air. In cold weather when the bees are quiet, they approach somewhat near, a dead-air space for the purpose of non-conductors. 2. Yes.—MRS. L. HARRISON.

The object of the bee-spaces is to make the frames *movable*. Except for that, during most of the year no space is needed either above or at the ends.—C. C. MILLER.

1. They allow full and free access to all parts of the hive, and that is the purpose for which they were originated. 2. Yes, except for wintering, when I prefer at least an inch of space.—J. E. POND.

Yes. The space acts to an extent as a non-conductor of heat and cold. Combs are not so liable to melt down in summer, and the bees are warmer in winter with this space than without it. The Langstroth principle of a bee-space *all round* the frames is now and forever right.—J. M. SHUCK.

I have never seen any other use for such spaces except those mentioned, unless it be a convenient loafing place for lazy bees. It is also a good place to mash bees when handling the frames. In my new hive I use frames the ends of which form the end of the hive, and I find them much more easy to handle, and bees summer and winter just as well in them as any other.—C. H. DIBBERN.

Mr. Langstroth arranged the bee-spaces all around the frames, to give the bees full control of every part of the inside of the case, and to induce the bees to do their gluing in the joints of the case instead of gluing the frames, as they never fail to do if there are no bee-spaces between the frames and the case. A bee-space over the frames is all right, and I think essentially right, and in a warm climate the bee-spaces cannot be dispensed with at the ends of the frames. I have transferred bees from the Mitchell hive, which had closed-end frames, fitting closely to the case, and found lots of ants and moth worms between the frames and the case. Frames cannot fit so close that ants cannot annoy the bees.—G. W. DEMAREE.

1. Bee-spaces at the ends of the frames are not only for the purpose of passage-ways, but also for convenience in lifting the frames in and out, additional to the uses mentioned in the query. 2. Bee-spaces over the frames are quite necessary on many accounts, both in warm and cold weather.—THE EDITOR.

CORRESPONDENCE.

CANADA.

Annual Meeting of No. Middlesex
Bee-Keepers' Association.

Written for the American Bee Journal
BY R. F. HOLTERMANN.

The above meeting was held in the Court House at Ailsa Craig, on May 24, and opened at 2 p.m. President Frank Atkinson occupied the chair. The usual attendance has been from 60 to 80, and only Oxford county can boast of meetings superior to that of Middlesex. The 24th of May being the Queen's birthday, many bee-keepers were away on pleasure trips.

The election of officers resulted as follows: The President was re-elected; Vice-President, W. J. Wilson, Greenway; Secretary-Treasurer, A. W. Humphreys, Park Hill; Directors, Jas. Mathews, D. Smith, J. B. Aikes, John Anderson, A. W. Humphreys, and W. J. Wilson were elected to represent the association at the Western Fair.

The question of affiliation with the Ontario Bee-Keepers' Association was then brought up, and after the benefits of such a step were explained by R. F. Holtermann, who was requested to do so by the President, a resolution was passed, instructing the Secretary to apply for such affiliation.

The benefits are for 1888 briefly as follows: Five dollars must be paid by the society affiliating, and it must have five members paying their membership fee of \$1 to the Ontario association. In return, every member of the Ontario gets one queen, purely mated. The association gets \$35 for the advancement of bee-keeping, and the members are allowed to choose two representatives who are entitled to all the privileges which members of the Ontario are granted.

Jas. Husband and Dave Collins were elected representatives for the year.

The funds on hand showed a handsome balance of 10 cents.

After selecting Park Hill as the place of the next meeting, upon reconsidering the matter, Strathroy was selected, with the time, February.

It was resolved that henceforth the association should be known as the Middlesex Bee-Keepers' Association.

Bee-questions were now brought up, and just here is it not rather to be regretted that these meetings should be taken up with so much necessary business.

Question:—"Is there any difference in the activity of colonies?" The general impression appeared to be that

there was; even when outward conditions appeared the same, a good queen was necessary. But conditions might appear similar, and yet not be. If a colony appeared inactive, and its neighbors working, it should be examined. It might be queenless; the brood-chamber might be clogged with honey, or from other causes it might have difficulties which might be remedied.

Question:—"How long will a drone live?" Several instances were related where drones had lived through the winter. D. Smith stated that he had a colony which had a queen, and yet permitted its drones to live through the winter.

Question:—"What is the best way to control swarming?"

This brought on quite a discussion as to the advisability of artificial swarming. W. Aikes practiced artificial swarming by dividing.

A bee-keeper from Brantford claimed that at the present prices of bees in the spring, the price only covered the hive, combs and honey consumed, and every colony lost, meant a loss of winter stores, therefore increase was not desirable. He kept down increase by giving shade, ventilation and room. The aim being to prevent the desire to swarm. If this, however, was established, he never broke down queen-cells, but let them swarm, putting the new swarm on the old stand with the old super. Second swarms were returned at the close of the second day, when one queen would be killed.

Aiming at breeding a strain of bees which would not readily swarm was advised. The advantages of Italian and Holy Land bees were brought out.

Some heavy losses from spring dwindling were reported, owing to an unfavorable spring.

Brantford, Ont.

HINTS FOR WORK.

What to Do, and How to Do it
Judiciously.

Written for the Western Plowman

BY C. H. DIBBERN.

The winter losses of bees have proved much more serious than was expected a month ago. All over the North, where the drouth was serious last season, bees have died principally from starvation. Some, however, have died with plenty of honey in the hives, and the cause is not so easily determined. It is probable, however, that the honey was of a poor quality, and long confinement in severe weather wrought the mischief. Wherever the honey crop was fair last week, they

seem to have wintered much better, and some are now reporting the bees as "booming." My own experience at the Rock River Apiary is not so encouraging. We have 130 good colonies left out of 180. This is the greatest loss we have ever had, in my experience of over twenty years. Many farmers have lost all they had, and I think I am safe in estimating a loss in the northwestern States of one-third. Surely, this business is not all sunshine.

How to Look at It.

It is poor policy, however, to look on only the dark side. Let us figure up and see what we have left. Hives in which the bees died are all right. Combs are all in good condition. Let us take good care of them. The prospect for a honey crop is good, and with plenty of bees left to fill up the hives again, with no foundation or hives to buy, why bee-keepers are in good condition. Then, too, prices of honey have improved so much, and with so many out of the race, there is surely a better day dawning for those who have the true grit, and are willing to "fight it out" on this line, if it takes all summer."

Spring Dwindling.

The past month has been pretty hard on the bees. The weather has been very unfavorable—cold, windy weather and sudden storms. When bees were gathering honey and pollen, and becoming chilled or lost in the river, it has kept the colonies pretty weak. As we write (May) fruit trees are in full bloom, but it is so cloudy and cold that the bees can take but little advantage of it. The dry time, however, seems to be over, and the splendid rains we have had, will bring out a fair crop of white clover, so that the prospects now seem to be all right.

Get the Bees Ready for the Harvest.

It will require good management and careful attention to get the bees in the best condition for the white clover crop. Of course everything should be done now that will help and save work when the busy time comes. See that all the material for sections, hives and crates is on hand that is likely to be needed. It is better to have a little too much than not enough. Experience has taught us that it will not do to depend on the supply dealers to furnish these things on the spur of the moment.

Seasonable Work.

Swarming will likely be upon us towards the last of the month. See that your hives are ready, and now is the time to use up the comb from the hives where the bees died out during the winter. It will pay to sort these

combs over and use only such as are straight worker comb. Cut out all the drone comb you find, and all crooked or very old, soiled comb. If you have not comb enough to fill the hive, fill out with full sheets of foundation. On no account use empty frames, as the bees would be almost certain to fill them with drone comb.

For a Combination—What?

We have been asked what can be combined with bee-keeping to make the pursuit reasonably safe and certain to support a man with a family. Well, in the first place, if the person has had no experience, or a great natural liking for it, we should say, do not go into it at all. So few have succeeded in making it a success, as an exclusive business, that some other undertaking would be more certain to yield an adequate income. But to answer the question, a good garden should be one of the first things to be thought of. Much can be produced in this way by working at odd times, that will be a great help, and greatly reduce the family expenses. All kinds of small fruits, and especially strawberries, raspberries and grapes, should be grown. If you have more than can be used by the family, there is usually good sale for the balance. A cow or two, where pasturage can be had, may be kept, also a flock of chickens, and in fact everything or anything that will contribute to the comfort and welfare of the family.

Selling the Honey Crop.

Now let us get ready for the honey harvest that will likely be a little late, but will probably put in an appearance early this month, and should last well into July. Should we be fortunate enough to get a reasonable crop, do not be in too great a hurry to sell it unless it is wanted at full figures. During the last few years, when a fair crop was secured, some bee-keepers seemed to be so anxious to get rid of their honey, and get ahead of their neighbors, that they sent it into the nearest town and sold it for whatever was offered. The price obtained was often ridiculously low, and the market was thus ruined for the balance of the year. The bees are not now in the country to gather a very large crop, even should the season be exceptionally good, and there will surely be no more honey produced than can easily be sold at about present rates. It is better to secure the crop first, in the nicest possible condition, and no matter if grocery-men begin to wonder why honey is not forthcoming, they will be all the more anxious to buy when it is brought in. Do not take in too much at a time, especially at

first—a crate or two is plenty. Better supply them often, and keep it neat and fresh, and keep it going. In this way it will never become old stock and unsalable.

Milan, Ills.

THE OTHER SIDE.

Experiments in Providing Pasturage for Bees.

Written for the *American Bee Journal*
BY MAHALA B. CHADDOCK.

I notice that many writers on bees speak of sweet clover as a valuable honey-plant, and they say that it yields honey all summer. Last fall I rode four times a week along a road that was lined for miles with sweet clover, and I never saw a bee on it—not one. This was in September and October. Perhaps the hot weather had dried up all the first growth, and this was only a second fruition, and contained no honey, or none worth the bees' notice. I masticated some of the blossoms, and they had a far-away sweetish taste, a little sweeter than rain-water.

Once Mr. Chaddock was with me when riding, and I asked him to let me stop and gather some of the seed to sow in waste places. "No, indeed," said he; "not on my land. I have weeds enough already. Don't you see those cows eating grass roots, and here is all this sweet clover going to waste. Nothing eats it; it is a pest." I told him that Mrs. L. Harrison and all the big bee-keepers took home much of it, and scattered it about, and the bees gathered honey from it. But it was of no use to argue.

About a year ago I decided to raise Alsike for the bees to work on, and I began talking Alsike to every one who would listen. When I went to the neighbors I took all the bee-papers along that had anything about Alsike in them, and read them aloud, and when they came to see me I did the same.

At last several of the farmers grew so tired of hearing about Alsike, that they agreed to get half a bushel of the seed and try it;—if what? If I could get a farmer *who did not keep bees* to say that it was as good as red clover. Then I wrote to the editors of all the agricultural papers that we take, and asked them—yes, begged them to say that it was as good. But none of them would quite say it. They would say that it was "about as good," and that on certain lands it would do as well, etc.; but not one of them would come squarely out and say, "Yes; Alsike is fully as good as red clover for a farmer's use."

Then I told the farmers that I would buy the seed if they would sow it. I told Mr. Chaddock that I would give him some of the seed if he would give it room to grow. He yielded, and said that he would sow a bushel of the seed. So I got two bushels of the seed, and the neighbors paid for their shares. (You cannot give anybody in Illinois anything; they are all too independent.) They sowed the seed, and it came up well; but the dry weather killed it all except a patch about as big as a table. This patch was in an old pasture, and was a hard, bare place where the sheep had been salted (I believe).

One of the neighbors says that he thinks he will try it again. I won't. I am through growing Alsike. It may be a very good clover for everything, and more so, but I shall not urge people to raise it. The sign does not seem to be right for us to raise it, and I shall not worry any more about it.

Dr. Miller says (I believe) that his honey cost him about \$2.50 a pound. Did he give the items anywhere? If he did, I have not seen them. Of course I do not doubt what he says. I know that the only year that I have ever had a fall crop of honey, was the kind of year that I never want to see again. We had 25 acres of corn, and obtained only 28 bushels; our oats rattled in the shock, and the wheat rattled in the stack. It rained, rained, rained all the time; all the corn on low ground was never plowed at all. Reapers mired in the fields when cutting small grain, and after the harvesting was done it did not get dry enough to stack. Every time the sun shone out for half-a-day men, women and children rushed out, tore the shocks apart, and spread the sheaves out to dry. The next day it would darken up again and out we went to shock it up again. Most of the grain, when stacked, was damp, and a great deal of it was ruined. We could get no hay dry without its being spoiled with rain. It was black, ill-smelling, musty stuff. Here we were with very little small grain, no corn to speak of, no good hay, and no corn-fodder, but we had a ton of honey, I suppose. The rain kept the corn from growing, and most of the corn fields grew up a solid mass of smart-weed, and this was what kept the bees swarming and carrying in honey all summer.

My bees swarmed from four to six times, and filled everything full of honey that they could find, even building combs beneath the hives, and storing honey in them. They had thousands of acres of smart-weed to go to, and they went to it; but I pray to be excused from having another fall crop of honey, if I have to pay the price for

it that we paid for that. Honey was worth 18 cents a pound then, but hogs were worth 8 cents, and we had no corn to feed them.

Vermont, Ills.

HANDLING BEES.

Hints about the Use of Smoke, Veil and Gloves.

Written for the Country Gentleman
BY JOHN M. STAHL.

The secret of handling bees is not to fear them. Not a few will say that I am wrong, but gloves for the hands, gauze for the face, etc., should very rarely be used. Bees do not sting until they are exasperated. Nothing exasperates them more than accidents. The person with gloves on his hands, and gauze before his eyes, is bound to be awkward. He handles the bees and all the paraphernalia of the apiary clumsily. He lets something fall, or topples something over. He jars the hive, or injures the bees. The less disturbance possible to the bees, the less the chances of arousing all their ill-temper. The person with gloves and gauze is more awkward and slow; he cannot handle the bees with celerity and deftness. Hence he precipitates the catastrophe. Angering the bees should be prevented, rather than protecting oneself by the very means calculated to anger them. The excitement and exasperation of the bees harm them—are a loss to the apiarist; hence are to be guarded against, for full as good a reason as the escape from a sting. The man who is more afraid of being stung than of exciting the bees, is not a good apiarist.

Because of this, I condemn the frequent use of smoke by many. Some bee-keepers are very fond of smoke. They must have a smoke in the yard almost every time they touch a hive. This is foolish, and worse. Smoke is to be used only as a last resort—in an emergency. It seems to me that few know how to use it judiciously. It is a violence to the bees; and as the apiarist values the well-being of his colonies, and the fullness of his pockets, he will do as little violence to his bees as possible. My observation convinces me that this ever-present smoke is responsible for more stings than it prevents.

I know some men who handle from fifty to one hundred colonies without gloves or gauze, and likely without using smoke once during the season. Of course I do not condemn smoke altogether. There is a great difference among colonies. I have met with a few colonies that could not be handled

much without smoke, and I gave them a dose with pleasure.

It is now easy to guess why the person who is afraid of bees is apt to get stung. He is nervous as soon as he gets within thirty yards of a hive. He makes quick, jerky motions, exasperating to anything that has sense. He spills and drops and jars until the bees could not be otherwise than angry; and he increases the evil by the precautions he has taken against being stung. I have seen these nervous men crush bees—in transferring, for instance—by the dozen, not through carelessness, but because they were so nervous and scared that they hardly knew what they were doing. Is it any wonder that the fellows of the crushed bees tried to avenge their untimely taking off? And I must confess that I was glad when they succeeded and made the murderously-nervous person howl.

I feel earnestly about this matter because I was *converted*, and *powerfully converted*. Once I was afraid of bees. Had only about 25 colonies, and got stung in handling them. A neighbor, Mr. Finlay, had above 100 colonies; used neither gloves nor gauze; it was very rarely that smoke was seen in his apiary, and yet he laughed at being stung. One day I was passing, and he called me in to see his bees, as he said. Trembling, I went, for I surmised that he wanted to try me. It was a "wet spring," and we both were bare-footed, with our trousers rolled up to our knees. We were in our shirt sleeves, and he had his sleeves rolled to his elbows. He took me in among his hundred colonies. To show how brave I was, I stood very near a hive. "I wanted to see if you knew how to handle bees," he said, "and I see already that you don't; any person that knows how to handle bees will never stand right in front of a hive" he will keep out of the way of bees all he can, and yet do his work. You can stand against the back or side of a hive and not disturb the bees; but get before the entrance, and you interfere with their movements. Now, stand here; stand still. If you strike at a bee you'll be stung to death. You know how to handle a horse as well as any one I ever saw, but among bees you are a coward. I want to make you a man among bees."

Reader, I was scared, and "Curg" laughs yet when he recalls the episode. I was so scared that I cannot give an account of what he did. I only know that in three minutes every blessed bee he had (so it seemed) was swarming around me. I stood there, still; and I have no doubt that my hair lifted my battered straw hat from my head. He kept me there until the bees re-

sumed their normal condition. I was not stung once; and I was cured of being afraid of bees.

Since then my line of action has been marked by sweetened water rather than smoke; and handling bees has become pleasant, instead of very disagreeable work; and I have been more successful.

CLOSE SPACING.

The Curiosities of Bee-Literature.

Written for the American Bee Journal
BY J. E. POND.

The article of Mr. E. P. Churchill, in the AMERICAN BEE JOURNAL, leads me to take the above heading for my text.

The matter of which he writes, viz: Close spacing of bees is one that has been discussed in the bee-periodicals of the United States and Great Britain for a number of years, and I had supposed that the glory or shame of introducing the subject belonged to another writer than Mr. Churchill. I therefore desire to ask him when he originated the idea? What scientific points he bases it upon? and what, in his judgment, is or are the reason or reasons why it produces the effects he claims?

As for myself I deem the matter one of great importance; I believe that the adoption of the principle, when fully understood, will work a revolution in bee-keeping, and with that belief I desire to learn all I can in regard to it, and wish that Mr. Churchill would devote an article to the subject of informing us on what natural theory it is based.

North Attleboro, Mass., May 29, 1888.

ONTARIO.

The Haldimand Bee-Keepers Meet and Talk.

Reported by the Secretary,
E. C. CAMPBELL.

The Haldimand Bee-Keepers' Association met at Nelles' Corners on Monday, May 28, at 1 p.m., the President, Mr. James Armstrong, in the chair. The following members were present: W. Kindree, E. Kindree, H. Smith, O. Fathers, E. Gee, F. Mehlenbacher, Israel Overholt, Geo. Snider, Geo. Werner, W. Best, F. Rose, H. Coverdale, Fred Harrison, Jas. Caldwell, Eli Grobb, H. Aekland, and the Secretary.

The minutes of the last meeting were read and approved.

The President addressed the meeting in reference to affiliation with the Ontario Bee-Keepers' Association, and explained the advantages to be derived therefrom. It was necessary that there should be at least five members from each local association, and a subscription of \$5, in order to become affiliated, and in return each member would receive an Italian queen, and the local association would receive a grant of \$35.

After the matter had been thoroughly discussed, it was moved by Mr. Smith, and seconded by Mr. W. Kindree, that the Haldimand Bee-Keepers' Association be affiliated with the Ontario Bee-Keepers' Association, and that the Secretary be instructed to forward the necessary fee of \$5. Carried.

How to Transfer Bees.

Mr. Kindree described his method of transferring from a box-hive, which was by taking a side off the hive and cutting out the combs, which he fastened into frames by means of sticks on each side, tied on top and bottom so as to hold them in place until the bees fastened them all right, when he took the sticks off.

Mr. Armstrong's plan was much the same as Mr. Kindree's, but he used a peculiarly shaped tool for taking the combs out of the hive, instead of taking the side off the hive.

The following diagram shows how a frame looks when transferred as described above :

The Best way to Hive Natural Swarms.

Mr. Smith placed an old newspaper in front of the hive, and when the bees were nicely clustered in the swarming-box, he shook a few on the platform, and they soon ran in.

Mr. Armstrong described his plan of using a swarming-box, which he held so that the swarm could easily cluster in it, when he took it to the hive and shook a few bees down on to the platform in front, and the whole swarm soon ran in with joyful haste.

Mr. W. Kindree's plan was the same as described by Mr. Armstrong, and he thought the swarming-box was worth its weight in gold for practical use to every bee-keeper.

Messrs. Mehlenbacher, Rose, Coverdale and Overholt gave their plans,

which were in the main the same as given above.

Which is Best, to Fill the Sections, or Use Starters ?

Mr. W. Kindree usually put in a starter, but he thought that the bees made straighter and nicer comb honey when the sections were filled with foundation.

Mr. Armstrong was in favor of filling the sections with thin foundation. If the lower story was full of combs, he used starters in the sections ; but if there were only starters below, he filled the sections with foundation.

Messrs. Overholt and Rose had used only starters.

Moved by Mr. Rose, seconded by Mr. Overholt, that this association give \$8 to the Cayuga and Jarvis shows, and \$4 to the Rainham show, on condition that they give twice as much in prizes for honey and apiarian supplies, and that the local members of the association be authorized to wait upon the directors of the above agricultural societies. Carried.

Moved by Mr. Smith, seconded by Mr. Fathers, that the next meeting of the association be held at Fisherville on Saturday, Sept. 29. Carried.

SWARMING.

Do Bees Select a Home Before Issuing a Swarm ?

Written for the American Bee Journal
BY C. L. LOVELAND.

Mr. J. E. Pond remarks on page 297 thus : "Whether bees ever select a home before swarming, is a question that probably no one can answer." I think that I can come very near answering it.

About 25 years ago I bought 2 colonies of bees in the spring. I knew nothing about bees, and did not know one bee from another. I had a hired man that had worked with bees some.

One Sunday I left him to watch them while I went to church. When I returned he said that the bees had swarmed ; that he watched them until he thought they had commenced alight-

ing on a bush about 8 rods from the hive. He then went 6 or 8 rods to the barn for a hive, and when he returned they were gone. My farm was what was called prairie-opening, with quite a number of large trees still standing. We took the direction that they went from the hive to the bush. We went about 80 rods and found them up about 20 feet in an oak tree. We cut it down and saved the bees. I saw the next swarm come out. They did not alight. I followed them directly to the tree, about 100 rods from the hive. We cut it down and saved the bees. A few days after I saw a neighbor that was quite a bee-man. He said to me, some one has got a swarm of bees on my place. I told him they were mine ; I followed them directly to the tree. He said he was watching that tree ; that he was there and saw the bees cleaning out the tree, a number of days before they swarmed, and thought that he was going to get a swarm.

My opinion is, that all first swarms look for a home before swarming. Perhaps some after-swarms do not. I want to know how any one knows that bees send out scouts. After clustering they may do it, but I think it is no easy matter to prove.

Plainview, Minn.

GIVE ROOM.

Giving the Bees Room, to Prevent Increase.

Written for the Ohio Farmer
J. A. B.

To obtain the greatest yield of honey, ordinarily, swarming must be controlled to a great extent, although we often gain in surplus by allowing strong, powerful colonies to cast a swarm. A certain amount of space may be profitably occupied by bees, but an over-supply of bees to the amount of space is not so profitable. Hence a division of the swarm is, I think, more preferable, and no better division can be made when surplus honey is in view than to permit the bees to make it themselves if at, or near the proper time. But in allowing such increase, a line must be drawn, as any increase except in such cases is a barrier to honey production.

The size of the hive, or space for the brood-chamber, as generally adopted by bee-keepers, is about 2,000 or 2,400 cubic inches, and the surplus department should have about the same dimensions. A prosperous colony in the honey season should occupy this entire space, filling every crack and crevice to such an extent as only to admit of working room, or, as the saying is, "elbow room."

When this space becomes crowded, and the bees are forced to the outside for room, loafing in large numbers, clustering on the outside of the hive will take place. If this occurs during the honey flow, it shows that something is wrong; that room is required, and I prefer, rather than to add another story to the hive, to swarm them naturally if possible, and thus have them divided into colonies. If the above is correct, the reader will readily understand what it takes to make a prosperous colony secure the best results.

In order to prevent all swarms that may not be desired, in most cases it is only necessary to keep down the construction of queen-cells. Swarming may be very easily foretold from six to eight days, by the construction of queen-cells. The destruction of these cells will discourage swarming, and in most cases prohibit it. But in rare exceptions bees will sometimes persist in issuing, even if queen-cells are not present, especially after frequent annoyance by removing their cells, from the fact that their leaving the parent colony in this condition does not injure it. If brood is present, their excuse for so doing may be deemed reasonable, but as this will at once check the process of storing surplus, the point aimed at, it is necessary that we keep them together, and the only way we can make a sure thing of it is to take away their queen. This is a never failing remedy to check swarming at the time.

If an abundance of young brood is present in the hive, I cannot see that it will do any particular harm, but as a general thing this is a preventive only for the present, for if the honey-flow continues there will likely be another effort made to swarm eight days thereafter. Queen-cells constructed from the brood left after the removal of the queen, will at this period be maturing, and swarms may be the result. At this stage of proceedings we have made the best progress by removing all queens or cells, and introducing a laying queen.

Another plan we have used, which may be equally as good with those persistent swarmers, is to allow them to swarm, hive them in a new location, and strengthen them up ready for occupying the surplus boxes at once, by drawing from either of these left, or other colonies. If, on the other hand, we wish to increase our number of colonies somewhat, and at the same time secure a fair crop of honey, we would manage to have all strong, as near the swarming point as possible at the opening of the honey flow. In fact, it matters not what particular method of management we intend to adopt for

the season, it is of the greatest importance in any case to have strong colonies at the commencement.

Doubling the number of colonies is a fair increase. This we can do, and at the same time secure a fair crop of honey, and we would do this by allowing the first swarms to issue. I think this better than dividing, if salable surplus honey is the object, together with a fair increase.

If we expect to make increase the sole object, we would manage quite differently. We would work entirely on the artificial plan of increasing by dividing. Previous arrangements should be made in rearing queens so that the supply is at hand at the time of operating. In making these divisions we should not separate into too many parts at one time. A colony divided into two is enough at once. Each queenless half should be provided with a laying queen, thus keeping each part strong, and furnished with laying queens. This keeps up a large portion of the brood at all times, and doubles the laying forces by the addition of an extra queen at each division.

When dividing a colony into many parts at one time, it weakens each part so that even if laying queens are furnished, the amount of brood-comb in which to deposit eggs is limited according to the strength of the colony. Hence comes the necessity of having each part as strong as possible, thereby accommodating the queen with room according to her laying capacity. The secret of success is in dividing more frequently, and not making so many parts at once out of the same colony.

A strong colony divided into two parts may be divided again into four parts, in six or eight days, when it may be kept up every ten or twelve days thereafter, being governed entirely by the flow of honey, which may be either natural or artificial.

LARGE HIVES.

Honey-Boards, Contraction, Pollen in Sections, etc.

Written for the American Bee Journal
BY JAMES HEDDON.

Without consuming more space than is necessary, I wish to say that all the points made against the usefulness of my hive by Messrs. Dadant and Hambaugh have been fully answered over and over again, more especially so by quotations from patent law, found on page 213 of the BEE JOURNAL for 1886. If the reader will read and carefully consider them, he will see the truth of this statement.

With reference to Dr. Tinker's article on page 330, no one can say but that he is entirely correct, but it is sometimes very hard for human nature to use pleasant words and kind sentences in response to those who are doing them an injury. A truth cannot be told harshly enough to make it false, nor can a falsehood be told kindly enough to make it true.

Contraction of Brood-Chambers.

Brother Tinker says: "Probably no man in this country has had a larger or more varied experience in the contraction of brood-chambers in the past five years than the writer." I am quite sure that I can prove that either Mr. E. J. Oatman or myself have had more than twenty times the experience in contracting that the Doctor has had. I am informed that Dr. Tinker has never really used divisible brood-chamber hives.

I desire to make these facts known in justice to us both: Soon after I made public my late invention, Dr. Tinker purchased a hive of me, and wrote me that he did not wish to use my invention as I had made it, but would use a portion of my principles, and sent me a model of the hives he was using, which had a brood-chamber of one section, composed of seven close-fitting frames, shallower than the Langstroth hive. A brood-chamber of too little capacity for all seasons of the year, and the very thing which the Doctor has been using ever since, when he suddenly departed from his "continuous-passage-way hive," adopting one on the principle of mine, arranging with me to use it for one year.

Pollen in the Sections.

But for arguments sake, suppose the Doctor really had experimented with my hive in its purity, the one which he refers to on page 330, and suppose he really had any evidence that there was $\frac{1}{2}$ too little room in the contracted brood-chamber, which caused the bees to carry pollen above, and that the bee-space in the center of the brood-nest proved an impediment to extensive brood rearing, we can but regret that he lives in such a peculiar location, or has such exceptionally obstinate bees that everything works so differently with him than with a hundred others who have reported publicly and privately.

I think three or four have reported "pollen in the sections" one year, but there are quite frequently years in which this occurs with all hives. Who has not seen surplus honey nearly ruined with bee-bread in days when nearly all the hives used were from 14 to 20 inches deep? Some way or other, as we have adopted shallow and shallower hives, we have in exact pro-

portion eliminated bee-bread from our surplus comb honey; not because bees are less liable to carry pollen above shallow brood-chambers, but because shallowness has little or nothing to do with it, and we have discovered and attended to the conditions which cause it.

Queen-excluding Honey-Boards.

The Doctor claims to be the first who used queen-excluding zinc in honey-boards, and the first to make it public; but on examining the record we find that this is not so, and believe we can prove that we have used more than twenty queen-excluding honey-boards to his one.

We say this in all kindness, and will try hereafter to show up the Doctor's mistakes in articles which shall combine both kindness and truth.

We trust we have written this kindly, that our brother bee-keeper will hereafter devote his attention to the statements and arguments made by those who differ with him upon these important points in progressive bee-keeping, rather than to the character of the writing or writer.

Dowagiac, Mich.

A BEE'S SOLILOQUY.

Written for the American Bee Journal

BY JOHN JAMESON.

As I sat musing one fine day,
I thus commenced to sing my lay.
The poet Virgil sang of bees,
His martial countrymen to please,
And now I will prolong the strain,
And sing about the bees again.

We must have perished in the flood,
In water deep, and slimy mud,
Except the pair in Noah's cell;
What kind they were, let wise men tell.
That's something far beyond my ken,
And puzzles e'en the wisest men.

I do not care for styllsh hive,
If in a keg could live and thrive.
I like the one as well's the other,
New inventions seldom bother.

Had I my way, I'd rather be
In hollow dark of some high tree,
Or in the cleft of some steep rock,
A way from human kind and smoke.

They ship me here, and ship me there,
Exhibit at the County Fair;
Where some great bee-man, I expect,
Expatriates on the great insect.
And when they get a costly prize,
I never see it with my eyes.

Above all insects we have fame,
There's none has sweeter, honored name.
We're found almost in ev'ry land,
On Mediterranean strand,
And on the shores of Norway bleak,
In Mexico, round Mozambique.
We're humming round on ev'ry hand,
Australia and Van Diemen's land.

Sometimes they ship us far away,
And then we travel night and day.
They crowd us up in little space,
Until we reach the destin'd place.

And then the same thing o'er and o'er,
My old home likely see no more,
A change of masters matters not,
Ours surely is a cruel lot.

For days we rattle in the train,
And weary to be out again,
Sometimes among the freight I'm jamm'd,
At other times I'm toss'd and slamm'd.
I do detest the din and dust,
But no use talking, go we must.

Left to ourselves, we'd rather be,
Along the Caribbean sea.
We love to be where it is warm,
Cold does incalculable harm.
We want some Raleigh, or a Penn,
To lead us out of this cold den,
We hope the rising generation,
Will all encourage emigration.

The Tropics suit us far the best,
In this cold climate too much rest,
The bee-men all should move their camp,
And with us take a southern tramp;
There daily we would better fare,
And keepers would have far less care,
And need no granulated trash,
Or any other kind of mash.

They brought my mother o'er the sea.
My daddy was a native bee;
So I'm a hybrid vicious pest,
And dreaded more than all the rest.

Yes, all I am, and have, I'll bet,
The pure Italian is the pet;
O, give me not so hard a name,
Organization is to blame.

No doubt you have a brighter band;
But can't call this your native land.
At home you had a balmier air,
A sky with which few can compare,
"I love my own, my native land,"
And care not for your triple band.

Some say you gather far more honey,
And make your owners lots of money,
Perhaps that's so; but last season,
For being short, we've good reason;
Nature withheld her precious stores,
Now poverty surrounds our doors.

I've often heard the natives say,
That blacks were in the earliest day,
Fresh from the great Creator's hand,
With all the humble, creeping band,
That climate, food, and habit chang'd,
According to the parts we rang'd.

It puzzles me and all the rest,
To find how we got so far West;
Perhaps we came by Behring's Strait,
On some rude craft with Indian freight.

Perhaps the Northerner brought us here,
This heterogeneous mass to cheer;
Perhaps we are a new creation,
Prepar'd to feed this Yankee nation.

My life is short; but I am proud,
For o'er me hangs portentous cloud,
A weary slave for selfish man,
And never pleas'd do all you can.

Some keepers well deserve a share,
Of us they take such gentle care;
Old fogies should not have an ounce,
Bees ev'rywhere on them should pounce.

The bipeds would get burning hail,
But they protect with gloves and veil.
If bees could only stop supplies,
Our masters then would ope their eyes.

Our keepers take some stores away,
And drones, alas! would always stay;
But we express no clement doubt,
We pinch their necks and hustle out.

The robbers come and plunder too,
A turbulent and murderous crew,
Moths, mice and ants give us no peace,
The human, lower, all us fleece.

I reckon we must not forget,
That man has got Dominou yet;
The land and sea subserves his end,
This state of things we cannot mend.

No doubt the premordial hoards
Had honey on their festive boards;
Not from a pretty Langstroth box,
But from the hollow trees and rocks.

Sometimes they pack us round with chaff,
And then we have a general laugh;
Sometimes they put us in the cellar,
And there we sleep, and sometimes *better*.

For four long months ne'er see the light,
Until we take our early flight;
When rosy spring cheers up the land,
They place us on the summer stand.

Our mother's wing they often clip,
Yet swarming time makes bee-men skip;
Where have they gone? up in a tree!
There! there! run fast! be quick! see! see!

Some plant the luscious melilot
As near as can be to our ent;
So that we need not travel far
To gather in the sweet nectar.

In spring we often have the *dwindle*!
And that the bee-man's ire doth kindle.
He's often left without a bee,
And that's a piteous sight to see.

How to increase all don't agree,
Some say divide, some let them be,
Some like the model old Langstroth,
Some Simplicity, some like both.

Five shining eyes, and hairy tongue
To see, and gather sweets amoug
The aromatic woods and dells,
And store the honey in our cells.

Like Robin Hood and bold Rob Roy,
Free booting ev'rywhere enjoy;
A fence to us is not a bar,
We find aroma near and far.

Now I will stop my cogitation,
And ply with zeal my avocation;
Adjust my wings, and busy go it,
'T will better pay than being poet.

—West Toledo, O.

FALL CROP.

Prospects for a Fall Crop— Honey vs. Increase.

Written for the Prairie Farmer

BY MRS. L. HARRISON.

In opening a colony of bees this morning, I found all the frames full of brood, but scarcely a day's ration ahead, and plenty of drones and drone-brood, with every appearance of coming swarms. All needed now for an outbreak of the swarming fever, is a flow of nectar. There appears to be plenty of pollen, and bee-bread is abundant. The locusts are in bloom, but there has been a great deal of rain of late, which washed out the sweetness. It is fair to-day (May 30), and there may be some nectar secreted.

Fall Crop of Honey.

So much rain promises well for honey in the future. The greatest flow ever known here was in the fall. This wet weather will bring forward white clover, and we may yet hope for a supply of this delightful sweet—real ambrosia, fit for the gods. When the electric conditions are just right, and the flow abundant, the comb is so delicate as to be almost imperceptible. I have yet to see a finer honey than from the white clover of the North and West. As this honey is so desirable, every effort should be made to secure as much as possible in the best shape.

Honey vs. Increase.

A large increase in colonies, and a large amount of surplus cannot be secured at one and the same time. It is best to secure all the choice honey possible, and if increase is desired, make it afterwards. Choice queen-cells should be saved during swarming time, and the young queens reared can be used in making colonies after the flow of honey is past. Italian bees often swarm even before starting queen-cells, and then the old colony builds and rears queens. It is good management to save all the cells built in a choice colony, so as to have good, vigorous queens, to introduce wherever inferior stock is discovered.

Before any of the queens emerge, the colony can be divided up; a frame containing a queen-cell, and covered with bees, can be removed to a hive, and confined to one side by a division-board. If there is not enough honey in this frame, another one containing honey should be given it. When the young queen is out, it is well to add a frame of eggs and larvæ. This will furnish employment for the bees, and, if the queen is lost on her bridal tour, furnish the means of rearing another. Where increase is the object sought, the after-swarms can all be hived and built up into strong colonies before cold weather. Of course these all contain young queens, and the old one leaves with the first swarm.

Hiving Swarms.

Many complain of their swarms deserting the hives. Whenever this is the case, there is some cause for it; either the hive is unclean, or has some disagreeable odor about. I once had a swarm come out of a hive and cluster several times. On examining the hive I discovered that it was a new one, and that the entrance was too small; the bees were simply too warm, and for fear of suffocating, deserted the hive. On putting them in a hive with a wider entrance, they went to work, with no more foolishness. I like to have my hives standing where they are to remain, and carry the swarm to it. If they cluster on a limb of a tree that I am willing to cut off, I do so, and carry it to the hive, and lay it in front upon a clean surface of a board or cloth, and then direct a few bees to the entrance with a little twig. If they are violently shaken off, all at once, they may take wing and cluster again. Sometimes I shake them off into a dish-pan, cover them with an apron, and pour them in front of the hive.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe; costs but 5 cents.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now SO CHEAP that no one can afford to do without it.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

Honey and Beeswax Market.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 13@15c.; the same in 2-lbs., 10@11c.; buckwheat 1-lb., 10c.; 2-lbs., 9c. Market dull. We are doing all we can to reduce stock, to make room for the new crop.
BEESWAX.—23c.

HILDRETH BROS.,

May 21. 28 & 30 W. Broadway, near Duane St.

DETROIT.

HONEY.—Best white in 1-pound sections, 14@15c. Extracted, 9@10c. Supply decreasing slowly.
BEESWAX.—23c.

May 21. **M. H. HUNT,** Bell Branch, Mich.

CHICAGO.

HONEY.—Prices range from 15@16c. for best one-lb. sections; other grades are low, at lower prices. Extracted, 7@8c. Light demand, and supply larger than usual at this season of the year.

BEESWAX.—23c. **R. A. BURNETT,**
May 1. 161 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 14@15c.; fancy 2-lbs., 12c. Lower grades 1@2c. per lb. less. Buckwheat 1-lb., 10@10½c.; 2-lbs., 3@9½c. Extracted, white, 7@7½c.; dark, 5½@6c. Market is dull for comb but improving for extracted, of which new from the south is arriving.

BEESWAX.—Scarce, 24@27.
May 21. **F. G. STROHMAYER & CO.,** 122 Water St.

CHICAGO.

HONEY.—We quote: Fancy white clover 1-lb., 16@17c.; 2-lbs., 15@16c. Dark is a slow sale at almost any price. Extracted is scarce, and sells at 7@10c.
BEESWAX.—23c.

Mar. 13. **S. T. FISH & CO.,** 189 S. Water St.

CINCINNATI.

HONEY.—We quote extracted at 4@9c. per lb., for which demand is good. Comb honey, 14@17c.—Demand slow.

BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Apr. 23. **C. F. MUTH & SON,** Freeman & Central Av.

MILWAUKEE.

HONEY.—Choice white one-lb. sections, 16@17c.; 2-lbs., 15@16c.; 3-lbs., 14c. Extracted, white in kegs and ¼-barrels, 8 to 8½c.; in tin and pails, 9½@10c.; dark in barrels and kegs, 5@7c. Market fair.
BEESWAX.—22@25c.

Apr. 23. **A. V. BISHOP,** 142 W. Water St.

DENVER.

HONEY.—Best white 1-lb. sections, 17@19c.; 2-lb. sections, 15@17c. Extracted, 7@10c.
BEESWAX.—20@3c.

Mar. 1. **J. M. CLARK & CO.,** 1409 Fifteenth St.

KANSAS CITY.

HONEY.—We quote: Choice white 2-lb. sections, 17@18c.; dark 2-lbs., 14@15c.; choice white 1-lb., 18 to 20 cts., dark 1-lb., 15@16c. White extracted, 7@8c.; dark, 5@6c. Demand is slow. White extracted in firm when in 60-lb. tin cans.
BEESWAX.—21 to 22c.

Mar. 29. **HAMBLIN & BEARSS,** 514 Walnut St.

BOSTON.

HONEY.—We quote: 1-lb. sections, 16@17c.; 2-lb. sections, 14@16c. Extracted, 6@9c. The market is not very brisk and sales are slow.
BEESWAX.—25 cts. per lb.

Mar. 24. **BLAKE & RIPLEY,** 57 Chatham Street.

SAN FRANCISCO.

HONEY.—We quote for new extracted 6@4½c., as to color and quality. New comb honey 14@10c., as to quality. Arrivals are still small, and demand of a jobbing nature.
BEESWAX.—Scarce, 20@24c.

June 2. **SCHACHT & LEMCKE,** 122-124 Davis St.

KANSAS CITY.

HONEY.—We quote: White 1-lb., unglassed, 15c.; 1-lb., white, glassed, 14c.; dark, 1-lb., 2c. less. California, 2-lbs., comb, white, 13c. Extracted, 7c. Considerable old honey is in this market. No new yet in. Sales are very slow.
BEESWAX.—None on the market.

June 9. **CLEMONS, CLOON & CO.,** cor 4th & Walnut.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, \$1.00 per 100, or \$8.50 per 1,000.

H. L. Pangborn, of Maquoketa, Iowa, says: "I can fill no more orders for bees."

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 18 cents per pound for bag and postage.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2.00	3.00	3.50
1,000 Labels.....	3.00	4.00	5.00

☞ Samples mailed free, upon application.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Cork for Winter Packing.—Its advantages are that it never becomes *musty*, and it is *odorless*. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed* \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Sweet, or Melilot, Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Advertisements.

ITALIAN QUEENS by Return Mail.
 Tested, \$1.00; untested, 75 cents. Bees 75 cents per pound. Albino queens same price.
GEO. STUCKMAN,
 NAPPANEE, IND.
 24Etf
 Mention the American Bee Journal.

SAMPLE COPIES of the AMERICAN APICULTURIST and our Price-List of Winter Strain of Pure Italian Bees sent free. Address,
 18Etf **APICULTURIST, Wenham, Mass.**
 Mention the American Bee Journal.

2-Story Langstroth Hive, 80c.

WE still have a few of those Two-Story Langstroth HIVES with 10 Brood-Frames, at 80 cents.

Who wants them? Speak QUICK, or it will be too late. Address,

SMITH & SMITH,
 10Etf KENTON, Hardin Co., OHIO.
 Mention the American Bee Journal.

CARNIOLAN

Gentlest bees known; not surpassed as workers even by the wicked races. Imported Queens, "A" grade, \$8.00. Tested, \$4.00; Untested, \$1.00.

QUEENS.

One-half dozen \$5 00
 Never saw foul brood. Cash always required before filling an order.
S. W. MORRISON, M. D.,
 14Etf. Oxford, Chester Co., Pa.

VICTOR

SAFE.

DESIGNED for the Farmer, Lawyer, Doctor, Postmaster, Merchant, Township and County Officer, the Bee-Keeper, the Home—in fact every one should have a secure place for valuables.

We offer in the VICTOR SAFE a first-class Fire-proof, Burglar-proof, Combination Lock Safe, handsomely finished. Round corners, hand decorated; burished portions are nickel-plated. Interiors nicely fitted with sub-treasuries, hook-spaces and pigeon-holes.

Prices range as follows:

	OUTSIDE.	INSIDE.	WEIGHT.	PRICE
No. 2.	22x15x16,	12x8x8½,	250 lbs.	\$30 00
No. 3.	28x18x18,	15x10x10,	600 "	40 00
No. 4.	32x22x22,	19x14x12½,	800 "	60 00

THOS. G. NEWMAN & SON,

EDITORIAL BUZZINGS.

For every Evil under the sun
There is a remedy or there is none.
If there is one, try and find it ;
If there is none—well, never mind it.

The Trial of Mr. Z. A. Clark, of Arkadelphia, Ark., is to come off about July 16, and the National Bee-Keepers' Union has engaged considerable legal talent, and we go to the trial in full confidence of gaining a substantial victory.

Mr. Jonathan Periam is again at the helm of the *Prairie Farmer*, for the past 3 or 4 years held by Orange Judd. The AMERICAN BEE JOURNAL extends a welcome, and wishes Mr. Periam and the *Farmer* abundant success.

Crates or surplus cases for holding the section-boxes should be made neat in form, so that they may be used as shipping-crates or retailing crates. Sections of honey well completed and nicely arranged in such crates will bear very rough handling, and will remain well preserved if the sections have not been removed after taken off.—*Ex.*

The Season is about a month late this year, and consequently everything seems "out of time." Still the prospects for a honey crop in some localities is considered to be excellent. Just as we go to press, the following expression comes in from Mr. M. O. Tuttle, of Osage, Iowa, showing that there, at least, the apiarists are buoyant and hopeful. He says:

The prospects are very encouraging here for a good honey flow. Last week I doubled up my colonies in order to lessen the number, and to get them exceedingly strong early in the season. Our season is 3 or 4 weeks late.

Tiering Up.—Concerning its advantages and the methods to be employed, Mr. W. J. Cullinan, of Kansas City, Mo., writes this in the *Farmer's Review* :

Tiering up.—Now we come to one of the nicest things connected with modern apiculture. By this plan we are enabled to secure 4 pounds of honey where 1 pound was obtained by the old method. The plan is briefly this: When the first case of sections is one-half or two-thirds filled, lift up and slip under it a case of empty sections; now watch close, and when the upper one is nearly completed, which can be ascertained by blowing a little smoke on the bees, and then looking down between the sections, lift up these two and slip another empty case beneath.

By the time the bees need more room, should the honey-flow continue abundant, the top case will be completed, and should be taken from the hive, when the others may be lifted and another case placed below. Be careful not to add too many at the close of the season, as you will get too many unfinished sections, and be sure to remove as fast as completed, that your honey may retain its snowy whiteness.

When removed store in a warm place and sulphur occasionally to kill any moth-worms that may hatch out upon the combs. The reason for raising the first case and placing the empty ones below, is that by this plan a vacant space is left between the brood and stores which the bees will take possession of more readily, and work all the harder to fill it up.

Another advantage is, that the finished sections being on top they are not so liable to be stained or soiled by the travel of the bees, and are more easily removed when finished. Those running for extracted honey can tier up in a similar manner, but the advantages are not so great as in the production of comb honey.

After-Swarms are prevented (says Mrs. L. Harrison, in the *Prairie Farmer*), in this way: "When they have a swarm, they place it where the parent colony stood, having removed it to one side, and facing differently. All of the bees flying in the fields, will, as they return, enter and remain with the new colony. After a few days, commence gradually to turn the old colony around, until about the time of the young queens, when the entrances will be side and side. Then remove the old colony to a new stand, and all the bees old enough to work in the fields will remain with the new one, making a very strong working force. When the first queen comes out of the cell, she will destroy all the others, and swarming will be prevented. By thus massing all the working force together in one hive during a flow, much more surplus will be secured, then if divided into several hives."

From New Zealand comes this paragraph in our Australasian cotemporary for May, which shows how the AMERICAN BEE JOURNAL is valued in the Southern Hemisphere:

I must compliment Mr. Newman, the editor of the AMERICAN BEE JOURNAL, on the improved appearance of the new volume of that periodical, the first numbers of which have just reached me. It is printed on good paper, its articles are well written, and it decidedly ranks as one of the first bee-papers in the world.

Carbolized Sheet.—A correspondent in the *British Bee Journal* says: "The recipe given by Rev. G. Raynor for quieting bees in preference to smoke is:

1½ oz. Calvert's No. 5 carbohc acid.
1½ oz. of glycerine.
1 quart of warm water.

The acid and glycerine to be well mixed before adding the water, and the bottle to be well shaken before using. A piece of calico, or preferably cheese-cloth, sufficiently large to cover the top of the hive should be steeped in this solution, wrung out dry, and spread over the hive on the removal of the quilt, when every bee will quickly disappear below, and manipulation may be slowly and quietly performed without annoyance from the bees. The same plan is effectual in driving the bees out of section-cases. From unsealed sections they often refuse to budge, but a little blowing through the strainer will always dislodge them. All of our sections are thus removed, and we have never experienced the slightest scent or flavor of the carbohc acid attaching to the comb or honey. This unpleasant result occurs only to bunglers, who either use too strong a solution, or do not wring out the carbolized sheet sufficiently dry, and so besprinkle the comb honey with the solution, and charge the evil result of their own stupidity on those who recommend the process. The strength of the solution quickly passes away, as the acid evaporates when exposed to the air.

Bees Take Possession of a House.—It frequently occurs in southern California that a swarm of bees take possession of a house, and fill the space between the lathing and rustic with honey, resisting all mild attempts to drive them out. The following is from the Tustin City correspondent of the *Santa Ana Blade*:

Sam Tustin has been having a war with bees. A half-dozen swarms had taken possession of his store building, occupied by J. W. Ballard, and threatened to hold it to the exclusion of its owners. And as the bees were very enthusiastic in their business, it looked as though they might stay, even though Sam had the first claim. Tustin, with an able assistant, first clothed themselves in complete armor of mosquito-cloth and heavy gloves, and, armed with an assortment of carpenter tools to tear off the rustic, etc., then, by the liberal use of brimstone and fire, made it warm for the pests. About two days finished one "houseful," and the boys had so much fight left in them, or wanted revenge, that they attacked a large colony in possession of the Presbyterian church, won the fight, and confiscated several barrels of honey.

The Nights have been so cool until last week, in this latitude, that work in the hives has been out of the question. As the season will be short, strong colonies will, in all probability, be the only ones to get much surplus, and but few are strong.

The Cincinnati Centennial Exposition opens on July 4, and closes Oct. 27, giving 100 exhibiting days. There will be reduced rates on all railroads. As to what the honey exhibits will be we are as yet un-informed. We hope it will be creditable to the pursuit. Of course our friend C. F. Muth will see that it is made such, for he never does things by halves.

GLEAMS OF NEWS.

Father Langstroth.—It has been known for some time that the bee-keepers of America have been trying to provide him an annuity to help him to a subsistence in his old age and many infirmities.

Our brethren in Great Britain have taken hold of the subject, and here is what the *British Bee Journal* has to say about our aged friend :

There is, perhaps, no man living to whom the bee-keepers of the present day owe more than to the Rev. L. L. Langstroth, or, as he is termed by our American friends, "Father Langstroth." How often in the progress and development of a science or industry the pioneers (those who were amongst the first and who worked the hardest), very soon become forgotten. It is so in bee-keeping; those who have done the most, and by their exertions have enabled many in the present day to become not only bee-keepers, but successful honey-producers, are forgotten and ignored. But this is not all, for those who have benefited by others' brain efforts and experiences are frequently those who do their best to crush them. Do we not find repeatedly that claims are made to inventions and improvements without regard to what has been done before? Names of inventors, discoverers, and benefactors are frequently forgotten in the eagerness to benefit at their expense.

We might mention numbers of instances at the present day, where inventions are used with but slight alteration, and the users deriving a pecuniary benefit, whilst the originators, to whom the invention cost a large expenditure of brain power, many sleepless nights, and perhaps a large sum of money into the bargain, are completely ignored. We have a most striking instance of this in the case of the Rev. L. L. Langstroth. We do not wish to enter into the question of whether Langstroth, Munn, or any one else, was the first to invent the frame, but what we wish to point out is that Langstroth was the first to make the movable-comb hive a practical success, and by his work, "The Hive and Honey-Bee," which is still the standard on the subject, he opened up to the world the improved methods of bee culture, which have led to the enormous success witnessed at the present time. Does every bee-keeper realize that in using a movable-comb hive he is morally indebted to Mr. Langstroth for its benefit he is deriving from it? And if he does, is he prepared to make some acknowledgment and return for this obligation?

For many years Mr. Langstroth, who is now 77 years of age, has suffered, and only from time to time, and at long intervals, has he been able to take up with his favorite pursuit. We regretted that when we visited America last summer he was not in a condition to see us, and nothing would have given us greater pleasure than to have grasped this veteran's hand and looked into his benevolent face. Ever devoted to the science he loves so well, according to a friendly letter we received from him a few days ago, he was even then, during a period of convalescence, at the apiary of Mr. Heddon, studying the capabilities of the Heddon system. His head troubles have prevented him from earning his living, and it is because this master of bee-keepers has been robbed of his means of livelihood by some of those who have reaped the benefit of his labors, that he is not now, in his old age, in comfortable and independent circumstances.

From time to time small sums have been subscribed, and in 1879 "The Langstroth Fund" was started in America. In that

year Mr. Newman visited England, and at a meeting of the British and Foreign bee-keepers, held at our residence in Horsham, a subscription was started, which amounted to about £l. 6s., the whole amount collected here and in America barely reaching 40l. Since that time small sums have been remitted to him, but how out of all proportion is this to the benefits conferred by him on the world! It is now proposed in America to raise a sum of money in order to purchase an annuity, and every bee-keeper there will have an opportunity to pay some tribute to his great leader.

But why should we stand aloof and do nothing? On another page our correspondent, "Amateur Expert," in his pathetic appeal, says, "Let us, as British bee-keepers give practical expression of brotherly feeling by subscribing to the fund; it will only stimulate his countrymen to do more, and make the annuity the greater." These sentiments we heartily approve, and think it the duty of the many who have benefited by Mr. Langstroth's labors to do something on his behalf, so that this good old man may pass the remainder of his days in comfort, cherished by the thought that there are noble and honest minds on either side of the Atlantic that do appreciate his efforts, and prove a brotherly love and feeling are ready to recognize them. We shall be pleased to open a subscription list to be called the "Langstroth Fund," and earnestly hope that our appeal will be heartily responded to. Let us bear in mind that "he giveth twice who gives in a trice."

Donations sent to us, or to Mr. Huckle, Kings' Langley, Herts, will be acknowledged in the *British Bee Journal*, and forwarded to America. The list of contributions is headed :

	£	s.	d.
T. W. Cowan.....	5	0	0
Geo. Neighbour & Sons.....	2	10	0
Rev. Geo. Raynor.....	1	1	0
W. Raitt, Blairgowrie.....	1	0	0
"Amateur Expert".....	0	10	0
Geo. Henderson.....	0	10	0

"Amateur Expert" refers to the matter in these words, which find a ready response in all true American hearts :

Dear Editor, you have given us in last week's *Journal* the long letter in defense of the poor drone, from the pen of the one whom "all the States own." Blood is thicker than water, and the whole Anglo-Saxon race is one people, moreover, "one touch of Nature makes the whole world kin." The dear old man has been afflicted, and with the saddest of all sorrows—head trouble. He is so far restored as to be able to write what you gave us last week, but as an actual fact he is past work in the way of bread-winning.

He has been defrauded of the results of his brains by his fellow bee-brethren, from lack of power to defend his rights, and being worn out and in poverty they have decided to buy him a small annuity. Surely we can endorse the sublime words of C. Mackay :

"I love you, if your thoughts are pure ;
What signifies your poverty,
If you can struggle and endure ?
'Tis not the birds that make the spring—
'Tis not the crown that makes the king.
If you are wise, and good, and just,
You've riches better than all other !
Give me your hand—you shall—you must—
I love you as a brother !"

Let us, as British bee-keepers, give practical expression of brotherly feeling by subscribing to the fund; it will only stimulate his countrymen to do more, and make the annuity the greater. What if the Maloneys, "Amateur Experts," and Heddon's do occasionally have a "rough and tumble," let us show we are one mother's children by giving our mite. Here are two dollars to start from—AMATEUR EXPERT.

Mr. A. I. Root, in relation to the unfounded statements put forth, that combs could be manufactured, filled with spurious honey, and capped over artificially, a statement that no intelligent man believes, writes thus to the *Farm, Field and Stockman* :

It may be well to mention that the principal ground or foundation for the slanderous stories mentioned on the other side, is the fact that bee-keepers have, for perhaps ten years past, used extensively for the production of comb honey, what is called "comb foundation." It is made of thin sheets of genuine beeswax, embossed with the imprint of the bottom of the cells of the honey comb. This is made by passing wax sheets between embossed rollers, and lays out the work for the bees, and at the same time furnishes the wax to contain the honey. Each honey-box (or section) contains in its center, when placed on the hive, a sheet of this embossed wax; and if these boxes are placed in the hive when honey is to be had in the fields, the bees grasp hold of the shallow walls of the cells and draw them up into honey-comb in the same way that a potter pulls up a ball of clay into a crock or jug. Nothing, however, will answer for this comb foundation but pure beeswax; and the comb built from this wax is filled with honey brought in from the fields, exactly as if the bee had to secrete all the wax from its body, as in old time, before bee-culture had made the great strides it has now, and before it became a great industry, as it is now, comparing favorably with the production of butter, cheese, eggs and milk. Visit any progressive bee-man in your vicinity, and he will post you about this matter.

Breeding for Business.—The following item is from the *City and Country*, and was written by Mr. A. H. Duff. It commends itself to the judgment of all thinking apiarists. More attention should be paid to the matter of selecting the best colonies to breed from. He says :

Does it occur to bee-keepers that they should select their breeding stock? I am well aware that quite a number of them do, but I am afraid there are many that do not. Should we not give bees the same attention in breeding that we do any other kind of stock? If not, why not. It is just as important in breeding bees as it is any stock, to select and infuse new blood, etc.

There is scarcely any one that has given bees attention at all, but knows that some particular colonies far outstrip others in gathering honey, breeding, or in some other point. Some colonies are more inclined to swarm than others; others are good comb-builders, and still others are better at filling for the extractor. Some colonies consume one-half less honey during the winter than others, and come out in better condition in the spring, others will breed up more rapidly, and far outstrip their superiors in early spring, while other colonies are inclined to rob, and are more bother than they are worth.

All dispositions and colors may be attained by breeding. The whole make-up of the colony, in whatever particular, is altogether in the queen. It appears that whatever point is the specialty in that colony, the whole colony inherits the same thing.

By breeding from the best honey-gatherers we produce a strain of bees that swell our honey crops largely, and to combine the best honey gathering qualities with the non-swarmling strain, we still add to our crop, and when we combine those two good qualities with gentleness, we have much satisfaction in gathering the crops. Hence, to secure the coming bee it is necessary for a combination of the several good qualities, and there is no doubt that a much higher state of excellence will be obtained.

First Swarms for the season have a peculiar interest, and Mrs. L. Harrison gives the following to the *Prairie Farmer* as her experience with her first swarm for this season:

Bees have a very poor reputation for observing the 4th commandment, and I suppose we notice more when they swarm on the day of rest. On Sunday, June 3, our first swarm for this year issued. I saw them in the air, and finally they scattered all over the leaves of a green ash; they did not cluster, thought better of it and returned to their hive.

This morning about half-past eight a neighbor called to me saying, "Your bees are swarming." There is nothing which so arouses my enthusiasm as to hear their tootin note. It is like the sound of the bugle to an old war-horse, or the bag-pipe to a Scotch highlander.

On going into the apiary, I found that it was the same one that was on the wing Sunday, and I went up to the entrance to watch for the queen, hoping to catch her, but failed to see her. I inferred that she might be unable to fly, from some cause. As soon as the bees were out, I moved the old hive and put one filled with frames of comb in its place, so if they returned they would give up swarming, and if the queen was in the grass she would crawl back. They did not cluster, but came pouring back pell-mell in their hurry, like children running from room to room calling, "Where is mamma." It is a pity that this bee had not been called mother instead of queen.—["Mother" is the correct name.—Ed.]

This swarm had hardly returned to their hive when another came pouring forth from its hive, as if driven out by some unseen power, and in lieu of clustering, came to the first one. Why they came there I could not imagine, as there were very few of the first ones in the air to attract them. I covered up the first swarm with my apron, to keep the others out; and finally carried them to a new stand.

I soon noticed however, that they were not satisfied, running around and touching the antennæ of their fellows, enquiring for mamma. Here was a pretty kettle of fish; a swarm entering a hive placed upon the former stand of the first swarm, while it was deserting its hive and returning. In despair I went to the house to write this paper, telling them to arrange matters to suit themselves.

After awhile I laid down my pen to go and see how matters were progressing. I found one queen balled, and while trying to rescue her she was stung to death. To be certain of a queen in this hive, I now opened the old colony which formerly stood there, and took out a frame upon which was a sealed queen-cell, and put it into the hive. If they have a queen it will do no harm, and if they have not, they will soon have one.

The first swarms that issue are the best bees; that is, they have a prolific queen—if they did not, they would not be ready so soon. If they are nice, bright bees, I like to save as many of the queen-cells as possible, for queens reared under the swarming impulse are thought to be the best. Acting on this principle this morning, I opened the hive that had swarmed, and found a number of large, well-built cells. I took out a frame that had a nice cell, and capped brood, and covered with bees, and put it into a hive with another frame of honey, and put in a division-board. As the bees have no queen, they will remain; the queen will be out in a few days, and become fertilized.

Where frames of brood and bees are removed from a hive having a fertile queen, so many bees will return that there will not be enough left to perform the work for the brood. Therefore it is a much better way to divide up a colony that has swarmed, and has choice queen-cells, as I have done.

If there are a dozen choice cells in a hive, and the bees decide not to swarm, the cells are all destroyed. And there is no way to preserve them, and have the young queen fertilized, but to have one in a hive. The cells can be preserved by being cut off and put into queen-nurseries, but they must be with a colony of bees, either large or small, or they will not become fertilized.

INTERROGATORIES.

Nevada Honey-Plant.—Mr. G. W. Cover, of Downieville, Calif., sends the following:

I send a specimen of one of our honey-bearing shrubs in the Sierra Nevada range for name. Bees are booming, and honey is coming in fast.

This Californian plant is *Chamaebatia foliosa*, (Benth), a shrub belonging to the rose family, but having no near relatives in the country east of the mountains. No common name is known to the writer.

Sundry Questions.—W. W. Morse, Worthington, Dak., on June 9, 1888, asks the following questions:

I have just started in bee-keeping. I have one colony of Italians, and would like to ask a few questions; will you please to answer them in the AMERICAN BEE JOURNAL:

1. I have an artificial grove. Would it be best to put the hives in the shade, or out in the open ground?
2. How high from the ground should they be?
3. Will they get the honey from white clover if it is with timothy grass, or would it be better alone?
4. Is buckwheat honey as good as any other?

1. A little shade would do, but it would be better out in the open ground than in too much shade.

2. There should be but little space under the hives, if any. It is so difficult for bees loaded with honey having pitched, to rise again and get into the hive, or up on the alighting-board.

3. Yes. The timothy will not be any disadvantage.

4. No; it is of the poorest quality—dark, and not fit for modern table use.

Painting Hives—When to Clip Queens' Wings, etc.—Mrs. Mary Blachly, of Delta, Colo., on June 1, 1888, requests answers to these questions:

I should like very much to ask some questions which I have been unable to get answered, and I thought as a last resort that the BEE JOURNAL would not fail to do so, as it can answer anything asked in regard to bees, I believe: 1. Should hives be painted different colors? My hives are all white. I lost a queen, having gone into the hive next to it, and the bees carried it out a few hours after dead. 2. What colors are best? 3. Should virgin queens' wings be clipped? and how can one know when to clip the same? 4. In S. A. Shuck's article, on "How to Rear Good Queens," on page 344, he speaks of opening sealed larvae, and

in the same article he says: "And the food from the cell from which the larvæ were removed, can be given to larvæ not yet sealed." How should sealed larvæ be removed? 5. Is it necessary to remove it when pollen is plenty? 6. For a nucleus to keep queens over winter, how many frames of bees are needed, and how large should the frames be; should there be empty frames put in with each queen's brood-chamber (or apartment)?

1. Yes; it is better to paint them of different colors, because it will aid the queens to find their proper hives when returning from their wedding excursions.

2. Red, white and blue alternated present a good appearance.

3. Virgin queens should not have their wings clipped, else how are they to go on their wedding trip. When they return from that trip, the successful fertilization will be apparent to the observing person. Then their wings may be safely cut.

4. Will Mr. Shuck please answer this and the two following questions, as the method there described is his own?

Mustard as a Honey-Plant.—W. H. Prior, of Madison, Ga., on June 9, 1888, asks the following questions:

I have three rows of white mustard across a square in the garden, which has been in full bloom for a week past, and the bees are very busy on it every morning, for several hours, since it came into bloom. 1. Is mustard a honey-plant, or is it pollen the bees are gathering? The mustard blossoms are literally covered with bees till two or three hours after sunrise. 2. Do bees ever remove eggs or larvæ from one cell to another, or from one comb to another for the purpose of making queen-cells and rearing queens?

1. Wild mustard (*Sinapis arvensis*) furnishes excellent honey. It is very light in color, and of excellent flavor. It commands the best market price, when put up in desirable packages. It is a great favorite with the bees.

2. Yes; eggs are removed by the bees, when forming queen-cells, from the cells destroyed to the reconstructed and enlarged ones made for rearing queens.

Botanical.—Wm. G. Cory, of Carson, Ind., on June 4, 1888, writes as follows:

I send herewith for name, a sample of a plant that grows on low, wet lands, about 2 feet high, and in many places the ground is white with it. Bees are swarming on it from morning until night. No one here knows the name of it. Bees are doing well so far, but the prospect is very poor for a crop of honey, as the white clover as well as all other clovers was killed last winter.

This is *Phacelia purshii*, a noted honey plant belonging to the water-leaf family. *Phacelia* is the common as well as the scientific name.

To Prevent Bees Robbing one another's hives, contract the entrance to the smallest space possible, as it compels the robbers to pass in singly, thus enabling the bees inside to repel them.

QUERIES AND REPLIES.

Excessive Swarming.

Written for the American Bee Journal

Query 552.—How can excessive swarming be checked or controlled?—Maine.

By using large, roomy brood-combs and hives.—J. M. HAMBAUGH.

By giving plenty of room, usually, but not always.—A. B. MASON.

Kill the queen, or get Mrs. Cotton's controllable (?) hive.—MRS. L. HARRISON.

A good honey harvest will usually do it. Aside from this I do not know.—G. M. DOOLITTLE.

It depends upon circumstances and location. Give plenty of room, and use young queens.—H. D. CUTTING.

By the use of the extractor. By proper manipulation where comb honey is produced it can be lessened.—A. J. COOK.

Destroy all the queen-cells in the old hive, and return the second swarm.—C. H. DIBBERN.

An answer to this query would require more space than this department allots. It can be checked by the extractor, removing frames of brood, cutting out queen-cells, etc.—J. P. H. BROWN.

Give plenty of room to store honey and for breeding, and plenty of ventilation at the top of the hive as well as at the bottom. I know whereof I affirm.—M. MAHIN.

If you mean first swarms, it is a pretty hard matter, in spite of all theories set forth. If after-swarms, destroy all queen-cells except one.—P. L. VIALLO.

By extracting the honey from the brood-chamber, and usually by cutting out all queen-cells but one, on the seventh day after a prime swarm has issued.—G. L. TINKER.

I suppose one swarm from each colony would not be called excessive. Further swarming can be prevented by hiving the swarm in a new hive on the old stand, removing the old hive, and cutting out all queen-cells but one good one, five or six days later.—R. L. TAYLOR.

If you mean to prevent the desire to swarm, keep all the honey extracted. I do not believe any one knows how to do it profitably, when working for comb honey.—C. C. MILLER.

This question is one of those that relates so much to localities that a general answer can be of no value. A special answer, to be of value, would

require more space than can be given here.—J. E. POND.

Get the back numbers of the BEE JOURNAL, and read the long essays on the subject. This question requires too much space for an answer, to be adapted to the Query Department.—JAMES HEDDON.

You may check it by giving the bees plenty of room before the swarming fever takes the bees, and continue to give them plenty of room by the tiering-up system, until the swarming season is past. But you cannot usually hope to control swarming.—G. W. DEMAREE.

1. By giving ample space for comb building early enough in the season to retard the desire to swarm. 2. After the first swarm issues, so manage that there will be no after-swarms, by getting all your working force in the new hive, and give them so much to do that they will not have time to swarm again.—EUGENE SECOR.

Establish early in the season the storing habit, and when once established, keep it encouraged by frequent inversions, and giving plenty of storage room at all times. There is something about this that an expert can do, but which it is difficult to communicate. Large hives do not do it, although they assist. Particularly empty brood-nests do not accomplish it, but they also assist. Good management does it every year, but that would require another book, and I have neither the time nor ability to write it.—J. M. SHUCK.

This question cannot be satisfactorily answered. Swarming can usually be checked by giving room, or extracting the honey, but as a rule it cannot easily be controlled.—THE EDITOR.

Bee-Spaces and Honey-Gathering by Divided Colonies.

Written for the American Bee Journal

Query 553.—1. Is a bee-space in the centre of a horizontally-divided brood-chamber a disadvantage? 2. Will a very strong colony in a large hive store as much comb honey as the same number of bees divided into 2 colonies in hives proportioned to their size, other conditions being the same?—Indiana.

1. No. 2. I think so.—A. J. COOK.

1. I suppose it is. 2. I think so.—C. C. MILLER.

1. I do not know. 2. They will, and more.—MRS. L. HARRISON.

1. It would be for me. 2. Yes.—H. D. CUTTING.

1. Yes. 2. Not if the two are crowded for room in the brood-chamber.—A. B. MASON.

1. I think so. 2. Yes, more.—J. M. HAMBAUGH.

1. I think not. It has some marked advantages. 2. Not only as much, but more.—M. MAHIN.

1. I do not know. 2. With me a strong colony will store more.—P. L. VIALLO.

1. I do not know that it is. 2. I think they would.—EUGENE SECOR.

1. I should say it was. 2. The strong colony if in not too large a hive.—J. P. H. BROWN.

1. Yes, most emphatically. 2. Far more, in my own experience, and I have tested the matter to quite a considerable extent.—J. E. POND.

1. Yes. The bees try to fill it up. 2. It depends on the prolificness of the queens, race of bees, and condition in the spring, etc.—DADANT & SON.

1. Certainly not. Why do our bees breed so fast and winter so well in box-hives full of cross-sticks and bee-spaces until the combs are all in pieces? 2. No, not if the hive is very large. There are extremes both ways.—JAMES HEDDON.

1. I think not materially. 2. I want the large colony every time, but do not want frames too deep. Still, this question will bear investigating. I like big colonies in medium-sized hives.—C. H. DIBBERN.

1. I have never found it to be a disadvantage, but often an advantage. 2. Sometimes as much, sometimes more, and sometimes less, depending on what the other conditions are. For instance, if the season passed with a short, heavy flow, the strong colony would store much more than the others, while if the season were much extended the others might store the more.—R. L. TAYLOR.

1. Reason would say that it would be better for bees to "brood" cells of eggs, larva and nymphs, to empty space and sticks of wood. What say you? Will a hen hatch chickens out of wooden eggs or empty space, if in the nest with her eggs? and had she not better sit on hens' eggs than on either of the other, for the good of her owner? What will hold good with the hen holds equally good with the bees. 2. I should prefer the large colony in a small brood-chamber during the honey harvest.—G. M. DOOLITTLE.

1. I think that it is, and my observations again this spring confirm my previously recorded views. 2. Strong colonies, other conditions being the same, always store the most honey, either comb or extracted, but if such colonies swarm, and the season of surplus is protracted, they will store more than those that do not swarm.—G. L. TINKER.

1. It is not a disadvantage to the bees, but is a nuisance to the bee-

keeper. The bees soon modify such a space by filling it to suit themselves. If it is to remain thus filled, and not broken, it is not needed. If it must be broken apart, it will be found not only useless, but an obstacle. I have been trying them thus for ten years, and I know. 2. Sometimes they will, and sometimes they won't. Rules cannot be applied to bees.—J. M. SHUCK.

I have used shallow cases tiered one on the other for brood-rearing, as an experiment for a number of years, and the plan has too many defects to be pointed out in this limited space. As to the bee-space between the shallow brood-chambers, the bees in course of time will attend to that by filling it with bits of comb, and they will economize space by hanging queen-cells into it like a row of teats on the nether side of an old suckling sow. Allow me to ask you, if the hive you speak of is "a horizontally-divided brood-chamber," how about it when it is not divided? 2. Yes, and more.—G. W. DEMAREE.

1. No. 2. Probably they would.—
THE EDITOR.

CORRESPONDENCE.

COMB SURFACE.

Calculating Hive Capacity, the Number of Cells, etc.

Written for the American Bee Journal
BY JOHN H. WIEDMAN.

I am not in the habit of contributing anything to the bee-literature of our country, but I cannot refrain from sending you this to correct an error which nine-tenths of the bee-keepers make in the bee-periodicals in speaking of the comb surface which a beehive may contain.

On page 364 of the current volume of the BEE JOURNAL, Mr. Jas. McNeill has come to the conclusion that a brood-frame of $10\frac{3}{4} \times 10\frac{3}{4}$ inches, inside measure (the size Mr. Doolittle uses), contains 115 square inches of comb surface, and that it would, therefore, take eleven of these frames to enable the queen to lay 3,000 eggs a day during the breeding season, without leaving any room for pollen or honey.

Now, as Mr. Doolittle only uses nine of these frames in his brood-chamber, and finds that these give his queen a capacity for 3,000 a day, besides room for pollen and honey, it seems strange that it should not have occurred to Mr. McNeill that each of these frames presents a comb surface of 230 square

inches, 115 square inches on each side, and nine combs would contain 2,070 square inches, or 103,500 cells, or 40,500 more cells than would be necessary to furnish 3,000 cells for the queen a day.

On page 327, in his article, Mr. Doolittle reckons on the same basis, giving credit for only one-half the comb surface his hive contains.

It must be a well-known fact that nearly all our writers in the bee-papers use this same method. It seems to have become a custom among bee-men to employ this method, but I think that they should use the proper basis, as this is not correct, and as I see it, cannot be defended on any grounds whatever.

It seems strange how this method should have come into vogue, of measuring only one side of a frame in calculating the number of square inches of comb surface it may contain.

Riverside, N. J.

INCREASE.

How to Prevent it, when it is Not Desired.

Written for the Canadian Bee Journal
BY D. A. JONES.

This is the subject that is attracting considerable attention, and all information is being eagerly sought after. There are a great many bee-keepers who have all the increase they require, and would prefer a larger crop of honey with less increase. At seasons of the year when the weather is suitable, with a moderate flow of honey, more especially if the honey is thin that is being gathered, and about enough to stimulate breeding and swarming, bees sometimes get the swarming fever, and swarm they will, after they get thoroughly started, apparently in spite of all efforts to prevent them.

There are various methods practiced by different bee-keepers, all with more or less success according to locality, season, etc. Yet, what does in one locality is often the reverse of the practice most desirable in another. This makes all the difference, or frequently much of it, with the various managements of different bee-keepers; for instance, a bee-keeper in the southern or middle States, or southern Canada, might give special instructions for a certain kind of management which would prevent increase in his locality, while further south or further north this would not be suitable; another point is the variation in the honey season. Some have one continuous flow, while others have several flows of longer or shorter duration.

Some have a long dry space in mid-summer, and no honey then to be gathered, while others at the same time are reaping a rich harvest in comb and extracted honey.

Therefore, if we told those to extract the honey from their colonies, or remove the sections at that particular time when their bees were starving for the want of stores, such instructions would appear ridiculous to those living in a locality where no honey was coming in, and *vice versa*; therefore, judgment must be exercised in all matters of this kind, and all things being satisfactory, the season, flora, weather, and everything that tends to affect the management in any way should be carefully taken into consideration.

We shall speak of our own locality, and while speaking of one of our methods of preventing increase, we are not sure that we will not have a better one before the season closes, as this is a subject we have been experimenting on considerably for years.

Last year we gave it a very thorough test, and we are satisfied on one point, and that is, in order to keep down increase, it is absolutely necessary to give the bees room from time to time; that the colony may not be overcrowded, they must have all the space that they can possibly occupy; that the queen should be kept in the small brood-chamber; that perforated metal should be used to prevent her from occupying any more room than you desire she should (that is, as soon as the honey harvest commences she should have less room to occupy for egg-laying than she had previously). This curtailment of the laying of the queen assists in keeping down the swarming fever.

Where section honey is taken in the earlier part of the season, the supers should be raised as fast as they are occupied, and others placed under them until there are as many supers as it is possible for the bees to occupy. About once a week it is well to look over those which you suspect are liable to commence queen-cells and prepare for swarming, and remove any such cells, giving them a little more room by putting on a super. This will assist in keeping down the swarming fever.

If extracted honey is being taken there may be from two to six supers with combs placed on, according to the strength of the colony, but those should not always be placed on at once. According as a colony increases, a super may be added, in from three to six days, and in each case by raising the one next to the brood-chamber. Putting on the one with combs or frames filled with foundation next to the brood-chamber causes them to

commence work in it sooner. In this way very large crops of extracted honey may be taken, but the hives should be kept cool.

We do not care to set ours more than 4 inches from the ground. The honey should be extracted as fast as ripened, and if the swarm issues it may be returned, two or three of the brood-combs taken out of the brood-chamber and put up in one of the upper hives where the brood will hatch. By putting two or three empty combs in their place, thus giving the colony more room, will usually cause them to remain. We had many colonies last year occupying over 10,000 cubic inches of room.

After the honey season began to close, and there was very little honey coming in, we tried an experiment to see if it would give them the swarming fever, or if they would build queen-cells—by taking off the top supers and crowding them down. This proved just what we anticipated. In taking off the supers where comb honey was being gathered, and any signs of queen-cells appeared, removing one or two supers, and crowding the bees down, caused them to start queen-cells at once. In one instance, by removing all the supers containing sections, and crowding them down, we thought they were nicely settled in the hive, but the next day they made preparations to swarm; in fact, one of these immense colonies we found was just the place to rear a lot of good queens. One occupying say 10,000 cubic inches crowded down to 5,000 would build a large number of fine queen-cells, and we were able to create the swarming impulse, when such did not exist previously to the crowding.

We once were acquainted with a party who prepared a special place for bees in a building. Each place was about 3 feet square, or over 40,000 cubic inches. Although he had a number of these places all along the side of a building, and each one contained bees, and were very strong, each working out on a spout of their own, they were so arranged that the rays of the sun did not strike on them. The hives always kept moderately cool in summer, and fairly warm in winter. Some of these apartments were filled with comb and honey, others were not filled at all, but there was no swarming for years. If our memory serves us rightly, we think there never was more than about one swarm issued, unless some did so unknown to the owner; but we scarcely think that would be likely.

We have known other instances where the apartments were not quite so large, and the bees swarmed after filling them. Now the points seem to

us to be, giving them room at the proper time, not allowing them to become overcrowded, but only continuing to keep them in a prosperous condition, adding room in proportion to the strength and increase of the colony. Better give them too much room in the honey season than too little when the surplus has to be taken by the extractor.

Another point is, if the supers are allowed to become capped over, or nearly so, before the honey is extracted, they are also liable to swarm, but as soon as one is capped, it may be extracted and set away and another put in its place. Some might argue that this required a large stock of combs, but these combs are a good investment, and at any time when desired, they can be used for increase.

Just here comes a point that has something to do in the matter. After the queen is being crowded up and given less room for egg-laying, the increase enables every worker to do its best towards gathering the crop. Now this excessive work wears out the lives of the old bees much faster, and they die much sooner than they would if they had their hives filled with honey, and had only to lay out on the hive to rest themselves.

Thus it will be seen that the breeding space is only large enough to keep up with the mortality of the hive, and the rapid increase in the colony does not appear on account of the extra comb given them. Then in a short time the mortality becomes as great or greater than the increase, and this, we think, is a point that has much to do with keeping down the swarming fever.

Should the honey crop be an average one, at the end of the season the colony is not as strong in bees as they were at the commencement. This system of keeping down the production of bees, and of having a large number of young bees hatching after the honey harvest is over, is one that should be practiced at least in this section, as it saves a large amount of honey that would otherwise be consumed in brood-rearing, which, as we have said heretofore, is quite unprofitable at this particular season.

LEGISLATION.

The Survival of the Fittest, the Right to the Soil, etc.

Written for the American Bee Journal
BY WM. J. WILLER.

Mr. Camm as witness (not supreme judge) for the defense of the present way (not system) of gathering nectar, gives his evidence on page 346.

Some claim that it would be a monopoly. If it is a monopoly to have partial control of a part of this country, then I am a monopolist, for I have partial control of a farm, the United States of America being the other party.

Others say, leave it to the survival of the fittest—fittest what? I think that Mr. Camm gives us a good idea of what is really meant, when he mentions leaving it to the winter to kill off those not able to stand the drouth, or in other words, "the survival of the fittest." I do not think that the present way shows who is the fittest.

We will suppose that Mr. Heddon (and no one doubts but what he has ability) owned only 100 colonies of bees, money enough to run him one year, and pasturage enough within reach to pay him for handling the bees.

Now there may happen to be a few farmers and men in other occupations who conclude to dabble in honey. They own in all 200 colonies in log-hives. Flowers, by their gay attire, advertise for workers; their motto being, "First come, first served," whether from the Heddon hive or log-gum.

Mr. Heddon secures only one-third of the nectar, it being barely enough to keep the bees. He sells out and leaves it to the survival of the fittest. But a doctor, lawyer, any other professional, or tradesman (we farmers are protected) would not need protection, for his employers would have it in their power to withhold the work from others if he was the fittest man.

If A was a doctor of ability, with a good practice (bees in Heddon hives), and B a quack doctor (bees in log-gums) who undertook to run A out, A's patients would say, A is a better workman than you, and he is the man that will do the work (fertilizing).

If a man succeeds in bee-keeping, he must have ability, but a man with more bees than brains, may succeed in crowding a fitter man out, and be no better off himself. If the legislature had left this country undivided until plants had stopped wandering in search of plant food, it would have been undivided yet; but being divided we may have our farm all into elm trees (I know they will go 4 rods each way, and I think they will go further for food), and still our next neighbor has some chance to succeed. But where would he be if all the plant-food were free to all, and he sowed wheat on a piece of land to gather the nourishment, and some one else sowed oats on the same land, and so on *ad infinitum*?

This may be a crooked evidence, but I have not been positive where I could prove nothing.

Sandusky, Mich.

STEALING HONEY.

A Grizzly Bear Caught in the Act.

Written for the Youth's Companion
BY A. WRIGHT.

The Holden brothers, Roswell and Frank, went to California from a New England town in 1881, for the benefit of Roswell's health, upon medical advice; and subsequently they found themselves engaged in the business of bee-keeping near Los Angeles — for circumstances, accident rather than design, first led them into it.

The children had inherited a constitutional tendency to pulmonary diseases, which had already begun to develop itself in Roswell. Indeed, he had become so far an invalid that his friends deemed it unsafe for him to set off on so long a journey alone. After many family deliberations it was arranged that Frank, and Ellen, their sister, should accompany him, and remain one winter, if not longer, in the West.

As their means were limited, Frank and Ellen began, soon after arriving in California, to look about for some way to earn a living. Roswell, too, as his health improved, wished for something to do; and at length they were, by chance, led to buy 13 colonies of bees of a lady—herself formerly an invalid—who had employed her leisure in apiculture, but now was about returning to her home in New York.

With these 13 colonies the young Holdens entered upon the honey-producing business early in 1882. For a year they resided in the vicinity of Los Angeles, but finding that the bees, as the number of colonies increased, were unpopular among their neighbors, they were led to move from so thickly inhabited a district, and lived for a time near Majave.

Thence, however, early the following spring, they again moved to a tract of unoccupied country further back among the mountains, in a kind of long defile, or crooked valley, inclosed by a wooded range on either hand, but which, from the great abundance of wild flowers, affords good pasture for bees. Here they are at present dwelling.

The Holdens have now between 200 and 300 colonies, having made it a rule, so far, to keep all the swarms which come out, though a few have escaped. The care of these numerous colonies of bees occupies all their time and attention, and they hired two Indian girls to assist them to watch the numerous sub-apiaries which they have established in different parts of the valley, generally within a mile of each

other. For it will not do to have all these 200 colonies, or more, collected near one spot, on account of the supply of flowers being over-fed, and the bees having to go too far.

The whole number of colonies is divided up into groups of 10 or 15 colonies, and these are often shifted from place to place as the season passes.

For moving colonies to fresh pasturage, the boys have a platform set upon four wheels, and drawn by two steady mules. Then, after the bees have entered the hive at night, they are closed in, and the hives are transferred to the platform. Very carefully then, and slowly, so as not to jar the hives too much, the transportation of the colonies to the distance of a mile or two is effected.

valley, well stocked with flowers and flowering shrubs, outspread before them; and so secluded did the place seem, that the young apiarists judged it entirely safe to leave the bees to gather honey here, unguarded, for a few days at least.

Having seen to it, therefore, that the hives were well placed, they returned down the valley to their shanty-house, where their sister and the Indian girls looked after the few simple domestic affairs of the household. In fact, it was their custom thus to colonize a new pasture, and they had met with few losses. Honey in small quantity had been stolen from them on one or two occasions, and once a number of deers, in their flight across the valley, had upset three or four hives.

The Grizzly Honey-Eater of California.

In March or April of last year the Holdens had pastured out 10 colonies at a point higher up the valley than any they had previously occupied. In point of fact, the new pasture was in a branch of the main valley. Hither they had come up from their beehives next below, two miles distant, with a load of hives, and built a "rest" for them near two large oaks—great trees with wide-spreading branches that nearly touched the ground—on the north side of the intervalle, at the foot of the mountain.

It was a favorable location, for on the south side the bees had the entire

But on this occasion they met with a mishap; for on going to the place two or three days afterward, to see how their swarthy "Italians" were prospering, Frank found one hive upset, and another of the ten missing altogether. From the latter circumstance, as also from certain marks and traces in the grass, resembling foot-prints, he at once concluded that some thief had "jumped" the hive—that is stolen it bodily.

A few days before they had heard the report of a gun several times, faint and at a distance, and had conjectured that there was a hunting party, either

of whites or Indians, on the other side of the mountain.

"Some of them have probably been spying about and got their eyes on that row of hives," was Frank's thought.

Whether the rogues would rest content with the honey of one hive, or come back after more, was what no one could guess. The brother, however, deemed it prudent to expect them again, and would have gone up and drawn the remaining hives down to camp, if the two Indian girls had not been sent down to the post-office—a little settlement twelve miles away—with the mules, to get the mail and a stock of groceries.

Roswell, therefore, proposed that, after supper, they should take a little shelter tent which they had, and go up to the new rest, in order to pass the night where they could guard the hives. For by this time the older brother had so far recovered his health as to be the stronger of the two.

As Ellen did not like to be left entirely alone, she proposed to accompany them. They accordingly set off, taking along the tent, three blankets, and a Winchester carbine.

Arriving at the rest just at dusk, they pitched their little shelter tent near the trunk of one of the oaks already referred to, and in such a manner that the ends of the drooping branches nearly or quite concealed the tent from view.

The night was warm, and the place was quite dry. Accordingly they did not kindle a fire, but made themselves comfortable with their blankets under cover of the tent, and the sheltering foliage of the tree.

They had really no serious expectation that the thief would come back; and after a time all three of them fell asleep, for Ellen Holden had become quite accustomed to this free, out-of-door life. They slept thus for three or four hours.

During the early part of the night there was a moon, but the moon set about midnight; the stars, however, gave some light, though everything was rather misty and dim. The now somnolent and quiet hives reposed on their rest, a few yards from the tree and the tent.

At length the sleepers were suddenly roused by a heavy thump, followed by a grating noise and a deep humming sound from the hives.

They all started up and listened intently.

"Something's afoot of the bees, Ros," whispered Frank.

Roswell, starting up, took the Winchester and peeped out amongst the oak branches. What looked like a tall, "slouching" man was in the very

act of taking one of the hives in his arms, despite the loudly buzzing bees. As Roswell stared in astonishment, the sturdy pilferer did actually clasp his arms about the hive, and raising it off the rest, started to walk slowly off with it.

"It's some Indian, I guess, by the looks of him," muttered Roswell. "I don't just like to fire at him; he don't seem to have any gun. But let's 'go' for him and give him a good thrashing."

Frank agreeing at once to his proposition, snatched up two stakes which they had cut for the tent, and handing one of these to his brother, who laid down the rifle, both young men ran quickly, but stealthily after the heavily-loaded thief, who was shambling awkwardly on across the open ground, beyond the rest.

The grass was thick and soft, and they were not long closing in with the marauder.

"You scoundrel!" yelled Frank. "Lug off our honey, will you?" and drawing off with his stake, gave the thief such a tremendous whack across the back and shoulders as to knock him half-forward over the hive.

"Take that!"

Drawing off again, he was about to repeat the dose, and Roswell on his part was just getting in a blow, when the supposed "Indian" suddenly came around on all fours, and gave vent to a growl which made the whole valley re-echo.

It was a grizzly! and as he growled, he rose on his hind legs and "lunged" at Frank.

Prodigiously astonished, Frank gave a long jump backward—not so far, however, but that one of the ugly creature's paw raked along his right side and sent him rolling over and over again on the ground.

Roswell, too, had executed an almost equally long leap backward, and ran plump into Miss Holden, who, with commendable foresight, had come quietly after her brothers, with the Winchester in her hands.

"Here, quick, shoot!" she exclaimed, thrusting the loaded piece into his hands. Turning on the instant, Roswell fired one, two, three, four shots into the bear, now in the very act of lunging again at Frank, and with such effect that the animal fell, roaring and whining, unable to rise for another lunge.

A few more shots finished it.

Frank, though considerably bruised and shaken up, was not seriously injured.

"Ellen," exclaimed Roswell, turning to his sister, when the bear had been fairly floored, and Frank had picked himself up, "Ellen, you're a brick!

You got around just in the nick o' time!"

"Well," said she, laughing, "when two fellows go after a grizzly with a couple of sticks, it's a good plan to have a Winchester not far behind."

WINTERING BEES.

An Experiment of Wintering Bees Under a Straw-Stack.

Written for the American Bee Journal

BY ANDREW UTZ.

I have been thinking of wintering bees under a straw-stack, for years, so last fall I set up six posts 7 feet high, and made a space 8x14 feet covered with lumber. Then to make it perfect, I made a "flue" of lumber, 3x4 feet at the bottom, and 6x8 inches at the top. Then I set this "flue" above the posts which I thought would draw all the dampness out, and then built a narrow gangway to carry the bees in and out.

Then when I threshed I had five men on the stack to have it well packed; when the stack was finished it measured 28x50 feet, and 40 feet high. The narrow sides were 10 feet on each side, and the ends much thicker. They all thought that it would be just the thing to winter bees in.

On Dec. 20, 1887, I put 27 colonies in the stack; then I packed the gangway well with straw, and closed it with a tight door on the out-side.

On March 31 I took them out; 14 colonies were alive, and 13 were dead. But such hives and combs I never saw. My poor pets had a hard time; I suppose they had the diarrhea nearly all winter. It made me sick. The combs and hives were moldy and musty, so I put them in clean hives and fed them on syrup made from A sugar. They all had plenty of honey, but I did not think it was fit for them to eat. One lost its queen, so I put two together, and since then I have given each two frames of brood, and yet they are weak. Since then all but 9 have died.

I would not have written this, but I was at Columbus last winter on business at the time of the Bee-Keepers' Convention, but could only be at the convention one-half day, so I asked whether any one had ever wintered bees under straw, but no one had. Mr. Boardman said he would be afraid to try it. His head was level on that. Dr. A. B. Mason said I might do it and report.

By my doing so I hope that none of my brethren will be so cruel to their pets as I was. We cannot control the temperature under straw. After Mr.

Boardman nearly scared me, when I got home I got two thermometers, and let one down through the flue from the top of the stack among the hives to test the temperature. The other one was placed outside, in the open air, only covered to keep it dry. Now I will give the temperature as I took it day by day :

	UNDER THE STACK.	OUT-SIDE.
Feb. 26	40	30
" 27	12	12
" 28	10	11
Mar. 11	38	33
" 12	31	29
" 13	12	13
" 14	43	42
" 18	53	31
" 19	29	29
" 20	60	59
" 21	40	31
" 22	19	11
" 25	22	19
" 26	61	61
" 30	39	41
" 31	60	60

I left 38 colonies on the summer stands. Of these, 2 starved, but the rest are all in good condition, and have from 5 to 8 frames of brood. Of course I could not help taking from the rich and give to the poor pets that were under the straw-stack. We had plenty of fruit-bloom this spring, but on account of the cold weather, bees could not work on it more than about two days in all, but yet they are doing well.

Kenton, Ohio.

SMOKE.

Its Value in the Modern Management of Bees.

Written for the Bee-Keepers' Guide
BY T. F. BINGHAM.

When honey was at the highest price ever known in this country, viz., from 1863 to 1866, little use was made of smoke by the greater number of bee-keepers.

Even Roswell C. Otis, the veteran who mainly introduced the Langstroth hive in New York and the West, only used a cigar in his demonstrative work.

It is true that Mr. Langstroth had explained the action and value of smoke in the control of bees, and the principle on which its effect rested, in his most efficient work, "Langstroth on the Hive and Honey-Bee."

Hunters of bees had used burning straw about bee-trees when cutting them down, and found the cloud of smoke a protection against stings. But the main conception of the value of the smoke in the management of bees was associated with the common pipe or cigar. This fact, no doubt well based, came from the prompt action of tobacco smoke—an action more

efficient than any other smoke, and also more convenient with the means then in use, especially when the bee-keeper was a tobacco smoker. (And such habit was likely to prevail with bee-keepers whose aversions to the habit of smoking were not strong.)

The invention and application of the direct-draft principle in bee-smokers at once revolutionized the management of bees.

Tobacco smoke was no longer of value, because more condensed and in use by pipe and cigar smokers. The great abundance—a cloud of smoke enveloping the user of a Bingham smoker—and the fact that such a smoker never went out—and that smoke in clouds could be instantly applied to bees—at once supplanted the tobacco pipe and cigar in their management.

While it is not the province of this article to discuss the tobacco habit, the direct-draft smoker plays an important part; as there is no excuse for a bee-keeper smoking tobacco, so far as bee-keeping is concerned.

The fact that bees fill their honey-sacs with honey when frightened, and do not, when so filled, volunteer an attack, and the ease with which smoke is applied, has led, no doubt, to the abuse of smoke in managing bees.

Bad habits are common from superficial methods of reasoning, when a more thorough analysis of apparent results would eradicate or modify them. This is especially true in the use of smokers, and the smoker in the case of the apiary.

The fact that a cloud of smoke around a bee-tree reduces the anger of the bees, and removes the danger of attack from them, leads directly to the conclusion that such a cloud of smoke would have the same effect in an apiary. Circumstances which have come under my observation lead at once to this conclusion. As an evidence of the fact, allow me to cite the sale of smokers at certain seasons of the year, and the sizes most sold at such season.

The inference from the sale of any particular sizes of smokers, at a season when smokers are not much in use, is that the most experienced bee-keepers provide themselves with such tools as they are likely to need, before they are actually required for use in the apiary, while the amateur waits until the case becomes urgent before he decides, and then is likely to consult the first cost (which he sees clearly) rather than the results and principles underlying his purchase, which he does not so clearly understand.

Early in the spring, and also in the autumn, our sale of smokers are as five of the two largest to one of the

smaller sizes, while in the middle of the season, when the young bee-keeper is obtaining his urgent outfit, the small and medium sized smokers lead in sale the three largest sizes somewhat, so that the entire season wings around with about the same total number of each as sold.

As the larger sizes hold more wood, and make as much smoke in proportion, it is safe to infer that bee-keepers of experience do not object to an immense volume of smoke in handling bees.

This conclusion, providing the premises on which it is based are correct, leads to the decision that bee-keepers, whether they understand the principle or not, recognize the value of a continuous cloud of smoke in the apiary at all times when bee-keepers are of necessity or choice among the hives and bees.

It is idle to presume that a peaceful, non-aggressive apiary can be found where gloves and veils are resorted to instead of constant and overwhelming smoke.

With abundance of smoke, the eye of the bee-keeper holds the temper of the bees, as the experienced horse-man holds the vicious horse, and any careful manipulation may be made without a puff of smoke, provided always that the smoke is abundant in the air, and at the service of the operator should occasion require.

The above leads directly to the much discussed fuel for smokers. Of course circumstances alter cases, and the means of obtaining fuel of any particular kind will play a conspicuous part. One thing, however, will be found advisable under all circumstances, viz., to consult the smoker.

It is useless to try to burn anthracite or hard coal in a box-stove designed for burning wood. It would be equally futile to attempt to burn stove wood in a smoker not having a strong continuous draft.

This being understood, a clear understanding of the principles leading to results desired, it seems to me but one conclusion can be reached, viz., that sound sun-dried, or other perfectly dried maple stove wood meets, in the highest degree, the needs of the bee-keeper using a direct-draft smoker.

Some of the reasons why perfectly dry hard wood is preferable for use, is that it burns only at the bottom or lower end. That is, it renders the direct-draft smoker a base burner. (Rotten wood burns all over, and is soon gone.) Wood in sticks does not obstruct either the draft or blast, both of which render quick and continued action easy.

Sound wood, which has live coals left after it has ceased to smoke, main-

tains sufficient heat to prevent unpleasant sooty accumulation, and furnishes hot, dry, strong smoke all the time without working the bellows, thus rendering it ready for use every instant.

Of course the direct-draft smoker will burn anything combustible, and he who uses it may choose his fuel according to circumstances and tastes.

It may be asked here if it would not be better to have cold smoke. Such an idea has been advanced very much, but as the object of smoke is to frighten bees, not convert them into bacon, anything that will accomplish the fright in the easiest and most effective manner, will serve the purpose best.

Hot air will do this just as well as smoke, as far as it goes, but the air cools so quickly it is of no value except just as it leaves the smoker. The making of smoke goes on fast or slow just in proportion to heat, so that when there is heat there is little smoke, and *vice versa*, where there is much smoke "there is some fire."

Abronia, Mich.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*
 Aug. 3. Ionia County, at Ionia, Mich.
 H. Smith, Sec., Ionia, Mich.
 Aug. 14.—Colorado State, at Denver, Colo.
 J. M. Clark, Sec., Denver, Colo.
 Aug. 27.—Stark County, at Canton, O.
 Mark Thomson, Sec., Canton, O.
 Sept. 8.—Susquehanna County, at Montrose, Pa.
 H. M. Seeley, Sec., Harford, Pa.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Three Weeks Late.—Wm. Enke, of Rochester, Minn., on June 9, 1888, writes :

The season here is about three weeks late. Dandelions are now in full bloom, and bees are gaining fast. My bees were in the cellar 163 days, and I lost 1 out of 90 (in the cellar), but these were reduced to 75 by uniting.

Spring Dwindling.—S. D. Haskin, of Waterville, Minn., on May 29, 1888, writes :

I will describe the condition of my bees and those of my neighbor: Mine were wintered on the summer stands, and his in an out-door cellar. About the middle of March it was warm, and I examined mine. They appeared to be in splendid condition, but they did not have a general flight until May 1, and as is usual with so hard a winter, and such a long confinement, they had soiled their lives badly, and many fainted and failed as they flew, and my 30 colonies were

now reduced to 6. The wild plums, cherry and willows, and many other wild flowers are open, that they usually work on, but they do not seem to work energetically. My neighbor's bees were inside over 6 months. There was no suitable weather to get them out. There has been so very much wet and cold weather. His bees are much reduced, but are in better condition than mine. I have taken 20 of his colonies to run on shares this season, giving him one dollar per swarm for the young swarms to hive in my hives, which are full of comb. I give him one-half of the honey of the old colonies, but the prospect so far is slim, indeed. To-day is warm and clear; the best we have had this spring.

Have Tested Them.—Daniel Whitmer, of South Bend, Ind., on May 16, 1888, writes :

Having used the Heddon divisible-brood-chamber hive for two years, I would say that I find it more convenient for handling than any hive I ever used. I can find queens very readily in it, and prefer it for the production of comb honey, as well as for getting it in the liquid form. For moving them in and out of the cellar I find them exceedingly convenient. Of course I shall test them more fully this year, if we have a good honey flow.

Moved my Bees.—W. H. Stringer, of Guthrie Center, Iowa, on June 1, 1888, writes :

I moved my bees this spring on a wagon about ten miles. I lost about 12 colonies through the winter. I had 3 colonies that I wintered out-of-doors; the rest were in the cellar. I have 36 colonies, including a few which I divided. I think that fully one-half of the bees in this county died last winter. I secured about 1,000 pounds of honey last year. I like the BEE JOURNAL very much.

That Three-Sided Hive.—Mr. D. Chalmers, of Poole, Ont., on June 2, 1888, asks us to make some corrections of his article on page 340. He says :

In giving a description of my improvements in bee-hives, there are a few mistakes which should be corrected: In the 19th line below Figure 1, it should read thus: "The upper level of the frames are that distance below the level of the top of the hive," then, again, in claiming the properties of the honey-board, it should read: "Only being propolized around the inner edge of the hive," instead of *under edge*. There is a misprint in the first line of the second column, in that you have "adjustable" side instead of *adjustable*.

Still Feeding the Bees.—Mr. O. R. Goodno, of Carson City, Mich., on June 10, 1888, writes very discouragingly of the prospects—but he is yet hopeful :

Spring is not yet in sight for bees. Spring dwindling still continues. I am feeding the bees every night to keep them from starving. Fruit bloom and dandelions are past and gone, with the above existing conditions. I would like to see Mr. Doolittle, or any other man, produce his starters for surplus which he advocates in fruit bloom, in this section this year. I have seen the first raspberry and white clover bloom to-day, for the season. For several days nothing has been in bloom, with a fair prospect for a slight frost to-night, but never mind. "Wind her up again, John."

Bees Scarce Here.—A. S. Camblin, of Selma, Iowa, on June 13, 1888, writes :

There are no large apiaries in this part of the State, and it is likely that there will be but few small ones for some time to come. Owing to the two years' drouth, the bees have nearly all died. There is not more than 25 colonies within four miles of this place, and 15 of them are what I saved out of upwards of 30 I put into the cellar last fall. I hope for a full honey flow. I put off feeding until late. The season here has been backward. During fruit bloom it was cold and windy most of the time, so that the bees could not fly; but by feeding I have my 15 colonies in pretty fair condition. I have nearly a clear field, and if the season is favorable, I expect to get some honey this summer. I have 7 or 8 acres of Alsike clover sowed this spring with fall wheat. Will it bloom this summer to afford any honey?

[Yes. It is an annual, and blooms the first year from the seed.—ED.]

But Little Surplus Honey.—C. Solveson, Nashotah, Wis., on June 14, 1888, writes :

In this vicinity we shall have but little if any surplus honey this year. Not only is the white clover badly killed out, but we will not have the bees to gather what little honey there will be. Out of 94 colonies placed in winter quarters last fall, I had 90 colonies left this spring in good condition; since then I have lost 30 per cent. from spring dwindling. No pollen was gathered in April, and but little in May. I have not a colony to-day that is stronger than when taken from the cellar on April 18, and I am feeding them daily to keep life in the few remnants I have left. The Editor's remarks in regard to that infamous Wiley, are to the point exactly. His position and present employment is a disgrace to the Nation!

Good Prospect for Honey.—J. M. McDaniel, of Peoria, Texas, on May 11, 1888, writes :

Our prospect for honey is good. Bees here have been near starvation for the last two years, but now the few that have survived are booming.

Successful Work.—A. S. Straw, of Edwardsburg, Mich., on June 14, 1888, says :

I have kept bees for 35 years of my life, and I thought I was well posted on them, but after reading the AMERICAN BEE JOURNAL, I find I am at the foot of the ladder. I can look back and see where I lost lots of bees by not reading and posting myself. I commenced two years ago with 3 colonies of bees, and got 300 pounds of comb honey. In 1887 I had 7 colonies; I got no surplus, but I increased them to 15. I commenced this spring with 15, all in good condition, and they are gathering honey fast now. They wintered in the cellar; the temperature was from 30° to 43° above zero. I give the AMERICAN BEE JOURNAL the credit for my success.

Has a Good Market.—J. M. Jacobs, DeWitt, Iowa, on June 14, 1888, writes :

I have, this spring, in good condition, 30 colonies of Italian bees. This year, in this region, prospects are good. The year 1887 was unfavorable for honey. I had orders for 10,000 pounds of honey more than I could fill. In 1886 I sold in 14 days 22,000 pounds of honey. I can sell this fall 100,000 pounds of one-pound sections of white clover honey.

Joined the Silent Majority.—Mr. H. Clark, of Palmyra, Iowa, on June 7, 1888, writes as follows :

The Lord has seen fit to call my daughter to the Land of Rest. She was an interesting worker among the bees. She had soft blue eyes and long yellow hair, and was a constant reader of the BEE JOURNAL, and spoke of it in her last hours. These lines were written by Mrs. Martha Thompson, of Clarkson, Iowa, concerning our daughter Emina :

She sleeps within the cold, cold ground,
The dark, blue skies above her ;
She was too fair and frail for earth,
None knew her but to love her.

Her sweet, fair form has faded now,
Her cheeks have lost their roses ;
Her guileless heart is free from sin,
In heaven sweet reposes.

We stood beside her bed of death,
Bowed down were we by sorrow ;
We knew she would be lost to us,
Upon the coming morrow.

From her fair lips the cheerful smiles
Could not by death be driven.
And with hopes of future bliss,
She passed from earth to heaven.

Hold your Breath.—L. Hammer-schmidt, of Amana, Iowa, writes on June 8, 1888, as follows :

In the *Scientific American* for June 2, 1888, I find this statement: "If you hold a bee by the legs, between two fingers, and let her sting *act* on the fleshy part of your finger's point, as long as you hold your breath, the sting will not penetrate the skin." I have tried this, and found it to be correct; even more, I have put my hand between two combs full of bees; have taken a hand-full of bees, and when I sweep off the bees from a comb, as long as I can hold my breath, they will not sting. Will some others of the fraternity try this and report?

[We republish the above letter, corrected because in our last issue the word *not* was introduced in the fourth line in the place of *act*—spoiling the sense.—Ed.]

Frank Leslie's Sunday Magazine for July, which begins the twenty-fourth volume, is a bright and entertaining summer number, full, as usual, of interesting reading and beautiful illustrations. Among the profusely illustrated articles are "Ancient Greeks in Modern Cyprus," by A. L. Rawson; "Sunday in the City of the Czar," by Rev. Frederick Hastings. These with other numerous articles, art pictures, music and miscellany, make up a very attractive number.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows :

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Cork for Winter Packing.—Its advantages are that it never becomes *musty*, and it is *odorless*. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2 00	3 00	3 50
1,000 Labels.....	3 00	4 00	5 00

✂ Samples mailed free, upon application.

J. T. Wilson, of Nicholasville, Ky., on June 4, 1888, writes thus: "My card in the AMERICAN BEE JOURNAL brings most of my orders."

Honey and Beeswax Market.

NEW YORK.
BONEY.—We quote: Fancy white in 1-lb. sections, 13@15c.; the same in 2-lbs., 10@11c.; buck-wheat 1-lb., 10c.; 2-lbs., 9c. Market dull. We are doing all we can to reduce stock, to make room for the new crop.
BEESWAX.—26c.

HILDRETH BROS.,
 May 21. 28 & 30 W. Broadway, near Duane St.

DETROIT.
HONEY.—Best white in 1-lb. sections, 14c.—Dull.
BEESWAX.—23@24c.
M. H. HUNT, Bell Branch, Mich.
 June 14.

CHICAGO.
HONEY.—Prices range from 15@16c. for best one-lb. sections; other grades are slow at lower prices. Extracted, 7@8c. Light demand, and supply larger than usual at this season of the year.
BEESWAX.—23c.
R. A. BURNETT,
 May 1. 181 South Water St.

NEW YORK.
HONEY.—We quote: Fancy white 1-lb. sections, 14@15c.; fancy 2-lbs., 12c. Lower grades 1@2c. per lb. less. Buckwheat 1-lb., 10@10½c.; 2-lbs., 9@9½c. Extracted, white, 7@7½c.; dark, 5½@6c. Market is dull for comb but improving for extracted, of which new from the south is arriving.
BEESWAX.—Scarce, 24@27.
 May 21. **F. G. STROHMEYER & CO.,** 122 Water St.

CHICAGO.
HONEY.—We quote: Fancy white clover 1-lb., 16@17c.; 2-lbs., 15@16c. Dark is slow sale at almost any price. Extracted is scarce, and sells at 7@10c.
BEESWAX.—23c.
 Mar. 13. **S. T. FISH & CO.,** 189 S. Water St.

CINCINNATI.
HONEY.—We quote extracted at 5@8c. per lb., for which demand is good. Comb honey, 14@17c.—Demand slow.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
 Jnu. 14. **C. F. MUTH & SON,** Freeman & Central A. V.

MILWAUKEE.
HONEY.—Choice white one-lb. sections, 16@17c.; 2-lbs., 15@18c.; 3-lbs., 14c. Extracted, white in kegs and ½-barrels, 8 to 8½c.; in tin and pails, 9½@10c.; dark in barrels and kegs, 5@7c. Market fair.
BEESWAX.—22@25c.
 Apr. 23. **A. V. BISHOP,** 142 W. Water St.

DENVER.
HONEY.—Best white 1-lb. sections, 17@19c.; 2-lb. sections, 15@17c. Extracted, 7@10c.
BEESWAX.—20@23c.
 Mar. 1. **J. M. CLARK & CO.,** 1409 Fifteenth St.

KANSAS CITY.
HONEY.—We quote: Choice white 2-lb. sections, 17@18c.; dark 2-lbs., 14@15c.; choice white 1-lb., 18 to 20 cts., dark 1-lb., 15@16c. White extracted, 7@8c.; dark, 5@6c. Demand is slow. White extracted is firm when in 60-lb. tin cans.
BEESWAX.—21 to 22c.
 Mar. 29. **HAMBLIN & BEARSS,** 514 Walnut St.

BOSTON.
HONEY.—We quote: 1-lb. sections, 16@17c.; 2-lb. sections, 14@16c. Extracted, 8@9c. The market is not very brisk and sales are slow.
BEESWAX.—25 cts. per lb.
 Mar. 24. **BLAKE & RIPLEY,** 57 Chatham Street.

SAN FRANCISCO.
HONEY.—We quote for new extracted 6@4½c., as to color and quality. New comb honey 14@10c., as to quality. Arrivals are still small, and demand of a jobbing nature.
BEESWAX.—Scarce, 20@24c.
 June 2. **SCHACHT & LEMCKE,** 122-124 Davis St.

KANSAS CITY.
HONEY.—We quote: White 1-lb., unglazed, 15c.; 1-lb., white, glazed, 14c.; dark, 1-lb., 2c. less. California, 2-lbs., comb, white, 13c. Extracted, 7c. Considerable old honey is in this market. No new yet in. Sales are very slow.
BEESWAX.—None in the market.
 June 9. **CLEMONS, CLOON & CO.,** cor 4th & Walnut.

Paper Boxes.—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 1¼x1¼ and 5¼x5¼. Price, \$1.00 per 100, or \$8.50 per 1,000.

New Subscribers can obtain the full numbers for 1887 and 1888, for \$1.75, while there are any sets of 1887 left.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices:—Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 18 cents per pound for bag and postage.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Advertisements.

LOOK!—Beautiful One-Piece Sections only \$3.60 per 1,000. Order at once from this advertisement—or if you wish T-Supers or other Supplies cheap, write for circular. Address, **R. L. CLEGG,** 25A1C PEORIA, Union Co., OHIO.

GLASS PAILS

FOR HONEY.

THESE Pails are made of the best quality of clear flint glass, with a ball and a metal top and cover. When filled with honey, the attractive appearance of these pails cannot be equalled by any other style of package. They can be used for household purposes by consumers after the honey is removed, or they can be returned to and re-filled by the apiarist.

Prices are as follows:
 To hold 1 pound of honey, per dozen, \$1.60
 " 2 pounds " " 2.00
 " 3 " " " 2.50

EDITORIAL BUZZINGS.

You Never Hear the bee complain,
Nor hear it weep nor wail;
But, if it wish, it can unfold
A very painful tail.

The Honey Crop of California is now reported to be only two-thirds of an average product. Our first reports said that it was large, but gave no comparison.

Mr. Joseph McCaul (late of McCaul & Hildreth Brothers), has again opened the "Bee-Keepers' Headquarters" at 191 Duane Street (near Greenwich), New York, and invites all apiarists who go to New York, to give him a call.

Mr. G. M. Doolittle, we regret to learn, has been confined to his residence for a week or more, with lumbago, or "criek in the back." The only easy position he has found so far, is being propped back in a rocking chair. This must be "misery" for our energetic friend. We hope that complete relief will soon be found, and that "Richard will be himself again," before many days pass.

New Bee Book.—We have received from the publisher, L. Upcott Gill, 170 Strand, W.C., London, England, a copy of "The Book of Bee-Keeping," by W. B. Webster. It is a pamphlet of 98 pages, and covers the whole ground of the modern "management of bees," Mr. Webster being a first-class expert of the British Bee-Keepers' Association. It is gotten up cheaply to fill the popular demand of English cottagers for a cheap manual of bee-keeping, and sells for a shilling. It gives, in a concise form, what to do in the apiary, and how to do it, but the methods and implements are not such as are used in America, except in a few particulars.

Major Von Hruschka, the inventor of the honey extractor, is dead. He died in Venice on May 11, 1888. This we glean from the *L'Apicoltore* for June, which is just received. Major Hruschka was a retired Austrian officer, and the invention of the honey extractor occurred in this way: His apiary was in Italy, and one day when the Major, who was a most observing and critical bee-keeper, was in his apiary, his little boy came there to him. The boy had a small tin pail tied to a string, which he was swinging, boy-like, around and around in a circle, holding the end of the string in his hand.

The indulgent father gave the youth a small piece of comb filled with honey, putting it into the little pail. The boy, after awhile, began to swing the pail again as before, with the honey in it. A few moments after, he became tired of that amusement, and put the pail down to talk to his father, who took it up, and, by chance, noticed that the honey had left the comb and settled down into the pail, leaving the comb perfectly clean that had been on the outside of the circle when the boy was swinging it around. The Major wondered at the circumstance, and, turning the comb over, bade the boy swing it again, when, to his great astonishment, the other side of the comb also became perfectly clean, all the honey being extracted and lying at the bottom of the pail.

During the following night Major Von Hruschka, after going to bed, commenced to think the circumstance over; he thought, and thought, and his thoughts troubled him so much that on the morrow he commenced a series of experiments which resulted in his giving to the world the first honey extractor, which, by whirling, something like his son whirled that little tin pail, gave him the pure liquid honey, extracted by centrifugal force, leaving the honey-comb entirely free from the liquid sweet, which he gave again to the bees to fill; allowing him the pure honey for making wine, mead and metheglin, or honey cakes, as desired, without employing the troublesome and primitive method in use up to that time, of mashing up the combs containing the honey, pollen, and sometimes brood, too, to let the honey drain through the cloth in which it was placed—giving what was formerly known as "strained honey."

Chapman Honey-Plant and White Clover.—S. Burton, Eureka, Ills., on June 15, 1888, writes:

"The Chapman honey-plant seed that I obtained in the spring of 1887, is doing finely now. It is from 4 to 6 feet high, and is heading for bloom. Will it bloom more than once from the old root? All who see the plant want to know what I am "raising those thistles for." I will write more about it later. I have had 10 swarms this spring, but none the past week. The white clover will be scarce until the new crop comes from the seed, which is abundant, and which, I think, will bloom in July.

It is a perennial, and blooms yearly from the same root until killed.

Squeezing Blood from a Turnip.—Those fellows who wager a thousand dollars without knowing what they are talking about, as Mr. Evans did (see page 388), are usually the kind of persons, financially, who "have nothing to lose."

Mr. H. M. Moyer, of Hill Church, Pa., writes thus on June 18, 1888, to the Manager of the National Bee-Keepers' Union:

I have read that article of yours on "the Wiley lie," on page 388. It is entirely too much to stand that wager of Mr. Evans. I will give three dollars if you will compel him to pay that thousand dollars into the treasury of the Bee-Keepers' Union. He is beaten, and should now pay it, just as Mr. Root would have had to pay if beaten.

Yes; he ought to pay the money, but had he been worth it, that wager would never have been made. Men who know the value of money do not make such wagers, unless they are drunk or crazy. Mr. Evans was, no doubt, sober, but lunny on morality and honesty—a pessimist!

You may as well try to squeeze blood from a turnip as to get money from such an idle boaster as the man who wrote on page 388 that characteristic letter which calls sacramental wine "the essence of hell." He is evidently a worthless "crank."

Comb Surface.—In last week's issue, on page 407, Mr. Weidman makes some calculations on the number of cells in a frame 10 $\frac{1}{2}$ x10 $\frac{1}{4}$ inches. As he comes to conclusions very different from those universally received, we fully intended to have added a foot-note to the article, calling attention to an evident error he had fallen into. But on account of sickness and consequent absence of our principal assistant, giving us extra cares, it was omitted. We will now give it attention here.

Mr. Weidman, in trying to correct Messrs. Doolittle and McNeill, makes a sad blunder himself. In one inch of comb there are about 27 cells—each cell averaging a trifle less than one-fifth of an inch—or 54 on both surfaces of one inch of comb. By an error Mr. W. has doubled this again, and so all his calculations are doubled!

Silver Lining to the Clouds.—Wm. Malone, of Newbern, Iowa, writes thus about the present discouraging season:

Have you seen the silver lining to the clouds so much talked of in 1888? I have not, but expect to do so very soon. Bees are swarming, but are not gathering any honey yet. The lindens will bloom in about ten days—then you will hear from Iowa. I am not discouraged, for I have not forgotten the season of 1882. We shall have a big honey flow soon, and "Don't you forget it!"

It will be welcomed by every apiarist. It now looks as though linden and a fall crop were our only hope for honey this year.

Mons. Alexander Jules, founder of the Society of Apiculture of Eure and Loir, died in the 58th year of his age, on April 25, 1888. He was an advanced apiarist, and a genial gentleman.

GLEAMS OF NEWS.

Swarm Catchers.—*Gleanings*, for June 15, is on hand, and, as usual, is full of very interesting matter. An article on swarming, and its attendant clustering, is timely and instructive. We will condense it for our readers:

The swarm basket of Dr. S. W. Morrison, of Oxford, Pa., is thus described:

It is made of two pieces of pine, 16 feet long, 2x2½ inches. One side of each is made flat, and a groove for a rope is made in the centre of each, from top to bottom. The other side of each pole is rounded.

The two poles are then placed upright, with the grooved sides together, the end of one pole being at about the middle of the other pole, and both are fastened together with an iron band near the connecting end of each pole. A pulley is then put at the upper end of the lower pole, and a rope fastened at the lower end of the upper pole, running up through the groove and over the pulley, is used to raise or lower the upper pole. At the upper end of the upper pole a peach-basket is fastened by means of ring staples to which the basket is tied.

A swarm of bees 35 feet above the ground can be reached by it, and a little jar under the cluster secures the bees in the basket. It is very easily made, inexpensive, and I am sure there can be none better.

The corn-popper catcher is thus mentioned:

The lid of the popper was thrown back, and the popper itself was crowded up gently against the lower end of the cluster. The bees very soon rolled over and over each other until the popper was level full of them. The wire-cloth top was thrown over, and snapped shut. We did not know whether he had secured the queen or not. It did not matter much, for half or two-thirds of the cluster was confined in the popper, and the queen, if outside, together with the remaining bees, would cluster around their captive comrades. We thrust the handle down into the soft dirt near where the bees were flying quite thick, and the popper was thus supported a couple of feet from the ground, where the bees could get at them. We then left them for an hour or so. When we returned, all the outside bees were clustered around the popper. They were now in such shape that we could carry them where we pleased, and hive them where we pleased, which we did with entire success.

Mr. A. E. Manum's method of catching and hiving swarms is thus described by him, after stating that he clipped the wings of all his queens:

I will first give a description of my swarm-catcher; and as there is no patent on it, all are at liberty to make and use the same. It is simply a wire-cloth cage fastened to a pole with two legs, so attached to the pole that they can be set out or in, something like a tripod. The lower end of the pole may be sharpened, to stick in the ground, in order to steady the catcher, and to prevent it from being tipped forward by the weight of the bees.

The head, or cage, is 10x10 inches square by 1½ thick, and is covered on each side with wire cloth. It is made in two parts, and hinged together, so as to open and close. When closed it is held together by a small hook. One of the parts of the head is fastened to the pole, forming a catcher, as may be imagined by referring to the cut.

The head is made of ¼x¾ inch stuff, hence is very light. I usually furnish 8 or 10 of these catchers to each of my apiaries.

Now, as we have our catchers all made and ready for use, by having them distributed through the apiary in order to have them handy, we will proceed to catch that swarm that is just coming out. We will take this catcher here, and open it; hold it to the entrance, and catch what bees we can; close it, and lay it on the ground near by, and watch for the queen. As she comes out, catch and put her in the catcher with the bees. Now set up the machine in some shady place, if convenient. The buzzing of the bees and the scent of the queen will soon attract the swarm, when all will alight on the catcher, where they may remain until we are ready to hive them; and if we fear another swarm may issue before these are hived, they may be covered with a sheet.

See! there comes another swarm! run with another catcher, and proceed as before, and set this catcher some distance from the first, if we wish to have the swarms separately. Although the first is covered with a sheet, it is safer to set them apart. In this way we can catch all the swarms that issue, and not be bothered by their clustering together, providing they do not all come out together.

When all have clustered, we may proceed to hive each separately, or two or three together, by taking up a catcher and bees, and

Manum's Swarming Apparatus.

carrying them to the hive previously prepared. We shake off the outside bees in front of the hive, and then open the catcher, and shake out the queen and bees, and the work is done.

If two or more swarms issue at one time, we proceed to catch the few bees and queens as before, using a catcher for each swarm (hence the necessity of several catchers); and, as is usually the case when more than one swarm issues at one time, they will mingle and cluster together. In such case we set the catchers near together, and await the results. If more bees settle on one catcher than on the others, we shake them off from this one; and on rising they will almost always divide up equally, each swarm clustering around its queen.

If we are too long a time in catching the queens and setting up the catchers, the bees may commence to cluster on a tree. In such a case it is better to set all the catchers under the cluster; that is, in the tree; and with a pole with a hook on the end, shake the bees off. Upon rising they will likely locate their queens; if not, shake them off again, and they will soon all separate, each swarm clustering with its queen, to the great delight of the apiarist.

There are many other ways to use these catchers that will suggest themselves during the swarming season.

Whereupon Mr. Root remarks as follows:

Our friend Mr. Manum is quite an extensive apiarist. In a private note we received from him, he said he was then locating his seventh out-apiary, so our readers may judge somewhat of the amount of experience he necessarily has had among bees, and of his ability to judge of a simple and practical swarming apparatus.

Just here it occurs to us that there are two ideas worth bringing up. The first is, that, if the queens are not clipped, the queen herself will usually be found on the outside of the cluster, or near the bottom end, for, it is said, bees will never hang to the queen. If, therefore, the corn-popper cage or other receptacle be pushed gently against the lower end of the swarm, you are likely to secure not only the larger portion of the bees, but the queen also; and in this event your swarming is practically done. The other idea is this: After these wire-cloth cages, such as the corn-popper and Manum's arrangement, have been used a few times for catching swarms, they will acquire the scent of the laying queen, and of former swarms. The catcher will, in consequence, be more readily accepted for clustering by succeeding swarms. In time these cages will have little bits of wax adhering to them, and these, also, form no small part of the attraction.

Dangerously Stung by Bees.—

The following item from the *New York Weekly Post*, has been passing the rounds of the press for the past two or three weeks:

XENIA, O., May 23.—George Hamill, a young farmer residing two miles north of this city, was attempting to hive a swarm of bees yesterday, when they settled on his head, face and neck. He began to fight them, and they began to sting. In a short time he was on the ground writhing in terrible agony; and when his wife and mother came to his aid with brooms, he was nearly dead. He became unconscious, and remained so for some time, his head and hands swelling up so as to make him unrecognizable. He is in a serious condition.

We do not know how much the above report has been exaggerated. In any case, it was very unwise in the young farmer to strike at and fight the bees, as he is reported to have done. If they started to cluster on his person, he should first attempt to jar them off gently, and then walk quietly away for the time being, until they found some other object on which to cluster. A few puffs from a bee-smoker would also have removed them. We thought best to insert the item, to warn our friends against striking bees, or fighting them when there are so many in the air that they can do a great deal of mischief. We presume the young farmer recovered, as we have seen nothing in print to the effect that he did not.—*Gleanings*.

The Supreme Court of the United States is a tribunal that exercises an immense influence, but is little known to the people. Ausburn Towner, in *Frank Leslie's Popular Monthly* for July, gives a very interesting account of the Justices, the room where they sit in judgment, their residences, as well as portraits, views, etc., that will open up the judiciary to all. In "The Rides of the World," Noel Ruthven takes up an attractive subject, and treats it in a most fascinating manner. The famous rides: Bois de Boulogne, at Paris, Rotten Row, London, Central Park, New York, the Vienna Prater, and Berlin's renowned "Unter den Linden," day by day see the wealthy and fashionable dashing by in elegant turnouts drawn by splendid specimens of horseflesh.

Bogus Comb Honey.—To its shame be it known that in the light of all that has been said, written and printed about the manufacture of comb honey being an impossibility, the *Grocers' Vindicator* of Chicago, has lately printed the following stupid and malicious falsehood:

The experts are in the "honey-humbug business," of which fact, perhaps, some of our readers are not aware; but for a long time there has been comb honey on the market which looks very fine and inviting, but it contains very little of the pure honey. It does seem strange that an article like honey should be allowed to be meddled with and so completely adulterated as to contain but a portion of the real honey; but such is the case, and to that extent that we would say to our readers that it is hardly safe to expect the pure honey from almost any source. The following is interesting; read it:

"I never saw honey look like that," remarked a reporter, who had ordered toast and honey for his breakfast. "I never saw a honey-comb look so white or so uniform." "Well, sir," replied the waiter, "I'll let you into the secret. That is manufactured honey. The comb is manufactured now of a white wax. Molds are made to the shape and size required, and the heated wax is poured in and becomes an imitation of honey-comb. A piece of this comb is placed in the jar, and the syrup poured in. They can't make a good imitation, though; nearly every one who calls for honey detects the imitation. The wax is whiter, and then it is unpleasant if you should get it into the mouth. It is much cheaper than real comb honey, and sometimes the supply of honey runs short, and the manufactured honey has to be used."

The fact is, that this stupid humbug has been so often exposed that it is somewhat monotonous! Why is it that editors of respectable sheets should so often be deceived? There is only one excuse that can be offered, and that is—ignorance!

We have hunted down many similar statements—and they are always without foundation, except that Jones told Smith that Benson told him that a friend had seen such things made in New York, Chicago, or some other place!! Here is a little experience of Mr. M. H. Tweed, of Allegheny, Pa., as related in *Gleanings*:

A short time ago a drummer, traveling for a Baltimore fish-house, was standing in a store as I was delivering honey in glasses, comb and extracted together. He picked up a glass and asked if it was pure, with the air of a man who thought that he knew it was not, but simply wished to see if I would tell a lie about it. I answered him that it was pure, and asked if there was such a thing as manufactured comb honey. He looked at me as though he thought I was a fool to ask such a question, as he replied, "Certainly they do."

I said, "My friend, have you seen it made?"

"Yes, sir," he replied. "I then said to him, 'I am glad I have met you, for I have heard that story about manufactured comb for several years past, but you are the first man that I have come across who has seen it done. Now, where did you see it made?'"

"Out in Ohio," was his answer. "Ohio! that's a big place. Where did you see it made there?"

He replied with some hesitation, "On the Western Reserve."

I said, "That is a big place too; where did you see it made on the Western Reserve?"

With a great deal less confidence, he replied, "In Orrville."

"Orrville?" I said, "that small country town? I have been there; who makes it there?"

Being fairly cornered he replied, "Well, there was a man told me he saw it made there."

Now, you see had I not cornered him he would have explained to the grocer all about how the comb was manufactured. You will easily see that his knowledge came simply through some man in Orrville having been seen making foundation comb; and by the time two or three smart fellows repeat it, the cells are completed, filled, and capped.

In order to counteract the baneful influence of such falsehoods, Mr. Root has issued the following "card," to which we call especial attention. Copies of it can be had of him, free of cost, by any one who can use them to advantage in attempting to refute the current lying about comb honey being adulterated. It reads thus:

TO WHOM IT MAY CONCERN.

In view of the false and damaging statements to the honey business, in regard to making comb honey by machinery, etc., I have thought best to silence all such falsehoods as they come up, by the following offer: I will pay \$1,000 in cash to any person who will tell me where comb honey is manufactured by machinery; or I will pay the same sum to any one who will find manufactured comb honey on the market, for sale. I am as aforesaid in making this offer, dear friends, as I should be if it were strawberries or hens' eggs. It never has been done, and it never will be done. If you wish to know whether I am responsible for the above amount or not, go to any bank and ask them to quote my standing in Dun's or Bradstreet's Commercial Agency, or write to the First National Bank of Medina.

A. I. ROOR,
Editor of *Gleanings in Bee Culture*,
Medina, Ohio.

Mr. Root profoundly remarks that the traveling men, who have done so much to spread these lies, should be taught that "telling lies is dangerous business in this present progressive age of the world." Let all such now be required either to "put up" the proof, or "shut up!"

The Apiarian Exhibit at Cincinnati, under the Governmental supervision, is provided for, and the following circular has been issued and sent to prominent apiarists:

U. S. Department of Agriculture.

HINSDALE, Du Page Co., Ill., June 15, 1888.

DEAR SIR:—Each one of the divisions of the United States Department of Agriculture is expected to contribute to the exhibit to be made by the Department at the Cincinnati Exposition, opening July 4.

I have just been instructed by Dr. C. V. Riley, the United States Entomologist, to make a collection of devices and implements used in bee-keeping, such as will represent the progress in the art in the United States, from the time when "log-gums" and box-hives were in common use, to the present time.

This collection will form a part of the exhibit to be made by the Division of Entomology at the coming Cincinnati Exposition. At the close of the Exposition, Nov. 1, this collection will be removed to Washington, D. C., and placed in a suitable apartment already set apart for the purpose in the National Museum, where it will permanently remain.

I would be glad to receive from you such contributions to this collection as you may be willing to make, either as a donation or as a loan for the Exposition. As far as possible, it is desired that the contributions be donated for permanent exhibition in the National Museum. The name and address of each contributor, and the purpose for which the device is used, will be attached to each article exhibited. Any article simply loaned will be returned at the close of the Exposition. If articles are sent by mail, the postage will be refunded. If sent by express, the express charges will be paid both ways by the Department.

You cannot fail to appreciate the great advantage you may receive from placing on exhibition such articles or devices as you may manufacture or offer for sale, both at the Cincinnati Exposition and also in the permanent exhibit in the National Museum at Washington, where they may be seen by tens of thousands every year.

It is believed that all bee-keepers will be interested in having a creditable display in the interest of our pursuit. The time allowed is altogether too short to do what might be done, and prompt action is necessary. Please write me *at once*, saying what you are willing to contribute permanently, or loan for the Exposition. I will write accepting such of those things you offer as I shall need, and will give shipping directions with acceptance. This method is adopted to avoid the sending of duplicates of the same devices or objects of interest.

Soliciting your hearty co-operation and an immediate reply, I remain, Very truly yours,
N. W. McLAIN,
Apicultural Agent.

T. D. Williams, who lived alone in Lebanon, Conn., was found dead on June 12, under a tree. He was 76 years of age, and while trying to hive a swarm of bees, he fell and broke a leg, and the New Haven *Palladium* says that he was stung to death by the bees. They probably had been "angered" by the accident in some way.

A man 76 years of age should not climb trees; especially if he lives alone, he should not take the risk of falling and dying when no assistance could be obtained.

Contraction of Entrances to Hives.—J. F. Gile, of Basswood, Wis., on June 11, 1888, asks for the following information:

State all circumstances under which the entrance to the Langstroth Simplicity hive should be contracted, especially with reference to newly-hived swarms.

Whenever the bees need protection, contract the entrance. Robbers sometimes trouble them, and disaster can be prevented by helping the bees in this way, to defend the hive against marauders.

CONVENTION DIRECTORY.

1888.	<i>Time and Place of Meeting.</i>
Aug. 3.	Ionia County, at Ionia, Mich. H. Smith, Sec., Ionia, Mich.
Aug. 14.	Colorado State, at Denver, Colo. J. M. Clark, Sec., Denver, Colo.
Aug. 27.	Stark County, at Canton, O. Mark Thomson, Sec., Canton, O.
Sept. 8.	Susquehanna County, at Montrose, Pa. H. M. Seeley, Sec., Harford, Pa.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

QUERIES AND REPLIES.

The Space Allowed Around Brood-Frames, etc.

Written for the American Bee Journal

Query 554.—1. In hanging frames as long and as shallow as the Langstroth, what space would you allow between the ends of frames and the hive? 2. What space between the tops of the frames and the surplus boxes? 3. How much space between each end of the top-bar and the hive, to prevent gluing, and admit of being easily handled?—Ohio.

To all of your questions I say $\frac{3}{8}$ of an inch.—P. L. VIALON.

1. $\frac{3}{8}$ of an inch. 2. A double bee-space. 3. 5-16 of an inch.—A. B. MASON.

1. $\frac{3}{8}$ of an inch. 2. 5-16 of an inch. 3. 5-16 of an inch.—MRS. L. HARRISON.

1. $\frac{3}{8}$ of an inch. 2. $\frac{3}{8}$ to $\frac{1}{4}$ of an inch. 3. Very little, if any.—DADANT & SON.

1. $\frac{3}{8}$ of an inch. 2. $\frac{1}{4}$ of an inch. 3. 3-16 of an inch is sufficient.—J. P. H. BROWN.

1. and 2. $\frac{3}{8}$ of an inch. 3. It is not important.—A. J. COOK.

1. 5-16 of an inch. 2. The same as at the sides. 3. 1-32 of an inch.—G. M. DOOLITTLE.

1. $\frac{3}{8}$ of an inch. 2. About 5-16 of an inch. 3. $\frac{1}{4}$ of an inch would prevent gluing, but I prefer 1-32 of an inch.—R. L. TAYLOR.

1. Anywhere from a bee-space to $\frac{3}{8}$ of an inch. 2. A bee-space. 3. The same.—EUGENE SECOR.

1. $\frac{1}{4}$ of an inch. 2. A bee-space. 3. $\frac{1}{4}$ of an inch is enough. The bees will glue, no matter what the spacing may be.—M. MAHIN.

1. and 2. $\frac{3}{8}$ of an inch. 3. Bees will daub their glue. I leave about 1-16 of an inch.—J. M. HAMBAUGH.

1. and 2. In both cases, $\frac{3}{8}$ of an inch, rather less than more. 3. $\frac{1}{4}$ of an inch is about right.—C. H. DIBBERN.

1. A full bee-space, say large $\frac{1}{4}$ inch. 2. A little less space than between the ends. 3. Just enough so that the frames can be easily removed.—J. E. POND.

1. $\frac{3}{8}$ of an inch. 2. Scant $\frac{3}{8}$ of an inch, if no honey-board is used. 3. $\frac{1}{2}$ of an inch, if any.—JAMES HEDDON.

1. Not less than $\frac{1}{4}$ of an inch, nor more than $\frac{3}{8}$ of an inch. 2. About an inch. 3. My bees will glue, no matter what space. The space in my hives is about 1-16 of an inch.—C. C. MILLER.

1. $\frac{3}{8}$ of an inch. 2. 5-16 of an inch works the best for me. 3. I cut the top-bars of my frames about $\frac{1}{8}$ shorter than the space in which they are to hang. I do not mind having the ends of the frames glued fast; it holds the frames in place when I move the hives about at swarming time.—G. W. DEMAREE.

1. $\frac{3}{8}$ of an inch. 2. $\frac{1}{4}$ to $\frac{3}{8}$ of an inch from the frames to the honey-board. The honey-board should be $\frac{1}{4}$ of an inch thick, and then $\frac{1}{4}$ to $\frac{3}{8}$ inch space from the honey-board to the sections. 3. Make the ends of the top-bars pointed, and allow them to just touch the hive.—J. M. SHUCK.

1. I do not allow over 5-16 of an inch. The space usually provided is $\frac{3}{8}$. 2. $\frac{1}{4}$ to 5-16 of an inch. 3. The top-bar should have movement endwise in the rabbet, of not less than 1-16 of an inch.—G. L. TINKER.

1. $\frac{3}{8}$ of an inch. 2. Use a double-space of 5-16 of an inch each. 3. 1-32 of an inch in this locality; in some localities you would want $\frac{1}{4}$ to $\frac{3}{8}$ of an inch on account of propolis.—H. D. CUTTING.

Each question may be answered by saying, give from $\frac{1}{4}$ to $\frac{3}{8}$ of an inch of space.—THE EDITOR.

Queen-Excluders and Break-Joint Honey-Boards.

Written for the American Bee Journal

Query 555.—When working for comb honey with an ordinary-sized brood-chamber contracted to 5 frames, or with one section of a shallow reversible hive, is it always necessary to use a queen-excluder, or will the slatted break-joint honey-board keep the bees from going into the surplus sections?—Minn.

I much prefer the queen-excluder.—G. M. DOOLITTLE.

It is not always necessary.—J. P. H. BROWN.

We do not contract the brood-chamber.—DADANT & SON.

In that case a queen-excluder is always necessary.—M. MAHIN.

You would want a good queen-excluder.—H. D. CUTTING.

No; I should hope not. If it did, I would not use it.—A. B. MASON.

I think the slatted break-joint honey-board will answer.—MRS. L. HARRISON.

I should always use a queen-excluder on so small a hive.—EUGENE SECOR.

I prefer the zinc perforated board, as the slatted break-joint honey-board does not always prevent the queen

from going into the surplus arrangement. These boards are not used to prevent bees from going to any part of the hive.—P. L. VIALON.

I have not found it necessary with the Langstroth frame, but with a single section of the new Heddon hive, I find it is.—R. L. TAYLOR.

Usually they will not go up, but it is safer to use a queen-excluding honey-board.—A. J. COOK.

I would use the queen-excluder, everytime. I have never used the break-joint honey-board.—J. M. HAMBAUGH.

A queen-excluder will certainly be needed, if the colony is in a normal condition and storing honey.—J. M. SHUCK.

It is necessary in all cases to use a wood-and-zinc honey-board in contracting the brood-chamber.—G. L. TINKER.

If you contract the brood-nest, you must put on a queen-excluder, or you will make a bad job of it. A "honey-board" is no hindrance to the queen going above.—G. W. DEMAREE.

As I do not work for comb honey in this way, and do not consider the plan of so doing practical or practicable, I cannot answer the question.—J. E. POND.

Without any queen-excluding honey-board, I find that with the brood-chamber contracted to 5 Langstroth frames, or one-half of the divisible brood-chamber, about one queen in 50 or 75 will go above and lay a few eggs.—JAMES HEDDON.

I have serious doubts whether a queen-excluding honey-board "pays" in an ordinary sized hive. I have found the slatted honey-board all that is required when using Langstroth hives.—C. H. DIBBERN.

With such a shallow or contracted hive it would probably be desirable to use the queen-excluding honey-board.—THE EDITOR.

The Queries written for and answered in the AMERICAN BEE JOURNAL have often been quoted not only in our British name-sake, but also have been translated into other languages and published in the periodicals of many nations. It is very flattering to know that they are of so much interest as to call for such reproduction and translation. The corps of contributors who make the replies may feel highly honored while knowing that their labors are appreciated both at home and abroad.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

CORRESPONDENCE.

YOUNG QUEENS.

The Balling of Young Queens by the Bees.

Written for the American Bee Journal

BY D. MILLARD.

I was much interested in the statements of Mr. Demaree, in answer to Query 5-13, on page 326. That unaccountable disposition of bees to "ball" their young queens was once a very perplexing problem to me. I spent much time, but patiently watched and observed, till I thought that I could see light upon the matter. I experimented further, and the light shone brighter, until the whole matter seemed perfectly plain to me.

I agree with Mr. D., that a young queen seldom if ever makes the mistake of entering the wrong hive. That she is signalled or saluted by her own bees is, I think, equally true, providing that the colony or nucleus, as the case may be, has a supply of young bees just commencing to fly.

A colony of bees that has been queenless for a great length of time, will usually accept a queen-cell, or a virgin-queen may be introduced, and she will be allowed to roam through the hive unmolested until she is disposed to take a flight, when the old bees will frown upon her; and if she persists in doing a little "side-walking" up and down the alighting-board, just to attract attention, they will tell her to just get inside and behave herself, or off comes her crown.

If the queen walks out and stays a little too long, or returns with her "ruffle" a little ruffled, she receives a reprimand that costs her life. But if there are plenty of young bees in the hive, of about the same age, they will go out together, and have a happy time flitting up and down the alighting-board; and if she flies off and is gone for a time, her young companions are all the more pleased to meet and salute her on her return, and thus the "signal" alluded to by Mr. D. (which lack of space undoubtedly forbade its explanation, and the lack of young bees at the time of the young queens taking their flight), is all there is of that unaccountable disposition of bees to ball and destroy the queen, or refuse her entrance to the hive.

If the apiarist has a colony of bees that has been queenless long enough to run out of brood, he should introduce a frame of capped brood in time to have it hatch, and the bees old

enough to begin to fly when this young queen is old enough to mate. Never give a queenless colony of all old bees much unsealed brood, but give capped brood, and when part are hatched, give eggs and larvae, and the newly-hatched bees will care for it and rear themselves a queen, which they will associate with and guard until she begins to lay, and then assist in driving out all laying workers.

The ancient rule was, "Old men for counsel, but young men for war." Applied to apiculture it would be thus: "Old bees for gathering honey and pollen, and young bees for inside work." But do not allow any colonies to become queenless and remain so, is my rule.

Mendon, Mich.

SCIENTIFIC.

Medicinal Qualities of Honey Explained.

Written for the British Bee Journal

BY R. A. H. GRIMSHAW.

We should like to inquire into the reasons why, or in what respect, honey is a medicine; supposing we take it as admitted that such is the case, an assumption many medical men might object to, seeing that the position of honey in the British Pharmacopoeia is such a very modest one, its use being chiefly that of a vehicle for other medicines, and as an adjunct to gargles. I should say that children in the stages requiring *Mel boracis* receive the greatest share of the official preparations of honey. True, oxymel (a mixture of honey, acetic acid and water) is used as a demulcent, softening mucus lodging in the air-passages and facilitating its expectoration. In my own household, however, I prefer the use of citric acid to acetic.

In bronchitis, pure honey and simple is always at hand, and more relief is obtained by frequently tasting it than from anything else. Nearly twenty years ago I found the greatest benefit in an attack of quinsy, by using a gargle of red sage, acidulated with vinegar, and well sweetened with honey. Honey *ad libitum* as a laxative, and mixed with borax for thrush, is, of course, a common household medicine for children. We will leave out of our view the value of honey as a food, as a heat-producer, consisting, as it does principally, of carbon and water, the two sugars dextrose and levulose, invert sugar. We know it is readily assimilated in the stomach, and should be eaten with some attenuating substance, such as bread.

Mr. Cheshire, in "Honey as Food," tells us: "Why honey has a curative

effect it is difficult to say for certain, but one may theorize, and ascribe this fact to the readiness with which it combines with mucous tissue. Honey is variable, and therefore its value as a medicine cannot always be the same."

In "Honey as Food and Medicine," we have a list of prescriptions which are almost incredulously efficacious, a few of which may be named as starters: Inflammation and congestion of the lungs followed by unconsciousness were cured by eating honey at all times of the day and night, until 10 pounds were consumed. Herr Karl Gatter was at the verge of the grave, and was restored to perfect health by the use of honey. Consumption is cured by it, and in ancient times it was used as a means of securing long life, and it is said to be an excellent remedy in diseases of the bladder and kidneys. The recipes are:

For asthma, honey of squills, honey cough syrup, eye-wash, balsam of honey, for croup, for bronchitis, honey salve, for coughs, colds, whooping cough, etc.; honey-wash for the eyes, gargle for sore throat, cancer plaster, honey-cough medicine, honey and tar cough candy, honey for sore eyes, honey and walnut cough candy, remedy for whooping cough, colds, etc.

Granting that all these prescriptions are good and effectual, what is there about honey that is absent in sugar which brings about such apparently wonderful results? It is in this direction we will turn our gaze.

We know the effect produced upon the nerves at the roots of our teeth by bringing them into contact with fresh honey, strong in acid, and it may be that the excess of formic acid secreted by the bees is used by it in giving its honey this strong acid reaction. Indeed, it is not beyond the bounds of reason to suppose that the supply of this acid to the bee is not intended for use so much as sting poison as for purely domestic purposes. There is not much doubt that the acid contained in honey is beneficial to both stomach and liver.

What else is there in honey? Well, myriads of pollen-grains, and these contain chemical principles of undoubted medical potency. Putting aside the husks (the extine and intine of the pollen grain) the outermost skin is found to be reticulated with ridges, the seat of a secretion of sticky oil. The contents are a sticky fluid rich in protoplasm, sometimes transparent, sometimes opaque, by reason of floating granules (fovilla), which granules are declared by Herapath to contain as much as 46 per cent. of a peculiar inflammable *azotized* (?) principle, insoluble in nearly every liquid. I imagine it is soluble by gastric juice.

These granules were found to be invisible in many fresh pollens, since the fluid in which they swim has the same refractive power as the granules; some of them are drops of oil, whilst others consist of proteine compounds.

Many pollen tubes will develop in nectar, by osmose of water, and produce in their own tubes other chemical combinations, and as the growth of these tubes often exceeds the diameter of the pollen grain by a hundred diameters, their chemical position in the honey must be somewhat considerable.

We have then (leaving the sugar of honey on one side) to deal with formic acid and the protoplasmic contents of pollen-cells, when we think of honey as a medicine.

The most important factor, in my opinion, remains yet to be considered. I allude to its flavor. Mr. Otto Hehner tells us "he has not been able by chemical means to distinguish between honey from one kind of flower and any other." We must all admit that such a difference exists. We know that honey collected from poisonous plants is materially affected by the active deleterious or objectionable or medicinal principle, secreted by such plant, the rhododendron family, azaleas and kalmias being an instance of this. Does it not follow, as nectar is a secretion and an exudation of the plant cell, that it is charged and pervaded by the active principle, beneficial or otherwise, of the plant? Many instances of the identity of the nectar flavor, and the distinguishing principle of the plant which secretes it, can be given:

Citric acid is found in fruits and flowers of the orange tribe.
Tartaric acid is found in grape juice.
Malic acid is found in the apple, gooseberry, etc.
Tannic acid is found in the oak, etc.
Hydrocyanic (prussic) is found in the cherry laurel.
Oxalic acid is found in sorrel and rhubarb.
Gallic is found in all kinds of galls.

Of poisonous principles we find alkaloids of—

- Quinine in cinchona.
- Morphine in opium.
- Solanine in plants of the potato tribe.
- Veratrine in sebadilla.
- Ac. ontine in monkshood and aconites.
- Strychnine in nux vomica.
- Atropine in belladonna.
- Piperine in pepper.
- Theine or caffeine in tea and coffee.

Some of the most poisonous plants bear the gaudiest flowers, and such we know are peculiarly attractive to bees, whilst many plants unwholesome as food are invaluable as medicine. Most of the umbellifera are poisonous—the same may be said of the ranunculaceæ, e. g., anemone, pulsatilla, delphinium, monkshood, aconitum vulgare. The poppy family, papaveraceæ, are notorious (*P. somniferum*). The crucifers are, however, non-poisonous.

When we come to the violet family we find one of our most valuable medicines (*ipecacuanha*), obtained

from the root of a violet grown in Peru. The buckthorn (*rhamnus*) gives us a valuable medicinal fruit; from the spindle tree family we get the valuable active principle euonymine. The seeds of the laburnum are poisonous. The cherry tribe (containing the almond, peach, nectarine, etc.) yields us prussic acid; this acid is also secreted by plants of the plum tribe.

A common plant (fool's parsley), common in gardens, is poisonous, as are generally the umbellifera, wet places being their home as a rule, when this principle is developed. Wild lettuce and wild celery are poisonous, whilst most members of the compositæ are medicinal. It is curious also to note that the ling or heather (the source of so much fine honey), has in its family the azaleas, kalmias, etc. The periwinkle (*vinca*) family have amongst them the nux vomica, from which we extract strychnine, a deadly poison, but at the same time the most valuable tonic in the Pharmacopœia.

Entire plants are wild lettuce (*Lactucin*, similar to *Manna*).

The following are the parts of plants used in medical preparations:

- Twigs and Tops*.....Savin.....(Savin oil).
Broom tops.....(Scoparin).
Woody nightshade.(*Solanina*, an alkaloid).
From Is obtained
- Flowers*. The Lavender..... Oil of lavender.
The Hop..... Lupulin and Humulin.
Peppermint..... A volatile oil.
Camomile..... A volatile oil (*Oleum Anthemidis*).
Orange Flowers..... A volatile oil.
Crocus..... Saffron.
Rosemary..... A volatile oil.
The Poppy..... " "
Elder..... " "
- Buds*.....Santonica (worm-Santonin, and a volatile oil seed).
- Barks*.....Larch.....Resin, Tannic acid and Larchinic acid, crystal and volatile.
Mezereon..... A volatile oil.
Oak..... Tannic acid.
Elm..... " "
- Leaves*.....Monkshood.....Aconitia (A).
Deadly nightshade.*Atropia* (A).
Hemlock.....*Conia* (A), and a volatile oil.
Foxglove..... Digitalin (A).
Henbane..... Hyocyama (A).
Cherry laurel..... Prussic acid and a volatile oil.
Stramony leaves..... Datura (A).
Bearberry..... Tannic, gallic acids, and volatile oil.
- Roots*.....Monkshood.....Aconitia (see Leaves).
Deadly nightshade.*Atroolia* " "
Colchicum..... Colenicia (A).
Gentiana..... Gentianite, a bitter principle.
Dandelion..... A bitter crystalline substance Taraxacin.
- Fruits*.....Dill..... Volatile oil.
Anise..... " "
Caraway..... " "
Coriander..... " "
Fennel..... " "
Hemlock..... Conia (A) see Leaves.
Poppy..... Opium from which Morphina.
- Seeds*.....Colchicum..... Colchicia (A) see Roots.
Mustard..... Myronic acid and a volatile oil.
Stramony..... Datura (A) see Leaves.

When we come to examine these products of the plant, from its very summit to its roots, taking leaves, bark, flowers, fruit, seeds, on the way, we find what we may call the characteristic or active principle of the plant pervading its whole system, but appearing in a stronger form in some particular place. We must try to think of the plant as a simple aggre-

gation of units, a mass of single cells, each of which is a laboratory in itself, forming of itself simple and complex compounds which it passes forward to its neighbors in order that they may be thereby further protected, and finally stored away for further use by the plant, or utilized by it as protective, resisting the attacks of birds, insects, and other animals, or else rendering the plant attractive to the particular animal whose services are desired.

Now the aroma of the plant is generally characteristic of its active principle, and this aroma appears in the nectar. The nectar owes its saccharine matter to the starch secreted by the single plant-cell from the carbonic acid of the atmosphere which it transforms into sugar, and flavors with its active principle. The sweet-scented sap exudes or transudes through the outermost cells, and appears as a degradation product in a similar fashion to resins and gums.

We find most active principles medicinal when taken in small doses, but distinctly poisonous in larger quantities; and again many of them are antidotal when taken together. Herein is a beautiful provision of nature exemplified in the minute quantities of medicinal matter gathered by the bee, and so mixed in its storehouse that strong doses are rendered almost impossible and innocuous.

The human system, however, when out of order (and it rarely, if ever, is in perfect health) has the faculty of sympathetically seizing hold of what it requires from the food to restore it to its normal state. Honey thus supplies us with numerous powerful agents in restoring to health disordered vital functions. I hold that the mixed honey, for these very reasons, is the healthiest and best for general use; that which bears distinct and pronounced flavor, at once betraying its origin, only so betrays it because it holds an undue proportion of the active principle of the plant whence gathered, be this beneficial or otherwise; and when honey is found to disagree with any one, it will probably be found to be honey of a distinct flavor.

We also lose sight of the fact when eating comb honey, that we swallow the waxen cell-wall which we are told is varnished over with a preparation (a sort of furniture polish) of the acid saliva of the bee and propolis—propolis consisting of powerfully medicinal exudations varying with the sources from which it is gathered.

Much that I have said is ideal and theoretical, but I think my conclusions are rational and practical, viz., that in dealing with honey we are dealing with a medium—nectar—flavored with powerful medical compounds whose

harmlessness is ensured by the wonderful antidotal mixing of the bee; but the beneficial properties are still present, ready to be seized upon by diseased or disordered organs, and if there be anything in the science of homeopathic medicine, the curing of disease by minute infinitesimal doses of such powerful drugs as produce *symptoms* of the disease in larger doses, then a new line of thought is opened up, and considerable support given to my hypothesis.

Horsforth, Leeds, England.

[The above excellent article opens up a wide field for interesting and profitable research and investigation. That the many beautiful flowers, which so delight and attract the bees, should contain, besides food, much of medicinal value to the human family is not to be wondered at; especially when it is known that nothing has been created which does not possess some value—even the thistle and dock, that are so troublesome to farmers, having their particular uses. Let us hope that our bee-keeping doctors and men of scientific inclinations may look into this matter more fully, and thus perhaps discover in honey other health-restoring virtues, which will add another laurel to the crown of those whose business it is to glean the sweets of nature to tempt and delight the palates of mankind.—ED.]

MOVING BEES.

A very Rough Experience Given in Detail.

Written for the American Bee Journal
BY H. E. HILL.

As the subject of "moving bees" is receiving some attention at present, I will relate a little experience of mine; not that the undertaking was anything "very great," but to show how much "knocking about" bees will stand, when properly cared for.

The bees were in 3-frame Langstroth nuclei hives, with wire-screen over the top and bottom, with frames supported by notched strips; but, doubtless, the moving could have been just as successfully accomplished had they been full colonies.

On the night of Oct. 14, 1886, 10 of these little colonies were confined to the hives, and on the following day they were expressed from Summit, N. J., to New York city. On Oct. 16, I found them buzzing in a third-story

room almost smothered by the smoke of a dozen or more cigars that were being smoked in the room, by those eagerly crowding around to see where the buzzing came from.

The bees were then placed in the elevator, let down, taken by a dray to the wharf, and placed on the deck of a Cuba bound steamer, where sponges of water were constantly kept on the screens, being refilled 8 or 10 times each day, and occasionally treating them to a sponge of sea-water, which they would drain in a short time.

Arriving at Havana five days later, they were placed in a small boat and taken ashore—a distance of about one mile—where they became the victims of the native "carretero," who "hustled" them over the cobble-stone pavements as though he was anxious to deliver as many loads as possible while the ship's cargo held out.

Arriving at the hotel, they were carried up into my room, where they remained for three days, being hauled again to the railroad depot across the city, thence by rail across the island to Batibano, on Oct. 24, and placed on board a Spanish coaster, which arrived at Cienfuegos on the following morning, when the bees were victimized a second time, in spite of all the English I used (which was just the same as so much Greek to him) to persuade the driver to "go slow."

Again to the hotel, and up-stairs, three days more in these quarters, when they were placed into a spring carriage, and driven into the country about three miles, arriving at La Gloria at 3 p.m. on Oct. 28. They were then released, and in less than 30 minutes several of the Jersey Italians returned to the hives laden with Cuban pollen.

FARM APIARIES.

Some Reasons for Having Bees on the Farm.

Read before the Farmers' Institute
BY T. S. SANFORD.

The honey-bee has been a topic for ancient writers, and from that time to the present, has received much time, attention and thought by our most practical and learned men. I am glad to see bee-culture given a place for discussion in our agricultural societies. Bee-culture is properly a branch of agriculture, and as such should be taught in every agricultural college.

The queen is, properly speaking, the "mother bee." She has no particular control over the colony other than her importance as mother bee. She does

not lead the swarm, but is often among the last to leave the hive. She is capable of laying from one to three thousand eggs a day. This is doubted by some, but I have repeatedly seen her lay two and three eggs in a minute, which is over 3,000 in 24 hours. It is wonderful to see with what watchful care the bees follow her from comb to comb, making a way for her as she proceeds with her daily duties, depositing an egg in every empty cell. They can be seen continually offering her partly digested food, which she takes as required. If she had to eat honey and pollen and digest it herself, she could not lay twice her weight in eggs in one day. The life of the queen is from one to three years.

Worker bees are the smallest in the colony. They are rightly named workers, as the labor of the hive is performed by them. They build the comb—this wonderful comb, which the ingenuity of man has failed to imitate. They gather the pollen and deposit it in the cells. In the working season they die off very rapidly, their age at this time being only about sixty days. Young bees in the fall live in a state of quietude through the winter, but only live a few weeks after commencing to work on the flowers in the spring. This is why we should be careful to have our colonies kept warm and comfortable through the winter, and especially in the early spring, to induce the queen to lay early, thus securing a populous stock of young workers ready for the first honey-flow in the spring. There are from forty to sixty thousand workers, one queen, and a few hundred drones in a good colony of bees.

The drones are the only male bees in the hive. They are large and clumsy, and make a great noise while on the wing. They cannot sting. They perform none of the labor of the hive, but live on the indulgence of the workers, and for this reason the practical bee-keeper should be able to control the drones in each colony. Before the advent of the movable-frame hive this was impossible; but with the improved method of handling bees, we can exclude drones entirely from our yards if we desire.

The hive is a very important feature in apiculture. Without properly constructed hives, it is impossible to secure the best results. In passing over the country the past few days I could but notice the large and expensive barns the thrifty farmer has provided for his stock, to keep them warm and comfortable. What a contrast to the average bee-keeper. He seems to think that a nail-keg or soap-box is good enough for his bees, then sets them off in some fence corner and gives them

no further attention, but allows the weeds to grow around them, and the moths to get into them, and then complains that bees don't pay. How could he expect anything to pay treated in this way?

An apiary properly kept and nicely arranged with good hives, well painted, is as much of an ornament as nicely painted and arranged houses and barns, and deserves a better place than an out-of-the-way corner. They should have a good, warm, double-walled hive, which is necessary either in summer or winter, and they *deserve* as much care as other stock. They do not require one-fourth as much, but what they do require they richly deserve. Hives should be so arranged that we can contract the brood-nest and enlarge it at pleasure.

By giving bees too much room in the brood-nest, they soon build more comb than the queen can fill with eggs, then they will build drone-cells intending to provide stores for winter use; but when the queen has filled the worker-cells with eggs, they will commence to lay in the drone-cells, and then instead of workers, we shall rear a lot of drones, to eat what the workers provide. The bees seem to tolerate an over-production of drones in the honey season, but as soon as the harvest is over, they are driven from their homes, and perish by cold and hunger.

For producing extracted honey more room may be given in the brood-chamber, as we can shave off the heads of the drone-brood when uncapping the cells for the extractor; but for comb honey four or five frames is ample. We can place wide frames filled with sections at the sides of the brood-nest with a queen-excluding honey-board between. By thus contracting the brood-nest, we force the bees to commence work sooner in the sections than they would do if they had all the room they wanted below.

Reversing the frames is of much importance in the culture of bees for profit; it pays to have frames that will reverse if only for one inversion, for thereby we can secure our frames built solidly full of comb from top to bottom, making them much stronger, and giving them a third more room in each frame. We can control swarming to a great extent, as we completely upset all their arrangements for swarming, and they at once commence to take the honey now at the bottom of the frame up into the sections, thus securing more surplus honey, and leaving nice, clean empty cells at the bottom that the queen will at once occupy and fill with eggs; and having plenty of room to deposit eggs, and the workers all the work they can do

filling out the empty space at the top of the frames with comb, they will nine times out of ten forget all about swarming, for the time being. The queen-excluding honey-board is an important invention, and very necessary in reversing frames.

To winter our bees successfully on the summer stands, requires care and attention at the proper time. As soon as the honey harvest is over I remove all the sections and surplus cases, and examine the brood-nest; if they have not five brood-frames well filled with honey and brood, I at once feed them sugar syrup made of two parts of granulated sugar to one part of water. I would prefer five well-filled frames for an average swarm to winter on, to a large number.

When I am sure that they have a sufficient amount of winter stores, I provide them a passage way through each frame by making a small hole through each comb near the centre, or by placing a Hill's device or a small wooden butter dish over the frames, so that the bees can pass from one frame to another over the top-bars, then I cover all with a woolen quilt, or pieces of burlap, and pack around the sides and over the top with 3 or 4 inches of chaff. After being thus prepared they should not be disturbed until settled warm weather has come in the spring to stay; when they should be united with some weak colony having a queen, or another queen procured for them at once.

Prof. Cook says that, "the study of rural pursuits helps to make home pleasant, and binds together the family, and finally it may be made a source of profit. I may be mistaken; but I thoroughly believe in bee-keeping on the farm."

New Castle, Pa.

REVERSING.

Experimenting with Circassian Bees and Reversible Frames.

Written for the American Bee Journal
BY JAMES W. TEFFT.

Early in April I received 2 colonies of Circassian bees, in Gallup hives, each having 8 frames 12x12 inches. They were purchased for experiment. I had heard that these bees were of no earthly use, as it was impossible to keep them together in large, strong colonies; they would swarm, and swarm, which broke up the working force into small "squibs;" they would build queen-cells by the quart, and yet they were hardy bees, very gentle, not stingers, and would gather honey after swarming equal to other races of bees,

all of which I found to be true; for it is impossible to manage them with any degree of success with hanging or suspended frames.

Swarm they would, in spite of all that could be done. They were returned to their hives three times each, cut out a quart or more of queen-cells the queens' wings being clipped, which made it easy to get them. When I returned the last swarm, and while closing up the hive, a swarm came out. They did not stop a minute, but away they went for the woods a mile off. I opened the hive, and almost the first bee that I saw was the old queen. Why did those bees depart from nature's laws?

Alsike clover was in full bloom, yet these Circassian bees would build no comb, neither would they go into the sections. Their reputation was well established, as being of no value. I was disgusted with them, and also with the suspended frame. At that time I would have given them to any one—my patience was exhausted.

But about June 1 I transferred their combs to good reversible frames. On placing the combs in the hive, the honey part was all down (reversed), and the brood up at the top-bar. The sections were put on, and the hives closed.

The next morning the bees were in the sections. Three days after, they had taken all the honey from the brood-frames, and the queens were busy. The sixth day I found any quantity of queen-cells just started in both hives, and they had considerable honey in the sections. I then reversed the frames that had the queen-cells (but not those that had hatching bees), which operation was departing from nature's laws, and the old theory practices of ages.

The next day not a sign of a queen-cell could be found. The side-storing sections were then put on, and from that time to the close of the season the brood-frames were reversed every sixth day. I seldom reverse combs with hatching bees—only at such times that the queen is again laying in them—and I have no more swarming. By July 1 I had in each of the hives a working force of at least 120,000 bees when they were divided.

I have come to the conclusion that nature's laws, with bees, has nothing to do with their swarming, as I understand it. Nature's laws are to build comb, gather honey, nurse baby bees, hatch and feed the brood, clean house, and guard the hive. Nature's law as regards the queen is the one which I try to study and manage. It makes a great difference to reverse the frames at the proper time. The advantages are four to one in favor of reversing,

and it is not problematical, but real, and not a particle of theory about it.

As soon as there are frames that really need reversing, the bees will at once empty the combs of all unsealed honey and convey it to the sections, thus giving the queen more room. At the second reversing, uncap all the honey in the brood-frames; that also will be conveyed to the sections.

I know there are many who have condemned reversible comb-frames, because, I think, they do not understand how to use them. Could they have seen my brood-combs after the third reversal, with no honey in them, (there were 8 frames of brood in each hive, but the 16 frames of comb built full from end to end, and from top to bottom—one solid mass of brood), they would have seen that there was no falsity about it. They would have "reversed" their opinion, the same as several old bee-keepers have done, who have examined my bees. They were amazed, astonished, and delighted!

By reversing the brood-frames, my bees put the honey where I want it. I get the brood-frames full of brood without being obliged to cut combs 7-16 of an inch thick; the bees do the cutting of comb better than I could possibly do it. I do not have to space the frames just bee-space apart. All of my frames are $1\frac{1}{2}$ inches wide, and space themselves.

In practice I find that it is an advantage, as well as natural and economical, to be able to control the bees so as to have them put the honey where I can sell it. The time it takes is a small item for the bees.

If the brood-combs contain any unsealed honey, reverse them late in the day, and the next morning you will find that honey in the sections, and the queen in possession of the empty cells. It seems to give new life, and more energy to the whole colony. The brood-nest is in better shape, the colony is stronger in bees, and there are more field-workers, which means more honey! It gets them in splendid condition to withstand any inclement weather, and just so long as there is sufficient room all around the brood-nest (except at the bottom), the bees will not crowd the queen by clogging the brood-combs with honey. I rarely reverse the outside comb that contains honey, as that comb is reversed for winter use. Neither do I reverse those combs with hatching bees, but only those combs that contain freshly laid eggs, or those with queen-cells, to prevent swarming.

Had I left the Circassian bees on suspended frames, in accordance to nature's laws, as a native writer expresses it, I should or would have destroyed them as being of no value. To

test them, I gave them extra work to do, and they performed it splendidly; it was just fun for them to re-convey the honey into the sections.

I care nothing for the natural laws of the bees, so long as I give them just room enough for them to store the honey. I do care to study the natural laws of my queens, and see that they have proper accommodations to display natural laws. She is the one I look after, not the bees—the bees will always do their duty, but the queen will not always do hers.

When you neglect to reverse the brood-combs, swarming is the result. To have the field workers broken up in small squads is bad, for from them you can get nothing but small returns. I want from 100,000 to 150,000 field workers in each hive at the height of the honey-flow.

The reversible frame is too good a thing for me to abandon, no matter what others may say against it. They have come to stay in my apiary. If they are objectionable to others, it is simply owing to their letting prejudice run away with their good judgment. Why, I have departed from the ancient practice of nature's laws in manipulating bees! Prof. Drummond remarks thus:

"The laws of nature are simply statements of the orderly conditions of things in nature—what is found in nature, by a sufficient number of competent observers. What these laws are in themselves, is not agreed. That they have any absolute existence, even, is far from certain. They are relative to man in his many limitations, and represent for him the constant expression of what he may always expect to see in the world around him. But that they have any casual connection with things around him is not conceived. The natural laws originate nothing, sustain nothing. They are merely responsible for uniformity in sustaining what has been originated, and what is being sustained. There are modes of operation, therefore, not operators; processes, not powers."

For one thing, we do not demand of nature, directly, to prove bee-keeping. That was never its function. Its function is to interpret, and this, after all, is possibly the most faithful proof. The best proof of a thing is that we see it. If we do not see it, perhaps proof will not convince us of it.

The Circassian bees on suspended or hanging frames are worthless; on reversible combs, with proper management, they are wonderfully successful. Had I transferred them the first thing, I know they would have outstripped any other bees in my yard; as it was, they did not show what they could do until the drought began—from July 6

to Aug. 10. The Italian bees lost, and could not make a living; the Circassians gained, both in brood and honey, clear up to the close of the season on Nov. 2.

In recapitulation, I must say that I now like the Circassian bees. The reversible frame-combs is what did it. The bees prove to be very hardy, great workers, being out in rain or sunshine, when other bees are quiet. They are out in the morning very early, fly later at night, and gather honey when other bees do not. The queens are very prolific. They are the most gentle bees to handle without smoke. Smoke will make them as mean as can be, and if abused they will sting fearfully.

They build straight combs, and not thick ones. I see no honey-bulged combs, but all being so even and clean looking. I worked the two old queens all summer on 8 frames each, and there was not one pound of honey in the whole lot, but the comb was completely filled with brood. I think they are magnificent bees, and a very valuable race for crossing with other races.

The one and only objectionable feature that I see to the Circassian bee, is the tendency to build brace-combs. They draw out the comb from the sections, and attach it to the separators, which, when taking off the sections, defaces the most beautiful cappings that I ever have seen. I am now sorry that I did not test them without separators; but this season I expect to give them a fair trial.

Their propensity to swarm is not desirable, as they cast such small swarms; but by reversing the combs as needed, and at the proper time, will break up their desire to swarm.

Collamer, N. Y.

INCREASE.

The Prevention of Increase by the Removal of Queens.

Written for the American Apiculturist
BY P. H. ELWOOD.

He who allows his bees to increase by natural swarming at their own good pleasure, may be called a bee-keeper; but it is only he who has learned to control increase, making it much, or little, or none at all, as circumstances may direct, that has earned the title of bee-master.

It is often well to know how to run a yard of bees without making any increase. When the bee-keeper has already more colonies than he can manage, it would seem foolish to make more, unless he has a good market for

bees. Quite often, when his locality is already overstocked, he finds it is his neighbors only who wish to buy, and at a price that barely repays him for foundation and hives.

Sometimes a person could profitably keep one yard in connection with some other business, if he knew how to manage them without increase, and with the least expenditure of time and work; the time and work to be chiefly given when the bee-keeper can best spare it, and not at the call of the bees. This method of running one yard with some other occupation, and the minimum amount of work and expense, may be the practice of the future, one strong argument against bee-keeping as a specialty being the uncertain value of the business when carried to a forced sale by the death of the bee-keeper, and the consequent uncertain provision for the apiarist's family.

Then another very large class are now producing honey at a greater cost than the selling price, and it would be unwise to enlarge a business already conducted at a loss. And it is always better to have the control of increase like everything else, well in hand and under well-laid plans, then a sufficient number of hives and supplies can be secured with some reasonable expectation of having them all used, and yet have enough in those years in which bees, when left to themselves, often swarm to death.

When running bees for extracted honey, it is comparatively easy to control swarming; for by giving them a large amount of room for both brood and honey, and extracting the old honey, and afterward the new just before the main flow commences (as ought to be done in any case, as it is of inferior quality) there will usually be no attempt to swarm; with reasonable attention to extracting afterward. This method is simple, and it would be well if beginners would stick to the extractor until they are successful with comb honey management.

When comb honey is produced it is much more difficult to control increase. It is easy in a swarming year to rear a crop of swarms, but not so easy to produce a crop of comb honey. The well-filled brood-nest so necessary to the successful production of comb honey is also very favorable to the forcing out of swarms.

A large hive well shaded and ventilated, with plenty of room in both brood and surplus apartments, will retard and sometimes prevent the issue of swarms, but there is no certainty about it, and it is better to have swarms issue earlier than in the middle of the honey harvest, as is apt to be the case with large hives.

Cutting out queen-cells, the withdrawal of brood, and the management of the brood-chamber as recommended by Mr. Simmins, will also delay but not prevent swarming, while there is danger of throwing the colony into a condition known as having the "swarming fever." In this state work to a large degree will be suspended, and the bees show by unmistakable signs that they are dissatisfied. Many bees will desert their own hives and enter others, which seems to disaffect these also. The bee-keeper will be similarly affected when in the midst of a honey flow he comes to look into the surplus receptacles, or to notice the number of idle bees hanging about the hives. It is only strong colonies that produce comb honey satisfactorily, and no system of management will be successful unless the colonies are built up strong before the harvest. This is particularly true of the method I am about to describe.

I recommend the clipping of the queens' wings, believing it to be the best. There is then no loss of unexpected swarms, and no swarms to be hived from inaccessible places. In every apiary there are some colonies (in some seasons a majority) that will work right along without any attempt to swarm. When no increase is desired, there is no need of molesting them, as they usually produce their full share of comb honey. All other colonies, as they complete their preparations for swarming, should have their queens removed with one or more sheets of brood, and enough workers to protect it, and be placed in another hive or small receptacle provided for her. All queen-cells old enough to hatch within nine days should be removed from the old colony, and the remaining brood-combs pushed together, contracting the brood-nest that much.

On the eighth or ninth day after, all cells should be broken from the now queenless hive, leaving them hopelessly queenless. In a week or ten days longer, the old queen may be smoked back into the old hive. The success of this will depend somewhat upon the race of bees kept. When I had black bees there was seldom a failure, but as my bees became Italianized, the losses were greater.

Mr. Crane, one of the best bee-keepers in the country, takes this time to re-queen the most of his colonies by giving them a virgin queen, which is usually well received. If the queen is to be changed, the old queen can be killed at the time of her removal, and the brood-nest not contracted. The brood removed may also be returned to the old hive, or it may be used for nuclei, or put into extracting colonies,

or used in a variety of ways that may suggest themselves to the average bee-keeper.

No colony should be left queenless longer than 21 days, as after the brood has all hatched, there may be no empty cells for storing pollen except in the sections. If the queen-cells are broken out at the end of seven days after the removal of the queen, there will often be another brood of queens reared from the brood remaining. I have never known such queens to lay anything except drone-eggs; but they are capable of leading off swarms, or of establishing a monarchy in the old hive that is hard to overthrow. Before I learned that the books were not right as to the time for breaking out cells to make a colony hopelessly queenless, I had many such cases, and this is the only kind of "fertile worker" I have ever been troubled with.

This system of non-swarming works well with me, and undoubtedly will do the same in localities having a similar honey-flow. In other sections, modifications of the plan may be adopted to meet the varying circumstances. With sectional hives like the Heddon, a whole half of the brood-chamber might be taken with the queen and returned with the queen at the proper time, which, with me, is usually near the close of the white honey harvest. Or the sections might be changed, leaving the queen out longer than the 21 days.

It is said that queenless colonies do not work so well, but I by this method get extra strong colonies, and as much honey as by other methods, with less work and expense.

This method of non-swarming is not recommended after a short trial, for it has been worked for several years with thousands of swarms in different bee-keepers' hands, and tons of honey produced. In answer to the objection, that honey produced by queenless colonies is not as choice as that produced otherwise, I will say, that honey so produced took the highest prize at the Centennial in 1876, and later at the Paris Exposition, after having been carried across the ocean and exhibited in the original packages.

In the fall I have not found the brood-chambers of such hives any heavier on the average than others, neither have I or other bee-keepers discovered that such colonies failed in winter because of too much bee-bread. With reasonable attention we are sure of having no swarms issue, and I know of no other way by which we can uniformly reach the same result.

Starkville, N. Y.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages)..... \$1 00
 " 100 colonies (220 pages)..... 1 25
 " 200 colonies (420 pages)..... 1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

CLUBBING LIST.

We Club the American Bee Journal for a year, with any of the following papers or books, at the prices quoted in the LAST column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

Cork for Winter Packing.—Its advantages are that it never becomes *musty*, and it is *odorless*. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels\$1.50	\$2.00	\$2.25
500 Labels2 00	3.00	3.50
1,000 Labels3 00	4.00	5.00

* Samples mailed free, upon application.

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 18 cents per pound for bag and postage.

Honey and Beeswax Market.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 13½@15c.; the same in 2-lbs., 10½@11c.; buckwheat 1-lb., 10c.; 2-lbs., 9c. Market dull. We are doing all we can to reduce stock, to make room for the new crop.

BEEFWAX.—26c. HILDRETH BROS., 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—We quote: White to extra white comb, 12½@15c.; amber, 8@11c. Extracted, white to extra white, 5¼@6c.; amber, 4½@5c. Arrivals of the new crop are small, the estimates being an average crop.

HONEY.—Best white in 1-lb. sections, 14c.—Dull. BEEFWAX.—23@24c. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—Prices range from 15@16c. for best one-lb. sections; other grades are slow, at lower prices, 15c. Light, thin and supply larger than usual at this season of the year.

BEEFWAX.—23c. R. A. BURNETT, 161 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 12c.; fancy 2-lbs., 10½@11c.; fair white 1-lb., 10½@11c., and fair 2-lbs., 8@9c. Buckwheat 1-lb., 7@8c. The demand is dull for comb but fair for extracted, of which new from the South is arriving, and sells for 55@65c. per gallon.

BEEFWAX.—Dull at 23½@24c. F. G. STROHMEYER & CO., 122 Water St.

CHICAGO.

HONEY.—We quote: Fancy white clover 1-lb., 16½@17c.; 2-lb., 15@16c. Dark is slow sale at almost any price. Extracted is scarce, and sells at 7@10c.

BEEFWAX.—23c. E. T. FISH & CO., 189 S. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb., for which demand is good. Comb honey, 12@15c.—Demand slow.

BEEFWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival. J. C. F. MUTH & SON, Freeman & Central Av.

MILWAUKEE.

HONEY.—Choice white one-lb. sections, 16@17c.; 2-lbs., 15@16c.; 3-lbs., 14c. Extracted, white in kegs and ½-barrels, 8 to 9c.; in tin and pails, 9½@10c.; dark in barrels and kegs, 5@7c. Market fair.

BEEFWAX.—22@25c. A. V. BISHOP, 142 W. Water St.

DENVER.

HONEY.—Best white 1-lb. sections, 17@19c.; 2-lb. sections, 15@17c. Extracted, 7@10c.

BEEFWAX.—20@23c. J. M. CLARK & CO., 1409 Fifteenth St.

KANSAS CITY.

HONEY.—We quote: Choice white 2-lb. sections, 17@18c.; dark 2-lb., 14@15c.; choice white 1-lb., 18 to 20 cts., dark 1-lb., 15@16c. White extracted, 7@8c.; dark, 5@6c. Demand is slow. White extracted is firm when in 60-lb. tin cans.

BEEFWAX.—21 to 22c. HAMBLIN & BEARSS, 514 Walnut St.

BOSTON.

HONEY.—We quote: 1-lb. sections, 16@17c.; 2-lb. sections, 14@15c. Extracted, 8@9c. The market is not very brisk and sales are slow.

BEEFWAX.—25 cts. per lb. BLAKE & RIPLEY, 57 Chatbam Street.

SAN FRANCISCO.

HONEY.—We quote for new extracted 6@4¼c., as to color and quality. New comb honey 14@16c., as to quality. Arrivals are still small, and demand of a jobbing nature.

BEEFWAX.—Scarce, 20@24c. SCHACHT & LEMCKE, 122-124 Davis St.

KANSAS CITY.

HONEY.—We quote: White 1-lb., unglassed, 15c.; 1-lb., white, glassed, 14c.; dark, 1-lb., 2c. less. California, 2-lbs., comb, white, 13c. Extracted, 7c. Considerable old honey is in this market. No new yet in. Sales are very slow.

BEEFWAX.—None on the market. CLEMONS, CLOON & CO., cor 4th & Walnut.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, \$1.00 per 100, or \$8.50 per 1,000.

EDITORIAL BUZZINGS.

Our Friends — The Flowers.—

Under this heading the following lines by Tudor Williams, of Albany, N. Y., may be found in *Vick's Monthly* for July :

Ye beautiful blossoms, bright and frail,
My spirit's sweet enchanters, hail !
N'er did your gentle magic fail,
Whether ye blushing be, or pale,
Or dyed in sunlight's golden hue,
Or wear the sky's unsullied blue ;
Swinging tulle censers of perfume,
Or gladdening me with scentless bloom ;
Whether low nestling on the ground,
Or decking shrub and tree are found ;
Whether in summer's prime ye blow,
Or nigh the season of the snow ;
Whether your home in open air
And all the clime's caprices dare,
Or in a crystal-walled retreat,
Pampered, ye bask in genial heat ;
Whether the tiller's pride ye be,
Or thrive in wilds, unkempt and free ;
Whether in myriads on the mead,
Tempting the swarming bees to feed,
Or in the twilight of the wood,
Pining, a sparse and puny brood,
Or, matchless, in lone nooks upspring,
Or to the creviced crags ye cling ;
Wherever hiding, still my friends,
Whose graceful forms my speech transcends.
In every mood, of gloom or joy,
When thought is light, or cares annoy ;
In sunny or in darksome hours,
Always my comrades boon, O, flowers !

Every Bee-Keeper who realizes the importance of the work now being done in the interest of the pursuit should send a dollar to this office and become a member of the National Bee-Keepers' Union for the ensuing year. "In Union there is strength." Reader, can you afford to remain outside any longer ?

Nothing has yet Developed relative to the admission of queen-bees to Canadian mails, so far as we have been able to learn.

A Pleasant Notice is given to the Rev. L. L. Langstroth by Mr. O. Poole, a correspondent of the *Australasian Bee Journal*, which has just come to our desk. He seems to have a keen appreciation of the labors of Mr. Langstroth, and the benefits conferred upon modern apiculture by his inventions. He says :

One interesting feature in the AMERICAN BEE JOURNAL is the portrait and biographical sketch of some member of the bee-keeping fraternity. The number for Jan. 25 contains an excellent portrait of Father Langstroth, with a short but concise biography of the reverend gentleman, who is now in his 78th year. I am sorry to learn that he has very indifferent health, and that peculiarly he is not situated as he should be. One of the American bee-societies recently raised a subscription and sent him a small donation, for which he expressed many grateful thanks.

Now, this is not as it should be. Do bee-keepers in America, in England and Australia realize to what extent they are indebted to Father Langstroth, not only for his invention of the frame hive, but also for his excellent work on apiculture ? I trow not. If they did, not a moment would be lost in getting up an universal subscription over the whole bee-world in aid of this veteran apiculturist.

We should be glad to know that the bee-keepers of the world had subscribed to and provided a life annuity for this good man, who has benefited them so much by his invention of the movable-frame hive. In order to start such a matter we will make an annual subscription of \$25.00. Who will follow ? Let us all club in and do the thing handsomely. European and Australasian apiarists are invited to join with us in providing for this annuity.

Sometime since we mentioned the fact that a move was made on the quiet to provide an annuity for our aged friend, and that Dr. Miller had the matter in charge. Any further subscriptions should be sent to him, and not to us. If desirable they may be sent direct to Father Langstroth, whose address is 923 Steele Avenue, Dayton, O.

In order to ascertain what Americans had been doing in this matter, we wrote to Dr. C. C. Miller, of Marengo, Ills., and we received this reply :

FRIEND NEWMAN :—You ask me if there is anything for the public, with regard to the fund for Father Langstroth. I had no thought originally of saying anything publicly about it, but in courtesy to your request I may say that a response has been made very gratifying in some respects. You will remember that whatever was sent to Father L. was to be entirely a free-will offering out of a sense of justice or goodwill toward the recipient, without even the reward of the little notoriety that might be obtained from the publication of the list of names of those participating. So it is a matter of unselfish and hearty cordiality, and this with warm words accompanying, highly heightens the value of the substantial aid received by the good old man. If a list of names were to be published with amounts attached, I have no doubt that the amount could be increased many times.

Our English friends are doing well in making the move they have, but it is only justice to say that a few on this side have responded just as liberally or more so, with no other reward than the consciousness of doing a

right thing. Some forty have thus far responded in sums of one dollar and upwards, amounting to about \$250 in all. How much happiness has been caused in the hearts of both donors and recipient is known to them alone.
C. C. MILLER.

We have no desire to parade these subscriptions, but a certain amount of such must be done in order to get anything like a unanimity in the matter. We do hope that American apiarists will do their whole duty in this affair, and do it promptly.

Another Biographical Sketch will appear in our next issue, with a portrait of one of America's prominent apiarists.

The Third Annual Report of the General Manager of the National Bee-Keepers' Union will be published in a few days and mailed to all the members with Voting Blanks for officers for the coming year. We hope that a general response will result in renewed subscriptions for the coming year. As the fees are now reduced to a dollar a year, thousands should flock to its standard at once.

Queenlessness of a colony of bees should be remedied as soon as possible, for the very existence of the colony is in danger—the means of perpetuation having been lost. When dividing a colony it is sometimes uncertain in which "half" the queen may be. It can easily be determined which "half" is queenless by looking at each about half-an-hour after the division. The bees will be excited, some running about as if looking for something. The queen is lost, and they are trying to find her. That half is without a queen.

Goods of every kind and description sell better when put upon the market in a neat and attractive condition. Honey is no exception to this rule. Crates should be neat and clean ; sections ought not to be covered with daubs of propolis here and there. The honey should be capped and nicely arranged in the crates, which should have at least one glass side, so as to prevent rough handling, by showing the delicate nature of the contents.

A Good apiarian display is to be made under Governmental supervision at the Cincinnati Centennial Exposition next month. Quite a number of articles, showing the history and development of the industry, have been sent from the Museum of the AMERICAN BEE JOURNAL. After the close of the Exposition they will be forwarded to the National Museum at Washington for permanent display. We will publish a list of such in our next issue.

We Regret to learn that Dr. G. L. Tinker has been quite ill for the past few weeks. He is now convalescing slowly.

GLEAMS OF NEWS.

Bogus Honey and Comb.

We have the following letter from Mr. W. M. Evans, relative to the manufactured honey-comb story. He starts it in this manner:

AMHERST, Va., June 22, 1888.

EDITOR AMERICAN BEE JOURNAL:—On page 388 I see that you have published some correspondence, and made some statements which demand a few words from me. I will try to make my remarks as "short and sweet" as is possible.

"A reward of \$1,000 to the person who will furnish evidence that Comb Honey has been manufactured, filled with honey and capped by machinery, etc.—A. I. Root."

Now compare this with Mr. Doolittle's statement in the *American Rural Home*, viz: "Mr. Root, of Ohio, has a standing offer of \$1,000, for a sample of manufactured honey in the comb." (Italics are mine.) Here Mr. D. does not say a word about making comb, filling or capping it by machinery. If Mr. D. should feed his bees any mixture and cause one colony to store 500 pounds of comb honey in one season, would this not be "manufactured honey in the comb?" Can any sane man say that Mr. Root's offer and Mr. Doolittle's statement of it cover the same ground?

Tut! Tut! You are too fast! There is nothing in Mr. Root's challenge about offering a Reward of \$1,000. A Reward is something given in exchange for goods, services required, etc. He did not desire to receive a sample of bogus comb honey! Mr. Root's words, in his card, were:

I will pay \$1,000 in cash to any person who will tell me where comb honey is manufactured by machinery; or I will pay the same sum to any one who will find manufactured comb honey on the market for sale.

Is there a word about REWARD in that? That idea is manufactured by Mr. Evans, we fear, for capital. Again, the manner of wording this REWARD sentence makes it nonsensical. The Reward is offered for evidence that "comb honey has been manufactured, filled with honey, and capped by machinery, etc." "Comb honey" is comb filled with honey, and when it is so filled it cannot be again filled with honey, or anything else. Mr. Evans has conveniently transposed these two words from "honey-comb," as we used it in the twelfth line of the second column on page 388. If you could get "honey-comb" made, it could then, perhaps, be filled with honey, etc., but comb honey, being full, cannot be again filled with anything!

The unfortunate wording of both Mr. Root's and Mr. Doolittle's statement concerning the offer, is to be regretted, because it may lead to complications. It must be understood that the offer of Mr. Root is as stated on page 388 in the 12th, 13th and 14th lines of the middle column, viz: that he offers \$1,000 for proof "that honey-comb is made, filled with glucose, and sealed up by a machine made for that purpose!" or for proof that such bogus stuff is on the market for sale. This is what Messrs. Root and

Doolittle intended to state, even if they did not do so very clearly.

Mr. Evans then gives the following historic account of the controversy:

Now, at the time I wrote (May 4) to the *American Rural Home*, I had never heard about Mr. Root's offer, nor I did not know that any one had made any such statement calling for any such offer; and, besides this, I had some months before, in the same paper, referred to some very remarkable statements made by a Jersey and Hudson River apiarist to a reporter of the *New York Times*. One of them said that he had sold that season 10,000 pounds of apple blossom comb honey; and the other claimed to have sold 20,000 pounds. At the same time I offered \$250 for a 5-pound box of pure apple-blossom comb honey, and my offer has not been accepted up to this date, and never will be.

At the time of the blooming of the apple trees, the bees are not in condition, usually, to gather much honey, even if the weather were propitious; and the little that is gathered is consumed by the bees while rearing the brood, so that comb honey from apple blossoms is a very rare article. That accounts for the non-acceptance of Mr. Evans' offer. Reporters get things MIXED, and very often convey a very different idea than that which was presented by the person interviewed. That might have been the case with the Hudson River apiarists—and probably it was a gross perversion of the matter as stated by them!

Again Mr. Evans reverts to "manufactured honey" in these words:

Now from Mr. Doolittle's reference to Mr. Root's offer, I understood that it applied to adulterated, or as Mr. D. puts it, "Manufactured honey in the comb;" and you will notice that I say that "the Wiley lie is true as to the adulteration of comb honey." I wrote to Prof. Wiley to find out whether he had ever stated that the comb had been made by machinery, though I then did not believe that he or any one else had ever made any such statement. I was not "non-plused" (as you say) at all, but merely wanted to get at the facts before I replied to Mr. Root's card.

To affirm that a lie is true, is equivalent to saying that it was wholly false, which it is, truly!

Prof. Wiley's statement was made in these words:

In commercial honey, which is entirely free from bee-mediation, the comb is made of paraffine, and filled with pure glucose by appropriate machinery.

And it is a positive falsehood which he made, believing at the time (as he has since stated) that it was not possible commercially to imitate the comb. It was a wilful, malicious, unprovoked, and deliberate falsehood, and yet Mr. Evans tries to make us believe that it is a true statement of fact, after its author has been driven to admit its untruthfulness, and to state that he had no proof upon which to predicate it!

Now here is a bluff from Mr. Evans. He says:

You say, I "propose to fight a wooden man in the shape of adulterated honey!" Now if you mean business, I will make my original proposition a little stronger; I will wager \$5,000 that American apiarists have

adulterated their comb honey. The names of those who have done so are recorded, and can be published if they wish it. "Barkis is willin'." "The proof of the pudding is in the eating." Try me.

The vile aspersion that "apiarists are adulterating their comb honey" by feeding the bees with trash, for that purpose, is too base to receive attention! It was born in the addled brains of an English clergyman tourist—repeated in the ears of our British cousins, to their delight, as some of the wonderful stories of this wonderful hemisphere of the West—and published in our British cotemporary apparently for the purpose of injuring the sale of American honey in Europe!

Now Mr. Evans tries to cram this tissue of falsehoods down our throats, and persuade us that it is an innocent sugar-coated pill.

True Christians are not gamblers; they do not wager, bet, lie, steal, etc. They leave that to the men of low morals, tendencies, and education. So we must decline to accept his "wager"—our principles are at stake!

Mr. Evans becomes aggressive, and makes this statement:

By the report of the Bee-Keepers' Convention last November, in Chicago, as published in the *Country Gentleman*, I notice that one apiarist said, that "it was none of the public's business what they fed their bees;" and this remarkable statement was at least endorsed by silence. Do you, Mr. Editor, endorse this sentiment?

There, again, is a misstatement of the matter presented. At the Chicago Convention, the subject of preparing food for the bees during their winter confinement, was discussed, and one member made this statement, as quoted from the official report as published in pamphlet form on pages 30 and 31:

Bees are not natives of a northern climate, and when we bring them here we may be obliged to make changes in their food; and to say that all this must be explained to the public is foolish; that is our business.

How different that is to the idea sought to be conveyed by Mr. Evans. He tries to convey the idea that bee-keepers feed the bees something to have stored in the surplus department to be sold as honey—while the discussion referred to is one on the best food to be supplied to bees in winter confinement to keep them from becoming diseased, because they have been taken from their natural, warm *habitat* to a cold northern latitude! How much interest have the public in such abstract discussions? Such absurd misrepresentations are certainly amusing.

From the fact that it WILL NOT PAY to feed the bees with glucose, or anything else, to have them store it in the surplus comb, there is no danger of the bee-keepers furnishing that bogus stuff to the bees to have them store it, and then to put it upon the market. Mr. Evans is, therefore, in a worse plight than ever, while attempting "to fight a wooden man in the shape of adulterated honey" in the comb.

Another point raised by Mr. Evans is thus stated :

One thing more, in relation to the publication of Prof. Wiley's letter to me : I do not know that he will care, yet Mr. Root should not have published a private letter without the consent of Prof. Wiley or myself.

Prof. Wiley never thought of asking permission of the apiarists to publish his lying fulmination, and anything that could explain his position on that subject belongs to the public. The fact is, that he should have written and published a refutation of his lying article years ago.

Mr. Evans then concludes with the following :

You say I am a "crank of the worst type," because I take more stock in the prayers of action, which give our neighbor the needed help or honest treatment, rather than by wind praying. Well, I am glad to be a "crank." I am a "crank" who does not believe that Jesus ever made or drank fermented hell-juice ; and I also believe that we can do more for God in humanity, than by running a wind-mill for His glory.

Your "cranky" servant,

W. M. EVANS.

It is not in order to discuss political or religious topics in our columns, but when a man calls sacramental-wine "hell-juice," we think he has justly earned the title of *crank*.

Thus is Mr. Evans driven from every position he has taken. He said that the Wiley lie was true, but its author admits that it is a mere fabrication as a "scientific pleasantry !"

He positively denied that any responsible man ever made an offer of \$1,000 for proof of the manufacture of honey-comb, filling it with bogus honey and sealing it over by machinery—but we introduced him to Mr. Root, who made the offer, who proved his identity, and exhibited unchallenged his responsibility for the amount offered !

He charges that the bees were being fed with glucose to store it in the surplus combs for the bee-keeper to put it upon the market for the fraudulent profit to be derived therefrom—but we have shown that repeated trials of even feeding back pure honey to be put by the bees into the combs to be sold as comb-honey is unprofitable, and can be done only at a loss ! No one would think of adulterating any article, when it could not be done at a financial profit !

We might go through his whole list of points with the same disastrous result to him—but it is quite unnecessary ! He is beaten at every turn, and now should "crawl into his hole" and "pull the hole in after him."

The North American Convention is to be held at Columbus, O., but the time is not yet decided upon. The following from Dr. A. B. Masou on the subject will explain itself :

Several months since I suggested that the place selected for the holding of the next meeting of the North American Bee-Keepers' Society be changed from Toledo to

Columbus, Ohio ; and after quite a good deal of correspondence with some of the members of the Society, the Executive Committee decided to take a vote of the Society in the matter.

A circular was prepared by the Committee a short time since, and a copy, with a postal card directed to me, was sent to each member of the Society by the Secretary, stating the reasons for, and desirability of, making the change, with the request that each say on the postal what his or her wish was in the matter. When all but thirteen had voted, I wrote to each of them asking them to vote. All but six have responded, and so far every vote but one has been for the change ; so the next meeting of the Society will be held in Columbus, Ohio.

I have delayed giving this notice, so that I might give the time of meeting, but as yet the Executive Committee has not been able to agree on the time.

Last week I sent the plan for the building for the Bee and Honey Department of the Ohio Centennial Exposition at Columbus, to the architect. It is to be 36x80 feet in size, and most of the space has been applied for. Applications for space and entries close Aug. 6.

A. B. MASON,
Pres. N. A. B. K. Society.

A Cuban Apiary is described by Mr. O. O. Poppleton, late of Williamstown, Iowa, but now in Havana, Cuba, in *Gleanings* for June 15, 1888. He described the hives used, and the primitive method of taking away the honey thus :

A few days ago, Senor Pedro Perez, who is as pleasant and friendly a neighbor as we ever had anywhere, offered to take me to see a native Cuban apiary, and I will describe the little I saw, so that your readers will get some idea how what is known to commerce as "Cuban honey" is obtained.

The apiary contained 80 colonies, which is a very small one for Cuba. The hives varied from 6 to 12 inches square, inside measure, the large majority being 8 and 9, and $3\frac{1}{2}$ feet long, made by nailing four boards, of the proper width and length, together, and a short piece of board over one end. So far they were very similar, except being longer, to the skeps, or gums, so many of which are still in use in our own southern States. They were not stood upon end, as our people use them, but laid down on the side, the same as are the earthen hives in use in Cyprus and Syria. One entire end of the hives was left open, and this is the only peculiar feature there is which is different from methods in use in other countries, and which have already been described in the journals. The hives were laid on poles, so they were about 2 feet above the ground, the poles being supported on crotches, old boxes, barrels, or anything they could get. They were scattered around among some large banana plants, to protect from the sun.

At least once a year during the honey-flow in the winter, and sometimes also in August, everything in the hives except the bees and the small amount of comb that may contain the brood, is taken away and mashed and strained by the old-fashioned processes. The result is strained honey containing all the different grades and flavors that may have been gathered during the year.

It was really interesting to walk around among the hives and look directly into their open ends, and see the bees clustered so quietly on their combs ; but I could not help thinking what an amount of fun there must be should they once get thoroughly to robbing. And, by the way, I find that bees do not rob so persistently here in the South as at the North, this being true, so far as I have observed, both in Florida and here in Cuba.

I am told that there are many large apiaries here in Cuba, of at least a thousand colonies each, all run on the same plan as is this small one I visited. I am also told that there are only three movable-comb apiaries on the island. The first was started by the Casanova Brothers, some five years ago ; this one about two years ago, and one now under way by Mr. A. J. King, near the centre of the island.

So far I am quite favorably impressed with the honey resources of Cuba ; and after I have been here at least a year, so as to know from personal knowledge what they really are, I will try to describe them.

Honey from the Poison-Ivy, etc.

—John R. Sample, Elizaville, Ind., on June 18, 1888, writes :

Bees in this neighborhood are in good condition for the honey crop, but the weather is too dry for them to do much. My bees are working on what I suppose is poison-ivy. Is the honey poisonous ? We are having a good rain now, and we hope to have a good honey-flow yet.

The American poison-ivy (*Toxicodendron*) is closely related to the poison-oak, of which there are two kinds very plentiful in California, one being poisonous, the other not. Mr. Pryal speaks thus of it, and the honey obtained from the one not poisonous :

I have studied this plant, of which there are two varieties in our vicinity—one poisonous and the other not—and I have found it to be a valuable honey-plant. In this I am borne out by the testimony of others in this State, who have watched bees working upon it during its season of blooming, which is in March and April—the two varieties keeping up a large supply of blossoms for almost two months. The honey is quite clear and delicious, and is in fact for clearness and flavor equal to any gathered in the vicinity of San Francisco.

We would refer Mr. Sample to the article on poisonous plants, page 425, first column, of last issue of the BEE JOURNAL, which shows that nectar, being a secretion of the plant cell, is charged with the active principle of the plant.

From C. H. Lake, of Catonsville, Md., comes a sheet of Comb Foundation of his "improved make." It has a parchment-paper "mid-rib," the corrugations being made in the usual way by passing the paper, with a sheet of wax on either side, through a Foundation Roller-Mill. He calls it the "indestructable," and we presume that it is rightly named ; a sheet of the proper size for a Langstroth frame weighs 7 ounces, and costs about 20 cents.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Scatter the Leaflets.—Look at the list (with prices) on the second page.

QUERIES AND REPLIES.

The Mating of Virgin Queens.

Written for the American Bee Journal

Query 556.—1. If it is necessary to put colonies as near as a foot apart, will virgin queens, on returning to the hives, be likely to enter the wrong ones? 2. How long after a prime swarm issues, will a virgin queen generally take her first flight?—Tenn.

1. Yes, unless well provided with land-marks.—C. C. MILLER.

1. To a certain extent. 2. From 15 to 21 days.—G. M. DOOLITTLE.

1. They will usually go to the right place. 2. About 13 days.—A. J. COOK.

1. I would be afraid of it. 2. From 10 to 20 days.—J. M. HAMBAUGH.

1. Not usually, but they may sometimes. 2. From 8 to 24 days; usually about 14 days.—A. B. MASON.

1. It is best to have them 3 feet apart. 2. If with a second swarm, 8 days after; if for her bridal flight, about 10 days.—P. L. VIALON.

1. Sometimes they will, but generally they will get safely home. 2. Generally in about 2 weeks, sometimes less, and sometimes more.—M. MAHIN.

1. Yes, they may. 2. It depends on the age of the queen-cell at swarming time. It may be only 5 days, and it may be 10 or 12.—DADANT & SON.

1. Yes, unless some pains are taken to so fix the hives that they can be easily recognized. 2. It will depend upon the weather, to some extent. Under favorable circumstances, in 5 or 6 days.—J. E. POND.

1. In many instances, if no special "land-marks" are provided. 2. About 12 to 15 days.—JAMES HEDDON.

1. Not often, especially if a twig of leaves be suspended just over the entrance of the hive before the virgin queen is expected to issue. 2. About 13 or 14 days.—G. L. TINKER.

1. It is better to have the hives at least 4 feet apart. There is considerable danger of losing queens by entering the wrong hives if of the same appearance when only 1 foot apart. 2. I do not know certainly, but I think about 14 days.—C. H. DIBBERN.

1. Sometimes they do mistake their own hive. 2. Probably in 10 or 12 days, on an average. This depends upon the advancement of the queen-cells when the swarm leaves.—J. P. H. BROWN.

1. They will often enter the wrong hive at that distance, unless you have some distinctive mark placed on the hive. A piece of red cloth 6x12 inches

is a good mark, tacked on the front of the hive. 2. From 2 to 21 days.—H. D. CUTTING.

1. Not often, except when their own bees threaten them as they alight at the entrance on returning from a flight. 2. Ten or twelve days, but the different circumstances make the time vary very much.—R. L. TAYLOR.

1. I think that they seldom get into the wrong hive. It would be an easy matter to put some temporary distinguishing mark in front of the hive from which a queen was expected to fly.—EUGENE SECOR.

They are not likely to do so, as a rule, but they sometimes may. There is more or less commotion at the entrance of the hive during the absence of the queen on her bridal tour. Italian bees often swarm without even starting a queen-cell, if they are strong, and there is a sudden flow of honey.—MRS. L. HARRISON.

1. I would not have my hives that close if I had to sell half of them to get more room. I do not think that young queens are often lost by entering the wrong hive. I have spent considerable time investigating the cause of the loss of so many young queens at mating time, and the cause is usually in their own homes. The young queens are "balled" when they return from their wedding flight, and sometimes killed. 2. If no after-swarm issues, the first young queen that hatches will destroy all queen-cells, and will be ready for her flight in 13 or 14 days after the swarm issues.—G. W. DEMAREE.

1. They may do so. It is best to mark the hives by paint of different colors, or by laying brieks or blocks or green boughs on the alighting-boards, so that the queen may distinguish her own hive on returning. 2. The time may vary greatly. I have examined a hive after swarming, and found no queen-cells even started, while on the same day I have examined another hive that had just swarmed, and found the virgin queen walking over the combs. The time has varied with me from 4 to 20 days. Some writers give rules, but I have never found any. The weather also affects the time of flight of the new queens.—J. M. SHUCK.

1. Yes; the danger lies in that direction. If they are placed so closely from necessity, they should be painted different colors, or some distinguishing objects should be placed to assist the young queen in marking the location of her hive. 2. Usually about two weeks—it may be much less, or more, depending upon the stage of development of the queen-cell at the time of the issuing of the prime swarm.—THE EDITOR.

Summer Management of Chaff-Packed Hives.

Written for the American Bee Journal

Query 557.—I use the double-walled chaff hives, the inside hive and also the surplus cases being $\frac{3}{4}$ of an inch thick. In working for surplus in June and July, I remove the wall of chaff at the sides, leaving the cushion on top. Will it pay to return the chaff to the side walls after each manipulation? Or shall I leave it out entirely?—S. P., Mich.

Leave it out.—A. B. MASON.

I should leave it out.—EUGENE SECOR.

Leave it out entirely.—J. M. HAMBAUGH.

I would leave it out.—J. P. H. BROWN.

I would leave it out, by all means.—G. W. DEMAREE.

No, no; leave it all off, certainly.—R. L. TAYLOR.

I would leave it out entirely.—MRS. L. HARRISON.

Leave the chaff out entirely, after settled warm weather arrives.—J. M. SHUCK.

It may be for your State, but in the South we use single-walled hives all the year round.—P. L. VIALON.

After taking out the chaff in the summer time, leave it out; also the cushion.—G. L. TINKER.

I would not bother about returning the chaff; a dead air space, or none at all, is just as good.—C. H. DIBBERN.

If you mean that when the wall of chaff is removed from the sides, I think it will pay to return the chaff to the side-walls. If not, not.—M. MAHIN.

If I wanted to use a chaff-packed hive, I would use one that I did not have to disturb the packing at all.—H. D. CUTTING.

I see no reason for taking it out. Surely, it would better be put back if taken out. I presume that I do not understand the question.—A. J. COOK.

If I understand the question rightly, I should say that it was not necessary to return the chaff. Chaff is not necessary in any part of a hive in July weather.—G. M. DOOLITTLE.

Leave it out entirely during the summer season. It only tends to keep the sun from warming up the hive.—J. E. POND.

At the present prices of honey, the man who makes a lot of extra work will not succeed in our business.—JAMES HEDDON.

Chaff is entirely unnecessary in the hive, in summer. It keeps the hive too cool early in the season by not permitting the sun to affect the inside, and later in the season it tends to keep it too warm.—THE EDITOR.

CORRESPONDENCE.

The June Bees and Flowers.

Written for the *Humane Journal*
BY H. G. ADAMS.

The bees are buzzing in the lane,
And the sheep-bell bath a crowsy sound;
There is no wind to turn the vane,
And send the mill-sweeps round and round.

The laden wagon creaks along,
With fragrant hay upon it piled;
The little brook, with a sleepy song,
Winds here and there, like a wayward child.

And where its waters gather clear
Beside the bridge, in a shady pool,
The happy boys, without a fear,
Can bathe when they come out of school.

The bud, half hid in blossoms, flings
Its sweetness on the balmy air,
And seems to slumber as it sings,
As one who is without a care.

Hot is the man who drives the sheep,
And hot are they who rake the hay;
All nature seems inclined to sleep,
Although 'tis broad and golden day.

The rooks are nodding on the trees,
Upon this sultry summer noon;
The heat is ninety odd degrees,
And 'tis the leafy month of June.

GOOD QUEENS.

The Laying Capacity of Good Queens.

Written for the *American Bee Journal*
BY G. M. DOOLITTLE.

On page 364, Mr. James McNeill has a "conundrum" which he wishes Doolittle to answer, and as I am in this world for a purpose, and that purpose to help my fellow men, especially bee-keepers, by explaining to them all I know of our pursuit, and giving a little light on dark points as far as I can, I will try to do the best possible on this conundrum, leaving the readers of the *AMERICAN BEE JOURNAL* to see how nearly right I am.

In the first place, if I conveyed to the minds of the readers by the article on page 323, or by any article, that a queen lays 3,000 eggs every day for two or three months in succession, I wish to say that I did not intend to convey any such an idea, for I am satisfied that all queens have certain periods of rest during which they lay very few eggs, these periods being brought about by the weather, secretion of nectar by the flowers, amount of pollen brought in, etc.

Then again, I am satisfied that queens lay eggs at many times which the bees never allow to hatch, and also that eggs are kept from hatching for indefinite periods by the bees, when again they allow such "kept" eggs to hatch within 24 hours to a far greater number than any queen could lay in

a day, the bees having all this under their control; all of which has an important bearing on the subject. However, the important part of the subject is in having a queen capable of laying 3,000 to 4,000 eggs a day when we most need them, and not one that can never lay more than from 800 to 1,200 under any circumstances, as is frequently the case with cheap queens, as the past has shown me.

A queen was once sent to me as a present, by quite a noted queen breeder, and with all the coaxing that I could do, she would not exceed 4 Gallup frames of brood, her usual amount being about 3. I kept her for two years, hoping that she would do better, but as no better results were attained, I became disgusted with her and killed her. But more closely to the point: "How do I manage to make 9 Gallup frames give room enough for a really good queen, as it would require 11 such to give room for a queen capable of laying 3,000 eggs a day?"

In this locality we have, as a rule, but one really good honey-flow, that being from basswood, which blooms from July 5 to the 15th, and lasts from one to three weeks, the extremes being 3 days for the shortest I ever knew, to 28 days as the longest, in which honey was gathered from it.

Now, as the wise man would prepare for a harvest by engaging help for a large harvest of any kind, having that help on hand at the needed time, I try to take advantage of what these good queens can be made to do by crowding them to their utmost capacity from 25 to 50 days before the basswood opens, so as to get the largest possible force of workers on hand just at the right time to give me the best results. To this end my hives are made so at this time of the year they can be enlarged by slipping out partition boards, so that 10, 11, 12, 13, 14, and even 15 frames can be used as a brood-chamber, thus giving the best of queens a chance to do all she is capable of doing; 15 frames in a hive, filled nearly solid with brood 30 or 40 days before the honey harvest, is one of the most pleasing sights to a honey-producer of anything in this line of business—except tons of honey being exchanged for *cash* at the end of the season.

Later on, the object of the bee-keeper who has no fall harvest should be to reduce the brood as much as possible, consistent with having the colony in good condition for winter, for the rearing of brood *very largely* right in the height of the honey harvest means much of our surplus being fed to this brood, which are only to become useless consumers after the honey harvest is over.

Working along the line of this reasoning, (which nearly 20 years of experience has proven to me to be sound logic), as the honey harvest commences, I begin to work in an opposite direction by contracting the room given to the queen, till at the close of the season, 5 to 7 Gallup frames of brood are all that my hives contain, and these are frequently from $\frac{1}{2}$ to $\frac{3}{4}$ full of honey. This gives all the bees required for winter, and nearly enough honey for the same, so that little work is done along the feeding line.

If the above is not the right principle to work bees upon, then a part, at least, of my bee-keeping life has been in vain. A thorough trial of the plan will, I think, convince the most skeptical that it is *the* correct plan to work on.

In the above I think that Bro. McNeill will find a full answer to his conundrum, and I will only add that if queens of poor or only moderate value are used, our crop of honey must be poor or moderate; for only as we have a large number of bees at the right time, can we expect to attain to the highest point in the production of honey.

Borodino, N. Y.

WAX.

The Secretion of Wax—Is it Voluntary?

Written for the *American Bee Journal*
BY EDSON GERRY.

On page 325 this question was asked: "Is the secretion of wax a voluntary, or an involuntary, act?" An opinion was given, stating that it was "voluntary."

I am fully convinced from my own observation, that this secretion is involuntary; that the bees have no control over the generating of the secretions; and that it is a natural production, which may be seen on the under part of the abdomen of the young bees.

It is produced in a singular manner. The construction of the muscular rings around the abdomen are so formed that they are especially calculated to permit these secretions to ooze out from small holes located under these muscular rings; and when the secretions are dried, they form small, white flakes or pellets of wax; when ripe, if not removed, they will drop to the bottom of the hive.

Wax is produced only by such bees as are in a condition to be able to generate these secretions. My impression is that the young bees (while young they are fat like all the young of both animals and insects) would naturally

produce these secretions, and when they are of sufficient age to go to the field to labor (about 15 days old), they then soon become lean and poor, and can no longer produce the secretions from which the comb is made; whereas, if they continued to generate these secretions, when crawling over the blossoms to gather nectar, these flakes of wax would be lost, consequently there would be no wax to manufacture into comb. A bee when lean and poor cannot generate these secretions.

Lummi, Wash. Ter.

HISTORICAL.

North American Bee-Keepers' Society—Interesting Table.

Written for the *American Bee Journal*
BY M. M. BALDRIDGE.

The following table shows the number of annual meetings, where and when held, and three of the principal officers of the sessions named, who were elected at the previous meetings, after the first one:

No.	Place.	Date.	President.	Secretary.	Treasurer.
1st.	Indianapolis, Ind.	Dec. 21, 1870.	A. F. Moon.	M. M. Baldrige.	N. C. Mitchell.
2d.	Cleveland, O.	Dec. 6, 1871.	L. L. Langstroth.	M. M. Baldrige.	N. C. Mitchell.
3d.	Indianapolis Ind.	Dec. 4, 1872.	M. Quinby.	H. A. King.	N. C. Mitchell.
4th.	Louisville, Ky.	Dec. 3, 1873.	W. F. Clarke.	H. A. King.	M. L. Dunlap.
5th.	Pittsburgh, Pa.	Nov. 11, 1874.	S. Hoagland.	A. Pope.	J. S. Hill.
6th.	Toledo, O.	Dec. 1, 1875.	W. F. Clarke.	Dr. L. Brown.	J. S. Hill.
7th.	Philadelphia, Pa.	Oct. 25, 1876.	G. W. Zimmerman.	B. B. Overmeyer.	J. S. Hill.
8th.	New York, N. Y.	Oct. 16, 1877.	W. J. Andrews.	J. H. Nellis.	J. S. Hill.
9th.	New York, N. Y.	Oct. 8, 1878.	J. H. Nellis.	T. G. Newman.	A. J. King.
10th.	Chicago, Ills.	Oct. 21, 1879.	T. G. Newman.	E. Parmlly.	J. H. Nellis.
11th.	Cincinnati, O.	Sept. 28, 1880.	T. G. Newman.	E. Parmlly.	Mrs. Dunham.
12th.	Lexington, Ky.	Oct. 5, 1881.	N. P. Allen.	E. Parmlly.	Mrs. Dunham.
13th.	Cincinnati, O.	Oct. 3, 1882.	A. J. Cook.	E. Parmlly.	Mrs. Dunham.
14th.	Toronto, Ont.	Sept. 18, 1883.	D. A. Jones.	A. J. Cook.	C. F. Muth.
15th.	Rochester, N. Y.	Oct. 28, 1884.	L. L. Langstroth.	C. C. Miller.	C. F. Muth.
16th.	Detroit, Mich.	Dec. 8, 1885.	L. C. Root.	F. L. Hutchinson.	C. F. Muth.
17th.	Indianapolis Ind.	Oct. 12, 1886.	H. D. Cutting.	F. L. Dougherty.	C. F. Muth.
18th.	Chicago, Ills.	Nov. 15, 1887.	C. Miller.	W. Z. Hutchinson.	C. F. Muth.
19th.	Columbus, O.	1888.	A. B. Mason.	W. Z. Hutchinson.	Mrs. Harrison

I have taken especial pains to look up the past history of this Society, and I think the foregoing will generally be found correct. Still a few words of explanation may be both advisable and necessary.

It is generally supposed that Father Langstroth was the first President of the North American Bee-Keepers' Society, but the foregoing table shows that A. F. Moon, now deceased, had that honor. The writer was present during that meeting, and knows that A. F. Moon was its President from first to last. Father Langstroth was elected as the President of the Society for the following year, and the writer was instructed so to notify him, and to secure his acceptance of the honor, after the meeting adjourned, which was done by and through a personal visit to his home at Oxford, O.

As will also be seen, the writer was elected Secretary of the first meeting, and was re-elected to that office for the ensuing year. As will be remembered by a few, there were more or less trouble and jealousy, in the year 1870,

about who should have the honor or credit of calling a National convention of bee-keepers, and the result was that there were two calls made—one for Indianapolis, by Prof. A. J. Cook, and the other for Cincinnati, by H. A. King. The Indianapolis convention met Dec. 21, 1870, and the Cincinnati convention on Feb. 8, 1871, and each held a two days' meeting.

Both conventions elected Father Langstroth for President, and N. C. Mitchell for Treasurer, but H. A. King was elected Secretary at Cincinnati to represent that convention for the ensuing year. Both conventions adjourned to meet in Cleveland, Ohio, on the same date, and at the same place. They so met, and as soon as they were called to order by W. F. Clarke, one of the Vice-Presidents, both associations were, by unanimous vote, dissolved for the purpose of consolidation.

The writer did not attend the Cincinnati convention, nor the one held the same year in Cleveland, nor in fact any of the annual meetings since, except the last one held in Chicago. So much for a historical explanation.

St. Charles, Ills.

tivated. The honey from this plant is quite dark, but of excellent flavor. I sowed Alsike clover, but the drouth last year killed it.

I received a package of the Chapman honey-plant seed from our Representative in Congress. I have now about 100 plants, and judging from the long, fibrous roots, it might stand our Iowa winters, and be of some value to bee-keepers.

My plan for watering bees in summer is as follows: Take a keg and make a small hole near the bottom, so that the water can drop. Now place a box or board in a convenient place, cover it with several thicknesses of cloth (old grain sacks are best); put the keg on this, and the cloth will be wet all the time. Cover the keg to keep the bees from getting drowned. Fill it with fresh water every morning, and a handful of salt once a week.

Before I adopted the above plan the bees were a source of trouble around the wells, watering-troughs and swill-barrels, and hundreds were drowned. Now I have no trouble with them, and the house-pump is only a few yards from the bees.

The spring was very cold and late here, and our loss was greater than ever before. The complaint is almost universal among bee-keepers. If one is met, and asked how the bees wintered, "O, I had bad luck," will be the prompt reply.

But there are a few exceptions in favorable localities where they sustained no loss in wintering; but after all the failure of the past year, we are hopeful, and the prospect for a good harvest is quite encouraging.

Signourney, Iowa.

WATER FOR BEES.

Bee-Pasture, Providing Water for Bees, etc.

Written for the *American Bee Journal*
BY MRS. O. F. JACKSON.

If I were going to raise a plant exclusively for honey, it would be mother-wort. It requires very little cultivation the first year, and after that it will take care of itself. It blooms the first year, and remains in bloom until frost. I think that it stands the drouth better than melilot. It is so much liked by the bees that they will not leave it even for white clover. I believe that it will pay bee-keepers to raise this plant. It will grow in the fence-corners, and on waste land; then why not raise it for the bees?

There is another plant which I value very much, and that is the pleurisyr-root. It grows in great abundance where the ground has never been cul-

LARVAL BEES.

The Glands and the Food of Larval Bees.

Written for *Gleanings in Bee-Culture*
BY PROF. A. J. COOK.

Since the article which I wrote on the glands of bees and the food of larvæ, I have had some correspondence with L. Stachelhausen, of Salem, Tex., one of our German-American bee-keepers whose information and opinion are worthy of great respect. He does not accept the view of Schiemenz and Leuckart, which I presented, but that of Schonfeld. He presents his case with so much of reason that I am a convert at once, as all must be if the facts stated are as he represents them, and I have little doubt but they are. I am glad we have one in our neighborhood who is so conversant with German research, and so excellent a

scientist, that he sees the true bearing of each fact. I hope that he will not be allowed to longer hide his light under a bushel.

At my request, Mr. S. has consented to the publication of his views. He asks that I comment upon the subject, which I am very pleased to do, as I had already contemplated writing another article, giving the views of Schonfeld. I have re-written the article, and have commented in []'s.—A. J. Cook.

Objections to the Gland Theory.

Until 1870 it was believed that chyme was fed to the young larvæ, or, rather, that the larval food in the cells is chyme. In that year, Von Siebold examined and described the salivary glands of the bee. The large size of these glands seemed to indicate that they had some other purpose than to secrete the saliva. It seemed possible that they might secrete the larval food. Fischer described these glands a year later, and expressed the same opinion as to their function. Leuckart then declared that he had taught this theory to his students for years.

I then thought this theory very plausible, and probably the true one; but I expected further study and a closer examination, but expected in vain. Von Siebold, and probably Leuckart as well, worked on other problems. I supposed a microscopic examination of the secretion from these glands would prove the identity of the same with the food of the larvæ, but no such proof was forthcoming. It may be said, that there is too little of the product of the glands for analysis. But just this seems to indicate that the comparatively small glands cannot secrete so large a quantity of larval food.

[This view alone would not count for much. There is too little nectar in most flowers for a successful analysis; yet the bees gather pounds of it in a day. Supposing that the lower head-glands of a single bee do not secrete enough material for successful analysis at any one time, yet thousands of bees might do this with the whole day before them, and have enough left to feed all the larvæ.]

In 1880, Schonfeld published his theory, which seemed to me nearer the truth.

Years before, Leuckart described the larval food as a granular, milky, uniformly colored fluid containing many microscopic corpuscles, similar or identical with the blood corpuscles, and with the corpuscles found in the chyle, or digested food, in the true stomach, which chyle passes directly through the walls of the stomach by osmosis. Wolff states that the blood corpuscles originate in the stomach.

Analogy of the mammalia favors the gland theory of Leuckart. It seems plausible that the young bee, like the young calf, is fed with milk; yet not so plausible when we remember that the larva is not a young bee. I would rather compare the larva to the embryo of a mammal, and this is nourished directly from the blood. The chyle of bees is, in fact, identical with their blood, and contains everything necessary to build up the body of the bee; so it seems rational and natural to suppose that the chyle is the larval food.

[Analogy is always an uncertain argument. In case of animals as wide apart as the mammalia and insects, it really has no force. Grant that it had, even then in the case in question it would be difficult to say which way the argument pointed.]

With higher animals, the origin of the chyle is more complicated, and digestion is completed in the small intestines. In bees, the structure of the canal is different; and it is possible that chyle originates in the stomach.

[Here chyle must mean the sum total of digestion. With higher animals, chyle means simply the digested fat, and is carried to the blood through a special system of vessels, while the other products of digestion are mainly absorbed directly by the blood-vessels.]

If the larval food and chyle are identical, of course we must depend on the microscope to prove it. If we examine the stomach of the worker-bee we find more or less partially digested food, but no chyle.

[From the fact that, in examining many bees, I have never found the granular milk-like substance fed to larval bees, was my principal reason for accepting the secretion rather than the digestion theory.]

Schonfeld made the following experiments, and hereby is explained how the chyle can be found in the true stomach of the nurse-bee:

a. Honey colored by cherry-juice is fed to bees in a starving condition.

b. Honey colored by holly-juice is fed in the same manner.

c. In like manner, honey mixed with pollen of the white lily, which is easy to distinguish with the microscope, was fed.

After feeding, in each case the contents of the stomach, and the larval food, were carefully examined with the microscope. In every case the food in the cells with larvæ was the same milky granular substance, with no color, nor any lily pollen. This larval food, then, could not consist of chyme or the material from the honey-stomach.

Every hour a nurse-bee was examined, and the process of digestion noted. The color was seen to fade

out, and the true chyle was found, differing in no wise from the food given to the larvæ. While in the intestine, red and dark-colored excrement, mixed with pollen-husks of the lily, were plainly evident. Many bees were caught, just about to feed the larvæ, and the chyle was found in each case.

[This, of course, is crucial. Not finding chyle, like larval food, in the stomach, does not prove its universal absence. Finding it once, proves its existence. Granting the fact, the conclusion must follow.]

Salivary Glands of Bees.

All mature bees—workers, drones, and queens—possess—

I. The upper head salivary glands, and—

II. The thoracic salivary glands.

Besides these the worker-bees have—

III. The lower head salivary glands.

Glands I. and II. have a common ending at the base of the ligula, in the groove formed by the paraglossæ. This secretion can, as the tongue is extended, flow into the groove and wet the ligula, but can go no further, because the ligula, or sucking-tube, is no fountain-pump, and the larva has no sucking arrangement to draw this out.

[A stronger argument, perhaps, lies in the fact that drones and queens also have these glands, and surely they do not feed the larvæ. No one can think that these are the milk-glands, even if milk-glands exist.]

The secretion from glands I. is oily; that from glands II. watery, which would indicate that they possess a different function.

The function of the sucking-apparatus will show that the saliva is necessary to wet the ligula, and to make it possible that the nectar can ascend. It would require too much space here to explain the function of the sucking-apparatus, which is a misnomer, as bees neither suck nor lick.

[Very likely the saliva, like our own, may serve to aid in keeping parts moist; but from the size of the glands, and quantity of the secretion, this, as is our own case, must be incidental. I think our friend is surely mistaken in his last assertion. I think I have shown that bees do both suck and lick.]

If bees do change nectar more than to evaporate it—that is, if they change the kind of sugar (I am not sure that they do), then it is probably done by gland II. Such a change could be due only to a ferment, and could come only from the saliva.

[I know that bees change cane sugar to reducible sugar, both when fed cane syrup or nectar. I have had analysis made in both cases. While not all cane sugar would be reduced, most

would be. That the saliva from glands I. and II. does this there can be no doubt. Honey is digested nectar, the digesting ferment being this saliva. While the drones and queen are fed in part by the workers, yet they take honey; and unless this is fully digested by the workers, the drones and queen must finish the work, and so must have glands I. and II.]

The most important purpose of glands II., or their secretion is for the test-organs which are in the groove at the base of the ligula.

[I do not understand this point.]

Very likely the secretion from glands I. may be used to wet and smooth the newly formed cells. Thus these secretions are true saliva, and cannot be larval food. This is without doubt true. Yet organized liquids do often have a double use. The pancreatic juice in the higher animals digest starch, fat, and may digest the albuminoids—will in an alkaline liquid.

The Lower Head-Glands.

The ducts from the lower head-glands open into the lower part of the mouth, between the muscles of the mouth. If the bee chews, this secretion must surely empty and be mixed with the chewed material. This, then, is mixed with the pollen. This is certainly true; for the pollen in the honey-stomach shows some of its caps open or elevated; and as no gastric juice is secreted in the honey-stomach, this partial digestion is accomplished by the saliva, and presumably that from the lower head-glands. Further, this saliva is used in kneading the wax by the jaws. F. Huber (*New Observations*) says that the fresh wax scales and the chewed wax are chemically different; and Eulenmayer and Von Planta found in the wax scales 0.5977 per cent. nitrogen, while in the chewed wax there was 0.95 per cent. This must be due to this saliva. So we see that these glands secrete true saliva, and so cannot be organs to secrete bee-food.

[I have replied to the last argument before. The above positions are well taken. Is it not quite likely that these serve merely to mix with and partially digest the pollen, and that Wolf's glands at the base of the mandibles are the glands that moisten the wax?]

The large size of these glands is no argument favorable to the gland theory, if we take it into consideration that the saliva is very important in digestion, and in part takes the place of the gastric ferment of higher animals. Surely a large quantity of saliva is added to the pollen food of bees, and so this saliva is indirectly a part of the chyle and larval food.

[This is surely a powerful argument. We secrete saliva almost entirely to

moisten our food, and the daily quantity is estimated at three pints. If this saliva in bees is to moisten the pollen, and the position of the duct adds powerfully to the argument, then much would certainly be needed. The fact, too, that drones and queens do not have these glands, and do not prepare their own nitrogenous food, is in harmony with, and, in fact, lends support to this view.]

We can find the same glands in other insects which do not feed the larva at all, as *Eristalis tenax*, which has these glands fully as large as those of the bee; and *Nepa cinerea*, which has these glands, and they are very similar to those in the bee.

[This is surely a very strong argument.]

The product of these glands cannot be spit into the cells, for bees never spit. Nor is it at all likely that this secretion is swallowed to be regurgitated into the cell. Nature always empties her products where they are to be used; so if there were milk-glands they would either empty into the honey-stomach, or else some apparatus would have been developed that this secretion might have been poured directly into the cells.

[I think these points are excellent.]

These glands are in full function all winter, when no brood is to be fed. They must then have another purpose.

[How is this when bees have no pollen for their winter food? Of course, they usually have the pollen.]

If a colony passes the winter queenless, and no brood be fed for five or six months, and then receives a frame of brood which has been kept out of the hive until the larvæ are in a starving condition, we observe that this brood is fed at once. If this food is a product of glands used only for such purpose, this would be absolutely impossible after such long rest.

[This is certainly a good point.]

If bees are fed honey mixed with indigo, the larvæ are no longer fed, but commence to starve, while the mature bees remain healthy. The indigo prevents contraction of the stomach, and so regurgitation is impossible; yet the food is digested and absorbed. If the larval food were a secretion it would still be supplied.

[Granting these facts, the conclusion must follow.]

The following experiments of Schonfeld prove that the larval food is chyle:

Bees were fed honey mixed with carmine. In the larval food of this colony, and also in the chyle of the true stomach of the bees, were found the chillinous points of the cochineal insects from which the carmine is made. The blood was normal, because the fine particles were not digested,

and, of course, could not be absorbed. As a secretion is derived from the blood, the secretion could not have what the blood did not have.

[This is also a crucial argument. The facts granted, the conclusion must be.]

Powdered iron was fed, with the same results.

Again, bacteria were fed to the bees—at first *Bacterium termo*, and then the bacillus of foul brood—*Bacillus aleocharis*. In both cases the organisms were found in the larval food, but not in the blood of the nurse-bee. As these were not in the blood, they could not exist in a secretion from the blood.

[This is an interesting point, as it explains fully why the fasting method, or the changing of the bees to clean hives, cures this dreaded malady.]

Von Planta finds the food of the young larvæ as follows:

	Queens.	Workers.	Drones.
Albuminous.....	46.5 ½ cent.	50.16 ½ cent.	39.91 ½ cent.
Oil.....	12.62 ½ cent.	6.84 ½ cent.	7.83 ½ cent.
Sugar.....	17.90 ½ cent.	27.65 ½ cent.	1.17 ½ cent.

We see that the food for the different kinds of larvæ varies greatly in composition. If this is a secretion it could not vary, as the glands could not secrete arbitrarily a richer or a poorer substance. But if this is chyle, it is easy to understand its variability; it would necessarily result from a variation in the food of the nurse-bees as to honey, pollen, or water. The defenders of the gland theory say that the secretion may be mixed in the honey-stomach with honey or water—pollen is out of the question, as we have seen that it is not given undigested to the larvæ. The experiments with colored honey shows this to be untrue.

That chyme [Mr. S. uses this term to denote partly digested food] is added to the secretion of the gland is out of the question, because chyme is surely prepared in the true stomach, and not in the honey-stomach. In the chyme are the shells, or husks (cuticulae) of the pollen, but no whole pollen grains. If we examine the stomachs of bees we shall never find such empty pollen grains—husks—in the honey-stomach, except in the case of quite young bees just recently emerged from the cells. These bees are fed by the older bees with chyme. In the true stomach we can find these shells, if we examine a bee at the proper stage of digestion.

As soon as the larva fills the bottom of the cell—from the close of the fourth day—the larva receives chyme, or partially digested material, from the true stomach, and this contains the cuticulae. At first these are few, but more and more are added, so that, just before the cell is capped, they are

numerous. This is also true of color when colored honey is fed.

[This is very interesting, and bears the impress of truth. This chyme is fed to the larvæ of workers always, and sometimes, not always, I think, to the larvæ of queens.]

The defenders of the gland theory say that it is impossible that bees regurgitate any material from the true stomach in the cells; for, as Schiemenz has shown, the stomach-mouth is prolonged into the true stomach, and so would act as a valve, and prevent any of the contents of the true stomach from passing back into the honey-stomach and mouth. But Schonfeld has shown that this is a mistake. The muscles are so arranged that this prolongation can be drawn up, and so in nowise prevent regurgitation. The bee itself proves that it can, for the full-grown larva does receive chyme, the product of the true stomach, and not of the honey-stomach. If the bees can regurgitate chyme or partly digested food, they surely can chyle, or that which is fully digested. This is chyme and not pollen, as the husks show.

Why should we be surprised that the bee does this? It is a master of regurgitation, vomiting up all its honey, and some of it several times. A full understanding of the stomach-mouth enables us to understand how it regurgitates its chyme and chyle.

L. STACHELHAUSEN.

LARVÆ-NUCLEI.

Removing Sealed Larvæ—The Frames for Nuclei.

Written for the American Bee Journal

S. A. SHUCK.

In compliance with the Editor's request on page 405, I will answer the following questions from Mrs. Mary Blaehly:

4. How should sealed larvæ be removed? 5. Is it necessary to remove it when pollen is plenty? 6. For a nucleus to keep queens over winter, how many frames of bees are needed, and how large should the frames be? Should there be empty frames put in with each queen's brood-chamber (or apartment).

4. With a thumb and finger pluck off the end of the cell, then with a small splinter or straw, such as timothy or blue-grass, lift the larva from the cell.

5. Yes. The principal object in removing the larvæ from all the cells found sealed on the fourth day after removing the queen, is to prevent 10 to 12 day queens.

6. This depends upon the method of wintering. If wintered on the sum-

mer stands, I should want a fair sized colony of bees, and not less than three frames the same size of those used in full colonies in my apiary, and these well packed for protection. I have wintered bees nicely in the cellar on three combs one-half the length and the same depth of the Langstroth combs. No; I should prefer to have the combs pretty well filled with good stores. If there is more than the bees can consume during the winter, it is much better than not enough.

The Rearing of Good Queens.

Concerning the rearing of good queens, perhaps it would not be out of place here to add a few remarks:

It should be remembered that the larvæ for good queens should be fed the royal food (food of larval queens) from the time the egg hatches until the cell is sealed. This is about five days.

When a queen is taken from a hive, it is some time before the bees miss her, and it is usually from 12 to 36 hours before they commence the construction of queen-cells.

Thus it will be seen that all cells, that are sealed inside of four days from the time the queen was removed, contain larvæ that were fed royal food for only a little over three days at the most, and in many instances less than three days. The queens from these cells will hatch in less than 12 days from the removal of the old queen.

These queens may prove to be quite prolific for a time, but they are very short lived, seldom living through the next season, and are the "cheap queens" so often condemned by our good editor.

With good Italian bees there is but little difficulty experienced in this direction, as it is seldom that young queens hatch in less than 14 days from the time the old queen was removed. But with black or hybrid bees it is quite different, as it is seldom over 12 days.

Liverpool, Ills.

FLORIDA.

A Beginner's Experience in Keeping Bees There.

Written for the American Bee Journal

BY N. C. LARSEN.

I began with 5 colonies of native brown bees in boxes or "gums." I let them swarm, and bived the swarm in a new hive on empty frames. I waited 21 days, and then transferred the old colony, using all the good comb that I could get. One of my old colonies had no brood, very little honey, and was queenless. I transferred them, but they left and went into an adjoining

old colony which I transferred a few days afterward. Some of the old hives cast 2 swarms. I lost one fine swarm which was bound to go to the woods. They crossed the bay, or river, so I could not follow them. I finished up with living 6 good swarms and transferring 4 old colonies, leaving me with 10 colonies, all strong and doing well.

Having no foundation, I have had some trouble to get good, straight combs. Some of the colonies persisted in building the combs in all sorts of shapes, but the most of them have built nice, straight combs. I put the empty frames between full combs, and in that way I have compelled them to build nice combs. Six colonies have filled both stories full of comb; 1 colony has over 56 one-pound sections in wide frames, with separators; 3 colonies are yet working in the lower story, and all have plenty of sealed honey; I have not taken any from them yet, as I wanted them to fill up with combs. I think that some colonies have as much as 50 pounds of honey now, and if they continue to gather I will have to extract to give them room.

I painted the hives two good coats, placed them on wooden blocks 6 to 8 inches from the ground, under orange trees; I made boards about 30x30 inches, and nailed a 2x3 inch piece on each end, and placed them on top of the hive so as to shed the water. Those boards I value highly; they shield the hive from the sun and rain, and also keep the cover dry and tight.

The bees are of the large brown variety, with yellow and black bands. I suppose the old veterans would call them "blacks." They are very gentle and easy to handle. I very seldom get stung unless I hurt one of them. They gather lots of honey, and have never been hurt by the moth-worm, even in the "old gum." I have had them 4 years, and they have always done well. I like them so well that I shall keep them pure. Italians may be better, but these are surely good.

I live on a river, or bay, and have a water frontage for 1½ miles belonging to me. I think that I could keep 50 colonies with profit. At first I thought to get honey for home use, but I think now of preparing to make my own hives and frames, and foundation, as the freight down here is too high to think of buying everything. I have frames yet on hand for next season's increase.

My first swarm issued on March 14, and the last one on April 2. Our bees now are at their best, though I think they work all the year. I know they fly every day when it does not rain too hard—in fact, here it is always warm. Shell Point, Fla.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*
 Aug. 3. Ionia County, at Ionia, Mich.
 H. Smith, Sec., Ionia, Mich.
 Aug. 14.—Colorado State, at Denver, Colo.
 J. M. Clark, Sec., Denver, Colo.
 Aug. 27.—Stark County, at Canton, O.
 Mark Thomson, Sec., Canton, O.
 Sept. 8.—Susquehanna County, at Montrose, Pa.
 H. M. Seeley, Sec., Harford, Pa.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Cells on a Square Inch of Comb.

—James McNeill, Hudson, N. Y., on June 21, 1888, writes as follows on the above subject:

Mr. Weidman, on page 407, is in error in supposing that I did not take account of both sides of the comb in my estimate of the cell capacity of Mr. Doolittle's hive. As we usually reckon 25 cells to the square inch, a frame of 115 square inches of surface would contain 2,875 cells on each side. To save figures, I multiplied the 115 by 50, which gives the number of cells on both sides of the comb. Mr. Weidman makes the mistake of doubling the surface of the comb, and then multiplying by 50, which gives him just double the number of cells that are contained in 9 frames of $10\frac{1}{2} \times 10\frac{3}{4}$ inches.

[You are quite correct. We referred to the mistake made by Mr. Weidman on page 419, of last week's issue.—ED.]

The White Clover Bloom.—B. H.

Standish, Evansville, Wis., on June 22, 1888, writes:

White clover has been in bloom for two weeks here, and during that time we have had warm nights, more or less cloudy days, plenty of rain, and wind in the southwest—the conditions of perfect honey weather. But the bees have gathered very little honey—not 25 pounds of surplus in my 100 colonies here at home. People say, "There is lots of white clover this year;" but beekeepers know better. There is not more than one-fourth of a full stand, and that amount seems overstocked by 100 colonies.

Strong Colonies, Tiering Up, etc.—H. C. Gifford, Morris, Ills., on June 21, 1888, writes:

Last fall I fed 21 colonies of bees 200 pounds of granulated sugar, and 10 pounds of uncapped honey. I packed them on the summer stands, and one colony starved to death; the balance wintered in good condition, but it was so cold and wet all the spring that they have not stored any honey yet. I never have had my bees stronger than they are at present. They have been ready to swarm for the last ten days, but they have not swarmed yet, although they are laying out all around the hives. I always place my hives up $\frac{1}{2}$ inch all around, to cool the hives, and give the bees a chance to clean the bottom-board and keep it so; and also to give them more room. I always put the sections on as early as possible, to delay swarming as much as I can.

I am commencing to "tier up" with snipers, hoping to prevent any swarming this season; for at this time, and especially such a season as this, I would rather not have any swarms, for if we have a good fall, the honey that 20 strong colonies will store is worth more than the bees.

This has been the poorest season, up to the present time, that I have seen in 20 years. Many bees in this locality are swarming out, actually starved out; but the prospects are good for Linden, which will come on soon. I am not discouraged, for the AMERICAN BEE JOURNAL gives me new life every week. The knowledge that I have gained from it in the last three weeks is worth five times its cost for the whole year. The benefits, and the plain, sensible reasons given by men of experience, derived from the system of "tiering up," to keep the bees all at work, and to give them plenty of room, and thereby destroy the inclination to swarm, is worth a great deal to any one who will practice it; and it costs money and time to learn these things by experience. I have never realized the half that I could from my bees, if I had taken the BEE JOURNAL years ago; and still my neighbors think that I am an expert, when in fact last year was my first real work in the bee-business, and I have kept bees for over 20 years.

No Room for Brood—Albino

Bees.—Chas. D. Barber, Stockton, N. Y., on June 25, 1888, says:

Would it not be a good plan to take out some of the frames from my old colonies and put in empty ones? They have no place for brood, having filled it all with honey. They swarmed three times before June 20. The outlook is very good for a large honey crop. I have had 4 swarms from 2 colonies, and will have more soon. I have bought a queen and one pound of Albino bees, and as workers they are ahead of any bees that I have ever seen.

[If the queen has no place in which to lay eggs, the colony will soon become depleted. To take out the frames of honey which are more than are necessary to supply the needs of the bees, would be a wise act in this case, in order to give the queen the necessary room to keep up the strength of the colony.—ED.]

But Little White Clover.—Geo.

Smith, Amadore, Mich., on June 21, 1888, says:

It looks at present as if the honey crop will be an entire failure. There is very little white clover, and but little honey in what white clover there is.

Managing Robber Bees, etc.—

Ira N. Lyman, St. Peter, Nebr., on June 22, 1888, writes:

1. Do bees ever gather poison that kills them? I have a colony that has lost some bees. They came out of the hive and looked full, and do not fly, walk or run out of the hive. Some tried to fly, and fell in the grass, where they soon died. 2. My bees began robbing badly, and when they were flying thick, I carried away the hive that was being robbed, after closing the entrances of both hives. I then put the hive of the robber bees off its stand, and put the weak colony in the place of it. I kept the hive of the robbers closed over night, and put it in a new place, a hundred yards or more from the old site. I opened the hive of the weak colony as soon as it was put on

the stand where the robber hive had stood. They carried their stolen sweets into the hive from which they stole it. The other colony seemed weak for awhile, and then were all right. Is that a good way to manage robber bees? I have done that way twice, and it seems to me it is a good way. I want to thank the readers of the BEE JOURNAL for information about Albinos and other bees, which I have received privately, and for circulars and books. Bees are not doing very well on the prairie. Honey is scarce yet. I have had no swarms, and swarming prospects are poor. I like the BEE JOURNAL first-rate.

1. The bees were evidently diseased, but it was not the result of gathering poisonous honey.

2. Interchanging hives is often practiced in case of robbing, and generally is an effectual cure.

Swarming, Chapman Honey-

Plant, etc.—Mrs. J. B. Curlee, Tamaroa, Ills., on June 23, 1888, says:

Last year nearly all the bees starved here. I had 30 colonies, and lost all but 9. There are but few bees in this part of the State. We are having plenty of rain now, and bees are swarming. Bees here gather honey mostly from white clover (but it was all burned out last summer), and the Spanish-needle, which blooms in the fall. My Chapman honey-plant will be in bloom in a few days. It is $\frac{1}{2}$ feet high, and has large balls on it, looking like the wild thistle.

White Clover not Plenty.—Dr. A.

B. Mason, of Auburndale, O., on June 26, 1888, writes:

It has been a poor honey season in my locality. A few days last week were favorable, but now the cold and rain keep the pets at home. White clover is not very plenty, and but few bees are working on it.

The Queen—Excluding Honey-

Boards.—J. F. McIntyre, of Fillmore, Calif., asks the following:

I have 500 colonies of bees in two-story 10-frame Langstroth hives. I do not want any more increase, as my field is fully stocked. I work exclusively for extracted honey. 1. Would you advise putting queen-excluding honey-boards on the hives of the whole 500 colonies? 2. How much would the honey-boards increase the disposition to swarm?

1. We should put on the queen-excluders.
2. In some years and some localities, such will tend to increase swarming—but this we would overcome in another way, which you will need any way, whether you use queen-excluding honey-boards or not.—HEDDON.

Honey Coming in Slowly.—Geo.

Eidemiller, McGregor, Iowa, on June 25, 1888, says:

The honey comes in slowly. The season is too late, the nights too cold, and the honey-producing plants are too backward. Last year I started with 3 colonies; now I have 9 colonies. I am very much pleased with the AMERICAN BEE JOURNAL.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4 1/4 x 4 1/4 and 5 1/4 x 5 1/4. Price, \$1.00 per 100, or \$8.50 per 1,000.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

- For 50 colonies (120 pages)..... \$1 00
- " 100 colonies (220 pages)..... 1 25
- " 200 colonies (420 pages)..... 1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

CLUBBING LIST.

We Club the American Bee Journal for a year, with any of the following papers or books, at the prices quoted in the LAST column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

Cork for Winter Packing.—Its advantages are that it never becomes musty, and it is odorless. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2 00	3 00	3 50
1,000 Labels.....	3 00	4 00	5 00

Samples mailed free, upon application.

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; 1/2 pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices:—Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 18 cents per pound for bag and postage.

Honey and Beeswax Market.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 13@15c.; the same in 2-lbs., 10@11c.; buckwheat 1-lb., 10c.; 2-lbs., 9c. Market dull. We are doing all we can to reduce stock, to make room for the new crop.

BEESWAX.—26c.

HILDRETH BROS.,

May 21. 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—We quote: White to extra white comb, 12 1/2@15c.; amber, 8@11c. Extracted, white to extra white, 5 1/2@6c.; amber, 4 1/2@5c. Arrivals of the new crop are small, the estimates being an average crop.

BEESWAX.—20@24c.

O. B. SMITH & CO., 423 Froust St.

DETROIT.

HONEY.—Best white in 1-lb. sections, 14c.—Dull.

BEESWAX.—23@24c.

June 14. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—We get 15c. per lb. in a small way for best comb; and less for off grades. Extracted, best white, 7@8c. None of the new crop received yet, but there is more than sufficient of the old crop for the light demand.

BEESWAX.—22c.

R. A. BURNETT, 181 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 12c.; fancy 2-lbs., 10@11c.; fair white 1-lb., 10@11c., and fair 2-lbs., 8@9c. Buckwheat 1-lb., 7@8c. The demand is dull for comb but fair for extracted, of which new from the South is arriving, and sells for 5 1/2@6 1/2c. per gallon.

BEESWAX.—Dull at 23 1/2@24c.

June 15. F. G. STROHMAYER & CO., 122 Water St.

CHICAGO.

HONEY.—We quote: Fancy white clover 1-lb., 16@17c.; 2-lbs., 15@16c. Dark is slow sale at almost any price. Extracted is scarce, and sells at 7@10c.

BEESWAX.—23c.

Mar. 13. S. T. FISH & CO., 189 S. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb., for which demand is good. Comb honey, 12@15c.—Demand slow.

BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.

June 14. C. F. MUTH & SON, Freeman & Central Av.

MILWAUKEE.

HONEY.—Choice white one-lb. sections, 16@17c.; 2-lbs., 15@16c.; 3-lbs., 14c. Extracted, white in kegs and 1/2-barrels, 8 1/2@9 1/2c.; in tin and pails, 9 1/2@10c.; dark in barrels and kegs, 5@7c. Market fair.

BEESWAX.—22@25c.

Apr. 23. A. V. BISHOP, 142 W. Water St.

DENVER.

HONEY.—Best white 1-lb. sections, 14@15c.; 2-lb. sections, 12c. Extracted, 6@7c.

BEESWAX.—20@23c.

June 25. J. M. CLARK & CO., 1409 Fifteenth St.

KANSAS CITY.

HONEY.—We quote: Choice new 1-lb. sections in good demand at 15@16c., not glazed; dark ones not searched; 2-lb. and extracted there is no demand for. Stock of old honey is light, and the sections are all glazed, which style the trade do not like.

BEESWAX.—None in market.

June 30. HAMBLIN & BEARSS, 514 Walnut St.

BOSTON.

HONEY.—We quote: 1-lb. sections, 16@17c.; 2-lb. sections, 14@15c. Extracted, 8@9c. The market is not very brisk and sales are slow.

BEESWAX.—25 cts. per lb.

Mar. 24. BLAKE & RIPLEY, 57 Chatham Street.

SAN FRANCISCO.

HONEY.—We quote: Choice new extracted, 5 to 5 1/2c.; amber to light amber, 4 1/2@4 3/4c. Choice comb in 1-lb. sections, 13@14c.; 2-lbs., 12@13c. Arrivals are small, as apiarists are holding back. Prices are considered high.

BEESWAX.—18@22c.

June 25. SCHACHT & LEMCKE, 122-124 Davis St.

KANSAS CITY.

HONEY.—We quote: White 1-lb., unglazed, 15c.; 1-lb., white, glazed, 14c.; dark, 1-lb., 2c. less. California, 2-lbs., comb, white, 13c. Extracted, 7c. Considerable old honey is in this market. No new yet in.

Sales are very slow.

BEESWAX.—None on the market.

June 9. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—We quote: Extracted, bright, 5@5 1/2c.; dark, 4 1/2@5c.; in cans, 7@8c. Comb, choice white clover, in prime order, 13 1/2@15c.; dark, less. Market quiet with fair demand for extracted.

BEESWAX.—22c. for prime.

June 27. D. G. TUTT & CO., Commercial St.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

EDITORIAL BUZZINGS.

Such boasting and taunting,
Just hear, oh, ye heavens—
But "Barkis is willin',"
Quoth W. M. Evans!!

We had a pleasant call last Saturday from Mr. A. I. Root's son-in-law, who is also manager of the establishment at Medina, Ohio.

Sugar Made from Honey.—On page 371 we made some remarks about Mr. Henry Alley's proposal to raise \$5,000 "from the bee-keepers throughout the United States, and paid to the person who will devise some method for converting honey into sugar, similar to granulated sugar." We remarked that we had some sugar made from honey in our Museum, which had been there for a dozen years, and said that it would not pay to make it.

By request we sent some of the sugar to Mr. Alley, and he does not seem to appreciate it. Of course we are sorry to differ from our friend, but the facts remain all the same. It is not a question of priority, particularly; but if a good article of sugar can be obtained from honey, which will compete with cane sugar, we shall be happy to see it.

The Third Annual Report of the General Manager of the National Bee-Keepers' Union is now published, and has been mailed to all the members with Voting Blanks for officers for the coming year. We hope that a general response will result in renewed subscriptions for the coming year. As the fees are now reduced to a dollar a year, thousands should flock to its standard at once.

An Apiarian Exhibit is to be made under Governmental supervision at the Cincinnati Centennial Exposition next month. The following list of articles, showing the history and development of the industry, have been sent from the Museum of the AMERICAN BEE JOURNAL. After the close of the Exposition they will be forwarded to the National Museum at Washington for permanent display:

Water and Salt for Bees.—Under this heading Mr. Wm. Urie writes thus for the *Farm, Stock and Home*:

Every apiary, however large or small, should have a convenient watering place for the bees. A shallow trough large enough to hold say a pailful of water, without its being over 2 inches deep, provided with some small floats for the bees to alight on to drink, is a convenient form. Bees drink and use much water, and they are often compelled to go long distances for it and be subjected to great inconvenience to get it, at that.

Foraging for water consumes much valuable time which would be employed in profitable work if water was kept at hand.

Bees need salting, also; it is as necessary to them as to cattle. About once a week put a handful of salt in the pailful of water contained in their trough, and notice with what avidity the bees will go for it.

Do not give too much salt, but the proportion noted will be found both gratifying and beneficial.

The Thirteenth annual meeting of the American Association of Nurserymen was held at Detroit, Mich. This industry does much to beautify the country and ennoble the people. Without fruits and flowers this would be a dreary land. The past season this society has secured reduction in freights by different classification, which is worth more to nurserymen and the people than the society ever will cost. No nurseryman can afford to exclude himself from such an association. Send \$2.00 for a membership fee to Chas. A. Green, Secretary, Rochester, N. Y. Then you will get the official report free of cost. The next meeting will be held in Chicago.

Basswood is in bloom now in quite a number of localities, and the yield bids fair to be plentiful. The weather is warm and moist, and everything augurs well for the secretion of nectar, and we hope to be able to report a bountiful harvest. A few trees are in bloom near the office of the BEE JOURNAL, and the bees are happy. Mr. Root, in *Gleanings* for July 1, makes these remarks on basswood in his locality:

This 30th day of June, bees discovered a little cluster of blossoms on one of the basswood trees that skirt the road in front of our dwelling. Only a dozen or two buds were opened, but the bees were having quite a rejoicing over them. The trees are loaded with buds. What shall the harvest be?

Chas. F. Muth & Son, of Cincinnati, have issued a set of 5 illuminated cards on "Bees and Fruit." The pictures are fine, and well colored and finished. On the reverse may be found three paragraphs from our Leaflet No. 1, entitled, "Why Eat Honey?" After these comes the following announcement:

"We have always made it a point, ever since we existed, to supply honey in its best forms, and never soiled our fingers by adulteration."

That announcement is something to feel proud over being able to truthfully make. It is worth more to a TRUE MAN than all the gold of California, or the diamonds of Africa. That it is truthfully made by our friends, "Muth & Son," no one who knows them would deny. It is almost proverbial that Mr. C. F. Muth is the personification of truth and honor, and bee-keepers are to be congratulated in having such a man among their number. We beg his pardon for this notice—but it was called out by those attractive cards, placed on our desk by the mail-carrier just as these forms were ready for the press.

Every Bee-Keeper who realizes the importance of the work now being done in the interest of the pursuit should send a dollar to this office and become a member of the National Bee-Keepers' Union for the ensuing year. "In Union there is strength." Reader, can you afford to remain outside any longer?

Dividing Swarms.—On this subject Mr. G. K. Hubbard remarks as follows in *Indiana Farmer* for last week:

When two swarms go together they may be separated by setting two hives on opposite edges of a sheet and shaking the bees between them and brushing them with a feather to see that an equal number of bees go into each hive. A sharp lookout should be kept for the queens, and one put in each hive. Sprinkling the bees with water retards their movements, so that you are much more apt to find the queens. When the swarms that cluster together are put into one hive they should be given plenty of room in the surplus boxes, and a little brood put into the brood-chamber to insure that no brood is put above.

GLEAMS OF NEWS.

Hot Summer.—It is now quite generally predicted that the rest of the summer is to be hot all over the country. The *Indiana Pharmacist* predicts it upon the following theory, which has been advanced by others:

The weather seems to run in cycles of about seven years, that is, when we have a hot summer, it is always followed by a cold one, and it takes about seven years to reach another equally hot. It will be remembered by many that the summer of 1867 was very hot, and so dry that during August the grass crumbled under the feet when trod upon. The summer of 1868 was noted for its coolness, the thermometer very seldom getting above 85°, and we did not reach the top wave of thermalty again until 1874, when it was extremely hot. The following summer was cold to a remarkable degree. From then on the summers grew gradually warmer until 1881, which was excessively hot and very dry, no rain falling for over nine weeks, and there were more sun-strokes that summer than there has been in all the summers since.

The summer of 1882 was quite cold, a few flakes of snow fell on the morning of July 4, followed by hail in the afternoon, and during the rest of the month and through the month of August the temperature was so low that overcoats were necessary for comfort, particularly at night. The summers since 1883 have grown warmer and warmer, and last summer was a moderately hot one, but unless all signs fail, the coming summer will be the climax of the cycle, and a hot, dry season may be expected. So far this spring the signs have been against the theory here advanced, but possibly the coolness of the spring may be succeeded by a regular old scorching summer whose temperature will rival sheol for hotness.

Small Sections for Comb Honey etc.—G. B. Olney, Atlanta, Iowa, on June 21, 1888, writes:

The 5-cent packages described on page 292, appears to be too cumbersome, and it takes too long to get them into shape. I take a board the thickness that I want, and the length of the inside of the frame; set the saw to cut half through, when I cut half the width of the saw on each end, doing the same with a board for perpendicular pieces. I set the jack-plane bit to cut 1-32 of an inch, and plane off all I will need in a very short time. I dampen and strighten them out, put foundation starters on the long pieces before I fasten the parts together, and after they are formed I have an ornament and useful article.

A Mr. J. E. Stoner sent me a sample of Alsike clover hay, with a note, stating that his stock of all kinds eat it well. They leave no stems as they do with red clover and timothy, and his bees are working on it splendidly. He has 12 acres of Alsike, and wants more of it.

I went to a fellow not long since, presented a long-standing-bill and met with this answer:

"Come and git your hives, bee's and all. I don't like them ere kind of hives, know how. I'm goin' to make a new kiue, some with draw's in, an' some glass in, so I k'n see what 'um doin'." I thought to myself, what a good subject you are for Lizzie Cotton.

The white clover is yielding some honey when it stops raining long enough to let it stand up. The corn fields are getting very weedy, owing to so much wet weather that farmers cannot work it. It has been very

discouraging thus far this spring, being dry early, and the squirrels took the corn as fast as it came up. Some farmers replanted the fourth time, but by using poison and shot-guns freely, and all the boys with snare-drums that could be found, we managed to have some corn growing. What would some men think of this extra work it perchance it would be done for the honey-bee?

Yes, indeed. While every kind of business has its drawbacks, that of keeping bees is no more liable to them than any other; neither is it an exception to the rule.

Nearly every novice, as soon as he enters the business, assumes to "know it all," and wants to get up a new hive. He knows more in one day than all before him in the business have been able to learn in a century. It is a *disease* which attacks nearly all who embark in the business.

INTERROGATORIES.

Cans for Extracted Honey.—A correspondent in Ulster County, N. Y., on July 5, 1888, asks the following questions:

1. Are not fruit-cans as good as anything to put up extracted honey for the market? When the honey is put in those cans should they be exposed to the light? 2. I have read that the best plan of taking care of extracted honey is to put it directly into fruit-cans and seal up when almost at boiling point. Does not heating honey spoil its flavor? Are the covers for said cans air tight?

1. Yes; but there are many kinds; they are made of glass, tin, etc., and exposure to the light is not detrimental to the honey.

2. Heating the honey does no harm, unless it is brought to a boil. The covers to all the self-sealing cans make the package air-tight; others are not air-tight.

Sterile Queens.—C. A. Pardee, Colesburgh, Ky., on July 2, 1888, writes as follows:

I send a queen which is a puzzle to me and my bee-keeping friends of this vicinity. She was reared under the swarming impulse from a good cell, and the last one of the batch to be capped. I was careful in handling this cell, leaving it in original comb, and never inverting, bruising, or jarring it. The cell was capped on May 17. I deemed further inspection of the colony unnecessary until June 23, when its weak condition warned me that something was wrong. Upon opening the hive, I found no brood, but the worker cells were filled with eggs, and the queen was attending to business. On June 30, I again opened the hive, and found that none of the eggs had hatched. Upon close inspection, I could see a tiny drop of larva food in the bottom of each cell, but instead of the larva, the egg still remained projecting from the cell-bottom. I found no eggs in the drone-cells.

I removed the queen immediately, and as there is no microscopist of sufficient experience in this vicinity, I send her to you, Mr. Editor, trusting that you will forward her to some skilled entomologist who will for the cause of science ascertain what is the matter with her. That she lays sterile eggs in worker-cells can be verified by introducing her into a nucleus. I would suggest that you make the report of the ento-

mologist public in the *BEE JOURNAL*, as the solution of this puzzle would surely be interesting, not only to myself, but to a large majority of its readers.

We sent the queen to Prof. A. J. Cook, with the above letter, and here is his reply:

Mr. C. A. Pardee, of Colesburgh, Ky., sends me, through the editor of the *AMERICAN BEE JOURNAL*, a queen, that though she lays eggs in great numbers, produces no bees. Mr. P. says as there is no microscopist at his place, he sends the queen for a full report. This is a case where a microscopist would do no good.

In last week's *Rural New Yorker* a subscriber writes: "My mare has produced one or two colts, but now seems sterile. What is the trouble?" The veterinarian editor replies that in many such cases it is impossible to explain the sterility. In the higher animals we speak of sterility, though with them, as with the queen, I presume, eggs are still produced, but are impotent, sterile or worthless.

The real trouble with the egg we do not know; we may never know. It is a very difficult subject to investigate. With this queen—and such queens are not so rare but that I have seen many of them—as with occasional examples of all higher animals, though eggs were ripened and passed from the reproductive organs, yet they were sterile. We can only say that the queen's are diseased, and so only can produce worthless eggs. What the disease is, or why the egg is sterile we cannot say. Some such queens which have come under my observation, have been very prolific of eggs; yet, not an egg would hatch.

So far as I have observed, such queens never recover from this inability. Breeders of cattle frequently have cows that ovulate regularly, yet never breed. Occasionally such a cow after being sterile for months, or even years, will become again a regular breeder. It would seem that in such cases, we have a disability, which, though very likely akin to that of the queen in question, yet is only temporary. This might lead us to expect that possibly a queen of this kind might in time become a breeder. However, it would not pay to keep one with such a hope in view, except as a matter of scientific interest. Even with our higher stock it is a questionable policy to breed from animals which have been for a time sterile. We should fear that the same disability might come in the offspring.—A. J. Cook.

Omission.—In the essay of Mr. T. S. Sanford, on *Farm Apiaries*, read before the *Farmers' Institute*, and published on pages 425 and 426, two lines were omitted through an oversight of the printer. The whole sentence should read thus:

After being thus prepared they should not be disturbed until settled warm weather has come in the spring to stay; when they should again be examined, and if any are found to be without a queen, they should be united with some weak colony having a queen, or another queen procured for them at once.

BIOGRAPHICAL.

DR. A. B. MASON.

This biographical sketch was written for *Gleanings* by Mrs. Mason :

The subject of this sketch was born 25 miles southeast of Buffalo, in the town of Wales, Erie Co., N. Y., Nov. 18, 1833. His father was born in Massachusetts, and was of English, Scotch, and Irish descent; was a soldier in the war of 1812, and assisted in the capture of Fort Erie. His maternal grandfather was killed by the Indian allies of Great Britain, in the same war. His maternal grandmother was of the old Knickerbocker, or Dutch ancestry.

Mr. Mason had six brothers older than himself, two younger, and two sisters. All were raised on a farm, and the brothers are all farmers. The only living sister is the wife of a farmer, and lives at Emporia, Kansas. His mother and grandparents all died in their 83d year, and his father was about 90 at his death.

In DeKalb Co., Ill., when about 17 years old, Dr. Mason taught his first school, for \$14 per month, and "boarded round." In relating some of the incidents in connection with that school, he says: "The three last teachers preceding me were turned out by the 'big boys,' the last being thrown through the window with the window shut. Of this I knew nothing until the morning I went to begin school. I made up my mind to teach that school or somebody would get hurt, and so I told the director. I was hired for three months, but taught four, and was offered \$40 per month to teach the same school the next winter. A majority of the scholars were older than I was."

At the close of this school, young Mason went to Beloit College, Wisconsin, and attended two terms, his chum and friend being the now well-known Gen. Warner, of Warner "Silver Bill" notoriety. With the exception of the above, and a few terms attendance at an academy in Wyoming, N. Y., when he was either at or near the head in all his classes except grammar, his school education was obtained in the common district school.

In his 19th year Mr. Mason joined the Baptist church of his native town, and has ever since been proud to be known as a Christian. Just previous to his 22d birthday, at the earnest solicitation of his parents, he commenced the study of medicine with the family physician, working, as opportunity offered, to earn money to help pay expenses.

During the winter of 1857 Dr. Mason attended medical lectures at the University of Michigan, at Ann Arbor. At the close of the lecture course, he went to Illinois to spend the summer, and to complete his medical studies. The following autumn he returned to the old home in New York, and on his 25th birthday was married to a Miss Clark. In the spring of 1859, in company with several families from New York and Illinois, the newly married couple went west and located at Irvington, Kossuth Co., Iowa, 40 miles west of the present home of Mr. Eugene Secor. The colony with which they went having broken up, in 1862 they moved to Waterloo, Iowa. Here Mr. Mason commenced the practice of denistry, which he has followed to the present

Dr. Mason has always been known as an earnest temperance worker, and has had his life threatened twice by saloon-keepers. He still delights in being a thorn to them.

His youngest child is a daughter 16 years old, and the oldest is 27. His children, like himself, use no tea, coffee, tobacco, or liquor in any form.

In 1869, a brother, in moving, left 2 colonies of bees with him till a more favorable time for moving them. He soon became interested in them, and, seeing an article in a newspaper that year about Mrs. Tupper's success with bees, wrote to her, making some inquiries, which were kindly answered. He at once became a subscriber to the AMERICAN BEE JOURNAL, which he has taken till the present time.

Dr. A. B. Mason, President of the North American Bee-Keepers' Society.

time. He was Secretary and Treasurer of the Iowa State Dental Society, and President of the Northern Iowa Dental Association for two years. For four terms he was Secretary and a member of the School Board of the city in which he lived, and was one of the originators of the city library, and librarian for several years.

For years Dr. Mason was an active, if not the most active member of the church to which he belonged, being at one time superintendent of the Sabbath-school, church clerk, a trustee, and clerk of the board of trustees. He was a leader in Sabbath-school work at home and in adjoining counties. One year he was secretary of eight different organizations, four of them religious.

The same year, Mr. Mason became a member of the Central Iowa Bee-Keepers' Association, and the next year was elected secretary, which position he held until he left the State.

In 1873, owing to frequent attacks of rheumatism, and an increasing desire to make bee-keeping more of a specialty, Dr. Mason quit the office practice of denistry, and the proceeds of the apiary have materially aided in furnishing "bread and butter" for wife and children.

In 1874, the family residence, a large new house, with all its contents, was consumed by fire. There were 18 first-class Italian colonies of bees in the cellar. On learning of the loss, some members of the Central Iowa Bee-Keepers' Association offered to

make him a present of 14 colonies as a starter.

The same year we moved to Ohio, which has since been our home. In the summer of 1875 we lived in a suburb of Cincinnati, and made and sold the Murphy honey-extractor, most of them going to southern States.

In 1876, Dr. M. was chosen secretary of the Buckeye Union Poultry Association, and held the position for four years.

In the winter of 1879 he tried what has since been known as the "Polen Theory," and, with the experience of that and succeeding winters, he has been made a firm believer in that theory. This was several years before anything was said about it in the bee-periodicals.

In 1881 Mr. Mason succeeded in getting the Tri-State-Fair Association at Toledo to offer Fair premiums for the display of the products of the apiary, and the display has increased in attractiveness each year; and last fall it was said the display was the most attractive of any on the grounds. He was appointed superintendent of the department the first year, and still holds the position.

During the year 1882 and 1883, when but little was generally known about foul brood, his apiary of 75 colonies was badly infected, nearly every colony having it in 1883, and he has frequently stated the loss was from \$300 to \$500; but he cured it that year, and has had none since.

For several years he has been a member of the Michigan State Bee-Keepers' Association, and in 1886 was made an honorary member.

At Chicago, in November, 1887, on his 54th birthday, Mr. M. was chosen president of the North American Bee-Keepers' Society.

Early in October last, he made what he called a "new departure" in bee-keeping. Having become satisfied, in theory, that it was of no special benefit for bees to be flying after frosts had destroyed all honey-producing blossoms, he concluded to prepare a few colonies for wintering, and place them in the cellar as soon as there came a killing frost. On the night of Oct. 15 there was a hard frost. On the night of the 19th he placed the prepared colonies in the cellar. On April 27, 1888, the bees were taken from the cellar, after undergoing a confinement of six months and eight days, and were in good condition, having lost in weight $7\frac{1}{4}$ pounds on an average.

The other colonies, put in the cellar in November, were weighed at the same time (Oct. 19), and, when taken out with those put in Oct. 19, were found to have lost in weight, on an average, over 11 pounds.

During the past winter he has delivered two addresses at farmers' institutes, and one at a horticultural meeting, the subject being "The Benefits of Bee-Keeping to the Agriculturist and Horticulturist."

Mr. Mason has been chosen to superintend the Apiarian Department of the Ohio Centennial Exposition, to be held at Columbus from next Sept. 4 until Oct. 19.

He is now serving his third term as assessor of the precinct in which we live, having been re-elected by an increased majority.

MRS. A. B. MASON.

Anburndale, Ohio.

QUERIES AND REPLIES.

Distinguishing Purely Mated Italian Queens.

Written for the American Bee Journal

Query 558.—How can a purely-mated Italian queen be distinguished from one mated with a Cyprian or Holy Land drone, or with a drone that is a mixture of Italian and one of these races?—Calif.

By her progeny.—H. D. CUTTING.

I do not know.—P. L. VIALLO.

By her progeny.—A. B. MASON.

I do not know.—J. M. SHUCK.

By her progeny.—MRS. L. HARRISON.

I doubt if she can.—EUGENE SECOR.

Only by her progeny.—J. P. H. BROWN.

You've got me.—JAMES HEDDON.

Only by the markings or disposition of her progeny.—C. H. DIBBERN.

I have had no experience with Cyprian or Holy Land bees.—J. M. HANBAUGH.

By the appearance of her progeny, and in that way only occasionally.—R. L. TAYLOR.

I doubt if it can in all cases. I doubt if it can be certainly in any case.—A. J. COOK.

In no way that I know of. This is one of the worst features about getting the Cyprians and Syrians into this country. I think we would have been much better off had we never seen either.—G. M. DOOLITTLE.

She cannot with certainty. Her progeny will be so nearly like pure Italians that I do not believe any one can distinguish them with certainty in all cases.—M. MAHIN.

The workers of such a cross-bred queen will many of them resemble the Cyprian or Holy Land workers, as the case may be, and others will resemble Italian workers. The close observer

can readily tell the workers of such a cross by observing the pure races by themselves.—G. L. TINKER.

There is no way by which the mating of a queen can be determined except by her worker progeny. It is only by strict attention to the matter that this can be done. Three yellow bands is the color test, and is the only test that I know of; and it will not apply to the crosses between the yellow varieties. All dependence must be placed upon the honesty of the breeder.—J. E. POND.

No one but an expert in such matters can make the distinction, and even then it is not certain that no mistake will be made. Pure Cyprians are marked by the solid yellow on the underside of the abdomen, which marking is not materially changed by crossing with the other yellow varieties. The other yellow races (Italians and Syrians) are marked with dark veins dividing the yellow with the segments of the body. One well acquainted with the peculiar motions and actions of bees of different races may detect a mixture of blood, but there is room for mistake all around.—G. W. DEMAREE.

No method has yet been discovered by which to determine the purity of the mating of queens, except by the markings and temper of their worker progeny. As the bees mentioned are so nearly like the Italian, we think that it would be exceedingly difficult to determine the matter even with the worker progeny of such queens—that is, to determine with any degree of certainty.—THE EDITOR.

Double-Walled Bee-Hives and Supers.

Written for the American Bee Journal

Query 559.—1. When wintering bees on the summer stands, which is the best, a double-walled hive with chaff between the outer and inner walls, or double-walls with a vacant space between the walls? 2. Which is best for winter, double-walled hives, with walls one inch thick and 2 inches of space between the walls, or single-walled hives with a wall 4 inches thick? 3. In working for comb honey should the surplus story be double-walled? If so, will more honey be obtained thereby?—Mich.

1. Probably with chaff. 2. Probably the double-wall. 3. No.—C. C. MILLER.

1. We prefer hollow double-walls. 2. It makes little difference. 3. No.—DADANT & SON.

1. I do not know. 2. Double-walled hive. 3. No.—R. L. TAYLOR.

1. A vacant space. 2. A 2-inch space between the walls. 3. No, no.—MRS. L. HARRISON.

1. I would use the chaff between. 2. I cannot say. 3. No.—J. M. HANBAUGH.

I have had no experience with chaff hives, as they are useless for the South.—P. L. VIALON.

1. Double-wall with chaff. 2. Double-wall. 3. No, but a shade-board will pay.—A. B. MASON.

1. If the space were perfectly air-tight it would be as good as the chaff—otherwise not. 2. The former. 3. No.—EUGENE SECOR.

1. I prefer fine or cut straw to either. 2. I prefer the double-walled hive, every time. 3. The single story is just as good.—G. M. DOOLITTLE.

1. Use the chaff to make sure of dead-air spaces. 2. No practical difference; these things do not cure or create bee-diarrhea. 3. No, no.—JAMES HEDDON.

1. The chaff makes it warmer, or more independent of outside temperature. 2. I do not understand. The character of the wall must be explained. 3. No.—A. J. COOK.

1. I do not think any difference will be found. 2. The first mentioned will, I think, be the better. 3. I prefer a single-wall for the purpose.—J. E. POND.

1. I use, for wintering on the summer stands, a single-walled hive with 4 inches of packing outside. 3. I do not know. I shall try with and without this season.—H. D. CUTTING.

1. I should prefer chaff to a dead-air space. 2. The double-walled hives, but I would neither use those nor a hive with 4-inch solid walls. 3. No; it is no advantage whatever.—C. H. DIBBERN.

1. I have never used chaff in that way. I have some double-walled hives with an inch of dead-air space between $\frac{7}{8}$ -inch walls, and the bees always winter well in them. 2. The former. 3. I prefer a double-walled surplus story.—M. MAHIN.

1. I am well satisfied that the hives packed with chaff are the safest in out-door wintering. 2. I should prefer the double-walled hive. 3. No, but further North, where the nights are very cool, some extra protection would appear to be necessary.—G. L. TINKER.

1. Double walls packed with chaff have proved best with me. Outside walls $\frac{3}{4}$ inch thick; inside walls $\frac{1}{2}$ inch thick, and 3 inches of chaff. Chaff over the frames 6 inches thick. 2. Double walls are better in winter for out-doors than single-walls. 3. Double-walled supers are no advantage. I have used them.—J. M. SHUCK.

1. Chaff between is the best. 2. I would say that neither is practicable, and I could not make a choice between them. 3. No, not according to

my ideas of a practical working hive. It pays best to use a light, properly arranged hive for storing honey, and for rapid manipulation. Then use an outer-case around it where packing is necessary for winter protection. Very few "combined" implements are a perfect success. The honey season is the all-important thing in bee-keeping.—G. W. DEMAREE.

1. For wintering bees, hives with double walls, having the space between them perfectly air-tight are on some accounts preferable to those having the space between the walls filled with chaff. 2. The former is, perhaps, preferable, but the difference is very slight. 3. No.—THE EDITOR.

CORRESPONDENCE.

A REVIEW.

Also a Reply to Various Writers on Current Topics.

Written for the American Bee Journal
BY G. W. DEMAREE.

I have been so busy of late looking after a multiplicity of business on my hands, that I have been compelled to pass by many things that otherwise I would like to notice.

Mr. Doolittle is still doing battle for his "swarming impulse" queens, and perhaps he imagines that he has silenced all opposition. Strange that Mr. D. has failed to see that he has not pretended to meet the real matter at issue. The question has nothing to do with the "dollar queen," and other loose and unscientific methods to force queens ready for the market. The real question is an important one, and should be treated with all fairness.

Can the art and skill of the apiarist be so applied as to improve the races of bees? This is the only phase of the question that I care to discuss. Man has succeeded in improving all the domesticated animals, and my experiments go to show that the honey-bee is not an exception.

Mr. Doolittle seems to be tender on this subject, and I am not surprised to see that a true, conscientious man like himself should instinctively feel "tender" when it comes to queens reared by "nater." For there has been as much humbug to the square inch connected with the "swarming impulse" queen business, as can be found anywhere, the shrewd hybrid business not excepted.

I have no hesitation in saying that as many persons have been disappoint-

ed, who have purchased advertised "swarming impulse reared queens," in proportion to the number sold, as have been disappointed by purchasing queens reared by the cheaper methods. But all such argument as this, and the condemnation of Mr. Doolittle of the shoddy methods, does not touch the real question.

That bees and queens can be improved in beauty of markings, size, etc., I have proved beyond question. I wish that I was able to speak as confidently of the improvement of the working qualities of my bees. Perhaps this desirable part will be found to baffle the skill of the most careful breeders.

After breeding up a strain of Italian bees that I believed was superior as honey-gatherers, I put into my apiary an imported Italian queen, and with daughters reared from her I re-queened about 20 colonies of my bees, having in view the introduction of fresh blood on the male side of the race, and to my surprise these colonies, headed by daughters of the imported mother, were in no way inferior to my carefully bred bees when it came to solid, hard work. The same thing has occurred twice in my apiary in the past ten years. I therefore conclude that *race* has more to do with industry and the other qualities which go to make up good working bees, than all else besides.

It has been quite common for queen-breeders to talk and write with all confidence about rearing queens for "business, etc." I really wish that there was more of the substantial about it, for the reason that any apiarist may dispel his delusion by trying the experiment that I have mentioned above. The main point in breeding bees is to keep the race or strain *pure* and keep up the introduction of fresh blood to give health, vigor and energy.

Bee-Culture Not a Fixed Science.

My friend and co-laborer in the apicultural vineyard in Kentucky, Mr. James M. Tyler, proposes to be unmercifully hard on Dr. Allen and myself, and perhaps all the old veterans in bee-culture. He demands of us that we *stand* to what we have written on bee-culture in the years that have gone by. Speaking for myself, I cannot afford to do this, though much of what I did write was fully up with the times.

Bee-culture is not a "fixed science." It is progressive, and hence the writer on bee-culture, if disenthralled from foggism, must always be moving. Still I do not demur to the bee "literature under your arms." Come on with it, and I am sure that you will not find me the stinging hybrid that you represent me to be.

I do not admit that Kentucky is behind the times. All States and peoples have their specialties, and no State excels in all departments of business.

Do Bees Select beforehand their Home ?

Mr. J. E. Hand thinks that I am a little "off" on this subject. I admit it. It is no unusual thing for an error to become so deeply rooted that it requires a bold man indeed to undertake to root it up. The old superstitious notion that bees "send out scouts" to locate the new commonwealth, has too much genuine romance about it to be given up without a struggle. Bees are sometimes seen passing in and out of hollow trees, and the conclusion is jumped at that the bees are "cleaning out" a new home! No one, it seems, has stopped to think that chemical changes that sometimes takes place in the rapid decay of wood is sufficient to account for this.

We are told that a swarm of bees have been seen to strike a "bee-line" for some hollow tree. Yes, but about ten times more frequently they do not go directly to some hollow tree, but wander from place to place, sometimes roosting out over night till they instinctively find a hole to crawl into. But the unerring habits of bees forbid any such thing. Bees never *do anything in advance* of their *present* wants. This fact alone ought to settle the question.

Loss of Young Queens.

Mr. Millard, in his article on page 423, explains the cause of the loss of so many young queens at the time of their mating, and I need only to say that the "cause" is not "unaccountable" to me; that is, the presence of too many indifferent, cranky old bees, but the unaccountable part is, why old bees should not only become indifferent to the future prospects of the colony, but full of jealousy and hate toward the only source of relief—the young queen. I am glad to see that light is breaking on this subject. No author of our standard works, so far as I have seen, has ever touched upon this subject.

Christiansburg, Ky.

CANADA.

Report of the Brant Bee-Keepers' Association.

Written for the American Bee Journal

BY R. F. HOLTERMANN.

A meeting of the above association was called to order by President Anguish, at the Court House in Brantford, Ont., on Saturday, May 5, at 2 p.m. The prize list for the county show to be

held at Brantford, on Sept. 12 to 15, was adopted, being as follows:

1. Display of comb honey in most marketable shape, product of exhibitor, and not less than 300 pounds, quality to govern, 1st prize, \$5 00; 2d prize, \$3 00; given by the Brant Bee-Keepers' Association.
2. Display of extracted honey, 1st, \$5 00; 2d, \$3 00; given by the assoc atioo.
3. Display of comb and extracted honey (exhibitors who have entered in Sec. 1 and 2 excluded), not less than 200 pounds of each, quality to govern, 1st, \$4 00; 2d, \$2 50; given by the association.
4. Ten pounds of clover extracted honey in glass, 1st, bee-hive, given by E. L. Goold & Co.; 2d, \$1 00, by T. Birkett.
5. Ten pounds of linden extracted honey in glass, 1st, bee-hive, by S. Dickie; 2d, *Canadian Honey-Producer* one year, E. L. Goold & Co.
6. Best 10 pounds of comb honey in sections, 1st, one colony of bees, by D. Anguish; 2d, \$1 00, by J. R. Howell.
7. Best honey vinegar, 1st, one smoker, by R. F. Holtermann; 2d, 75 cents.
8. Best assortment of fruits put up in honey, 1st, swarm-catcher, by R. F. Holtermann; 2d, 75 cents; 3d, 25 cents.
9. Best display of bee-keepers' supplies, the manufacture of the exhibitor, 1st, \$5 00; 2d, \$2 00.
10. Best hive for comb honey, 1st, diploma; 2d, 50 cents.
11. Best hive for extracted honey, 1st, diploma; 2d, 50 cents.
12. Best honey extractor, 1st, diploma; 2d, 50 cents.

O. McAlister and W. R. Brown, who were not yet members of the Ontario Association, were appointed representatives for the year, in accordance with the Ontario Bee-Keepers' Association by-laws.

S. A. Dickie asked how we should know of the proposed shipment of queens, one of which every member of the Ontario Association will receive. T. Birkett said that doubtless notice of shipment would probably be sent a few days previously.

Experiments in Burying Bees.

The report of the "buried bees" was next given. The President, D. Anguish, stated that his bees had been taken out alive. The combs were, however, damp and moldy. One colony was very strong, but the others were on the weak side. The unfavorable weather which followed had affected them, and they were all lost.

S. A. Dickie reported 2 colonies dead when taken out; the rest were in very fair condition, one in fact being first-class. They had since perished from the same cause as Mr. Anguish's. He intended to try again.

The Secretary stated that all his bees had come out about equally strong, but the combs were slightly moldy. None had perished since being taken out. In closing, he stated that they had been taken out dead. He would leave this experiment to be continued by the man who had wintered his bees that way successfully. T. Birkett reported that his bees had wintered well, but that several had since been robbed.

This question was asked: "What is the best time to Italianize bees?" Answer, "During the honey season."

THE UNION.

Report of the General Manager on the Third Year's Work.

It becomes the duty of your General Manager, at the end of the third year of the existence of the National Bee-Keepers' Union, to review the important events of the fiscal year just ended, and with special pride he makes the announcement that, so far, the Union has been successful in every case it has undertaken in defense of the pursuit of keeping bees. No decision has yet been obtained inimical to the pursuit of bee-keeping.

The officers were re-elected in July, 1887, by almost an unanimous vote, and during the year they have aided in every possible manner to make the Union triumphantly successful in every case it has undertaken.

Amended Constitution.

The proposed amendments to the Constitution were all carried unanimously, and went into effect on Jan. 1, 1888; as amended it reads thus:

ARTICLE I.—This organization shall be known as the "National Bee-Keepers' Union," and shall meet annually, or as often as necessity may require.

ARTICLE II.—Its object shall be to protect the interests of bee-keepers, and to defend their rights.

ARTICLE III.—The officers of this Union shall consist of a President, five Vice-Presidents, and a General Manager (who shall also be the Secretary and Treasurer), whose duties shall be those usually performed by such officers. They shall be elected by ballot, and hold their several offices for one year, or until their successors are elected; blank ballots for this purpose to be mailed to every member by the General Manager.

ARTICLE IV.—The officers shall constitute an Advisory Board, which shall determine what action shall be taken by this Union, upon the application of bee-keepers for defense, and cause such extra assessments to be made upon the members as may become necessary for their defense; provided that only one assessment shall be made in any one fiscal year, without a majority vote of all the members (or all its franchises for that purpose), together with a statement showing why another assessment is desirable.

ARTICLE V.—Any person may become a member by paying to the General Manager an Entrance Fee of ONE DOLLAR, for which he shall receive a printed receipt making him a member of this Union, entitled to all its rights and benefits. An annual fee of \$1 00 shall be due on the first day of July in each year, and MUST be paid within 6 months in order to retain membership in this Union.

ARTICLE VI.—The Funds of this Union shall be used for no other purpose than to defend and protect its members in their rights, after such cases are approved by the Advisory Board; and to pay the legitimate expenses of this Union, such as printing, postage, clerk-hire, etc.

ARTICLE VII.—This Constitution may be amended by a majority vote of all the members at any time.

The membership of the Union has not increased as much as it was expected, but this may be accounted for in the fact that the drouth of last summer prevented the bees from gathering much honey, and therefore bee-keepers have felt too poor to add to their ordinary expenses. It is to be hoped that a good crop may be obtained this year from basswood and fall flowers, so that all may be able to contribute their *mite* to aid this important adjunct to the pursuit of apiculture.

In several cases your Manager has been consulted as to the best course to pursue when bee-keepers were threatened with lawsuit, by envious or jealous

neighbors. After giving due consideration to the detailed facts in each case, they have been advised as to the best course to pursue, and in many cases lawsuits have been averted by the conciliatory measures advised by the Union. In two cases, where the bees were *really an injury* to the neighbors by being too close to the line where sweaty horses were driven almost constantly, the bees have been removed by advice of your General Manager, and thus all trouble has been averted. In other cases compromises have been advised, and the wisdom of such has been seen in the amicable relations now existing, where trouble had been brewing.

California Raisin-Growers.

The decision reached in the Bohn case not only averted the trouble which at one time wore a serious aspect, but now a proposition has been made to buy the apiary and remove it—thus saving the apiarist from the loss which would have resulted from his being unceremoniously driven out of his honorably-acquired and just rights.

This, however, was quite unnecessary, for the bees not only did no damage, but vastly increased the crop. The California *Horticulturist*, last fall, admitted that the crop was greatly in excess of all expectations. So the bees are the fruit-growers' very best friends! They increase their crops, and enlarge their bank account balances. This is how the bees have rewarded the makers of the "late war" forced upon them by some ignorant and selfish raisin-growers.

It was proven at the trial that the bees could not bite into the skin of a grape. A San Diego bee-keeper, says the San Francisco *Chronicle*, settled the question in this way:

He took a perfect bunch of grapes, every berry of which was sound and in good order, and suspended it in the middle of a hive of bees for an indefinite time. It remained there several weeks, and at the expiration of the period was removed in as perfect a condition as when first put in the hive. Thousands of bees had been crawling all over the fruit during that time, only too eager to attack the juice thereof, but had been unable to do so.

History repeats itself. Sometime ago, in a certain town in New England, so strong was the belief that bees injured the fruit, that an ordinance was passed obliging the bee-keepers to remove their bees to another locality. After a year or two, the fruit-growers decided to have the bees brought back, because so little fruit matured upon the trees.

Had the raisin-growers been successful in California, and had driven the bees away, it would only have been a short time before they would have been just as anxious for their return as they then were to drive them out of their borders! It was the work of ignorance and prejudice to demand

the removal of the bees, but as soon as light and knowledge was allowed a place, better judgment prevailed.

The "Rich" Lawsuit.

As mentioned in our last report, Mr. S. W. Rich, of Hobart, N. Y., was sued by a jealous and disagreeable neighbor for \$1,200 damages, and also to compel him to move his home-apiary outside the city limits. Bee-keepers from several States attended the trial, which was held last October before Judge Boardman, at the Delaware county court. About 40 witnesses were called.

The plaintiff asked for \$1,200 damages for injuries inflicted by the bees upon his person and property, but the jury, from which every person having bees was excluded, gave him but *six cents* to cover wounded feelings and damaged property!!

This virtually declared that the bees were *not* a nuisance. The result is an overwhelming defeat for the enemies of the pursuit of bee-keeping, and another victory for the National Bee-Keepers' Union.

But as the award of even 6 cents as damages carried with it costs amounting to \$468.04, the case has been appealed to the Superior Court, which will cost about \$500 more. Judge Boardman ruled against the bees every time, and in charging the jury compared the bees to a pig-sty and a slaughter-house. This was the first case with one exception ever tried in the State, and the Judge having no law or precedent to go by, ruled just as *he* thought right, with the above result.

It will not do to let bee-keeping be likened to a pig-sty or a slaughter-pen! It is an honest and honorable pursuit and its rights must be preserved. This appeal will be heard this fall, the Union having engaged lawyers, and guaranteed the expenses of the new trial. Had the Judge been inclined to be as *fair* as the jury, this would have been unnecessary.

Bogus Comb Honey.

The Wiley *lie* about honey-comb being manufactured, filled with glucose and sealed over by machinery has received considerable attention from the Union during the past year.

In order to counteract the baneful influence of that and similar falsehoods, one of our Vice-Presidents, Mr. A. I. Root, has issued a "card," offering \$1,000 for the proof of the existence of such a fraudulent article on the market, but as it does not exist, the offer is not taken! When pressed for proof, the peddlers of the lie have to admit that the evidence they rely on is mere hear-say, and at the critical moment vanishes out of sight!

An insolent Virginian braggart is the latest defender of that lie. The Union took up the case and demanded the proof. In short, this modern Goliath was frustrated—beaten at every turn—and his vaunting trailed in the dirt before his very eyes!

Such offensive braggarts must be taught to make sure of their proofs before parading them in the face of the intelligent public. The National Bee-Keepers' Union exists to fearlessly teach the impudent, that Truth shall triumph, even though such a "Goliath" may defiantly and tauntingly say: "Come on, saints and sinners, 'Barkis is willin'," "I can prove it," etc. Audacity cannot win, especially when the Union lifts up the standard, and defends the pursuit.

In this connection, the Union has foreed Prof. Wiley to make this astonishing confession:

At the time, I repeated this statement more in the light of a pleasantry than as a commercial reality, for I did not believe that it was POSSIBLE commercially to imitate the comb.

Therefore, he "knowingly, wilfully, and maliciously" lied, out of whole cloth, just to cause a sensation, and to injure an honest pursuit. It is astonishing that any man could make such a bare-faced confession without blushing for the infamy it exhibited!

Lawyers, doctors and ministers have been caught repeating the diabolical *lie*, and even this Virginian ventures to repeat it! But all have come to grief before the Union's triumphant banner of truth!

Poisoning the Bees.

A paper in Atlantic, Iowa, published a malicious article against bee-keeping, and advised the grape-growers to poison the bees in their localities, making wild and untruthful assertions about the "grape-raising industry having been almost entirely killed out in Ohio, by this nuisance." The Union proved this to be a malicious falsehood, and the author of it was shown to be either ludicrously ignorant, or a vile slanderer!

Mr. W. M. Bombarger, of Harlan, Iowa, a member of the Iowa Horticultural Society, and a fruit-grower, in a letter to the Bee-Keepers' Union, states that the article in the *Messenger* should "receive the condemnation of the intelligent grape and fruit grower of the State which it *mis*-represents," and adds:

That the grape-raising industry in Ohio has been killed out by honey-bees or apiarists following their harmless pursuit, I assert is false, whether the assertion be made maliciously or ignorantly, and is proven so by the report of the commissioner of agriculture for 1886, page 116, where, commenting on "The shrinkage of yield in Ohio," he reports as follows: "The shrinkage of grapes in 1881, 1883 and 1885 was due principally to three facts which cannot be separated—rot, mildew, and the effect of the previous severe winter."

I regard the honey-bees as one of my very best friends in grape and small fruit culture, and keep a small apiary in my smaller vineyard, which is so located that the path of the bees, in the air to their best pasturage during the blossoming season, is over my larger vineyard.

I find the bees so valuable in fertilizing fruit bloom that I not only encourage my neighbors to keep them, but intend doubling my stock in the near future. Their value is greatest whenever we have cool, wet weather during the fruit-bloom, and the winds cannot carry the pollen in dust form from flower to flower.

Arkadelphia "Nuisance" Case.

This case, mentioned in the last Report, will come to trial about July 16, 1888. Meanwhile Mr. Clark has been sent to jail in default of paying a daily fine for maintaining a nuisance by keeping bees in Arkadelphia, Ark.

The "Union" has employed several of the most noted attorneys in that State to defend the case, and confidently expects a decision in favor of the pursuit. It would be very detrimental to the pursuit to allow a decision against bee-keeping to be put upon record on the plea of its being a "nuisance."

Mr. Clark gives the following particulars of the case:

I was released on a *habeas corpus* bond on March 2, for my appearance at 10 a.m. the next day. I had not been home with my family more than about three hours when I was re-arrested and taken before the Mayor and fined \$14 and costs, and remanded to jail again. Of course it would be nonsense to pay the fine, and go back and have the same thing to go over again the next day.

The Mayor fined me one day when no one had seen any bees about my place. He sent the Marshal to my house to ascertain if he could see any bees—it was cool, and no bees were flying. The Marshal did not see any bees, and swore that he did not, but the Mayor fined me "all the same."

We have appealed all the cases—even in number—the first day's fine was \$5.00, and an additional dollar for each day; the last day's fine being \$15.00. He even fined me after we had made affidavit asking for a change of venue, averring that I "could not get a fair trial, and that he was prejudiced," etc.

I am confident that if bee-keepers could fully realize my condition, the Bee-Keepers' Union would have 10,000 members in 24 hours.

By the enforcement of an unlawful ordinance of the city, Mr. Clark has been deprived of his liberty, and the constitutional rights guaranteed to every citizen of the United States. Even granting that it was wrong in Mr. Clark not to obey the city authorities, he should have had a speedy trial by an *impartial jury*—all of which have been denied him. Even when released under a writ of *habeas corpus*, he was, within three hours, re-arrested and fined. After demanding a change of venue, because of the prejudice of the Mayor, that functionary again fined him, denying him his constitutional rights. Mr. Clark has a strong case, and in justice to the pursuit, ought to be defended. The Union agreed to pay the Hon. S. W. Williams \$250 for defending the case up to and including the trial at the Circuit Court next week.

A member of the Union gives his views of this case in these words:

It is our duty to stand by him, and hold up his hands while he suffers imprisonment, and put to great inconvenience and pecuniary loss in the defense of a principle which is dear to us all. Surely, in a matter of this character, the injury of one is the concern of all. I would willingly pay a

dozen assessments rather than have Mr. Clark worsted in this matter.

No extra assessment would be necessary, if but one-tenth of the bee-keepers of America should join the Union. The Manager does not favor an *extra* assessment, and will not consent to such, unless it becomes an absolute necessity. If its devotees will not defend the pursuit, who should do so? The defense should have universal support. A few ought not to bear the burden for all. Donations of any amount will be cheerfully received, but extra assessments are not desirable, because what may be a mere bagatelle to some might prove a *burden* to those less able to contribute their quota.

The only wonder is that there were not 10,000 members of the Union within a few months after its organization. There ought to have been a *general rush* to the defense of the pursuit.

It is a shame that, with 300,000 bee-keepers in the United States, so few are willing to defend the pursuit against its enemies. Many are selfish, and think that so long as they are not molested, they will not join the Union. But as soon as they are even threatened, they rush around for some help, and want the Union to tell them what to do, etc. But the Advisory Board has decided that the Union can defend only those who have become members before they were in trouble of that kind.

It will take nearly two thousand dollars to successfully defend the cases now on hand, and the Union must have two thousand members during the coming year, or it will be obliged to let the cases go by default—and the pursuit will suffer an ignominious *defeat!*

To those Not Members of the Union.

Reader, are you satisfied to accept the latter as the result of your apathy? If not, sit down at once and send a dollar as a membership fee to the National Bee-Keepers' Union. You will get a receipt by return mail, and may then have the consolation of knowing that you have done your duty in this case! It is *now or never!* Inaction will insure defeat—activity is *life*—energy—power!

UNION IS STRENGTH!

The Election of Officers.

It now becomes my duty to call for \$1.00 for the coming year, as dues from each member. The enclosed Blank is to be used for that purpose; and also a Voting Blank. Fill up all the blanks, and send to the Manager with a postal note or money order for \$1.00 in the enclosed envelope. It must be received by Aug. 1, 1888, or the vote will be lost.

Financial Statement.

From July 1, 1887 to June 30, 1888.

Balance as per last report.....	\$224.25
From 87 members at \$1.00 each.....	87.00
From 194 members at \$1.25 each.....	242.50
	<hr/> \$563.75

Paid S. W. Rich's suit.....	\$100.00
Paid Z. A. Clark's suit.....	125.00
Printing, stamps, stationery, etc.....	80.48
	<hr/> \$305.48

Balance on hand July 1, 1888.....	\$258.27
-----------------------------------	----------

Concluding Remarks.

I now submit my third annual Report with the hope that it will meet with general approval. Having served the Union for three years to the best of my ability, with the consciousness of having done my duty for the pursuit, I shall welcome my successor as soon as your choice is revealed.

Yours fraternally,

THOMAS G. NEWMAN,
General Manager.

IOWA.

The Condition of the Bees, and the Prospects.

Written for the American Bee Journal

BY EZRA. J. CRONKLETON.

As so many complain that the prosy side of bee-keeping is always told, I will give a little of the other side as regards this part of Iowa. My bees were wintered in the cellar, on good linden honey, and lots of it, with no loss of colonies. They were put on the summer stands on April 1, the weather that month being cool and unfavorable. During May the weather was cool, wet and unfavorable in the extreme, there being at least 20 days that the bees were confined to the hives.

The whole spring bloom passed away with but very little benefit to the bees; still with all these discouraging circumstances, when June arrived, my bees were in very good condition for white clover; but, alas, the clover bloomed and the cool air that has prevailed all the spring continued. The clover seems to secrete nothing, and the consequence is that I have not had one swarm of bees.

My bees are now fully as weak as they were last April. I have fed hundreds of pounds of honey, and probably 100 pounds of sugar, to keep them alive until linden bloom arrives; if that does not secrete any nectar, I will be discouraged. It keeps down increase, and entirely does away with the swarming, that so many are so uneasy about. I have lost no colonies yet, but I hear of many that have lost all within the last ten days.

I have 42 colonies of bees this season. I have been very successful until this season, but I have not learned it all yet, I presume; at least I have not

learned how to run my bees the whole season through on sugar syrup, and report a success.

I hope the above condition of affairs is confined only to this part of the State. The trouble is entirely climatic. This country is (to look at) a perfect garden; clover blooms and corn grows as it never grew before. We have had plenty of rain—rather too much—and everything is booming except bees. Is it not strange?

Dunlap, Iowa, June 26, 1888.

NEW YORK.

Various Honey-Plants — Super-seding Queens.

Written for the American Bee Journal
BY LESLIE STEWART.

We have had a very poor season here. Every bee-keeper says that it has been the worst season they have known for many years. The weather has been very cold and cloudy, with a great deal of rain. The honey crop has been an entire failure so far. Fruit bloom yielded but little, and that was very thin.

The ground is white with clover, but not a bee can be seen on it. Raspberries are in full bloom, and the bees are getting a little honey from that source, but hardly enough to keep up brood-rearing.

Basswood will be in bloom in about one week, and there will be quite a large amount of blossoms, but not more than two-thirds of what we had last year. I shall expect to get a good amount of honey from that and buckwheat, as they are our only hope.

In May, after doing the transferring, I had a large amount of second quality of honey, most of which was in combs; shortly after fruit was through blooming, I put it at different places about 20 rods from my apiary, and allowed the bees to take the honey, which caused the queens to fill the hives with eggs, and has added largely to the strength of the colonies. After the honey was all gone, they showed some signs of being crosser, and were a little inclined to rob; but there is no danger if the bees are Italians, and the entrances are not too large.

Superseding the Queen.

The question of superseding queens has for a long time been a perplexing one to me, but after several years of careful watching, I have come to the conclusion that not more than half of our queens should be kept longer than two years. Of course I do not believe in killing good queens because they are two years old, but all that have not proven themselves good layers, pro-

ducers of good workers, etc., should be superseded. There certainly should be but few kept that are over three years of age, as prolific queens are the making of our colonies.

Jefferson, N. Y., July 1, 1888.

NEBRASKA.

The Season and Blooming Plants in Nebraska.

Written for the American Bee Journal
BY R. R. RYAN.

The past spring has been rather a poor one for bees, as it was so cold and windy that they were deprived of the plum blossoms, excepting for two days. They have not built up as strong as last season up to this date, and I have heard of only two swarms. Bees are now doing finely, and are building up fast. They are getting considerable honey from the red clover. The white clover seems to have no honey in it, and I seldom see a bee working on it. We have just had a fine shower, that will help the bees, or rather, produce more nectar for them.

I think that about 20 per cent. of the bees were lost in winter and spring, and a great many had to be fed during the month of May. Since then they have gathered enough to keep up breeding. We do not expect much honey in this locality until fall, when we have always had a good yield from buckwheat, heart's-ease, golden-rod and other fall flowers. We missed the raspberry bloom, as most of them were winter-killed, like the grapes.

Considerable Alsike clover is being sown now, and while clover is spreading on the roadsides nicely, and on wild pastures, wherever the seed has been sown or scattered. My Chapman honey-plant was winter-killed. I had some 25 stalks covered with straw or light manure, the latter part of the winter, and now I have two left, and one is very weak, while the other is looking very nice. It has several balls nearly ready to burst open. I shall try to give a report of the work of the bees on it later.

There is no sweet clover in this locality, but there is considerable black mustard in the flax fields. Bees are also very fond of working on rhubarb blossoms. They were very busy on the strawberries, and are lovers of the Russian mulberry blossoms, and of the fruit of the white ones. I expect to double my number of colonies, and get at least 40 or 50 pounds of honey per colony, which I have been able to do the past two years.

Bradshaw, Nebr., June 26, 1888.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*
 Aug. 3.—Ionia County, at Ionia, Mich.
 H. Smith, Sec., Ionia, Mich.
 Aug. 14.—Colorado State, at Denver, Colo.
 J. M. Clark, Sec., Denver, Colo.
 Aug. 27.—Stark County, at Canton, O.
 Mark Thomson, Sec., Canton, O.
 Sept. 8.—Susquehanna County, at Montrose, Pa.
 H. M. Seeley, Sec., Harford, Pa.
 Dec. —Michigan State, at Jackson, Mich.
 H. D. Cutting, Sec., Clinton, Mich.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Poor Prospects for Bees.—Byron Benton, Bronson, Mich., on June 28, 1888, says:

The season in this locality has been a poor one for bees. It has been too cold and wet the most of the time. They are up fair with brood-rearing, but they have not done much swarming or storing honey yet. They have gathered barely enough to live on as yet. They are much behind, as compared with this date last year. The prospect is very poor for the bees to store enough to last them until another spring.

Bees Selecting a Home before Swarming.—Wm. Anderson, Sherman, Mo., on June 30, 1888, says:

Do bees have a place to go to before leaving the old home? The other day while I was out in the barn-yard, I heard a swarm of bees coming. I ran and made a noise until I could obtain a bell. I followed the bees up a steep hill, ringing the bell, and finally I got them to stop, as I thought. They formed a funnel shape around a dead hickory tree, beginning at the top and lowering to the roots of the tree. Not thinking of a hole being in the tree, but thinking that I was going to have a good time in getting the bees into a hive, and the bunch of bees getting no larger than at first, I went to see, and to my surprise I saw a hole in the roots of the tree, and they all went in it, and are now at work in the hickory tree.

My Experience with Bees.—W. J. Netherton, Raglan, Ont., on June 28, 1888, writes:

On June 20, 1886, I bought a colony of bees, and I took 64 one-pound sections of honey that summer; but I had no increase, so I packed that colony in a box about Dec. 1, with chaff around it. They wintered all right, and I put them out in the spring of 1887. I had 2 swarms, but no surplus honey in 1887. Last fall I packed 2 colonies in boxes the same as before, and the other colony I sold; one colony died about April 1, with about 3 frames of honey in the hive. The other one appeared all right then, but it has dwindled to a mere handful. They are in the Langstroth hive. It has been a cold, backward spring, and very dry; more rain has fallen to-day than for weeks past. Bees in this locality are not doing much. A great many died in the spring, and many more dwindled down so that they are not worth much.

Expects a Surplus from Basswood.—B. W. Peck, Richmond, Ohio, on June 28, 1888, says :

Bees in this locality are not storing honey very fast yet, and now it is wet and rainy. The bees are in good condition, however, and basswood is budded, so we may get a fair surplus yet. I lost only one colony out of 48, although 2 or 3 colonies just squeezed through ; they were too weak to build up, so I will use them to hatch queen-cells, and work 45 colonies for honey. Bees are swarming but very little yet.

No Swarms and Little Honey.—S. K. Carson, Chatsworth, Ills., on June 28, 1888, says :

Bees are doing nothing here this season. The winter losses were very heavy. I saved 14 colonies out of 96, and that is about an average throughout this part of the country. What colonies are left are now strong in bees, but there is little honey even in the brood-combs, and no swarms have issued.

Honey Prospects in Michigan.—S. J. Youngman, Lakeview, Mich., on June 24, 1888, writes :

The strongest colonies of bees have stored from one to two gallons of honey, from white and Alsike clover, with but little increase. Many colonies have failed, however, to store any surplus as yet ; and owing to the extremely hot and dry weather, the clovers have begun to fail, and are yielding but little nectar. I have been building great hopes on the basswood, but upon felling a large tree, I find that there will be but little nectar from that source, as there are but few buds put forth for bloom, for some reason ; consequently it really looks bad for the bee-keeper in this part of Michigan. We may get a large crop of honey from buckwheat, of which a large amount has been sown. It certainly looks discouraging, as we had a poor season and light crop last year.

Bees did Well on White Clover.—W. Addenbrooke, North Prairie, Wis., on June 27, 1888, writes :

The following is my report for the winter of 1887-88 : I put 120 colonies into winter quarters, and removed from the cellar 117 colonies in good condition on March 19, 1888. I sold 9 colonies, and have now 93. We had a cold, wet spring, and I had to feed my bees until two weeks ago, when white clover came into blossom ; we have had very hot weather for one week—over 90° every day. Bees did well, filled up their hives, and some colonies very nearly finished one set of sections ; but the last four days have been cold and wet, and bees have not been able to fly for two days. It is cold and raining yet. It was the worst spring for getting colonies in good condition in time for white clover, that I have ever seen.

Experience with Bees.—Mr. L. D. O'Dell, Protection, N. Y., on June 20, 1888, writes :

A year ago I bought one colony of bees, which cast one good swarm, and stored 27 pounds of comb honey. In November, 1887, I bought 8 colonies, which I put into the cellar. In January I bought 5 more colonies that were on the summer stands. Owing to the severe weather, I did not move them until Feb. 20, when I brought them home (22 miles) and put them into the cellar. On March 20 I put them out for a

cleansing flight, and at night replaced them. I left them in until April 26, when I placed them on the summer stands. They were all in good condition excepting one colony, which was queenless, and it was united with another. I replaced that colony by buying another one. My apiary has increased to 28 colonies, and now the bees are booming on white clover.

Some bee-keepers advise starting with one colony, and working up ; but I believe that a person who has energy enough to succeed in bee-keeping, can as well start with 20 colonies as with one. At first no one need expect to succeed unless he educates himself in the business, by reading at least the leading works and periodicals published on bee-culture. Six of my colonies were in box-hives, but I transferred them into the Langstroth hives, by the Heddon method.

My bees have been gathering surplus quite fast for a few days. I sowed 9 acres of Alsike clover mixed with red clover and timothy, and I am sowing about 5 acres of buckwheat. I have the only bees within three miles of this place.

Favorable Prospects for Basswood.—Christian Weckesser, Marshallville, O., on June 30, 1888, writes :

Our clover season is pretty much a failure, but bees have been getting considerable aphides honey of very poor quality ; though being mixed with clover honey, we think it will answer for wintering. The prospects for some surplus from basswood are favorable, and recent rains have revived white clover, so that it looks more promising than before. During such seasons we find it more profitable to have only from 15 to 20 colonies at a place, about two miles apart ; as they almost always get enough honey so as not to require any feeding.

Waiting for Basswood and Buckwheat.—O. R. Goodno, Carson City, Mich., on July 1, 1888, writes :

At this date from 100 colonies I have not had a single swarm, and as yet I have not seen even one drop of honey in a case, though I have several cases on the strongest colonies. Last year our swarming had nearly ceased by this time, and our surplus was nearly all gathered ; none was gathered after July 5—the bees only sealed up the partly filled combs. Last year the first basswood was in bloom on June 26 ; but it will be several days before the first will open this year. Basswood and buckwheat are our only hope this year.

Worse than Moonshine.—Ben Foggy, of Iowa, describes his apiary and its surroundings in the following graphic manner :

I must tell you how I manage my bees. They are beautiful creatures, being instead of 60,000 in my colony, only about 100. These bees are large and golden in appearance, and about the size of a bumble-bee without the bumble. I have them situated in a room on whose walls are hanging the most natural paintings of all the best honey-producing plants in this vicinity—such as sweet William, honey-suckles, sweet Cicely, etc., and these are framed in gilt frames, from which the bees gather pollen. When I desire a certain kind of honey, I take down all of the other paintings, and so secure just what I want.

In one corner of this room I have all the best honey records in the world, and the old saying being true, that the bees will partake of the spirit of the master, these bees will not be surpassed in any respect, and their record outshines any record ever

made ; in fact it is so flaming that I am tempted to believe that none would think it true were I to tell it. When the paintings get faded, I have them re-painted and varnished.

With the above arrangements I can keep bees as well in the winter as in the summer. The bees work nights, Sundays only being excepted—(this last idea would suit some farmers, all but the "Sundays excepted"), as I have this room so well planned with reflectors so arranged as to collect the rays of the moon and throw them just where they are most needed. There may be some Mr. Wiley, for instance, who is incredulous enough to doubt this statement. To those I would say, do not go to New York or Boston, thinking to find it. It is a Western enterprise.

Poor Prospects for Honey.—Reuben Havens, Onarga, Ills., on June 29, 1888, says :

I put 104 colonies into the cellar, strong in bees, but some of them were light in honey. I have lost 45 colonies, being the heaviest loss I have ever had. I examined some of my best colonies this week, and I find but little honey, and not a queen-cell in any of them. There is not one pound of surplus honey. White clover is nearly all winter-killed. The prospects for a honey crop are the poorest that I have ever seen. Bee-keepers here are all discouraged, and many disusted with the business. Many have lost all their bees. More than one-half of the bees in the county are dead. I have been so crippled with rheumatism for the last 15 years that I could do no heavy labor, and a great part of the time helpless ; hence I have depended, to a large degree, upon my bees for my bread and butter. With almost a failure last year, and a prospect for an entire failure this season, the future does not appear very encouraging. I shall try to keep what there are left in as good condition as possible, and hope for a change in the programme.

Excellent Prospects.—Jno. Blodgett, Flag Springs, Mo., on July 1, 1888, writes :

My bees are booming. My 9 colonies came through the winter all right. I lost only one, which was weak, and ooc packed in chaff on the summer stands. I have today hived the twelfth natural swarm, and I have made 3 by dividing. Fifteen are working in the sections, 5 have two racks on each hive. I never saw better prospects, so far. I expect to have several more swarms, and a large report this fall. Linden is on the eve of blooming now, there is clover enough for what bees are left, and the nice rains we are having will keep it fresh for a long time. We had a fine rain last week, so that it hindered plowing corn for four days. Wheat, oats, corn and hay are very promising ; in fact everything is lovely.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4 1/4 x 4 1/4 and 5 1/4 x 5 1/4. Price, \$1.00 per 100, or \$8.50 per 1,000.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

CLUBBING LIST.

We Club the American Bee Journal for a year, with any of the following papers or books, at the prices quoted in the LAST column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

Cork for Winter Packing.—Its advantages are that it never becomes musty, and it is odorless. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2 00	3 00	3 50
1,000 Labels.....	3 00	4 00	5 00

* Samples mailed free, upon application.

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; 1/2 pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 18 cents per pound for bag and postage.

Honey and Beeswax Market.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 13@15c.; the same in 2-lbs., 10@11c.; buckwheat 1-lbs., 10c.; 2-lbs., 9c. Market dull. We are doing all we can to reduce stock, to make room for the new crop.

BEEWAX.—26c. HILDRETH BROS., 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—We quote: White to extra white comb, 1 1/2 @ 15c.; amber, 8 @ 11c. Extracted, white to extra white, 5 3/4 @ 6c.; amber, 4 3/4 @ 5c. Arrivals of the new crop are small, the estimates being an average crop.

BEEWAX.—20@24c. O. B. SMITH & CO., 423 Front St.

DETROIT.

HONEY.—Best white in 1-lb. sections, 14c.—Dull. BEEWAX.—23@24c. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—We get 15c. per lb. in a small way for best comb, and less for off grades. Extracted, best white, 7@8c. None of the new crop received yet, but there is more than sufficient of the old crop for the light demand.

BEEWAX.—22c. R. A. BURNETT, 161 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 12c.; fancy 2-lbs., 10@11c.; fair white 1-lbs., 10@11c., and fair 2-lbs., 8@9c. Buckwheat 1-lbs., 7@8c. The demand is dull for comb but fair for extracted, of which new from the South is arriving, and sells for 55@65c. per gallon.

BEEWAX.—Dull at 23 1/2 @ 24c. F. G. STROHMEYER & CO., 122 Water St.

CHICAGO.

HONEY.—No white clover left in this market. Dark slow sale at 8@10c. Extracted ready sale on arrival. New crop will meet with good demand.

BEEWAX.—23c. S. T. FISH & CO., 189 S. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb., for which demand is good. Comb honey, 12@15c.—Demand slow.

BEEWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.

Jun. 14. C. F. MUTH & SON, Freeman & Central Av.

MILWAUKEE.

HONEY.—Choice white one-lb. sections, 14@16c.; 2-lbs., 13@14c.; 3-lbs., 12@13c. Extracted, white in kegs and 1/2-barrels, 8@9c.; in tin and pails, 9 1/2 @ 10c.; dark in barrels and kegs, 6@6 1/2 c. Demand good for extracted, but dull for comb.

BEEWAX.—22@25c. A. V. BISHOP, 142 W. Water St.

DENVER.

HONEY.—Best white 1-lb. sections, 14@15c.; 2-lb. sections, 12c. Extracted, 6@7c.

BEEWAX.—20@23c. J. M. CLARK & CO., 1409 Fifteenth St.

KANSAS CITY.

HONEY.—We quote: Choice new 1-lb. sections in good demand at 15@16c., not glazed; dark ones not searched; 2-lbs. and extracted there is no demand for. Stock of old honey is light, and the sections are all glazed, which style the trade do not like.

BEEWAX.—None in market. HAMLIN & BEARSS, 514 Walnut St.

BOSTON.

HONEY.—We quote: 1-lb. sections, 14@16c.; 2-lb. sections, 12@13c. New Florida extracted, 8@9c. Sales are very dull.

BEEWAX.—25 cts. per lb. BLAKE & RIPLEY, 57 Chatham Street.

SAN FRANCISCO.

HONEY.—We quote: Choice new extracted, 5 to 5 1/2 c.; amber to light amber, 4 1/2 @ 4 3/4 c. Choice comb in 1-lb. sections, 13@14c.; 2-lbs., 12@13c. Arrivals are small, as apiarists are bolding back. Prices are considered high.

BEEWAX.—18@22c. SCHACHT & LEMCKE, 122-124 Davis St.

KANSAS CITY.

HONEY.—We quote: White 1-lbs., unglazed, 15c.; 1-lb. white, glazed, 14c.; dark, 1-lb., 2c. less. California, 2-lbs., comb, white, 13c. Extracted, 7c. Considerable old honey is in this market. No new yet in. Sales are very slow.

BEEWAX.—None on the market. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—We quote: Extracted, bright, 5@5 1/2 c.; dark, 4 1/2 @ 5c.; in cans, 7@8c. Comb, choice white clover, in prime order, 13 1/2 @ 15c.; dark, less. Market quiet with fair demand for extracted.

BEEWAX.—22c. for orime. D. G. TUTT & CO., Commercial St.

Jun. 27.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

FOR SALE—600 Colonies in the movable-comb hives, at \$4.00 for Italians, and \$3.00 for Hybrids.
25A13t **G. H. ADAMS, Troy, N. Y.**
Mention the American Bee Journal.

ITALIAN QUEENS—Untested, 75c. each; 6 for \$4.00; 12 for \$7.50. Address,
26Atf **John Nebel & Son, High Hill, Mo.**
Mention the American Bee Journal.

SHIPPING-CASES to hold 12 1-lb. sections or 14 7-to-the-foot. Nicely cut. Per 100, \$6.00. Glass for same 65 cents per 100. Two and 3 frame Nuclei cheap. (Free Price-List).
28Etf **M. H. HUNT, Bell Branch, Wayne Co., Mich.**
Mention the American Bee Journal.

75 COLONIES of Italian and Hybrid Bees for sale, or trade for land; in A. I. Root's Simplicity hives, 10 frame, L. F. Nearly all wired, and nice straight combs. Everything on the most improved modern principles. I am changing climate for my health, is the reason for my selling.
28A2t **E. SANDFORD, NOKOMIS, ILLS.**
Mention the American Bee Journal.

HANDSOME ONE-PIECE SECTIONS.

WE have a limited quantity of One-Pound Sections, 4 1/2 x 4 1/4, a trifle less than two inches wide, with narrow tops, in packages of 1,000 each. They are manufactured from extra white lumber planed on both sides, making them the finest and most attractive honey-section in the world. Price, \$4.00 per package.

THOS. G. NEWMAN & SON,
923 & 925 West Madison-Street, - CHICAGO, ILLS.
Mention the American Bee Journal.

SOUTHERN HONEY WANTED!

WE are likely to have good use for a lot of Southern Honey in the near future, and invite shipments now. Address,

CHAS. F. MUTH & SON,
26A3t **Freeman & Cent. Ave., Cincinnati, O.**
Mention the American Bee Journal.

HEDDON HIVES FOR SALE.

I HAVE a hundred, all complete—just finished. Purchaser given right to use them, by Mr. Heddon. Will sell at \$3.00 each, in lots of 10 or more. Inquire of,
27Atf **E. D. KEENEY, Arcade, N. Y.**
Mention the American Bee Journal.

NEW ONE-POUND HONEY PAIL.

THIS new size of our Tapering Honey Pails is of uniform design with the other sizes, having the top edge turned over, and has a ball or handle, making it very convenient to carry. It is well-made and, when filled with honey, makes a novel and attractive small package, that can be sold for 20 cents or less. Many consumers will buy it in order to give the children a handsome toy pail. Price, 75 cents per dozen, or \$5.00 per 100.

THOS. G. NEWMAN & SON,
923 & 925 W. Madison-Street, - CHICAGO, ILLS.
Mention the American Bee Journal.

CARNIOLAN

Gentlest bees known; not surpassed as workers even by the wicked races. Imported Queens, "A" grade, \$8.00. Tested, \$4.00; Untested, \$1.00.

QUEENS.

One-half dozen \$5 00
Never saw foul brood. Cash always required before filling an order.
S. W. MORRISON, M. D.,
14Etf. Oxford, Chester Co., Pa.

Queen Shipping-Cages.

WE have a lot of Queen-Cages, like the one illustrated, not provisioned, which we will sell 3 for a dime, by mail, postpaid.

THOS. G. NEWMAN & SON,
923 & 925 West Madison-Street, - CHICAGO, ILLS.
Mention the American Bee Journal.

Eaton's Improved SECTION-CASE. BEES & QUEENS. Send for free catalogue. Address **FRANK A. EATON,** 7Etf BLUFFTON, OHIO.
Mention the American Bee Journal.

ITALIAN BEES AND QUEENS.

ONE Untested Queen, \$1.00; 3 for \$2.00. BEES by the Pound and Nucleus. Send for Price-List. Address, **H. G. FRAME,** 9E13t **North Manchester, Ind.**
Mention the American Bee Journal.

VICTOR

SAFE.

DESIGNED for the Farmer, Lawyer, Doctor, Postmaster, Merchant, Township and County Officer, the Bee-Keeper, the Home—in fact every one should have a secure place for valuables.

We offer in the VICTOR SAFE a first-class Fire-proof, Burglar-proof, Combination Lock Safe, handsomely finished. Round corners, hand decorated; burnished portions are nickel-plated. Interiors nicely fitted with treasures, book-spaces and pigeon-holes.

Prices range as follows:

	OUTSIDE.	INSIDE.	WEIGHT.	PRICE
No. 2.	22x15x16,	12x8x3 1/2,	250 lbs.	\$30 00

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. July 18, 1888. No. 29.

EDITORIAL BUZZINGS.

Raise the pickens for the chickens,
Raise the baby on your knee,
But never raise a rumpus
With a numble honey-bee.

Don't you slight him, don't you fight him,
Even on your own domain;
If you do it, you will rue it
While you wrestle with a pain.

Don't you boss him, don't you cross him
When the flowers are in bloom;
If you meet him, try to greet him
With respect and lots of room.

We Regret to learn that Mrs. L. Harrison has been quite seriously ill. Her last letter to us was written while propped up in bed, with a bowl of ice and a spoon in it by her side. She is convalescing now, and we hope will soon be well again.

Honey Prospects.—Mr. C. H. Dibern, of Milan, Ills., in a letter just received, gives this as his opinion concerning the prospect of a honey crop for this year:

About one-half of my colonies have swarmed, and most of them are now working in the sections. Sweet clover is now in full bloom, and the bees are just swarming on it. Basswood is about done blooming, and there is not much white clover, but I think it will come out again in August. I think the prospect for a large fall crop are very good.

Concerning the prospects in Canada for a honey crop, Mr. R. F. Holtermann, Brantford, writes as follows:

The clover in Canada is a complete failure. We shall not have on an average 4 pounds to the colony. Basswood may yield well in the western counties, but in the eastern counties I doubt if it will do so, because the drouth is so great. The pasture fields are all bare, and cattle are starving. We shall have a poor yield generally, I feel certain. Basswood here is just opening.

To Prevent Stings.—Nearly every one is aware that the human body is covered with many thousands of tiny pores in the skin, and that health depends largely upon keeping these pores open by frequent bathing. From the facts given by W. L. Wilder, in a recent number of *Science*, it would appear that these pores are so many mouths, capable of opening and closing in unison with the action of the lungs. Mr. Wilder says:

It is a fact not generally known that if one holds his breath, wasps, bees and hornets can be handled with impunity. The skin becomes sting-proof, and, holding the insect by the feet, and giving her full liberty of action, you can see her drive her weapon against the impenetrable surface with a force that lifts her body with every stroke, but let the smallest quantity of air escape from the lungs, and the stung will penetrate at once. I have never seen an exception to this in 25 years' observation. I have taught young ladies with very delicate hands to astonish their friends by the performance of this feat, and I saw one so severely stung as to require the services of a physician, through laughing at a witty remark of her sister, forgetting that laughing required breath. For a theory in explanation I am led to believe that holding the breath partially closes the pores of the skin. My experiments in that direction have not been exact enough to be of any scientific value, but I am satisfied that it very sensibly affects the amount of insensible perspiration.

We have repeatedly called attention to the fact that it has been proven that any one can prevent being stung by holding the breath. If it is a fact, as Mr. Wilder avers, that the lungs and pores act in concert, and that when breathing the pores open and close involuntarily, then the peculiarity of the situation is fully explained. We would commend this subject to the attention of the physicians and scientists of whom there are hundreds on our subscription list. Let some experiments be made to test the matter most fully, and then let our readers learn the results in detail.

Open-Side Sections.—Mr. Walter S. Poudre, of Groesbeck, O., has sent us a sample of his new sections. They are nicely made, and show a considerable amount of ingenuity, but as they could not be used in the T-super and ordinary crate there will be but little chance for them to come into use. Another point is that four-piece sections are driven out of use by the one-piece sections, and no four-piece sections can now fill the demand for these useful receptacles.

Study and Labor are the means leading to success and profit in apiculture. This is how the *Rural Canadian* puts it:

The subject of honey and marketing is one which concerns nearly every bee-keeper, and very properly too, because in these, aside from pleasure, rests the just reward of study and labor, for it is fallacy to think that without study and labor in bee-keeping, as in all other pursuits, any great results can be accomplished. In marketing honey it should never be forgotten that a good article, in an attractive form, will always command the highest price, the best reputation and a steady demand.

Astonishing.—The July number of the *Bee-Keepers' Magazine* makes a strange blunder. Everybody knows that the AMERICAN BEE JOURNAL and *Gleanings* have for years been making a vigorous fight against adulteration. The *Magazine* must have been sleeping, and having just awakened from a troublesome dream, perhaps, imagines that we have been on the other side of this question. In its July number it says:

We are at a loss to know why *Gleanings* and the AMERICAN BEE JOURNAL should take sides with the adulterators who are ruining the honey market of America.

And so are everybody else "at a loss to know" it—for it is *not so!* No sane man would ever think of such a thing.

All this is in reference to the "Report of the Dairy Commissioner of New Jersey," on the purity of honey, as published on page 387, and there commented upon. The *MAGAZINE* further says:

By referring to page 108 of the *MAGAZINE*, it will be noted that at the head of the results of the analysis are placed the words, "strained honey," and that the words "comb honey" was simply the legend on the label. Men who adulterate will not hesitate to lie.

The labels on this bottled honey, are as great a lie as any Wiley ever told, and yet Mr. Newman and Mr. Root both call the man who put up this vile trash, "honorable men." Shame on you, brother editors! We do not impute to you dishonorable motives in taking sides with these rascals, but simply believe you do so through ignorance. We propose to fight adulteration whenever and wherever it appears.

We repudiate the imputation—and positively deny that we called the persons who put up the honey in question "honorable gentlemen." Let the proof be presented, or Brother Aspinwall must take it back as an "honorable gentleman." We regret that the *Magazine* should have made the unkind allusions. Though it was the only bee-periodical which published the "Report" in question, we refrained from making any unkind remarks upon that fact, because we desired a continuance of the pleasant relations then existing between the editors of all the bee-papers.

Surely, "it would seem that when a man performs a kindness, he seldom gets any credit for it"—as the *Magazine* says at the head of the article.

Mr. J. T. Wilson, of Nicholasville, Ky., has a very pleasant notice in the *Jessamine, Ky., Journal* for June 15. After reviewing his queen-rearing facilities, and the location of his apiary and surroundings, the *Journal* says that the care of his bees takes up the greater portion of Mr. Wilson's time. It is a business requiring intelligence, watchfulness and patience. He says that this immediate neighborhood is not the most favorable for bees and honey. The land is too closely cultivated. He prefers the vicinity of creeks and rivers, and lands with trees and undergrowth.

Scatter the Leaflets.—Look at the list (with prices) on the second page.

GLEAMS OF NEWS.

Bees Clustered on a Cow's Back.—Mr. E. C. Jordan, of Jordan's Springs, Va., has sent us the following items taken from the Campbell County, Va., *Record*. The first dated June 7, 1888, reads as follows :

We are informed that a cow belonging to Mr. Craddock, near Winfall, came up one evening not long ago with a whole swarm of bees quietly settled on her back. We did not learn whether Mr. Craddock succeeded in hiving the bees.

We have heard of the prognostic swarm of bees that settled on the lips of Plato. Virgil told us how, when the stock was lost, a new supply was obtained by slaying four heifers and four bullocks, and leaving their carcasses in a grove for nine days, when, behold! they were found filled with bees, and the grove resonant with their hum. The Bible tells us how Samson found honey and bees in the carcass of the dead lion. But this is the first time we ever heard of bees selecting the back of a living cow for their resting place.

The second, published a week later, reads thus :

Several persons have expressed to us their incredulity with regard to that swarm of bees on the cow's back, reported last week. We are authorized by Mr. David Craddock, the owner of the cow, to say that the facts as stated are absolutely true. His wife milked the cow while the bees were yet on her back. They remained four or five hours, and then sought other quarters.

How Bees Make Cells.—In *Murray's Magazine* we find the following explanation of the geometrical forms which the cells of a honey-comb assume :

Recent measurements and observations have tended to dissipate the cell myth, and to show not only that the honey-comb is far from regular, but that such regularity as it has is due merely to mechanical conditions.

Mr. Frank Cheshire tells us in his recent volume, that careful measurements of the finest pieces of comb, built with every advantage for securing regularity, show that, so far from every cell being geometrically accurate, it is difficult to find a hexagon presenting errors of less than three or four degrees in its angles. On the other hand, there is a growing tendency to accept a modification of Buffon's explanation of the origin of cell structure. Buffon attributed the regularity of the cells to mutual pressure ; in illustration whereof he packed a closed vessel with dried peas and filled up the interstices with water. The peas, which were thus caused to swell, assumed, under the pressure which resulted, the form of more or less accurate geometrical figures.

Perhaps a still better illustration of this principle of mutual inter-action is seen in soap-bubbles. If a little soapy water is placed in the bottom of a tumbler and air be blown into the water through a tube until the upper part of the glass is full of bubbles, the hexagonal form which these bubbles assume under mutual pressure, and the trilateral pyramids at their bases, will be readily seen. Not that these geometrical figures are the same as those which the wax assumes, but they illustrate the principle. For, at the temperature of the hive, the wax, pared thin by the smooth-edged jaws of the workers, has all the plasticity of a fluid membrane. The bee has indeed to avoid the danger of paring away too far, and thus

making a hole through the wall. But even here it may be aided by mechanical conditions.

If we take a thin piece of soap and pare away one face with the blade of a pocket-knife, we shall soon form a transparent patch where the soap is very thin. But if we continue to pare we do not cut through the soap at this point ; but for a time at least, we merely enlarge the area of the transparent patch. The thin film of soap yields at this point, and the stress of the blade falls on thicker and less yielding edges. Some such mechanical yielding of the wax may guide the bee in its work.

Honey Harvest Closed in Alabama.—B. B. Toney, Padgett, Ala., on July 6, 1888, gives this information concerning the honey harvest of Alabama, and that locality as a profitable place for bee-keeping :

I closed my honey harvest yesterday for the year 1888. I commenced in the spring with 120 colonies of bees, about 20 colonies were weak, and 100 were strong and populous. I have not finished measuring yet, but my crop will go to about 1,000 gallons when done. This makes an average of about 8½ gallons, spring count. Quite a large number of colonies gathered from 12 to 14 gallons each. Our poplar was the largest flow, and the quality of the honey fine, thick, and well flavored. The linden was only one-half of a crop, but very good. This year is the best for honey that we ever had. Of this I expect to sell 800 gallons.

This county lies in the northeast corner of Alabama, and is without doubt the best for bees in the State. If any one wishes to locate in Alabama, let him come and see before locating. Perhaps the rough mountains will fright him away. Its roughness is the secret of my success. This is in answer to Mr. Geo. W. Morris' request on page 332 of the BEE JOURNAL.

Investments in Bee-Keeping.

The following are given in a late number of the *City and Country*, as the statistical items concerning bee-keeping :

Statistics show that the total amount of honey produced annually in America is estimated at 120,000,000 pounds, which at the average of 15 cents per pound, places the value of the products in first hands at \$18,000,000. The product of the hives is not the only thing valuable about this industry, evidenced by the fact that the colonies in this country number over 3,000,000. At the average price of \$11 per colony their value would be \$33,000,000. This sum added to the total product of the hives make the total involved \$51,000,000. The United States and Canada produces the bulk of the product.

The average price of honey at wholesale is not now over 10 cents per pound, when counting the whole crop of both comb and extracted ; and \$11.00 per colony for bees is double the amount of their value.

Chapman Honey Plant.—Mr. L. Highbarger, Leaf River, Ills., on July 7, 1888, says :

Those who have the Chapman honey plant should examine it closely, as there is a worm that is cutting the balls off. It resembles a caterpillar, but is whitish in color. It does its work very quickly, and needs looking after every day. A friend of mine tells me that it is destroying his plant, and he lives five miles from here.

Recipes for Honey-Cakes, etc.

—J. W. Tefft has sent us a lot of recipes for making honey-cakes, etc., which we publish for the benefit of our readers. The use of honey in making cakes, cookies, and other fine articles of food, has long been practiced, and some of the nicest we ever ate were made with honey. We wish that honey was more generally used than it is in making such articles. Here are the recipes :

HICKORY CAKE.—Stir one cup of honey and one-half cup of butter to a cream ; add the yolks of four eggs beaten up, one-half cup of sweet milk, two cups of flour, one tea-spoonful cream-of-tartar, one-half tea-spoonful of soda, whites of eggs well beaten, one coffee-cup of hickory nuts, a blanched almond chopped fine, and one coffee-cup of raisins.

BRIDE'S CAKE.—One cup of butter, two cups of honey, three and one-half cups of flour, one cup of corn-starch, one cup sweet milk, and the whites of six eggs beaten to a stiff froth. Beat the honey and butter to a cream, then add the starch and flour, and two tea-spoonfuls of cream-of-tartar mixed in flour, and one of soda in the milk. Put the eggs in the last thing.

ANGEL CAKE.—One and one-half cups of white honey, the same amount of flour, one tea-spoonful of cream-of-tartar, one of Coulton's vanilla, the whites of eleven eggs ; sift the flour four times, add the cream-of-tartar and sit again. Beat the eggs to a stiff froth, add the honey, beat lightly, then add the flour. Do not stop beating until you put it in the pan. Bake moderately.

PUMPKIN OR SQUASH PIE.—Pare and stew a pumpkin or squash until it is soft and dry. It must be done slowly at the last to prevent scorching. Put through a colander, and to one cupful of the sifted pumpkin add one egg, four table-spoonfuls of honey, a pinch of salt, one tea-spoonful of ginger or cinnamon, and one pint of milk. This will fill one pie on a large plate. Make a crust as for any pie, and turn the edge under on the plate, pinching in shape to form the rim, but make it thin and delicate. Bake slowly until of a golden brown.

Then Mr. Tefft offers the following suggestions concerning the systematic use of honey, and its desirable effect on the system :

Sweeten your tea and coffee with extracted honey. It is a true brain and nerve food and tonic. It gives refreshment and nutriment to the mental and physical exhaustion, and tired and confused brain ; gives new life to the weak and debilitated, relieves nervousness from excess or any causes ; improves the appetite, tones the system, and has proven to be of great value in many diseases, producing a contraction of the muscles of the digestive organs ; and as an aid to digestion it is wonderful in building up lost power. It would be difficult to conceive of anything more nourishing and strengthening, creamy and delicious. For nursing mothers it is highly recommended. For lung and throat diseases nothing can be better. It is a cheap remedy for the consumptive, and in fact it should take the place of sugar in many things.

Most Valuable to the horticulturists, is what the *Farm, Field and Stockman* says of the honey-bee. Here is an item from its last issue :

The bee is the friend of horticulturists and agriculturists, and as there is no insect that increases in such vast numbers so early in the spring, when their services are so much needed, they are of more value to the farmer, gardener and fruit-grower than all other insects.

Humorous.—Mr. Eugene Secor writes from Lime Valley Apiary, Forest City, Iowa, on July 9, 1888, in this humorous strain:

THOS. G. NEWMAN—*My Dear Sir and Friend:*—I enclose a draft for \$1.00, and my vote for officers of the National Bee-Keepers' Union for the next year. As a general thing I am opposed to the principle of holding remunerative office for more than three terms, but in your cases I have such high regard and warm personal feeling for you, that I am willing for you *all* to enjoy the fat salaries another term. After you all get rich from the official emoluments, I expect you to form a *Trust*, and buy all the honey offered at less than 30 cents per pound.

So far as the Manager is concerned, he would be *delighted* to pass over the duties and "fat salaries" (often consisting of vigorous kicks and abuse) to some person who has more time to gratuitously devote to the management of the Union's affairs. He has given *months* of time to the Union, besides paying yearly dues like any other member. Why not put Brother Secor in that place for one year at least? He is a lawyer, a gentleman, a scholar, and a poet; and is eminently fitted to fill the place honorably—and when he gets rich on the emoluments of the office, he can form the "Trust" himself, and buy all the honey in the world—we shall certainly vote for Brother Secor.

We know the other officers would like a change—a chance to divide the honors and "fat salaries" with some others. Let us have a change all around. A change sometimes works wonders, and may give us 2,000 members during the coming year. Try it.

Rushing Honey to Market.—The *National Stockman* remarks as follows concerning the above subject:

Many make a mistake by rushing their honey upon the market as soon as it is obtained. Honey is not a perishable article, and during the latter part of summer, while fruits are plenty, is the duldest part of the season for the sale of honey. Better be putting in your time arranging and putting your honey in the best possible shape; just as though it was your intention to keep it for one year at least. There will be nothing lost if you improve your time in this manner.

A Young Man residing near Ettrick, Wis., while hunting early this month, saw a swarm of passing bees, and fired his gun at them. At once they settled on him, stinging him so badly that he died within an hour. Hunters should not attempt to interfere with a passing swarm of bees. If numbers count, especially when all are armed, it is an unequal contest, especially when the hunter was not posted as to the means of defending himself by creating a smoke. As hunters have no mercy on harmless and innocent birds and animals, they cannot complain when their merciless attacks meet with a vigorous response.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

INTERROGATORIES.

Wood Sage.—Dana Twining, Green Garden, Ills., on July 10, 1888, writes as follows:

I enclose a stalk of a plant that I would be pleased to have you name. I see but little of it in this vicinity, but the bees are making good use of that little. Bees are gathering but a little surplus, and that mostly from red clover.

[It is wood sage, *Teucrium Canadense*, sometimes called American germander, and has purple flowrets. It is of the mint family, grows along small streams, and is a favorite with the bees.—Ed.]

Sweet Clover.—T. F. Hawley, of Eureka Springs, Ark., on June 27, 1888, asks the following questions about this excellent honey plant:

1. Is the bloom yellow or white? Is it a fine bee-plant? 2. Will it thrive on a steep gravelly hillside that has an eastern slope? 3. I enclose a sprig of a plant growing here that I suppose to be sweet clover. The bloom is small, and bright yellow. It comes up year after year on the same plot of ground. Please give me as good an idea as possible of melilot, that I may know it when I see it, and also if bee-keepers value it much.

1. There are two kinds of sweet clover. *Melilotus alba* has a white flower, while *Melilotus officinalis* has little pendant yellow flowers; in both, the flowers are disposed in delicate elongated racemes, exhale an agreeable odor, and both are very rich in nectar.

2. It will generally grow anywhere except on a flat rock.

3. The sprig sent with this query is from the yellow variety. The plants are assiduously frequented by the bees, come up year after year on the same ground if sown twice on the same place (it being a biennial), and will last until long after frost and snow comes in the fall.

Foul Brood.—A. D. Lord, Amiret, Minn., on June 22, 1888, asks:

How do you detect the first appearance of foul brood. I have one colony among 9 that the brood is very scattering in the comb, and about one half die and turn black when nearly ready to cap. If not foul brood, what is it?

What is erroneously called foul brood is a disease which attacks not only the brood (sealed and unsealed), but also the full-grown bees, and even the queen is sometimes affected by it. It is usually said that "you will always find the cells sunken, and a small hole the size of a pin-head in the centre of the comb looking brown and bad;" that the "foul stench arising from the diseased colony" will indicate the disease, but there are so many different shades and kinds of the disease that these are not the only indications. Sometimes brood, which to all outward appearance is sound

and healthy, upon closer inspection will reveal the disease which has not yet attained the condition of sickening stench which is found in brood thoroughly roty and rotten. When it has reached the latter condition, the only remedy we could advise would be fire to utterly consume bees, hives, combs, and honey.

In the milder forms of the disease, pure phenol is no doubt the best remedy. But as it is difficult to obtain the pure article except at the large wholesale dealers, it can be obtained at the office of the AMERICAN BEE JOURNAL. One drop to 500 drops of the syrup is the formula recommended by Mr. Cheshire, as will be seen by the following from his pamphlet:

"I found that 1-200 (that is one part of pure phenol to 200 parts of syrup) was refused by the bees altogether; that 1-400 might be given constantly to a sound colony without appearing to limit the queen in breeding, or touch her health; that 1-500 dispatched foul brood quickly, even while honey was coming in; and that 1-750 appeared enough when it was not. I have established these quantities as the correct ones." Moderate quantities are, therefore, not injurious.

We would refer Mr. Lord to the Report of Mr. McLain, found on pages 473 and 474 of this issue, which gives another remedy for this much-to-be-dreaded disease.

Honey from Corn, etc.—James B. Riggins, Swanton, Nebr., on July 11, 1888, asks the following questions:

I started last spring with 18 colonies of bees. I had no increase, and obtained 1,300 pounds of comb honey. All but one came through the winter of 1887 in good condition. They are booming on Alsike clover now. The outlook is very good for a large honey crop. I received some of the Chapman honey-plant seed, and it is growing nicely now. I would like to ask whether broom-corn ever yields much honey?

Corn, when in silk and tassel, ordinarily yields both honey and pollen in good quantities. The honey is of fair quality. In some localities and seasons it has been the sole honey-producer upon which bees could work in the fall, and build up for winter.—Will some one tell us about broom-corn? Does it yield honey or pollen?

Pleased.—Mr. W. F. Kanzler, of Fulda, Ind., on July 6, 1888, writes as follows about royal jelly, larval bees, etc.:

A thousand thanks for the article on "Larval Bees," on page 440. The valuable AMERICAN BEE JOURNAL steps on the high platform of scientific research, and thereby honors itself. Prof. A. J. Cook showed himself the greatest reformer, for he could reform himself. Mr. Stachelhausen, of Texas, gives a sample of his learning in apiculture, and will probably enlighten us hereafter. All nonsensical talk will now stop about royal jelly, stating that it is "young brood in the white state," "I saw legs and breasts plainly in it," (see the BEE JOURNAL for 1881, page 133, third column, 16th line from the top), and even the "bread-and-butter-men" will be pleased to learn how young bees are fed and nourished, and how old bees prepare their food.

QUERIES AND REPLIES.

Building a Bee-House.

Written for the American Bee Journal

Query 560.—I. I propose to build a beecellar in the following manner: My apiary is on high, sandy land, and descends about 1 foot in 15. Commence on the lower side and excavate on a level 4x5 feet for the entrance-way, with an outer and an inner door. Then excavate 27 feet and 2 inches by 7 feet and 8 inches, for the cellar proper. Build a sod wall on the margin of the cellar 1 foot in thickness, and in height 7 feet from the bottom of the cellar. Build a second wall outside of the first, with 10 inches of air-space between them. The plates to support the shingled roof are to rest on cedar posts set in the ground outside, and on a level with the sod walls. Cut gains in plates for joints to support a double floor overhead, covered with 2 feet of sawdust. The outside of the posts are to be rough boarded. It will have no windows, and be ventilated with two 3-inch iron pipes, one passing through the wall near the door 1 foot above the cellar bottom, leading into the open air, and the other just passing through the floor overhead, from the attic above. Will such a repository be a suitable one for wintering bees?—Mich.

Yes.—H. D. CUTTING.

I should think so.—G. L. TINKER.

Yes, if dry.—DADANT & SON.

I think it would.—J. P. H. BROWN.

It will do nicely.—C. H. DIBBERN.

As I understand your description, it certainly will.—J. M. HANBAUGH.

I see no reason why it would not.—EUGENE SECOR.

Yes; but I think you can dispense with one-half of the sawdust.—MRS. L. HARRISON.

Yes, but I would have the ventilators so arranged that they could be closed and opened at will.—A. B. MASON.

I have no experience with cellar or in-door wintering of bees, and so I am not prepared to give an opinion.—M. MAHIN.

I always winter my bees on the summer stands, so I have no practical knowledge on the subject.—J. E. POND.

I have to leave this Query to those who have experience with cellar-wintering, as in the South we have no use for them for wintering bees.—P. L. VIALLO.

If I understand you, your building will be a house rather than a cellar, as the bottom is only about 2 feet below the surface of the ground at the deepest part. Something more underground, I think, would be better.—C. C. MILLER.

I should say that it would answer very well, but at the present time I think that the iron pipes for ventilation are not necessary. Three years of experience tells me that such a cellar needs no special ventilation, more than comes through the ground.—G. M. DOOLITTLE.

It all depends upon how thoroughly the work is done. I should not want to put bees in it until some one else

had tested it. It is too much above ground, and sod walls, I fear, are too unstable. Make a radical change in your plan.—R. L. TAYLOR.

Yes, and if they do not have the diarrhea, which depends mainly upon their food, they will come out in first-rate condition in the spring.—JAMES HEDDON.

Such an arrangement in this climate would be so damp that everything would mold and decay in a very short time. In your Michigan climate, where the air carries less moisture in winter, your repository may winter bees all right.—G. W. DEMAREE.

I think that the cellar described would be a good one, if you can keep the rats and mice out of it. The ventilating tubes seem small to me. I would prefer them 6 inches in diameter, with a contrivance to entirely close them in zero weather.—J. M. SHUCK.

I should think so. The thing to be gained is to keep the temperature above 38°. I have now wintered bees several years without loss. Last winter my cellar was down to 28°, and for weeks below freezing, and the loss was great. Cellars must be frost-proof.—A. J. COOK.

To dig deeper and have something more substantial than sod-walls, would be preferable—making it more of a cellar than a bee-house. The ventilating tubes should be so made that they can be closed or opened when desired—and they are also too small.—THE EDITOR.

Position of Bee-Spaces—Honey-Boards, etc.

Written for the American Bee Journal

Query 561.—1. In using T-supers without a honey-board, which is preferable—to have the bee-space made in the top of the brood-apartment, or in the bottom of the case? 2. What kind of a honey-board do you prefer? 3. How much space should there be between the ends of the top-bars and the hive, to guard as much as possible against the bees fastening the ends to the hive?—M.

1. I prefer the bee-space at the bottom of the section-case.—J. P. H. BROWN.

1. There is no difference. 2. A slatted queen-excluding honey-board. 3. Three-eighths of an inch.—A. J. COOK.

1. In the bottom of the case. 2. Wood slats with zinc queen-excluders between. 3. Five-sixteenths of an inch.—A. B. MASON.

1. I prefer the bee-space in the top of the brood-chamber. 2. If I have a honey-board at all, I prefer one composed of slats. 3. See Query 554, on page 422.—M. MAHIN.

I know nothing of the matter practically, as I have never used them.—J. E. POND.

1. On top of the brood apartment. 2. The slatted break-joint of wood. 3. Five-sixteenths of an inch.—MRS. L. HARRISON.

1. I prefer the space in the bottom of the case. 2. The Tinker improved wood-and-zinc. 3. One-thirty-second in this locality.—H. D. CUTTING.

1. At the top of the brood apartment. 2. Perforated zinc. 3. They will stick their glue more or less at any distance.—J. M. HANBAUGH.

1. I use the bee-space at the top of the brood-chamber. 2. Wood and zinc combined. 3. I use 1-32 of an inch.—G. M. DOOLITTLE.

1. At the top of the brood-apartment; but I would not use them without a honey-board. 2. The Heddon slat honey-board. 3. One-sixteenth of an inch, and let them fasten.—C. C. MILLER.

1. At the top of the brood-apartment. 2. The Heddon slat break-joint until swarming, then a queen-excluder on the swarm. 3. Bee-space, or $\frac{1}{4}$ of an inch.—EUGENE SECOR.

1. Either will do, and there is but little difference in handling. 2. A slatted board with 3-16-inch spaces between the slats. 3. See Query 554.—C. H. DIBBERN.

1. I would prefer to have the spaces at the bottom of the case, although it is generally used the other way; but either does not make any difference. 2. A perforated-zinc honey-board. 3. Three-eighths of an inch.—P. L. VIALLO.

1. I do not think it would make any difference. I would not want to use a T-super without a honey-board. 2. I prefer a wood-and-zinc honey-board. 3. Not over 1-16 of an inch.—G. L. TINKER.

1. I would prefer it in the bottom of the case, if I could use no honey-board. 2. I prefer the slatted honey-board described on page 297. 3. Make the top-bars of the frames pointed, and allow them to just touch the ends of the hive.—J. M. SHUCK.

1. So far as results are concerned, consult your tastes; but how could you easily put a cover on a brood-chamber full of bees, with no space over the frames? 2. The Heddon slatted honey-board with strips of queen-excluding zinc between the slats. 3. I prefer 1-32 of an inch.—R. L. TAYLOR.

1. I prefer to have half of the mechanical bee-space at the bottom and top of the cases; and have the top of the brood-chamber reduced to half the usual bee-space. 2. A horizontal di-

vision-board made of perforated zinc, with a wood rim 3-16 of an inch (half a bee-space) above the plane of the sheet, on each side. Mr. John S. Reese, of Kentucky, who has a perforating machine, has improved the zinc queen-excluding honey-board by perforating the sheets in rows, so as to come right over the centres of the top-bars of the frames, thus insuring a perfect break in the upward passways. I like his plan the best of all. 3. Three-eighths of an inch.—G. W. DEMAREE.

1. At the top of the brood-apartment, to take the cover when the surplus cases are not on, and to take a cover to the T-super, which must not have two bee-spaces, or how about tiering them? 2. My own; that is, one containing the bee-space and break-joint principle. 3. One-fourth inch, or none to speak of.—JAMES HEDDON.

1. There is practically no difference—either place will do. 2. The slotted queen-excluding honey-board is preferable. 3. About $\frac{3}{8}$ of an inch.—THE EDITOR.

CORRESPONDENCE.

QUEEN-REARING.

How to Rear the very Best Queens.

Written for the American Bee Journal
BY WM. H. BALCH.

There has been very much written on this subject, yet not one has centered the mark. This is written in all kindness. I do not rear queens for sale, and I do not write this to start a controversy *pro* or *con* on artificially reared or naturally reared queens, but that the inexperienced may profit by what I have proven for many years.

All are well aware what queen-breeders say about naturally and artificially reared queens, and how much stress is laid on the "swarming impulse," larvæ three days old, strong colonies, and the first set of queen-cells reared in a colony, etc. In the AMERICAN BEE JOURNAL for May 16, 1888, is an article in which the writer says, "divide the colony." When I read that article, I felt a sympathy for the writer, and much more for those who read the article that have had small experience in queen-breeding, and expect good queens. I then thought that it was my duty to correct the error immediately.

It is a very simple and easy matter to divide a colony of bees, and rear a

lot of queen-cells; one that I *once* practiced until I found some of my queens died in three months, and many within one year. This caused vexation and loss, and I began to study and experiment, and from those experiments I have found that I could rear the *very best queens*. It is done in the following manner:

At any time when bees carry natural pollen, and the drones are out, or will be at the time the queens will be old enough to make her bridal tour (early in the spring, summer, or late in the season), take the queen from a strong colony, then wait eight days, and cut out every queen-cell and insert a frame of eggs, not larvæ. Be sure that there is not one egg hatched. This is the secret, not *larvæ* but *eggs*. About treble the number of queen-cells will be constructed, and the queens will be of the very best! The longest lived queens that I ever had, were reared according to the above method.

Oran, N. Y.

OLD QUEENS.

Shall We Supersede Old Queens Ourselves?

Written for Gleanings in Bee-Culture
BY O. O. POPPLETON.

The assertion, that bees know better when to do this work than we do, is in a certain sense true, and in other ways not true; for while they frequently supersede their queens before the apiarist can possibly detect any failure of the queen, or, at least, before he would detect it in the ordinary routine of work, they frequently retain failing queens, if allowed to do so, for months after they are nearly worthless; but all are agreed that such queens should be replaced by the beekeeper. The fact that, in following any rule of superseding on account of age, we will sometimes destroy queens good for yet another season, is also true; but this is only one item to be considered in making a decision of what is best to do, and not the conclusive reason that the one who made it seemed to consider it was.

The entire question is one simply of profit and loss; that is, a question of which way costs the least. On the one hand we have the expense of furnishing the colonies with the young queens, which any one can easily determine for himself, and to this must be added the value of an occasional queen that would be destroyed that would be useful for yet another season. This last item is much less than many suppose it to be, and less than I sup-

posed it was until after I had closely observed the matter for several years. On the other hand, we have a material reduction of our honey crop, resulting from the failure of many old queens at a critical time of year.

In the northern States the time of year when such failure will lessen the amount of honey stored by the colony extends from late in the fall until about July 1 next; and it is practically impossible to detect this failure in time to entirely prevent the loss of honey.

The bees do very little superseding of their own accord at this season of the year; in fact, practically none at all of the queens that are commencing to fail, but not yet entirely so. At least nine-tenths of the superseding in my apiary in northern Iowa was done in the months of July and August.

To aid me in getting at the real facts in this matter as well as in others, I have always kept a complete record of all my queens, and have practiced clipping their wings. This last enabled me to keep a correct record of each queen, without any guess-work.

I soon noticed that those colonies whose queen was in her fourth season nearly always gave me less than the average amount of honey, and enough less, too, to much more than pay for the expenses of having given them young queens the fall before, and allow largely for the value of such good queens as might be killed while doing so. I never killed all of my third-season queens, although I think it would have paid to do so; but I always kept a few of the best ones, so I have had both kinds of queens to compare results from many years.

A colony which is very strong at the commencement of the honey-flow, will store more honey according to its numbers than will a medium strong one, and only queens in prime vigor can get their colonies strong by the time white clover commences to yield; and even if old and yet good, they are rarely ever as vigorous as are younger ones; and my main reliance for surplus honey was always on those colonies having queens in their second or third seasons.

It is quite a long while from the time brood-rearing ceases in the fall and the first of July following; and any failure of the queen during this time, even if only partial, seriously diminishes the number of mature bees the hive will contain during the honey harvest, and no failure of a queen can take place during this time that can be noticed by the apiarist, soon enough to prevent a serious reduction of the amount of brood that will be raised in time for the harvest.

A much larger production of colonies having old queens will be weak in

the spring than of those having younger queens; and as re-queening can be done so much cheaper and better in the fall than in the spring, I prefer to do it then, even if half the queens I destroy would be good for yet another year.

Many of our best apiarists—Doolittle, Hutchinson, and others, recommend the contraction system during swarming; but all seem to agree that swarms having old queens seem much more inclined to build drone comb than do others.

In speaking of old queens, I mean those that have done duty for three seasons, including the one in which they were reared. In rare cases I have known queens to do duty the fifth season; but a very large proportion will not do satisfactory work during their fourth season, a much larger proportion than many suppose is the case, unless they have specially observed this point for a number of years.

As already said, the question is one of relative profit and loss. On one hand we have the expense of the young queens, and the value of the few good queens that will be destroyed; on the other, we have the very material shrinkage of the honey crop, the probable loss of some colonies, etc., and there is no question in my mind that the last items exceed the first ones many times over.

Apartado 278, Havana, Cuba.

EXPERIMENTS.

A Report of Some Experiments in Apiculture.

Report to the Commissioner of Agriculture
BY N. W. M'LAIN.

The study of some forms of disease to which bees are subject, including an inquiry into the causes of disease, and the discovery and application of suitable remedies, has occupied much time, and the results from this line of investigation have been in a good degree successful and satisfactory.

The excellent classification and complete history which have been given of the micro-parasitical forms which affect the life and health of bees simplify diagnosis and facilitate the discovery and application of preventives and cures. Modern science has shown that it is often necessary to unlearn much of what was supposed to have passed beyond the region of doubt. The subject in hand furnishes no exception. It is not strange that there should be confusion and error in dealing with the origin and habits of these micro-organisms which baffle the skill

of the investigator. We are now collecting and tabulating data and testing theories in the crucible of experience, and while our investigations are incomplete, and many seemingly determined facts lack full confirmation, and while significant manifestations await interpretation, we must be slow in reaching conclusions. We may indeed be in the region of the knowledge we seek after, but we must hold the evidence under survey until many-sided experience fully determines its value.

Bacillus Alvei (Cheshire).

This disease, commonly but inappropriately called foul brood, is indigenous in all parts of the United States, and is infectious and virulent to the last degree. Concerning the origin of *Bacillus* and other allied organisms, but little is certainly known, but that the organism classified as *Bacillus alvei* is the active agent in the destruction of both bees and brood is certain, for this agent is always present, and although its action in the living organism is exceedingly complicated it is also well defined.

The symptoms of this disease may be more clearly described by contrasting the appearance of bees' brood and combs in a healthy colony with the diagnostic symptoms attending *Bacillus alvei*. The bees act as if discontented and discouraged; the combs commonly present a dingy, neglected, and untidy appearance, and a characteristic odor is present, sometimes not noticeable until the hive-cover is removed, at other times offensive at some distance from the hive. This odor is very like that emitted from glue which has been prepared for use, then put aside and allowed to ferment. Instead of the plump, white, smooth appearance common to healthy uncapped larvæ, the membranes more or less wrinkled and shrunken, are streaked with yellow, which with the succeeding stages of the disease changes into a dingy, gray brown; then as putrefaction follows, the color becomes a dirty red brown. As evaporation progresses the mass settles to the lower side of the cell, and if the head of a pin be drawn through the mass, that which adheres appears quite stringy and elastic, the tracheæ and tougher tissues resisting decay adhering to the cell. Later nothing remains but a black, flat scale on the lower side near the bottom of the cell. If the disease does not assume the acute form before the pupa stage the brood is capped over, but the cell cap, commonly of a darker color than that covering a healthy brood, settles, leaving the cover concave instead of flat or convex, and shortly small holes appear, as if inquiry had been instituted

to learn the condition of the occupant, or to liberate the gases and odor and facilitate evaporation. Torn and ragged cell caps are frequent, and some cells may be empty and cleansed; and in the midst of ragged and sunken caps a live bee may occasionally emerge.

The means by which these deadly agents are commonly introduced into the hive and into the bodies of their victims has not been certainly determined. Prof. Frank R. Cheshire, F.L.S., F.R.M.S., to whom we are indebted for the classification of this species of *Bacillus*, and also for much that is valuable concerning its life history and pathogenic character, speaking of the means of propagating this disease, says (see *Bees and Bee-Keeping*, vol. 2, pp. 157, 158, London, 1888):

"My strong opinion is, that commonly neither honey nor pollen carry the disease, but that the feet and antennæ of the bees usually do." "It is also extremely likely that spores are carried in the air and taken in by the indraft set up by the fanners. There will be no difficulty in this supposition when it is remembered that the organisms are so minute that a cubic inch of material would form a quadruple line of them from London to New York."

My own experience and observation is in agreement with this last proposition, as witness the following paragraph from my report of last year (see *Report of U. S. Entomologist*, 1886, p. 587):

"That the contagion may sometimes be borne from hive to hive by the wind appears to be true, as it was observed in one of the apiaries which I treated for this disease during the past summer, that of a large number of diseased colonies in the apiary, with the exception of 2 colonies, all were located to the northeast of the colony in which the disease first appeared. The prevailing wind had been from the southwest."

Mr. Cheshire says further, page as above: "The bee-keeper is unfortunately almost compelled to become himself a probable cause of infection. His hands, made adhesive by propolis, carry the spores or bacilli, and so may transfer them, even hours later, to healthy hives. The clothes should be kept as far as practicable from contact with suffering colonies, and the hands after manipulating them should be disinfected by washing with a weak solution of mercuric chloride (corrosive sublimate), $\frac{1}{2}$ of an ounce in 1 gallon of water being quite strong enough."

The concluding paragraph under this heading in my report for 1886 is as follows:

"That the disease germs may be carried upon the clothing and hands appears probable, from the fact that in one neighborhood this disease appeared in only two apiaries, the owners of which had spent some time working among diseased colonies at some distance from home, while other apiarists in that locality who had kept away from the contagion had no trouble from foul brood."

It has been the common belief that honey is the medium through which the disease is most frequently introduced from both near at hand and remote sources of infection. That undue importance has been attached to honey as the common source of infection appears certain, for I have proved by repeated trials that if frames containing combs of capped honey, and having no cells containing pollen, be removed from infested hives and thoroughly sprayed or immersed, using an acid and alkaline solution of suitable strength to destroy the germs exposed to its action, the honey in such combs did not communicate disease when placed in healthy colonies and consumed by the bees as food for both summer and winter uses. I have found it altogether practicable to feed honey which had been extracted from the infested combs without boiling, always adding, however, as a precaution, a disinfectant suitable to destroy any infection possibly lurking in such food.

In speaking of honey as a means of carrying this contagion, Mr. Cheshire says: "I have searched most carefully in honey in contiguity with cells holding dead larvæ; have examined samples from stocks dying out with rottenness; inspected extracted honey from terribly diseased colonies, and yet in no instance have I found an active bacillus, and never have been able to be sure of discovering one in the spore condition, although it must be admitted that the problem has its microscopic difficulties, because the stains used to make the bacilli apparent attach themselves very strongly to all pollen grains and parts thereof, and somewhat interfere with examination. I have now discovered that it is impossible for bacilli to multiply in honey, because they cannot grow in any fluid having an acid reaction."

As to pollen being the medium by which this contagion is commonly introduced into the hive, not wishing to appear as speaking *ex cathedra*, I venture to say that further experiments in the line indicated in my report of last year, leave little room to doubt the accuracy of the opinion then formed, namely, that pollen is the medium by which this contagion is most commonly introduced, and most rapidly spread

and persistently perpetuated. Continued observation showed that in those colonies where the largest quantity of pollen was being gathered, the disease quickly assumed the malignant form, even when the quantity of brood was not greater than that being reared in other colonies where but little pollen was being gathered, and in which the disease was far less virulent; and in this latter kind, where little pollen was being gathered, the contagion yielded most readily to treatment. But what seemed more to the point was, that from those colonies from which the combs containing pollen were removed, and a suitable substitute furnished in the hive, thus avoiding the necessity for bringing supplies from the fields, the disorder was cured, and the colony speedily regained their normal condition.

The fact that queen larvæ seldom die from this contagion, taken in connection with what we know to be true concerning the character of their food, is significant, namely, that it is wholly composed of digested material, pollen grains being rarely found therein, and then as if present by accident and not by design, seems to justify the conclusion that the absence of pollen accounts for the absence of bacilli; while on the contrary the food of worker larvæ, secreted in excessive quantity and deposited in haste, occasional grains of pollen being dropped, and no reason for their removal existing, the bacilli finding congenial cultures, multiply apace; and if perchance the larvæ escape infection, as is commonly the case until near the time of weaning, then live pollen being supplied, speedy and complete ruin results. Moreover, few if any bacilli are to be found in the chyle stomach of an adult queen at the head of a stricken colony, subsisted, as she must be, almost entirely upon secreted food produced by the worker bees; while in the chyle stomach of the worker, which partakes freely of pollen, they are present in quantity, and in fact line the whole intestinal tract.

The evidence presented in support of this pollen theory of the means of introducing and spreading this contagion is circumstantial, still it is component; and if it fails to reveal the true source of infection, the fact that the consumption of such live pollen as is obtained from the fields during the prevalence of this disease, or such old pollen as is stored in cells in which it may have molded or rotted, and become a possible source of infection, aggravates the disease and makes it more persistent, and the fact that if the old pollen be removed from the hive, and artificial pollen be substituted, the malignant and persistent

characteristics disappear, and that the contagion then readily yields to suitable treatment, is settled beyond question.

While it is true that queen-bees have less to fear from infection in the larval stage, it is also true that queens reared in infested colonies are commonly worthless. Of 25 queens so reared in one apiary, and successfully established at the head of as many colonies, not one survived the period of hibernation. In case the contagion does not assume the acute form in the larvæ it may localize and become chronic, and so, the bacillus of disease being as unnatural as disease itself, both worker and queen may live on for weeks and months, and the queen, with both life and death within her, transmitting the possibilities of both. Mr. Cheshire has counted as many as nine bacilli in a single egg, a discovery full of significance when striving to account for the spread of the disease. It is but natural that this contagion, being a disease of the blood, should find congenial and luxuriant feeding-ground among the most delicate and highly organized glands and tubes of the ovaries.

We reason thus: The bee-pap furnished to the queen larva, the protoplasmic egg-food, copiously furnished to the queen during the breeding season, is continuous, and passes from cell to cell. The germ cell of bacillus contributed to the organism of the queen in larval or in egg-food, borne along through the digestive and circulatory system, passes within the ovarian tubes and from thence into the nascent egg-cell, and once within the yolk is ready to contend for supremacy against the spermatozoid soon to be introduced. But the strife is unequal, and instead of the differentiating principle determining the form, function, and instinct of a new creature appointed to long life and service, the bacillus, finding the environment suited to multiplication, sterilizes the blood and riddles the tissues and viscera.

The remedy which I have found to be a specific—by the use of which I have cured hundreds of cases, many of which seemed hopelessly incurable, without failure, and without a return of the contagion, except in the case of two colonies of black bees, where the disease reappeared in a form so mild that each colony was speedily cured, each one casting a swarm, and storing a fair amount of surplus honey—is prepared and applied substantially as directed in my last annual report.

In 3 pints of warm soft water dissolve 1 pint of dairy salt. Add 1 pint of water, boiling hot, in which has been dissolved 4 table-spoonsful of

bicarbonate of soda. Dissolve $\frac{1}{4}$ of an ounce of pure salicylic acid (the crystal) in 1 ounce of alcohol. Add this to the salt and soda mixture, then raise the temperature near to the boiling point, and stir thoroughly while adding honey or syrup sufficient to make the mixture quite sweet, but not enough to perceptibly thicken, and leave standing for two or three hours, when it is ready for use. An earthen vessel is best. I have tried other acids and alkalis in other forms, but the remedy prepared as directed and applied warm is that which I prefer.

Treatment of Bacillus Alvei.

Upon removing the cover from the hive, thoroughly dampen the tops of the frames, and as many bees as are exposed by blowing a copious spray of the mixture from a large atomizer. Beginning with the outside, lift a frame from the hive and throw a copious spray over the adhering bees on both sides of the comb, shake off part of the bees into the hive, and spray those remaining; then shake and brush these into the hive; then blow a copious spray of the warm mixture over and into the cells on both sides of the combs sufficient to perceptibly dampen both comb and frame. In like manner treat all the frames, serially, returning them to the hive in order. From combs containing very much pollen, the honey should be extracted and the combs melted into wax. This extracted honey may be fed with safety, $2\frac{1}{2}$ ounces of the remedy being added and well stirred into each quart of water.

All the colonies in the apiary should be given a thorough spraying the first time the treatment is applied, but combs containing pollen need not be removed from healthy colonies. After the first thorough treatment the combs and bees should be thoroughly sprayed with the remedy at intervals of two or three days until cured. Three treatments after the first thorough application are commonly sufficient; first one frame being lifted from the hive and sprayed, and the others simply set apart, so that the spray may be well directed over and copiously applied to both bees and combs. An essential feature in my method of treatment, which I failed to make duly significant and prominent in my last annual report, is that medicated honey or sugar syrup should be continuously fed to all infected colonies while they are convalescing, for not only must the contagion be driven from the organism of the adult bee, and suitable food and tonic given to aid in repairing the ravages of disease, but a constant and even supply of the remedy serves as a preventive and cure for the diseased larvae.

The honey or syrup should be fed warm, and 2 ounces of the remedy should be well mixed in each quart of food, which may be given in feeders, or by pouring over and into empty combs, and placing these in the hive.

To prevent the bees from going abroad for supplies, make a thin paste of rye flour and bone flour, three parts of the former to one of the latter, adding the medicated honey or syrup. Spread this over a small area of old comb and honey in the hive, or feed in shallow pans or wooden butter dishes in the top of the hive or outside in the apiary, under shelter from rain. I prepare the bone flour by burning dry bones to a white ash. The softest and whitest pieces I grind to dust in a mortar, and sift through a very fine sieve made of fine wire-strainer cloth. The coarser pieces of burned bone I put in open vessels with lumps of rock salt, which I keep half covered with sweetened water, and sheltered from the rain, at all times accessible to the bees. The rapidity with which depleted colonies recuperate and become populous is surprising. I have tried supplying the saline, alkaline, and phosphate elements in bee-food by using boracic acid, phosphoric acid, etc., but I find that the bees take kindly to the supplies prepared as I have directed, and the amount consumed shows their appreciation and need. Such supplies of food and drink should be kept at all times in the apiary, easy of access. I have not found disinfecting of the hives necessary further than to simply dampen the inside with a copious spray of the remedy, and sometimes no care was taken to do even this.

BEE-HIVES.

The New Heddon Hive Considered and Criticised.

Written for the American Bee Journal

BY DR. G. L. TINKER.

In the controversy with Mr. Heddon I have had no ill-will towards him, nor cause for it. My course has been prompted wholly by a desire to forewarn the public against a recognized wrong. Mr. Heddon charges that I have done him an "injury." In reply, I will say, that it is better that he should suffer injury than that the bee-keepers of America should do so by the introduction of such a hive.

Mr. Heddon devoted a chapter in his book, "Success in Bee-Culture," to the claims for his new hive, alleging that he had used it two years, and that it had been fully tested by himself and "students."

The "new principles" set forth were new indeed, and would no doubt have caused a revolution in bee-culture had they proved in practice what they were represented to be. But they did not so prove, and it now remains to be seen if they were not wholly theoretical from the beginning. They were captivating and plausible, and bee-keepers generally accepted them as established facts on Mr. Heddon's statements.

The feature above all others, that was heralded in advance of the issue of his book, was the alleged fact that we could "handle hives" if rightly constructed, instead of many frames in all needful work in an apiary. It was confessed at the outset that it would cost about twice as much as other hives, but the advantages were such that the extra cost was a small item in summing up results, for "success in bee-culture" was over assured to every bee-keeper!

Many bought rights, and many more bought hives with genuine Yankee enthusiasm. Mr. Heddon says over 500 got the hives. At last it appeared that the hive was not what it had been represented to be, that it was in fact a fraud. Then reports were called for, but only 58 bee-keepers out of the 500 made favorable reports. Over 400 were silent as a tomb! Had the hive been the great success it had been represented to be, can any one believe for a moment that all these men would have remained silent?

The hive must stand or fall on the claims that have been made for it. First, Mr. Heddon's new super is not a success. If it was, we would find that all who use his divisible brood-chamber also using his new super. But all do not. A large number of bee-keepers use and prefer Mr. Heddon's old super on his new hive. That "settles the merits" of the new super.

There remains only his divisible brood-chamber to be considered, and every bee-keeper must now see that it is a failure, if it cannot be handled as represented; for if it cannot be, why handle 16 brood-frames when 8 can be handled just as quickly, and answer the same purpose; why be to the extra cost? It was claimed to be an easy task to shake out the bees and queens from the cases, discover queen-cells, etc. But the bees and queens cannot be shaken out as represented. It can neither be done readily nor easily, and if it could be, we are often unable to see all the queen-cells, as I have found in many instances. As well try to shake the bees out of a case of sections. It can be done, but it is a laborious undertaking.

One of the 58 men who reported favorably on the hive, who lives not

far from here, and obtained his hives direct from Mr. Heddon, recently made a thorough test of the "shake out function" of the hive. Aided by another expert bee-keeper who had charge of the hives the attempt was made to shake out the bees and queens from several hives without success. The attempt was also made to drive the queens down on the bottom-board with smoke with no better success. One colony of hybrids were so enraged by the shaking, that the apiarists were driven out of the apiary. At last, our friend, unable to find a queen, or to shake out the bees, gave up the experiment in disgust, and declared that he would transfer the bees to other hives.

The experience of these gentlemen is the same as my own, that the "shake out function" is a humbug. Add to this the difficulty from brace-combs, and the divisible brood-chamber has not a thing to recommend it. It becomes at once a complicated, expensive and worthless contrivance.

But Mr. Heddon claims that I have not used *his* hive, but instead a modified one, and not a divisible brood-chamber at all. Let us see about that. The idea was given out by Mr. Heddon that there was no need of handling brood-frames, but instead, hives. I would make the most of this valuable (?) function of the new hive. So I made it the exact capacity of the eight-frame Langstroth hive. The cases were made very light, of $\frac{3}{4}$ -inch stuff, and the frames $\frac{1}{2}$ inch more shallow than Mr. Heddon's. Besides, to make sure of the "shake out function" the top and bottom bars were made only $\frac{3}{4}$ of an inch wide. These cases were illustrated in *Gleanings*. But after all my care in the matter, and numerous trials, I found the "shake out function" to be impracticable to a man of ordinary strength and endurance, even with my little cases.

Mr. Heddon is fond of alluding to what he is pleased to call my "mistakes." But my mistakes, if I have made any, are trivial indeed as compared with the grand mistakes of Mr. Heddon in his unfortunate hive theories. It is human to err, but I must object to one of the most signal failures in the history of apiculture being paraded before the public under the false guise of "success." Charging me with mistakes will not blind the public to the fact that the principle of his new hive is wrong, and that his theories regarding it are highly deceptive and misleading.

In conclusion I must observe, that Mr. Heddon has made no improvements in bee-hives as alleged; at least not in the so-called new hive. The

Heddon-Langstroth hive with the Heddon-More super have met with favor, but as an "original inventor" we shall hope that our friend may yet distinguish himself.

New Philadelphia, Ohio.

[It is difficult to find the right place to stop a discussion when once begun. We thought we had terminated the controversy about the merits of the Heddon hive some months ago, but some persons imagined that an injustice was done to Dr. Tinker in stopping it there, and we now admit the above just to show that no injustice was intended. As the essay of Dr. Tinker's opened the "ball," if Mr. Heddon desires to make a short reply, that will positively close the discussion in our columns. We hope this will satisfy all the friends of both parties, While many are tired of the discussion and desire to see it terminated, we will not give either side the advantage.—Ed.]

WINGS CLIPPED.

Thoughtlessly Clipping Wings of a Virgin Queen.

Written for the American Bee Journal
BY JOHN CADWALLADER.

On June 14 a swarm was cast by a colony having a queen with her wings clipped, which was properly hived. To my knowledge none has issued from that hive, until to-day one came forth. While they were issuing I discovered the queen in the grass in front of the hive. I captured her, and before reflecting I clipped her wings. 1. Is it likely that she is a virgin queen? 2. As she cannot take wing, will she ever become fertile?

On May 27, I was examining a colony which I had known to be strong, and finding no eggs, but an abundance of brood and numerous queen-cells, I concluded that the colony had suddenly become queenless. So on the following morning I began to cut out a lot of the queen-cells which were chiefly in one frame. As fast as the cells were taken they were placed in a wooden butter-dish. When I had finished, the comb had been so weakened by the removal of the queen-cells, that it broke loose from the frame. I at once began to repair this, but before I had finished it, the queen-cells in the butter-dish began to hatch, and the queens to crawl away. I hurriedly caught and caged six, but two got away; one I afterward found dead un-

der the hive with a lot of bees around her, trying to bring her to life.

I then fixed some nuclei in which to place this flock of queens, which were threatening to cut their way out of the cages. The hive had been smoked and all broken up for an hour. It was about 11 o'clock. I had in the meantime hived a first swarm which had issued with a wing-clipped queen, when the swarming note was again heard by a swarm issuing from this hive which had been smoked and broken up for an hour, which had yielded me six bright queens, and the two which "got away." This swarm was hived, and both it and the parent colony have had laying queens for several weeks. I therefore concluded that the parent colony had become queenless by having cast a swarm (the queen's wing not being clipped) unknown to me, which absconded.

There seems to be little prospect for white clover. Basswood is in bloom, alive with bees, but honey is not coming in as it did from fruit-bloom, poplar, and probably honey-dew. So far all the honey stored is of a dark color and bitter taste.

North Vernon, Ind., June 30, 1888.

[It is very likely that the queen you found in the grass was a virgin, and if so, in clipping her wings you destroyed her usefulness by preventing her from flying and becoming fertilized.—Ed.]

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*
- Aug. 8.—Ionia County, at Ionia, Mich.
H. Smith, Sec., Ionia, Mich.
- Aug. 14.—Colorado State, at Denver, Colo.
J. M. Clark, Sec., Denver, Colo.
- Aug. 27.—Stark County, at Canton, O.
Mark Thomson, Sec., Canton, O.
- Sept. 8.—Susquehanna County, at Montrose, Pa.
H. M. Seeley, Sec., Harford, Pa.
- Dec. —Michigan State, at Jackson, Mich.
H. D. Cutting, Sec., Clinton, Mich.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

SELECTIONS FROM OUR LETTER BOX

No White Clover Honey.—Geo. W. Fair, Chrisman, Ills., on July 9, 1888, says:

I wintered 32 out of 34 colonies of bees, coming through in splendid condition, and are now boiling over with bees; but they have not gathered a pound of surplus honey, and there is no prospect of any soon. This is a good locality for white clover honey, but it is a complete failure this year. What is in bloom seems to afford little if any honey.

Measuring Comb Surface.—J. H. Weidman, Riverside, N. J., on July 6, 1888, writes:

In answer to the editor's remarks on page 419, I would state that I discovered the grievous error soon after I had sent the article in question, but not in time to prevent its appearance in print. But I was in the wrong only in calculating the number of cells to the square inch of comb surface, for the fact remains that a square inch of comb (which means a square inch of comb surface, as square measure is surface measure, and cannot be anything else), contains 27 cells, and that a frame $10\frac{1}{2} \times 10\frac{1}{2}$ will contain 230 square inches of comb, or of comb surface; and by taking 27 cells to the square inch, we get the true capacity of the frame, 6,210 cells. Now I claim that this is the only proper method of calculating the capacity of comb in a hive, and my remarks in my previous article apply to this matter, with the exception of the error already noticed.

[The error of Mr. Weidman has been corrected several times by others, and now by himself. This will dispose of the matter at present. The error was very apparent at first sight.—ED.]

Supporting a Good Cause.—T. H. Kloer, Terre Haute, Ind., on July 9, 1888, writes:

My bees have not produced one ounce of honey, and have not a day's supply in the hives now. They are weak, having lost half the old bees and all the brood by starvation between June 10 and June 20. There was no white clover, and linden furnished only a living. Although I am heavily involved, and in great financial distress, I enclose \$1.00 as my annual dues to the Bee-Keepers' Union, so as to hold up the good cause.

Pleurisy-Root and Buckwheat Honey.—Jacob N. Becker, Oakfield Centre, Mich., on July 8, 1888, says:

Bees are not doing much in this locality. White clover was plentiful, and is gone, but there was no honey in it. The bees just gathered enough to keep up brood-rearing. I have 120 colonies, and they are over-running with bees, but not one swarm has issued. They are gathering some honey from pleurisy-root and milk-weed at present. Basswood is budded for bloom, and there are 100 acres of buckwheat sowed within bee-range of my apiary. I shall look for some honey from that source.

Managing Swarms, etc.—T. M. Herrick, Woodstock, N. Y., on June 30, 1888, writes:

The last winter was the hardest here that we have had in many years, fully 20 per cent. of all the bees having died, and the spring was backward and cold. I put 32 colonies into the cellar, and left 25 on the summer stands. I lost in all 17 colonies; but things are booming now. Honey from clover and vervain is coming in as fast as I ever saw it. I have had 22 swarms, and all is going well.

I handle swarms in the following manner: First, it is best to get 8 frames of brood in the colony, or as near it as possible before swarming, then when the swarm issues, I take out two-thirds of the brood, and all the bees that are on the frames, and put into another hive, taking all the queen-cells; or, if there are cells on all the frames,

I take the best and destroy the others. Now if there is number of them, I cut them all out but one (leaving the best one), and put them in a cell-hatcher, inserted in one of the colonies that has cast a swarm. As Italians are apt to swarm without mated queen-cells, I am always ready with mated cells or virgin queens to give the old colony as soon as they have cast a swarm.

The way I put cells into the hive is as follows: With my finger I scratch the comb down to the division wall, a spot a little larger than the cell, and stick a pin through the fringe of comb at the top of the cell, and through the comb in the frame, so that the cell hangs into the place I have scratched out; they will soon fasten it so that the pin may be removed, and leave the cell fast. I leave four frames with the swarms that I work for comb honey, using starters 2 inches wide, if they have not frames enough of brood to leave $\frac{1}{4}$, after taking away $\frac{1}{2}$. I use a frame $10\frac{1}{2} \times 17\frac{1}{2}$ inches.

Overstocking a Locality.—G. A. Adams, Perrysburgh, O., on July 10, 1888, writes:

A few of us began keeping bees here in 1885, but there were not many colonies kept. When we began, Mr. Puhl, of Momence, was the only extensive bee-keeper in the vicinity. Since then, a Toledo man has planted an apiary within 10 rods of my farm, and last year his 200 colonies took all of my fall pasturage. They have taken all my raspberry honey this spring. My bees have no chance against such numbers. This spring 40 colonies of this apiary were taken one mile south of mine. The other is $1\frac{1}{2}$ miles east. I live in the town, and the bee-keepers are thus surrounded by the apiaries of this man, who does not own a foot of land in the county. He will kill bee-keeping in this neighborhood. I can get along with ignorance by teaching, but how am I to fight greed? Can the Bee-Keepers' Union devise any method? We small bee-keepers in Perrysburgh would be rejoiced if a remedy could be provided.

[That is a hard matter to adjust. Dr. C. C. Miller is the man to grapple with questions of territorial right to the nectar in the flowers; and he may have something to suggest on the matter. We should think, however, that the intruder would see that he was overstocking the locality even for his own bees, and remove the bees further away. For one thing is certain, if your bees can get nothing, his are in the same condition, for if the nectar was there they would all get a share of it.—ED.]

Strong Colonies and Drowned Bees.—Chas. H. Wiele, Stoddard, Wis., on July 5, 1888, writes:

This has been the hardest spring on bees here, that I have witnessed in the last 27 years. I put them out of the cellar on April 13, with the loss of but one colony out of 80. Two swarmed out the same day, it being pretty warm. They almost immediately began to work and carry pollen, and were strong and lively, but it did not last very long; wet and chilly weather set in, and then it could not be called "spring dwindling" any more, but "spring killing." They would fly over on the islands of the Mississippi, and the water being high, they would drop right into it in returning, and drown by the thousands. A person could just dip them up by the handfuls along the bank. Of course the colonies became so weakened that I expected to lose the most of them; I had to double up 26, and the rest pulled through well enough. It was well

that we had good, warm weather during plum and apple blooming (of which trees I have several hundred), and so the bees became strong again, and are all in good condition now.

Clover did not yield much honey, or rather none, and linden will commence to bloom in a few days; if no honey comes in then, there will be poor prospects for honey in this neighborhood, because the islands are still covered with water, and the fall flowers will have little chance to grow and to bloom before frost. I had about 3,000 pounds of comb honey last year, and I shall be satisfied if I get half that amount this year. Still we cannot tell, and have to hope for the best.

Fine Harvest Expected—Hiving Swarms.—E. T. Smith, Bowling Green, Mo., on July 9, 1888, writes:

White clover has bloomed but little here, but the fields are now covered with young clover, just beginning to bloom, and I am expecting a fine honey harvest. My colonies are building up, and are beginning to be very strong, the honey-flow being sufficient to encourage increase, but not sufficient for surplus. I started in the spring with 8 colonies, and I now have 16. In hiving swarms I adopted the Heddon method in part, to prevent increase; that is, I move the old stand and put the new one in its place. The result has been, that I have had only one swarm from each of those colonies. I allowed one old colony to remain, and hived the swarm in a new place, and that colony swarmed three times. In hiving my swarms, I went contrary to Mr. Hutchinson's advice, given in his little book—that is, I hived them on combs, left from the previous year, and I have never seen colonies build up faster. I am satisfied that Mr. Hutchinson is right, and the result would have been as he says, if the honey-flow had been good, but with such a season as this has been, I think that the empty combs are a great help. Our season is excellent, and crops of all kinds are very fine.

Alsike Clover on Dry Land.—Eugene Secor, Forest City, Iowa, on July 4, 1888, writes:

I have sowed Alsike clover seed a couple of times within the last ten years. On dry land I fear this is not going to prove a very profitable crop for either hay or pasture. It does not stick like common white clover, and does not grow large enough to take the place of red clover. But a couple of my neighbors sowed Alsike on wet land a year ago in early spring; the land was such as produces only wire grass. Open ditches had been cut the year previous, taking off all the standing water. On this kind of land they tell me it is a success—standing up in the wild grass 15 to 20 inches high, and growing luxuriantly.

Working on the Linden, etc.—S. Burton, Eureka, Ills., on July 5, 1888, writes:

I notice on page 444, Mrs. J. B. Curlee says that the Chapman honey plant will be in bloom in a few days; that it is 4 feet high, and has large balls on it, looking like the wild thistle. It is not like mine. My plants are from 5 to 7 feet high, with balls on them, and has no resemblance to the wild thistle. There are from 30 to 50 balls on a stalk. It began to bloom on July 1. The bees are busy on it all the time. I have had 14 swarms up to this date. The linden is in bloom now, and the bees have had a lively time for the last two days. The white clover is not coming on as fast as I expected it would, but we had a good rain last night which will help it out now.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4 1/4 x 4 1/4 and 5 1/4 x 5 1/4. Price, \$1.00 per 100, or \$8.50 per 1,000.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions to the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:
For 50 colonies (120 pages).....\$1 00
" 100 colonies (220 pages)..... 1 25
" 200 colonies (420 pages)..... 1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

CLUBBING LIST.

We Club the American Bee Journal for a year, with any of the following papers or books, at the prices quoted in the LAST column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

Cork for Winter Packing.—Its advantages are that it never becomes musty, and it is odorless. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2 25
500 Labels.....	2 00	3 00	3 50

Samples mailed free, upon application.

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; 1/2 pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 18 cents per pound for bag and postage.

Honey and Beeswax Market.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 13@15c.; the same in 2-lbs., 10@11c.; buckwheat 1-lbs., 10c.; 2-lbs., 9c. Market dull. We are doing all we can to reduce stock, to make room for the new crop.
BEESWAX.—26c.

HILDRETH BROS.,

May 21. 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—We quote. White to extra white comb, 1 1/2@15c.; amber, 8@11c. Extracted, white to extra white, 5 1/2@6c.; amber, 4 1/2@5c. Arrivals of the new crop are small, the estimates being an average crop.
BEESWAX.—20@24c.

June 18. O. B. SMITH & CO., 423 Front St.

DETROIT.

HONEY.—Best white in 1-lb. sections, 14c.—Dull.
BEESWAX.—23@24c.
June 14. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—We get 15c. per lb. in a small way for best comb, and less for old grades. Extracted, best white, 7@8c. None of the new crop received yet, but there is more than sufficient of the old crop for the light demand.
BEESWAX.—22c.

June 30. R. A. BURNETT, 181 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 12c.; fancy 2-lbs., 10@11c.; fair white 1-lbs., 10@11c., and fair 2-lbs., 9@10c. Buckwheat 1-lbs., 7@8c. The demand is dull for comb but fair for extracted, of which new from the South is arriving, and sells for 5 1/2@6 1/2c. per gallon.
BEESWAX.—Dull at 23 1/2@24c.

June 15. F. G. STROHMMEYER & CO., 122 Water St.

CHICAGO.

HONEY.—No white clover left in this market. Dark slow sale at 8@10c. Extracted ready sale on arrival. New crop will meet with good demand.
BEESWAX.—23c.

July 2. S. T. FISH & CO., 189 S. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb., for which demand is fair. Comb honey, 12@15c.—Demand slow.

BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
July 11. C. F. MUTH & SON, Freeman & Central Av.

MILWAUKEE.

HONEY.—Choice white one-lb. sections, 14@16c.; 2-lbs., 13@14c.; 3-lbs., 12@13c. Extracted, white in kegs and 1/2-barrels, 8@9c.; in tin and pails, 9 1/2@10c.; dark in barrels and kegs, 6@8 1/2c. Demand good for extracted, but dull for comb.
BEESWAX.—22@23c.

July 2. A. V. BISHOP, 142 W. Water St.

DENVER.

HONEY.—Best white 1-lb. sections, 14@15c.; 2-lb. sections, 12c. Extracted, 6@7c.
BEESWAX.—21@ 3c.

June 25. J. M. CLARK & CO., 1409 Fifteenth St.

KANSAS CITY.

HONEY.—We quote: Choice new 1-lb. sections in good demand at 15@16c., not glassed; dark ones not so good. 2-lbs and extracted; there is no demand for. Stock of old honey is light, and the sections are all glassed, which style the trade do not like.
BEESWAX.—None in market.

June 30. HAMLIN & BEARSS, 514 Walnut St.

BOSTON.

HONEY.—We quote: 1-lb. sections, 14@16c.; 2-lb. sections, 12@13c. New Florida extracted, 8@9c. Sales are very dull.
BEESWAX.—25 cts. per lb.

July 5. BLARK & LITTLE, 57 Chatham Street.

SAN FRANCISCO.

HONEY.—We quote: Choice new extracted, 15c. to 5 1/2c.; amber to light amber, 4 1/2@4 3/4c. Choice comb in 1-lb. sections, 13@14c.; 2-lbs., 12@13c. Arrivals are small, as apiarists are holding back. Prices are considered high.
BEESWAX.—18@22c.

June 25. SCHAUCHT & LEMCKE, 122-124 Davis St.

KANSAS CITY.

HONEY.—We quote: White 1-lbs., unglazed, 15c.; 1-lb., white, glassed, 14c.; dark, 1-lb., 2c. less. California, 2-lbs., comb, white, 15c. Extracted, 7c. Considerable old honey is in this market. No new yet in. Sales are very slow.
BEESWAX.—None on the market.

June 9. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—We quote: Extracted, bright, 5@5 1/2c.; dark, 4 1/2@5c.; in cans, 7@8c. Comb, choice white clover, in prime order, 13 1/2@15c.; dark, less. Market quiet with fair demand for extracted.
BEESWAX.—22c. for prime.

June 27. D. G. TUTT & CO., Commercial St.

Frank Leslie's Sunday Magazine for August continues Geo. Macdonald's fine story "The Elect Lady," and begins a new story, the scene laid in Old France, entitled, "Genevieve or The Children of Port Royal." There is also a short story by Amanda M. Douglas, entitled "Miss Brooke's Adventure." An illustrated article, "Glimpses of Mission Life Among the Maories," tells of early missionary struggles in New Zealand. "Pen and Pencil Sketches of Shadelaad," depicts a charming spot in our own country, and an elaborately illustrated article on "La Fontaine's Fables" tells us much about the French fabulist and his work. There are many interesting short articles and beautiful illustrations. It concludes with a fine hymn tune, "We Give Immortal Praise," by Frank L. Sealy, of Newark, N. J.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Sweet, or Melilot, Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

EDITORIAL BUZZINGS.

Only a Little. modest flower,

But the bee, that busy rover,
Gathers many a store of sweets
From the modest, wee white clover.

And so, in the quiet walks of life,
Sometimes a song is given,
Only a strain that our ears have caught
Of the melodies sung in heaven.

—Maud Meredith, in *Vick's Mag.*

The Territorial Fair of south Dakota will be held at Mitchell, on Sept. 24 to 28, 1888. Charles Keith, of Volga, is the superintendent of the Apiary Department. Thirty dollars are offered in premiums.

Comb Honey keeps best in a warm, dry room—the temperature should not go below 80°, and a little warmer would be even better. The whiteness of the comb would be better preserved in a dark room. The honey will “gather moisture” when the temperature goes below 60°.

Capt. J. E. Hetherington is represented by an engraving in the Norwegian bee-paper, *Tidsskrift Biskjotsel*, for July. Mr. Ivar S. Young, the editor, was entertained by the Captain at his residence in Cherry Valley, N. Y., when he visited America last year. Capt. Hetherington is the most extensive apiarist in America, as well as a genial companion and friend.

Justice for Bee-Keepers.—W. H. Shirley, Millgrove, Mich., on July 12, 1888, writes thus when sending his dues to the National Bee-Keepers' Union:

While the prospect here is that I shall not get one dollar's worth of honey from my bees this season, yet, when I see what people will do for spite or jealousy, I gladly give the \$1.00 to the National Bee-Keepers' Union for justice, which will “ever come uppermost.”

The Annuity.—Concerning the proposed annuity of Father Langstroth, Dr. C. C. Miller, of Marengo, Ills., on July 13, 1888, wrote us as follows:

FRIEND NEWMAN:—I enclose a letter from “Amateur Expert,” which explains itself. I am confident that American bee-keepers, as a rule, will be only too glad of any interest that the British apiarists may take in “Father Langstroth,” who belongs not to us alone, but to the bee-keepers of the world. Yours truly, C. C. MILLER.

The letter from our English friend, who signs himself as “Amateur Expert,” is as follows:

HERTS, England, June 19, 1888.

DR. MILLER.—*Dear Sir:*—You will have seen in the columns of the *British Bee Journal* what a letter of mine to the Editor, on behalf of “Father Langstroth” has led to, amongst British bee-keepers. Sufficient time has not yet transpired for my appeal to be commented on in the States, and for those comments to have reached us on this side. The last of your bee-papers to hand is the *AMERICAN BEE JOURNAL* of June 6, which came yesterday. I am writing you in this matter, as I find you have the matter in hand, and several on this side are slow to subscribe, [as they say, judging from past experiences, the movement is liable to give offence to Americans. The collection made for the poet Whitman, they quote as a case in point.

I venture to think there is sufficient fraternity amongst bee-men to enable us all to unite in helping our friend Langstroth, considering the man and the circumstances, without our for one moment offending the dignity of Americans. We are nothing if not proud, but I trust our pride is not of that false kind that would not allow us to accept the co-operation of Americans in any work of philanthropy we may undertake, and I am sure I can count on Americans for a similar feeling.

Should such an expression arise on your side, I am sure I can count on you to rightly express our feelings about it, but for myself I confess I have no such fears, my experiences of Americans lead me to give them credit for better things. I trust you will get a good round sum for our old friend, and that many will remember the injunction, “To do good and to communicate forget not, for—.” Believe me to be,

Yours very sincerely,
“AMATEUR EXPERT.”

Let none of our English friends think for a moment that American apiarists are so vain and foolish. We rejoice in the hearty co-operation expressed by “Amateur Expert,” for Father Langstroth belongs not to America alone, but to the bee-keeping world, as Dr. Miller so nobly expressed it—like Huber and Dzierzon.

Our English cotemporary, the *Bee-Keepers' Record* for July, contains the following editorial remarks from Mr. W. B. Carr, on the same subject:

We draw attention to the fact that an effort is just now being made among British bee-keepers to supplement the fund in course of collection in America for the benefit of the Rev. L. L. Langstroth, to whom apiculture is indebted perhaps more than to any man living. He it was who first demonstrated the fact that bees would build a comb within a given rectangle inside a beehive without attaching the frame either to the hive sides or floor board. Here lies the basis whereon all our modern improvements are built; and “Father Langstroth,” as he is affectionally known in America, to whom we thus as bee-keepers owe so much, is, we are sorry to learn, none too well provided

with the worldly comforts which should accompany the declining years of a well spent and useful life. Owing to his advanced age, and some affliction in the form of a “head trouble,” the reverend gentleman has, for some years past, been compelled to relinquish his clerical duties, while, chiefly as we believe owing to his unrequited labors in the cause of apiculture, his pecuniary circumstances are known to be such as will render a generous public appreciation of his work very acceptable. Had “Father Langstroth” been less unselfish in his labors, there would have been less need for the present effort.

As it is, there is need for it, and we trust our readers will not ignore the fact. Something has been said—and well said—in our cotemporary, the *British Bee Journal*, on the need for bee-keepers this side of the Atlantic aiding their American brethren in the good work of which we speak. We, however, prefer to place it before the readers of the *Record* in a very matter-of-fact way, and earnestly hope our appeal may be responded to. It is less to the few who are able and willing to give their five guineas, or even their one guinea, as to the great bulk of bee-keepers gentle and simple who will read these lines. Nothing would be more gratifying to us, as editors of the *Record*, than to receive even a single shilling from every one of its readers, in aid of the Langstroth Fund. It would enable us to hand over a very handsome addition from this country to the sum being raised, and it would confer on all contributors the privilege of lending a helping hand in a very worthy effort for the benefit of a worthy Christian gentleman.

(Donations may be sent either to W. Broughton Carr, Higher Bebington, Cheshire, or to W. Raitt, Blaugowrie, Perthshire.)

We are only too glad to see that Father Langstroth is appreciated by English apiarists, and that they are willing to honor him as one of the greatest living lights in the apicultural world.

Queen Bees can now be sent by mail to Canada. The following letter from N. M. Bell, Esq., Superintendent of Foreign Mails, to Dr. S. W. Morrison, Oxford, Pa., shows that the Canadian Postal Department decided on July 10, 1888, to receive queen-bees and their attendants in the mails from the United States. Thus ends another annoyance to which American queen-breeders have been subjected, and one which came at the time when the interruption was the most annoying—just at the shipping season! Here is the letter:

WASHINGTON, D. C., July 14, 1888.

Sir:—Referring to my letter No. 82,033, of the 7th instant, in reply to yours of the 6th, I have to inform you that, under date of the 10th instant, the Canada office has advised this Department that it assents to the proposition that packages of queen-bees and their attendant bees shall be admitted to the mails exchanged between the United States and Canada, when so put up as to prevent injury to those handling mails, while at the same time allowing an easy verification of the nature of the contents.

Pursuant to this notice, United States postmasters have been instructed that, for the future, packages of bees are entitled to be forwarded by mail to Canada at the same postage rate, and under the same conditions as would apply to them if they were addressed for delivery in this country. I am, very respectfully, your obedient servant,

NICHOLAS M. BELL,
Superintendent Foreign Mails.

GLEAMS OF NEWS.

The Scientific Plesantry.

Referring to our comments on his letter published on page 388, Prof. H. W. Wiley has sent us the following apologetic and explanatory, though ill-tempered, reply:

Dear Sir:—Often, men who indulge in language more becoming a fish-market than the columns of a reputable journal, have a sense of fair play, and therefore I may hope you will allow me a word in reply to the intemperate vituperation contained in the issue of the BEE JOURNAL of June 13.

You may excite the prejudices of unsuspecting readers when you call me a "wilful liar," and so distinguished a scientist as Dr. Shippen Wallace, a "so-called professor;" and you may gain an ephemeral notoriety, when you slander the veracity of Dr. E. J. Hallock—a man of unblemished reputation, a scientist of the highest promise, whose death too early deprived chemistry of one of its most promising students.

We used STRONG language because the Professor had taken no notice of the *soft* and *mild* words which we had used previously. Our object was to cause him to forsake his dignified silence, and either to defend his "scientific plesantry," or to own up to its falsity. But we deny that we indulged in any language other than might be read in the most refined and delicate society. The Professor continues:

In regard to the matter in question, viz., the fabrication of artificial comb—there is only one opinion among informed men. Such comb is used, whether as you say made of purified beeswax or other materials, you will be informed in due time. That a wholly artificial comb had been made, Dr. Hallock was fully assured. As I said in my letter to Mr. Evans, he may have been misinformed. He was not a "wilful liar." Neither he nor I supposed at that time that such comb could be made commercially successful. Perhaps the day may come, when by improvements in machinery it can be made so. Of the probability of this, I will make no certain prophecy. It would have been better had I added to my article in the *Popular Science Monthly* such a limitation as mentioned above.

My statement in the *Popular Science Monthly* was not a "wilful lie," but rested on authority as reliable as could be had. The fact that I did not believe it to be commercially practicable had nothing whatever to do with the veracity of the statement. If you are at all disposed to be just and honorable yourself (which your language would lead me to doubt), you will be able to see the mistake into which you have fallen.

When "comb foundation" was first introduced it was inappropriately called artificial comb by some, and now the Professor is inclined to try to extricate himself on that article upon which he says, "there is only one opinion among informed men—such comb is used." Very true; it is, but it is made of pure beeswax, and some are now making the cells $\frac{1}{2}$ -inch deep for the bees to fill with honey, but that is quite another thing from the charge made in the "scientific plesantry!" That article was said to be "entirely free from bee-mediation—the comb is made of paraffine, and filled with glucose, by appropriate machinery!" The Professor cannot get away

on such a flimsy excuse as that! We will adopt the language of the astute Professor himself: "If you are at all disposed to be just and honorable (which your language would lead me to doubt), you will be able to see the mistake into which you have fallen." If the Professor's prescription is good for anything, that dose ought to relieve him! The Professor now tries a *new dodge* in this manner:

You may think you deceive the public in your ill-advised and I fear ill-meaning endeavors to cover up the enormous adulteration of honey which is now practiced. I have labored earnestly, in conjunction with others, to determine the nature of the adulteration in honey, and the best methods of detecting it, and no amount of buncombe billingsgate can drive me from the work of securing to the honest bee-grower an honest market. Your statement that, "It has no foundation except in the Wiley lie, when any one says that comb honey is adulterated," is false, and betrays either a pitiable ignorance or a reprehensible maliciousness.

The Professor can get no comfort from such tactics. It is too well-known and incontrovertibly established, for him to contradict that the AMERICAN BEE JOURNAL has valiantly fought the adulteration of honey for many years. For him now to attempt to create an *impression* that he is "securing to the honest bee-grower an honest market," and that the BEE JOURNAL is defending adulteration is simply monstrous! Such an assertion "betrays either a pitiable ignorance or a reprehensible maliciousness!" The Professor must here take another dose of his own medicine, after which we will quote from his letter the following paragraphs:

I have the honor to send you a reprint of an article in the *American Apiculturist*, containing an analysis of three samples of "Choice Comb Honey," viz: 2, 3 and 4, which consisted of almost pure starch glucose. How this glucose got into the comb I will leave you to surmise. There were brave men before Agamemnon, and long before the days of Wiley, the honey of our country was famous for its adulterations. Hehner, a distinguished English analyst, in Vol. IV of the Analyst, says: "Corn syrup is actually most frequently found in honeys imported from America." "Of nine American samples, seven were adulterated." "In August, 1884, one Campbell was arraigned before the police court of Glasgow for selling adulterated honey. The sample was found to contain 57 per cent. of starch glucose. Campbell said, in defense, that the honey was warranted to him to be genuine American honey, and he believed it to be so. The defendant was convicted."

Commenting on these instances, I said in an address to the Indiana bee-keepers, Jan. 22, 1885: "Every adulteration of honey is not only a fraud upon the producer, but is downright robbery of the honey-growers. How much more profitable would it be for the apiarist, how much more satisfactory to the consumer, were the people to rise in the majesty of public opinion and of law, and say to the world, 'The adulteration of American honey is a thing of the past!'"

The reprint article which the Professor sent includes five tables, the total unreliability of which is shown by the fact that samples of honey Nos. 15, 16 and 17, were obtained from Mr. C. F. Muth, of Cincinnati—a man known by every bee-keeper of prominence to be the essence of honor and hon-

esty, and who has never soiled his reputation by adulterating honey or anything else! and yet these three samples are said by Prof. Wiley to be "*Honey apparently adulterated with inverted sucrose!*" Two other samples obtained from Mr. Muth are classed as "apparently genuine."

Prof. Wiley had the assurance to send to Mr. Muth for more samples to analyze. This was indignantly refused—in these words: "We know what we deal in, and handle only straight goods—and want nothing more to do with your 'apparently pure.'"

The component parts of honey from different soils, vary so much that but few (if any) can *positively* determine, even by analysis, the purity thereof. Some candied honey, which we know to be pure, was analyzed, a short time ago, and pronounced adulterated!

As to the Scottish honey dealers' trial, the Professor should know that it was extracted honey, and *not comb honey* that was adulterated. The full particulars may be found in the AMERICAN BEE JOURNAL for 1884, and yet Prof. Wiley quotes it as *news* to us four years later! It would be advisable for the Professor to read the AMERICAN BEE JOURNAL before attempting to correct its editor, or instruct its readers. The Professor concludes with this shot:

I can see but one explanation of the frantic attempts you are making to conceal the gravity of the fraud which is practiced on the honey-growers of this country by adulteration. If you really believe there is no adulteration, you are ignorant; if not ignorant, your motive is easily understood.

Respectfully, H. W. WILEY.

We are *not* "ignorant" of the fact that extracted honey was quite generally adulterated when it brought higher prices, but *now* its price is so low that it will not pay to adulterate it, and it is in consequence hardly ever done! Persons will not adulterate any article when it does not pay them to do so! Adulteration of honey, (now "a thing of the past,") we fought with all our energies until it ceased to exist!! To bring up that ghost now, as the Professor has done, is but to fight a *dead* issue!

A Brief Review of Seven Years.

Now, in 1888, Prof. Wiley wants to figure as the *friend* of "the honest bee-grower," and the enemy of the adulterator—as the *defender* of "an honest market" for honey, and as a "detective" to pursue the sophisticator of honey.

But in 1881, in an address before the Farmers' Institute at Crawfordsville, Ind., when advising farmers to grow corn to be made into glucose, he is credited in the *Indiana Farmer* with saying that "really better honey can be made from glucose than the genuine article itself!!" In June of the same year he wrote over his own signature to the *Indiana Farmer*, these characteristic sentences, which were copied into the BEE JOURNAL, then, on page 370:

"Glucose" has the same effect on the BEE JOURNAL man that a red rag has on an infuriated bull, and it is decidedly amusing to see the awful anger which this INNOCENT *taffy facient* can produce.

In commercial honey, which is entirely free from bee-mediation, the comb is made of paraffine, and filled with pure glucose by appropriate machinery.

This last clause which, when written, was meant for a scientific pleasantry, came near throwing the whole bee-world into epilepsy. It appears that persons who devote themselves to BEE JOURNALS undergo a certain cerebral inspiration which renders them incapable of seeing a joke. The only point they can appreciate seems to be the sting of a bee.

Gov. Porter, in his able and interesting address, said something similar to the above, and succeeded, as he intended, in raising a hearty laugh.

I am appalled to think of the awful solemnity with which the Governor's remark would have been received had his audience been composed exclusively of the editors of the BEE JOURNAL, instead of the intelligent yeomanry of Bartholomew county.

Perhaps in order to secure a "posthumous reputation," for which I care little, I might undertake here to show the BEE JOURNAL the great similarity between genuine honey and good glucose, but I fear it would be "love's labor lost." He is evidently suffering from an acute attack of gluco-phobia, and what I might say with the best intentions would only throw him into another spasm.

Our remarks after publishing these selections, seven years ago, are as appropriate to-day as then, for we have been on the same side all the time, while Wiley has been flopping hither and thither, as the years have come and gone. We then said:

Could any possible good result to society at large from such reckless assertions, there might be some palliation; but when the only justification which can be urged is, that it was intended as a "scientific pleasantry," it leaves the author but little to congratulate himself upon, even though he has succeeded in disgusting the world.

Not a pound of "paraffine-comb, filled with glucose and sealed by machinery" (in imitation of honey) can be found on the market, even though three years of failure of the honey-crop offer the greatest inducement for its appearance, and honey in the comb brings high prices! This fact proves that it does not exist!

The Apicultural Station.—In the recent report of Norman J. Colman, Commissioner of Agriculture, to the President, we find the following, on page 18, concerning the work of Mr. N. W. McLain:

The work of the Apicultural Experiment Station has been carried on in the same lines laid down in my last report. For convenience in obtaining supplies, and for other reasons, the station has been removed from Aurora, Ill., to Hinsdale, Ill. The work has consisted of the study of the various kinds of diseases to which bees are subject, including an inquiry into the causes of disease and application of suitable remedies. The work in this line of investigation has been singularly successful and satisfactory. Suitable fixtures have been devised and constructed for securing the benefits resultant from selective breeding by means of skillful crossing of the different races of bees, and persistent effort has been made to secure the control of the process of reproduction. This feature of the work has been only partially successful, owing to the prevalence of a drouth of unprecedented duration and severity, but much information of scientific value has been obtained which will be of practical service under more favorable climatic conditions.

Some progress has been made in testing the qualities and characteristics of some varieties of ancestral stock, and the results attained furnish encouraging assurances of what may be realized in the future in producing a variety of bees completely adapted to domestication under the varied conditions existing in different parts of the United States. Information concerning the wintering of bees, the values of different varieties of bee-forage plants, etc., have been obtained, and will have place in the reports of the agent in charge.

The Union.—Mr. J. E. Pond, of North Attleboro, Mass., thus writes about the National Bee-Keepers' Union and its special work:

Why do not our bee-keepers all join the Union? It is a surprise to me that so few as yet have enrolled themselves under its banner.

I am aware that as yet no real necessity has arisen that demands of the many that they should join, still they (the many) ought not to take the "self alone" view of the matter. To-day A and B only are pursued; still, C, D and the rest of the alphabet may be pursued to-morrow, and even if they are not, it does seem to me that such a band of brothers as the bee-keeping fraternity ought to co-operate in a common cause, and for a common purpose.

In my own correspondence upon this subject, I have been met with the idea, that the Union should take up every trouble and difficulty a member gets into, and fight it out for him; and in one case I was asked in good faith, if I did not think "the 'Union' ought to fight a personal suit for debt of a member." Of course there is but one answer to such a question; but in a case like that of Mr. Clark, of Arkadelphia, if he is being persecuted, he ought to have not only the sympathy, but the solid cash of every bee-keeper in America. If, on the other hand, he is violating a law, then no matter whether just or not, the Union ought not to support and sustain him, but should use its best efforts toward wiping out the law if unjust.

The fee is small, and if every bee-keeper would enlist, a force would be raised that would cause factious complainants to think twice before they pitched into a member.

Mr. Pond asks *why!* We have often asked why bee-keepers do not *en masse* join the Union, but have never yet been able to solve the problem. Such an organization is of no particular interest to the editor of this JOURNAL—except as it entails considerable labor and trouble upon him—but to the pursuit in general, it is a mountain of strength—a tower of defense!

The annual fee is so small that there can be no reasonable excuse for any one remaining outside—the only word that can convey the exact condition of affairs is *apathy*. It is a kind of selfish indifference—a feeling of "don't care," as long as I am left alone." Brethren, is it not quite time to

Shake off dull sloth, and early rise
To make so small a sacrifice?

Admit that you do not personally need the protection which the Union endeavors to give, is it not the duty of every apiarist to assist in upholding the pursuit, and secure to its devotees their rights and privileges? While we are writing this paragraph, the Union's attorneys are fighting for a bee-keeper's rights in Arkadelphia, Ark., before a high court in that State.

Mr. Z. A. Clark kept bees in the outskirts of that city—was arrested and placed in jail for maintaining a public nuisance, by the arbitrary Mayor and prejudiced Councilmen.

There seems to be no complaint (says an exchange) that the bees have ever disturbed any one, or that any person has ever been stung by them, and the only charge brought against them, is that "They eat peaches and destroy young ducks," a charge so absurd that it does not require any one's

serious consideration. Mr. Clark is a poor man in advanced years, trying to make a living from his bees. He is highly spoken of by his neighbors as a Christian and a temperance man, minding his own business, and letting that of others alone.

If this will not arouse bee-keepers to a sense of *their duty*, as well as the dangers which threaten them, we despair of anything doing so. The Union should have ten thousand members within the next 30 days. Reader, if you have not already sent your dollar for membership in the Union, you should do so at once. Sit down now and send for a membership ticket, and thus show your patriotism and appreciation of the Union's defense of the pursuit, and your own good sense and level head.

The Honey Harvest.—Mr. G. W. Demaree, of Christiansburg, Ky., gives his views concerning the prospects for a short crop, and the cause which led to it, in the *Canadian Bee Journal* in these words:

Not unexpected by me the surplus honey harvest is not a "harvest" of surplus honey in the Middle States of the United States, the present season. Of course, some favored localities have done much better than the general field of operation. But taking all together the honey season for 1888 is a great failure in Kentucky, and perhaps in the Middle States, and wherever the drouth was severe, and of long duration last season.

When I had less experience in such matters, I used to insist that the honey seasons were no more affected by the state of the weather than are other branches of agriculture. But a more extended experience and observation has dissipated this fond delusion. The fruit trees on my grounds which withered and faded under the scorching drouth of last season, are now green and flourishing, and are loaded with fruits of their kind in a healthy, growing condition. All annual vegetation has come forward handsomely, and up to this writing, June 25, promises an abundant harvest. But such is not the case with the *surplus honey* bee-forage, which is catalogued with the hay crop, including all perennial grasses.

The surplus honey resources of a large portion of the Middle States depends on the perennial nectar producing plants, chiefly the clover, which must be developed one season in advance of their usefulness as honey-bearing forage. Hence a severe and protracted drouth during any one season does not necessarily cut down the honey yield of that particular season, but its effects are felt more surely the following season. This because the drouth of one season destroys the young plants which otherwise would furnish bee-forage for the succeeding year.

The present season, following two severe years of drouth, makes a very good honey season at the present, out of the question. The earth is covered at this time with a healthy growth of young white clover, and if there is sufficient rain from now forward to keep it in a growing condition, there is a hopeful future ahead—hopeful to the younger members of our fraternity—the loss of a *precious* year to us older ones is more keenly felt. But after all it is by no means certain to human foresight that the decade of drouth years is at an end, the rain-fall up to this date has been light, and the showers have been partial.

In some localities there has been rain enough for the needs of the crops at the present stage of this growth, while in other localities the crops are suffering for rain. This state of things makes the outlook not at all bright to the most hopeful.

QUERIES AND REPLIES.

Wet Bee-Cellars—Material for Cellar Floors.

Written for the American Bee Journal

Query 562.—I have a cellar under my house 26x30 feet, and divided in the centre by a brick partition. The walls are hollow and frost proof. Bees have wintered well in it, none dying except from starvation; but it seems to be quite wet. It has two chimneys that commence in the cellar and have openings 3½ feet from the bottom. It has a ground floor which is heavy clay. 1. What material is the best for a floor to keep the dampness down? 2. Is a cellar in clay ground as good as in gravelly or sandy ground?—Wisconsin.

1. Cement. 2. Yes, if cemented.—M. MAHIN.

If bees winter well in your cellar, you had better let it alone.—C. C. MILLER.

1. A board floor raised 1 or 2 feet. 2. No.—DADANT & SON.

1. Brick and cement. 2. I think so, though I am not certain.—J. M. HAMBROUGH.

1. A coarse grout, or gravel, and cement. 2. It is not as dry.—Mrs. L. HARRISON.

If the bees have wintered well, you should be satisfied that the dampness does no harm.—G. M. DOOLITTLE.

1. A good cement bottom made from water-lime and sand. 2. I prefer a cellar in sand or gravel.—H. D. CUTTING.

The fact of your cellar being a little wet I think would not make it unsuitable for a winter repository. Put in a wood floor of fat yellow pine, with the same sort of sleepers.—J. P. H. BROWN.

1. Drain thoroughly, and then if you want a harder and smoother bottom, cement it with water-lime mortar. 2. Yes, if as dry as the gravelly or sandy ground.—A. B. MASON.

2. A cellar in clay would generally be damper than one in sand. For most purposes to which a cellar is devoted, one in clay would be best. For bees, I prefer one in sand.—R. L. TAYLOR.

Gravel or sand would be better than clay. Our Kentucky clay is very retentive of moisture. Brick laid in cement makes the best floor for a cellar or "mound house" that I have tried.—G. W. DEMAREE.

1. As your own report indicates, dampness does not hurt bees if the temperature keeps up, and I should as soon have water 6 inches deep in my cellar bottom, as otherwise, as far as injuring the bees is concerned.—JAMES HEDDON.

That bee-cellar is exactly like mine, with the exception that mine has a cement bottom, and is dry. 1. Dig

out a foot or so of clay unless it is deep enough. Then put in 6 inches of broken stone and gravel. Make your cement quite thin, and pour over the stone, filling all holes. Put on two or three coats, smoothing it down with a trowel. 2. Yes.—C. H. DIBBERN.

Work a tile drain in under the cellar wall all around with sufficient fall to carry the water off to the outlet; then cement the bottom of the cellar thoroughly. I have a cellar that winters bees perfectly, and it has a clay floor, but it is as dry as a bone.—J. M. SHUCK.

If your cellar has wintered your bees well so far, why make any change? 1. It will be difficult to prevent dampness by any change of bottom. 2. This depends upon so many other considerations that it is impossible to answer.—J. E. POND.

1. "The proof of the pudding is in the eating." If your cellar has always wintered bees successfully, that beats any man's theories. I should let well enough alone. 2. If a choice were possible, I should choose gravelly or sandy ground.—EUGENE SECOR.

The only way to have a dry cellar in clay soil is to drain it thoroughly. Even the best cement floor will not keep the water out if undrained. But why mind the damp, if the bees winter well, unless for your own health? A well-drained cellar in clay is as good and as dry as one in sand or gravel.—A. J. COOK.

1. Cement; but you must have a good drain if you would keep it dry. Dampness, however, is not detrimental to bees in winter. 2. Yes; if it is as dry as one in the sand or gravel.—THE EDITOR.

An Apiary in a Town Lot.

Written for the American Bee Journal

Query 563.—I have 18 colonies of black bees, and only a small town lot to keep them on, where they are liable to intrude upon persons on adjoining lots. 1. Would it be advisable for me to change them to another variety? 2. If so, what variety? 3. Are there any particular instructions that would be of benefit to one who lacks room for bees?—Strawberry, Iowa.

1. For profit, Italianize them. 3. No.—Mrs. L. HARRISON.

1. Change them to Italians. 3. Keep them on a roof, as C. F. Muth does.—G. M. DOOLITTLE.

1 and 2. I should prefer Italians. 3. You had better have high fences or hedges.—C. C. MILLER.

1 and 2. I would change to the Italian. 3. No. I would locate them on the part of the lot furthest from the street.—J. P. H. BROWN.

1. Yes. 2. Italians. 3. Smoke them carefully whenever you handle them, so that they will not sting the neighbors.—DADANT & SON.

1. Yes. 2. Italians. 3. A high board-fence is sometimes essential to protect timid neighbors.—J. M. HAMBROUGH.

1. No, not for the purpose stated. 3. Make room, go where you will have plenty of room, or quit the business.—H. D. CUTTING.

1 and 2. I would change them to Italians or Carniolans, and keep them pure, if possible. 3. Bees will bear a great deal of crowding.—M. MAHIN.

1. Yes. 2. Italians. 3. Observe the "Golden Rule." "Soft words" and a little honey, properly used, will do lots towards getting, and keeping, good neighbors.—A. B. MASON.

Yes, either Italian or Carniolan bees are less likely to sting. 3. A high, close fence, or evergreen hedge between your lot and that of your neighbor, makes the danger far less.—A. J. COOK.

1 and 2. I should change to Italians in any case, as they are far more pleasant to handle, and less liable to trouble travelers. 3. Yes, plenty of them; far too many for this department. Unless very peculiarly situated, I should risk the present location with Italians. Be sure and get them pure.—J. E. POND.

1. I would change my location, or sell the bees. I doubt if you can be prosperous with any race of bees on a small town lot, surrounded by near neighbors, and retain the good-will of the neighbors. If you can, you have solved the problem.—EUGENE SECOR.

There ought to be no difficulty in keeping 18 colonies on a town lot. You do not state whether the trouble arises from swarming, or people being afraid of stings. If your bees are very cross, change to some gentle variety. I now give the preference to the Carniolans.—C. H. DIBBERN.

1. I would change the bees, anyway. Italians are generally less inclined to attack than blacks, and Carniolans or Krainers are still less inclined to make trouble. 2. A "house apiary" is an excellent arrangement where there is lack of room.—J. M. SHUCK.

1. I think not. Destroy the queens which you find produce irascible bees. 2. A quiet strain of Italians would be a little less likely to cause trouble. 3. A high, tight board-fence, or a close row of trees around the apiary would cause the bees to rise in going a-field, so that with proper care the chance of their disturbing neighbors would be very slight indeed. Beware of leaving

honey where the bees can get at it in time of dearth.—R. L. TAYLOR.

1. Yes. 2. Italians would be the safest bees to keep under such circumstances. 3. Perhaps so. You can enclose the plat of ground on which your bees are located, with a high, tight board-fence, so as to habituate your bees to a high flight when passing over the adjoining grounds. Under such circumstances I would clip the wings of the queens so as to control the swarms, without having to go after them on adjoining grounds.—G. W. DEMAREE.

1. No, I should change them to another place more suitable. Placing a board-fence around the bees, is equal to moving them further from a road or neighbor's lot. 2. Brown German bees are no more liable to sting than other varieties. 3. The best instruction upon the subject will be by reading books and back numbers of periodicals devoted to bee-culture.—JAMES HEDDON.

As pure Italian bees are less liable to interfere with the neighbors, it would be very desirable to Italianize the bees as soon as possible. A row of trees, an evergreen hedge, or high board-fence would be advantageous, but to move the bees to where there is more room is the best advice which can be given.—THE EDITOR.

CORRESPONDENCE.

EXPERIMENTS.

A Report of Some Experiments in Apiculture.

Report to the Commissioner of Agriculture
BY N. W. M'LAIN.

(Concluded from page 474—last week.)

Starved Brood.

A disorder which has been quite common in several States during the past season, is resultant from conditions prevalent during severe and protracted drouths, and long periods of extremely high temperature, such as has existed over large areas.

The disorder is significant and important, not so much on account of the actual numerical loss entailed upon colonies affected, which in my own case, and in many cases reported to me, have been severe, as in furnishing proof of failure on the part of those food elements indispensable during the breeding season to meet the large demand for larval food, and essential in maintaining the health and vigor of the bees while the digestive and secretory organs are being taxed to

the limit of their capacity. This failure of natural resources results in low vitality, susceptibility and predisposition to disease, and inability to successfully perform the function of hibernation. With some exceptions, due to local advantages, throughout the States stricken by the drouth of the past summer, the bees have entered upon the period of hibernation under conditions more or less unfavorable in proportion as they have suffered in greater or less degree from the effects of the all-consuming drouth and heat.

The symptoms of starved brood are distinctively characteristic. Upon opening the hive a slightly offensive odor may be noticed if the colony has been suffering for some time. If the comb frame be lifted from the hive, and the bees shaken off, few if any eggs can be found. Of such brood as is sealed, the cappings appear to be thin and flat, and slightly sunken, and commonly of darker color than is usual in prosperous colonies. Upon opening the cells they are found to contain dead pupæ in various stages of development, always inferior in size, and the food supply exhausted.

In the midst of sealed brood patches of uncapped larvæ appear, and sometimes a patch of 5 or 6 inches square, and sometimes there seems to have been no effort made towards sealing half the grown larvæ in the hive, although the time for such sealing may be far overdue. The membranes of such larvæ do not present the plump, pearly-white appearance common to well-fed larvæ. On the contrary, the membranes are more or less shrunken and wrinkled, and not infrequently, when the larvæ have reached the advanced pupa stage, the compound eyes begin to color, and the cells are partially capped and then abandoned, and the appearance is that commonly designated by the term, "bald-headed bees." Sometimes a few of these bees, dwarfed in size, emerge from the cells and engage in the labors of the hive with what vigor and for such term as their limited development will permit.

In a number of tests made during the past season, the progeny of the same queen, reared under directly opposite conditions of larval growth, so varied in size as not to be recognizable as offspring of the same progenitors. The reason for this variation was not far to seek. The changed conditions of the colony during the time when the different generations were being reared, determined the modification in development. The remedy I used and prescribed for others was a preventive rather than a curative. Starved brood means starved bees. If the cause be removed, the effect speedily disappears. All that

needs to be done is to supply them with a substitute for those resources essential to their own health and vigor, and indispensable in brood-rearing, in search of which they are rapidly and vainly wearing out their vitality.

The recipe for preparing the remedy is as follows:

To 10 pounds of sugar add half a pint of dairy salt, 2 table-spoonfuls of bicarbonate of soda, 2 table-spoonfuls rye flour, 2 table-spoonfuls of very finely powdered bone ash, and 1 table-spoonful of cream-of-tartar. Mix thoroughly, then add 2 quarts of hot water, and stir until thoroughly dissolved, then boil for two or three minutes only. To one-half a pint of fresh milk add 3 fresh eggs thoroughly beaten, and when the syrup is cool enough to feed add the eggs and milk, and when thoroughly stirred, feed warm. Feed in the hive as one would feed honey or syrup.

I used this same food for preventing spring dwindling, and for building up colonies to full strength and efficiency, so that all colonies may be ready for work at the very beginning of the season, when surplus honey may naturally be expected. This food fed in the hive keeps all the bees at home to aid in performing the functions of brood-rearing, and in keeping up the temperature of the hive instead of spending their little remaining strength in battling against the cold, damp winds while searching for the food elements needed to repair the waste and drain upon their vitality while hibernating, and indispensable in brood-rearing. This food is not intended for use until after the bees have had a good flight in the spring, and almost any grade of honey or sugar may be used. This special food is a potent stimulant and tonic to the adult bees, giving tone and vigor to the organism, and furnishes the elements essential in brood-rearing in the place and in the manner suited to the convenience and tastes of the bees. No greater quantity should be fed than is required for the current needs of the colony.

The Control of Reproduction.

In order that the laws of heredity and the active principles of selection may be practically and persistently applied in the breeding of bees, I have in obedience to your instructions continued my experiments, striving to discover a simple and practical method for securing control of the natural process of reproduction.

I devised and constructed a fixture, which I call a fertilizing cage, 22 feet square and 26 feet high. Selecting a level plot of ground I set 4 rows of posts, 4 posts in each row, forming a quadrangle. These posts are 4 inches square, and 30 feet in length, set into

the ground 4 feet, and exactly 7 feet apart. Four rows of girders, 2 by 4 inches by 22 feet and 4 inches are halved in two and bolted to the inside of these posts, the first row 5 feet from the ground, then three rows at intervals of 7 feet until the top is reached. The upper 3 lines of girders are continued from each side of each inside post, forming a brace on each side of each post at intervals of 7 feet, and forming the bearings for the wire-covered frames which cover the top of the cage. The space from the ground to the first girder, 5 feet, is covered with matched lumber nailed to the outside of the posts, leaving a smooth surface on both sides. The upper 21 feet on the sides and the top of the cage is inclosed by wire-covered frames 7 feet square, bolted to the girders on the sides, and securely fastened with screws to the frame-work at the top.

The height of the cage is thus adjustable at 26 feet, 19 feet, or 12 feet from the ground by simply lowering the screen frames forming the top, and the upper row (or two upper rows as the case may be) forming the sides of the inclosure, the purpose being not only to determine whether queens or drones would mate in this cage at full size, but also how small an inclosure would be sufficiently large to give suitable freedom and range of flight.

These wire-covered frames are framed like a two-light window-sash, with a mullion in the centre, on which the two breadths of wire-cloth meet. Strips of wood secure the edges of the cloth, and cover all joints at the sides of the frames. With the lower board of the siding settled into the ground, and earth filled against the inside, and the door tight-fitting, the cage is bee-tight. I used drab-colored wire-cloth, which obstructs the light but very slightly. A shelf is fitted against the four sides of the cage on the inside 1 foot from the ground, and alighting-boards directly opposite on the outside. Upon this shelf the hives are placed.

Each hive has an exit cut in either end, and an exit is cut through the wall of the cage registering with the outer exit of each hive, over which, on the outside of the wall, a piece of queen-excluding zinc is nailed. These hives are painted strikingly distinguishing colors, as red, white, blue, green, yellow, and black, and a space opposite each on the alighting-boards, and a corresponding space on the outside of the wall of the cage are painted in corresponding colors. The colors are repeated in the order named, which separates the hives of the same color a sufficient distance to prevent confusion, and the bees and queens readily distinguish their own hive by means of color as readily as by location.

If the inner exit be left closed for a day or two after a colony is placed in a cage, the worker-bees readily learn to enter their own hive upon returning from the fields. I found that the queens had no difficulty on returning to their own hives after taking flight in the cage. To test that fact I frequently opened a number of hives in succession, and placing the queens upon the palm of my hand tossed them high in the air, when they would take wing and fly away.

Upon re-opening the hives a few minutes later they would be found upon the combs. The queens and drones appeared to fly and disport themselves with as much freedom and regularity in the cage as they did in the apiary outside. The virgin queens were introduced from the nursery by various methods. Some were hatched in colonies in the cage from cells matured in strong queenless colonies, and some from cells built under the swarming impulse, which this season could be produced by artificial means only. Mature drones were selected from the hives in the apiary, and also from those returning from their excursions and liberated in the cage, and sealed drone-brood was removed from the hives in the apiary and hatched in strong colonies built up in large hives in the cage, and these drones all flew with freedom and regularity.

A few times I observed a queen embrace a drone and fly all about the cage with entire freedom, and then, the embrace being broken, each flew away in different directions, the queens returning to their hives, and the drones at once rejoined their fellows in the upper part of the cage. It is needless to add that in such cases no accomplishment had taken place.

The results realized from this line of experimental work have been so meager, and the circumstances attending the experiments so exceptionally unfavorable that it is not easy to form an estimate of their value, or determine their significance. Of the many scores of trials made, but six were successful; but six queens, were fecundated in the fertilizing cage. However, as the improvement of the bee to the highest attainable excellence outranks all other considerations in practical importance and scientific interest, the methods and results of any intelligently-conducted experiments having this end in view, are well worth placing on record. Besides future trials may receive direction from a multitude of failures, and the trying experience of the past season is not without compensating features, for even the little grains we make in positive knowledge, although apparently trifling in themselves, have often significant meaning and broad

bearing on questions of great value and importance.

My experience and observation lead me to believe that the main reason why this experiment was not satisfactorily successful was because of the protracted drouth and high temperature which lasted through the entire breeding season, the like of which has not before been known in this region. From May, 1885, until December, 1887, drouth prevailed, broken only at long intervals by light showers. The succession of two summers of excessive heat and unbroken drouth insured disaster to the present season cumulative in kind and intensified in degree. Continuous feeding has been required to keep up breeding and to prevent starvation.

Whenever feeding was suspended for two or three days, throughout nearly the entire season, oviposition would cease, and the bees ate their eggs, and it has required persistent trials and careful management to rear drones and keep them alive. It has been difficult to get three or four queen-cells matured in colonies such as in ordinary seasons would rear from 25 to 40, and of those permitted to remain outside in the apiary and seek a mate at will, two of every three failed of fecundation.

During the entire season a large majority of the larval queens, being insufficiently fed, died in the cell, and when for days and weeks together the temperature ranged from 110° to 120° F., in the sun during several hours each day, the pap-food would ferment and turn a dark amber color and dry up to the consistency of thick glue at the bottom of the cells with the dead pupæ. When the temperature ranged from 100° to 110° F., in the sun, the average temperature in the hive was from 5° to 2° higher until 112° was reached. Then, when the range in the sun was from 115° to 125° the temperature did not go above 112° in the hive. The fanners were able to prevent the temperature rising above 112° in the hives standing in the sun with a shade-board above the hive-cover. The worker larvæ seem to be able to endure a higher temperature than queen larvæ.

This season, as a rule, the drones were much smaller than drones from the same ancestors in the summers of 1885 and 1886, and there was a great inequality in the size of the drones and queens of the same parentage, and reared at the same time in the same hive, and a very unusual proportion of the queens were deformed and unable to fly.

Continued observation and experiment furnish corroborative evidence of the correctness of the theory advanced

in my last annual report, namely, that drone bees differ in degrees of procreativeness, properly classified as the impotent, the conditionally potent, and the potent; and that it is the prerogative of the worker-bees to determine the degree of development, and dominate the function of the drones as they determine the kind and degree of development of instinct and organism, and dominate the functions of the queen.

The volition of the queen determines the sex of every one of her descendants; but the life of every individual, as well as the modifications in organism and instinct, depends upon and receives its direction from the worker bees, whose unerring prescience forbids the rearing or maintaining of individuals for whose services there exists no present or prospective demand. It is only when this keen apprehension of the present and prospective conditions of environment indicates a necessity for rearing and maturing potent or potentially potent individuals that such are reared and matured and furnished for the functions they are to perform.

Under circumstances unfavorable in the extreme, a condition of seeming prosperity may be artificially produced, and drones numerically plentiful may be reared and preserved alive. It has taxed my skill and patience to the last degree during the past season to do this. I resorted to every stratagem I could devise to secure a supply of mature drones, but in most cases the workers were either unable or unwilling to supply the drone larvæ with food suitable in kind and quantity, for a large proportion of the drones were dwarfed. Dissection showed the sex organs of this sort to be inferior in size, dry, and empty.

Not one drone in one hundred of those which were fully developed, when held by the legs or wings, or when pressed upon the thorax, were able to perform the expulsion act, and the sex organs of such, with rare exception, contained nothing but a little clear, thin mucous. I have during the past season at various times examined the contents of the sex organs from scores of drones well developed and structurally perfect of the class which I believe to be potentially potent, in which I have not been able to discover active spermatozoa, nor was the mucous secretion present of that color and consistency which I believe to be the product of special feeding, and indispensable to sexual desire, and for liberating and floating the spermatozoa into the spermatheca.

Without wishing to appear dogmatic, after another season exceptionally favorable for such observation and ex-

perience as has furnished more complete data and corroborative evidence, I venture to reassert my belief as set forth substantially in my last annual report, that the preparation for and exercise of the reproductive faculty in drone bees, as well as in queens, depends upon and is determined by the workers. As with the queen, so with the drone, desire and capacity wait upon the will and resources of the workers.

As the queen must be bountifully supplied with egg-food before the egg-cells begin to germinate and mature in the ovaries, so I believe the drone must be well supplied with that special food suited and intended to produce the desire and capacity for performing the act of copulation, the giving and withholding of which is instinctively determined by the worker bees, as the present and prospective condition demands.

Throughout the past season of extreme heat and protracted drouth there was almost a total failure of all natural resources, and all the influences of nature to which bees are subject, warned them that there was no actual necessity for feeding and maturing drones, and that the abundance and prosperity with which I had supplied them were artificial and deceptive.

In the impotency of the drones, almost universally prevalent, I find the reason for the almost total failure of this experiment. The fact that both drones and queens flew with freedom and regularity in the cage, and the fact that in a few cases queens were successfully mated in the cage when but few were successfully mated outside, leads me to believe that under favorable conditions satisfactory success may be expected. Experiments in breeding bees during the prevalence of such climatic conditions as those of the past season, are attended with hindrances which I have not been able to overcome. My experience and observation have suggested some changes in the size, shape, and manner of constructing the cage which I believe would be an improvement. If, under favorable circumstances, the control of the process of reproduction can be secured by the use of a device permanent in kind, and of moderate cost, then every queen-breeder and progressive bee-keeper may apply the laws of heredity, and the principles of selection to the breeding of bees with assurance of realizing results alike in kind and degree to those which have by the persistent application of the same laws and principles been realized in breeding all kinds of domestic animals.

I have, by establishing mating stations in localities remote from other

bees, secured the mating of queens and drones selected on account of their excellent paternity and perfect development. I controlled the flight of the different varieties by the use of queen-excluding zinc.

By crossing selected individuals of different varieties, and by mating selected bees of the same variety avoided in breeding, I have laid the foundation for some ancestral stock of superior excellence. This kind of work requires much patience and persistence during such a season as that just ended. I have begun many other experiments, many of which failed, and others, lacking in completion, require no mention here.

Hinsdale, Ills., Dec. 31, 1887.

BEE-CULTURE.

Bees, their Functions, Habits, Uses and Products.

Written for the American Scientist

BY GEORGE H. HASTINGS.

In the oldest writings mention is made of the bee, honey, and the honey-comb, and a land flowing with milk and honey. From this we infer that the common honey-bee has been known since the dawn of civilization, and that it is of Asiatic origin.

This insect has been the theme of many writers. Volumes have been and are being published, and there are journals devoted wholly to this subject.

Bee-culture possesses a fascination peculiar to itself. The study of any other species of the animal kingdom cannot equal it. This is due, in a measure, to the many superstitions with which it was regarded. To-day, even, there are many people who believe that when a bee-owner dies, some member of the family must communicate this intelligence to the bees by rapping on the hive. You will be interested in reading a poem by Whittier, entitled, "Telling the Bees."

In the 18th century, Huber, a Swiss naturalist, who became blind at the age of 15, published many articles on the natural history of the honey-bee. These writings are the first to tell the truth, and are quite remarkable, considering the way in which the experiments and observations were made.

If a prosperous colony be examined in June, there will be found three kinds of bees, viz., the queen, the workers, and the drones, also three kinds of cells. Two of these will be horizontal and hexagonal, and will differ in size only. The smaller is the worker-cell, the larger the drone-cell. The third cell is much larger than the

others, and resembles an inverted cone with the opening at the apex. The different cells will be found to contain various substances—such as honey, pollen, eggs, and immature bees.

The queen, or mother-bee is rightly named, for without her no colony can exist but for a short time. She is longer and more slender than the others, and is armed with a sting. The abdomen is quite tapering, and the wings short. She is the only perfect female in the hive, and during the height of the breeding season lays from two to three thousand eggs per day. This seems an exaggeration, but it does not equal the fecundity of the female of the white ant, which lays at the rate of sixty per minute. The queen has it in her power to lay drone or worker eggs. She will deposit in the worker-cells the right eggs, and as it happens many times, the drone-cells border these, but no mistake is made, for on examination no worker is found in a drone-cell, but drones may be found in worker-cells as was intended. This takes place when the apiarist removes all the drone comb, which gives no other place for the drone-eggs. About ten days before swarming, eggs are laid in the queen-cells, so that when the swarm issues a new ruler will be ready to take steps to carry on the work of the old. This work consists mainly of laying the eggs. The queen is much respected by the workers, a body guard of which encircles her. The food consists mostly of honey, which is taken from the proboscides of the workers.

The worker-bee, incorrectly called the neuter, is a female with ovaries imperfectly developed. It is smaller than the queen or drone, but has longer wings, is armed with a sting which it is ever ready to use in defense. The instrument is less than one-eighth of an inch in length, is hollow, and has two sacks at the base that contain poison. The sting is left in the wound, and the poisonous sacks and a portion of the intestines adhere to it. If the sting is removed from the wound immediately, little harm will result. Otherwise the muscles of the sacks contract and force all the poison into the system. When a bee loses its sting, it soon dies. Hornets, wasps, etc., do not have a barbed sting. They retain it, and can sting many times in a moment. Does it seem that the worker would be as ready to act on the defense if it knew what would be the result? The queen is quite different in this respect. She cannot be induced to sting except in mortal combat with another queen. The bystander will not interfere, and after a short conflict, one falls a victim and the other becomes supreme ruler.

The hinder legs of the worker contain a spoon-shaped cavity or basket in which the pollen from the flowers is gathered, and a sticky substance called bee-glue.

The worker is furnished with a tongue or proboscis, with which it takes the nectar from the flowers. Honey is gathered, not made. The honey is conveyed to the honey-bag or first stomach. This receptacle is about the size of a pea, and is furnished with muscles which enable the bee to compress it and force the contents into the cell. When honey and pollen are abundant, a load of each is gathered. Less than twenty minutes are consumed in doing this. When gathering pollen but one kind of flowers is visited, else there would be considerable confusion in the vegetable world. During the busy season the worker has no rest, and, of course, wears out quite fast. At this time few live to be more than six weeks old. At other times they may live five months. An old bee can be distinguished from a young one by the ragged edges of the wings. In the abdomen of the worker are pouches or sacks for the secretion of wax, which is the fat of the bee. This can be formed or not, as required.

The drones are the male bees. They are longer and stouter than either the queen or workers, but their bodies are not so long as that of the queen. They are not armed with a sting, and have no suitable proboscis for gathering honey from the flowers. There are no baskets on their thighs for holding bee-bread, and no pouches on their abdomens for secreting wax. Many allusions are made about the drone because he is such a lazy fellow. He does what nature intended him to do, and that is all—to impregnate the young queens. Soon after this is accomplished, the workers destroy them. This is done by biting and stinging, but the sting is not left in the wound.

The comb is made of wax, and consists of hexagonal cells of two sizes. The smaller are the worker, the larger the drone cells. It has been found that no other arrangement will give an equal strength and volume with the same material.

The more we read and reflect on such subjects, the more we find

"Tongues in trees, books in running brooks,
Sermons in 'bees,' and 'God' in everything."

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

BEE-HIVES.

The New Heddon Hive again Re-considered.

Written for *The American Bee Journal*
BY JAMES HEDDON.

In response to Dr. Tinker's article on page 474, I must say that I am very glad to note that the Doctor holds no ill-will toward me, for truly, as he says, he has no cause to do so. He states that his whole desire has been to forewarn the public against a recognized wrong. Now, candidly, I do not believe that one bee-keeper in one thousand recognizes or contemplates any wrong on my part. Nor do I think that the Doctor, with his comparatively limited experience with my hive, and as a honey-producer, exhibits good taste in hastening forward to "forewarn the public." I did and do think that the Doctor has done me an injury, simply to my feelings, but by no means any perceptible injury to my business. When such men as Father Langstroth, Prof. Cook, W. Z. Hutchinson, R. L. Taylor, Franklin P. Stiles, and many other honest and skillful apiarists, without solicitation, publish reports of such splendid results flowing from the use of the new hive, it cannot be possible that the Doctor's displeasure with its use can have much tendency to persuade the inexperienced that his views are correct.

I thank the Doctor, who I believe is a better apicultural historian than practical honey-producer, for aiding me in setting forth the truth, that the principles of my hive are new and novel. As I have three apiaries, and have been a specialist in our chosen pursuit for 20 years, having realized a life competency from the business, nearly all of which has been made from the production and sale of honey, and further, that I have several inventions connected with apiculture, which, after thorough and repeated trial, have gone into general use to stay, while nothing of the kind can be said of the life-work of the Doctor—certainly my judgment should be as good as his. It has been said that I am the one financially interested party, but could I not apply the same muddy argument to my chief disputant? For years past he has been offering a hive to the public in opposition to my own. First, it was something altogether different from my new hive in both construction and principle. At first his hive possessed, and its patentee plead, for continuous passage-ways. As soon as my hive came out, this hive was laid aside and another entirely different one was offered to the public, and this one contains features embraced in my

patented hive, entirely casting aside the main features of his former hive. While I allowed the Doctor to use a part of my inventions in his latter-day hive, he praised them as I have before published in this JOURNAL: but now he repudiates their value altogether. I am not blaming any one, but simply telling how it is, which the records show.

The Doctor mentions my claim to handling hives more and frames less. By way of modifications of the Langstroth hive and discoveries in manipulation, I had succeeded, much to my gratification, in "handling hives more and frames less," and so wrote to this JOURNAL before I invented my new hive. My great satisfaction realized from such manipulation, was one of the principal factors which led to my late invention, and I have found that I made no mistake.

The Doctor says that "at last it appeared that the new hive was not what it was represented to be; in fact, it was a fraud." I would ask, to whom did that appear? Now I consider this statement not only unkind, but untruthful, whether wilfully so or not. I know of no reason why those who did not like the hive would not be as apt to so report in this JOURNAL as those who did, and of those who did report, the majority in favor was unprecedentedly overwhelming. But the Doctor says that over four hundred were as silent as the tomb. Is this strange? When we consider the thousands of bee-keepers who read bee-periodicals, how many are there who can be induced to write anything for the public eye? I can show hundreds of private letters speaking in praise of the new hive, and I think I have but one or two reports of failure with it. The same mail which brought the Doctor's article to my desk, brought three letters of praise for my new hive. One of these I have filed away and forgotten the name, but I will quote from the other two, as follows:

M. S. Morgan, of South Elgin, Ills., says: "I have 17 of the new hives in use, and they are just the thing. If we get any honey this year, it will be because of the new hives."

Geo. W. Peck, of Roselle, N. J., writes: "It is a pleasure to handle bees in your improved hives. I get more honey with less labor than with the American style of hives, and the bees are always under easy control."

I quote from these two letters only because they came in the same mail with the Doctor's article, as I said before. I can show "stacks" of the same kind. It seems to me that this completely answers the Doctor's claim of "fraud." I should be glad if my late invention could be left by honest men to "stand or fall" on its merits.

My new style of reversible surplus case referred to by the Doctor, is, in my judgment, far superior to any other wide-frame super yet known to bee-

keepers; but as I have said in my circulars, they are more costly than I could wish, and for those who prefer to work without separators, my old style of cheaper surplus-case is, as the Doctor says, well-nigh perfection, never having been improved. I have been astonished at the tendency to praise my less valuable, unpatented devices, while making war upon my more meritorious inventions upon which I obtained letters patent.

The Doctor discourses on the divisible brood-chamber of the new hive. I will say that it is one of the best functions therein possessed, and has brought hundreds of splendid testimonials. That it has ever been successfully handled as represented, in my apiary, and by a large majority of bee-keepers, and that, too, in some cases where the hive has been improperly constructed—all this I stand ready to prove by letters on file in my secretary, and by sworn testimony, if necessary.

The Doctor says: "Why use 16 brood-frames when 8 can be handled just as quickly, and answer the same purpose?" I will answer, because they do not answer the same purpose; but if any one thinks they will, there is no objection in using them that way, making the brood-chamber a single story, in which case it will carry out a part of the valuable functions of my late invention, and do not let it be forgotten that it will come strictly within the limits of my patent.

The Doctor speaks of a case of failure in performing the shake-out function. I am aware that this is not the first case of the kind. More is necessary than simply the proper construction of the hive. Ask Mr. Langstroth how many years elapsed after he gave the public the valuable functions of his hive before that public learned to take advantage of them. In the month Mr. Langstroth visited me, much of the time of which was spent in examining and testing the hive in question, every claim of which Father Langstroth fought step by step, the shake-out function was repeatedly tested, and I will refer the Doctor to Father Langstroth, not only as to whether my men and myself make it work practically or not, but if the improvements did not succeed perfectly in accomplishing all that I ever claimed for them. I am glad to be able to cite to you a witness whose intellect is a mountain, and whose integrity is a monument.

The Doctor says he made my hive (which, in the same article, he says was novel and original with me) just as I made it, and to prove it, cites us to his article in *Gleanings*, where he described and illustrated it. In that article in *Gleanings* my name is not

mentioned, and he claims to be the inventor. Is there not a discrepancy here from which we can draw no other conclusion than that he was not using my "new and novel" invention, or that he intended to rob me of the credit of the same?

To conclude, I will say that I thank the Doctor for justly crediting me with the novelty and originality of the hive in question, and hope that the next attack, which will likely be against the novelty, and by some one who sees its merits, may be promptly met by the vigor of the Doctor's pen. I thank him further for hoping that I may yet distinguish myself as an inventor, and will say that it is evident that I have, in the eyes of some of our people; but if I have not in the Doctor's vision, it seems to me that he does not properly value the functions of my late invention which he does not use, and does not know that some of those he does use in his latter-day hive, belong to me.

History repeats itself. The Langstroth invention was a thirty-years' step in advance, and the patent-office records show a storm of bee-hive patents immediately following. Now examine these records again, and you will see that the same thing has followed the issuing of my patent.

Hives possessing cherished and stoutly-defended functions—functions claimed to be superior to anything we had or were likely to have—at once dropped into oblivion, and out came new hives, some of which were unpatented, and others having patents upon some unimportant and well-nigh useless features, but nearly all infringing the "invention" from which their devisers drew their inspiration. But such is life.

Dowagiac, Mich.

[Now, as both disputants have had their statements of the case anew, this closes the controversy in our columns, as intimated on page 475, in the BEE JOURNAL of last week.—Ed.]

CONVENTION DIRECTORY.

	Time and Place of Meeting.
1888.	
Aug. 3.	—Ionia County, at Ionia, Mich. H. Smith, Sec., Ionia, Mich.
Aug. 14.	—Colorado State, at Denver, Colo. J. M. Clark, Sec., Denver, Colo.
Aug. 27.	—Stark County, at Canton, O. Mark Thomson, Sec., Canton, O.
Sept. 8.	—Susquehanna County, at Montrose, Pa. H. M. Seeley, Sec., Harford, Pa.
—	—North American, at Columbus, O. W. Z. Hutchinson, Sec., Flint, Mich.
Dec. —	—Michigan State, at Jackson, Mich. H. D. Cutting, Sec., Clinton, Mich.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

SELECTIONS FROM OUR LETTER BOX

Abundant Honey Crop.—C. Theilmann, Theilmanton, Minn., on July 13, 1888, writes:

Bees did not do much until within ten days. They have been swarming at a great rate, and filling up their hives with honey, and placing considerable in the sections from the white clover, which was, and is still, abundant; but it has not yielded much the last few days. Alsike and red clover are the sources where my bees get most of their honey at present. Linden is just opening. It looks healthy, but only about one-fourth of the trees have buds. The weather is nice. We have a heavy hay crop here this season.

Join and Help the Union.—J. E. Breed, M. D., Embarrass, Wis., writes:

I send my dollar and vote for the Bee-keepers' Union, and wish I could stir up the bee-men to join and help. It is a shame that they do not! Well, I am busy, though I am sorry to say I am rather shaky, and getting on in years; I cannot do much in a day, though I am always astir, and never idle. I have lots of "irons in the fire"—a little office physic, lots of bee-watching, and some work. What with watching and reporting for the United States Signal Office, company to visit with, and a garden, etc., I have little time to lounge. Bees are doing well, and the season is favorable.

No Honey Taken Yet.—G. S. Heckman, Monroeville, Ind., on July 14, 1888, says:

The honey crop in this (the eastern) part of Allen county is almost a failure. The northern part of Adams county, Ind., and the western part of Van Wert county, O., is the same. I have about 20 colonies of bees, and have kept them from swarming, which was hard to do, as they gathered just enough to make them "cranky." I have not taken off a pound of honey yet, although I have sections on every hive, and they are partly finished. I have been a specialist for 14 years.

Placing the Hives—Spraying Swarms.—O. B. Barrows, Marshalltown, Iowa, on July 16, 1888, writes:

On page 438, in Query 556, it is asked if it is "necessary to put colonies as near as a foot apart; and will virgin queens on returning to the hives be likely to enter the wrong ones?"

I have five rows of Concord grape-vines, each about 70 feet long, and 6 feet apart; between these rows of grapes I keep my bees. I began about 16 years ago with 2 colonies, and I now have 84. I have had 98 colonies, and until two years ago, my hives were all made after one pattern, and nearly all of them were painted white. They were often placed less than one foot apart, and in all this time I have never had reason to believe that one queen was lost by entering the wrong hive.

There are other objections to placing hives as close, if it can be avoided, and there can be no harm resulting from painting the hives different colors. It may amuse the bee-keeper, and can do no harm to the bees, to tack red flannel and other distinguishing marks on the hives. Nor does the

beating on tin pans and ringing bells do the bees any harm when they swarm. I have a pipe run right in among my colonies with hose attached, and a pressure from our water works, of 40 to 60 pounds, and have given the spraying a pretty fair trial, and now I am inclined to think that it did no good in causing the bees to cluster.

Bees are booming on basswood, and if it lasts a few days we will get some surplus; but if it stops now, we will be no better off than last year, unless we get a fall crop like we did six years ago.

Bees are Booming.—Moses Bailey, Winterset, Iowa, on July 16, 1888, says:

The bees are booming in my yard, some 50 colonies, and more coming. My health having been poor for the last two years, my preparations for the bees are behind somewhat, but I am in a pretty fair way to be up with them soon, Providence permitting.

Results of the Season so Far.—Abe Hoke, Union City, Ind., on July 15, 1888, writes:

I will now make my spring report. As reported last fall, I had 23 colonies packed on the summer stands in the best style that I could possibly put them, though one colony was queenless, which I expected to lose; but it began to "hibernate" in early winter, and is there yet. The balance of the bees came through to April in good condition, but then the trouble commenced. I had 6 more colonies queenless, and some that had unmated queens, all of which I had to double up with the others; the rest came through the winter in splendid condition, and at fruit-bloom one-half were strong enough to go into the sections, as they were storing honey in the brood-nest very fast. But in the middle of this jubilee we had rain; the wind shifted north, northwest and northeast, and remained until the bloom was gone. Bees made no more than a living up to about June 13; from that time to July 1, I do not think that I ever knew bees to gather honey so fast as they did for that brief space of time. What they got it from I could not tell, as our white clover was all dead, being killed by last year's drouth, or last winter, as we had very little snow. Up to this time I have had an increase of 3 swarms, one I made by division, and two natural swarms. I am ashamed of this report, but nevertheless it is a stubborn fact. If I get as much surplus honey this year as I did last, I will feel better than I do to day.

Colonies Starving, etc.—Mr. D. R. Rosebrough, Casey, Ills., on July 17, 1888, writes:

Bees are starving to death. It is very gloomy. I have not had a swarm for two years, and it looks as if it is going to be a failure this year. My bees wintered in good condition, but the spring was cold, and they did nothing until the middle of June, and then was honey dew; the bees just hummed on that until it began to rain, and then the honey-dew was gone. Starvation commenced then, as the queens had filled every part of the combs with eggs, when in a short time after, the young bees commenced to hatch out, and there being no white clover (as it all died out last fall, on account of the drouth) they had nothing to work on.

A man lives near me who had 2 strong colonies, and they looked as though there was a bushel of bees in each hive. Two weeks ago yesterday I was there, and he told me that his bees were being robbed, as the ground was covered with bees. One colony was dead, and half of the other. They did not have a drop of honey, and the

bees were in wads lying around as though they were numb. I told him that they were starving; after giving them some honey, they went to drawing the dead bees out of the hive, and clearing up the hive. I have heard, for the last week, of the bees swarming out and leaving their hives, so I am safe in saying that one-half of the bees have died in this township since spring opened. It will take feeding to bring them through till Spanish-needle and buckwheat bloom appears; and then if my bees get enough to winter on, it is all I will ask for this year.

In some parts of this county, where there was any linden in reach of the bees, they are in good condition, but I am out of the range of linden, there being but five trees near my bees, and when they were on them it sounded like a swarm passing over the trees. Our main crop is white clover; it looks well, but it had to come from the seed, and will have no bloom to speak of this year.

Lend a Helping Hand.—Mr. T. E. Turner, Sussex, Wis., on July 14, 1888, says:

I deem our Bee-keepers' Union as very important to the general interest of bee-keepers in America. I do hope that more bee-keepers will see the need of such an organization, and lend a helping hand by each one forwarding his \$1.00 membership fee. If only one bee-keeper is aided in defending himself against the enemies of our pursuit in each year, the general interest of all bee-keepers is subserved, and the use of the small sum (\$1.00) each, annually, is justified, and much more.

Honey from the Linden.—Mrs. L. Harrison, Peoria, Ills., on July 13, 1888, wrote thus:

There has been a hard, quick shower of the nectar from basswood (*Tilia Americana*). It was like the passing of the "Salvation Army" with drum and fife, singing to martial music, "Marching on, Marching on," until the sound died away in the distance. It made me think of the fast trains on the Pennsylvania Central railroad during the Centennial year, that scooped up the water at stations without stopping. This "flying train" left in its wake every cell and cradle full of delicate nectar; no time for building cells now, even if the bees had the material, for the "flying train" passed with a puff and a blow, singing, "Hasten on, hasten on." I wanted to share with the bees some of this delicious sweetness, and got out the almost forgotten extractor. I knew there was not a spoonful of honey when this angelic visitation came, so it would be unmixed. I could not wait for it to be sealed, oh no! so with a few turns of the extractor, my eyes were gladdened once more with delicious nectar pouring out of the spout. I lied cheese-cloth over the top of the receptacles to keep out insects, and put it out in the sun to ripen, with the mercury at 100° in the shade. A way back in the seventies, Dr. Geo. Lucas lived in this city. He was an enthusiastic bee-keeper, and planted basswood trees, both the American and European varieties, and gave to his neighbors to plant, until an entire square is surrounded with this magnificent tree. He emigrated to Nevada, and shortly after fell dead from the back of a horse, but he left a grand monument behind him. Every year these trees are dressed in beauty, and offer up sweet perfume in grateful remembrance. Peace to his ashes. Go and do likewise.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4x4x4 and 5x5x4. Price, \$1.00 per 100, or \$8.50 per 1,000.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

CLUBBING LIST.

We Club the American Bee Journal for a year, with any of the following papers or books, at the prices quoted in the LAST column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 18 cents per pound for bag and postage.

Honey and Beeswax Market.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 13@15c.; the same in 2-lbs., 10@11c.; buckwheat 1-lbs., 10c.; 2-lbs., 9c. Market dull. We are doing all we can to reduce stock, to make room for the new crop.

BEEWAX.—26c. HILDRETH BROS., 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—We quote: White to extra white comb, 12¼@15c.; amber, 8@11c. Extracted, white to extra white, 5¼@6c.; amber, 4¼@5c. Arrivals of the new crop are small, the estimates being an average crop.

BEEWAX.—20@24c. O. B. SMITH & CO., 423 Front St.

DETROIT.

HONEY.—Best white in 1-lb. sections, 14c.—Dull. BEEWAX.—23@24c. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—We get 15c. per lb. in a small way for best comb, and less for of grades. Extracted, best white, 7@9c. None of the new crop received yet, but there is more than sufficient of the old crop for the light demand.

BEEWAX.—22c. R. A. BURNETT, 161 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 12c.; fancy 2-lbs., 10@11c.; fair white 1-lbs., 10@11c., and fair 2-lbs., 8@9c. Buckwheat 1-lbs., 7@8c. The demand is dull for comb but fair for extracted, of which new from the South is arriving, and sells for 55@65c. per gallon.

BEEWAX.—Dull at 23¼@24c. Jun. 15. F. G. STROHMMEYER & CO., 122 Water St.

CHICAGO.

HONEY.—No white clover left in this market. Dark clover sale at 8@10c. Extracted ready sale on arrival. New crop will meet with good demand.

BEEWAX.—23c. S. T. FISH & CO., 189 S. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb., for which demand is fair. Comb honey, 12@15c.—Demand slow.

BEEWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.

July 11. C. F. MUTH & SON, Freeman & Central Av.

MILWAUKEE.

HONEY.—Choice white one-lb. sections, 14@16c.; 2-lbs., 13@14c.; 3-lbs., 12@13c. Extracted, white in kegs and ½-barrels, 8@9c.; in tin and pails, 9¼@10c.; dark in barrels and kegs, 6@8c. Demand good for extracted, but dull for comb.

BEEWAX.—22@25c. A. V. BISHOP, 142 W. Water St.

DENVER.

HONEY.—Best white 1-lb. sections, 14@15c.; 2-lb. sections, 12c. Extracted, 6@7c. BEEWAX.—20@23c.

Jun. 25. J. M. CLARK & CO., 1409 Fifteenth St.

KANSAS CITY.

HONEY.—We quote: Choice new 1-lb. sections in good demand at 15@16c., not glassed; dark ones not searched; 2-lbs and extracted there is no demand for. Stock of old honey's light, and the sections are all glassed, which style the trade do not like.

BEEWAX.—None in market. Jun. 30. HAMBLIN & BEARSS, 514 Walnut St.

BOSTON.

HONEY.—We quote: 1-lb. sections, 14@16c.; 2-lb. sections, 12@13c. New Florida extracted, 8@9c. Sales are very dull.

BEEWAX.—25 cts. per lb. July 5. BLAKE & RIPLEY, 57 Chatham Street.

SAN FRANCISCO.

HONEY.—We quote: Choice new extracted, 5 to 5½c.; amber to light amber, 4@4½c. Choice comb in 1-lb. sections, 13@14c.; 2-lbs., 12@13c. Arrivals are small, as apiarists are holding back. Prices are considered high.

BEEWAX.—18@22c. Jun. 25. SCHAUCHT & LEMCKE, 122-124 Davie St.

KANSAS CITY.

HONEY.—We quote: White 1-lbs., unglazed, 15c.; 1-lb., white, glazed, 14c.; dark, 1-lb., 2c. less. California, 2-lbs., comb, white, 13c. Extracted, 7c. Considerable old honey is in this market. No new yet in. Sales are very slow.

BEEWAX.—None on the market. June 9. CLEMENS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—We quote: Extracted, bright, 5@5½c. dark, 4½@5c. in cans, 7@8c. Comb, choice white clover, in prime order, 13¼@15c.; dark, less. Market quiet with fair demand for extracted.

BEEWAX.—22c. for prime. Jun. 27. D. G. TUTT & CO., Commercial St.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. Aug. 1, 1888. No. 31.

EDITORIAL BUZZINGS.

The Bee-Keepers' Advance and Poultrymen's Journal has now swallowed the *Poulter*. It is nicely printed, and well gotten up. It is a matter for congratulation that all the bee-periodicals are now well printed—presenting a vast improvement in a dozen years.

J. W. Bittenbender, of Knoxville, Iowa, has sent his foundation fastener for brood-frames, and one for sections, to be exhibited at Cincinnati, O., at the Centennial Exposition, and after that to go to the National Museum at Washington for permanent exhibition.

Bees to Manitoba.—We learn from our Canadian cotemporary for June 20, that Mr. D. A. Jones, of Beeton, Ont., has made a shipment of 50 colonies of bees to Manitoba, to a point beyond Winnipeg. This is the greatest distance to which so large a shipment has ever been made. The bees were sent in combination hives, by express, and a practical bee-keeper went in charge of them.

More Recruits.—E. Lovett, Bernardo, Calif., on July 17, 1888, thus expresses himself about the National Bee-Keepers' Union:

I hope that our membership will increase during the next term. I will try and get two or three friends to join us, as it is to their interest as well as ours. If each of the members can get a friend to join and double the membership, we would then be in a better position.

Yes; that is just what every member should do—get another recruit. By so doing they are conferring a favor on the *new member*, because such a person is fully as much interested as an older one.

More "Wiley" Nonsense.—The editor of the Danville Daily *News* of July 7, contained an item stating that "comb and honey are made by machinery." Mr. J. P. Faurot, of Hope, Ills., replied to it on July 24, and showed that the story had no foundation except in the imagination of Prof Wiley. The editor of the *News* follows it with this paragraph:

We wish to do no injury to any honest industry. Our statement was, that honey-comb is made by machinery, and also honey (so-called), which is a fact. It is this fact, well-known to the people, which injures the producers of real honey, as the fact of adulterated tard, buckwheat, butter, and a long line of foods injures the producers of the real articles.

Mr. A. R. Simpson, of State Line City, Ind., sends us the paper, desiring the Union to take the matter in hand, and to demand the *proof* for the glib assertions of the *News* editor.

The Manager of the "Union" has written to the *News*, demanding the proof for the assertions—asking how he knows it to be a fact, etc.? Has he seen it? If so, where and when? Of course he is but another dupe of "the Wiley lie." The injury done by that nefarious "pleasantry" is enormous, and to bee-keepers it is very UNPLEASANT.

The Officers of the Bee-Keepers' Union are all re-elected—the exact figures we shall be able to give next week. Mr. R. F. Holtermann, of Brantford, Ont., thus expresses himself concerning the Union:

Probably no better staff of officers than the old could be secured; certainly the Union has firmly and consistently carried out, through them, its object; at the same time avoiding unnecessary litigation, which is very desirable. Whilst the officers of the Union have so ably done their work, I am afraid bee-keepers at large have not done their part, but I trust a heartier response will be forthcoming during the coming year.

Yes; it is surprising that the membership is less than ten thousand—but we imagine that a good honey year would show an enormous increase.

Wax Adulteration.—Sometimes beeswax is adulterated, but not often, for it is so easily detected. An exchange remarks that when earth or meal is used to sophisticate it, the wax becomes brittle and grayish, and may be detected and separated by melting the wax, when the impurities may be strained out. Resin makes the fracture smooth and shining instead of granula, and may be dissolved in cold alcohol, while the wax remains untouched. Tallow or suet renders the wax softer, and gives it an unpleasant odor when melted.

Mr. Jas. Heddon says: "Basswood bloomed well here, but yielded only about one-eighth of the usual crop. Clover was a total failure. The crop is light, but what there is will sell readily at good figures."

The Union.—James McNeill, Hudson, N. Y., on July 23, 1888, when sending his vote and fee for the National Bee-Keepers' Union for the ensuing year, remarks as follows:

It seems like an imposition to ask you to continue to perform the duties of General Manager, which, I doubt not, imposes considerable additional labor upon an occupation which you already find quite engrossing of your time and energy. But the Union has been so eminently successful in your hands, that I hope you will find sufficient compensation for the extra labor which the Union imposes upon you, in the thought that you have earned the hearty commendation of all its members.

Brother McNeill is right. We have more to do than we ought to undertake, but regarding it a *duty* to continue to conduct the Union's business, we cannot say No, when such a unanimous vote is given for us.

The Canadian Bee Journal, to which Prof. Wiley sent an explanatory letter concerning "the Wiley lie," and complaining of attacks being made upon him, etc., gives a good editorial answer in these words:

To make the statement which Prof. Wiley did without sufficient foundation, even though it did emanate from the authority which he says in his letter, was very wrong; and very much harm has been wrought by it to our common industry. The least that the author of the statement could have done would have been to have corrected the erroneous statement as soon as it was brought to his notice, instead of which, this is the first intimation that we have seen wherein he gives his authority for what he wrote as far back as 1881....

His delay in not before setting the matter before the people in its right light is sufficient cause for violent attack. He should have taken pains to have first ascertained the effect such a statement as the one he purposed making would have on the bee-keeping industry at large. While we give the above communication space, yet we incline to the opinion that bee-keepers will put just about as much faith in this letter as they did in his former one—which wasn't much.

The Professor need not look to bee-keepers for sympathy. They have suffered enough both in mind and purse from the effect of his nefarious "scientific pleasantry," so-called.

Open-Side Sections.—On page 467, we noticed the open-side sections of Mr. Walter S. Ponder, of Groesbeck, O. In reference to that "notice," Mr. Ponder remarks thus:

In regard to my new open-side sections, permit me to say that they can be used in the T-super, or any other super, and still be open-side sections. Please refer to the sample again; also, that they can be made of one piece just as well.

To be of any value, of course these sections *must* be made in the popular "one-piece" style. This can be done, as Mr. Ponder says. We had not put the section together when we wrote the item—having now done so, we see that Mr. Ponder is correct about their use in the supers. They are very well made, and smoothly finished.

GLEAMS OF NEWS.

Honey Prospects.—A correspondent writes us in the following very disconsolate manner:

Not a swarm from my apiary consisting of 100 colonies, and not a tea-spoonful of surplus honey this year. At least 50 of the hives are running over with bees ready for the harvest, but clover is gone, basswood is fast passing away, and the only hope now for honey is from buckwheat and fall flowers.

Apropos to this doleful account is the following from the *Bee-Keepers' Record*, concerning the season in England:

Our anticipations of an early yield of honey have not been fulfilled, and we have to record an exceptionally backward state of things in all that pertains to surplus storage. Colonies which had made splendid progress all through the month of May, have some of them perceptibly fallen off in strength, while others have barely kept up their condition of a month ago, and the complete dearth of nectar, coupled with cold nights and dull, cheerless days, have caused bees to desert surplus chambers previously being well pushed forward. It is a long time since we can call to mind a more irritating state of things from a bee-keeper's view than has been experienced during the past three weeks, in fact all through June. Sometimes we have had several bright, sunny days in succession completely lost to the bees through a steady, cold northeast wind blowing the whole time.

A forcible illustration of the way in which adverse weather militates against bee-keepers has just occurred to ourselves in this way: Within a minute's bee-flight of our apiary, was an eight or ten acre field of what should have been oats, but which, owing to the thick undergrowth of Charlock, or wild mustard, has for many days been a perfect sheet of beautiful yellow bloom, so dense that the unfortunate farmer gave up as hopeless all idea of clearing it. He was gazing at it sorrowfully one day as we passed, and could not help observing, with just a little bitterness, "this will suit you bee-keeping gentlemen, won't it?" "Come, come now John," we replied, "you know we didn't plant it, but it just shows that 'it's an ill-wind that blows nobody good,' that's all." Of course we fancied that a very marked increase to our crop would result from the close proximity of such a magnificent bee-garden, but the "ill-wind" (northeast) blew so persistently while the bloom lasted, that all this sweetness was wasted, and only on two days did the bees work on it at all.

Of the season in Scotland, the same paper remarks as follows:

The month of June has hitherto been exceptionally cold. The second week opened with unprecedented snow-storms—in some parts 6 inches of snow was reported. Since then we have scarcely had a night free from frost, and this is the 20th of the month. The consequence has been in not a few instances the death of colonies from starvation, and in many the adult bees only saved themselves by devouring the juices of the grubs. The apply of pollen previously obtained having been unusually large, colonies that were syrup fed during the cold spell, kept on advancing in strength, and on the whole are not much behind usual.

Up till now we have seen no preparation for swarming. Most of our colonies are occupying two stories, one being nearly full of brood. Until honey comes in more freely

we shall not use any sections. From other districts we hear complaints of backwardness, swarms being still reported "early" in the newspapers. Highland bee-keepers should look forward to a full heather bloom, which is ensured by the fine rains we have had already, and which will probably be early.

Concerning the season in Ontario, the *Canadian Bee Journal* remarks as follows:

At this date we have nothing encouraging to say as to the prospect of the entire season's crop. Up to this time the take has not been large, and as the dry weather continues basswood will not likely amount to much. In some localities there has been a fair amount of yield from clover—Muskoka has not done badly. Waterloo has come out with a medium crop, as have also the southern counties. Simcoe has nothing to boast of, as far we can learn. On the whole, there will not be over one quarter crop.

The price will, however, be in proportion, and we strongly advise all who have honey to sell, and who can do so conveniently, to hold it until the fruit season is over, and then to ask a reasonable price for it, commensurate with the supply.

If "misery loves company," it may have considerable of it this year—for, on the whole, so far, it has been the poorest of all the poor years immediately preceding it. But such comes occasionally to all pursuits, and is usually followed by a booming season, so that we may reasonably expect such a refreshing time next year. Let us hope that its realization may be duly and promptly enjoyed.

Swarm of Bees in a House.

This is how a newspaper reporter "dishes up" an item for the press concerning the antics of a swarm of bees:

While S. S. Brown, of Long Island, was at lunch with his family, the doors and windows being open, a swarm of bees entered and made themselves at home on the furniture and brie-a-brac, and inspected at leisure the food on the table.

Mr. Brown, his two daughters, and a friend from New York, who had precipitately retreated from the house, rallied some of the neighbors and returned. The bees being still in possession, a counsel of war was held.

Some wanted to attack them with noise, and some with brimstone, while others argued that brimstone would make fearful odors, and a terrible mess with dead bees. Loud shouts, pounding on pans and kettles and all that sort of thing, would possibly result in the enemy making a bayonet charge that would be disastrous.

It was decided to give them a little more time, and the family found refuge in an adjacent building. Some of the neighbors finally got tired of this, put covering on their faces and hands, built fires in the grates, covered the chimneys and smoked out the visitors.

The buzzing began to increase again, and the bees migrated. It has not been ascertained where they came from, or where they went to. The walls, ceilings and curtains of Mr. Brown's residence were considerably soiled by the insects. The number of bees is estimated to have been between four and five thousand.

The Augusta, Georgia, National Exposition for 1888, opens Oct. 10, and closes Nov. 17.

The *British Bee Journal*, our esteemed cotemporary in London, was deceived by the statement of the Dairy Commissioners of New Jersey, in reference to the adulteration of American honey, as shown on page 387 of the *AMERICAN BEE JOURNAL*. The matter receives attention in the last number of our *British cotemporary*, in this manner:

Our article was written in the interest of bee-keepers and bee-keeping, and we have never hinted that bee-keepers ever adulterated honey, and we should repudiate such an idea quite as strongly on behalf of our American cousins as our friend the *AMERICAN BEE JOURNAL* does. . . . Our object is to protect the interests of bee-keepers, be they English, American, or of any other country, and we should not be doing our duty if we did not expose what we knew was doing them harm. If it is shown that the whole thing is a hoax or a trick of trade, we shall give it every publicity.

We have no desire to prolong this discussion, but will say that we are very glad to learn that the *British Bee Journal* desires to protect the interests of American bee-keepers—which, from its former articles, we were led to doubt.

Still Another.—In the *Farm, Field and Stockman* of last week we notice this:

Of the several hundred samples of honey examined at a late meeting of the St. Louis Society of Microscopists, not one was imitation, but the majority of them were adulterated with such stuff as glucose, grape sugar, etc.

The State chemists and microscopists are apparently making a raid on honey just now—to try to crush its use, and drive it out of the market. It is very sure that they are talking of something they know nothing about.

The fact is, that honey produced on different soils and under various climatic conditions, differs so much in its constituent parts that no one can with *positive certainty* decide upon its purity.

This fact accounts for all the floundering among the chemists and microscopists when they attempt to decide on the purity of honey.

To believe the assertions made by this St. Louis Society, we must admit that more than one-half of the honey on the market is adulterated, very many of the honey-producers and all the honey dealers are frauds!! A thing which will be utterly repudiated by honey-producers universally. They may not be *more honest* than other men, but they certainly are *not more* fraudulent. We know hundreds, and perhaps thousands, who would *rather die* than to perpetrate frauds upon innocent purchasers of their products.

A lazy, careless, slovenly Person will fail in bee-culture as in everything else. There can be no harmony or feeling of sympathy between such a person and this marvelous insect, whose name, for ages past, has been emblematic of industry. So says an exchange.

Honey Crop of California.—Mr. J. S. Harbison, the celebrated apiarist of southern California, was interviewed by a reporter of the *San Diego Union*, relative to the report about a large crop of honey being gathered this year in that State.

The report in the *Commercial Bulletin* was represented as being derived from conversations with men prominent in business circles of California, and the substance of it was that honey is going to be cheaper and more plentiful this year than ever before. Particular attention was called to San Bernardino and San Diego counties, where it was reported that honey had opened at low prices, and that $3\frac{1}{2}$ to 4 cents would be the maximum price.

This report, Mr. Harbison said, was, to say the least, a most remarkable statement, probably written in the interest of brokers' firms, and is a fair specimen of a "bear trap." He then added:

The truth is, that not one-half as much honey will be gathered this year as has been in some years past. The spring bloom, which should yield one third of the total crop of the year, has gone by, and it yielded but little honey. Owing to the long-continued cold weather, the bees in the mountain ranges had hardly made a living up to June 1, and now only about 60 days remain for the flowers and the storing of honey.

Even if the weather is favorable from this time on, the honey gathering cannot be large. Another reason why the report referred to must exaggerate the amount of honey in this season's crop, is the fact that there are not at present half so many bees in southern California as there were six years ago, and the supply of sage and other honey-furnishing shrubs has been diminished at least 50 per cent. by the clearing up of land.

Moreover, the low prices at which honey has been sold for some years past have destroyed the incentive to care for and work the remaining bees to their full capacity, and the supply this year will not glut the market.

Arrangements have been made, however, for the handling of the honey crop in this county, which will insure better returns to the producer than they have received in years, and the honey industry here be stimulated.

A Swarm on a Man's Hat.—Mr. E. C. Jordan sends us the following from the *Record* of July 19, 1888, published at Rustburg, Va., as a supplement to the circumstance mentioned on page 468:

Mr. W. E. Ballard, in conversation with us about the bees swarming on the cow's back, told a little of his own experience. He was in a field with several other persons when a swarm of bees came over. They resorted to the usual methods to induce the bees to settle; ringing bells, beating tin pans, etc. Mr. Ballard soon found the bees settling on his hat. He did not like the proximity, so he quietly took off his hat and laid it on the ground. The whole swarm soon settled upon it. They were hived and taken home.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

INTERROGATORIES.

Hill's Device.—H. S. Ball, Granby, Quebec, on July 19, 1888, asks thus:

Will you inform me through the AMERICAN BEE JOURNAL the best device for putting over brood-frames, to give space above the frames for wintering. How much space is required? How is this device constructed?

Hill's device for covering frames in winter is placed over the frames and under the cushions, and forms a chamber for the bees to cluster in, and permits them to pass freely from one comb to another, even during a shady zero freeze. It consists of four pieces of half-inch basswood strips sawed on a curve that would make a circle of about 11 inches in diameter; the two middle ones being 9 inches in length, and the two outer ones 8 inches. These are held together by a strip of hoop iron about a foot long, holding the ribs about 4 inches apart. The hoop iron runs parallel with the brood-frames.

No Nectar in the Flowers.—Henry Stewart, Prophetstown, Ills., on July 19, 1888, makes this inquiry:

Are there any scientific principles known in reference to the formation of nectar in flowers? If so, why under the apparent favorable circumstances, has the white clover and other honey-producing plants yielded so little bee-forage?

Unfavorable atmospheric conditions, as well as the direction of the wind, often account for the lack of nectar in the flowers. Rain also will apparently wash out the nectar from the opening buds. Last season's drouth dried up the clover in many parts, and the weak and sickly growth of this spring yielded no bloom worth mentioning—now it looks like blooming again.

What Ails the Bees?—Mrs. Ada Dorsey, Holliday, Mo., on July 18, 1888, asks the following question:

What ails my bees? In search of queen-cells to cut out, yesterday, I found that four of my young colonies of bees were diseased. I do not know what the disease is. The old bees are well, and working right along, but the uncapped brood are dead in the cells, and the bees do not seem to be cleaning them out. Please answer through the BEE JOURNAL, as it may benefit some one else as well as myself.

It is evidently what is usually called *foul brood*. Remedies were considered in our issue of July 18.

Foul Brood.—P. M. Aldrich, Fairmont, Nebr., on July 19, 1888, asks the following question:

About three-fourths of the bees in this vicinity have died from foul brood; and in Grafton, seven miles west of here, quite a number of colonies died last year. I think that the hives were left on the stands, not knowing what had killed the bees; and nearly all are dying this year. I watched

mine, and those near me, and killed and burned them as soon as I found it in a hive. Please tell me if I did right. Do you think that there is a cure? I have not seen a sign of it among my bees this season. I had 25 colonies left from 60 last year. They are swarming and doing finely now.

You did just as we should have done, upon discovering the disease in our apiary. We have but little confidence in the so-called cures for foul brood. The editor of the *Canadian Bee Journal*, giving his experience with foul brood, says: "Last season we experimented with phenol, as did also Mr. A. I. Root, and neither had the success which would enable us to recommend it as a permanent cure. It did relieve, and to a certain extent cure, the colonies afflicted, but we could not depend upon it as lasting."

Mr. A. I. Root says that if he should own a small apiary and discover foul brood in it, he would burn up the whole rather than endeavor to experiment in curing the disease. If the larvae be elastic and rosy, it is a sure indication of foul brood. This is a sure test, but the odor is not to be relied upon. Fire is our favorite remedy.

Lost Twenty Dollars.—The Rev. John Nemmers, of Gilbertsville, Iowa, on July 14, 1888, gives a little of his experience in these words:

If I had subscribed for the AMERICAN BEE JOURNAL two months sooner, I would be \$20 better off than I am now; and if I had sooner known what a good and instructive paper the BEE JOURNAL was, I would have been a subscriber long ago.

The experience of our reverend brother is but a counter-part of hundreds of others, who lost money by not knowing what was going on in the apicultural world, by not taking the AMERICAN BEE JOURNAL.

A Californian, in *Gleanings*, says that a sick man planted a little hoar-hound, intending to use the product in making tea for the cure of his ailment. Wind and water and sheep have scattered the seed abroad, and the plant flourishes far and near. The writer says his bees have access to it, but complains that the honey they make is strong, dark, granulates easily, and is bitter. He offers his honey at five cents a pound. Possibly the hoar-hound honey may be utilized by hoar-hound candy makers, and for medicinal syrup with that flavor.

The Tri-State Fair (Ohio, Michigan and Indiana) opens at Toledo, O., Aug. 27, and closes Sept. 1. Dr. A. B. Mason is superintendent of the Aplyry Department. The premiums amount to \$87.00. Those interested should send for a premium list. Address, John Farley, Sec., 209 St. Clair St., Toledo, O.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

QUERIES AND REPLIES.

Terrible Mortality of Bees in Winter.

Written for the American Bee Journal

Query 564.—During December, January and February of the winter of 1884-85 I lost 700 full colonies out of 900, located in five apiaries. Some were dead without breaking the cluster, and others had their noses up all around the lid, and were scattered all over the hive. The frames and combs were badly smeared with excreta, where there were a few bees and queen left. I closed them up on what frames they would cover, but they nearly all either swarmed out on the first nice spell, or dwindled so low that they died in the cluster during slight cold spells in March and April. The winter of 1885-86 was the same, with 600 colonies. The winter of 1886-87 all of 400 colonies came through to February. They commenced dwindling then, and went down one-third, leaving the balance weak, and although I had plenty of good combs and honey, I could not build them up. The past winter has been the same. I have some 15 or 20 colonies that have withstood all these winters, and have come out good every time, under the same conditions. 1. Have you had this experience? 2. What is it? 3. How can I stop it?—Illinois.

I have had no such experience.—P. L. VIALLON.

I have had nothing like it.—G. M. DOOLITTLE.

It would take a book to answer this. Read the articles on wintering bees.—DADANT & SON.

That is a puzzle. I give it up.—C. H. DIBBERN.

1. No. 3. I do not know of anything to say in reply, unless to go over the whole ground covered by books and papers, and you probably have all that.—C. C. MILLER.

I am unable to divine the cause or suggest a remedy. Go to some good bee-man near you, and see if he cannot help you solve the problem.—EUGENE SECOR.

1. No. 2. Diarrhea, and very bad management. 3. Construct a good bee-cellar for each apiary.—Mrs. L. HARRISON.

1. On a much smaller scale, yes. 2. I cannot answer unless I knew all the conditions. 3. I have lost but very few colonies except by starvation since I have left the entrances wide open all winter.—M. MAHIN.

1. I never experienced the loss of 1,300 colonies in three winters, but I have had "frames and combs badly smeared with excreta," etc. 2. That was diarrhea. 3. It can be stopped by giving proper food and the right temperature. Read what the AMERICAN BEE JOURNAL has said on this subject during the last three years.—A. B. MASON.

1. From your description I am forced to the conclusion that your bees gather honey that is not suitable for winter-

ing. I would try removing it, and feed granulated sugar syrup. 2. It is bee-diarrhea.—J. M. HAMBAUGH.

1. No. 2. If all the other conditions are favorable, it is the result of unwholesome honey. 3. Extract all fall honey, and feed granulated sugar syrup.—J. P. H. BROWN.

1. No. 2. I should think that your trouble was in the honey. 3. Feed sugar syrup to a few colonies, and see if it will not make a change.—H. D. CUTTING.

1. To some extent. 2. The common trouble—diarrhea. 3. By giving the bees sound stores for winter, and wintering them in a cellar with a temperature of about 40°, Fahr.—R. L. TAYLOR.

1. Yes, I have. 2. It is bee-diarrhea. Bees never spring dwindle when they are entirely free from that complaint. 3. You can prevent it by having no bee-bread in the combs which the bees winter on, nor any honey, but properly prepared sugar syrup, instead.—JAMES HEDDON.

3. I believe that a good cellar would stop it—a cellar where you can keep the temperature above 38°, Fahr. I believe with a proper cellar and proper food we need have no loss.—A. J. COOK.

I would get a stock of bees from some one who has not been troubled in this way. I would rid myself of these old bees entirely. I would not ask, "What is it?" It does not pay to doctor bees. Get rid of them, and get healthy ones. If they become diseased in the same way, change the location.—J. M. SHUCK.

Mr. Heddon will say, "Pollen theory." Some one else will give another cause. For myself, I can only say that I do not know, as the data given is not sufficient to enable me to give an intelligent answer. For a guess, I should say the cause was either insufficient food, or food of poor quality.—J. E. POND.

The only thing peculiar about your disastrous wintering of bees is found in your statement, that "15 or 20" of your "colonies have withstood all these winters." This would indicate, at least apparently, that the constitution of the bees had something to do with the different results. Please give us the particulars. What sort of stores did they have? How were the bees prepared for wintering, etc.? 1. No. 2. Echo answers, "What is it?" 3. That is the question.—G. W. DEMAREE.

We should surmise that the cause could be located in the winter stores. To extract all the honey in the fall, and provide good sugar syrup would probably prevent a repetition.—THE EDITOR.

Wet and Moldy Combs in a Bee-Cellar.

Written for the American Bee Journal

Query 565.—In my bee-cellar I am very much troubled with the combs getting wet and moldy. The temperature does not vary much above or below 40°. 1. Would sub-earth ventilation improve it? or would it be best to put in a stove? 2. If sub-earth ventilation would be a good thing, how far ought the pipes to extend under ground?—H. H., Ills.

I have no experience in this.—P. L. VIALLON.

We would use a stove in the coldest weather, or not use the cellar at all for bees.—DADANT & SON.

I think that sub-earth ventilation would answer. Fully 50 feet—more would be better—and below the reach of frost.—J. P. H. BROWN.

1. Put in a small stove, and use open boxes of air-slacked lime.—H. D. CUTTING.

Raise the temperature to from 45° to 48°, by some means, and you will be all right.—G. M. DOOLITTLE.

1. Either or both might help. 2. Two hundred feet, if the pipes are 6 inches or more in diameter. If 4 inches in diameter, 100 feet long.—C. C. MILLER.

1. I presume that sub-earth ventilation will benefit your cellar. 2. I am not authority on this. Correspond with Mr. G. M. Doolittle.—J. M. HAMBAUGH.

Thorough drainage and ventilation will do it. For the purpose mentioned, sub-earth ventilation is not necessary.—A. J. COOK.

If your bees winter well, I advise you to leave your cellar as it is. If the mold frets you, give the bees more ventilation from the bottoms of the hives, and raise the temperature of your cellar 4° or 5°, by packing the outside windows, etc., better.—R. L. TAYLOR.

1. I should put in the stove. 2. I am not in favor of adopting sub-earth ventilation. It costs more than it amounts to.—JAMES HEDDON.

1. Yes, I believe it would. If that is too expensive for the number of colonies kept, use artificial heat. 2. Two hundred feet would be desirable, but perhaps a shorter distance will answer.—EUGENE SECOR.

Dampness is a common condition of cellars in this (Kentucky) climate. No doubt but the changeable condition of climates is the cause. When the air outside of the cellar becomes warmer than the air contained by the cellar when it enters the cellar and comes in contact with a lower temperature than itself, it parts with a portion of its moisture by condensation, and thus

dampness accumulates in the cellar. I. No. Put in a stove and heat up the cellar to a high temperature about once a week. Keep up the heat for a whole day, and then leave the bees quiet till next time. Some experiments of mine have proven this plan the best of all to counteract the deadly effects of continued dampness, etc.—G. W. DEMAREE.

I. Sub-earth ventilation would improve it, and without knowing the conditions and surroundings of your cellar, I think that I should prefer it to a stove. 2. It should enter the cellar under the outside wall, and cross to the opposite side of the cellar.—Mrs. L. HARRISON.

Raise the temperature. I like to ventilate with a stove, without a fire. Of course, if the temperature is too low, have a small fire. A little looseness around the pipe where it goes into the chimney does for upper ventilation, and the draft at the stove's bottom does for lower ventilation.—A. B. MASON.

I. It may be that sub-earth ventilation would be an advantage. 2. That depends upon circumstances. If it is easy to keep the temperature up to what it ought to be, the pipes may be very short.—M. MAHIN.

I. You say nothing about hive-ventilation. I have never found that moisture injured where hives were properly ventilated. 1. Do not put in a stove. 2. Extend the pipe far enough so that the temperature will not be affected.—J. E. POND.

1. Sub-earth ventilation will improve it very much. The temperature is all right. 2. The pipes ought to extend 50 to 100 feet. Do not put in a stove, as it is difficult to keep an even temperature without great trouble.—C. H. DIBBERN.

1. Ventilation is needed wherever there is mold. Such a cellar should be disinfected by the fumes of burning sulphur before putting in the bees for winter; and if the rooms over it are inhabited by human beings, it should be fumigated *often* during warm weather, unless corrected by ventilation. 2. A sub-earth pipe should extend 150 to 200 feet under-ground.—J. M. SHUCK.

Either the addition of a stove, ventilation, or good drainage will remedy the difficulty. Outside protection will raise the temperature in the cellar, and make it more suitable for the bees.—THE EDITOR.

CORRESPONDENCE.

FINDING QUEENS.

How to Proceed when Looking for the Queen.

Written for the American Bee Journal
BY G. M. DOOLITTLE.

Many seem to be troubled in finding the queen, not a few writing me to that effect, and asking how I proceed in that work.

One of the most important things to be remembered in looking for a black or hybrid queen is, not to use too much smoke so as to get the bees "crazy," so that they will run pell-mell all over the hive, and even outside of it; for with such a state of affairs no one is very likely to find the queen, and the hive might as well be shut up without trying.

Go to the hive and remove the cover as quietly as possible, so as not to disturb the bees the least bit, if you can do so. Now as the quilt is raised, blow the least bit of smoke under it, and after it is removed, keep for a moment or so, blowing just a little smoke on the guards as they poke their heads up over the tops of the frames—just enough to turn them about again, and no more. In this way you will soon have all quiet and nice, no running or anything of the kind.

Having thus brought them into subjection, you are ready to proceed; but before doing so, I wish to say that there is a proper time of day to do this hunting for the queen, and that time is governed by the way the hive is placed, or faces. As my hives all face south, we will suppose that we are in my bee-yard, and in such case the time will be at from 11 to 12 o'clock. Now, why this? Simply because at this hour the sun shines so as to obliquely strike the east side of the combs, as these run with the entrance to the hive.

One other thing: As the sides of any queen is much more yellow than her back, a queen is much more easily seen when looking obliquely on her, than when looking squarely on the comb or on her back, and as she walks about, while looking at her in this manner, her abdomen is sure to attract our attention, thereby causing us to see her when we would not otherwise do so. Having explained this matter so, I think, all will understand it, we will take out the first frame next to the east side of the hive, standing or sitting on that side.

For various reasons I prefer to sit down when hunting for the queen,

chiefly because it brings the eyes in a more natural position for seeing over the combs.

To get the first comb out, if the hive has not a movable side, commence four or five frames away from the side next to you, and with a heavy knife or screw-driver loosen the frames, pushing them a little from you so as to gain room to lift out the first one without injuring the bees so as to irritate them. Whenever the bees come up on the frame tops in a threatening manner smoke them a little, gently as at first, thus keeping them in subjection, yet at no time give enough smoke so as to thoroughly frighten them. A little experience along this line will enable one to handle even the most vicious hybrids without stings or getting them excited.

Having the first frame liberated, gently raise it from the hive, looking over the side next to you as it comes out, for the queen, and as soon as it is out look over the other side, by looking down obliquely from the top. Having made sure the queen is not on this frame, put it down outside the hive, or have another hive to place it in. In time of robber bees, the hive is best, throwing a sheet over it to keep the robbers off this exposed comb, but at all other times I put the combs on the ground outside of the hive.

Now remove the next comb, and as quickly as it is out of the hive, glance down the face side of the comb next to you in the hive, and if the queen is on that side of the comb, you will surely see her, for her first impulse is, upon the light striking her, to get on the other side of the comb, and in doing this she shows herself to a much better advantage than she would if she kept still, the sunlight making her appear "as natural as life, and twice as big."

As soon as satisfied that she is not there, look on the other side of the comb you hold in your hands the same as before, and if the queen is not found, put this also in the hive with the first, or on the ground.

Now proceed with each frame as you did with the last one, bearing in mind that there is no need of looking at the side of the frame next to you after it is taken from the hive; for should you miss seeing the queen when looking down on the comb as it stands in the hive, she would, if there, get around on the inner side before you got to taking it out.

After two of the combs are out of the hive, I usually set the next on the side of the hive the colony occupies, which is next to me, for with two frames out, the sun can shine down between the combs as well as if more were out. In this way it is a

rare thing that I miss a queen in going over a hive, but if I do, I never try longer at that time, but close the hive and try again when the sun is right another day.

To show what can be done, if the above course is pursued, I will say, that in six hours, during the middle of the day, I have found and clipped the wings of 40 black and hybrid queens, for a party who had concluded that he wished his queens' wings clipped; and I have reason to believe that any one can do as well after a little practice along this line.

To keep the sun just right, wheel the hive around a little, one way or the other for the time being, where you have to work five or six hours at a time.

Borodino, N. Y.

SAVING HONEY.

Removing Queens to Save Honey Consumption.

Written for the American Bee Journal

BY ALEX. W. STITH.

As nearly all persons now seem to be desirous of something new, I will describe a method by which an apiarist may secure (or rather, save) many pounds of honey, and at the same time not injure a colony of bees, and as far as my knowledge extends, this idea originated entirely within myself.

It would be almost as reasonable to permit a number of harvesters to remain boarding with us, after the harvest is over, as to have a surplus of bees reared during the latter part of June, and the first part of July, which bees will only answer as consumers instead of producers, as bees at this time of the year will only create a home market for honey, in the way of consumption in rearing brood, which is only necessary at certain intervals during the season.

All practical bee-keepers in Kentucky well know that here our surplus honey is usually gathered in a period of about six weeks, and after this time has elapsed, a surplus of bees is only detrimental to the welfare of a colony of bees, as well as to the apiarist. To obviate this difficulty, about the middle of June I kill all of my queens that are three years old, and such others as do not exactly fill the bill, regardless of age; and for those that I wish to retain, I prepare empty hives of sufficient size to accommodate three frames of brood.

I then remove the queens from the old hives, together with three frames of combs containing brood and ad-

hering bees, and put them into new hives or nuclei. The colonies from which the queen are taken will at once proceed to build queen-cells; and those colonies should be examined every ten days, and all queen-cells destroyed; at the same time exchange with them a comb of brood and eggs, taken from some of the small, or nuclei colonies, containing a queen, to prevent the appearance, or presence, of fertile workers, which often infest colonies that are long queenless, without the necessary material, such as eggs or larva, from which a queen can be reared; and as the queens in the nuclei have only use of three combs, consequently only a limited amount of brood can be reared.

I let the queens remain as described for a period of six weeks, and at the end of this time, the queens can usually be introduced to their future habitation, by placing the three combs, queen and all together, near the center of the hive, provided, however, there are no queen-cells remaining in the old hive at the time of introduction, or, for a certainty, the queens may be caged for 24 or 36 hours. The only objection that could be urged against such procedure is, the extra labor in manipulating, but I have experimented far enough in this line to be thoroughly convinced that the amount of honey thus saved will richly repay the apiarist for the necessary labor required.

In order to make the matter more plain to the reader, suppose that we figure a little, and that an apiarist has 50 colonies of bees, and that by the method above described, one pound of honey per colony is saved each day that they are thus queenless, which is surely a very low estimate; and allow one week of the time for most of the brood in the old hives to be sealed, and say they are allowed to remain queenless for 5 weeks or 35 days. Now 50 colonies at this rate would in 35 days save 1,750 pounds of honey, which, at 10 cents per pound, would amount to \$175; and counting \$50 expense for nuclei hives, \$15 for extra labor, and say \$10 for perhaps a loss of a few fine queens, it will be seen that we have the nice little sum of \$100 left by the experiment.

The first thing that drew my attention to the perceptible difference in the amount of honey in the hives that remained queenless for weeks, and those that had queens, was made manifest to me as a queen-breeder, by removing queens for the purpose of queen-rearing; and I am so honestly convicted that if the above described method be strictly adhered to, the most fastidious will be convinced.

Portland, Ky.

BEE-SENSE.

Bees do Select a Location Before Swarming.

Written for the American Bee Journal

BY GEORGE POINDEXTER.

Having hunted bees for more than thirty years, and started my apiaries from the wild bees captured in the forest, I am armed with experience and observation enough to satisfy me that bees do locate a home before leaving the parent hive; and also after they do leave, some will go direct to the tree or hive that has been cleaned out by the scouts. I have given them chase direct to the tree, cut the tree within half an hour, and found the hollow clean and varnished with propolis.

Some swarms leave, not knowing anything of a future home, and will fly until tired out, and alight on any object that comes in their way; but if exposed to the hot sun or rain, they will get up again and go to a more favorable place. Then in obedience to the instinct imbued within them by nature's law, they leave the cluster in almost every direction, by the hundreds, in search of a home. Then they will be found cleaning a half-dozen different places at the same time, but they will accumulate the strongest at the most favorable hollow, and when the swarm "breaks camp," a quart or more of bees will be found hanging where the swarm had left; these are the scouts that were clearing other trees, and not knowing the location of the swarm, they stay there until they dwindle away and finally disappear.

Some swarms alight on a limb of a large tree, in a fence-corner, or in a grape-vine, and being full of honey before the scouts find a suitable location, they start combs, and then the scouts cannot entice them to go, as the queen has laid a few eggs. I have found bees in all of these places, but I have never found any honey in such combs; yet I have thought they sniffed the battle from afar off, and never thought it worth while to gather any honey except for present use, as they would only leave it for the raccoons to enjoy.

I have transferred them to frame-hives, from their open-air hive, and in 2 or 3 days the combs would be full of honey. Some swarms will clean out a hive with the intention of swarming, but the weather or honey-flow will make a change in the programme. I have seen scouts clean out a hive and stay at the entrance for 3 or 4 days, evidently waiting for the decision at home, and if any intruder comes

around on the same mission, they pounce upon her, and by physical force settle the question of priority of location.

Kenny, Ills.

SHIPPING-CRATES.

Historical and Practical Consideration of their Use.

Written for the American Bee Journal
BY JAMES HEDDON.

After we have procured the best white, hard wood sections, another main factor in the successful marketing of comb honey is, to clean those sections from bee-glue, and place them in such crates as will show them to the best advantage and most perfectly protect them, from the time they leave the hands of the producer until they are removed by the retailer or consumer.

Soon after the invention of sections, the "necessity" for a shipping-crate for them, became the "mother of invention" in that line, and the first we knew, Mr. Doolittle, or some of his neighbors, had made, used and described a crate for holding them. I sent for one. It came as described, rather roughly made of pine, and the following is a description: It was made to hold twelve two-pound sections, which were placed endwise with the case, four in a row sidewise, and three in a row endwise. The tops and bottoms were rightly made of $\frac{3}{8}$ material of proper size. The end pieces were about $\frac{5}{8}$ of an inch thick, if I remember correctly, nearly square with the grain running horizontally. The sides were composed each of two slats about $\frac{3}{8}$ of an inch thick, and an inch and a quarter wide, the ends of which were nailed to the ends of the end pieces at their upper and lower corners.

Now, to get in the glass, saw-cuts were made in the corners of the end-pieces, and a pane of glass as large as the whole side of this crate was slipped down in this groove. Hand-holds were cut with a wabble-saw in the end-pieces of the crate. No sooner did I look at it, than improvements suggested themselves. These short end-pieces, wabble-sawed almost in two, might, if the material became checked or got a bump, come in two while carrying honey, and of course the remaining whole end would give away at once, and down would go the contents. The slats on the sides of the crate were so narrow that they showed more of the honey than was necessary, or than was sometimes best to show to make the best impression on first sight.

I made the side slats wider. "Why use so much glass?" said I. "Then I

made the saw-cuts in the slats instead of in the end pieces, using about half the amount of glass. I think this was the first time glass was ever slid into the slats instead of the end pieces. This soon became popular. It made the case more solid and nicer in appearance, and with less expense.

Next I began to use pound and half-pound sections of varying widths as follows: Six to the foot, seven to the foot, and eight to the foot, and "coined" the term of so many "to the foot." I made half-pound sections the same height as the pound, and just $\frac{3}{8}$ the width; not thickness of the comb, but width of the comb. For instance, a wide frame which held just four one-pound sections seven to the foot, would take six half-pound sections seven to the foot. The half-pound sections over-run, while the pound sections fall short in weight, but this is all right, especially where they fall short.

We always sell all sections by weight, both at wholesale and retail.

Crate for Shipping Comb Honey.

This led me to make another alteration, which was to make the sides of the crate whole, placing the slats and glass in the ends by making slats half inch thick, and having the bottom and cover flush with their outer edges, they serve for handles. When we handle such a crate, the combs are always run to and from the body just as they should, and the crate is in the best shape to handle.

The engraving shows the crate described, which is $12\frac{1}{2}$ inches long, $8\frac{3}{8}$ inches wide, in the clear, and takes five different sizes of sections, all of which fit perfectly. It holds twelve sections $4\frac{1}{2} \times 4\frac{1}{2} \times 2$, or six to the foot; 14 sections $4\frac{1}{2} \times 4\frac{1}{2}$ by seven to the foot; 16 sections $4\frac{1}{2} \times 4\frac{1}{2} \times 1\frac{1}{2}$, or eight to the foot; 21 sections $4\frac{1}{2} \times 2\frac{1}{2} \times 1\frac{1}{2}$ by seven to the foot; 24 sections $4\frac{1}{2} \times 2\frac{1}{2} \times 1\frac{1}{2}$ by eight to the foot.

The reader will see that this crate was not only a radical improvement in its simplicity and cheapness, but likewise in its strength and convenience. The crate is just as long as our storing cases are wide, and should it ever happen that a whole row of sections, by accident, become "grown" together, they could be taken out *en masse* and be put into this crate. Although we have never had a case of the kind, we have seen such in other apiaries.

A minor mathematical convenience arises from the fact that just one storing-case fills two shipping-crates of honey. One-story crates are best on account of any possible leakage, and one of the great advantages of this small crate is, that any quantity of honey is sold direct from the producer or jobber to the consumer. Make these crates of white basswood, and dress all parts on both sides, so that they are handsome without, and easily wiped within, in cases where any leakage occurs.

The material for these cases of the quality I mentioned, will in most localities cost about 10 cents each in the flat, and the glass about a cent per light. Of course these figures will vary according to the location of the manufacturer. I have found less trouble from breakage, the smaller I have made my shipping-crates. I think I can safely say that in past years I have shipped more than 50,000 pounds of honey in these crates, and

have never had any breakage whatever, except two crates, which were promptly paid for by the railroad company. By freight is the cheapest and safest way to ship. I am confident that this style of shipping-crate now used by so many of our leading producers, will not be soon superseded by any other.

Dowagiac, Mich.

BEE-KEEPING.

Fogysm and Fertile-Brained Reporters its Injurers.

Written for the American Bee Journal
BY HENRY K. STALEY.

Within the last decades, what business or pursuit has had a greater development and metamorphosis than that of bee-keeping? Commencing with the old primeval gums, and going through the various kinds of hives, until finally culminating for a time in one glorious achievement, viz: the invention of the reversible hive, with its concomitant fixtures. This hive, like Eli Whitney's cotton-gin, is a great time-saver—especially to those who are pursuing apiculture as a bread-and-butter pursuit.

Down in the dingy cellar of Mrs. Green, Eli Whitney toiled nearly all winter, tinkering away on his invention, until he finally machinated the cotton-gin. It has been said, that to get one pound of clean cotton, without wasting any, used to require a whole day's labor; but Whitney's cotton-gin, instead of taking a handful at a time, could take bushels, and do more work in one day, and neater at that, than 10 men could do in 20 days. Hence it has been well said, "The Southern seaports were heaped high with cotton," which, but for him, would never have been grown. And so with respect to apiculture, we can say that the invention whereby the manipulation of hives instead of frames can be had, will render the saying,

"Full many a flower is born to blush unseen,
And waste its sweetness on the desert air,"

untrue to a great degree, albeit it is a poetic jewel.

Invention of the Movable-Frame Hive.

The firm beginning of this vast transformation was made by one stroke, and that was the invention of the movable-frame hive, which, with its paraphernalia following soon after, put bee-keeping upon stanch feet, so that it could become a pursuit capable of giving a person a livelihood, and followed as a money-making occupation, thereby catering employment to thousands of people over our grand and glorious globe.

Yet, within the shadows cast from the burning and light-giving lamp of bee-lore, prevails the oozy, green-scummed, stagnated fogyism, accompanied with sophisticated stories anent bees, emanating from the fertile brains of reporters (fabricators of coek-and-bull stories), who, in their mind's eye, see honey-comb fabricated from paraffine, filled with honey obtained from the parings of rotten apples, and capped over with a red-hot poker, just as the bees do it; and yet they say these things in the face of great rewards, offered to any one who will find the place—but, alas! it seems that it never can be found.

Persistence of Fogy Bee-Keepers.

The old fogy still persists in keeping bees in box-hives (maintaining that in the manipulation of frame-hives many bees are killed), who, if his cerebellum had any power at all toward taking all sides into consideration, would find his idea ridiculous nonsense, when compared with the thousands of bees lost annually by box-hive bee-keepers during the interval of the swarming season. Moreover, he cannot remedy the *lusus naturæ* among his bees, control the queen, clean out moth-worms, and so forth; and yet they still use

box-hives (fit breeders for the confounded bee-moth), following in the path trodden by their great, great granddaddies, who, if they went to the mill with the grain in one end of the sack, and a huge stone in the other, to balance it over their shoulders, still seem to believe in following out by not becoming cognizant of the great and useful modern inventions in our pursuit.

Fogyism is a ban to bee-keeping, because many uninitiated, when they embark in that pursuit, through it are caught up into the flexible web of ignorance, and failing to see their mistake, continue in it. It is the coadjutor of fertile-brained reporters—the bunko-steers of apiculture. They feed their taffy (made-up lies) to the open-mouthed ignoramuses, who stand like gawkies and "take it all in," as corn-cracker farmers are bamboozled in the city of Cincinnati. The consequence is, the rumor—that comb honey (the partitions between the cells being 1-180 of an inch thick) is made by hand—flies like wild-fire through our cities, magnetizing and surfeiting on all the compatible material that it can find, becoming more and more portentous as it goes. Its journey is well described in the way Virgil did the supposed nuptials of Dido and Æneas, thus:

Extemplo Libyæ mognas it Fama per urbes,
Fama, malum qua non aliud velocius ullum,
Mobilitate viget, virisque adquirit eundo;
Pars metu primo; mox sese attollit in auras,
Increditus que solo, et caput inter nubila condit.

Think of it, in the United States (where, during the year of 1884, 20,297 patents from the Patent Office at Washington, were issued), such ignorance should continue! Fogyism is a drawback to the process of inventing in bee-keeping, the which (inventing) is breathing dephlogisticated air under the sickly ribs of umquhile apiculture, and through its arteries sending renewed strength to every branch thereof. The limners (inventors) of our pursuit have already environed its head with the nimbus of fame, and placed the aureola of glory around its body; but nevertheless we cannot expect the end desired to be gained in a second.

Hardships and Triumphs of Inventors.

"Procrastination is the thief of time," and until we collar him we must take our dose of being jeered at as other inventors. It was thus with poor Johnny Fitch, who devised and invented the steamboat. He was rich in genius, but penury so held him under its sway, that one day, in a crisis of his invention, he said, that "if he could get £100 by cutting 'one of his legs, he would gladly give it to the knife." He was the man by whose discovery people now in a week's time can be transported over the briny

deep, Arctic explorers penetrate within a few miles of the North Pole; and yet he was made the recipient of jeers, and pitied as a bedlam. Cast down and broken hearted, the *finis* of this grand character, I am sorry to say, was suicide, by taking 12 opium pills. This is the way many benefactors of mankind are treated; and it is the same in apiculture as in other pursuits.

Herr Von Hruschka should have at least a line on the tablets of our memories indelibly stamped; but, lo! how few are they who ever knew the name of the inventor of the "Mel Extractor!" A man who made it possible to obtain honey in a liquid state, clear and pure, free from the juices obtained by squeezing the heterogeneous mass of comb, cocoons, larvæ, bee-bread and young bees, should not have his name left to oblivion.*

How our own inventors have laid awake at night, thinking over and picturing in their minds their inventions, even into "that hour, o' night's black arch the key-stone," I leave it to the bee-keeper's fraternization to judge by the above paragon. These men, above all other men, ought to be remembered; they are the time savers who have willingly used up their time so as to save time for others.

How to Dispose of Fogy Bee-Men.

Why then should we not, since we live in a country of which Joseph Hutton says: "Ten years in the history of America is half a century of European progress," wipe out fogyism and the fertile brains of reporters, which together make up the vile monster to our pursuit? A regular Polyphemus stalking through the land. *Monstrum horrendum informe ingens cui lumen ademptum*—"If its eye be not out, let us take it and end the agony."

Although his body is strong and corpulent, and in his hand an enormous bole he twirls, yet like the sparrow to the crow, in the long run we can exhaust him, and pry out that eye in the middle of his forehead, and thus render him *hors de combat*. But is it being prided out by publishing the "extemporaneous descantings and unpremeditated expatiations" of old fogies? No! and it never will be in that way.

Instead of talking so much about the ways of fogies, apiarists who have such men in their vicinage, should take them to their apiaries—for "a pound of fact is worth a ton of theory"—and show them with what alacrity they manipulate their hives, how to control swarms, how to obtain nice, white, comb honey, and eradicate that idea of theirs concerning the manufacturing of it by some New York firms.

It seems to me that those firms must be very occult, or else hidden away in

obulietts, and so magnificently pent up that a lynx-eyed detective is not able to find one iota of it, even with a \$1,000 reward behind him. It is a shame for that "eye" to remain there while inventors are painting the cheeks of bee-keeping a rosy hue, and giving it a healthy appearance. Let every bee-keeper do as above, and it will have a great tendency toward stopping and checking the canards and malicious statements circulated about bees, grapes and honey.

"Ignorance is the mother of accidents," and as Garfield said, "Secession, the tocsin of eternal war;" therefore, while people remain in ignorance of (dabblers especially—for "a little knowledge is a dangerous thing"), secession to modern apiculture lies will not cease; but since our strong arm is mailed with the thunderbolt of truth, we ought to cast all scoundrels down to the vile dust from which they sprung, or else set them on higher planes.

But as we look up the corridor of generations yet to come, yea of centuries, let us furtively hope that those inhabitants who patter upon the proscenium bee-life, and toss about the ball of bee-keeping, will render the saying, "How slow a judge is time," untrue in this particular occupation, by means of the great inventions produced by the leading geniuses of the day.

Pleasant Ridge, Ohio.

*[The invention of the honey-extractor by Maj. Von Hruschka, was detailed on page 89 of our book entitled, "Bees and Honey,"—the first edition of which was published ten years ago.—Ed.]

HONEY-CRATES.

Convenient Crates for Comb Honey, etc.

Written for the American Bee Journal
BY LESLIE STEWART.

The weather is quite warm and rather dry, although it shows some signs of rain to-day. Basswood is just beginning to bloom, and it looks as though we would get some surplus honey from it. Although we will not have a very large amount of blossoms, it may be all that the bees can attend to.

White clover has not yielded much honey, and it is now failing fast. I obtained about 20 pounds per colony of extracted honey. There were but few sections of comb honey that were full enough to take off. I think that the bees have enough to winter on, which is pretty good for this season.

My extracted honey is nearly all sold at home, but the comb honey I prefer to ship to cities, as I do not like too much retailing.

Small Crates for Comb Honey.

The small crates are becoming very popular with me, as they answer for what the groceryman calls "family crates," meaning a crate that just suits a customer; and they sell a great many in this way, especially to the wealthy class, as the style and size just suit their fancy.

These crates are made to hold 12 one-pound sections, and as they are cheap, I would advise all bee-keepers to try a few of them, and see for themselves. They should be made of the finest quality of white basswood, and when filled with nice honey, they will attract the attention of every lover of that luxury.

The crates also are very handy for the city people who come out in the country to spend the summer months; they nearly always want some honey to take home with them, and are usually bothered to carry a large crate. Honey put up in these crates is less liable to get broken. I shall use them altogether this season.

Jefferson, N. Y., July 19, 1888.

HONESTY.

A Dishonest World Concludes that all Persons are Alike.

Written for the American Bee Journal
BY WILLIAM KLINTWORTH.

In almost every business, we find dishonest men. Men that are honest often have to bear, and are looked upon as dishonest by other men that are in the same business. Bee-men are accused of manufacturing artificial honey—yes, even comb honey.

I was passing a house last winter, and saw bee-hives and honey in great quantity. I went in to see the honey, and where it came from. I was informed that it came from New York State, and that he had bought some at 6 cents per pound. It was selling at 15 cents per pound. Some of it was the worst looking honey I ever saw. The proprietor said to me that they were making artificial honey now. I said that they could not make comb honey. He said they can adulterate almost anything. They can make chicken eggs that would hatch, but the chickens would not have any feathers.

Then you claim that they can make comb honey like you have there? "O, nicer looking than that. You are away behind the times."

I told him (for the crowd were taking sides with him) if he would furnish me with a pound of artificial comb honey, I would find a man that would pay him \$1,000 for it.

Now, how do people get such impressions? I think that comb foundation is one cause. People in general know nothing about bees. They have heard something about comb foundation being made, and as they do not know anything about bees and their nature, they get the impression that comb honey is being made; and when they get some poor honey, they think that it is artificial.

A man said to me last summer, "I got some honey and we can't eat it." I asked him where he got it, and he said, "at the grocery." I went there and saw some honey that was brought by a farmer. The store-keeper saw me looking at his honey. He said, "That is nice." I told him that some one told me that he had honey that was not good. "O!" said he, "that was some that I bought from a drummer, and only paid 6 cents per pound for it." Honey at that time was selling at 25 cents, and the farmer that sold the honey there had to bear the blame of the poor honey that was mixed with his.

Another person told me that her daughter went to market and got some honey. She said, "I never saw such stuff. It looked like coal tar. It must have been artificial. We put it in the slop-bucket, as we could not eat it." Now, I wonder if the person that sold it in the first place thought that it was good, or even fit to eat. But we see and hear too often that people will sell such things as they will not eat themselves.

I often see where bee-keepers have explained how they work up a home trade, and can sell all their honey at home in their town. If we are honest, we will not have much trouble in selling. If I sold honey to a party—honey that is wormy, or is not as good as I represent it to be, could I sell them any again? I think not.

A woman lectured at the Farmers' Institute last spring, on this subject: "All men and women are liars." There is some truth in that. For instance, we have some honey to sell. It is not very good. We know that, but we want to sell it for a number one article—yes, for the best. The party that buys, gets a poor article. We have lost our reputation for being honest.

For the first colony of bees that I bought, I went to a bee-yard, and looked all around. I saw different kinds of hives. I saw a box that suited me. I said to the man, "What will you take for that hive?" He took his pencil and commenced figuring

thus : Box, so much ; comb, so much ; bees, so much ; and queen, so much. The bees were black, but I wanted Italians. The man said he would put in an Italian queen. I said, "Suppose she does not mate right." He said he would put in another. I took the hive and bees at his price, thinking that I had pure Italian bees, but after a time I saw that I had yellow and black bees mixed.

I afterward said to the man from whom I had bought them, "The bees live longer than you said;" for I had black ones from last fall, that I got of him. So one day he came and looked at them. I pointed to some old ones. He would not acknowledge that they were old ones, but he did not explain how it came to be so. Now, why did he not tell me that the queen did not mate all right? I might have asked for another queen.

If we would do to others, as we wish others to do to us, we would have just as much money, and I know we would be happier, and would not complain about some things.

SELECTIONS FROM OUR LETTER BOX

Circassian Bees as Honey-Gatherers.—J. W. Tefft, of Collamer, N. Y., on July 18, 1888, wrote as follows :

Our bees are doing finely so far. The Circassian bees are gathering nearly double the amount of honey of any race or breed of bees that I have ever seen. They are truly wonderful, now that I have got the honey from them. I only wish that I had more of them. The Italians are nowhere compared with them for prolificness, hardness, honey-gathering qualities, gentleness, and on all points they are a superior type of bees. I have taken, from one colony, 47 pounds of honey, and they yet have 72 one-pound sections two-thirds finished, and 12 solid frames of brood, 10 by 15 inches. I also have taken from the same colony 17 frames nearly full of brood, and given them

to a queenless colony which I keep, in order to see how much one queen will do during the season. What in the world would Mr. Doolittle do with such queens in his nine 11 by 11 frame hives? He would condemn them as worthless as honey-gatherers, for they would swarm a dozen times during the season.

Should the honey-flow continue as it has been, I should have some great stories to tell the coming winter. I am not the owner of all the bees that I have the superintendency of, but I am for the Circassian bees. Every bee-keeper in this neighborhood is delighted with this strain of bees.

Bees are Doing Well.—Mr. T. C. Whiting, Athens, N. Y., on July 23, 1888, writes :

My bees are doing well. I had 2 colonies this spring, and I now have 7 very fair colonies. One I am afraid is worthless, but I will try to build it up. I shall experiment with it a little. This is my second year with bees, and I have all the bees I want. Next year I shall work more for honey. I expect to have 100 or more pounds of comb honey this year. I do not work for anything else.

Young White Clover, etc.—S. J. Church & Son, Cedar Rapids, Iowa, on July 23, 1888, writes :

The past winter and spring our loss was two thirds of our bees. The middle of June we had 37 colonies left from 110 put into the cellar last December. Our first swarm issued on June 24. We are just through getting honey from basswood. There has been no honey in the white clover, but we hope there will be next month. The young clover looks nice and promising.

White Clover in August.—G. R. Fox, M. D., Sandyville, Ohio, on July 19, 1888, writes :

I have had 10 natural swarms from 6 colonies, but so far I have had very little surplus honey. There is a good prospect for white clover bloom in August, and we may have a fair yield of honey yet. For the last 10 days there has been plenty of rain, and all vegetation is growing rapidly. It was too wet during the linden bloom, and the bees could not work.

Good Prospects for a Fall Crop.

—J. W. Bittenbender, Knoxville, Iowa, on July 18, 1888, says :

White clover and linden is over, and the surplus honey is not 5 per cent. of an average crop. Clover bloomed well, but it was mostly in June. It did not secrete any nectar. Linden bloom secreted nectar, but our heavy rains fell during its bloom. We had heavy rains every few days. The prospects for a fall crop are good.

Chapman Honey-Plant Worms.

—Geo. Kirkpatrick, New Paris, Ohio, on July 20, 1888, writes :

I notice on page 468, Mr. L. Highbarger says that those who have the Chapman honey-plant should examine it closely, as there is a worm that is cutting the balls off. The same worm worked on my plants. I sprayed them with Paris-green, which destroyed them. My plants are from 3 to 5 feet high, and have from 30 to 60 balls each. They began to bloom on July 13. I am so well pleased with the plant that I shall save

all the seed. I wish that I had 10 acres of it. I have seen as many as 27 bees on a single ball at one time, and I have seen as many as 17 bees visiting a single blossom in one minute. I am quite sure that the average number of visits made by the bees all day long is not less than 5 per minute ; and as they work on it from daylight till dark. I know of nothing better. I have covered a few balls with paper, and in 24 hours I could see a large drop of nectar in each cup.

Death of E. W. Landon.—M. A. Williams, Berkshire, N. Y., on July 20, 1888, writes as follows :

It is with regret that we announce to the readers of the AMERICAN BEE JOURNAL the death of our brother bee-keeper, Elmer W. Landon, of Brookton, Tompkins county, N. Y. Mr. Landon was one of the most extensive bee-keepers in this part of the State, and will be greatly missed by his brother bee-keepers. Inclosed please find a notice taken from the *Ithaca Journal* of July 13 :

OBITUARY.—In the sudden death of Elmer W. Landon, on Friday of last week, the society of Brookton and vicinity sustained a shock as severe as it was unexpected. He had been seriously ill for several days, but was supposed to be improving until within an hour of his death.

Mr. Landon was born in this community, and during the 29 years of his life, had, by his filial and fraternal affection as a child, his genial nature and conscientious deportment as a youth, together with his business enterprise and integrity as a man, endeared himself to all in the domestic, social and business circles of which he was a member. His anticipated marriage at an early date, fills to overflowing the measure of sadness connected with the event of his death.

His burial took place from the Congregational church on Sunday at 11 a. m. The choir, of which he had long been a member, could render no music on that occasion. The large concourse of people in attendance, and the universal expression of sorrow apparent, betokened the esteem in which he was held, and the profound sympathy felt for his family and friends by the community.

Metal Rabbet.—J. F. Latham, Cumberland, Maine, sent some metal rabbet, and wrote us as follows, on July 20, 1888 :

I send by mail a piece of the metal rabbet which I use on my hives. It is different from any that I have ever seen, and I think better than the single strip.

[It is a T tin with one of the edges usually bent to the angle of a square, left straight with the double fold. The two single edges form one angle of a square, and fit over the inside edge of the hive where the frames rest, and can be nailed fast on the top and side. It is certainly quite an improvement, because the frames have a double thickness to rest on, and a smooth edge instead of a sharp, single surface to cut the fingers, when baulding.—ED.]

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4 1/4 x 4 1/4 and 5 1/4 x 5 1/4. Price, \$1.00 per 100, or \$8.50 per 1,000.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in Cheshire's pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being available, it must be sent by express.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

CLUBBING LIST.

We Club the American Bee Journal for a year, with any of the following papers or books, at the prices quoted in the LAST column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

Cork for Winter Packing.—Its advantages are that it never becomes *musty*, and it is *odorless*. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2 00	3 00	3 50
1,000 Labels.....	3 00	4 00	5 00

* Samples mailed free, upon application.

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; 1/2 pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 18 cents per pound for bag and postage.

Honey and Beeswax Market.

NEW YORK.
HONEY.—We quote: Fancy white in 1-lb. sections, 13@15c.; the same in 2-lbs., 10@11c.; buckwheat 1-lbs., 10c.; 2-lbs., 9c. Market dull. We are doing all we can to reduce stock, to make room for the new crop.
BEESWAX.—26c.

HILDRETH BROS.
May 21. 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

ST. LOUIS.
HONEY.—We quote: Extracted, dark, 4@4 1/2c.; bright, 5@5 1/2c.; in cans, 7@8c. Comb, white clover in prime condition, 13 1/2@15c.; dark, 11 1/2@12 1/2 cts.—Market quiet and demand fair, owing to the warm weather.
BEESWAX.—22c. for prime.
July 26. D. G. TUTT & CO., Commercial St.

“The Battlefield of Gettysburg: Its Memories and Memorials,” is most interestingly treated in *Frank Leslie's Popular Monthly* for August. The famous points of the great battle, the visits paid to it by the commanders and by officers and soldiers of both armies, the monuments that now mark the ground where regiments held their own under withering fire—all these come before the reader vividly. “Life in Pompeii” is depicted by pen and pencil. “Striking a Light,” “Lightning Photographed,” stories, adventures, and a continuation of Clarence M. Boutelle's absorbing novel, “The Grave Between Them,” make up a most attractive and seasonable number to while away many a pleasant hour, and give topics of conversation.

New Subscribers can obtain the full numbers for 1887 and 1888, for \$1.75, while there are any sets of 1887 left.

Scatter the Leaflets.—Look at the list (with prices) on the second page.

EDITORIAL BUZZINGS.

Father Langstroth, in acknowledging the receipt of our nite subscribed to the Annuity Fund, expresses himself thus to all who have helped to ameliorate his latter day infirmities:

I cannot well express how much the kindness of my bee-keeping friends has done to make me comfortable in my old age. Your kind wishes make what you sent me the more acceptable.

He concludes his letter thus: "May we all meet at last in that blessed fold from which no friend ever departeth." This sentence will strike a responsive chord in every true heart, for he is one of the best and most God-like men we ever met. To spend an eternity with such, is worth the "battle of life."

Prodigious Stories are being told every day by the sensational news-mongers, but the following sent to us by a correspondent, is "about as bad as they make them." It is from the *Omaha World*:

Honey made in California is shipped through Omaha to Philadelphia to be extracted from the comb and then shipped back to Omaha and sold to consumers with freights both ways added. This is what is called progress.

The exclamation of our correspondent was, "What a liar!" or something of that import, and we do not wonder at it. There is not the slightest foundation for such a statement. They have honey extractors in California, and know how to use them! They ship extracted honey by the car-load and ship-cargo to all parts of the world, and in fact at least three-fourths of the honey crop of California is extracted. It is a "prodigious yarn"—nothing more!

The Union.—The election just held under the Constitution has resulted in the re-election of the former officers, as will be seen by the following, which gives the vote in detail: (There were 140 votes cast; necessary to a choice, 71.)

For President—James Heddon, 105; G. M. Doolittle, 10; Prof. A. J. Cook, 8; Dr. C. C. Miller, 6; Dr. A. B. Mason, 3; W. Z. Hutchinson, 2; G. W. Demaree, 2; A. I. Root, 2; and Thomas G. Newman, 1.

For Vice-Presidents—A. I. Root, 133; Prof. A. J. Cook, 130; Dr. C. C. Miller, 127; G. M. Doolittle, 126; G. W. Demaree, 124; James Heddon, 17; Dr. A. B. Mason, 8; Charles Dadant, 5; Eugene Secor, 4; J. E. Pond, 4; W. Z. Hutchinson, 3; 2 each for R. L. Taylor, Dr. G. L. Tinker, Thomas G. Newman, Henry Alley and E. France; and 1 each for Mrs. L. Harrison, L. C. Ront, Geo. E. Hilton, Oliver Foster, Chas. F. Muth, John Aspinwall, A. E. Manum, P. H. Elwood, J. M. Shuck, C. H. Dibbern, Dr. J. P. H. Brown, T. F. Bingham, and John H. Martin.

For Secretary and General Manager—Thomas G. Newman, 135; Eugene Secor, 4; and Dr. C. C. Miller, 1.

While the General Manager would have been pleased to have seen a new set of officers elected—just to exhibit an interest in the organization—still he would also say that the President and Vice-Presidents have all worked so harmoniously for the general welfare, that it would be next to impossible to find those who would have done better, and we presume that the members of the Union have concluded that they could not better show their appreciation of what has been accomplished in the past, than by re-electing them for the ensuing year. Let us hope now that thousands of bee-keepers will join the Union, and thus make it more brilliant and successful than ever.

Approved.—Our old friend and former co-worker, Mr. A. J. King, of New York, for ten years or more editor of the *Bee-Keepers' Magazine*, writes very appreciatively of the *AMERICAN BEE JOURNAL* and its management, as well as the *Bee-Keepers' Union*, in the following manner:

You have not only kept "abreast of the times" in this industry, but in your own, and the efforts of your widely extended staff of contributors have served to continually break up new ground. This, together with the increasing success of the National *Bee-Keepers' Union*, and the "soft words" but "hard arguments" used in its support, must command the respect, and should secure the support of all right-thinking bee-keepers. Wishing you the largest measure of success in all ways, I remain your old friend and former co-worker,
A. J. KING.

Crop Reports generally are very flattering, and of the honey harvest, the interest is centered on the fall crop from the autumn bloom. Now that promises well where such flowers abound.

The North American Bee-Keepers' Society will meet at Columbus, O., on Wednesday, Oct. 3, 1888, and continue as usual in session for three days. Dr. Mason wrote to the Rev. L. L. Langstroth relative to his attending the meeting, and his reply was as follows, dated July 16, 1888:

My health is not such as permits me to plan much for the future. If possible I will be present at your meeting, and will make some suggestions as to what can be done to revive an interest in bee-keeping among farmers. The excitement of the last convention I attended at Detroit, was too much for me, and I had a severe attack soon after my return home, which lasted nearly two years. I am always, when well, glad to be among bee-keepers, and I shall be specially glad to see again your genial face.

Your friend,
L. L. LANGSTROTH.

Dr. Mason sends us the following concerning the exhibit of honey and apiarian supplies to be made there:

Preparations for the honey exhibit at the Ohio Centennial Exposition at Columbus, Sept. 4 to Oct. 19, are being made, and we hope to have the building, now being erected for us, and which is 36x80 feet in size, well filled with the products and appliances of the apiarium. A. I. Root is to be there with his buzz-saws and section machinery, and will show just how they do things at the "Home of the Honey-Bees." He is also to make a fine showing of bees, and if it is possible we shall have a small apiarium "in running order," on the grounds, and the way work is done in the apiarium will be shown to "wondering thousands." The log "gum" box hive, and straw hive will stand by the side of the Langstroth and other modern hives.

Discouraging.—The following letter from J. C. Armstrong, Bromley, Iowa, written July 28, 1888, is a sample of many of such very discouraging reports of the present season. He says:

We can pay our money to the Union to fight bee-enemies in the shape of cranks, but we have a worse enemy that has been preying on us the last year and this so far, and that is the unfavorable weather. My bees have done less this year, so far, than last. They are lying around idly for the want of anything to gather. The white clover has furnished no honey to speak of. When it first began to bloom they went to work on it, but soon quit it in disgust. The basswood has come and gone. They worked on it pretty lively for a few days, and perhaps gathered enough to "keep the wolf from the door" for a little while. Our only hope is from the fall bloom; if that fails us we will have to draw on the sugar barrel for winter stores. Last year I got a little surplus, but will be agreeably disappointed if I get any this year.

Linden Honey is still being gathered by the bees in some localities, especially is this so in Canada and the States in the same latitude as Ontario.

Mr. J. M. Hooker, one of the most progressive and popular apiarists of Great Britain, is about to publish a new book on *Bee-Keeping*. Mr. Hooker is one of the oldest subscribers to the *AMERICAN BEE JOURNAL*, and is well posted in American inventions and management, as well as British implements and methods.

GLEAMS OF NEWS.

Driven Him to Explain.—Prof. Wiley has at last been driven to explain his "scientific pleasantries" in several of the agricultural papers. We have tried to get him to do this for years, but he studiously maintained strict silence.

We well remember some of the stories in the school books of half-a-century ago, and among them of a boy who was up in an apple-tree knocking down the apples. The owner found him at it, and at first tried persuasion; that not availing anything, he pelted him with wads of grass. Upon finding the boy apparently enjoying the fun and laughing in his sleeve, he concluded to try some more effectual method. He went to a stone-pile and began to pelt the boy with rocks. This soon brought the young thief down, and saved the apples from being destroyed or stolen.

Just so have we acted with Prof. Wiley. We *politely* pointed out the blunder he had made in his "scientific pleasantries," and advised him to publish a correction. Finding this unavailing, we pointed out the *great damage* that its circulation throughout the world had done, and was still doing—that while no word from him had been published which in the slightest degree had modified the story, or cast any doubt upon its reliability, it was traveling "at lightning speed," and creating a sentiment against the purity of comb honey everywhere in its course, and demanded a public retraction from him.

This receiving no attention, we used the hardest arguments we could find, couched in the *strongest* language that the Dictionary afforded, to show up the *infamy* of such a course of procedure on his part!

Then came his friend, W. M. Evans, to the rescue, and with two to one to fight, we "rolled up our sleeves" and "gave it to them right and left," with all the vigor and enthusiasm at our command, until the Professor was induced to explain some, and try to dodge the responsibility of the damage done, by saying that he "was sincere" in repeating what Dr. Hallock had told him about the "full outfit of machinery for the manufacture of artificial comb" in Boston.

His Virginian friend re-asserted that such comb was being made, filled with glucose, and sealed by machinery—and blurted out this self-contradiction: "The Wiley lie is true!"

Then we demanded the production of at least a single pound of the *vile trash*, or the confession from Mr. Wiley that the story was only fictitious! Driven into a corner he finally makes this astonishing confession:

At the time, I repeated this statement more in the light of a pleasantries than as a commercial reality, for I did not believe that it was POSSIBLE commercially to imitate the comb!

This infamous and bare-faced "confession" of Prof. Wiley came, not because he wanted to make it, but because we had goaded him until he could stand it no longer! It had the same effect as the throwing of the rocks and pelting the boy in the apple-tree, in the old-fashioned, school-day story.

Then the ice being broken, the Professor rushes to the principal agricultural papers with an explanation about that wonderful "scientific pleasantries," but complains most bitterly of the manner in which we followed him up, and of the strong language we used to bring him to terms.

As that was the only thing which aroused him to a sense of the position in which he had placed himself, we think he should feel thankful to us for it. He may now clear up the matter, and do some small part in counteracting the evil which was done to an honest pursuit by his former ill-timed "joke!"

This is how the matter is viewed by Bro. Root, in the last number of *Gleanings*:

While our good friend Newnan, of the AMERICAN BEE JOURNAL, may not have used just the language that some of us would have used in obliging Prof. Wiley to take some notice of the consequences of his foolish statement, we of the bee-keeping fraternity certainly owe him a vote of thanks for having at length driven the Professor into a corner, as it were, and for having literally made him recall his foolish statement.

With all the explanations that can possibly be made, I think the world at large are pretty well satisfied that no professor or scientist has any right to make such statements, jokingly or otherwise; and I believe that the consequences of this piece of folly will damage Prof. Wiley's reputation in spite of all the explanations and apologies he can possibly make.

Yes; Brother Root, the vigorous "rock-pelting" did it. As nothing else would answer the purpose, we had to use the "rocks," even though we disliked to do so—much preferring the pleasant words of life!

Seasonable Gossip.—The following written by Mrs. L. Harrison on July 28, 1888, for the *Prairie Farmer*, is very interesting and seasonable talk:

This showery weather makes fox-tail and other grasses grow like Jonah's gourd, and the lawn-mower has to be run in the apiary every few days, or it would be difficult carrying around hives, etc. The leaves of fox-tail serve as receptacles for holding water a long time, and large, sparkling drops may sometimes be seen a day after a rain. No grass that I am acquainted with grows in summer like it. It is a continual pest to me, by growing up in front of hives, and obstructing the flight of bees. This morning I noticed a row of hives, where it had grown up in front, and as it rained last night, was sparkling with water. The bees were darting in and through it very fast, heavily laden with pollen, and many pellets were brushed off. The squash family is blooming, and abounds in pollen. It saves labor to sow salt in front of hives, to keep down vegetation, and it is cheap.

Bees swarm very irregularly this season, and I have no doubt many will be lost, for their owners will tire of watching. A little flow of honey, and they rush out in search of a new hive; and many swarms come out

quite early in the morning—a little past seven. The first after-swarm of the season came off to-day; it was unnoticed until clustering; had I known where it came from, I should have returned it to its former home; the hive from which it issued is now no doubt almost without a tenant. When I discover it, I will extract the honey and exchange the combs with some populous one, for those containing brood. If that hive full of combs and honey were let alone, it would take it all summer to get bees enough to winter, and where would be the profit? Every hive must pay its rent, or the more the owner has, the poorer he will be.

No bee-master allows his bees to cluster on the outside of the hive for want of storage room. Better have too much storage-room than not enough, for bees love to work, and should not be enforced into idleness.

Statistics obtained for *Gleanings* on July 4, are thus summarized by its editor:

The average price of comb honey throughout the rural districts of the United States is very nearly 16 cents; the average price of extracted, 11 cents. In looking over these reports we find that comb honey is selling in a good many places for 20, 30, and 35 cents. We observe, also, that in other districts it is selling as low as 5 cents; that extracted bears very nearly the same proportionate variations. Both comb and extracted sell for a great deal less in the South than in the North. It is also interesting to note that, in the rural districts, honey brings a much higher price than in the cities. Producers should not fail to take this into consideration when about to dispose of their crop.

The average number of pounds per colony secured by those who report anywhere from 0 to over 100 pounds, is only 16. The large number of those reporting no honey (53) reduce the average very materially. Counting out this number, the average would be 36 instead of 16. In looking over the statistics we find there are only two who have reported as high as 100 pounds per colony. There are very few who obtained over 50 pounds. Quite a number secured only 8 or 10 pounds per colony. Twenty report the season good; 17, average; 12, fair; 21, poor; 20, bad.

Putting the sum of the numbers corresponding to good, average and fair, over against the numbers corresponding to poor and bad, the ratio stands 49 to 41. In a word, not only has a very small crop of honey been secured, but the season with nearly half of those who reported has been poor. Taking it all in all, it is discouraging; but we must not be discouraged.

The average date at which the reports were given, is July 4. Please bear this in mind, then, that the foregoing summary applies to and up to about July 4. Since that time the outlook for the bee-keepers may have been changed quite materially.

Postage on Seeds, etc.—A new law has just passed reducing the postage on seeds, cions, etc. It is not yet operative, but soon will be. This is how it reads:

Hereafter the postage on seeds, cuttings, roots, cions and bulbs shall be charged at the rate of one cent for each two ounces or fraction thereof, subject in all other respects to the existing laws.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

BIOGRAPHICAL.

MR. F. Y. TYRREL.

After a short illness, Mr. F. Y. Tyrrel died of diabetes, on Friday, July 13, 1888, at Madison, Neb. The funeral services were held in the grove adjoining the house, on Saturday. A few remarks were made by Rev. Mr. Kimball, and the remains were laid at rest in the Madison cemetery. Mr. Tyrrel was in the sixty-eighth year of his age. He was born at Lanesborough, Mass., but he lived in Madison for the past thirteen years, and was honored and respected by all who knew him. He leaves a wife and five children and a large circle of friends to mourn his death. His son, Mr. A. C. Tyrrel, one of the correspondents of the BEE JOURNAL, has sent us the following tribute to the memory of his father, who was an ardent lover of bees and the pursuit of apiculture:

"Life evermore is fed by death,
In earth, and sea, and sky;
And that a rose may breathe its breath,
Something must die."

If it is true, as the poet has written, that "Nature is indifferent to the fact of human pain," it is also equally true that nature is kinder to us than we are to ourselves; it prepares us for the transition we call death, by a process we cannot describe, much less comprehend. It prepares the emaciated form for the separation of the spirit from the body. It comforts us during the saddest moments of our lives; it assuages our grief when our loved ones lay down the burden of life—give up the life long struggle for existence; and in the performance of the last tender acts for the departed, and ever after.

To those capable of having their sensibilities moved by human sorrow and pain—whose memory retains and loves to dwell upon and recall all that was ennobling in the lives of those of our number who have passed from earthly vision to brighter and higher spheres, the grand and perfect adjustment of nature's laws, lessened in time the poignancy of grief and fit the sorrowing for the duties they owe the living. If the reverse were true, life would be unendurable—a living tomb, without a cheering ray of sunshine. "All would be dark and dreary, for into each life some rain must fall."

Our father's every act of kindness, every loving word, every deed of charity, every sacrifice he made for those he loved—all his labors of love, his self abnegation, are living monuments, the grandest testimonials to his worth, that can be erected—a sacred tribute to his memory, more eloquent, expressive and enduring than cold, gleaming, marble slabs, storied with his praise. All that was beautiful and in harmony with his surroundings, he loved. The birds that caroled their sweet songs in the trees which he thoughtfully planted in the once wild prairie soil, and tended so carefully—the flowers of exquisite hue

and fragrance—the bees flitting from flower to flower in quest of golden nectar—all these were objects of interest to him. Nothing of beauty in earth, sky or air escaped his notice.

His home was his palace—his family his loving subjects, and objects of solicitude to the very last, although everyone is traveling the decline of life. His associations with his companion were hallowed. She was in every sense of the word a helpmeet, to whom he was indebted for whatever of success he achieved—his steps guided by and his character moulded by her. The world will be wiser, yes, better, when it can truly say—

"O, woman—mother! Woman—wife!
The sweetest name that language knows;
Thy breast, with holy motives rife,
With holiest affection glows;"

when it will concede that she moulds the character of individuals and the destiny of the nations of the earth; that we are indebted to her for the breath of life, for our intellect, good impulses and influence. To her the statesman owes his eloquence and power; the laborer in the vineyard of life his influence for good—all must acknowledge her supremacy.

The cycle of years will still roll round, bringing to all his little family joys and sorrows, incident to life. The burdens must be borne, the struggles and vicissitudes of life must be met. All that tend to fill up and complete the full measure of our days, is before us, yet the tender recollection of his manly life can never be effaced—will ever be a green oasis in the desert of our hearts. The mad, head-long rush for position, fame, power.—perchance for the very necessities of life, may sear our hearts, render them more barren and desolate than the desert of Sabara; let us hope not. Such has been the lot of those ere now, with such blessed and hallowed associations as now cluster around our pathway. Our destiny is shrouded in impenetrable mystery, and beyond our control, but let us hope that the pain and sorrow father bore so meekly and without a murmur, and withal his example be a beacon light to steer our barks from the treacherous shoals, the maelstrom and breakers of life. Let us exercise the same kindly feeling of charity he ever manifested toward his fellow men.

Father was one of those peculiarly constituted men in whose composition there lurked no discordant, strife-producing elements. We can truly say that within our knowledge he had not one enemy. It is said that a man amounts to but little in this busy world unless he can number his enemies by the score—a mark of greatness. In the estimation of his family he was a nobler and a grander man than he who dips his sword in the blood of his fellow man, no matter how just the cause. We are content with those traits of character that were our admiration when a child, and which abided with him to the last hour of his life, having only kindly thoughts and words for all mankind.

It seems fit and proper that one who has known him so long and well should pay this last tribute to his memory—the last sad office we can perform for him. The little acts of kindness and

the little deeds of love which the world takes no cognizance of, yet they are as a little spark kindled in obscure places that has revolutionized the world. Good deeds in a community may be of some benefit, and extend beyond our ken; and what is the world but an aggregation of communities?

INTERROGATORIES.

Uncapped Sections of Honey.—Rodman Lovett, Rome City, Ind., on July 30, 1888, says:

Bees are not doing very much at present, as it is too dry. I will give a report at the close of the season. Would you remove sections of honey before they are capped?

All comb honey should be well-filled and sealed over before being removed from the hive, in order to be attractive and salable.—

Bees Don't go Home till Morning.—says a correspondent from north-western Ohio, in a postscript to a letter on Aug. 1, 1888:

The Chapman honey-plant is in "all its glory," and some of the bees have such an affection for it that they stay on it all night, and "don't go home till morning." A few days since I did not know what to do with my bees. I never had such strong colonies before, and but few were getting any surplus, and many of them were "just living from hand to mouth;" but now the sweet clover, of which there are acres and acres in the waste places and vacant lots, and along the streets of the city of Toledo, has blossomed finely, and the bees are having a jubilee on it.

Yes; sweet clover is the main source of supply for bees, in many localities this fall; and the honey is of a superb quality.

Freaks of Bees.—H. Earl Wilson, Arcade, N. Y., on July 24, 1888, writes:

The bees do not seem to be doing very well in this vicinity at this time. The basswood is in blossom, yet the bees are not as lively as they ought to be. 1. I wish to ask a question—the case occurring a few days since. I do not understand it. About two weeks ago a swarm came out four times, and every time I searched, but could not find a queen-cell in the hive. On the fourth time a miller in a worm-state was found in one of the combs in the hive, boldly crawling and devouring the wax and uncapping the worker-cells. A few days ago another swarmed the fourth time, and I found the same thing in it as in the former one. Is it possible that a miller can scare a virgin queen to go out of the hive? 2. As I was in school last year, not reading all the queries in this paper, what hives do Prof. Cook and Mr. G. M. Doolittle use? 3. What hive is the most used?

1. No. The miller was not an uncommon occurrence, and did not in either case cause the swarm to issue. Swarms sometimes issue when no human eye could discover queen-cells started. However, they soon after appeared. Bees do all sorts of things, occasionally, especially in poor seasons like this. 2. They both use the Gallup frame, $1\frac{1}{4} \times 11\frac{1}{4}$ inches. 3. The Langstroth hive.

The Honey-Bee and the Grapes.

Paraphrased from the *Youth's Companion*
BY GEO. W. YORK.

"You are a little thief," I said,
To honey-bee so blithe and gay,
"You stole my grapes so ripe and red—
To that, now what have you to say?"

In buzzing speech she sweetly said—
Her golden bands glowed in the morn—
"I take my pay in grape-juice 'red,'
For working in your vines and corn.

"But grapes I touch not till the same
By bird or insect have been broke;
Then I the oozing juice reclaim—
Which should not anger any folk.

"My sweetest song I hum for you,"
She said in music soft and slow,
And then her wings shook "pollen-dew"
In showers on the blooms below.

Like tears the "dew" fell, and I said—
When came the pauses of her strain—
"Sweet bee, just eat my grapes so red,
I will not call you thief again."

Now every year, when summer's come,
Bees visit all the flowers gay,
And decked in golden bands they hum,
With cheering songs at dawn of day.

The honey-bees—my choicest pet,
I wish them joy and length of days;
They pay me well for all they get,
In skillful toil and songs of praise.

Chicago, Ills., July 30, 1888.

QUERIES AND REPLIES.**Cementing a Bee-Cellar Floor to Lower the Temperature.**

Written for the *American Bee Journal*

Query 566.—My bee-cellar is all under ground except the front end which is walled with sand-stone. A honey-house is overhead. I want to cement the bottom; by so doing will it prevent the warmth of the earth reaching the cellar, and make the temperature lower in the winter?—K., Indiana.

No.—R. L. TAYLOR.

No.—MRS. L. HARRISON.

No.—M. MAHIN.

No.—EUGENE SECOR.

No.—C. H. DIBBERN.

No, sir.—JAMES HEDDON.

I think not.—H. D. CUTTING.

No, we think not.—DADANT & SON.

I have no experience with bee-cellar.—P. L. VIALLO.

I should think not.—A. B. MASON.

I think not.—J. M. HAMBAUGH.

I think not, but I should rather have the earth floor.—C. C. MILLER.

Not at all. What is cement but earth?—A. J. COOK.

There is not a particle of difference. Cement it, by all means, if you are able to do so.—J. M. SHUCK.

The difference in reduction of temperature would hardly be perceptible.—J. P. H. BROWN.

I think the cementing would make no difference as to the warmth.—G. M. DOOLITTLE.

I do not think it will affect the temperature to any appreciable extent.—J. E. POND.

Perhaps it would have some effect in that direction, but I would cement the floors of all cellars, notwithstanding. The temperature can be regulated by artificial means.—G. W. DEMAREE.

There would probably be no perceptible difference in the temperature—but it would be advisable to cement it nevertheless.—THE EDITOR.

Proper Management when Hiving Swarms.

Written for the *American Bee Journal*

Query 567.—1. When hiving swarms in a 10-frame Langstroth hive, is it advisable to contract the brood-chamber? 2. If so, to how many frames? 3. Had I better use starters, or full sheets of foundation in the brood-frames?—Northern Iowa.

1. No. 3. We use full sheets.—DADANT & SON.

1. Yes. 2. I should use only five. 3. Starters.—G. M. DOOLITTLE.

1. No, not unless the swarm is very small. 3. Use full sheets alternated with frames of comb, if you have them.—J. P. H. BROWN.

1. Yes, sir, contract to five frames, which are enough to hive any swarm on in this latitude. 3. I am still using full sheets.—JAMES HEDDON.

1. No; a good sized swarm will need all the room, especially in warm weather. 3. Use full sheets, every time.—C. H. DIBBERN.

1. I think that 10 frames are too much. 2. I do not know; somewhere from 5 to 8. 3. Full sheets.—C. C. MILLER.

1. Contract according to the size of the swarm. 2. I put in just enough frames which will be well covered by the bees. 3. Full sheets, using wired frames.—P. L. VIALLO.

1. If you wish to get all the comb honey possible, contract. 2. Four to six, according to the size of the swarm. 3. Full sheets, except experimentally.—R. L. TAYLOR.

1. It will depend upon the size of the swarm. Give as many frames as the bees will cover. 3. I think it better to use full sheets of foundation.—J. E. POND.

1. Yes, unless the swarm is very large. 2. Eight. 3. That will depend upon the season, and the condition of the honey-flow.—MRS. L. HARRISON.

1. If the swarm be large, I would give them the whole ten frames. 2. That will depend upon the size of the swarm. 3. I would use full sheets.—M. MAHIN.

1. "That depends." If working for extracted honey, no. 3. That depends also. If working for extracted honey, use full sheets of foundation in wired frames.—A. B. MASON.

1. You do not say whether you want comb honey or extracted; if the former, I would contract to 6 or 7 frames. 3. I am not sure on this point. I am using starters, myself.—EUGENE SECOR.

1. If working for comb honey, yes. 2. Five to seven, with surplus receptacles from the parent colony above. 3. Should you wish to propagate bees for a fall crop, use full sheets of foundation.—J. M. HAMBAUGH.

1. It depends upon what plan you are working your bees. If for comb honey, contract to 6 or 8 frames. 3. If you work for extracted honey, use full frames of foundation; if for comb honey, use $\frac{1}{4}$ foundation, with sections well under way on top.—H. D. CUTTING.

1. I think that 8 Langstroth frames are sufficient when hiving swarms. I would transfer the supers from the hive of the colony that cast a swarm, to the hive holding the new swarm, and then use full sheets of foundation in the brood-chamber. If I had to put new supers on the swarm, I would use only "starts" of foundation in the brood-frames.—J. M. SHUCK.

It all depends. If you are desirous of obtaining comb honey, I should say contract to 5 frames, and use only the starters. If extracted honey is your aim, then I should advise full brood-chambers and full sheets of foundation. Read Mr. Hutchinson's excellent book.—A. J. COOK.

1. There are differing opinions on this subject. Many ideas and things have had a great run for a period of time, and then "steal silently away." Such, I think, will be the case with the "contraction system." The contraction system is very much like a man trying to make money by trading with himself, all the time driving a sharp bargain with *no one*. It is a case of one trying to lift his corporal system by the straps of the boots. 3. If you are making bee-culture a permanent business, it will pay you best to use full sheets of foundation in a full-sized brood-chamber.—G. W. DEMAREE.

Much depends upon the size of the swarm. If you are working for comb honey, it would be better to contract to from 5 to 7 frames. If extracted honey is your object, the full brood-chamber may not be too much. Full sheets of comb foundation in the brood-frames will give you more satisfaction than starters.—THE EDITOR.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

CORRESPONDENCE.

FOREIGN BEES.

Temper and Characteristics of the Eastern Races.

Letter written to S. W. Morrison, M. D.,
BY FRANK BENTON.

As to your questions: 1. "Do you not have in Carniola, and in your apiary, queens which produce some workers with yellow bands?" Yes, yes; and I have yet to see an apiary in Carniola where such do not exist, although I have visited all the most important apiaries existing here, and have seen hundreds of colonies. There is in therace a tinge of yellow blood that crops out every now and then, do the best one may. I breed only from such queens as produce *gray workers*—such as show no yellow or orange bands—not even a *tinge* of orange, and I permit no drones to be reared in my apiary except those from Carniolan queens whose workers and drones are quite gray; but there are several native apiaries (box hives) near me, over which I have no control, and whose owners care nothing for yellow bands if they exist.

There were at my residence to-day, two intelligent bee-keepers from the northern part of Carniola, and I questioned them on this point, and they replied that an occasional tendency toward orange or rusty-red bands was always the case with all Carniolans, but that it was no mark of impurity in the race, since it exists so all over Carniola. This agrees with my own observations made here in 1880, 1883, 1886, 1887 and 1888. Please refer to the article on Carniolans which I published in the leaflet "*Bees*," for Jan. 20th, 1886, and you will see that I mentioned this in the second paragraph.

2. "Are all Carniolans the gentlest bees known?" Like all races, individual colonies differ in temper. The cross-est Carniolans are likely crosser—less gentle, than the gentlest Italians. But for all this, it is none the less true that the race—Carniolans—are far gentler than Italians, and the cross-est Carniolans by no means equal, in crossness, the cross-est Italians. And, though I kept Italians in Michigan for many years, and also several years in Tennessee, and have handled them in many different apiaries in the North and South, it has never been my lot to meet with any, (in America nor in any part of Italy, which I have visited some six or eight times, and the length and breadth of which I have travelled several times), that were as gentle as the gentler Carniolans. When now we take into account the fact that Carniolans are much hardier and more prolific than Italians, we have abundant reason to place them as superior to Italians. Yellow bands or no yellow bands, they are better, and the best we can do is to try to avoid the bands in breeding. Hybrid bees are common in Italy except in a few districts. Moreover, several prominent Italian breeders have imported Cyprian

and Syrian bees from which to breed in order to have *yellow* stock! Perhaps also to give *energy* to their lazy, sluggish, drone-like workers!

I suppose when you advertise Carniolans as just "as *prolific* as the *wicked* races," you mean by this last, Egyptians, Palestines and Syrians. Surely, you would not commit the blunder of including under this expression also the *Cyprians*! Well, at any rate, you have made a decided mistake in saying that Carniolans are as prolific as any other race, except other European races, which they excel in prolificness. But Syrians exceed all other races. Cyprians are little behind them, and, indeed, individual Cyprians nearly or quite equal the best Syrians, Palestines, Egyptians, and Tunisians are close on the tails of all these others; and then come Hymettus (Greek) and Dalmatian bees standing about the same as Carniolans.

Strange to say, if I were to send you a Hymettus queen, you would not know her, nor her bees, from Carniolans—except in their *temper*. The Hymettus bees, or bees of Attica, will fly at one when he approaches their hives, with much more vigor than even blacks, and also in greater numbers. Disturb them without smoke, and you will want a brook near at hand to jump into. The same rusty-red bands, only occasionally slightly lighter—almost a dirty white, appear with them as with Carniolans.

Dalmatians are curious, shining blue-black bees that play and chase each other like flies at the hive-entrances. They are not difficult to manage, and are splendid comb-honey bees.

Carniola, Austria, July 4, 1888.

BEE-WORK.

Methods and Implements Used in the Apiary.

Written for the American Bee Journal
BY G. P. HACHENBERG, M. D.

The maximum standard of my apiary is about 100 colonies, but like the tide, it swells and recedes in number, not as the moon would have it, but the contingency of a Texas climate—its temperature, aridity, the yield of honey pasture, etc. Bees multiply here rapidly, but they are often destroyed in the same ratio. The past spring I found my apiary cut down to about 60 colonies, many were destroyed by starvation and moth, some by the cold, and a few by solar heat, drowning the bees in their own honey; and in time of swarming many took flight to the woods. Many of these disastrous results might have been avoided by attention and labor; but an old army officer like myself, made stiff and clumsy by age, and in Uncle Sam's service, necessarily has to conduct an apiary on principles and a method of his own. When I made my *debut* here as a bee-man, I went it strong. I put up a work-shop, honey-house and store-house, and spent a little fortune to get together the whole stock and paraphernalia of a first-class bee-establishment. If my income was not always in keeping with my expenditures, never-

theless many of my bee-friends thought I had extraordinary success. And so I had, when we take into consideration that I commenced about seven years ago with only three colonies, and bought none since.

How I began Bee-Keeping.

About ten years ago I bought 10 colonies with no knowledge whatever of the bee-business. I had an idea that bees would shift for themselves, and all that I had to do was to take honey from them *ad libitum*. Under this system, they all died but two colonies, and these had a remarkable history. I kept them in a dark chamber in my house (to keep them from being stolen) with a large auger-hole through the wall for their exit. Each colony was in two hive-stories, and as their location made it impossible to take honey from the hives, they became very strong, and finally made large clusters of comb with honey outside of the hive, inside of the house. For some time I cut from this comb all the honey we needed for table use. This was in the mountains of Texas, about 50 miles from here, where I had tarried for a few years to heal up my lungs by the mountain ozone.

How I moved my Bees.

On my return to the vicinity of Austin, I brought these two colonies with me, which had their habitation in rough boxes of my own make, admitting free ventilation from all corners. I don't believe that there is any thing in the annals of history that equals the rough usage that these bees got in their transportation to this place. I nailed up the bottom of the hives with boards, and secured the stories with side-strips. The question of favoring them with much breathing space was barely taken into consideration, perhaps for a lack of interest in a business I felt I did not understand. I moved them in a common farm-wagon ten miles, over the roughest road in Texas, running over rocks of a prodigious size; and what was worse, I then left them in their confinement, stored in a house on my ranch on the Perdanalis, for over two weeks. Then for 40 miles they were taken through the mountains to Austin, with such rough usage, even to break away some of the strips of the hives, liberating some of the bees. Of course they promptly notified me of the break, with the song into my ears, "Stop that team." To save horses, bees, and myself, I at once repaired damages.

When I got here, their music and activity was very much subdued, and my prognosis of them was anything but favorable. I put them on stands and liberated them. Poor things! it was a painful interest to see them come out one by one, looking like crippled invalids of a hospital. Soon some took wing and appeared to locate their mysterious drop-down. I watched them with interest and sympathy, and I noticed in particular that for a time they had lost all their combativeness. As I found that they survived the most cruel treatment (no doubt owing to the cool weather at the time, and the mixed arrangement of the comb), I concluded that I would try my luck again, but not as an ignoramus, but with the necessary intelligence for

the business I at once secured the AMERICAN BEE JOURNAL, and some of the most reliable literature on the bee, and carefully read them. At the same time I added an Italian colony, making the three in number. After I had a few swarms of this stock, I employed a bee-expert to transfer all my bees into the "Simplicity hive," and to watch him to do other wonderful manipulation of the art. In another year I had Italian queens introduced in the most of hives.

Carling for the Bees.

I soon found out that knowledge with attention worked well in this enterprise and in a few years I had more bees, and at times more honey, than I knew what to do with. Every year I bought comb foundation without stint. In 1885 I had incurred extra heavy expenses in laying in supplies, and in return realized little or nothing. This rather took the fun out of the business. I then resolved that my three millions of subjects must work and board themselves. I stopped feeding them, but consolidated the weak, and gave them comb from the strong. I ceased supplying them with foundation, but had them to make their comb without foundation. All the assistance I gave them in this was to pencil with nice, hot wax, the inside upper piece of each frame as starters. Much time and labor I saved by discarding the use of the wire in frames. In short, I promised my bees to give them a favorable and comfortable habitation—guard them from harm individually, as much as possible, keep them strong and powerful to protect themselves, but otherwise the apiary must be self sustaining. Not only have I curtailed my expenses to the lowest notch; but what was of greater importance in my case, was to bring the force of my labor to the same mark. Such a thing as hired bee-help is, perhaps, not known in this country. To carry out my plans, I enforced a rigid system.

Keeping a Record of each Colony.

In the first place I discarded all slates, and have each hive (painted white) numbered in bold, neat black figures. In a large blank book, the number of pages, corresponded with those of the hives giving the age, condition and running history of each colony. Any time a hive was examined, or any thing done to it, an entry of the transaction was made. The numbers on the hives were so arranged that they could nearly all be easily read from the honey-house. As this record was kept from the beginning, it is already a work of interest.

A Bee-Veil for Perfect Protection.

Of implements, I made a veil that would not impair vision by any network. I constructed one with a piece of mosquito-netting with a small, clear glass window 3x6 inches in front, to look through. The glass was set in a tin frame, with holes around the outer margin, to which the netting is sewed. The veil is placed over a straw hat with a narrow brim, and fastened to it to keep it in place. In stooping, to keep the glass from dropping forward, it is secured to the neck by two pieces of strings. The netting is long enough to tuck the lower end under the vest. It

is a perfect protection, and one can work with it with the facility that he could with the naked eye. I will venture to say, if any bee-man will try the "window" he will long for nothing else in way of a bee-veil.

A Handy Frame-Hook.

Another good thing I got up is a hook to lift loaded combs out of a hive. Take a firm, thick, galvanized wire about 8 inches long, and bend one end into a large round hook for the handle; flatten the end, for lifting wire nails out of the frames presently to be described; then bend the other end into a short angle of a square. With the short hook the

My Frame-Hook.

frames are taken out, the purchase being made inside of the frame. This small hook serves another very convenient thing, viz: I have the slats of my mats made by the thousand, and put them together myself with copper wire. At the two ends of one side I leave a twisted loop of the wire, to receive this small hook in removing it. This is done without delay, and without breaking the slats. Mats put together with twine are a nuisance, and those of gum-cloth are not much better, as the bees make havoc with both of them.

Swarm Catchers.

To secure swarms I use two ordinary coffee bags, the opening of each being fastened to a firm wire ring. One is at-

My Swarm Catcher.

tached to a long pole, and the other to a short one. I have likewise two hooks inserted in the end of long poles to correspond with each.

Where the bees cluster high up, very often even without the aid of a step-ladder, they can be readily secured with the long poles. As soon as the bees are in the bag, a twist of it will close it up, and without any loss of bees, it can be carried to any desired place, where an empty hive is ready to receive them. If I do not get the entire swarm at the first trial, I repeat the operation, until I have entirely secured them.

If the queen is secured in the first operation, the remaining bees will migrate on their own accord to their new home without any help, and even if they should return to their former hive, nothing would be lost.

Keeping the Frames a certain distance Apart.

There is a desideratum to have all the frames permanently fixed at equal distances apart. For a few years I used

the frames with metal-corners. I likewise discarded them on account of their ready displacement before fastened by the bees, and the extra labor they demand in putting them together, and afterwards to make good the results of their displacement. There is one trifling merit in them, and that is, they do not adhere much about the tin—but the troublesome wax adhesion is not so much on the top as at the bottom and sides. I now use only the wooden frames, and even with them I made a special provision to secure their fixed locality, for several reasons. Instead of adjusting the frames at the stand, I do that preparatory at the honey-house. In moving the hive to the stand, no handling, or subsequent jarring, will displace the frames. All the combs are very likely to be built in proper regularity, thus saving frequent examination of the hive. The regular open space between the comb will give the bees an advantage in their warfare with the moth, and will prevent the bees themselves from crowding the frames out of line! etc.

I have a measure made out of tin about one by fourteen inches long, with ten holes, to correspond with the ten frames of the hive. This measure is laid inside of the hive where the frames are to rest upon. Then with a punch, corresponding holes are made through the tin into the hive. Each of the ends of the upper pieces of the frames are perforated with the same punch, in a true line with the holes in the hive. Each frame is now readily retained in its proper place by dropping wire nails into the holes.

Bee-Smokers.

I have used and worn out different kinds of smokers, and found objections to all of them. Their want of durability—the smoke giving out at times when specially needed, and often they irritate the bees before they are subjugated, throwing them into a belligerency that is transmitted to those not touched by the smoke. It is a golden rule that bees are best handled with gentle manipulation, and in the absence of all noise; the working and the rattling of a smoker, *per se*, surely is not the thing to meet this important axiom.

I finally discarded all smokers now in use, and made one that is so very simple, that I almost hesitate to bring it into notice, notwithstanding it is the best I ever used. I make it thus:

I take an old gallon paint-can with a handle fastened to one side, and running straight out. Then I have a circular tin lid from a lard can, about 14 inches in diameter; it likewise has a handle fastened on one side, leaving the other side smooth and even. The former is the "smoker," and the latter is a "fan" to regulate the fire. This smoker gives a large volume of smoke, and in opening a hive, if there is a favorable current in the air, the "deck" is cleared instantaneously. In a dead calm, the fan is used two or three times, with the same effect. Should there be a blaze in the can, lay the fan over it and it is immediately extinguished, and by removing the fan a great volume of smoke follows.

As there is no puffing and blowing to excite the ire of the bees, consequently

they never make fight with this smoker, and with it you can go in the midst of the most vicious bees with perfect safety.

Selling Honey-Vinegar.

A few years ago honey sold here at a ruinously low price. As I would not deviate from my fixed minimum price, I stored away the finest of my honey, and the rest I turned into wine and vinegar, and made money by the operation. The vinegar I then sold by the barrel as "Honey Vinegar," which met with a ready sale, and soon I was not able to supply the demand. The market was created in this wise:

I put up a few dozen bottles, and had them labeled in attractive colors. These bottles I distributed freely to physicians, and others of the city. This donation created a demand for the article at once.

Making Honey-Vinegar.

As this vinegar was favorably received, for invalids, table use, and for preserving fruit, I will give the process of making it:

From the cappings, and the washing of honey-vessels, cloths saturated with honey, etc., make a clean solution of honey. If it needs more to give it a rich, saccharine taste, add such honey that may be objectionable for the market. Never sell poor, dirty-looking honey. After a perfect solution is made, put it through the percolator, to secure a pure, transparent fluid. Now acidulate the solution with a small quantity of chemically pure acetic acid. This acetic acid is a chemical, concentrated vinegar, and in this connection is perfectly harmless.

The acid will promptly bring the solution of honey into acetic fermentation. After this is effected, add about half an ounce of pure alcohol to the gallon. This will bring about a vinous fermentation, and develops the acetic ether, which gives the honey-vinegar such an excellent body. Without it, it would taste coarse and flat, with no body about it but a burning acidity, so common in poor and ordinary vinegar.

Marketing the Honey.

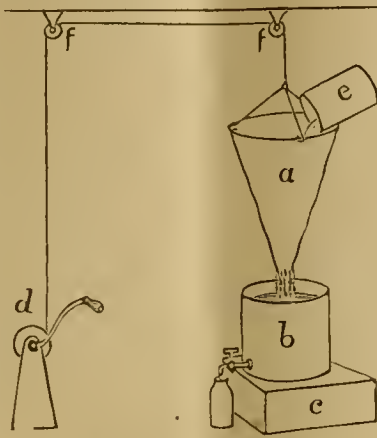

I find a ready sale for my honey in Austin, and if I command the highest price for it, it is because I furnish the finest honey in the market. Yesterday (July 17) I took 100 pounds out of one hive, the half it had, and sold it to my grocer at 10 cents per pound; while country honey was a drug in the market at 6 cents per pound.

I will cheerfully submit my process of purifying and clarifying my honey for the market. It is as follows:

Taking advantage of the fact that it is difficult to retain honey in almost any vessel except glass, I made a percolator (*a*) of a very fine, close muslin, six feet long, with an opening of about 16 inches in diameter, gradually coming to a point, large enough to hold about 100 pounds of extracted honey. This cloth is so fine and close, that when moist it can be made to retain air like a bladder. The honey that oozes through the cloth is a transparent, crystal-like fluid, and in a clear jar it looks so pure, that one is

tempted to think it was nectar only fit for angels to eat.

The operation, strictly speaking, is not one of straining, but a percolation, leaving pure honey and nothing else to pass. The process is one of exosmosis favored by a pressure of its own weight.

My Honey-Percolator.

REFERENCES.—*a*, is a cone percolator made of muslin, through which the honey oozes into the receptacle *b*, which has a faucet through which to draw off the honey into jars. *c*, is the stand for the honey can. *d*, is a pulley wheel to hold up and raise the percolator. *e*, represents a jar of honey being emptied into the percolator. *f*, shows the pulley-wheels in the ceiling, through which the rope passes, holding the percolator in place.

I have only to say to my enterprising bee brethren, try it; but do not let your success in producing wonderfully fine honey, tempt you to extortion, but keep yourself to a reasonable and dignified price for your honey, and go hand in hand with the fair reputation of your articles.

Austin, Texas.

QUEENLESSNESS.

Will Removing the Queen, increase the Honey Yield?

Written for the Country Gentleman

BY W. Z. HUTCHINSON.

Quite a number of bee keepers assert that more honey can be secured by removing the queen about three weeks previous to the close of the honey harvest.

The theory is, that stopping the production of brood turns the energies of the bees entirely into honey-gathering; besides this, no honey is used in feeding the brood. Mr. F. Cheshire says that the rearing of a bee, from the egg to maturity, costs a colony the equivalent of four cells of honey; and it is only because a bee, in a fair yield, is able to requite the colony with many times its cost, that a large population means surplus; but if this large population is brought upon the stage after the harvest is over, it becomes a consuming instead of a producing population.

Removal of the queen also prevents increase, which, in out apiaries, is especially desirable. When the bee-keeper has a large number of colonies, and

prefers honey to increase, the prevention of swarming is quite desirable. In some localities and seasons the honey flow is early and of short duration, and if the bees turn their energies in the direction of swarming, but little surplus is secured.

When a queen is removed, a frame of brood covered with bees is usually taken with her, and they are put in a small hive, where they are kept until the time arrives for their return. After her removal, if preparations for swarming have not already been commenced in the old hive, queen-cells will at once be started, and the bees thus endeavor to retrieve their loss. At the end of eight or nine days the queen-cells must be cut out and the bees given a frame of eggs or unsealed brood, from which they can start another batch of cells. Just before this lot of cells hatch (in eight or nine days), they must be cut out, and another comb of brood given. This method of management must be continued as long as the colony is left queenless, because, if hopelessly queenless, the bees seem to lose courage; they must have a queen or the hope of one.

The small hive containing the removed bees and queen is sometimes placed upon top of the old hive, and when they are returned, the bees that have learned to recognize the upper hive as their home, will, upon finding it gone, gather in a cluster upon the top of the hive, where they will remain a short time, and then take up a line of march down over the front of the hive to the entrance, and join the parent colony again.

It will be seen that this method of removing the queen entails considerable labor, and is, we think, not advisable, unless to prevent swarming, as the production of brood can be greatly curtailed by contracting the brood-nest, which is a short and simple operation, requiring very little work.

The method of removing the queen, that strikes us the most favorably, is that of allowing the bees to swarm, then removing and destroying the old queen, allowing the bees to return, and then, at the sixth or seventh day, cutting out all the queen-cells except one. This prevents increase, deprives the colony of a laying queen for about eighteen days, besides furnishing it with a young queen.

Flint, Mich.

THE SEASON.

Hiving Swarms—Ants in the Apiary—Bloom, etc.

Written for the Western Plowman

BY C. H. DIBBERN.

It is an old axiom that in order to obtain a good honey crop, you must keep all colonies strong. But this is much easier said than done. As well might it be said that to obtain a good crop of corn, you must have plenty of stalks, of the right size and at the right time. We cannot make the weather and so many other necessary conditions to produce bees in abundance, that we have to do the best we can.

Then, too, it is not always that strong colonies produce a good crop of honey, for did we not have booming colonies last year, and not a pound of honey? This year the cold, wet, stormy weather has been very detrimental to the breeding up of weak colonies, and most of them were weak when they came out of the cellar. Though we had to commence feeding at once, owing to the short supplies, and kept it up till fruit bloom, still they increased but slowly.

The season is fully three weeks late, and we may expect it to last so much longer, and can certainly hope that it will yet prove a good year for bee-keeping. Then, too, the weather that has been so unfavorable to the bees has been just the thing for the honey-producing plants. A good stand of white clover is springing up almost everywhere, and though this will not bloom much this year, it is a promising sign for years.

Our honey plants are coming along finely. I have three acres of sweet clover in one patch that is now as tall as one's head, and will be immense when it comes into bloom. The Chapman honey-plants that I nursed so tenderly in the house a year ago, did not bloom last year, as expected, but they are very thrifty now and will likely bloom this month, and I well then be able to form some idea of them as a honey-plant.

What to do with Second Swarms.

There are likely to be many second swarms this year, and what to do with these often perplexes the inexperienced. I like these late, second swarmings, not to put into hives by themselves and starve the coming winter, but to help weak colonies or to replace inferior queens. If you have any colonies weak at this time, it is almost a sure sign that the queens are worthless.

Now when your second swarms come out, hive them in any convenient box without a bottom. Then go to any weak or queenless colony, and, after smoking them, shake them off the frames in front of their hives on a sheet, and if there is any worker brood in the combs, it is a pretty sure sign that they have a queen—find and kill her. Now get your box and shake the second swarm out, and let all march back to the hive together. Should they be inclined to fight, give them a good smoking with your smoker. If the bees are very cross, it is a good plan to sprinkle them liberally with water sweetened with sugar, not honey, as it is apt to draw robbers and make things worse.

Hiving Swarms.

Much difficulty is experienced by some in hiving swarms, and much bundling up in hot weather is indulged in, and the awkward manner in which the bees are handled produces many stings. Much of this can be avoided. When the swarm issues, go to the hive and see if you cannot catch the queen when she comes out. Usually she can be found a few feet from the hive, trying to fly, or a cluster of workers may be about her. Have a little wire cage ready, made by wrapping a small piece of green wire cloth around a broom stick and one end bent shut. When you see the queen, place the open end of

the cage gently over her. She will at once run up into it, and now close up the cage with any convenient stopper.

The bees are, probably, all in the air by this time. Now remove the hive from which the swarm has issued, to a new location, and place the one you wish the bees to occupy in place of the one removed. Now place your queen in the cage on top of the frames, and cover over with mats or anything to confine the bees to the main hive. About this time the swarm will have missed their queen, and will begin to conclude that, "There's no place like home," and will at once proceed to return, and thus hive themselves just where you want them.

But suppose you do not find the queen? then just wait till they settle on some convenient branch. Do not be in any hurry, but wait till they become quiet. Now remove the hive of the colony that has swarmed, as before, and place the empty one in its place. Get a ladder, cut off the limb, if a small one and of no particular value, and if on a high tree, let the branch, bees and all, down gently by means of a rope. Carry the bees to the hive and shake them off on a sheet in front. Usually they will march in readily, but should they show signs of clustering on the outside, take a small twig and scrape them down.

See that nearly all the bees go into the hives, otherwise the queen may be out and in due time they may be expected to leave for the woods. Should the swarms settle on a valuable tree that you do not like to mutilate, they may be shaken into a basket or box, and carried to the hive. It also sometimes happens that they alight on fence-posts or in the crotch of large trees, where it is difficult to get them. In such cases one can usually dip off a part of them with a common tin dipper, and carry to the hive, and the balance can be driven either to the hive, or some place where they can be secured with a good smoke.

Ants and Roaches In the Apiary.

Of all the annoyances about an apiary, ants are perhaps the worst. Often, when putting on cases, one will find their nests in the warm places directly over the bees, under the mat or any convenient place. When disturbed, they at once spread over everything, and if they get among the bees, they make them very cross.

The little red and black ants are the worst, because the more common, but the big black ant is not to be despised. I do not think they do any harm to the bees or that they steal any honey from them, but they are certainly a great nuisance. Salt has often been recommended to drive them away, but I have found that they will make their nests right in the salt, and they seem to rather like it.

Roaches are also a great nuisance, but if hives are kept tight-fitting, they are more easily guarded against.

The best remedy for ants that I have found is a little kerosene oil in an old fruit can, and apply it sparingly on them, and where their nests are, with an old paint brush. This will kill them, but should be used very sparingly, as the bees dislike it greatly, and it would probably kill them if used carelessly.

Milan, Ill., July 1, 1888.

YELLOW JACKETS.

How to Destroy *Vespa Arenaria*, or so-called Yellow Jackets.

Written for the American Bee Journal
BY HENRY K. STALEY.

Many are the various ways that have been promulgated for the eradication of this stinging insect when its ire is up.

The yellow-jacket, albeit it has many good qualities, yet to some people it is a nuisance and a pest; at least often so to the grape-growers—when its waxy domicile is incased in his vineyard—for they nonchalantly linger after feminines, which causes them to be scared and to put a good amount of terra firma between it (the vineyard) and the house. It is probably this diminutive rascal that helps to puncture our sound grapes, and thereby make enticing holes for the bee to put in its slender proboscis and sip up the juice, that *nil* may be lost. The bees, in turn, by following out the old aphorism, have the voided rheum of angered grape-growers spat upon them; but it cannot cover up there "little carcasses and keep them down forever;" for the "Bee-Keepers Union" is firm, and twirls the whip of justice. The bee-keeper and grape-grower should ever be on the alert to destroy this insect, which by doing mischief causes blame to be cast at the innocent, is my idea.

It is a great bother to the apiarist when too near his apiary; for, many an hour of needed quietude are the guard bees kept on the *qui vive* for the yellow jacket thieves. I have seen them enter the hive, and in all probabilities they went away full. I have tried many ways of getting rid of this nuisance, such as pouring hot water down their exit hole, which was the means of raising their cholera, and bringing them out by the hundreds, fired mad, bent on destruction; smoking them and also trying to smother them, but in no case have I completely eradicated them without being stung; for, unlike the honey-bee, they stick on a person, and crawl up one's breeches and down his back; so that even if he has completely devastated their nests, he may be made the recipient of a *terrible stinger* an hour or two afterward—when not cogitating about them—from a yellow-jacket *in hoc* among his clothes that will send him skeddaddling over the meadow or field to his home for some soothing panacea—for I tell you a yellow jacket's sting, although petite, is felt!

Now the mode of eradicating a nest of yellow-jackets without being *bitten* and exhausted is this:

About four or five feet from the hiatus of the waxy domicile, rear a brush pile, by gathering up all the old brush lying around which ought to be consumed by fire anyhow; and then leave it remain there until night with its encompassing arms environs all. Now let your mind be nonchalant anent them until Phoebus' fiery steeds shall have waded knee-deep into the waters beyond the western hills, and he (Phoebus) shall have allayed his steaming axles with *gelid aqua*; or let it be that hour of night which the following passage

describes, when "Comus" speaks after this manner:

The star that bids the shepherd fold,
Now the top of Heav'n doth hold;
And the guided Car of Day
His glowing axle doth alay
In the steep Atlantic stream;
And the slope Sun his upward beam
Shoots against the dusky pole;
Pacing toward the other goal
Of his chamber in the East.

Moreover, let it be in that part of the month when the moon is plethoric, and the tide high; also let it be that hour of night before the moon shall have reared his full golden face above the horizon; or let it be in that part of the month when you can see the new moon, "with the old moon in her arms," for little reflected light is then cast from that defunct planet or satellite upon this mundane globe. The darker the night the better, even if it is as dark as the shades of Erubus or black as the atmosphere under the "sooty flag of Acheron," where many hosts of defunct Romans were supposed to trudge.

Supposing, now, everything is in readiness according to the preceding provisions, it is time to go forth to do battle with your enemies, and go it like the "Gibraltar of Chicamauga!" In the first place, ignite your brush-pile and let it get a good start before you excite the inmates of the waxy palace. Interim, procure a brace of base-ball bats or clubs, and beat the terra firma where the nest is. This racket on the outside will soon bring up the inquisitive little fellows, which, peering into the terrible darkness, will discern the light-giving fire, and without more ado, into it will dart and be cremated—yes, stinger and all, for the whole includes the part.

Keep on pounding until you throw they are nearly all out, when the nest should (if convenient) be dug up and twirled into the fire so as to avoid any ripe capped yellow-jacket brood from espying the glowing Eye of Day.

This is a neat, easy, quick and efficacious way. If you have them in your vicinity, try this plan, and instead of being assiduously harassed by them, like Cato was with the Carthaginians, when he said "Delenda est Karthago," you will soon have your enemy *hors de combat*, and able to pour his own ashes down into his own hole and fertilize the soil.

Pleasant Ridge, O.

BEE-STINGS.

What Becomes of the Part left in the Flesh?

Written for *Gleanings in Bee-Culture*,
BY PROF. A. J. COOK.

I am requested by a subscriber to *Gleanings* to explain how the bee-sting is removed from one's skin when broken off in the act of stinging. He suggests that, if it does not work out, it must be absorbed by the system; in which case he thinks that some bee-keepers must be largely composed of stings.

The skin consists of two layers—the outer scarf skin, or cuticle, also called

epidermis, and the inner true skin, or corium, also called *cutis vera*. The outer skin is made up of what is known as scaly, or pavement epithelium; that is, it consists of innumerable minute overlapping scales. The inner scales contain pigment in their substance, and thus the color of skin. The albino has no pigment, and hence his skin is transparent, and looks pinkish, as we look right through and see minute blood-vessels filled with blood. The inner skin consists of an outer part, which, like the cuticle, has no nerves, and so is not sensitive to pain or touch. This is made up of white fibrous tissue and small involuntary muscles that contract if the skin is chilled, and drawing the skin away from about the hairs forms the well-known "goose flesh." Beneath this layer, which is known as the reticulum, because of its intercrossing fibers, is the papillary layer. This is the very inner part of the skin. It takes its name from the fact that little teat-like processes—papillæ—push up against the outer part of the skin. The ridges seen on the inside of our hands are but the elevations of these papillæ. Into these papillæ from beneath come nerves and blood-vessels. Thus from here comes all nourishment to the outer skin; and here is the sensitive part of the skin. Thus, a bee to hurt us must push its sting through the cuticle and reticulated part of the corium till it pierces the papillæ, where the blood receives the poison, and the nerves twinge with its venom.

Now, as we understood the anatomy of the skin we can see how the sting, if broken off in the skin, is loosened and liberated. The scaly, or outer skin, is constantly being worn off. When we bathe, the water often is clouded with these minute scales. The snake sheds its scales once a year; but we are doing it all the time. As these scales are constantly wearing off, any minute portion of sting which is held in them is also worn off and separated from the body. Even if a small portion of a sting is caught by the reticulum, the part would probably suppurate and loosen the sting, as is done with slivers that enter and are caught and held in the skin. We thus see that a bee-keeper is not made up of stings, by any means.

In case of porcupine quills, which are barbed like a bee's sting, they are thrust through into the muscle, so that every move of the muscle pushes them; and as they cannot go back, they are pushed on. Thus a porcupine quill my pass some distance through the unlucky animal which has caught them in its tissues.

Agricultural College, Mich.

Convention Notices.

The Darke County Bee-Keepers' Society will hold a basket meeting on the Greenville Fair Grounds, on Friday, Sept. 7, 1888.
J. A. ROE, Sec.

The fall meeting of the Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association will be held on Aug. 21, 1888, at Leaf River, Ills. D. A. FULLER, Sec.

CONVENTION DIRECTORY.

1888.	Time and Place of Meeting.
Aug. 14.—	Colorado State, at Denver, Colo. J. M. Clark, Sec., Denver, Colo.
Aug. 21.—	N. W. Ills. & S. W. Wis., at Leaf River, Ills. D. A. Fuller, Sec., Cherry Valley, Ills.
Aug. 27.—	Stark County, at Canton, O. Mark Thomson, Sec., Canton, O.
Sept. 8.—	Susquehanna County, at Montrose, Pa. H. M. Seeley, Sec., Harford, Pa.
Oct. 3-5.—	North American, at Columbus, O. W. Z. Hutchinson, Sec., Flint, Mich.
Dec. —.	Michigan State, at Jackson, Mich. H. D. Cutting, Sec., Clinton, Mich.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Bees are Doing Well.—Charles D. Barber, Stockton, N. Y., on July 27, says:

It is very warm here at present. My bees have stored more honey in the past ten days than they did in twenty days before. They are doing very well. I have increased them from 2 colonies to 8, and all are good ones.

Wet Weather and Cool Nights.—S. W. Rich, Hobart, N. Y., on July 28, 1888, says:

Bees are not doing very well here this year. I do not think that we will have over one-half a crop. The trouble here has been too cool nights and too much wet weather.

No Surplus Taken Yet.—Mr. John Peters, Eldora, Iowa, on July 25, 1888, says:

It is extremely wet and cold here. Bees have gathered enough to build up on, and to keep up breeding, but I have taken no surplus yet. The clover has not yet come into bloom. I sowed some Alsike clover, but the oats were so rank, and are down so badly, that the bees cannot get at the clover.

Hardly an Average Crop.—B. F. Little, Brush Creek, Iowa, on July 28, 1888, writes:

The weather is warm, and the bees are doing fairly well. Basswood is nearly a failure. White clover is in bloom yet, but the flow of honey is not excessive. The crop will hardly be up to the average, unless the fall honey-flow is extra good. I hope that many new members will join the Union.

White Clover Yielded Well.—Thos. O. Hines, Anamosa, Iowa, on July 28, 1888, says:

This season is a good one for the little honey-gatherers, if we only had them to gather it. Fully 75 per cent. of the bees were lost last spring in this locality, by dwindling. There were but few days until May 20, that bees could fly; so what survived were so weak that they built up slowly, and when the fruit-bloom came, we had but few bees to work on it. White clover yielded well, and they are still getting honey from various plants. Iowa honey will not overstock the market this season.

No White Clover to Bloom.—A. R. Simpson, of State Line, Ind., on July 24, 1888, writes :

This is the poorest of poor bee-seasons here. The dry, hot weather of last year injured the white clover so badly that there was none to bloom this year of any consequence. It looks now just like it does early in the spring, when it is beginning to start up nicely ; and as white clover is our main honey source, the bees are not doing anything, for there is no other bloom of any consequence. The bees are not gathering any more honey than is necessary to live on, and we will have no surplus here, unless we have rain sufficient for fall bloom. If this fails, bees will have to be fed again for the winter, or they will starve. The outlook is gloomy indeed.

Expecting a Fall Yield.—Mr. Levi Reichard, of Ellison Bay, Wis., on July 27, 1888, writes :

On Oct. 27, 1887, I put 6 colonies into the cellar, and on April 25 I put them on the summer stands again. One colony had lost its queen, and one had the diarrhea pretty badly, so I united the queenless and sick ones, but they are weak yet ; the rest are doing just fairly well, and now it is too dry to do much. They have stored about 35 lbs. of surplus honey all together, from raspberry bloom. The basswood has no bloom, for some reason, but I have 1½ acres of buckwheat, and there will be plenty of goldenrod and asters this fall.

Bees Have Done but Little.—Dr. H. J. Scoles, Knoxville, Iowa, on July 25, 1888, writes :

Bees have done but little here this summer. During fruit-bloom they could scarcely get out of the hives, on account of the cold and disagreeable weather. I had to feed them up to white clover bloom, and that yields but little nectar. We then hoped for the linden, but, alas, our hopes were vain ; there was but little bloom, so that if we do not get a fall flow (of which I do not see much prospect), the bees will hardly have enough stores to carry them through the coming winter.

Thousands Wanted for the Union.—W. Addenbrook, North Prairie, Wis., on July 28, 1888, writes :

I send you my annual subscription for the Bee-Keepers' Union. I should feel more satisfied if we only had members amounting to thousands instead of hundreds, as I think that if I could not spare a dollar to defend any pursuit that I was engaged in, I would quit the business, and let some one with more brains attend to it.

Large Fall Honey-Flow Expected.—S. J. Youngman, Lakeview, Mich., on July 24, 1888, writes :

As I predicted in my letter of June 24, there was but little basswood honey, consequently we have had no honey from any other source but the white and Alsike clovers, and mostly from the latter. I built up my bees to very large colonies, having three hives, Langstroth size, one above the other, and I have taken 4 gallons of extracted honey per colony, and have had but 2 swarms. I am expecting a large flow of fall honey, as there is both early and late sown buckwheat, and the bees have already commenced to work from that source. In

consequence of the extreme drouth, the bees have bred but little, seeming to care little about swarming, unless confined in small quarters. Bees under such conditions have swarmed considerably, but have yielded no honey to their owners. Although no large amount of rain has fallen, the atmospheric conditions seems to be right for a honey-flow, and the bees are humming joyously, and are working with great vigor. But the season is too far advanced for a successful year with bees. Honey will again be scarce, and bring a good price.

Sterile Queens, etc.—Edward C. Luce, Hillsboro, Oregon, July 23, 1888, says :

I noticed on page 452 an item from Mr. C. A. Pardee, about a sterile queen. I removed a queen on July 19, affected in a like manner. Bees have stored some surplus from white clover, when it did not rain, it being the only good honey-plant that we have. I have 8 colonies of bees in Simplicity hives. I am 15 years of age, and I have transferred 10 colonies of bees for neighbors and my father, besides doing other work.

Rearing Brood Rapidly, etc.—J. O. Shearman, New Richmond, Mich., on July 28, 1888, says :

Bees have done but little with honey here. Clover was a failure on account of unfavorable weather. Basswood was short and sweet ; I got some, but no finished sections. The bees are getting some fall honey now. Bees have reared brood at a tremendous rate, as there is just about enough honey coming in to breed fast, and not any to store for surplus ; therefore my colonies have increased more than usual.

Preventing Bee-Stings—Honey Prospects.—Mr. Wm. Malone, Newbern, Iowa, on July 26, 1888, writes :

I have tried holding my breath to prevent bee-stings while putting my hand between two combs one cool morning. I did not hold my breath very long, I can assure you. The first conclusion I arrived at was, that there was one fool that was not dead yet. If any one thinks that the fools are all dead, just try the experiment once, and I think you will be satisfied.

There is not much honey yet. I have taken only 500 pounds from 46 colonies, spring count, and I increased them to 75 colonies. If August does not give us any honey, we will be "left" this year. The prospects are good for August, and we will live in hopes, even if we do not get the honey.

Good Report from Texas.—W. S. Douglass, Lexington, Tex., on July 28, 1888, says :

Bees have done better in Texas this year than they have for 5 or 6 years. Every bee-keeper has some honey for sale. One county alone produced 100,000 pounds of honey ; and one man in Williamson county had 20,000 pounds. Comb honey is selling for from 10 to 12½ cents ; extracted from 6 to 8 cents per pound. I started in the spring with 36 colonies, and increased them to 51, by natural swarming. I have sold some honey at 12½ cents, and I have a great deal more to take out of the hives. I have tried several different kinds of hives, and I am now going to adopt the Langstroth. I believe it is the best for producing either comb or extracted honey.

Honey from Corn, etc.—William Crowley, Redwood Falls, Minn., on July 28, 1888, writes :

The linden yielded the first honey here on July 15, and will close about Aug. 1. I expect to get about 1,800 pounds of linden honey, nearly one-half of it in one-pound sections, from 47 colonies, spring count, and 2 queenless ones, which were not much better than nuclei. It took so long to get my colonies queened. Bees did not build up much here until the middle of June, on account of the cold, wet spring. Part of them were not in a condition to take advantage of the honey-flow. I was obliged to do some feeding, and pack them on the summer stands, in order to bring them through. As near as I can learn, about three-fifths of the bees in this region perished during the winter and spring. My bees work very diligently on corn ; they did not desert it for basswood. I have had only 4 natural swarms this season. I expect a moderate honey-flow from now until frost, as we are having an abundance of rain, and all kinds of vegetation has a rank growth.

Full Treasury a Safe-Guard.—A. S. Goodrich, Worthington, Ohio, on July 30, 1888, writes :

Here is my dollar and my vote. I live in a locality where I never will be troubled by my neighbors or the public, therefore I do not expect to be benefited by the Union, but I feel it a duty to "cast in my mite" to assist those who are not so favorably situated, and to sustain an honorable pursuit. It is very strange that so few respond to the call. If one-half of the bee-keepers in the United States would join the Union, it would fill our treasury so full that they would never need another assessment, and we would be able to kill all opposition "too dead to skin."

Bee-Culture in Arizona.—Messrs. Harmon & Skinner, Zenos, Arizona, on July 25, 1888, write :

Bees are doing fairly well here. We have taken 520 gallons of honey, and have about 60 gallons more ready to take off. Our first extracting was entirely unfit for table use. We began with 32 colonies in good condition, and about the same number that were rather weak. We have purchased some, increased some by dividing, and by natural swarming, and now we have 120 colonies, mostly in good condition.

Honey Coming in Slowly.—M. L. Spencer, Little Genesee, N. Y., on July 24, 1888, says :

Here we are having a very cold season, especially the nights are cold. Bees have been getting a little honey for some time, but it comes in very slowly. Colonies are very strong. I send \$1.00 for membership-fee to the Union. It seems to me that the bee-keepers of the United States are not looking to their own interests, in not joining it.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, Ills., is published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4 1/4 x 4 1/4 and 5 1/4 x 5 1/4. Price, \$1.00 per 100, or \$8.50 per 1,000.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in Cheshire's pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being available, it must be sent by express.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages)	\$1 00
" 100 colonies (220 pages)	1 25
" 200 colonies (420 pages)	1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

CLUBBING LIST.

We Club the American Bee Journal for a year, with any of the following papers or books, at the prices quoted in the LAST column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

Samples mailed free, upon application.

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; 1/2 pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 18 cents per pound for bag and postage.

Honey and Beeswax Market.

NEW YORK.

HONEY.—We quote; Fancy white in 1-lb. sections, 13 1/2@15c.; the same in 2-lbs., 10@11c.; buckwheat 1-lbs., 10c.; 2-lbs., 9c. Market dull. We are doing all we can to reduce stock, to make room for the new crop.

BEEWAX.—26c. HILDRETH BROS., 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—We quote; White to extra white comb, 13 1/2@15c., amber, 8@11c. Extracted, white to extra white, 7 1/2@9c.; amber, 4 1/2@5c. Arrivals of the new crop are small, the estimates being an average crop.

BEEWAX.—20@24c. June 18. O. B. SMITH & CO., 423 Front St.

DETROIT.

HONEY.—Best white in 1-pound sections, 14c. No new in market, and old is not selling.

BEEWAX.—22@23c. Supply limited. July 24. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—We get 15c. per lb. in a small way for best comb, and less for off grades. Extracted, best white, 7 1/2@8c. None of the new crop received yet, but there is more than sufficient of the old crop for the light demand.

BEEWAX.—22c. R. A. BURNETT, Jun. 30. 161 South Water St.

NEW YORK.

HONEY.—We quote; Fancy white 1-lb. sections, 12c.; fancy 2-lbs., 10@11c.; fair white 1-lbs., 10@11c., and fair 2-lbs., 8@9c. Buckwheat 1-lbs., 7@8c. The demand is dull for comb but fair for extracted, of which new from the South is arriving, and sells for 55@65c. per gallon.

BEEWAX.—Dull at 23 1/2@24c. Jun. 15. F. G. STROHMEYER & CO., 122 Water St.

CHICAGO.

HONEY.—No white clover left in this market. Dark slow sale at 8@10c. Extracted ready sale on arrival. New crop will meet with good demand.

BEEWAX.—22c. Aug. 2. T. FISH & CO., 189 S. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb., for which demand is fair. Comb honey, 12@15c.—Demand slow.

BEEWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival. July 11. C. F. MUTH & SON, Freeman & Central Av

MILWAUKEE.

HONEY.—Choice white one-lb. sections, 14@16c.; 2-lbs., 15@16c.; 3-lbs., 12@13c. Extracted, white in kegs of 1/2-barrels, 8@9c.; in tin and pails, 9@10c.; dark in barrels and kegs, 6@8c. Demand good for extracted, but dull for comb.

BEEWAX.—22@25c. July 2. A. V. BISHOP, 142 W. Water St.

DENVER.

HONEY.—Best white 1-lb. sections, 14@15c.; 2-lb. sections, 12c. Extracted, 6@7c.

BEEWAX.—20@23c. Jun. 25. J. M. CLARK & CO., 1409 Fifteenth St.

KANSAS CITY.

HONEY.—We quote: 1-lb. sections, not glassed, at 18c.; 2-lb. sections and dark ones, also extracted, is not in demand. New honey is arriving freely, with a fair demand. This part of the State is favored with half a crop.

BEEWAX.—None in market. July 20. HAMBLIN & BEARSS, 514 Walnut St.

BOSTON.

HONEY.—We quote: 1-lb. sections, 14@16c.; 2-lb. sections, 12@13c. New Florida extracted, 8@9c. Sales are very dull.

BEEWAX.—25 cts. per lb. July 5. BLAKE & RIPLEY, 57 Chatham Street.

SAN FRANCISCO.

HONEY.—We quote: Choice new extracted, 5 to 5 1/2c.; amber to light amber, 4 1/2@4 3/4c. Choice comb in 1-lb. sections, 13@14c.; 2-lbs., 12@13c. Arrivals are small, as apiarists are holding back. Prices are considered high.

BEEWAX.—18@22c. Jun. 25. SCHACHT & LEMCKE, 122-124 Davis St.

KANSAS CITY.

HONEY.—We quote: White 1-lbs., unglassed, 15c.; 1-lb., white, glassed, 14c.; dark, 1-lb., 2c. less. California, 2-lbs., comb, white, 13c. Extracted, 7c. Considerable old honey is in this market. No new yet in. Sales are very slow.

BEEWAX.—None on the market. June 9. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—We quote: Extracted, dark, 4@4 1/2c.; bright, 5@5 1/2c.; in cans, 7@8c. Comb, white clover in prime condition, 13 1/2@15c.; dark, 11 1/2@12 1/2 cts.—Market quiet and demand fair, owing to the warm weather.

BEEWAX.—22c. For prima. July 26. D. G. TUTT & CO., Commercial t.

Conventions.—The time for holding Bee-Keepers' Conventions will soon be here, and we cannot give any better advice than this: Let each one attend who can do so, and take part in making these meetings interesting and instructive. If you have not already obtained the "Bee-Keeper's Convention Hand-Book," do so at once to post yourself up on how to conduct such meetings correctly. It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for Discussion—List of Premiums for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents. We will club this book and the AMERICAN BEE JOURNAL for one year for \$1.25.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$3.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Sweet, or Melilot, Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the BEE JOURNAL, and will send two or more free of cost to any one who will use them, and try to get up a club.

Exchange.—We will accept Honey and Beeswax in exchange for Bee-Keepers' Supplies in any quantity. Those desiring to make a trade are invited to correspond with us, stating quantity, quality, and price, and the goods they want in exchange.

Wanted.—One copy of the AMERICAN BEE JOURNAL for July 21, 1886, Vol. 22, No. 29. Any one having it to spare will confer a favor by writing to Arthur C. Miller, Drownville, Bristol County, R. I.

The Fourth Annual Fair at Mitchell, Dakota, will be held on Sept. 24, 25, 26, 27 and 28, 1888. Send for a premium list to W. F. T. Bushnell, Secretary, Huron, Dakota.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Scatter the Leaflets.—Look at the list (with prices) on the second page.

EDITORIAL BUZZINGS.

August—month when summer lies
Sleeping under the sapphire skies:
Open all the windows wide,
Drink the orchard's fragrant tide—

Breath of grass at morning morn
Through the leafy vistas blown—
Hear the clinking of the scythe
Sound mellifluent and blithe.

August, month when everywhere
Music floats upon the air,
From the harps of minstrel gales
Flaying down the hills and dales.

—Frank Dempster Sherman.

We Have received photographs of Mr. H. E. Hill, of Titusville, Pa., and his apiary, which are placed into the BEE JOURNAL Album, with thanks. Mr. Hill has had charge of an apiary in Cuba, and may return thither this fall to superintend it again during the coming winter.

Fifty Years Ago.—Mr. Lemuel Stout, of Philadelphia, Pa., writes us that he has been overhauling a hive of bees at the Penn Hospital in that city, which the Rev. L. L. Langstroth placed there over 50 years ago. They are in a Colvin hive. Of course they are not the same identical insects, but their progeny; and the hive is old.

England is not more favored than America in the matter of a honey crop this year. In a letter just received from Messrs. George Neighbour & Sons, of London, England, they say: "This is a sad year for honey producers. We are experiencing so much rain." Even though misery does love company, we are very sorry to hear the discouraging report from our English brethren. We must have a good season next year, surely, after so many poor seasons.

Decidedly Unpleasant. is what the *Australasian Bee Journal* calls the so-called "scientific pleasantry" of Prof. Wiley. It says:

Coming from a scientific man, the statement was generally believed by the public, and incalculable harm was done to the honey trade in America, and the fable is still believed by many persons. On the Professor being called to account, he excused himself by saying that he meant it only as a "scientific pleasantry,"—amusing, no doubt, to himself, but decidedly unpleasant for the unfortunate bee-keepers with touts of comb honey on hand.

Nebraska Fair.—Arrangements are being made for a grand display of bees, honey, and apiarian supplies at the coming Nebraska State Fair, to be held at Lincoln, Nebr., from Sept. 7 to 14. This department is to be assigned to permanent quarters, and \$600 has been appropriated by the Board for the erection of a suitable building. For further information write to Hon. R. W. Furnas, Brownville, Nebr.

Mr. E. Whitcomb, of Friend, Nebr., is Superintendent of the Apiarian Department. We hope that the display will be even better than last year, when it was excellent, and a credit to the bee-keepers of that progressive and enterprising State. Mr. Whitcomb is editor of the weekly *Telegraph*.

The Michigan Farmer of last week contains a very *wily* article on the explanation offered by the National Chemist. Among other fallacies and foolishness, it says:

The AMERICAN BEE JOURNAL admits that honey *has been* adulterated, but alleges it is not done now, but simply because the price is so low it does not pay. Prof. Wiley's article in the *Popular Science Monthly*, which stirred up such a bees' nest, was written in 1881. Both charge adulteration, but differ in how it is done. It makes little difference to the consumer how he gets his glucose, if get it he must.

While Wiley was speaking of comb honey, we were writing of extracted honey, and the writer of the above ought to have known it, if it did not wish to deceive, and in this *wily* way endorse the Wiley lie!

Holding the Breath to Prevent Stinging.—J. H. Amos, Andes, N. Y., on July 30, 1888, says:

On page 467, there was an item on how to prevent stinging. It said that by holding the breath, bees, hornets, etc., could be handled without stinging, thus being unable to sting, as holding the breath closed the pores of the skin. Now I believe such to be untrue, as I have tried it myself, and have seen it tried, until I am satisfied that it is a humbug; or else I lack knowledge of how to hold my breath. If there is any truth or virtue in the thing, please let me know in your next issue.

We published it for just what is now being enacted—experiments. The reports already received are against the theory advanced. Next.

The Forests and Rain Fall.—Last year the theory was advanced that the destruction of the forests was the cause of the drouth. Now the opposite is the case; rain is abundant, and Mr. J. A. Foote, in the *Indiana Farmer*, makes these unanswerable arguments against that theory:

Will you now be so kind as to tell us whether the forests have been restored? This is not a child's question—it is pertinent—it is unanswerable. If the want of forests was the cause of drouth last year, why do not they prevent rain this year. The only possible answer is that there are other and greater factors in the case. That is exactly what I have all along contended for. The causes of rain and drouth are world wide—beyond man's control, unless he can erect barricades like the Rocky Mountains, in other directions across the continent, or pump the Gulf of Mexico dry, or do some such feats as these.

Some one, in your columns last year, in view of the serious drouth, proposed as a remedy, numerous ponds throughout the State, on the theory that these would furnish moist air to be precipitated in rain. If he had only taken a moment to look at Wisconsin, bordered on two sides by great lakes, and spotted throughout with little ones, and observed that the drouth was as bad there as in Indiana, he might have saved the premature birth of that theory. Then later, in your columns Prof. Barker showed that the rainfall near Lake Michigan was less than in the interior of Indiana. That was conclusive too, as regards that theory.

The Prairie Farmer of last week was silly enough to defend "the Wiley lie," claiming that glucose was cheap, and like oleomargarine, was healthy, and would be used because of its low price. It also approves of the assertion of Mr. Wiley, when he said that "the adulteration of honey is practiced now to an alarming extent"—when every one knows that it is not so practiced, because it will not pay to do so, on account of the low price of honey.

Two Fine Photographs of our friends Charles Dadant and Son are received and placed in the BEE JOURNAL Album. The likeness is striking in each, and it seems almost as though they could speak—they are so natural.

Funny-dote.—The Crawfordsville, Ga., *Democrat* is responsible for this amusing item:

Charley Mason, of Crawfordsville, Ga., was intently watching the process of taking honey from a hive when a bee flew into his ear and was immediately out of sight. Charley turned in alarm to the doctor. "Hold perfectly still Charley, maybe he'll come out." Charley, with wonderful nerve, did as directed, and stood like a statue. In the meantime his adviser, in deep sympathy, watched for the appearance of the bee. Pretty soon, to his great delight, he saw the insect slowly backing out, and Charley had not yet been stung. But here comes the fun. No sooner did the bee get freedom of his wing, that it made a centre shot for the doctor, and became entangled in his hair. Maybe you have read "Sut Lovingood's daddy acting boss and plowing into a hornets' nest." Charley held perfectly still—the doctor didn't.

UNION AND VICTORY.

Still Another Victory for the National Bee-Keepers' Union!—Z. A. Clark's case, who was put into jail at Arkadelphia, Ark., last spring, for maintaining his apiary in the suburbs of that city, came on and was tried before the Circuit Court in the July term. The case was tried on the "clean-cut" law question, viz: That the "city ordinance was illegal and void." The first victory in this case is for the Union, the Circuit Court deciding that the city ordinance was *illegal and void*—that the keeping of bees was **NOT A NUISANCE!!**

When the prosecution realized that beekeepers had an organized body for defending the pursuit against the malicious attacks of the ignorant and the prejudiced, it *weakened*—it tried "to hedge"—was willing to dismiss all the cases against Mr. Clark on a pretended informality in his bonds!

The City of Arkadelphia has decided to appeal the case to the Supreme Court. This is very fortunate, for we want a decision which will count! One from the highest court is what we need to declare that beekeeping is *not a nuisance!* And it will be done. The Union has paid the retaining fee, and it will be ably defended again by Judge Williams, the most successful attorney in Arkansas, who assures the General Manager of the Union that he is ready for the fray. The Supreme Court meets next October.

Here is what the Little Rock daily *Gazette* of Aug. 7 remarks about the trial, under these headings: "A Celebrated Case. After a Long Legal Contest, the Little Busy Bee is Set at Liberty at Arkadelphia."

The celebrated bee-case, which excited so much interest in Arkadelphia, last summer, was decided yesterday in the Circuit Court, Judge Hearn presiding. The case was the *City vs. Z. A. Clark*, for violating a City ordinance declaring the keeping of bees, within the city limits, a nuisance. Mr. Clark resisted the ordinance upon the grounds of interfering with a natural right. Judge Hearn held that the ordinance was void because it declared the keeping of bees a nuisance *per se*, which the law does not recognize. Considerable interest is manifested in the case, the National Bee-Keepers' Union, of Chicago, being the backers of Mr. Clark. The city has appealed to the Supreme Court.

It is not only the **privilege** of apiarists to belong to such a "Union" for defense—but it is a **high honor**. Like the Royal Huzzars of history, the Union has never yet been beaten! **Victory** has perched upon its banner in every contest so far undertaken in the defense of the rights of its members! This is, of course, attributable to the care exercised in canvassing the cases before deciding to defend them; to make sure that they are **MIGHT** before going ahead with them! For if not *right*, it would be better to be beaten than to be victorious.

Mr. Clark writes us the following statement of the case, which will be read with interest:

ARKADELPHIA, Ark., Aug. 7, 1888.

FRIEND NEWMAN:—I received your telegram yesterday evening, in answer to the one I sent you, asking me to send full particulars. I have been feeling so elated, being congratulated by friends so much—(since the burial of the "nuisance case") that I hardly feel able to write. Everybody in our little City, white and black, are rejoicing but the anti-bee-council and their followers.

The case came up on Saturday, Aug. 4, when the City Attorney began to show weakness by trying to turn us out of court, on a motion to dismiss all the cases against me, on the informality of my bonds, stating that my bond was not sufficient, but Judge Hearn over-ruled the motion.

When my attorneys, Judges S. W. Williams, Witherspoon, Murray and McMillan made a motion to dismiss the cases against me upon the *voidness* of the ordinance, Judge Williams made an able speech in defense of bee-keepers, in which he showed that he knew something about bees himself, having been an old bee-hunter in the early settlement of Arkansas. After which, the Judge stated to the attorneys that he had lived a long time in Arkadelphia, and that bees had been kept here all the time, and that he had not heard any complaint until this case came up—and that the keeping of bees *per se* was not a nuisance. He reserved his decision until Monday morning at 9 o'clock, when he stated that the case would go to the Supreme Court, no matter in which way it was decided, but stated he wanted to be found on the *right* side, when decided in the Supreme Court. He then sustained our motion to dismiss the case, and declared the ordinance void. The City Attorney then gave notice of an appeal. Hence we go up higher amid the cry of "victory" and "hallelujahs."

This shows what brothers can do when banded together, with a captain like Thomas G. Newman, to direct our battles against ignorance and the prejudicial whims of an ignorant populace. Z. A. CLARK.

Reader, did you ever think of what a power there is in an organized defense? and what a powerful defense it is, when the members of the pursuit combine and engage the best legal talent which can be had—and plenty of it—and planting their feet squarely upon the constitution of Freeman—in this "Land of the free and Home of the Brave"—they demand the rights guaranteed to every "honest son of toil" by that *magna charta* of American liberty and independence—the Constitution of the United States!!!

INTERROGATORIES.

Races of Bees—Verbena, etc.—Ira N. Lyman, St. Peter, Nebr., on July 28, 1888, writes:

I read of so many kinds of bees, and so much difference of opinion as to different markings of bees, that I would like to ask a few questions:

1. Should not thorough-bred Italian bees have three broad, yellow bands? and are they not lighter colored than the common brown or black bees, as they are called?

2. Are not the bees reared in the Northern States the best to get queens from, to live in the Northern States? Are not Southern bees something like Southern

cattle, that cannot stand the hard, cold winters of the North as well as Northern-raised cattle?

3. I received a queen from New York on June 24. It was introduced into a queenless colony of hybrid-Italians, that had two nice, broad, yellow bands; and at this time I cannot see any change, only I think there are some of the bees with one and two bands, that are darker at the rear than there were in the hive before. It is 84 days since I got the queen; ought not the young thorough-breds to be out in full force before this?

Bees are doing pretty well now, but we had so much bad weather before and during the time they ought to have swarmed, that they were not able to get honey to rear brood, and were very light. Some bees had to be fed to keep them alive at the time they should have been swarming. There is one man here that had 80 colonies in the spring, and has had only 12 swarms. Bees are doing well now. Mine are storing honey in the surplus boxes.

4. I send a honey-weed to be named. The bees worked on it nearly all summer—longer than on anything else.

1. Pure Italian bees have three bright, yellow bands, and their bodies are of a light brown color.

2. Bees carefully reared in the South are usually quite as hardy as those reared in the North.

3. Yes; the Italians would now be out in force, if the queen was pure and safely introduced. But are you *sure* the colony was queenless? If not, the new queen might have been killed, and no change has been made in the race of bees.

4. The stem and flower sent is that of the verbena, one of the vervains, which, having a dense spike of blue flowers, grows 2 or 3 feet high, along the streams and barren waste-places throughout all the Northwest. It is a valuable honey-plant.

Clover Dodder.—The Rev. L. L. Langstroth, of Dayton, O., on July 30, 1888, writes thus to Prof. Cook:

I send you a plant for name. It twines around the red clover and kills it. I send you one clover plant killed, one closely hugged, and the plant in blossom. It seems to be new here, and might become very destructive. Please answer this in the AMERICAN BEE JOURNAL.

The following is the reply forwarded by Prof. Cook:

The plant sent by our friend is the clover dodder, *Cuscuta trifolii*, so named because it encircles and kills our common clover. The plants resemble wrapping twine, and by coiling around other plants, destroy them. Thus the dodders are really garroters. They seize and strangle their victims. We have several American dodders. The clover dodder is imported from Europe. The only remedy is to root up like any other weed.

Hood's Political Points.—A handy little book for the Presidential campaign, is just out. It contains finely engraved portraits and sketches of the candidates for President and Vice-President (Rep., Dem. and Pro.), electoral and popular votes in previous elections, and other useful information. Copies may be had free at the druggists, or by sending a 2-cent stamp to C. I. Hood & Co., Lowell, Mass.

BIOGRAPHICAL.

Major Francesco de Hruschka.

The following biographical sketch of Major Hruschka, is from the pen of Mr. Charles Dadant, of Hamilton, Ills., who wrote it for *Gleanings* some time since:

The Major Francesco de Hruschka died in Venice, May 11, 1888, aged about 75 years, leaving a beloved wife and several sons. Nothing is publicly known, so far, of his birth and younger years, the major having been very reluctant to speak of himself.

From information published by an Italian bee-journal, *L' Apicoltore* (August, 1878), it appears that he served in the army, and, later, in the navy, of

Major Francesco de Hruschka.

the Austrian Empire, the Italian province of Venetia, in which he lived, being then under the dominion of the Emperor of Austria.

He had attained the rank of major when he relinquished the service to enjoy the happiness of living with his family in his home at Dolo, near Venice, where he kept a large number of colonies of bees, rearing Italian queens for Germany, and manufacturing hives and other bee-keepers' appliances.

His increasing business compelled him to remove to Venice, where he resided for part of the time. The city of Venice is built on 70 or 80 very small islands, which connect with one another by more than 300 bridges. Instead of streets, Venice has mostly canals, traversed by gondolas, which are used as conveyances from house to house, instead of street-cars or carriages. The city is separated from the *terra firma* by a lagoon of shallow water, from two to four miles wide, on which the gondolas may be seen day and night. Such position makes Venice the most wonderful city for the tourist to visit, but, for the same reason, the worst city in which to keep bees, that can be imagined.

Hruschka owned a palace, in the city in which he dwelled, though boarding at the hotel, to follow his trade, while his bees were at Dolo.

Fig. 1—Hruschka's First Extractor.

From what he narrated, on his invention, to the Italian bee-keepers, it appears that, in 1865, a small piece of comb in a dish having been put in a

funnel-shaped; a glass was fastened under it to receive the running honey.

The glass was soon discarded, and replaced by a stopper. The box was suspended by a rope, and turned like a sling (Fig. 1). But as the work of extracting was very slow with such a primitive machine, Hruschka invented a large, triangular frame, at the center of which a vertical spindle, turning on a pivot, supported a horizontal beam 12 feet long, at both ends of which the boxes were suspended. Two ropes, one rolling round while the other unrolled, moved the slinging-boxes, which, dropping vertically as soon as the motion stopped, prevent the honey from running out. The length of the beam helped the extracting by increasing the speed of the motion (Fig. 3). But this big machine proving too cumbersome, Hruschka invented another extractor, with a crank and two different-sized wheels, joined by a string. Nearly all the machines now in use are only modifications, or, rather, improvements, of this (Fig. 2).

Fig. 2—Hruschka's Perfected Honey-Extractor.

basket fixed to a rope, and whirled around like a toy, by his little son, a few drops of honey were slung out of some of the cells. These few drops were, for his observing mind, the germ

Fig. 3—Hruschka's Second Extractor.

Reduced models of these first three extractors were exhibited at the Exposition of Insects, held in Paris, in 1868, entered under the name of Angelo Lessame, of Dolo, Venetia. It is very probable that the Major de Hruschka, in borrowing this name, was prompted by his modesty. It is useless to add, that the grateful remembrance of Hruschka will last as long as his invention will be used by bee-keepers—I mean, for ever. CHAS. DADANT.

Hamilton, Ill.

We noticed the death of this very distinguished gentleman and apiarist several weeks ago, on page 419, and gave the interesting history of his invention of the mel-extractor. The additional biography given above by our friend Dadant, is very entertaining, and with the engravings, present the history of the development of the useful honey-extractor very clearly. It doubtless will be read with no little pleasure by every bee-keeper.

of the large step in bee-culture which resulted from his invention. The application of this idea underwent several changes and experiments.

The first machine made by Hruschka was a square tin box, the bottom of which, covered with wire cloth, was

QUERIES AND REPLIES.

Hiving Bees on Sunday.

Written for the American Bee Journal

Query 568.—Which is the proper thing for a Christian man to do on the Sabbath, in swarming time—stay at home from church and hive the swarms that issue, put on drone-traps on that day, so as to detain the queens, often causing worry and loss to both bees and bee-keeper? or let what swarms issue go to the woods, as some of our most conscientious people say that we should?—*Apis*.

Clip queens' wings.—*P. L. VIALLO*.
Stay at home and hive the bees.—*DADANT & SON*.

The Christian man should always stay at home and hive his swarms when necessary.—*J. P. H. BROWN*.

I stay at home and care for the swarms, but I do no work with bees on Sunday that can be done on another day.—*G. M. DOOLITTLE*.

Save the bees, by all means. On the subject of religion and morals, why not consult the good and earnest Christians about you, or in your neighborhood?—*A. B. MASON*.

Being a preacher of the Gospel, I of course do not stay at home to watch the bees. I clip the wings of my queens, and if a swarm issues on the Sabbath while I am at church, they will return to the hive, and try it again on Monday. If it is right to pull an ox out of a pit on the Sabbath, it is right, under ordinary circumstances, to have a swarm of bees on that day.—*M. MAHIN*.

He should be governed by the dictates of his conscience. If my ox should fall into the ditch on the Sabbath day, I should pull him out if I had to get a derrick.—*MRS. L. HARRISON*.

I see no harm in staying at home and taking care of issuing swarms. The queen and drone trap will prevent swarming, and can be safely used for that purpose. I do not allow my bees to swarm naturally.—*J. E. POND*.

I would stay at home rather than lose them. I would clip the wings of all the queens, and cage them when they swarmed, letting the swarming bees return to the old hive—unless I could find a better way.—*C. C. MILLER*.

It is certainly our duty to adopt measures to prevent temporal loss, but not at the expense of the spiritual; and here we will let every man's conscience decide.—*J. M. HAMBAUGH*.

Save your bees any way. If the wings of the queens are clipped, it is easy to save colonies with scarcely any labor. We have simply to catch and cage the queen. If one person must remain at home each Sunday (but it is only for a few weeks), by taking turns this is not very trying, especially if one has a good book or paper, as all should have.—*A. J. COOK*.

If one's colonies are not numerous, traps can be used with little loss or inconvenience, and therefore should be; but it is otherwise if the apiary is a large one; then, in my opinion, it would be a Christian duty to stay at home and save one's self, and therefore the

world, from loss. But the injunction, "Let every man be fully persuaded in his own mind," is of the first importance.—*R. L. TAYLOR*.

This is a moral question which I think every Christian man or woman is capable of deciding for himself or herself. The swarming season in my locality does not include more than three or four Sabbath days in the year; and while watching over and caring for my bees on these three or four Sabbaths, I devote less time to my apiary (on Sundays), taking the year around, than I am compelled to do with my small herd of Jersey cows.—*G. W. DEMAREE*.

I think that every "Christian man" should be governed by the dictates of his own conscience in cases of this kind. If you are really a good Christian, you will not lose any of your christianity by remaining away from church in the day time, for a few Sundays, to hive what bees may swarm. At the same time, you can read something besides political and sensational papers.—*H. D. CUTTING*.

If you must keep bees, I see no more harm in giving them necessary attention on the Sabbath than feeding your horses, milking the cows, etc. I have had no experience with drone-traps—you might try them and see how they work. It would be folly to allow the swarms to go to the woods.—*C. H. DIBBERN*.

It is proper for a Christian man, or any other man, to be diligent and correct in his business. We should feed our horses, milk the cows, or if an animal has fallen into the pit, pull it out on Sunday, if we did not know it before. We have no "Sabbath" as such; we have instead the Lord's Day—a day of religious festivity and Christian work—not a day in which nothing is to be done, but the one day in the week in which the Lord expects full time. If we have farms, if we have animals, if we have bees, if we have families, the Lord gave them, and he expects us to care for them daily.—*J. M. SHUCK*.

What is the proper thing for a Christian woman who has a baby, to do on the Sabbath? to go to church and let the baby disturb half the congregation, or stay home with it? Some maintain that she should go, even if she has to take the infant squall along. So some argue that a bee-keeper should go to church anyhow, to the neglect of important and unavoidable business, which, if he is successful, God has commissioned him to attend to. I think that no man should neglect important business for the sake of appearing unto men to be religious. The Savior did not so teach. I believe in the spirit of Christianity, and in the gospel of good works, rather than in the letter and the appearance. If we are especially fitted to carry on any business, I believe it is our duty to guard it. Success is a good thing for a Christian if he will do good with the money. If one has a large apiary, I hardly see how he could neglect it in swarming time, if the weather was fine. But we need not watch the bees all summer. The swarming fever is usually of short

duration, and a skillful man knows pretty nearly when to look for it. If the queens' wings are clipped, and the apiary managed to prevent after-swarms, but little harm could come from a short absence. I hardly ever stay at home myself to look for swarms, nor do I require the boys to do so on Sunday. I never have lost but one swarm while at church. But I live within 80 rods of church, and am not necessarily away more than two hours. This is a question which every one must answer for himself, in the light of his surroundings, and of the appliances which are known to the fraternity to control swarming. When we have learned to control swarms at pleasure while working for comb honey or increase, then the Sabbath question will be easily answered. If it is right to milk the cows and feed the teams on Sunday, I cannot see where the harm is for us to look after the bees, since God implanted in them the instinct which impels them to swarm.—*E. SECOR*.

The proper thing for the Christian man, or any other man, woman or child to do is, to do right according to the dictates of their own consciences, whenever they are not, by so doing, infringing upon the rights of others. You will fail to find any injunction anywhere within the Bible against working or playing on Sunday. There are such against working on Saturday, the Sabbath; but such able, religious historians as Martin Luther, John Calvin, Peter Heylin, John Frith, John Milton and others, agreed that these commandments were binding only upon the Jews, else the Christian's day of worship could not have been changed from Saturday to Sunday—the day which the Sun worshippers always held sacred. The Bible Sabbath once having been abrogated, there is no longer any need of Christians keeping any day as a holy day.—*JAMES HEDDON*.

A "Christian" should make no attempt to keep the Jewish Sabbath. It cannot be done in this latitude—no matter how much it may be attempted. Christians are not bound by the old Jewish law which Christ "took out of the way, nailing it to his cross." Sunday is a day for religious devotion and work, and it is no more harm to "hive the bees" than it is to "milk the cow" or "feed the stock" on that day. Christ approved works of mercy and charity even on the Jewish Sabbath; and when his disciples went through the corn-fields on the Sabbath day and "plucked" some of the "ears" for food, some of the captious ones wanted Christ to rebuke them—but he raised himself high above the plane of their thoughts, and refused to rebuke his followers, remarking: "The Son of Man is lord [or master] also of the Sabbath." If the bees swarm on Sunday, and you do not use drone-traps, then stay at home during the day and take care of the swarms, and go to church in the evening, if you have the opportunity; it will not interfere with your public devotions more than two or three Sundays at most. We do not believe in being "over righteous" or pharasaical—preferring to have our life and every day actions plead for truth, justice and right.—*THE EDITOR*.

CORRESPONDENCE.

BEE-PASTURAGE.

Season, Sweet Clover, Chapman Honey-Plant, etc.

Written for the American Bee Journal
BY JAMES A. GREEN.

The present season in this locality has not been one to encourage the apiarist who hoped for at least an ordinarily good yield after last year's failure.

Basswood yielded reasonably well for about six days, but there is so little basswood about here now, that by itself it does not amount to much. It was in bloom from June 30 to July 12, but yielded little except between July 2 and July 8.

Previons to basswood the bees had brought in nothing except a little very poor stuff, probably honey dew. White clover yielded nothing until about July 27, when the bees began to work on it somewhat. Sweet clover also began to yield honey at about the same date, and since then there has been a very fair honey-flow. We may get quite a crop of white honey yet.

The prospect is excellent for a good fall yield from heart's-ease, of which there is a great deal.

Value of the Chapman Honey-Plant.

On July 16 the Chapman honey-plant came into bloom. I had been watching closely for the first blossom, but the bees found it before I did, and evidently appreciated it.

For some days, from two to five bees could be found almost all the while on every fresh blossom, but since sweet clover began to yield, it has been rather neglected.

Its period of bloom is evidently almost over. Only a few small heads remain to blossom. The individual flowerets yield honey only a short time. Judging from my slight experience with it, I should say that its value as a honey-producing plant has been overestimated. That the bees work on it freely does not prove that it is valuable. I could find more bees on motherwort and catnip, on the same area of ground that it occupied. In a more favorable season it might show to better advantage. I tried the experiment of tying paper over some of the heads, but the honey did not become visible.

These plants are growing in a rich, loamy soil. They are about five feet high. A single plant in clay soil did not grow so large, nor bear as many blossoms. I now have young plants growing in a variety of soils in order to learn its adaptability. Nearly a fourth of the plants were killed last winter by being "heaved" out by the frost. The plant has at least one serious enemy—two, I think. The first is a light, green worm, beginning its ravages when about half an inch long, but growing to an inch and a half. This eats the substance of the immature flower-head. At one time there was a worm on nearly every head.

When this pest had been destroyed after careful search, several times repeated, a new trouble appeared. The flower-stem just below the head would be eaten half way off, causing the head to wither and die. No other place was attacked, and I was unable to discover the enemy. I do not think, though, that it was the worm that had been devouring the heads. A brown, striped worm bored into some of the stalks, but did not do much damage.

Considering these enemies to the plant, and the fact that it must be cultivated one year, during which year it yields no honey, while it is useless for anything but honey, it would seem advisable not to plant it to any extent until further careful experiment has proved its value.

I am inclined to think that we will find it more profitable to establish more apiaries, than to attempt to increase the resources of the home apiary, by planting anything that will not pay aside from the honey it yields.

I am also inclined to believe that it will never be found profitable to plant anything solely for honey, that requires cultivation or occupies land useful for other purposes. To scatter the seeds of such plants as sweet clover in waste places, and let them take care of themselves thereafter, will pay well, but beyond this, the real profits of planting for honey are apt to be exceedingly small.

Dayton, Ill., July 31, 1888.

OUR APIARY.

What and How the Bees are Doing—Sweet Clover, etc.

Written for the Western Plowman
BY C. H. DIBBERN.

The honey-flow, though long delayed, put in a very welcome appearance about July 1, and since then the bees have been working early and late, and even in the rain. Last month I was somewhat discouraged by my inability to get the bees to breed up to strong colonies, by the time for the honey harvest which I confidently expected by the middle of June; but it seems the bees knew better. At any rate they were on hand at the right time, and right busily have they improved the time. The prospect now is a cheering one for the bee-keeper, who has his "tubs right side up." The season is certainly a peculiar one for bees. All through May and June there was great scarcity of honey, the poor bees not being able to get more than was required for their urgent necessities.

On June 12 I hived a strong swarm on empty comb, and supposed of course all would be right. What was my surprise when 3 days later they swarmed out. Feeling quite certain that there must be something wrong with the hive I proceeded to open it, and was surprised to find not a drop of honey in it. They were literally on the verge of starvation. Such a thing I had never known before. I supplied a frame of honey

and brood and returned the swarm, and that satisfied them.

We have now had abundant rains, the young white clover plants are growing finely and will probably furnish a good bloom all through August, so that the usual honey-dearth will not occur this year, or be of but short duration. Then, too, weeds that furnish the fall pasturage are growing everywhere, and prospects are for rather weedy cornfields, which means business for the bees. Taken altogether, we, the bees and bee-keepers are "all right."

Sweet Clover Yields Well.

My three-acre-patch of sweet clover is now in full bloom and on a pleasant day it is a sight to behold. The bees are on it from early morning till dark puts an end to their labors. Last night I watched them for full half an hour. They were coming from this clover patch in a perfect stream. By hundreds, thousands, and ten thousands, laden with the nectar of this little sweet clover field, and yet there are professional bee-keepers that say that it don't pay to plant for honey. My Chapman honey-plants are just coming into bloom. To-day they were only some six or eight of the little flowerets out on one of the balls; but the bees had already found it, as an Italian or two were constantly hovering over it.

Prevention of Swarming.

Last season I tried some experiments to prevent bees from swarming. It is well known by bee-keepers that if this could be certainly accomplished without too much care and labor, a great problem would be solved. Well, last season bees did not swarm, and nothing was determined. I tried the same experiments again this year, and must own up to an entire failure. The experiments consisted of two kinds. One was simply a box, about 6 inches deep, without top or bottom, but filled in with boards about half an inch apart, grid-iron fashion, with an entrance for the bees at the lower front end. The hive containing the bees, which is also without top or bottom, was now put on this "non-swarming bottom," and the bees compelled to march up and down the boards placed in this bottom.

The theory was that this bottom would furnish plenty of air, prevent the bees from becoming crowded, and take away their desire to swarm. Everything went well; they worked nicely, did not lay out, but swarmed on July 1.

Another plan was, to use one of my new hives, but filling every alternate comb with a board, and the other frames with narrow strips of foundation. My idea was, that a strong colony, placed on a bottom like that, would have plenty of room, could build comb at their leisure, and would naturally forget to swarm. I was pretty confident this plan would work, and to give the matter a more severe test, I prepared a second bottom and doubled up two colonies and put on that, thinking that if that stood the test, I had accomplished my object. This, too, appeared to work nicely, the bees commencing work promptly in the sections, and I was be-

ginning to feel like throwing up my hat, when, lo, on July 4 they swarmed. The single colony, prepared in the same way also swarmed on the next day, dashing all my hopes completely.

Upon examining the bottoms, I found the bees had built but little comb between the boards, and that almost entirely drone-comb. As I had expected to use these combs in dividing after the honey season was over, drone-comb was consequently not wanted. Although these experiments have proved failures, I think I have got some new ideas from them, and I will try another year.

Bees Hanging Outside.

Some people seem to think that because bees "lay out," they are about to swarm, or that they are more apt to swarm in warm weather than when it is cool. This is a mistaken notion. It is true that bees do swarm on the approach of warm weather, but it is because other conditions are then favorable, and they are then no more inclined to swarm on a warm day than a cool one.

Another popular mistake is, that bees are inclined to sting in warm weather, or because a person is sweaty. The truth is that they are much easier to handle in warm weather, and they are not nearly so cross.

Carniolan Bees.

The Carinolan bees are still at the front. They have all swarmed, and they are also all in the sections. While other bees are inclined to lay off, on account of hot weather, they seem to be all business.

Milan, Ill.

DIVISION-BOARDS.

Their Utility and Historic Use in Bee-Keeping.

Read at the Maine Convention

BY L. F. ABBOTT.

Division-boards should have a place in every well-regulated apiary. In fact, every well-managed apiary will include the division-board as a necessary adjunct to successful handling of bees. The division-board fits into a place in the handling of bees which no system of management can fill without them, hence they are a necessity.

This necessity in their use has grown out of the system by which bees are kept, an understanding of their ways and workings calling into requisition many things, as movable frames, the extractor, section-cases, honey-sections, and the various appliances which render bee-keeping profitable, and among them all, the division-board ranks as important a feature as either of the requisites named.

Introduction of Division-Boards.

Although the use of division-boards in the apiary as a factor of prominence dates back but a few years, it may be known to some of the more advanced apiarists that as long ago as 1852 a patent was taken out on division-boards

by Rev. L. L. Langstroth. This was 36 years ago, but the division-board, we think, did not very generally come into use till quite recently. Mr. Langstroth's board was made as follows, and will be found described on page 376 of his book, "The Hive and Honey Bee:"

"One piece $18\frac{1}{2} \times 9\frac{3}{8} \times \frac{3}{8}$, each side of each end made $\frac{1}{4}$ inch beveling, for easy adjustment. One piece $\frac{5}{8} \times \frac{3}{8} \times 19\frac{1}{2}$ nailed on the first piece, like the top-piece of the movable comb-frames. By this divider, the size of hive can be determined at will."

This reveals the use the division-board was first put to, to contract or enlarge the size of the hive. And this is an important matter when rightly considered. While there are various ways in which division-boards are useful in handling bees, perhaps the two most important advantages derived from their use is, in preparing colonies for winter, and in adapting the size of the hive to the strength of the colony in spring.

Preparing Bees for Winter.

In preparing for winter, it is known to be best to allow the bees only space according to their numbers. That may be to occupy four, five or six frames. We all know that it is easier to heat a small room in winter than a large one, and so this principle applies to the beehive. And, again, we do not want to depart from established rules in building hives as to size; were we to do so, we might lumber our premises with a large number of different sized beehives, of no use only as occasion called for wintering, and occasionally for nuclei colonies in summer.

If we use division-boards, the question of making hives to carry eight or ten frames is easily solved. It is an advantage to have some hives which will carry ten frames, as side-storing can then be practiced if one likes that way, and in working for extracted honey it is an advantage to use ten frames in the lower story, as a prolific queen will occupy that number and leave the upper story clear of brood. Then if such hives are desired to work for comb honey, and five to six frames in the brood-chamber are found sufficient, the contraction is easily made by using division-boards, or the same contraction made for wintering, and, if deemed necessary, the spaces between the walls of the hives and division-boards can be filled with some material which is non-conducting to cold, as leaves, chaff, etc.

Use of Division-Boards in Spring.

In rearing large numbers of bees early in the season, queens are induced to early breeding from two especial causes, viz: heat and a supply of proper food. A requisite of spring care is to reduce the size of the brood-nest to just as small compass as the bees can comfortably fill. Having done this in the fall previous, while the bees were more numerous, crowding them upon six frames, we will say, April may find the bees only able to cover two frames comfortably. The division-board upon each side has been the means of contracting their domicile, enabling the bees to more easily warm up their house, and

the consequence is, the queen will commence laying earlier by some weeks than if the whole space of eight or ten frames had been given the colony in the fall.

Often winter and spring dwindling will be such that two frames will be adequate to the requirements of the colony. It is, then, of the highest importance that the division boards be used so that the heat may be utilized, and by that means a few bees be enabled to do in small, contracted quarters, in the way of rearing brood, what double the number could not do in three or four times the space.

Division-Boards in Surplus Chambers.

In case of extracting, division-boards are indispensable, to place over the brood-chamber and grade the number of frames as they are put in from time to time. It is a fact known by all practical bee-keepers, that bees, in order to build combs, must keep a high temperature where they are working, to keep the wax in a proper consistency to admit of being manipulated into combs. Hence, if the surplus room is much larger than the bees can occupy, because these conditions of necessary heat are waiting, comb building will often be delayed for the necessary amount of bees to engender sufficient heat. By the use of division-boards, combs or sheet of foundation can be supplied as the bees require them, and are able to occupy them.

Construction of Division-Boards.

How to properly construct division-boards is of some importance. Solid boards answer very well, but such are liable to warp and make their use not quite so handy as those that are true. Those made of thin material and the interior filled with chaff, have advantages. Whatever kind are used, it is of importance that the ends have some material of a yielding nature tacked to them, so as to allow this board slight friction to hold it when crowded into place.

SWARMING.

Do Bees Select a Habitation before Swarming?

Written for the American Bee Journal

BY J. F. LATHAM.

Although the above caption is destitute of originality, the question is a much mooted one, judging from the correspondence, *pro* and *con*, that has appeared in the bee-periodicals during my acquaintance with the subject. As I have been much interested in the diversity of opinion by those who have given their testimony with reference to bees "seeking a home before swarming," I feel prompted to add my mite to the general fund of observation and experience.

Eight years ago I had a powerful colony of black bees in a box-hive. The colony had wintered excellently, and as the season was favorable, by the middle

of June they began to "hang out" in large masses, which the knowing ones admonished me to be a *sure* indication that I might expect a swarm from the colony at any time.

As I had but three colonies at that time, I watched them closely for about three weeks. The morning of July 8, 1880, was cloudy with a heavy fog, and as I could not work at haying, I took my ax and went to repair some fence about a hundred rods from the apiary. Being busy with the fence, the thought of bees had deserted my mind, until Old Sol from a rent in the clouds, warned me of my forgetfulness. It may be truthfully imagined that I took a beeline for the apiary, double-quick and—more.

On my arrival, I found my long-looked-for swarm clinging to the underside of a large limb, on an old-fashioned apple-tree. The cluster was about two feet long, and must have contained at least ten quarts of bees—a black, seething mass, presenting to a novice of my experience, a serious job of hiving, with the experience of the hiving of but one swarm to "fall back on."

After "fixing up" as per instructions, viz: pants tucked into my boots, thick coat on and buttoned up, thick woolen mittens on my hands and a couple of yards of mosquito-netting enveloping my head, I tackled the swarm with brush and basket. A couple of swoops with the brush landed about $\frac{2}{3}$ of the bees in the basket; the remainder went back to their hive.

After emptying my captives on a sheet in front of the hive that I had prepared for them, and getting them started in, I went into the house to "unharness," and cool off. In a short time I returned to the yard, to note the success of my efforts, and while I stood complacently observing laggards disappear as they entered the hive—*presto!* out they all came with a rush, some returning to the old hive, while the rest, after circling in the air awhile, clustered on a high limb.

I took them down on the limb and put them into the hive again; but they would not stay. On coming out, they circled around a few minutes, as if to marshal their forces, and took a beeline for the woods, some ten rods distant. After following the rovers twenty rods or more, and marking their course, I concluded to give up the pursuit and postpone the concluding act of the drama to a more favorable opportunity, deciding that the weather was extremely hot, and that two quarts of bees were not worth further effort.

On the third day after leaving the swarms, I took the line where I left it, and after following the directions a short distance, I found my absconders passing in and out of a knot-hole in the trunk of a decaying hemlock, 25 feet from the ground, not more than 40 rods from the apiary.

On reviewing the course afterwards, I was satisfied that the swarm went in a direct line from where they were clustered when I attempted to hive them, to the tree in which I found them, impressing me very strongly in the belief that they had selected a home in that same tree prior to leaving the maternal

domicile. Had I kept the swarm in view, from the time they left the bee-yard until they reached their abiding-place, the proof of pre-emption—a "forethought"—would have been very conclusive.

SOPHISTICATION.

The History and Results of the Adulteration of Honey.

Written for the American Bee Journal
BY CHARLES DADANT.

The first intimation of adulterated honey came to me about 20 years ago, when, after sending six or seven barrels of extracted honey to Mr. Perrine, a dealer of Chicago, at 17 cents per pound, I saw at a grocery in Hamilton, one or two dozen small glasses containing liquid honey, sent by the same firm, at 16 cents per pound. This adulterating business was a paying one, the glucose added being sold at 16 cents, with a profit of about 11 cents per pound.

After having made this discovery, I hastened to write in the bee-papers, and to put on our labels, that the best proof of purity for honey was its granulating. Of course this statement was fought by the adulterators, who affirmed that it was just the reverse. But now this truth is accepted by all the consumers who buy our honey; so it would be a hard task for the adulterators to sell their stuff around us. Had all the bee-keepers insisted on selling their honey granulated, as we did, the adulteration would be altogether a thing of the past.

Nine or ten years later, while offering our extracted honey to some dealers in St. Louis, I was shown comb honey in small glass-jars, filled with liquid glucose, sold by Messrs. Thurber & Co., of New York, cheaper than I asked for my extracted. I bought one of these bottles and exhibited it at a meeting of bee-keepers held at Burlington. On my request, a committee composed of Messrs. Thomas G. Newman, Rev. O. Clute, and myself was appointed, with the mission of sending to Congress a petition against adulteration.

I took the affair in hand, and sent to Washington the petition signed by more than 30,000 names. But all my trouble was for nothing, for the petition, although well backed, was sent to a committee which never reported on it; our "honorable" having no time to spare for the health and the interest of the people.

It was at about the same time that Mr. A. I. Root invented his comb foundation machine. The announcement of this new step in bee-culture gave to many people the idea that, to produce comb, we could dispense altogether with bees; especially when it was hinted that paraffine could be used instead of wax. Yet paraffine was soon discarded by those who tried it, not only because the bees objected to it, but on account of its lower melting point, for its smallest adjunction increasing

the ductility of the wax, the comb dropped in a mess to the bottom of the hives.

Yet those who consider nearly all men as rascals, continued to speak about this business of using paraffine, and soon got the idea that bee-keepers had found the means of making comb honey entirely free from bee-mediation. Such a statement was so absurd that it would have collapsed of itself, had not a professor of chemistry, Mr. H. W. Wiley, taken it under his own responsibility, by writing the following sentence in the *Popular Science Monthly* for June, 1881:

"In commercial honey, which is entirely free from bee-mediation, the comb is made of paraffine, and filled with pure glucose by appropriate machinery."

These fallacious ideas spread like fire in the whole country, not only on account of the large number of comb-foundation machines bought by bee-keepers, but especially because the statement was backed by a professor of sciences. The *British Bee Journal* for March 8, 1888, speaking of the Wiley lie says: "Naturally, subjects coming from a professor would be considered facts;" and it is for this reason that a man who fills the high office of professorship, ought to be careful not to frontish scientific jokes, like clowns in front of the tents of the Barnums; especially when their jokes accuse of fraud a large class of citizens. Such a slander deprives its author not only of the honor attached to a good name, but of all the confidence indispensable to pupils towards their professor; inspiring doubts as to the reliability of his teachings and experiments.

But this joke did not suffice for Mr. Wiley; angry at seeing bee-keepers "handling him without gloves," he published a report, to prove that nearly all the honey put upon the market was adulterated. Of course this *pretended analysis* continued to injure the trade of bee-keepers, by increasing the suspicion of buyers; the sale of honey became more difficult, and its price lowered.

But a large number of bee-keepers were not duped by the chemist of the Government; for he had gone too far; accusing of adulteration several men who were above suspicion.

To my mind, either Mr. Wiley is a poor chemist, or he continued his slander. He says that he desires to fight adulteration in the interest of bee-keepers. Then he acted as the bear of the fable, that used a big stone and broke the head of his friend to kill a fly resting on his nose while he was sleeping. The bee-business would have been more prosperous had not Mr. Wiley busied himself about it.

I think that we were among the ones who could best see to what extent the Wiley slander took root in the minds of the people at large; for after showing to visitors the shops in which comb foundation is manufactured, we have often been asked for the privilege of seeing how we put glucose in the combs!

As soon as Mr. Wiley saw his lie reproduced by other papers, his strict duty was to write to the *Popular Science*

Monthly, and to the other papers, that he was regretful of the consequences of his low joke. But he seems to be void of the sense of right to make such an apology. His haughty language shows that he thinks himself far above all of us bee-keepers, since he finds nothing but insults in answer to the reprobatious of those whom he has slandered. I doubt whether he could find a gentleman in the whole United States who would dare to excuse him.

It is perhaps necessary to add for the instruction of the professor, that when extracted honey is worth from 4 to 8 cents, adulteration is not possible, for it does not pay. We find the proof of it in the closing out of most of the manufacturers of glucose, and in the failing of Hoge, who had gone to England, where his adulterating business was so ruinous that he left about *two mills to the dollar* to be divided among his creditors!

As to the adulteration of comb honey, not only its manufacture is impossible, but bees cannot be induced to put glucose into the combs if there is a drop of honey in the fields; and the rearing of brood when bees are fed during a scarcity, employs too much food to leave a profit. Therefore, we beekeepers beg the *illustrious* (?) chemist to let our business alone, for he has already injured it too much.

Hamilton, Ills.

ROBBING.

When once started, It is very Difficult to Control.

Written for the *Southern Cultivator*
BY J. M. JENKINS.

When the honey-flow is over, and there is very little to be gathered, there is danger of one colony of bees robbing another. If, in an unguarded moment, a pilfering robber is allowed to enter a hive and escape with a load to its own hive, the bees there will be quick to detect it, and the robber will go back with a dozen excited bees determined to have some of that honey or *die*, and if the entrance is not strongly guarded they will be apt to get it.

Then a still larger crowd comes next time; the excitement runs high; battle ensues, and bees of other hives are drawn into the fuss, and the long and short of it is, they make a "run" on the unfortunate colony and clean it up in a few *minutes*. Like a lion that has tasted blood, their fury is aroused and they are ready for other victims, and woe unto the colony that is unable to withstand the first assault.

To guard against such disastrous proceedings, we must be particular in opening hives during a dearth of honey-flow, and not let robbing commence. We must see that there are no cracks whereby a prowling robber-bee may sneak in to get the coveted treasure. Then keep the entrance contracted to correspond with the strength of the colony, so that they may be able to guard it. The man that has one real good case of whole-

sale robbing on his hands, will never forget it; and for the time being, at least, he will wish he never saw a bee.

RACES OF BEES.

Different Varieties of Bees and the Plants they Prefer.

Written for the *American Bee Journal*
BY C. A. BUNCH.

Quite likely a great many bee-keepers have noticed that certain kinds of bees prefer some kind of flowers, while other races of bees work on different kinds of bloom at the same time, and as a general thing brown or German bees work on weeds more than the Italians do. I have all Italian queens, except one which is a Syrian queen; some of those queens are pure Italian, and some were mated with black drones.

One Italian queen I have reason to believe was mated with a Syrian drone, on account of the different markings on the abdomen of the workers, and the great number of queen-cells that they will build; also their different disposition. This queen was reared in 1886, and last year through the month of August its colony of bees gathered about 15 lbs. of comb honey from the common blue-thistle (this is not a large amount of honey, as we had a drouth at that time) and was capped a pale white, but the honey was quite white.

The cross between the black and Italian races were hauling in and sealing the yellow (or amber) honey, the cappings of which were so much different when the sections were mixed with the sections from the Syrio-Italian colony; they could very readily be picked out, though they were not built down so nicely at the bottom, there being more space between the bottom of the sections and the bottom of the comb. I noticed this more on account of the dark bees having a reputation for capping their honey whiter than the yellow bees, but it was the reverse this time.

The dark hybrids and black bees seem to work well on fall flowers, such as asters, Spanish-needle, smart-weed, and other fall flowers. After the thistle was out of bloom, there was but little difference in the looks of the honey.

There is always lots of timberland being cleared around here, as this was a heavily timbered country, and these clearings are mostly covered with thistle, besides lots of swamp land with fall flowers, and of course the bees have their choice.

Now, as I have had the German or black bees, the Italians in their purity, and also the Syrian bees, and watched them closely as to disposition, honey-gathering and comb-building qualities, I much prefer the best strains of Italians. The bees that are my choice are, first, bees that are gentle; second, bees that are industrious and pay well in dollars and cents for their keeping; and third, bees that are yellow and three-banded, for beauty, as I am a great lover of the beautiful.

FOUL BROOD.

What is the Cause of that Dreaded Disease?

Written for the *American Bee Journal*
BY O. B. HUNTINGTON.

In a monthly bee-paper before me it is stated that "foul brood never starts in an apiary unless there has already been some of it in the vicinity," etc. It further states that foul brood cannot "originate itself;" but says that it is *not* the result of certain conditions; and any of us can state that it "is not" the result of many other conditions, and no person would be any wiser as to the real cause of foul brood.

I have not found any positive statement, by any one, as to the cause of foul brood. I have had very little experience with the disease, but so far as I have observed, in cases where the body of the brood is in full form, the inward parts are consumed with the disease, and the sharp end of the brood is presented, which, to me, accounts for the puncture in the cap of the cell.

I would like to know if any other man has made similar observations on the subject; and if he has, may we not calculate that foul brood is caused by certain conditions similar to what physicians would call "a wrong presentation?"

One writer assumes that foul brood does not exist except by contact with affected parts. How does it start? or how did the first in a certain locality originate? I presume that no one will attempt to say that the disease is co-equal with the bee, or that it does not break out in localities far removed from any possibility of contact.

Then what is the *cause* of foul brood? Now if any man knows, I hope he will tell, so that we can all hear it, and oblige many, as well as the writer.

Springville, Utah.

QUEENLESSNESS.

Removing Queens from Colonies to Save Honey.

Written for the *American Bee Journal*
BY FRIEDEMANN GREINER.

A. W. Stith may flatter himself in the idea of giving us something new in his article on page 504—depriving vigorous colonies of their queens to "save honey." I would say that this old practice has been known to us for years; was advised over 15 years ago by Baron von Berlepsch, and many others; it also formed a part of the discussions at the German bee keepers' convention at Strassburg, in 1875. Such men as Dzierzon, Hilbert and Pollmann, there and then gave us the results of their experience, and their views on the subject, the substance of which was this:

"Removing queens for the purpose of increasing the honey crop is a risky and dangerous business, too much depending upon the season." Dzierzon

advises a better method, the *caging* of the queen and leaving her near the center of the hive.

Hannemann, of Brazil, South America, ten years ago wrote in the *Bienen-Zeitung*, of his giant colonies, which he formed out of a number of young swarms, often having from 50 to 70 pounds of bees working in peace and harmony in one box, all queens being caged in the so-called Hannemann's queen-cages (which were so constructed as to allow the bees free access to their queen, but prohibited the latter one escaping). Under such treatment brood could not be reared, and in consequence a great deal of honey was stored.

Hannemann's enthusiasm over this, his novel way of managing bees, was great, and much talked about at the time; he reaped large quantities of honey when others did not. (I have not given the details of H's management of bees, simply because I think we have better methods of securing the same object.)

When one makes the production of extracted honey a business, I have found it practicable and successful, in most seasons, to deprive, or, better, cage the queens for a short period; but when comb honey is the object, the practice is not to be commended, as it will surely result in failure.

Naples, N. Y.

EASTERN BEES.

The Foreign Bees and their Importation.

Written for the American Agriculturist
BY SAMUEL CUSHMAN.

Since the first importation of Italian queens into Austria, England and America, bee-keepers have shown much energy in their search for something still better. Long voyages have been taken to various parts of Europe, Asia and Africa, and the forests of Java and Ceylon, the home of the *Apis Dorsata*, have been visited in search of this famous race. A few years after the importation of Italians it was learned in Europe that the bees of the Island of Cyprus were a superior yellow race, and they were soon procured by leading European bee-keepers, who were loud in their praises. Several Americans procured some of this stock from these bee-keepers, and in 1880, when there was such an interest in them, and when news came of the good qualities of the Syrians, D. A. Jones of Canada started out in search of the new varieties and returned with one hundred colonies of Cyprian and Syrian bees.

Others have visited Cyprus, Syria and Egypt for queens, and for a few years an American (Frank Benton) has made this his business, and now has queen-rearing apiaries in Syria, Cyprus and Carniola, from which he supplies queens to bee keepers in all parts of the world. They are packed to take long voyages in safety at the proper season.

We are now able, for a moderate sum, not only to obtain queens from Italy,

but Cyprians from the Island of Cyprus in the Mediterranean, Syrians from Northern Syria, Palestines from the Holy Land, Egyptians from Egypt, and Carniolans from the mountains of Carniola, a small district in Southwestern Austria. Each race or variety has certain qualities not found in the others, and from this list the modern bee-keeper may select his breeding stock and combine whatever qualities he may require in his location, or for any special branch of the pursuit he may desire to follow.

For instance, one who runs his colonies entirely for extracted honey, to do the best needs different stock from one who makes a specialty of choice comb honey only; while one who makes a business of rearing queens for sale, finds certain varieties far superior for this work. Others who do not work for honey but simply for increase may do best with still another strain; and again, the one who combines these branches wants the best all-purpose bee.

Certain varieties do the best in the South; others are most desirable in the North. In some locations, very early and heavy honey-flows are the main reliance; in others, the fall crop furnishes the only surplus; while in another place a moderate flow extends through the whole season. Therefore, each locality must be studied, not only to learn the special management required, but the race or strain of bees most adapted to it. My own bees, in four different locations, require different management in each apiary. A few miles may make a great difference. When there is a failure of the crop in one apiary, another differently situated may have a full yield.

Pawtucket, R. I.

COLORADO.

How to Cure the Foul Brood without the Aid of Fire.

Written for the Colorado Farmer
BY V. DEVINNEY.

I have taken some trouble to investigate the extent of country over which this disease has spread, and I find that it includes the country bounded on the north by Clear Creek, Denver, and the Platte River on the east, Bear creek on the south, and the mountains on the west. I have reports of several cases near Morrison. Indeed cases may be found beyond the country described but I have not had the means to ascertain.

One of my worst cases, I transferred to a clean new hive, and buried the foul comb instead of the bees, and sprinkled the new made comb, bees and brood with salicylic acid, according to the formula, and now they are healthy and prosperous with sound brood. The treatment given them was of a surgical nature. We cut away with a big-bladed knife all of the worst diseased brood, leaving some which seemed all right, but had occasional cells of foul brood in it.

The good brood as we anticipated hatched out, but the occasional cells of bad brood did not—and "that was where we missed it;" for these bad cells caused new brood adjacent to them to become diseased, and thus nothing was gained by not removing the slightly-affected, as well as the wholly-affected brood. I desire to say that my thirty colonies which in spring were sick "nigh unto death," are doing well now, gathering honey in abundance, and have plenty of sound brood.

I will close this matter by describing my present method of treating foul brood. I disinfect my old hives and frames thus; I place them in the warm midday sunlight, long enough to soften the coating of wax on them; then I remove it thoroughly with a knife; when cleaned thus, I place upon the ground a small wisp of straw or hay, not to exceed two ounces, upon which I place a small "pinch" of sulphur, upheld by a cotton rag. I ignite this with a match. When in a full blaze I invert the hive over it. When I fumigate the frames I support them in a barrel or box by a movable slat. When properly treated thus, they are as good as new. I remove all the brood from a diseased hive and transfer to a new or disinfected hive. But as I transfer each frame, I sprinkle it, bees and all, with a solution of salicylic acid, one ounce dissolved in three pints of hot water and applied with a whisk broom. I disinfect old hives, after scraping them clean, by igniting a small handful of straw or hay upon which is placed a half teaspoonful of sulphur; then I invert the hive over it. I fumigate the frames in a special box in like manner.

The colonies which I have treated thus, are doing well, gathering an abundance of honey, and the brood seems sound and good.

Denver, Colo.

Convention Notices.

The Darke County Bee-Keepers' Society will hold a basket meeting on the Greenville Fair Grounds, on Friday, Sept. 7, 1888..
J. A. ROE, Sec.

The fall meeting of the Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association will be held on Aug. 21, 1888, at Leaf River, Ills. D. A. FULLER, Sec.

The North American Bee-Keepers' Society will meet at Columbus, O., on Wednesday, October 3, 1888, and continue as usual in session for three days.
W. Z. HUTCHINSON, Sec.

The Cortland Union Bee-Keepers' Association will hold their fourth annual picnic at the Floral Trout Ponds, in Cortland, N. Y., on August 30, 1888. Let all bee-keepers and their friends come and have a good time.
W. H. BEACH, Sec.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

New Subscribers can obtain the full numbers for 1887 and 1888, for \$1.75, while there are any sets of 1887 left.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*
 Aug. 21.—N. W. Ills. & S. W. Wis., at Leaf River Ills.
 D. A. Fuller, Sec., Cherry Valley, Ills.
 Aug. 27.—Stark County, at Canton, O.
 Mark Thomson, Sec., Canton, O.
 Sept. 8.—Susquehanna County, at Montrose, Pa.
 H. M. Seeley, Sec., Harford, Pa.
 Oct. 3-5.—North American, at Columbus, O.
 W. Z. Hutchinson, Sec., Flint, Mich.
 Dec. —Michigan State, at Jackson, Mich.
 H. D. Cutting, Sec., Clinton, Mich.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Good Season in Texas.—A. C. Aten, Round Rock, Tex., on Aug. 4, 1888, says :

The report of my honey crop up to the present time is as follows: From a little less than 100 colonies worked for extracted honey, I have taken 7,000 pounds, with at least 2,000 pounds more surplus now in the hives. Bees are now working on cotton and morning-glory, gathering a surplus slowly, with broom-weed, rich-weed, etc., still to bloom in a few weeks. Horse-mint produced a great deal of honey this year. On the whole, this will be a pretty good season here.

The Wild Basil.—Mrs. J. B. Currie, of Tamaroa, Ills., on July 27, 1888, writes :

I enclose a specimen of a bee-plant; it is perennial, and about 2 feet high. It has white blossoms with purple edges. It grows in the prairie fields, and is covered with bees from daylight until sundown. Our bees pass over a field of buckwheat in bloom in order to go to this plant. It roars like a swarm of bees when I walk among the plants. I do not know the name of the plant. My Chapman honey-plant has been in bloom for a month, and the bees are working on it finely.

[This is *Pycnanthemum unifolium*, one of the wild Basils, but having much less fragrance than its congeners. It has often been noted as a good honey-plant.—T. J. BURRELL.]

Uniting Colonies and Italianizing.—R. A. Williams, Poultney, Vt., on Aug. 6, 1888, writes :

I commenced the past winter with 8 colonies of bees, mostly in Langstroth hives. The tops of the hives were filled with quilts or bran sacks. They were wintered on the summer stands, which are protected, for the most part, from the north and west winds. All of my colonies wintered in fair condition, and I have increased them, by natural swarming, to 16 colonies, besides one swarm that absconded. There has been a large amount of white clover here, but it did not seem to contain much honey. About all of my surplus honey will be obtained from 4 or 5 colonies—from 20 to 60 pounds each. The rest of the bees have ample stores for winter, save a few late or second swarms.

My bees are mostly blacks, with some that are $\frac{1}{4}$ or $\frac{1}{2}$ Italians. I have wondered if it were best to Italianize my bees; but I know that it would be a hard matter to

keep them pure (some in this vicinity having tried it, but failed, as they would mix with the blacks, which are on all sides, from $\frac{1}{2}$ to 2 and 3 miles away).

I would like advice in regard to the following: I usually take up at the close of the honey season, all that I think have not honey enough to winter on, sprinkle with peppermint water, and put the bees in with a strong colony, with plenty of stores, taking the honey where there is not more than 14 to 16 pounds. I prefer to do this rather than feed the bees; and besides, I am in need of the honey, and care less for the number of colonies. Is my way right? Can you suggest a better way? I have kept bees for eight years, but I have learned more since I read your book—"Bees and Honey"—and have taken the AMERICAN BEE JOURNAL, than all the years previous.

[Oh, yes; it is better to unite the weak colonies before putting them into winter quarters. Your plan is good.—ED.]

Never Say Fail.—H. E. Hill, Titusville, Pa., on Aug. 4, 1888, says :

Last year was a failure in this locality for honey producers, and this season is worse. "No surplus" is my report for 70 colonies, in fair condition; while in 1886 I took from 33 colonies in the same yard, 2,000 pounds of finished comb honey, and 500 pounds of extracted, after transferring the bees from boxes during fruit-bloom of that year. Two entire failures in succession are discouraging; but "never say fail!"

Ionia Co., Mich., Convention.—Harm Smith, of Ionia, Mich., Secretary of the Association, sends the following report :

The Ionia County Bee-Keepers' Association met in convention at the City Hall in Ionia, Mich., on Aug. 3, 1888, 17 members answering to roll call, 8 being new members. The following statistics will indicate the condition of the honey yield :

Number of colonies reported, 878; increase since May 1, 1888, 40; losses since May 1, 38; sold since May 1, 12; honey taken, pounds of extracted, 70; honey taken, pounds of comb, 761. The present condition of the brood-nest is $\frac{1}{2}$ filled. From reports abroad, the same condition of affairs exists throughout the northern States. There is very little, if any, surplus of clover or basswood honey taken anywhere. The failure is attributed to cold, and especially cool nights. Colonies are generally reported strong, and the fraternity are hopeful of a good fall yield. The convention adjourned to the spring meeting, when called by the executive board.

Alsike Clover Yielded Well.—Thos. Stokes, Minesing, Ont., on Aug. 3, 1888, writes :

As I sit and listen to the joyful patter of the soft rain on the roof to-night, I feel a good deal more buoyant as regards the future welfare of the bees. After seven steady weeks of dry weather—with the exception of a few light showers, none of which wet the ground over an inch deep—this is a glorious day, shower after shower, until the ground is pretty thoroughly soaked. Alsike clover has yielded very well here during meadow blossom; in fact, my best colony produced 50 pounds of extracted honey in six days from it. During those days it was warm, and the sun was partially hid by summer clouds, with little wind. The bees coming over from the back of the hive dropped down at the entrance

like pouring peas out of a pail. This clover is sown more every year by farmers, simply for hay and pasture, as no seed is raised, and those that had it in this dry season have cut a far larger tonnage than the others; so it will still be in vogue among them. So far the bees have averaged 50 pounds per colony of extracted honey, with good prospects ahead.

Culver's Physic.—C. H. Dibbern, of Milan, Ills., on July 30, 1888, writes :

I send you a specimen of a plant which I find growing wild, that is new to me. It is just now coming into bloom, and seems to be very rich in honey. I counted six bees on one head, and quite a number had two and three, and they seem to stay quite awhile, like they do on the Chapman honey-plant. I shall cultivate some of this another year, and would like to know its name.

[The plant is *Leptandra Virginica*, or Culver's physic.—T. J. BURRELL.]

No Swarms and No Honey.—O. R. Goodno, Carson City, Mich., on Aug. 6, 1888, writes :

It continues as before—no swarms from the 100 old colonies, and as yet I have seen surplus honey in but two sections, and a table-spoon would hold all they contain. One week ago I had 79 colonies so full of bees that they were hanging on the outside of the hives. Some have enough to winter, and others not enough to last them 30 days. There are not enough drones to mate the queens that fly. Many light colonies, when disturbed, will "ball" the queen, and kill her. Bees are working on buckwheat for two or three hours in the morning; they have access to nearly 100 acres. In the afternoon they spend their time in petty quarreling. The air is full of one bee trying to carry off another, with no disposition to sting each other, but from the alighting-board one will catch another by the leg, and they go sailing through the air, sometimes becoming detached, and both return to the hive.

Government of Bees.—John W. Pigg, Riverside, Iowa, writes as follows :

The desire of man to govern bees, and obtain knowledge of their habits, etc., was the incentive to efforts which, by the Rev. L. L. Langstroth, resulted in the invention of the movable comb-frame. With the use of this invention began the control of bees, aided much by later inventions, especially in the use of the extractor and comb foundation.

Contemporary with the advancement in the control of bees, there have been increasing opportunities to observe their habits and disinclinations; but apiarists, except a few, have seemingly been satisfied in their governing, and have not recognized that it is a discordant government, as opposed to what is natural or self-government, with the adaptation of hives to certain habits and tendencies of bees.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4 1/4 x 4 1/4 and 5 1/4 x 5 1/4. Price, \$1.00 per 100, or \$8.50 per 1,000.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in Cheshire's pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being available, it must be sent by express.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

CLUBBING LIST.

We Club the American Bee Journal for a year, with any of the following papers or books, at the prices quoted in the LAST column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	Club

Cork for Winter Packing.—Its advantages are that it never becomes musty, and it is odorless. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2 00	3 00	3 50
1,000 Labels.....	3 00	4 00	5 00

Samples mailed free, upon application.

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; 1/2 pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices:—Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 18 cents per pound for bag and postage.

Conventions.—The time for holding Bee-Keepers' Conventions will soon be here, and we cannot give any better advice than this: Let each one attend who can do so, and take part in making these meetings interesting and instructive. If you have not already obtained the "Bee-Keeper's Convention Hand-Book," do so at once to post yourself up on how to conduct such meetings correctly. It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for Discussion—List of Premiums for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents. We will club this book and the AMERICAN BEE JOURNAL for one year for \$1.25.

Clover Seeds.—We are selling Alsike Clover Seed at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. White Clover Seed: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. Sweet, or Melilot, Clover Seed: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the BEE JOURNAL, and will send two or more free of cost to any one who will use them, and try to get up a club.

Exchange.—We will accept Honey and Beeswax in exchange for Bee-Keepers' Supplies in any quantity. Those desiring to make a trade are invited to correspond with us, stating quantity, quality, and price, and the goods they want in exchange.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, Ills., is published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

Scatter the Leaflets.—Look at the list (with prices) on the second page.

Honey and Beeswax Market.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 13@15c.; the same in 2-lbs., 10@11c.; buckwheat 1-lbs., 10c.; 2-lbs., 9c. Markets dull. We are doing all we can to reduce stock, to make room for the new crop.

BEESWAX.—26c.

HILDRETH BROS.,

May 21. 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—We quote: White to extra white comb, 12½@15c.; amber, 8@11c. Extracted, white to extra white, 5¼@6c.; amber, 4½@5c. Arrivals of the new crop are small, the estimates being an average crop.

BEESWAX.—20@24c.

June 18. O. B. SMITH & CO., 423 Front St.

DETROIT.

HONEY.—Best white in 1-pound sections, 14c. No new in market, and old is not selling.

BEESWAX.—22@23c. Supply limited.

July 24. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—We get 15c. per lb. in a small way for best comb, and less for off grades. Extracted, best white, 7@8c. None of the new crop received yet, but there is more than sufficient of the old crop for the light demand.

BEESWAX.—22c.

R. A. BURNETT,

Jun. 30. 161 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 12c.; fancy 2-lbs., 10@11c.; fair white 1-lbs., 10@11c., and fair 2-lbs., 9@9c. Buckwheat 1-lbs., 7@8c. The demand is dull for comb but fair for extracted, of which new from the South is arriving, and sells for 55@65c. per gallon.

BEESWAX.—Dull at 23¼@24c.

Jun. 15. F. G. STROHMEYER & CO., 122 Water St.

CHICAGO.

HONEY.—None here, and market in good condition for new crop. There is some demand for the extracted.

BEESWAX.—22c.

Aug. 2. S. T. FISH & CO., 189 S. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb., for which demand is fair. Comb honey, 12@15c.—Demand slow.

BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.

Aug. 8. C. F. MUTH & SON, Freeman & Central Av.

MILWAUKEE.

HONEY.—Choice white one-lb. sections, 14@16c.; 2-lbs., 13@14c.; 3-lbs., 12@13c. Extracted, white in kegs and ½-barrels, 8@8½c.; in tin and pails, 9¼@10c.; dark in barrels and kegs, 6@6½c. Demand good for extracted, but dull for comb.

BEESWAX.—22@25c.

July 2. A. V. BISHOP, 142 W. Water St.

DENVER.

HONEY.—Best white 1-lb. sections, 14@15c.; 2-lb. sections, 12c. Extracted, 5@7c.

BEESWAX.—20@23c.

Jun. 25. J. M. CLARK & CO., 1409 Fifteenth St.

KANSAS CITY.

HONEY.—We quote: 1-lb. sections, not glassed, at 18c.; 2-lb. sections and dark ones, also extracted, is not in demand. New honey is arriving freely, with a fair demand. This part of the State is favored with half a crop.

BEESWAX.—None in market.

July 20. HAMBLIN & BEARSS, 514 Walnut St.

BOSTON.

HONEY.—We quote: 1-lb. sections, 14@15c.; 2-lb. sections, 12@13c. New Florida extracted, 8@9c. Sales are very dull.

BEESWAX.—25 cts. per lb.

July 5. BLAKE & RIPLY, 57 Chatham Street.

SAN FRANCISCO.

HONEY.—We quote: Choice new extracted, 5 to 5¼c.; amber to light amber, 4¼@4¾c. Choice comb in 1-lb. sections, 13@14c.; 2-lbs., 12@13c. Arrivals are small, as apiarists are holding back. Prices are considered high.

BEESWAX.—18@22c.

Jun. 25. SCHACHT & LEMCKE, 122-124 Davis St.

KANSAS CITY.

HONEY.—We quote: White 1-lbs., unglazed, 15c.; 1-lb., white, glazed, 14c.; dark, 1-lb., 2c. less. California, 2-lbs., comb, white, 13c. Extracted, 7c. Considerable old honey is in this market. No new yet in. Sales are very slow.

BEESWAX.—None on the market.

June 9. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—We quote: Extracted, dark, 4@4¼c.; bright, 5@5½c. in cans, 7@8c. Comb, white clover in prime condition, 13@15c.; dark, 11¼@12¼ cts.—Market quiet, demand good and receipts light.

BEESWAX.—22c. for prime.

Aug. 10. D. G. TUTT & CO., Commercial St.

Vol. XXIV. Aug. 22, 1888. No. 34.

EDITORIAL BUZZINGS.

Oh! Consistency! great law

That holds vast nature's boundless realm
Fast in thy clutches. Matchless boon!
As man goes from thy law to artifice,
Thou wilt stand immovable, the wrong disclose,
Until finding his mistake, he turns again
Into God's eternal law. T. S.

September is a busy month for bee-keepers, farmers and others. The Fairs keep them very busy showing their products. We hope there will be enough honey produced to make a good exhibit, if no more. The crop is very scarce generally.

The Weather in Europe, says the *L'Apiculteur*, of Paris, during July was very wet and cold. The bees have kept their colonies strong, but have gathered only a little honey. The so-called "foul brood" is troublesome there also, and in France they are passing laws to prevent the contagion spreading.

To Go by Default.—The *Michigan Farmer* of last week intends the following paragraph for a hint to stir up the bee-keepers to a sense of their duty in joining the Union, but the last line needs comment:

Out of a total of 300,000 bee-keepers in the United States, less than 300 have become members of the Bee-Keepers' Union. Unless more funds are forthcoming, the Clark case at Arkadelphia, which has already cost the Union \$125, and is to come up for a new trial, will have to go by default.

No! No! *It could not* go by default. It was tried, and victory won by the Union! Will the *Michigan Farmer* please make a note of that fact. It is true that every one of the 300,000 bee-keepers ought to be members of the Union, and then it would be a power in the land—a mountain of strength which would protect the pursuit everywhere.

Another "Pleasantry."—Mr. P. M. Puhl, of Maumee, O., thus describes another traveling fraud, who is perpetrating another wily peddler's "pleasantry"—charging that the editor of the AMERICAN BEE JOURNAL is making, by a copy-righted receipt, so-called liquid honey, and that he is commissioned to sell the same all through the country. He avers that we are making comb honey, and fill the combs with the fraudulent stuff for which he offers to sell the receipt for 25 cents. Now let us present the letter of friend Puhl:

It is getting to be unpopular in this locality to keep bees. By the fruit growers such are despised more than saloon-keepers, and the great majority of people believe that you, Mr. Editor, adulterate the honey. Even while I am writing this a peddler comes in selling a receipt for making genuine honey, and telling of you, Mr. Newman, using it to make comb honey. Now please do not get as mad as I did, for I took the fellow by the collar and out he went. I closed my business and followed him around town, and whenever he offered to sell anything, I said this man is a liar and a fraud. I succeeded in driving him out of town without making a sale; before he came here he was in a town across the river, and sold a good many receipts at 25 cents each. Now he has gone to Toledo. From the mischief he has done here alone, I shall be obliged to fight constantly, to say nothing about the fruit growers, and we have several of the bull-headed kind here, who will not read or try to find where the trouble is, or let any one else show them. In the face of this, does it not look a little discouraging, with no honey to sweeten one's sugar-tooth with? I told this scoundrel of Mr. Root's offer. I offered to go to the telegraph office and telegraph to you and Mr. Root to prove to him that he was wrong. It was all to no purpose. I got the last AMERICAN BEE JOURNAL and read to him Willy's explanation; and he laughed at it! Now how can bee-keepers manage to show that they are not humbugs and malicious destroyers of other people's fruit? The honey receipt is copy-righted, at least so marked.

That scoundrel ought to be sent to the State's Prison. We have devoted a lifetime to the exposure of fraud, adulteration, etc., and point to our record with pride, because of its spotlessness. Now for such a villain to try to rob us of it, in this mean way, is diabolical! Among those who know us, he could not do us any harm, but he operates among those unacquainted with bee-keeping, and hence is the more damaging to the producers of pure honey.

Takes it Back.—On page 500 we referred to an item in the *Farm, Field and Stockman*, which stated that the St. Louis Society of Microscopists had examined several hundreds of samples of honey, and found the majority of them adulterated. We well knew that it was not true, and said so. The *Journal of Agriculture*, which was fooled by the item it published, has investigated the matter, and this is what it says in its issue for Aug. 2, 1888:

The facts are as follows: John C. Falk, a practical druggist and active member of the St. Louis Microscopic Society, examined about a score of specimens of honey obtained from dealers in St. Louis. He found pollen in some, and detected its absence in others, but he did not discover an evidence

of adulteration in any. Those without pollen appeared to be otherwise pure. He took a few specimens to a meeting of the society, and incidentally mentioned the facts recited. A reporter of a daily paper was present and heard his remarks. Some members informally examined specimens, but expressed no unfavorable opinion of them. That was all there was to it.

The next day a daily paper had an article which purported to be an account of the investigation of the subject of honey by the society. The editor of this department never saw the report, never wrote anything concerning the alleged microscopic examination of honey, but the editor of another department of the *Journal* read it, and deeming it an item in which honey producers would be interested, he reduced it to a short paragraph, handed it to the printer, and it was put in type without this editor's knowledge. But we feel very sure the writer never thought of doing injustice to honey producers. No one suspects them of adulterating honey. They are universally credited with sending pure honey to market, and whatever adulteration may occur is on the part of the city or town people for the gain there is in it.

The real facts now developed, show how imaginative a reporter may be, and further show that an expert microscopist has been unable to detect an evidence of adulteration in any one of twenty specimens of honey indiscriminately collected in St. Louis, all of which is to the credit of honey producers, and of retail dealers in St. Louis. We are gratified at so pleasant an outcome to the matter which had its origin in a grievous misstatement of facts on the part of a reporter.

The *Farm, Field and Stockman* also publishes this correction—but without comment. These sensational reporters are being found and exposed.

Just look at the facts in the case: A "druggist" examined a score of samples of honey, but *did not find any adulterated!* This he stated at a meeting of microscopists. The sensation-scribbler reported that the St. Louis Society of Microscopists examined several hundreds of samples, and found the majority of them adulterated! Could lying be more premeditated and pernicious?

To Save Losses we offer a word of caution. The crop of honey, be it ever so small, will soon be put upon the market, which is everywhere empty and ready to receive it. The caution we want to give is this: Do not sell honey to any person of whose financial standing you are not posted, unless you get cash in advance; no matter what are the promises or flattering offers. Either *know* that the party offering to buy it, is either perfectly good for ten times the amount, or pays you cash down. Last year there were several swindlers trying to get honey without paying for it. Hence this advice.

The Coming State Fair at Elmira, N. Y., Sept. 17 to 22, promises to be among the largest and best ever held in the State. Intended exhibitors should bear in mind that the closing date for entries is Aug. 18, and *not get left.* Secretary Woodward informs us that all entries mailed on that date will be accepted, but why wait until the last day? The railroads will return all exhibits free of freight.

GLEAMS OF NEWS.

Alsike and Sweet Clover.—Mr. W. Z. Hutchinson, editor of *Bee-Keepers' Review*, some time since took strong grounds against planting for honey. At that time we concluded not to say anything about it, because we felt sure he was mistaken, and that time would soon demonstrate the falsity of his position. It has now come. In the last issue of the *Review* we find the following which shows that it has not been for sweet clover, many honey crops already gathered would never have existed. The crop of honey yet to be gathered seems to promise exceedingly good results. Tally another one for sweet clover. The *Review* says:

In our "Planting for Honey" number, some thought that we did not do justice to the raising of plants for honey; that we dressed it in too somber colors. We still think that it was shown in its true colors. Here are two little items upon the bright side, however, and we are very glad to give them:

While riding in the cars lately, we occupied a seat in company with a young physician who keeps bees in a small way in an adjoining county. In response to our doleful tale of few swarms and scarcely any honey, he regaled us with a report of hives full of honey, and swarms more numerous than desirable. After enjoying our surprise to his heart's content, he finally let it out that all these happy results came from a sixty acre field of Alsike. We must not forget, though, that he had only a few colonies; still, we think, and have always believed, that the introduction of Alsike, in large quantities, among the farmers surrounding an apiary, is an advantage to the owner of the apiary, especially where there is no basswood, provided it does not bring with it a crop of bee-keepers.

The other item is a clipping from a letter received by us, July 27, from Dr. A. B. Mason. It reads as follows: "I was 'awful 'traid' we shouldn't have honey enough to make a display at the Fairs, but the bees are just booming, sweet clover is in all its glory, the weather is 'just the ticket,' so I guess we'll 'get there.'"

Just as we were ready to make up the "forms," the following came on a postal from our friend A. Snyder, of Coeyman's Hollow, N. Y.: "After testing sweet clover again this season, I think more of it than I ever did. Basswood was a complete failure, and had it not been for sweet clover, we Albany county bee-keepers would not have had any honey. It is such a wonderfully good honey-plant that I am saving large quantities of seed."

Minorcan Queens.—Mr. Simmins, of Rottingdean, informs us that he has received a queen from Mr. Andreu, of Minorca, and that he has successfully introduced her, and nine other queens, to their respective hives, by his method of "direct introduction." There are now in England three Minorcan queens safely introduced by three eminent bee-masters, Messrs. Abbot, Blow, and Simmins. Bee-keepers will therefore in the coming season have an opportunity of comparing the virtues of this new race with those of Carniolans and Ligurians.—*British Bee Journal*.

Humiliated, but yet Hardened.

—The astute professor of chemistry at Washington, whose humiliation was caused by our persistently-administered chastisement, presumes to court the favor of the bee-keepers he has injured so long, and without the least show of pity or remorse. His *check*, in so doing, is astonishing—and only exhibits the characteristics of the man. The following from Mr. J. F. Dunn, of Ridgeway, Ont., concerning that unbounded cheek, is commended to his careful consideration:

I am glad that you have at last forced Prof. Wiley to attempt a defense of the damaging and cowardly statements which he made some years ago. He is now, through several periodicals devoted to apiculture, publishing what he is pleased to call an explanation of the position he then took, and a very "thin" reason for his reticence since, and throws the blame on one who cannot answer his charge, as he has passed over to the "great majority." He (the *wily* man, of course) is now trying to get the sympathy of the very men he has greatly injured, and who will take all he says with the "regulation grain of salt."

I have just finished reading a New York letter in which the following sentence occurs: "Among the wonderful productions of nature in the diamond family, is a class called 'round-bort,' or by the French, 'extreme durette.' One specimen belonging to the Tiffanys was placed on a polishing wheel a hundred days, with a wheel revolving 2,700 times a minute under a pressure of 40 pounds, and it never phased that diamond." The question has been pretty freely discussed among scientists, if there was anything in nature harder than that gem; but I think it is now definitely settled by a chemist living in Washington, who is in possession of something harder than Tiffany's jewel, namely, his *CHEEK!* Cheek, before which brass melts like ice, and adamant crumbles into dust.

Indiana State Fair.—The year 1888, although a campaign season, with so many and varied counter attractions, does not diminish the interest which exhibitors take in the Indiana State Fair.

An immense two story amphitheatre is approaching completion, ready for the opening, Sept. 17. The steady growth of the State Fair proves its importance as an educator in those matters which so interest and are indispensable to the most successful farming.

Frank Leslie's Sunday Magazine for September concludes George Macdonald's beautiful story, "The Elect Lady," and gives two more chapters of the new story, "Genevieve; or, The Children of Port Royal," begun in the August number. It contains also a short story by Florence B. Hallowell, entitled "A Little Flirtation," with a very excellent moral. Dr. Talmage's sermon is "Songs in the Night," and editorially he comments on "War against Newspapers," "The Power of Prayer," "Good Examples," and "The Best of Friends." The departments are well kept up, and poems and short articles all entertaining and useful. It is a good summer number.

Bees and Honey in England.

The following from the last number of the *British Bee Journal*, for Aug. 2, 1888, will give our readers a good idea of the state of apiculture in England at the present time. It is very discouraging, not only in the United States and Canada, but also in Europe. But here is the matter referred to by our cotemporary:

The weather does not improve, and affairs now look very serious indeed. We hear on all sides not only of hay rotting in our fields, but of wheat, barley, and oats in little better condition. Wind-storms and pouring rains have "laid" the crops, and an almost total absence of sunshine, with a very low temperature, prevents the ear from filling, the grain from forming, and mildew has already appeared.... Grass and corn crops would seem to have no better fate in store than ensilage, and farmers who devote them to this are probably the wisest of their class. In an equal degree with vegetation do our little sun-worshippers, the bees, suffer. The white clover has failed to secrete nectar, the limes are in bloom, and beginning to fail, and the bees have little or no opportunity of visiting either, if, indeed, it were of any use for them to do so.

Still, in the midst of all this discouragement, swarms have rarely been more abundant. The aim of all skilled apiarists is to obtain colonies over-flowing with bees by the arrival of the main honey-flow. When that comes, with bright, settled weather, the spreading of the brood-nest is checked by the storage of honey, and a limit is placed on the production of bees, the queen being said to be "crowded out." During the present season there has been no honey to check the fertility of the queen. Hence every cell is filled with brood, and the hives, being over-crowded (almost to suffocation) with bees, swarming follows as a necessity. In our own apiary we have instances of the departure of large swarms before even a rudimentary queen-cell has been commenced. Returning swarms to the parent hive, queen-cells having previously been cut out, would seem to be useless, since the swarm, in a few days, re-issues. Many of our colonies, over-flowing with population, have less honey than they possessed in April, and we are feeding largely both swarms and swarmed colonies.

Hold your Breath while you read the following from Prof. A. J. Cook, of Agricultural College, Mich., written for *Gleanings*, and published in the Aug. 15 number:

I heard years ago of the absurdity, that holding one's breath would exempt him from stings. I thought at once that it was nonsense, but put it to the test. It was one of the most satisfactory experiments that I ever tried. I think the bee appreciated the joke, for I rarely get a more painful thrust. It was like Bro. D. A. Jones' ice water. He told me the ice water would prevent all pain from a bee-sting. I said, "Produce the water." I pinched a bee, got the sting, and at once thrust my hand *into* the cold water. I do not think I was hurt worse from a bee-sting that whole season.

This explodes, most fully, another "scientific pleasantry" given in a recent number of *Science*, and signed by one W. L. Wilder. Surely, the so-called scientists grow *wilder* and *wilder* on every matter they attack—or they are so full of *wild* theories and scientific pleasantries that they can give *real* science no time or attention.

EGYPTIAN APIARY.

The engraving on this page represents the apiary belonging to the Khedive of Egypt. It was first published in Milan, Italy, by Sartori and De Rauschenfels, on the cover of their "Apicoltura in Italy," and is there described thus:

Pavilion apiary, for 100 colonies, designed for the Khedive of Egypt, and built under

Fall Honey.—The indications now point to a good fall crop of hooley. The weather is rainy, the atmosphere hot and damp, the growth of the fall flowers luxuriant, and if no unforeseen calamity comes, there certainly will be a good crop of fall honey.

Mr. Samuel Cushman, of Pawtucket, R. I., writes the following encouraging items to the New England *Homestead* last week:

In many parts of the country, the roadsides and waste places are covered in the

C. E. Watts, of Rumney, N. H., in 1886, increased from 1 colony to 6, and obtained over 100 pounds of honey, mostly comb, all but about 25 pounds of which was gathered after golden-rod blossomed. Others in Virginia, Maine and elsewhere have done as well.

Can You Do Anything that will do more to advance and defend the pursuit of bee-keeping, than to aid its Weekly Exponent and Defender? The AMERICAN

Pavilion Apiary of the Khedive of Egypt.

the direction of Giorgio Sipos, pupil of the establishment of Luigi Sartori.

These hives are of the German type, with three stories of frames and opening at the rear.

New York Honey Crop.—Capt. J. E. Hetherington, Cherry Valley, N. Y., writes thus concerning the honey crop of Central New York, on Aug. 14, 1888:

The crop of white honey in this section of the State is light, our own being about one-fifth of last season (our own last season was good, exceptionally so). We have just had a heavy rainfall, which, we think, will insure a good crop of buckwheat, or fall honey.

fall with golden-rod and wild asters. Of golden-rod there are many species, and of the latter, often called frost-weed, several sizes and colors, and most of these yield honey. Coming so late in the season, when there is little room to store it, and bees are quieting down for winter, the honey is not usually obtained as surplus.

Rev. J. W. Shearer, of Tennessee, once commenced in the spring with one colony, increased to 5, and extracted 500 pounds of aster honey, besides leaving a full supply in each hive for winter. Aster honey is a pale amber, very bright and clear, and in flavor is delicate and delicious. That from golden-rod is thick, darker, and stronger in flavor. When extracted it is generally obtained mixed. Both have a rank, weedy odor when first gathered.

BEE JOURNAL is the pioneer bee-paper of America, and is fully entitled to the active support of every progressive apiarist, for it works constantly and faithfully for the best interests of the pursuit. We therefore specially request all our readers to use their influence to double our subscription list during the coming autumn. Reader, will you please send us a new subscription with your renewal or before that time? A good weekly at one dollar a year is surely cheap enough to command patronage.

Abner Brown, possibly the most extensive apiarist in Ingham county, Mich., states that the honey yield this year will be an absolute failure. His 41 colonies will not produce more than enough to feed them during the winter.—*Lansing Repub.*

QUERIES AND REPLIES.

Do Queens Lay Eggs in Royal Cells?

Written for the American Bee Journal

Query 569.—1. Does the queen ever deposit an egg in the royal cell? 2. In what kind of a cell must an egg be laid to produce a female? 3. Are eggs ever put into the royal cell? 4. At what age should the larvæ be to produce a perfect female or queen?—G.

1. I think not. 2. In a worker or queen cell. 3. Yes, of course. 4. Not over three days.—DADANT & SON.

1. Yes. 2. In a royal cell to produce a perfect female (queen), and in a worker-cell for an imperfect female (worker-bee). 3. Probably so. 4. From 1 to 3 days.—P. L. VIALLO.

1. I do not know. 2. It makes no difference, so that it is hatched in a queen-cell. 3. Yes, by the bees. 4. Not more than 3 or 4 days' old.—C. H. DIBBERN.

1. Yes. 2. All impregnated eggs produce females, no matter in what kind of cells laid. 3. Yes, by the queen, and sometimes carried there by the workers, but not often. 4. From 1 to 36 hours' old.—G. M. DOOLITTLE.

1. I never saw her do it. 2. If the queen controls the fertilization of the eggs, the kind of cell has nothing to do with the sex. 3. Certainly, or there would be no royal bees. I have known eggs to be put into royal cells by the workers.—A. B. MASON.

1. The queen deposits the egg, and workers construct the royal cell. 2. If by "female" you mean queen, it is the food upon which the embryo bee is fed, which causes it to become better developed and become a perfect female. 4. See Langstroth's book.—MRS. L. HARRISON.

1. Yes. 2. The cell has nothing to do with sexuality. 3. Evidence proves that they have. 4. As early as possible after being hatched, and not over 3 days.—J. P. H. BROWN.

1. Yes, undoubtedly. 2. An egg that would produce a female in one kind of a cell, would produce a female if deposited and nourished in any other kind of a cell. 3. Yes, by the queen; not otherwise. 4. The younger the larva is when devoted to the purpose of producing a queen, the more perfect will the queen be, other things being equal.—R. L. TAYLOR.

1. I suppose that she does. 2. If by "female" you mean a queen, it may be laid in any kind of a cell, although nearly always an egg laid in a drone-cell will produce only a drone. 3. Certainly. 4. I should rather have them more than a day or so old.—C. C. MILLER.

1. I do not know. 2. It is my opinion that the cell must be worker size. 3. They must be "put there" or they would not be found there. 4. The books say not to exceed 3 days.—EUGENE SECOR.

1. I do not think that I ever saw one do it. 3. Yes, always. 4. It is best to produce from the egg; an egg just hatched will do.—H. D. CUTTING.

1. Yes, I have seen it done. 2. I have seen them in all cells of the hive except royal cells. 3. I think they are. 4. O, 2 or 3 days. I would risk them over 4 days old.—J. M. SHUCK.

1. I think she does. 2. A queen can lay an egg in any kind of a cell that will produce a female. 3. It is doubtful. 4. The younger the better. I have had good queens produced from larvæ three days old from the time the eggs hatched, but only a few.—M. MAHIN.

1. Authority says they do; yet I have doubts. Who has seen the queen in the act? 2. I have never known workers to be produced from drone-cells, however such a thing might be demonstrated on scientific investigation. 3. I think not, though it may be. 4. Four to six days.—J. M. HAMBAUGH.

1. This is a mooted question. I myself do not know. 2. I do not understand the question. Workers are females, and are reared in worker cells. Queens are reared in queen-cells. 3. See No. 1. 4. Not over 3 days old.—J. E. POND.

1. She does. 2. The cell is immaterial, though it is usually in a worker or queen cell. 3. Yes. 4. This question is indefinite. If the larva is fed 4 days as a worker larva, it will usually produce a drone-laying queen, and always a very poor one.—A. J. COOK.

1. Yes, but I never knew any but very old queens to do so. Very old queens instinctively fall into the plans of the workers, or at least submit to what is best for the future good of the colony. 2. It makes no difference about the kind of cells, a female is a female any day. 3. Sometimes by very old queens. 4. From 1 to 2 days old. I once had two queens reared from larvæ three days old, that made first-rate queens. On one occasion I transferred a 4-days' old larvæ to a provisioned queen-cell, and it came out a good, strong queen.—G. W. DEMAREE.

1. I think that she does, but I do not know positively. 2. To develop the perfect female, the egg must hatch in the queen-cell. 3. I fully believe that eggs are often carried by the bees and placed in the royal-cells, and fed with such food that they bring forth perfect queens instead of workers, as they otherwise would have done. 4. I suppose it might reach $4\frac{1}{2}$ or 5 days of age, and then be changed; but I make a rule of $3\frac{1}{2}$ days in my queen-rearing.—JAMES HEDDON.

1. Yes. 2. The only perfect female in the hive is the queen. An impregnated egg, no matter where it may be deposited, will produce a female if allowed to mature. 3. Yes. 4. Not over 3 days to produce a good queen.—THE EDITOR.

We will Present a Pocket Dictionary for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

CORRESPONDENCE.

BEE-NOTES.

Various Items Relating to the Management of Bees.

Written for the American Bee Journal

BY REV. J. D. OEHRING.

This is my fifth year in bee-keeping. I began by transferring 3 colonies from box hives and 1 from a sugar barrel. The latter I transferred in December, the work being done in a dark cellar by lamp-light. It was a very populous colony, with plenty of nice comb in large pieces, but without any stores. I put them into an Armstrong hive, using ten frames, and fed them 20 pounds of granulated sugar syrup, within five days after transferring, and left them in the cellar until about Feb. 18, when I put them out for a flight. That season (1884) this colony gave me 2 good swarms, and 34 pounds of fine comb honey in sections.

This experience, when I was a "greeny," convinced me that transferring can be done almost any time when there is but little brood, if the work is carefully done, and the colony properly taken care of afterward.

Packing Bees—Extracting Craze.

I now have 34 colonies, mostly in new hives, which are cool in summer and warm in winter, like the log-house of our fathers. This is equivalent to saying that I winter my bees by packing, and tucking them carefully in before freezing weather has come, and then leaving them thus until warm weather is a settled fact. I have never lost a colony on account of cold or starvation (?). (The interrogation and exclamation points are intended to express my doubt that bees freeze to death if they have available food, and my astonishment that any intelligent bee-keeper will allow a colony to starve.) I think the extracting craze is much to blame for the latter, as many bee-keepers—notably those who love bees because they love money—extract too closely early in the fall, hoping and expecting that the bees will fill up the hives (with what?) before winter.

I think that such conduct is not only foolish, from a business standpoint, but it is absolutely wrong—wicked. What right has any man to rob—yes, rob is the word—a family of bees which has worked for him all summer, and made seven or twelve dollars for him? What (moral) right has he to take well-filled frames from the brood-chamber late in the season, extract the honey, and give them back the empty combs? I say again, it is foolish and wrong! If they do not need all the honey they have stored in the brood-chamber, it is not lost by remaining there through the winter. Besides, I am very much misled by observations that I have repeatedly made, if a well-filled frame of honey on two sides of a brood-nest are not worth several times more than a

blanket or a basket of packing stuff to keep them warm.

This is my conviction on this subject; and until I shall repeatedly fail to winter my bees successfully, I shall persist in the "notion" that the much-dreaded and much-written-about "winter problem" should be made a "moral issue." I mean that plenty of young bees and plenty of good honey will prevent—if not cure—"winter killing" of bees.

Moving and Italianizing Bees.

I have moved my bees—not for fun or for play—four times in as many years; and here again I have failed to find wherein the danger and loss consist.

I began the business with black bees. My efforts, though persistent, to Italianize, have brought success only to hybrids—except 3 or 4 colonies from which I breed. I try to rear only pure drones, but all the bees kept in the neighborhood are blacks and hybrids, and my nice yellow young queens, nearly every time they go out, get into bad company and are spoilt.

Bees "of Color" Underestimated.

But, after all, I think that the bees "of color" are underestimated at the expense of the "bleached" race. Talk about the blacks being cross, and lazy, and what not! Why, last summer, I was stung nearly to death (figuratively) by a swarm of pure Italians when I tried to take them down from an apple tree! "They fit, and fit, and fit;" and after all the trouble, vexation and pain, and hiving them three times (in a nice, clean hive, too, in which they had empty frames, frames of honey, and a frame of brood), they finally left without so much as a "thank you, good by!" No colony of blacks ever served me in such a vindictive and ungrateful manner.

And robbing! They beat the worst pirates at that when once on a "scent." The only cure I have yet found for your "beautiful Italians," when they go out "coon hunting" during melon time, is to play "tit for tat" on them. That brings them home.

"But they gather honey from red clover, which the blacks and hybrids can't do." Yes, they can, but they do not do it much—at least not here where the clover gets very large. Besides, the blacks can beat them on "fitting and finishing;" they make nicer, whiter capping to their comb honey, every time.

Report and Prospects of the Season.

I wintered 18 colonies. In the spring (April 1) they had plenty of honey and brood, and though located in an orchard of 12,000 fruit trees (mostly apple and plum), they gathered nothing but pollen. In May I had to feed every one of them, and yet they "dwindled" some. White clover came on abundantly, but did not yield much. During linden bloom, which is abundant here, the weather was cold and wet until the best was past, and they got in only four or five days' work on it. Three hundred and fifty pounds of comb honey in sections is my whole crop, so far. I am getting 20 cents per pound for it.

There are about 80 acres of golden-rod within easy range of my apiary. It will begin to bloom soon, and I expect a good yield from it, if nothing befalls it. Last year a heavy frost overtook it in all its golden glory.

Next fall I shall (*D. V.*) pack up and go to Alachua Co., Fla., and I shall take a few colonies along.

Union Army and Scientific Plesantry.

But before I go South I shall join the "Union" army. Hadn't we better send out recruiting officers? I will send you the fee when I sell my remaining honey.

Mr. Editor, you have "done up" that Wiley fellow in hot glucose now. No wonder he snarls and squirms. Thus may it happen to all the authors of "scientific plesantries" on the honey question. We owe you a vote of thanks and a "gold-headed cane."

Parkville, Mo., July 25, 1888.

Summer Work of Bees.

Written for the American Bee Journal
BY GEORGE W. YORK.

The nectar so sweet the bee-keeper sees,
His hives filling up by the work of the bees,
Each coming laden with sweets from the trees.

A merry young bee goes forth from the home,
Mingling with others thus ready to roam—
Every one off for the flower-decked fields,
Right where the basswood so gratefully yields
Its bountiful treasure of bright, golden sweet,
Cheering each bee that so gladly they meet;
A busy and buzzing crowd are they—
Not stopping to idle, but working all day.

But to rid their keeper, we must allow,
Every bee makes it a solemn vow,
Ever to labor as hard as now.

Just over the hillside decked with flowers,
On field and meadow, "neath blooming bowers,
Unseen and unheard does the "busy bee" work,
Rushing hither and thither, but never to shirk;
Now dandelions, butter-cups, lady-slips too,
Are yielding their sweetness for me and for you—
Loving the bees for all that they do.
Chicago, Ills. —Acrostic.

STINGING.

A Dream About "Holding the Breath" to Prevent Stings.

Written for the American Bee Journal
BY EUGENE SECOR.

I had a dream. You know it has been asserted as a scientific fact that a bee-sting cannot penetrate a man's cuticle while he holds his breath. I have a profound respect for science. When science says a thing is so, it's got to be so. Science *used* to say the world was flat, and that the sun made his daily circuit around it. Of course it *was* flat then. Even Galileo openly recanted the spherical heresy. But now the world is round because science says so. When science says "thumbs up," thumbs must go up. People never suspect science of joking. When it said several years ago that, "*In commercial honey, which is entirely free from*

bee-mediation, the comb is made of paraffine and filled with pure glucose by appropriate machinery," they believed it, and all the bee-keepers in Christendom have failed to convince them that it is not a fact. But to my dream.

My mind had been exercised over that scientific discovery, or the revelation of it rather. I wanted to test it. I had no doubt it was scientifically true, but you know the spirit of enquiry that pervades the mind of young America. For a man to be an agnostic in religious matters is considered smart in some circles, but to be a know-nothing in science is to lose caste.

This is a practical age, too, and the Yankee wants to demonstrate every theory he hears of. The only reason he does not, is because life is too short to devote to scientific investigation and money-making too.

It was a hot day at the close of the basswood harvest. But little honey was coming in. Swarming was apparently over. Bees were cross. I had lain down in the hammock for a short rest after dinner. I could hear the sweet hum from 40 colonies as the happy young bees sported in front of their hives. I lay there enjoying the music when I saw an after-swarm rushing with new-born zeal from one of my hybrid colonies. The frisky young queen soared high. After an unusually long frolic in the air they alighted in a jack-oak tree fully 25 feet from the ground.

As luck would have it, the swarming-pole was broken, and the boys had gone to the hay-field. The great 20-foot ladder was brought into requisition. As I could reach about 8 feet myself, it looked easy enough to secure them without any assistance. I leaned it against a dead limb, and it did not lack more than 5 feet of reaching to where the bees hung. With saw in one hand I ascended. Reaching next to the top round I could reach the limb on which the bees were clustered. I proceeded to hold the limb with one hand and to saw it off with the other. Just as it was severed, the added weight of the limb and bees with my own, broke the dead limb. The ladder dropped back 2 or 3 feet with a sudden jerk, shaking about half the bees off on my head, neck and hands.

Didn't I have a veil on? Not much. I am no green-horn in this business. Besides I was determined to demonstrate a great truth in science. I had the opportunity. They were not amiable. They were bent on mischief. With a wonderful unanimity of purpose, and surprising concert of action, they unsheathed their swords and proceeded to business. Of course I held my breath. I had been holding it for the major part of a minute in anticipation of just such a contingency. I filled my skin so full of resistance there wasn't any room for even the point of a javelin.

About a thousand bees, more or less, were humping themselves to get in the first "lick" at me. It sounded like frying fresh fish in salted butter. I held the fort, *i. e.*, I held my breath. I thought they would get tired of resist-

ing the inevitable laws of science, but they "held the fort" too.

In my zeal to demonstrate a scientific truth, I forgot to descend the ladder until I was as red in the face as a boiled lobster. I then for the first time realized the fact that I could not hold my breath more than several minutes even to accommodate science. I must have some oxygen anyhow, or my lungs would collapse like a pan-cake with too little soda in. I was not organized like a fish, that is sure (unless it was a whale), for I wanted to *blow*.

I was all the time standing on next to the top round of the ladder, holding on nervously by one hand to a small limb, and the severed limb and a part of the bees in the other. The rest were clutching my naked flesh with their claws, their backs elevated like a cat on the back fence at a feline concert. No matter, breathe I must.

Just then the faithful dog appeared on the scene, under the tree, as interested as if I was capturing a coon for his especial delectation. Although I was the center of attraction, enough scouts paid their respects to him to give him a warm reception. After rolling over several times, he started for the house in haste. You see he had not been educated to hold his breath. In going he ran against the foot of the ladder, and down it came, and "me too." When I struck the ground, I awoke. It was only a dream. A couple of robber bees were angrily buzzing around my head.

Forest City, Iowa.

SILVER LINING.

A Poor Crop, but Higher Prices are the Result.

Read at the Maine Convention

BY PRES. J. B. MASON.

Last year we passed through one of the hardest seasons in our pursuit that has been known for many years. This will totally dampen the courage of many of the beginners, and will cause a sifting out of the chaff from the wheat. It is said there is never a cloud so dark but it has a silver lining.

I think it is not hard to see at the present time that this poor season may be a blessing in disguise, and may work for the good of our business. Our large markets had got overstocked with honey, prices had been knocked down by shipping honey into the already overstocked markets, until honey was selling at ruinous prices. The Wiley lie was floating over the country, that there were numerous manufactories where bee-comb was manufactured and filled with glucose syrup, and sealed over with hot irons. The newspapers wafted this story along, and thousands believed the story although it was so inconsistent.

This failure of honey from the flowers has cleared out the honey markets so that commission men have been calling loudly for honey, at good prices. Where are these glucose manufactories all this time, that they allow the markets to become so bare of honey even

at doubled-up prices? This ought to open the eyes of the community on this subject, and strike a death-blow to that infamous lie.

We owe a vote of thanks to Bro. Newman, of the AMERICAN BEE JOURNAL, for the fearless and manly way in which he has fought this falsehood from the start. Our product is now in good demand at remunerative prices, and it remains with the bee-keepers whether they will allow our markets to become so demoralized again, or whether they will, by some arrangement, have our honey more evenly distributed over our country. This is one of the great questions of the day.

Mechanic Falls, Maine.

THE UNION.

Join the Bee-Keepers' Union Before it is too Late.

Written for the American Bee Journal

BY HENRY K. STALEY.

Pursuant to the call for apiarists to become members of the Bee Keepers' Union, and cognizant of the dirty, mean, outrageous and untruthful lies circulated (a good deal like the way the Canadian thistle scatters its seeds over mother earth) concerning our occupation, by people who either seem to like to create a sensation for reputation by writing an untruthful statement, and then nonchalantly placing it under the title of an ("S. P."); or else by those who hold our pursuit as their "bone of contention," that they may have something upon which to gnaw and pick, and dilly-dallyers in it who very often are disgustingly ignorant and ignorant apiculture; and also aware of the many cases in our pursuit *in re* bees puncturing sound grapes, being condemned as a public nuisance, and eating sound, young ducks, brought up before the courts through circumstantial evidence—that robber, very often, of a fair trial, under whose bloody banner many an innocent man has gone to the gallows—I feel it my urgent duty, although I have no need of linking myself to the Union, but towards helping to defend our pursuit in general, to contribute my mite of one dollar to the fund of the Union, which I heartily do.

I hope that the Union will still keep "banging" that vile monster in the "eye"—the enemy of our pursuit who is trying to wipe it out of existence—until it becomes so "black and blue" that he will have to hide his disgusting face for shame, veueered with lies of the most horrible stamp.

Reader, if you know any who are inclined to trudge after this monster into the depths of untruthfulness, catch him by the coat-tail (like alligators are about to do, often printed on the outside of envelopes, which say, "If not caught within 10 days, return to" so-and-so) and "churn" him until he perceives his mistake, whereby, rest assured, you have saved him from a horrible calamity.

Right it is to look out for number one in this age in which swindling and

bulldozing are indulged in to such a great extent by so many people, such as sharks, bunko-steers (fellows who make light the pockets of head-raised and open-mouthed swains), confidence men, etc. Any one acquainted with the habits of such scoundrels as mentioned above, knows that he cannot get "something for nothing" in this world, or the Latin saying applies as well, viz: "*Ex nihilo, nihil venit*;" but understands that he must look out for himself, and that is right, for we know that God helps the man who helps himself; but nevertheless, that is no reason why we should not look out for number two, especially when in return number two looks out for us.

Remember also, that if you get into a scrape or pickle, and then a few, after you have sent in your money for the first time, petition the Union for aid, your case would be in the same dilemma as the little girl, who, having obtained a pitcher of milk at the store, on the way home let it fall, and lost the contents; then, that it might soothe her, she wept tears until they coursed down her dimpled cheeks in tiny streams; but the crying over the "spilt milk" was to no avail, as the pitcher was broken and the *lac* gone.

And so of no use to you would it be to ask the Union for help, if you sent in your membership dues for the *primus tempus*, simply to get out of trouble, expecting the Union to bring about the end desired; for if you are not pumpkin-headed, you will understand what the Union means. If it should say, "It's too late to shut the stable-doors when the steed is stolen;" and more so if you are minus a couple of fine trotters by horse-thieves.

The parable of the "Ten virgins" would apply quite well to your situation; the Union would be willing to advise you, but of its "oil" it would give you none.

In conclusion let me say, "delays breed dangers; nothing is so perilous as procrastination." Yet it is "better late than never," as the saying goes.

Pleasant Ridge, Ohio.

DEAD BROOD.

Several Ailments which Affect the Brood.

Written for the American Bee Journal

BY H. E. HILL.

In reply to the query, "What ails the bees?" on page 501, I would say: Two years ago I met just such a condition of affairs in my apiary, and forwarding a specimen of the brood to Prof. Cook, I awaited the verdict with no little anxiety. It came, and was "chilled brood;" and I have since observed dead brood from different causes, which, owing to existing circumstances, remained untouched by the bees. Such conditions are, not infrequently, to be noticed in such colonies as possess great swarming propensities—if allowed to swarm until the remaining bees become so reduced as to leave the brood exposed to the chilly night air; and

such colonies will allow the brood thus chilled to remain until it becomes black and dries up in the cell.

This, however, would not appear to be the cause of the disorder in the "young colonies," which the lady reports "diseased," though the fact that it was necessary to cut out queen-cells from the young colonies, would go to prove one of two things, viz: they are "swarmers," or else the United States honey crop of 1888 is "bunched," and fortune smiles on Mrs. Dorsey's locality.

Another cause is, "scalded" brood. Last season (1887) the covers of several hives were laid directly over the brood-frames, without a cap, cushion, or other protection from the direct rays of the sun, and the intense heat, when no honey was flowing, would cause the bees to cluster outside the hive; and the result was thousands of dead larvæ, which remained in the cells for weeks. I am an advocate of *fire* for foul brood. Titusville, Pa.

VENTILATION.

While Such is Necessary, it Must Not be Much.

Written for the Farm, Stock and Home
BY WM. URIE.

A great deal has been said about bees wintering without upward ventilation, and quite a number of bee-keepers claim that they winter better without any upward ventilation, saying: Bees in their natural state—in the trees of the forest—have no ventilation and winter well, and seem to do much better than those having the best of ventilation. We have found many wild swarms in the last thirty years in many kinds of trees, and in nearly every instance we found, either above or on the sides of the swarm, rotten wood which the perspiration from the bees could pass into, acting the same as upward ventilation. Some parties claim that they winter bees safely without upward ventilation, and that it is the proper way. If they will invert their hives and pour water into them it will run out, therefore they are not air-tight, for where water will run through, air will escape.

It is true, if bees are kept in a perfectly dry place and at a temperature of from 45° to 50°, they require much less ventilation than they would if kept in a damp, cold place. If bees are kept where it is continually freezing and there is no place in the hive for the escape of the perspiration that passes from the bees, it will commence to freeze on the outside of the hive, and if it continues cold you will find your bees dead, and ice formed all around the cluster of bees. Had there been a small opening at the top, or near the top of the hive, for the air to escape, nothing of the kind would have happened.

It only needs a very little upward ventilation for bees; a good many bee-keepers give altogether too much. They need all the heat in the winter and spring months that can be obtained. Give only what will be necessary to let the perspiration out so that the hive

will not become damp on the inside. It is a good plan to leave the bottom-board off, or raise it up on blocks one inch, when wintering, especially in cellars; as the foul air always settles, and if the hive is raised it gives a chance for it to escape; and if there is any dampness in the winter depository it will prevent the combs from moulding.

The heat and circulation of the cluster of bees render the combs dry for some distance around the cluster, but there is not enough of this circulation of air, nor force, to drive it to all parts of the brood chamber, and a part (often a very large part) of the comb that is damp with moisture extends up at the sides of the cluster to the top bees. This moisture gets into the honey and causes it to sour; and as the foul air is impure, gas rises on top of the brood-chamber, making the bees uneasy and they begin to move about, use the sour honey (which causes the diarrhoea), and the destruction of the colony ensues. We are safe in saying that a colony of bees never was known to have the diarrhoea when the honey and combs were kept perfectly dry.

Those that winter their bees without proper ventilation are often heard to complain that their bees got restless and uneasy from being too warm. My experience has proven that it is not the warmth, but the fumes of the sour honey arising below and accumulating in the upper portions of the brood-chamber that makes them uneasy, and the removal of the tight cover on top of the hive at such a time will convince any person that proper ventilation is necessary to the health of the colony. Minneapolis, Minn.

THE SEASON.

Experience with a Laying Worker, etc.

Written for the American Bee Journal
BY REV. S. ROESE.

On Nov. 14, 1887, I put into winter quarters 47 colonies of bees, but not in good condition, and the most of the hives with upper stories on all winter. On April 12 I put them out, and found 7 colonies dead; the rest very weak, and two were queenless. I lost 5 colonies by spring dwindling, making 12 lost in all, which was not very bad considering the cold and backward season.

In June one colony became queenless. I tried to have it rear a queen from unsealed brood given them, but a laying worker seemed to destroy the cells when nearly ready to hatch out. This laying worker annoyed me more than anything in the bee-line this season. Twice I gave them a new set of combs with brood, and twice I united them with a new swarm, and each time they became queenless, and went to naught. I finally removed the hive, placing in its stead a newly-hived swarm, most of the working bees going back to the old stand, and leaving the laying workers with a few bees alone, which I afterward shook on the ground, and made better use of the combs.

White clover yielded little honey in this part of the country. I left it all for the bees to breed on.

On June 1, I purchased 5 more colonies in Langstroth hives, for \$12.00. Then I had just 40 colonies to begin the season with, which I have now increased to 82 colonies, 3 swarms having absconded.

The basswood honey flow was short, being only for a few days. Raspberry and corn have furnished the only surplus honey that we have had thus far; and for the last two weeks, the weather being so cold and wet, bees have not been doing anything, and they are so cross that no one dares come near the hives.

I extracted just 600 pounds of honey in all, up to date, and there are about 6 or 8 Simplicity section-cases nearly filled. This is not half the quantity of honey from 82 colonies that I had a year ago from only 47 colonies.

I fear that our honey season is over, at least for surplus, and bee-keepers had better prepare their colonies for winter early. If we are disappointed by an unexpected honey-flow this fall, it will be a happy disappointment. Crops here are almost a total failure. Winter wheat is not half a crop, and spring wheat is not worth cutting. Barley amounts to almost nothing, oats are partly filled, and if an early frost comes, corn will also be a total failure; thus people will have a reason to feel low spirited. But we will trust in Providence, having the promise that seed-time and harvest shall continue to the end of time.

Maiden Rock, Wis., Aug. 9, 1888.

CONVENTIONS.

The Benefits Derived from Bee-Keepers' Meetings.

Read at the Indiana Convention
BY C. H. HALL.

The old and familiar adage that, "Whatever is worth doing at all is worth doing well," is no truer in any other undertaking than that of the culture of bees. It was thought for a long time that the bee was guided wholly by instinct in the performance of its domestic duties, and that it did the best possible when alone. But since bee-culture has become a science, it has been found that the bee is capable of reasoning and being taught.

What the Bee has Taught Us.

The bee is much older than Adam, but it was left to the sons of Adam to make it possible for a single colony, which formerly yielded from 50 to 75 pounds of honey, to yield from 500 to 700, and even 1,000 pounds per annum. While man has enabled the bee to improve upon its old methods of work, and increase its products ten-fold, it has in return taught him not a few important facts. Through observations of this little animal in the field, he has learned the best method of cross-fertilization of all kinds of vegetation. The bee has taught him that a good fruit

year does not depend as much upon the fact that it is preceded by a white or black Christmas, as upon the number of bees that survive the winter.

Bee-Conventions are Modern Societies.

Bee-culture is a modern science. Thirty years ago a bee-keepers' association was scarcely thought of; to-day they are found in nearly every progressive county of the Union, where any attention is paid to the culture of bees at all. He who will take the time to run over the records of the last thirty years, will very soon discover some of the benefits derived from such associations. No single individual has ever been able to discover all that can be found out concerning any one thing. God never designed that he should. Man's dependency is one of the causes of his sociability; and should he become independent in any one particular thing, in that proportion will he become reserved and selfish. So the benefits of sociability and meeting with friends and neighbors, and the exchange of opinions that come to the members of every association are found as well in this organization.

But it is our purpose to ascertain some of the special benefits derived from a bee-keepers' association. These benefits may be classed in two divisions, viz: the immediate and remote. I take the prime object of bee-culture to be the production of honey; and whatever relates especially to that in this essay, I have denominated as immediate benefits; and those things which relate to the study of the bee as an animal, or to the development of the flora, I have designated as remote benefits.

Bee-Hives Used Long Ago.

It was thought at first that the hive most nearly like the one the bee used in its wild state, would be best suited for her demands; so a portion of a hollow log was used, and probably received the name of "gum" from the tree of the same name, from which it was taken. When the tree could not be obtained, a box opened at one end, whose diameter was about the size of the supposed tree, was used. Where do you find such a hive to-day? Show me such a hive and I will show you a man who either does not take much interest in bee-culture, or else he has been compelled by emergency to use it merely as a temporary convenience.

With such a hive the colony was almost destroyed every time the honey was taken; and then we called it "robbing" the hive; the word hardly expresses the act, unless we think of it as a highway robbery, where the individual is knocked down and left for dead. To-day, with the aid of recent inventions, we are enabled to take the honey without either robbing the hive or destroying the bees.

Value of Movable Comb Hives.

The invention of the movable comb-frames has added probably as much to the real progressive spirit in bee-culture as any other one thing. With these the frames can be removed with the comb, and the honey extracted without injury to either the bees or the

comb. This method of removing the honey from the combs and then replacing them, is a great saving, both in time and honey.

Mr. Milton, of Wisconsin, says that it takes the bees as long to produce one pound of wax as it does to procure 20 pounds of honey; and Dr. Kirtland says they consume 25 pounds of honey in producing one pound of wax. For every pound of wax they produce it costs 45 pounds of honey. All of this is saved to the farmer by the investment of a little means in improved hives, and a cheap apparatus by which the honey is driven from the combs by means of centrifugal force.

Besides the increase in honey obtained on account of the movable frame hives, they greatly aid in the regulation of the breeding. The drones are like some who go by the same name in the human family, eating much and doing little; hence, when the drone season is over, the workers kill the drones or drive them out to starve; but, if the workers make a mistake and form too many drone-cells, the drones will sometimes be so numerous as to eat the honey as fast as the workers can procure it; but with the improved hive containing the movable comb, the drones can be removed and a comb for rearing workers can be inserted in its place. In fact the whole breeding department can be regulated to suit the convenience of the bee-keeper.

In the cross-fertilization and the rearing of queens, the movable frame hives, says Richard Colvin, of Baltimore, are indispensable. He says that without them he would despair of Italianizing an apiary of even moderate size.

The inventions in bee-hives during the last few years, have been quite numerous; and it is the design of these associations to take up these different inventions and discuss their relative values, and select the best from all.

Knowing How to Winter Bees.

It is of great importance to know just how to take care of bees through the winter. Some farmers seem to be very successful with their bees without any special care, while others with all their care lose nearly all. One will leave his hives standing during the winter just in the same place, and with no more protection than they had during the summer; while another places straw, or perhaps carpet, around his bees, and a few will put their hives into the cellar; and it happens frequently that each one has some peculiar experience. In these meetings these peculiarities are made known, and their causes inquired into. The annual or semi-annual meetings are fraught with more good than we at the time realize. It not infrequently happens that many facts are recorded with all their coincidences which at the time illuminates nothing, but in the course of a few years become of great interest.

The Purpose of Bee-Conventions.

The meetings are to a great extent for the purpose of collecting and comparing data; and among the abundance

that will be collected, there will be not a little that will be classed as "trash;" but a great deal of it will be of untold value to the progressive bee-keeper. In making our deductions from these data, we should be very careful to make the fullest examinations of all the facts. No conclusions must be hurriedly formed. It is not sufficient to say that one man lost his bees because they were left out-of-doors; for probably his neighbor never lost a single colony, and to all appearances they had the same things to encounter. It is a common occurrence that two thermometers of the same make, and only a short distance apart, will register from one to three degrees differently. The circumstances should be given in all their particulars, as to the make of the hive, the protection from the wind, rain and snow, how near the ground, etc.

Wintering Bees in Cellars.

Bee-keepers in general, who have tried it, recommend the wintering of bees in the cellar, which should be kept at a temperature of about 40°. It has been found that bees when well protected in this way, consume about two-thirds less honey than when left exposed to the weather. The bee must be treated in a great many respects as we treat other domestic animals. They do not hibernate during the winter as a great many persons suppose. Two things are absolutely necessary, namely, food and warmth; without either they are sure to die. It not infrequently happens that colonies are very poorly supplied with honey for the winter, and must be fed. To ascertain how well the provision is lasting, examinations must occasionally be made. This can be accomplished with any degree of satisfaction, only with the use of the movable frames.

Bees Dying Without Apparent Cause.

Occasionally bees seem to die without any apparent cause, and the question is asked all over the country, "What was the matter with my bees?" They have all died while the combs are full of honey. They could not have starved to death, for the hives were found to contain an abundance of honey. It is hardly probable that they froze to death, for in former years they withstood days of severe cold." Such has been the reasoning in respect to this puzzle. I remember one year ago, some thought owing to the drouth in the fall, the bees had been compelled to gather poisonous honey, and therefore they had all been poisoned. But all of the bees did not die; and if some colonies had gathered this poisonous honey, would not all in the same apiary have gathered it? The theory of being poisoned does not seem to me to be a reasonable one.

I remember at the same time some reported a few hives empty of both bees and honey, and the conclusion reached was, that these were weak colonies and poorly supplied with honey, and did actually starve to death. One bee-keeper stated that a portion of his bees he wintered in the cellar, and another portion were left out and were well protected. Of those that were

wintered out-of-doors, nearly all died, while those in the cellar nearly all lived. It seems to me that with the evidence presented at that meeting, the coroner would have been compelled to render a verdict after this form :

The majority of the bees which died during the winter of 1884-85, came to their death by freezing; but why they should not have frozen during previous winters when the weather was much colder, does not come within the jurisdiction of this case. But the question does arise in the minds of every bee-keeper, why did they not die at any other time when the winters were fully as severe?

Loss of Bees by Freezing.

In looking over the records of the past year, I find that this same question was asked of nearly all northern bee-keepers in the spring of 1863. Mr. Richard Colvin, of Baltimore, says that this question was asked him more than a hundred times. He says that the anxious inquirer has unconsciously answered his own question, when he says, "The hives are full of honey." He says that if you had examined your hives, you would have found your bees huddled between the cold walls of honey where they froze to death; and probably you would have found a late swarm which had starved to death in and between the empty combs. The simple exchange of a few full combs for a few empty ones among these colonies would have saved both, and placed them in their best condition for breeding in early spring; for it must not be lost sight of, that the colony in which the combs are filled with honey, has no room for breeding, while the others would have nothing to feed the young, if bred, until it would be furnished by the flowers, which may not bloom before the following May.

If the above be the true explanation of this mystery (and I have no doubt that it is), how many thousands of dollars might have been saved last year had every bee-keeper been aware of this fact. Such questions as these are the vital questions to be discussed in these meetings, and just as much of the discussion as possible should be spread upon the minutes and kept for future reference.

Personal Experience in Conventions.

The methods of breeding, rearing queens, dividing colonies, producing crosses, strengthening weak colonies, etc., are subjects which cannot be discussed too frequently, and with too much enthusiasm in these meetings. As the result of these gatherings, I believe that more will be accomplished when each member gives his own personal experience in the work, rather than that which he has obtained from some work upon bee-culture. Whenever anything is presented to this body that has had no practical test by any member of the association, it amounts to nothing more than a mere suggestion. You want to know what success your neighbor has had in this or that experiment, and he desires to know what success you have had. Theories are good, but facts are better.

PURE HONEY.

How to Create a Demand for Liquid Honey.

Read at the Maine Convention

BY I. F. PLUMMER.

Pure extracted honey is a fit dish to set before kings and queens, and yet cheap enough to be placed upon the table of every poor man in this country. Let the bee-keepers of Maine produce all of the extracted honey that can be produced, and try with all their powers to develop a good home market for a nice, pure, unadulterated article, put up in neat, glass-jars or bottles, with the bee-keeper's name and address, saying that the contents of the glass is of strictly pure honey stored by bees. Label your honey in this way, with neat, colored labels put on in a tasty shape, and I affirm that you will soon develop a good home market for your extracted honey at fair prices, but not high prices, by any means.

Often when I carry my extracted honey to market to sell, I will meet men who will say, "I know that honey is not pure;" and they will say what honey they consume, they want it to be pure comb honey. To such, I almost always explain and tell them of the different points in regard to extracting, and the reason for the honey candying, and by so explaining to them, I many times sell them a jar of honey, and the next time I see them, and many times they come where I am, before I have time to see them, and their talk will be something like the following:

"Mr. Plummer, I want some more of that nice honey. How much have you on hand? That was good honey you let me have the other day; it went so nice on hot-cakes that we had for supper the other night, and the children just went wild over it. I treated some of my friends to a dish, and all of the time they were partaking of it, they smiled and just boiled over with a sweet look that I never shall forget, no, never! Now, be sure, Mr. Plummer, and bring me some more of that honey when you come to town. My cousins, and my uncles, and my aunts want you to save a few pounds for them; so good-day, Mr. Plummer; but please remember that honey you are going to bring me next week, sure!"

Now, brother bee-keepers, you see that I can sell this man and his friends lots of honey in the future, if I only put up a nice article in an attractive shape, and of first class quality. My crop of extracted honey is all sold, though the demand is not so good as in 1886. What I mean by that is, the store keepers in my market do not call so much for extracted honey as a year ago, but with private consumers, or my customers, the demand is good.

When the consumer learns to like nice extracted honey in all its purity, comb honey will then take a back seat, and extracted will come to the front to stay; but of course we bee-keepers, who produce extracted honey, have to labor hard to educate the public up to the use of a pure, unadulterated, virgin

sweet, gathered by the honey-bee from nature's store-house, and stored in the hive, and taken by the bee-keeper from the combs with the honey extractor, placed upon the markets of the world in competition with comb honey, and what is worse, in competition with that mean, contemptible set of men who adulterate every nameable thing that comes on the table of the rich man and the poor man, the high and the low.

Extracted honey is more easily produced than comb honey, as you all know, and comb honey is harder to get when we have cold nights in the honey season, as bees will not take to the boxes in cold spells when they will work below in the body of the hive; and in this locality, last September and the first of October, we had a fine flow of honey from fall daisies, put in the frames below, but not a pound of comb honey was stored in the surplus boxes, so we got lots of honey below, more than was wanted for winter, and here was where the honey extractor came in play in the apiary. The bee-keeper at times must produce extracted honey, or none at all, and more so some seasons than others. I for one know that it pays to produce extracted honey any season, when there is any honey in the flowers for the bees to gather.

Augusta, Maine.

MANAGEMENT.

How I Manage my Bees—Some Questions.

Written for the American Bee Journal

BY A. C. WALDRON.

In my two years' experience with bees, I have learned a great many things, and there are a great many things that I do not know. I find by handling bees I get more confidence and less stings; I find that the poison does not affect me as at first, unless stung on some sensitive nerve; and I find that a good veil and smoker are essential, as well as a uniformity of hives. I do not use gloves, but use "false sleeves," such as grocers use, with rubber bands, and when in a critical place, I draw them down over my hands.

When bees swarm they sometimes cluster in a place where it is very annoying to the apiarist. This can be remedied by a liberal application of smoke, when they will seek another place.

I find that dry corn-cobs make excellent fuel for smokers. To prepare them, take a small mallet and strike the cobs on the sides until they split, which will generally be in four pieces.

In uniting bees, smoke them well or there will be a "fight." To build up a weak colony, remove a strong colony and place the weak one in its place; or, in other words, exchange places with the hives; and last but not least, take the BEE JOURNAL and read it.

There are some things I would like to know: 1. Why will bees insist on filling the brood-chamber full of honey, when there is plenty of room above?

Some of my colonies have done so to such an extent that I was led to think that they were queenless. 2. Will some one who uses the Simplicity hive, give some instruction in regard to the use of wide-frames. I am using them this year for the first time, without honey-boards or separators. I fear I have made a mistake.

Bees came through the winter rather weak, but have done well as far as building up and increase is concerned; but we have failed so far to get much surplus. We have good bee-pasturage here, consisting of white clover, basswood, and an abundance of wild flowers. Our most critical point is the wintering of bees. To any one who may contemplate moving to the West, I could offer some suggestions of value. Buffalo, Minn., Aug. 10, 1888.

[1. Their nature and instincts teach them so to do; they store above the brood-nest when it is all full below, because they are obliged to do so, or not store at all.

2. The use of wide frames without separators is one of the greatest "mistakes" that could be made. The comb will be built so irregular that the sections cannot be crated for the market. You should either put on the separators or use some other surplus arrangement calculated for such non separating method.—ED.]

CONVENTION DIRECTORY.

1888

Time and Place of Meeting.

- Aug. 27.—Stark County, at Canton, O.
Mark Thomson, Sec., Canton, O.
- Sept. 8.—Susquehanna County, at Montrose, Pa.
H. M. Seeley, Sec., Harford, Pa.
- Oct. 3-5.—North American, at Columbus, O.
W. Z. Hutchinson, Sec., Flint, Mich.
- Dec. —.—Michigan State, at Jackson, Mich.
H. D. Cutting, Sec., Clinton, Mich.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Removing the Queen.—Gerd Wendelken, Marietta, Ohio, on Aug. 10, 1888, writes:

I believe that a removal of the queen about 3 weeks before the close of the honey harvest secures more honey, because it prevents increase, and lessens the number of consumers; but will this gain of honey be stored in the sections instead of in the brood-nest, like the bees do after a swarm has issued? Besides this, I think that it weakens the energies of the bees to work, after no brood is in the hive to work for. Bees, I believe, work for the brood only, not for themselves, nor for any other purpose. When a queen is taken from a colony, the bees find plenty of empty cells to store honey in, and will do it before filling the sections.

Much Rain, but Little Honey.—N. Staininger, Tipton, Iowa, on Aug. 14, 1888, says:

Bees have not done much here this summer. White clover yielded pretty well. The colonies built up strong in bees, and stored some honey in the sections; then came basswood, which yielded well for a short time, and since then bees have hardly made enough to live on. They swarmed mostly before the basswood honey-flow, about 50 per cent. of mine swarming this season.

We are having a great deal of rain now, and all kinds of weeds are growing fast. We may have some honey yet—enough for the bees to winter on at least, if no surplus.

I would say to the readers of the BEE JOURNAL, do not hold your breath till the bees get done stinging. I was soon convinced of this fact, the first trial I made, and any one having any doubt, let him just pull off a hive cover with a jerk, and not use any smoke, and I think he will be convinced.

Fall Crop of Honey.—T. F. Bingham, Abronia, Mich., on Aug. 13, 1888, writes:

Bees are doing better now than at any time before this season.

Must Not be Discouraged.—H. M. Seeley, Harford, Pa., on Aug. 11, 1888, writes:

Bees in this vicinity have done poorly, as it has been so very dry. I have 2 colonies which have given me 75 pounds of honey each, from raspberry and white clover. From the balance of my colonies (5) I have taken only about 10 pounds in all. The first 2 colonies I did not let swarm, but each of the others gave me a good swarm. They are now storing honey from buckwheat quite fast. Taken all together, we shall have to count this as the third poor season in succession, and yet it will not do to get discouraged, at least it will not do for me.

Well Pleased.—Arthur F. Brown, of Huntington, Fla., on Aug. 2, 1888, writes thus concerning our bee-book:

The book, "Bees and Honey," is received, and I am well pleased with it. I think it should be in the hands of every bee-keeper.

Rearing Queens.—J. W. Tefft, Collamer, N. Y., writes as follows:

As early as possible in the spring, I select two of the best queens that had the best record the previous season; one dark and one light-colored queen. I put both to work for honey, and from one I rear all the drones for the apiary, and push this drone queen as fast as I can, to get the swarming fever. I then remove the queen from the drone hive, and in five days after I cut out all the queen-cells, and again on the tenth day, and then reverse all the brood-frames, so as to make them hopelessly queenless. On the twelfth day I give them a frame of fresh eggs from the breeding queen; seven days after I cut out all the queen-cells that are capped over, and four days after this I do the same, and form a nucleus colony of them, leaving but one in the parent or drone colony. By this system I get strong, vigorous queens and drones, that can fly several miles if the queen can go so far; and we have high authority from such as Huber, Dzierzon, Langstroth, Cook and Chester, that the queen mates with the drone that

can keep up with her. This is the way to produce honey-gatherers, and the only way. When a good queen mates with a pigmy of a drone, we get poor workers. "Dollar queens" are a detriment to any apiarist. The bee-keeper who makes an investment for the purpose of getting something for nothing, generally succeeds in getting something in addition to "getting left;" he usually get a little experience.

A Peculiar Colony.—C. Kellogg, Hokah, Minn., on Aug. 10, 1888, says:

I have only a few colonies, and one of them has performed so strangely, that I would like to have it explained. It cast a swarm on June 13, and just three weeks afterward the queen left the hive, taking a portion of the bees with her. On examination I could not find any sealed brood, and but very few eggs—not even one queen-cell; but the remaining bees soon built some, but failed to rear a queen from them, and now they are queenless. I should like to know the cause of it, and if it is a common occurrence. The remaining bees appear to be of inferior quality, but the swarm that issued from it are nice bees, and are doing finely.

[It is evidently one of the perplexing cases of "after swarming." In some of such cases, the bees, especially Italians, do many eccentric things, such as leaving without constructing queen-cells, going off without clustering, etc.—ED.]

Much Bloom but No Honey.—John B. Avery, Stittville, N. Y., on Aug. 13, 1888, says:

The honey crop in this locality is very poor. There was plenty of white clover in bloom, but it was too cold for it to secrete much nectar. Basswood was loaded with blossoms, but not much honey. Last year I obtained 975 pounds of honey from 13 colonies, and increased them to 26 colonies. This year I obtained 600 pounds of honey from 25 colonies, and increased them to 33 colonies.

Convention Notices.

☞ The Darke County Bee-Keepers' Society will hold a basket meeting on the Greenville Fair Grounds, on Friday, Sept. 7, 1888.
J. A. ROE, Sec.

☞ The North American Bee-Keepers' Society will meet at Columbus, O., on Wednesday, October 3, 1888, and continue as usual in session for three days.
W. Z. HUTCHINSON, Sec.

☞ The Cortland Union Bee-Keepers' Association will hold their fourth annual picnic at the Floral Trout Pond, in Cortland, N. Y., on August 30, 1888. Let all bee-keepers and their friends come and have a good time.
W. H. BEACH, Sec.

☞ The Susquehanna County Bee-Keepers' Association will meet in the Court House at Montrose, Pa., on Saturday, Sept. 8, 1888, at 10 a.m. Sharp. The following subjects will be considered: Preparing Bees for winter; Preparing for, and Marketing, Surplus Honey; Does the Raising of Small Fruit Conflict with Bee-keeping? All bee-keepers are cordially invited to attend.
H. M. SEELEY, Sec.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, \$1.00 per 100, or \$8.50 per 1,000.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexations delay and trouble.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in *Cheshire's* pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being mailable, it must be sent by express.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the *Apiary Register* and begin to use it. The prices are as follows:

For 50 colonies (120 pages) \$1.00
 " 100 colonies (220 pages) 1.25
 " 200 colonies (420 pages) 1.50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the *American Bee Journal* must be sent with each order for another paper or book:

Cork for Winter Packing.—Its advantages are that it never becomes *musty*, and it is *odorless*. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels\$1.50	\$2.00	\$2.25
500 Labels 2 00	3.00	3.50
1,000 Labels 3 00	4.00	5.00

☞ Samples mailed free, upon application.

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 18 cents per pound for bag and postage.

Conventions.—The time for holding Bee-Keepers' Conventions will soon be here, and we cannot give any better advice than this: Let each one attend who can do so, and take part in making these meetings interesting and instructive. If you have not already obtained the "Bee-Keepers' Convention Hand-Book," do so at once to post yourself up on how to conduct such meetings correctly. It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for Discussion—List of Premiums for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents. We will club this book and the AMERICAN BEE JOURNAL for one year for \$1.25.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$3.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Sweet, or Melilot, Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the BEE JOURNAL, and will send two or more free of cost to any one who will use them, and try to get up a club.

Exchange.—We will accept Honey and Beeswax in exchange for Bee-Keepers' Supplies in any quantity. Those desiring to make a trade are invited to correspond with us, stating quantity, quality, and price, and the goods they want in exchange.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, Ills., is published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

Scatter the Leaflets.—Look at the list (with prices) on the second page.

Honey and Beeswax Market.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 13@15c.; the same in 2-lbs., 10@11c.; buckwheat 1-lb., 10c.; 2-lbs., 9c. Market dull. We are doing all we can to reduce stock, to make room for the new crop.

BEESWAX.—25c.
HILDRETH BROS.,
 May 21. 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—We quote: White to extra white comb, 12@15c.; amber, 8@11c. Extracted, white to extra white, 5@6c.; amber, 4@5c. Arrivals of the new crop are small, the estimates being an average crop.

BEESWAX.—20@24c.
O. B. SMITH & CO., 423 Front St.
 June 18.

DETROIT.

HONEY.—Best white in 1-pound sections, 14c. No new in market, and old is not selling.
BEESWAX.—22@23c. Supply limited.
 July 24. **M. H. HUNT,** Bell Branch, Mich.

CHICAGO.

HONEY.—New crop offered at 16@17c., demand being very light yet. Extracted is not in much demand, and prices are nominal at 7@8c. for the best grades.

BEESWAX.—22c.
R. A. BURNETT,
 Aug. 14. 161 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 12c.; fancy 2-lbs., 10@11c.; fair white 1-lb., 10@11c., and fair 2-lbs., 7@8c. Buckwheat 1-lb., 7@8c. The demand is dull for comb but fair for extracted, of which new from the South is arriving, and sells for 55@58c. per gallon.

BEESWAX.—Dull at 23@24c.
F. G. STROHMEYER & CO., 122 Water St.
 Jun. 15.

CHICAGO.

HONEY.—None here, and market in good condition for new crop. There is some demand for the extracted.

BEESWAX.—22c.
B. T. FISH & CO., 189 S. Water St.
 Aug. 2.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb., for which demand is fair. Comb honey, 12@15c.—Supply is large of last year's comb honey, and for which the demand is slow.

BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
C. F. MUTH & SON, Freeman & Central Av.
 Aug. 15.

MILWAUKEE.

HONEY.—Choice white one-lb. sections, 14@15c.; 2-lbs., 13@14c.; 8-lbs., 12@13c. Extracted, white in kegs and 4-barrels, 8@9c.; in tin and pails, 9@10c.; dark in barrels and kegs, 6@7c. Demand good for extracted, but dull for comb.

BEESWAX.—22@25c.
A. V. BISHOP, 142 W. Water St.
 July 2.

DENVER.

HONEY.—Best white 1-lb. sections, 14@15c.; 2-lb. sections, 12c. Extracted, 6@7c.
BEESWAX.—20@3c.
J. M. CLARK & CO., 1409 Fifteenth St.
 Jun. 25.

KANSAS CITY.

HONEY.—We quote: 1-lb. sections, not glazed, at 18c.; 2-lb. sections and dark ones, also extracted, is not in demand. New honey is arriving freely, with a fair demand. This part of the State is favored with half a crop.

BEESWAX.—None in market.
HAMBLIN & BEARSS, 514 Walnut St.
 July 20.

BOSTON.

HONEY.—We quote: 1-lb. sections, 14@16c.; 2-lb. sections, 12@13c. New Florida extracted, 8@9c. Sales are very dull.

BEESWAX.—25 cts. per lb.
BLAKE & RIPLEY, 57 Chatham Street.
 July 5.

SAN FRANCISCO.

HONEY.—We quote: Choice new extracted, 5 to 5 1/2c.; amber to light amber, 4 1/2@4 3/4c. Choice comb in 1-lb. sections, 13@14c.; 2-lbs., 12@13c. Arrivals are small, as apiarists are holding back. Prices are considered high.

BEESWAX.—18@22c.
SCHACHT & LEMCKE, 122-124 Davis St.
 Jun. 25.

KANSAS CITY.

HONEY.—We quote: White 1-lbs., unglazed, 18 to 20 cts.; 2-lbs., 15@16c. California white 1-lb., 18c.; 2-lbs., 15c.; extracted, white, 9c.—amber, 7c.
BEESWAX.—None on the market.
CLEMONS, CLOON & CO., cor 4th & Walnut.
 Aug. 10.

ST. LOUIS.

HONEY.—We quote: Extracted, dark, 4@4 1/2c.; bright, 5@5 1/2c.; in cans, 7@8c. Comb, white clover in prime condition, 13@15c.; dark, 11@12 1/2 cts.—Market quiet, demand good and receipts light.
BEESWAX.—22c. for prime.
D. G. TUTT & CO., Commercial St.
 Aug. 10.

CARNIOLAN

Gentlest bees known; not surpassed as workers even by the wicked races. Imported Queens, "A" grade, \$6.00, Tested, \$4.00; Untested, \$1.00.

QUEENS.

One-half dozen \$5 00
 Never saw foul brood. Cash always required before filling an order.
S. W. MORRISON, M. D.,
 14 Etf. Oxford, Chester Co., Pa.

SELECTED Tested Breeding Queens, Only \$1.00 by return mail; 2-Frame Nuclei with same Queens, \$2.50 each—two for \$4.00. Also Hives for sale cheap. Address at once, **S. F. REED,**

33A2t NORTH DORCHESTER, N. H.

EDITOR.

Vol. XXIV. Aug. 29, 1888. No. 35.

EDITORIAL BUZZINGS.

Be True to yourself, and then you cannot be false to others, nor to your principles.

We have received a lot of samples of new honey labels from Abbott Brothers, Southall, London, England. They are elegantly printed, and make a very attractive appearance.

In answer to Query 564, last week, on page 550, top of middle column, Mr. Shuck's answer should read thus: "I wouldn't risk them over four days old." The omission was an oversight of the writer.

A **New Bee-Book** is just published in the Welsh dialect, by H. P. and M. D. Jones, at Bala. Its title is "Y Gwenynda; sef Llaw-lyr Ymarferol ar Gadw Gwenyn." It has 50 illustrations, and is sold in Wales for a shilling.

Our **Pamphlet** on "Honey as Food and Medicine," has been translated into French and printed in large pamphlet form, 20 pages. It is published at the office of *Le Rucher* by Alexander Le Roy, Rue Blinde-Bourdon 22, Amiens, and sold at 10 cents. It may also be obtained at this office.

Orange County, New York, it seems has had a good honey crop—or at least E. D. Howell, of New Hampton, says that his white clover honey crop is the best for 11 years. There are spots where they can enjoy the fun of making such a fine showing, but in the great majority of places the cry is "no honey and no swarms," or "we have had the poorest crop of honey in a dozen years." But variety is pleasant!

Not a Nuisance.—Mr. Z. A. Clark writes that he was fully prepared to prove that his bees were not a nuisance, had the opportunity been presented at the trial before the Circuit Court. This is what he writes:

I had 25 witnesses summoned in defense of the Union, by whom I would have proved that the bees were not a nuisance; in fact, I never knew of a team or teamster ever being stung while passing my premises. The sole ground-work was prejudice and ignorance. They have now taken the case up to the Supreme Court.

Bee Stings.—The *British Bee Journal* gives the following remedy for bee-stings: Drop one drop of phenol diluted in water on the place stung; moisten with alum and rub for a few seconds, and the pain will disappear quickly.

New Bee Feeder.—M. E. Hastings, of New York Mills, N. Y., has sent us one of his Perfection Feeders, which is illustrated by the engraving. It will hold two quarts, and the letting down of the feed is regulated

by thumb-screw C. The cap screws on at A. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for \$3.50, and it can be obtained at this office. Postage 10 cents extra.

How to Get Rid of Ants.—There are, says Prof. Cook in *Gleanings*, two good ways of destroying ants in the apiary. One is to find their nest and make a hole in the center of it with a crow-bar or other iron rod, then turn in half a gill of bisulphide carbon, and immediately fill the hole and cover it with a little clay, which should be trampled down. The liquid vaporizes and kills all the ants. Like gasoline, it is very inflammable, so it must not be exposed, either the liquid or vapor, to the fire.

Another way is to mix a little London-purple with thin syrup, and enclose it in a box with wire gauze so that the ants can reach it, but not the bees.

Hiving Bees.—W. J. Daniel, of Kentucky, has just patented a device for hiving bees. It consists of a double pole, the two lengths being held together by clamps, and adjustable at any height, with a hiving box at the top. As will be noticed by the following description from the *Scientific American* of Aug. 18, 1883, it has been repeatedly described in the *BEE JOURNAL*:

It is constructed with a standard having points on its lower end to take a firm hold on the ground, and a guide loop near its upper end for holding a sliding box or hive supporting section. The sliding section has a loop to clasp the standard, and at its lower end has a hinged extension piece, which serves as a handle for sliding the upper section, this extension piece having a sharp pin to strike into the upper section for holding the piece in folded position. The sliding section is held at any desired place by inserting a pin beneath it in holes provided therefor in the standard.

It was also described and illustrated in *Gleanings* for this month, page 611, and is claimed by A. C. Williamson, of Friendly, W. Va. A similar thing was also described several months ago both in *Gleanings* and the *AMERICAN BEE JOURNAL*, as the invention of S. W. Morrison, M. D., Oxford, Pa.

Some Curious Insects, by Noble M. Eberhart, B. S., Ph. D. This is a neat little cloth-bound volume, giving an account of the habits and peculiar characteristics of a number of interesting insects. The book is especially suited to children, affording wholesome and interesting reading, combined with valuable information and instruction. Illustrated. Price 50 cents. It is published by Eberhart & Son, 182 Dearborn St., Chicago, Ills.

When the Buckwheat Yields Honey.—Mr. S. J. Youngman, of Cato, Mich., under date of Aug. 12, 1888, remarks thus about buckwheat bloom:

I have observed that the buckwheat bloom yields no nectar in the afternoon in this vicinity. Is this a characteristic of the plant throughout the United States? Are some varieties better than others to yield honey?

Will those apiarists who have watched buckwheat bloom in various localities, please give the result of their investigation on this point.

The White Sulphur Springs, of Virginia, belonging to Mr. E. C. Jordan, one of Virginia's famous bee-keepers, had a very complimentary notice in the *Havre de Grace Republican* last week. In the "Bill of Fare" we notice as usual that "honey" holds a prominent place among the excellent variety of viands therein enumerated. The whole-souled "Host" looks out for the comfort and welfare of his numerous guests. If any of our readers want to take a "quiet rest," and enjoy the comforts of life, they should go to White Sulphur Springs, Va.

GLEAMS OF NEWS.

A Cartoon appears on page 635 of *Gleanings* for Aug. 15. It seems that a "Rambler" is abroad in the land "taking notes," and is printing them. He mentions a plan for wintering bees which was being developed by a 16-year-old bee-keeper. Having purchased a swarm of a Frenchman he followed his directions for management. The Frenchman told him he never lost a swarm in wintering, if the hive was placed upon a wagon-wheel. The young novice followed directions; and what was the surprise of the father to find nearly all of his wagon-wheels arranged in an upper room, and hives placed upon them! The story runs thus:

"For the land's sake, Brodie, what are you going to do if you get a hundred swarms?"

"Why, dad, I can borrow wheels of the neighbors, or I can hire a wheel for a pound or two of honey, and it will pay; for the Frenchman said it's a sure way to winter bees."

After the Rambler's amusement subsided, a sober second thought led us to believe that the boy was only acting out the modern bee-keeper's spirit. Looking over the field we found nearly every prominent bee-man hanging on to his wagon-wheel. Doolittle's wheel is nature; Heudon's is pollen; W. F. Clarke, hibernation; A. I. Root, anti-patents; Miller's T supers, etc.

Our dreams that night as we rested under the roof of a cousin's residence, were filled with floating visions of wheels, potato-sacks, balloons, etc. Here is a mental photograph of the sublime scene. **THE RAMBLER.**

As the description by Brother Root is richer than the cartoon itself, we copy the following from it:

Now, friend R., that is really too bad. I was prepared to accept the fact that the rest of you have had at different times various wheel hobbies; but to put A. I. Root among the crowd touches a tender spot. Never mind; I believe I would rather be pictured bouncing patents (that is, the "individual-right" department) than anywhere else.

J. H. and W. Z. H. seem to be pretty near the top of the heap, with the pollen theory and "new revolution" bee-hives.

The editor of the AMERICAN BEE JOURNAL is represented next as very industriously fighting the "Wiley lie," and we are glad he has finally got it under foot.

C. C. Miller is still enthusiastic on T-supers, even if there is not any honey to fill supers of any kind, during this poor season.

Doolittle is taking things very philosophically under the shade of a tree. Even if there is a swarm hanging on the limb overhead, he does not propose to disturb himself until he gets ready.

Just beneath friend Doolittle we see a colony fixed for hibernation. I guess it must be under a strawstack. Our good friend W. F. Clarke, however, does not seem quite satisfied to "let 'em hibernate" after nature's fashion, for he has removed his plug hat, and our artist has taken him in the act of poking his head into the strawstack, to see how things are going. Very likely it is all tranquil. The Rambler, tired out by the adventures of the day, is sleeping the sleep of the just. We know it is the Rambler him-elf, for he has put his hat on the foot of the bed, and deposited his documents inside of it.

The Weather and Crops.—Old earth seems to be crazy. While we in America and those in Central and Southern Europe have been experiencing such cold and wet weather, in Norway the heat has been very uncomfortable. At Nyborg it has been as high as 95°, Fahr., and at Christiania it has repeatedly been from 86° to 89° in the shade.

In Great Britain this month has been characterized by cold rains, which have not done so much damage as might naturally have been expected. Everything turns upon the continuance of the good weather to the close of the month.

In France July has proved an exceedingly unfortunate month. Rain and cold, with very little sun, have damaged the crop prospects in every direction. The critical periods of the blooming and earing were passed under the most favorable conditions; and the complaints, which are increasing on all sides, make a late and deficient harvest certain.

In Germany the weather has been generally cold and rainy, with an occasional day or two of warmth.

The month has not particularly advanced the prospect of the Austro-Hungarian crops.

Up to the 10th of the month the general Russian prospects have seldom if ever been so brilliant. Later in the month dangerously persistent rains, accompanied by hail, were common in Southern Russia.

The wheat crop in Sicily has proved very deficient, but an average was obtained in Apulia, and the Neapolitan districts. Sardinia has almost lost her entire crop. In upper Italy the harvest is expected to prove fairly good in quality, but will not reach an average in quantity.

For thirty years the rainfall in Spain has not been so great, or the mean temperature so low all over the kingdom as in June and July of this year. There was snow at Valladolid on the 16th, and from every direction came news of damage to crops from the unseasonable temperature and the raging gales.

Telegrams from Greece about the middle of the month report that the current crop was in imminent danger of being lost; the vines being dried up with the scorching wind.

The harvest anticipations in Prussia are quite discouraging. The rye-fields, from which the great masses of Germany derive their chief bread supply, have suffered to a great extent, and the continued inclemency of the weather has likewise done severe damage to the fields.

Postage on Seeds, etc.—The new law making the rate of postage for seeds, etc., one cent for each 2 ounces, took effect on July 24, 1888. The new section reads thus:

That hereafter the postage on seeds, cuttings, bulbs, roots, cions and plants shall be charged at the rate of one cent for each 2 ounces or fraction thereof, subject in all respects to the existing laws.

Growing the Linden.—There has been some inquiries about sowing basswood seed, and for general information we copy the following from the *Western Tree Planter* for this month:

Heretofore it has been nearly impossible to obtain basswood seedlings, and even now the supply is very limited. Wherever we have run across any one in the West who was growing them, we have found that they were highly pleased with their rapid growth and extreme hardiness.

When the roots once become established it will be found to be next to impossible to kill the tree so that it will not at least start up from the old root and make rapid growth. If one is cut off close to the ground one or more shoots will immediately start up and make a rapid growth. We have seen logs cut and piled up in a mill yard out of which young trees had started and made a growth of 3 feet in a season, their entire sustenance having been drawn from the wet log. The basswood is certainly a hard tree to kill, and we hope it will be universally tried and tested the coming season.

We have, during the past two years, been experimenting on basswood seeds, but were obliged to work entirely in the dark, as from no one could we learn what was necessary to make the seed start. We now have a barrel of seed mixed with damp sawdust, which has been kept moist, for over 15 months, has frozen and thawed, but not sprouted when we last examined it. The seed, even after this long time, is in perfect condition. We are now trying the scalding process, which is always used on locust seeds, and hope that by this method to attain our object. Mr. McKinstry, of Chapelle, Dak., says that he has tried to grow basswood seeds, but never succeeded; but that the following year or two, he had found on the ground sowed to basswood seeds, a few seedlings. This would go to show that the seeds required at least two seasons to cause germination. If any one else has made any experiments, let us hear the result so that all our readers may be benefited.

Honey Season in Vermont.—A correspondent writing from Brandon, Vt., says: The honey season in this section seems to be a very poor one; bees are doing but little swarming and storing of honey.

G. S. Brown, of Salisbury, reports the loss of 42 colonies by spring dwindling.

The following printed in a local paper at Vergennes, gives the situation here:

The honey product will fall far below the average this year, owing to the cold and wet weather early in the season. A prosperous bee-man in this place considers the falling off in the product of his 200 colonies will be two thirds. He should be able to market six tons of honey, but will be satisfied, from the present outlook, with two and one-half tons.

About the Chapman honey-plant our correspondent continues: "I have a small patch of the Chapman honey-plant, and I never noticed a plant which attracted the bees so much as did this globe thistle, during the height of its flowering season. There were two or three bees on every blossom about all the time. In raising it I have met with no difficulty from winter-killing or worms. If it had any other value than for honey, I should think bee-keepers would want ten acres apiece of it, as was expressed recently by one of your correspondents."

That Arkadelphia Bee-Suit.—

In reference to the argument of Judge Williams before the Circuit Court, relative to the rights of bee keepers to pursue their usual vocation (that of honey production, by keeping bees), Mr. A. R. Nisbet, of Dobyville, Ark., writes as follows:

I wish all the members of the National Bee-Keepers' Union, and in fact all the bee-keepers of America, could have been with us during the fight at Arkadelphia on the 4th inst. It would have made them all feel good to have heard Judge S. W. Williams read section after section of law, in Mr. Clark's favor, showing that a man's right to hold property is paramount to all legislative power; and any attempt to take away such right is unconstitutional. He certainly made an able defense, proving to all present that he was equal to the task before him. The trial was well attended by citizens of this county, a great many of whom were in sympathy with Mr. Clark. After the debate was over, the court adjourned until Monday, Aug. 6, when Judge Hearn, who occupied the bench, declared that the ordinance was unconstitutional and void. The ordinance forbade any person or persons to keep, rear, or own bees in the city of Arkadelphia, after thirty days from the date of that ordinance. I understand that the city has taken an appeal to the Supreme Court.

We fully believe that bee-keepers have constitutional rights which they should defend—which they are in duty bound to defend—and cannot be just to themselves and their successors in the business if they do not defend them! For that reason a *test case* was made in Arkadelphia, and the most popular and influential lights in the legal profession were engaged to defend the case. These were Judge S. W. Williams, and Maj. Witherspoon, assisted by attorneys Murray and McMillan.

The case now goes to the Supreme Court of the State, on an appeal made by the city of Arkadelphia. The Supreme Court meets in Little Rock next October, and it will there be defended by Judge Williams.

From Across the Border.—Our Canadian friends often send us words of congratulation, but none have been more welcome than the following dated Aug. 16, 1888, from our friend Mr. S. T. Pettit, of Belmont, Ont., the ex-President of the Ontario Bee-Keepers' Association:

EDITOR OF THE AMERICAN BEE JOURNAL:—I cannot let another mail pass without writing to say that your many thousands of friends over here are very thankful to you for the plucky manner in which you so effectually brought down Prof. Wiley from his exalted position, in the top of that official apple tree.

The missiles you so persistently hurled at him were ugly, sharp and heavy; but they had the desired effect, and the Professor had to come down, though he lingered long.

How any sane mind could charge the AMERICAN BEE JOURNAL with taking sides with adulterators is a puzzle—but then it often does turn out that those who work the hardest for the general good, get blamed and falsely accused, even by those whose good they seek; but we have faith in God and the future, that *truth, righteous truth*, will come to the front, and that justice will be done. We must not forget that *Gleanings* also did valiantly for the truth.

BIOGRAPHICAL.**Hon. Jonathan W. Cattell.**

From the Iowa *State Register* we copy the following biography of this distinguished citizen and life-long apiarist:

Jonathan Wright Cattell was born in the county of Fayette, Pennsylvania, June 25, 1820. He was consequently 67 years and 3 months old at the time of his death. He remained in Pennsylvania until he became of age, when he moved to Columbiana Co., Ohio. Here, in the year 1842, he was united in marriage with Miss Deborah Edyson, who, now, after 45 years of a very happy wedded life, is left to grieve over his departure. In 1846, he and Mrs. Cattell removed to the then territory of Iowa, settling in Springdale township, Cedar county. Six years later the people called upon him to take the clerkship of the District Court, a position he occupied for four years. In this office Mr. C. showed the mettle of which he was made, by the manner in which he protected the interests of the county.

Upon retiring from the clerk's office, Mr. Cattell was elected to the State Senate from the county of Cedar, just then made a Senatorial district by itself. Almost from the first Mr. C. was influential. Here, as everywhere, he was a worker. Both in committee and in the Senate, this trait was conspicuous; so that when he spoke, which was not often, his associates listened, for they soon found out that he had something to say worth listening to. Such characteristics readily suggested him as a proper person to place at the head of the Department of Finance. Accordingly he was elected Auditor of the State in 1858. The same painstaking fidelity to duty marked his distinguished career in this responsible office. He introduced improvements into the manner of conducting monetary transactions of the State, as well as in the system of book-keeping. So well was this done that there has been no substantial change in these particulars since.

During Mr. Cattell's incumbency, which covered nearly the entire period of the war, when the expenditures were very heavy, the work was greater than it had ever been before; and it was well done, honestly, systematically, cautiously done. He was three times elected, as no one had been before him, and was very strongly supported for a fourth term. Now, after a lapse of twenty years, no higher praise can be bestowed on a public officer than to say he does as well as did Auditor Cattell.

After his retirement from the auditorship, he remained a resident of Des Moines. The following fall (1865), to his great surprise, he was called from his retirement by the Republicans of Polk County, to go back to the Senate. Again in that body, he was a member of almost the ablest Senate in the State's history. In this body, and the one which followed, which comprised in its membership our present Govern-

nor and many other strong men, Mr. Cattell was a leader, not because he sought leadership, but because it gravitated to him. His long experience in public affairs, the accuracy and fullness of his information, and his candor and conscientiousness caused his judgment on any question to be looked upon with especial favor. While in the Senate, or shortly after, he became President of the State Insurance Company, which position he retained for some years, establishing firmly the company's business, and its reputation for fair dealing.

About five or six years ago, Mr. Cattell removed to a farm he owned in Delaware township, which has been his home since.

In 1885, he was again placed in charge of the office of Auditor of State. The ability with which he conducted its affairs under the very trying circumstances which surrounded his incumbency, his ready knowledge of the duties of the position after an absence of twenty years from public life, were a surprise to those not intimate with him. His rulings upon doubtful points in law were never influenced by those circumstances, or affected by any extraneous consideration. This office he left in January, 1886, since which time he has lived quietly upon his farm.

Being childless, Mr. and Mrs. Cattell adopted and reared two children; one, Mr. Wm. H. H. Cunningham, now a resident of the territory of New Mexico; the other, Mrs. Edward Grimes, who, with her husband and children, lived with her adopted parents.

To the afflicted wife and children will be given the heartfelt sympathy and kindred grief of the entire State.

When he last visited Chicago, as his custom was, he spent an hour at the BEE JOURNAL office, for he was an enthusiastic lover of bees and their management. We little thought then that it would be our last meeting in this life.

Mr. Cattell, by accident, fell from a wagon on Sept. 23, 1887, and the hind wheel ran over him, producing internal injuries, which proved fatal on the Sunday following at 7:30 a.m.

This was a serious accident, but no one thought that it would prove a fatal one until just before he died. Even the words from his bedside were of a cheering nature, for the hope was generally entertained that he would survive and live many years, for he had a strong constitution.

In personal appearance, character and disposition he much resembled the late President Lincoln—plain, modest, unassuming, but of sterling worth and noble mind.

We will Present a Pocket Dictionary for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

The Traveled Bumble-Bee.

A bumble-bee, belted with brown and gold,
On a purple clover sat;
His whiskers were shaggy, his clothes were old,
And he wore a shabby hat;
But his song was loud, and his merry eye
Was full of laughter and fun,
As he watched the bob-o'-links flutter by,
And spread his wings in the sun.

A butterfly spangled with yellow and red,
Came flying along that way;
He had two little feathers on his head,
And his coat was Quaker gray;
He carried a parasol made of blue,
And wore a purple vest;
And seeing the bumble-bee, down he flew,
And lit on a daisy's crest.

Then from the grass by a mossy stone
A cricket and beetle came;
One with black garb, while the other shone
Like an opal's changing flame;
A swaying buttercup's golden bloom
Bent down with the beetle's weight,
And high on a timothy's rounded plume
The cricket chirruped elate.

The bumble-bee sang of distant lands
Where tropical rivers flow;
Of wide seas rolling up shining sands,
And mountains with crowns of snow;
Of great broad plains, with flower-gems bright,
Of forests, whose fragrant glooms
Showed crumbling ruins, ghostly and white,
Old forgotten nations' tombs.

Then wisely the beetle winked his eye;
The cricket grew staid and still,
The butterfly, in his great surprise,
Went sailing over the bill;
The beetle scrambled her eath his stone,
The cricket, he gave a hop,
And there the bumble-bee sat alone
On the purple clover top.

—Dumb Animals.

QUERIES AND REPLIES.

Rendering Beeswax.

Written for the American Bee Journal

Query 570.—In rendering out the wax from old brood-combs, does it make the wax darker if it is boiled in a cast-iron kettle, than it would be if a tin or copper kettle was used?—Bee-Keeper.

Yes, a trifle.—MRS. L. HARRISON.

I do not know.—M. MAHIN.

I do not know.—EUGENE SECOR.

Yes, usually.—A. B. MASON.

I do not know.—J. M. HAMBAUGH.

Yes.—R. L. TAYLOR.

Yes, sir, much darker. Iron should never come in contact with hot wax.—JAMES HEDDON.

I think not, if the kettle is clean.—C. C. MILLER.

I think not. A sun wax-extractor is the proper thing for a bee-keeper to use.—G. M. DOOLITTLE.

Iron kettles will always turn the wax dark.—P. L. VIALLON.

If the iron kettle is clean and bright, it will make no difference; but we prefer copper or tin.—DADANT & SON.

I tried this once and nearly ruined the wax. Tin, copper or galvanized iron is the proper material, and much lighter to handle.—C. H. DIBBERN.

I do not think that it does, if care is taken in the boiling, and after straining. Some of the wax-extractors, however, are preferable.—J. E. POND.

I do not see why it should. But I should not wish to boil the wax much in any kettle.—A. J. COOK.

I prefer a cast-iron wash pot that has been long used, rather than tin; for as soon as the sheet-iron loses its flimsy tin covering, it discolors the wax badly. Copper or brass will do very well if the wax is not allowed to stand too long in such a vessel.—J. P. H. BROWN.

The kettle does not color the wax. Excessive heating colors it, and worse that that, ruins it. Heat it just enough to get the wax out, and no more; boiling does no good.—J. M. SHUCK.

Some grades and mixtures of cast-iron will darken wax every time, while other grades will have no effect on it. You will notice that some iron kettles will always rust after use, and put away for a few days, while others never rust. Copper is best, as you are sure of the results.—H. D. CUTTING.

I have tried both when I used to have no better way to render wax, and there is no difference if the cast-iron vessel is smooth and clean. If there is red rust adhering to the inside of the kettle, it is sure to color the wax. But since the improved solar wax-extractor has been described and given to the public by the "undersigned," there is no further need of musing with kettles of any kind.—G. W. DEMAREE.

Yes. Take the tin or copper kettle every time. If the iron kettle is old, well-used and perfectly clean, it might be used, but the ordinary run of iron kettles will color the wax.—THE EDITOR.

The Sex of Bee-Eggs and How Produced.

Written for the American Bee Journal

Query 571.—1. What is the sex of an egg before the queen has become pregnant? 2. When the queen mates with the drone, does it change the sex of the egg? 3. How is the sex produced?—E.

All the unimpregnated eggs produce drones, or males.—G. M. DOOLITTLE.

1. Male. 2. Yes, to a great extent. 3. I do not know.—C. H. DIBBERN.

1. Male. 2. No. 3. Refer to some of our bee-books.—P. L. VIALLON.

1. Male. 2. No. 3. By fertilization when the egg passes by the spermatheca.—DADANT & SON.

1. Male. 2. No. 3. The egg in passing down the oviduct, is impregnated in passing the mouth of the spermatheca.—MRS. L. HARRISON.

1. Male. But "pregnant" is not the proper word. 2. No. 3. Eggs become female by receiving the male germ in the act of being laid.—M. MAHIN.

Please read the books; get Cook's "Manual," or Cheshire's "Bee-Keeping." They are up to the times on this subject eggs-actly.—J. M. SHUCK.

1. Male. 2. No. 3. At the will of the queen. She has the control, and can fertilize the egg or not, as she may desire.—H. D. CUTTING.

1. Male. 2. It makes it possible for the queen to lay male or female eggs at

pleasure. 3. See scientific works on bees.—EUGENE SECOR.

1. Male. 2. No, not until the egg is brought into contact with the male sperm. 3. There is a difference of opinion. Not by difference in the size of the cell; most likely by the *volition* of the queen.—J. P. H. BROWN.

1. I hardly think there is any egg before the queen is pregnant. 2 and 3. You had better send 15 cents to Mr. Newman for the "Dzierzon Theory," and get a full answer to this and many other questions.—C. C. MILLER.

1. The egg of an unfertilized queen-bee produces a bee of the male sex. 2. The mating of the queen does not of itself change the sex of the bee. 3. The sex of a bee seems to depend upon whether or not the egg from which it was produced was impregnated by the seminal fluid deposited by the drone.—R. L. TAYLOR.

1. Always masculine. 2. It changes the sex of every egg which comes in contact with the drone sperm. 3. I believe that the sex is controlled by volition on the part of the queen.—JAMES HEDDON.

1. It has no sex. 2. No. 3. If the egg, as it passes by the spermatheca, is impregnated—that is, if it receives sperm cells—the result will be queen or worker, otherwise drone. See some good book on bees.—A. J. COOK.

1. Male. 2. No. 3. Dzierzon says that the egg is "fertilized by one of the spermatozoa from the seminal receptacle of a fertile queen entering it as the egg passes down the oviduct;" it becomes transformed into the germ of a worker bee or queen.—J. M. HAMBAUGH.

1. Male, in all cases whether pregnant or not. 2. It does not. 3. By being saturated with the contents of the spermatheca when deposited in the cell. The question is too big for this department. Read "Dzierzon's Theory," or some text book on bees.—J. E. POND.

1. Your query is misleading, because it infers that the queen *may* lay eggs before she is impregnated, which is not true if the queen is impregnated at all. All my experiments in this direction, and they have been many and carefully made, tend to show that the virgin queen lays eggs until her amatorial period has passed. If she passes this period without meeting the male, she is likely to lay male eggs only. 2. No; but many of us believe that her "mating" gives potency to her male issue, which is lacking in drones from unmated queens. 3. Nature has provided the how.—G. W. DEMAREE.

1. The question is not properly stated. It cannot be said that the eggs of a virgin queen have any sex, but they invariably produce drones. 2. No; but she is then enabled to produce male and female progeny at her pleasure. 3. The egg is impregnated in the act of being laid, when it receives the male germ in passing the spermatheca. The pamphlet called "Dzierzon's Theory," would be very interesting to you.—THE EDITOR.

CORRESPONDENCE.

SHIPPING HONEY.

Time of Capping Brood—Do Bees Hear?

Written for the American Bee Journal

BY G. M. DOOLITTLE.

Some seem to think that it is better, in putting up honey for shipment, to pack it in the case with the top-bar of the section downward, or in a reverse position from what it was in building, claiming that it will stand more rough treatment without breaking down if put up in that way, than it would if shipped with the same side up as it was on the hive. This I think is a mistake, and a neighbor of mine says "he knows it to be so," after having packed some that way, which was badly broken, and having none broken when packing it right side up, as he always did till he tried this way. To prove his position, he says:

Take a section and fill it with comb foundation, attaching it only at the top, allowing the room at the sides and bottom, which is necessary to prevent it from being bulged in drawing out; and after the foundation is thoroughly secure, stand the section in the position which it is to occupy on the hive, then suddenly sway it from side to side. In doing this you will see that the foundation will stand any amount of sudden jarring, and not break from the box; but turn the section over and the foundation will hardly support its own weight, let alone any jarring or rough treatment, without falling over and off, especially if the weather is a little cool."

Formerly I used to pack my honey with the top-bar of the section down, as I was so instructed in my first shipment; but of late years I pack it the same way that it was on the hive, and after carefully going over the results of the past, I find that not nearly so much has been broken since I adopted the latter method of packing, as was formerly. Of course it may have been handled more carefully of late by the railroad companies, but I think not. In any event, this is a matter worth careful consideration, and I bring it before the notice of our apiarists at this time, so that it may be in season for immediate action, for it will soon be time to send our honey to market, if we have any to send.

At What Age Is Brood Capped?

Picking up a paper not long since, I ran across an item setting forth the merits of the "bees-by-the-pound method." In it the party tells how they (the bees) were put in a hive on such a date, and ten days later they had enough brood capped over "to fill one whole frame." As the writer of the article uses the Langstroth frame, it is supposable that this was the frame meant, and if so, it would give about 7,000 as the number of cells of brood capped over.

There is a mistake here somewhere, or else I have been at fault all of my bee-keeping life, in my reckoning of the length of time that must elapse between the time the egg is laid by the queen, and the time the brood is capped over. Quinby stated in his "Mysteries of Bee-Keeping Explained," that the bee remained in the egg form three days, and in the larva form six days, covering a period of nine days from the laying of the egg by the queen to the time the larva was sealed over, this being accelerated a little by very warm weather, and retarded to some little extent by cool weather.

In all my observations along this line, I have found Quinby to be so nearly correct that I have taken him as authority on these points; therefore there must be a mistake somewhere, or else the queen in the case given above must have laid 7,000 eggs on the first day of her introduction with the bees to that hive. This is not at all probable, even if it were possible for a queen to reach that number of eggs in a single day; for no queen comes up to her maximum speed of egg laying the first day or first week after being placed in new quarters.

Some claim that the larva may be sealed over in five or six days from the time the egg is laid, but I cannot help thinking that such claims are made by those who have not thoroughly looked into this matter.

In many of the manipulations of the hive, a correct knowledge of this matter of brood-rearing is of much importance, and none ought to be satisfied with their "bee-education" till they have conducted experiments along these lines, so as to know for themselves.

Have Bees the Sense of Hearing?

Many seem to think that bees have the sense of hearing, but so far all of my experiments go to prove to the contrary. One says that he has known bees to run out of the hive to the queen when she had been removed with the surplus arrangement, or show their desire to get to her when she was on the frame he held in his hand, attributing such action of the bees to their hearing the queen call to them; but with me I see nothing in it but that the bees knew where the queen was by her scent.

One time, in hiving a swarm, the bees balled their queen, and in order to make a cage for her protection as I wished, she was hung in the shade on a limb of a tree not far off. Upon returning, after making the cage, I found that many of the bees had left the hive and clustered about the queen.

At that time I received the impression that the bees might have some sense of hearing, in order to get to their queen so quickly, but this thought was dispelled a little later in the season when, upon hiving two swarms together, I caged one of the queens for a little while, till I could dispose of her.

After disposing of her, I hung the empty cage in the shop several feet from the door, leaving the door open. After a little, the bees going with the double swarm became dissatisfied with

the other queen, and balled her, when the usual excitement began which always exists in such cases. In a little while after, I went into the shop, when, to my surprise, I found a part of these bees on the cage that their queen had been in, thus showing that there was no hearing about the former proceedings of the others.

SWARMING.

Bees do Select a Location before Swarming.

Written for the American Bee Journal

BY S. J. YOUNGMAN.

My experience of the last week will, I think, bear me out in saying that one of the mysteries of bees is solved, and the question, "Do bees find a location before swarming?" may most emphatically be answered in the affirmative. I will relate what came under my observation on Aug. 13 and 14, 1888:

My brother, and three other men, were at work about 100 rods west of my apiary in the edge of a forest at about 10 o'clock, a.m. They discovered bees in the top of a large ash-tree. I was called to see the bees, and to say what the prospects of saving them would be. The bees were about 50 feet from the ground, and were working very briskly. The sound of their humming could plainly be heard from the ground, at some distance from the tree. I proclaimed it a bee-tree, containing a large swarm, as there seemed to be thousands of bees at work. Arrangements were made to cut the tree the next day after dinner.

The men were at work near the tree, splitting rails, and about 11 o'clock one of the men observed a swarm of bees coming from towards my house near him. He instantly gave the alarm, and all the men gathered in time to see the bees fly to the ash-tree, and go into the same hole that the bees were issuing from the day before. I proceeded to cut the tree, as arranged, and found them to consist of a medium sized swarm, with a young unmated queen, and I succeeded in successfully transferring them to a Langstroth hive.

No honey was found in the tree, but it showed unmistakable signs of having been occupied by bees before, as there were chunks of propolis and fragments of comb adhering to the sides of the hollow.

The way I view this is, that when the bees were first discovered on Aug. 13, a very large force were cleaning out and preparing the hollow for occupation the next day; and had the tree been cut on the morning of Aug. 14, no bees would have been found; but on that day the bees occupied the tree in full force.

I think that this is the strongest evidence that bees do select a home in advance of their swarming, and prefer a tree that has been occupied by bees before, or at least such a place is not distasteful to them.

Cato, Mich., Aug. 19, 1888.

SULPHURIC ACID.

Its Use in Germany to Cure Foul Brood.

Written for the American Bee Journal
BY GERD WENDELKEN.

On page 345 is an article written by Wm. Klintworth, about bee-keeping in Germany, and how foul brood was cured there about 40 years ago. He mentions my name as one of those who cured the disease by the use of feeding sulphuric acid, but he does not tell how and in what proportion it was fed. I will therefore try to give briefly some information about it.

When in Germany, as Mr. Klintworth said, 40 years ago I cured foul brood with sulphuric acid, to my full satisfaction, and three other cases are known to me that were cured in the same way. Our fathers did not understand the nature of foul brood, but some understood how to cure the same.

Sulphuric acid has powerful destructive properties, and must always be handled with the greatest caution. If mixed with water, at the moment of mixture great heat is given out, and therefore the dilution should be performed by very gradually adding the acid to the water. The dilution should not be kept in tin vessels, but in glass bottles.

When fed with honey or syrup to foul-broody bees, it will kill the foul brood germs; but it has to be diluted to such an extent so as not to kill the bees and brood—1-700 or 1-800 part will do.

For an experiment in the spring of 1887, I fed sulphuric acid to my bees in the following way: I diluted one ounce of acid in one quart of water; then mixed this with syrup, and fed it to one colony, beginning with small, weak doses, and increasing by degrees until the bees refused to take it. Every night from March 15 to April 20 I fed $\frac{1}{2}$ a pint of syrup with $2\frac{1}{2}$ tea-spoonfuls of diluted acid. I found that this was not injurious to the health of the queen, bees or brood. At the end of that time I fed the rest of the medicated syrup to 10 or 12 other colonies. I have been told that the acid would kill bees and brood, but it does not, and cannot be done, because the bees do not take it when too strong.

If foul brood should ever get into my bee-yard, I would not be much alarmed. I would simply feed the bees regularly every night as described until well; and I would expect them to be all right in about two weeks. I know that what has been done can be done again.

It is best not to feed such a quantity with the acid mixed, as to be stored for winter use. There is no sure way to cure the disease without feeding the remedy to the bees, but it is a great mistake to feed or treat only such colonies as have already dead or diseased brood. Every colony must be fed and disinfected, because some seemingly healthy colonies may have the germs of foul brood in great numbers in the hives; old bees have them in their stomachs, and therefore they must be

fed. The young larvæ must be fed in the cells, which can be best done and prepared by the nurse-bees.

Some prominent bee-keepers have recommended spraying the larvæ with the remedy, but the nurse-bees know better how to prepare the doses, and how much to feed the larvæ.

Some have also recommended burning the diseased colonies, but this is another mistake, I think. It does no good, for soon after some other colonies will be diseased, because the germs had been there before.

Marietta, O., Aug. 20, 1888.

PLEASANTRIES.

Review of the "Scientific Pleasantries"—Experiments.

Written for the American Bee Journal
BY G. W. DEMAREE.

A great many bee-keepers believe that Prof. Wiley is a sinner above other scientists in the perpetration of "scientific pleasantries," and doubtless some of the most credulous believe that the Professor laid "awake o' nights" in his scientific musings and searchings after the most effective "pleasantry" to hurl at bee-culture with deadly effect. No greater mistake than this could be made. Scientists do not do things in that way. No scientist expects anybody to credit his "pleasantries." In fact, the scientist of the evolution school is *never certain of anything* under the sun, nor above the sun.

Of course the frail, waxen fabric which we call honey-comb, with its dividing walls too frail to bear the touch of the most skilled finger of a life-trained artist, or any machinery known to the arts in realms sublunary, has not been wrought by machinery as yet, but when "Evolution" has had time to sweep the circle with his magic wand, it will be said, "Let there be machinery wrought honey-comb," and the thing will be "done." This is all the scientist knows about it, and he is not certain of that. It is to be hoped that the brethren will let up on Prof. Wiley for a spell, and turn their attention to some other scientific pleasantries. Our bee-literature is chock-full of them.

Honey as "Digested Nectar."

I have read, and it comes from high authority, that "honey is digested nectar." This is a "scientific pleasantry," stupendous in its magnitude and bearings, and yet we have heard no objections to it. It is by no means impossible for a pound weight of bees of the proper age to handle 15 pounds of crude nectar in eight hours. I think I have seen it done when the black locust was at its best, and the weather was exactly right. In this case a pound weight of live bees would have to furnish by ordinary secretion, gastric juice in sufficient quantity to digest 15 pounds of crude nectar in eight hours. No uncrazed thinker on the earth possessing brains enough to frame a thought, could believe such an impos-

sibility. Notwithstanding, this "scientific pleasantry" has been handed around to the injury of the reputation of honey as a delicious food for mankind.

Not long since a pedagogic scientist in a lecture delivered in our town, referred to this matter, and asserted that honey was a "disgusting digested stuff disgorged from the stomachs of the bee," and therefore unfit for food for mankind. If it was true that honey is "digested nectar," that fact would take all the romance out of the word "honey," heretofore the synonym of all sweetness, and leave the article itself truly disgusting. But nothing never was further from the truth. Pure honey is nectar of flowers gathered by bees and reduced to proper consistency by the internal heat of the bee-hive. That's the whole of it.

Holding the Breath to Prevent Stings.

Some scientist has got off a "pleasantry" to the effect that a bee cannot sting a person "while he holds his breath." In fact one would take this for a "practical joke," to provoke a laugh at the expense of the "dupes" who would be credulous enough to try the experiment. A little practical good-sense ought to teach anybody better sense than these scientists seem to possess. I have felt the sting of a bee through a thick buckskin glove.

Well, the other day I tried the experiment to answer in a practical way, the query, "Can a bee sting a man while he holds his breath?" You see I am so indifferent about a bee-sting that any practical joker would fail when practicing on me. I selected a cross hybrid colony, and without the use of smoke, I turned up the quilt and rapped on the top-bars of the frames; this brought the little "war-dogs" bristling as they came. I held my breath firmly and passed my left hand with a rather quick motion just above the top-bars of the frames, and received a red hot thrust in the end of my middle finger, which drew blood in sight. I raised no question. No "umpire" was needed; the thing was well and fairly done.

Most people would have been fully satisfied with the experiment, but I did not care a great deal for one sting, and was willing to risk another. So I repeated the motion, with the right hand this time, and in a twinkle I was philosophically looking at a bee twirling round and round in its economical way of parting with as small a portion of its "inward parts" as possible when leaving its sting deeply set into the flesh of my third finger. That was the "best two out of three;" quoth I, "what fools these mortals be!"

I wish I had the time at my command to pursue this subject further. It is a wonderful subject. "Scientific pleasantries" are to be found in every department of our bee-literature, from the "business end of the bee" to the mighty claims of the "patent bee-gum man." But I cannot spare the time now. In fact I am really low down as pertains to the future prospects of bee-culture in Kentucky. The surplus honey crop has been a failure, or nearly

so, for the past three years, owing to the decade of drouth years which has nearly destroyed the white clover. Hope revived, however, in May and June, as the young white clover looked very fine at that time, but the great heated spell of the past three weeks, without rainfall, has killed the young clover to an alarming extent. It is not so hot now, but the rain tarries, and hope is deferred.

Christiansburg, Ky.

AUTUMN BLOOM.

Golden-rod and Aster Honey, Fall Management, etc.

Written for the *New England Homestead*
BY SAMUEL CUSHMAN.

Most colonies in our apiary are so contracted that there is little room for honey in the brood-combs, and it will not be extracted, but as soon as the boxes (or sections) are removed, a sufficient amount of sealed stores will be given from other hives. One colony in the home apiary has been employed for a month in storing syrup in empty brood-combs, which, as soon as they are filled and sealed, are removed and replaced by empty combs. These are to be carried to an out apiary, where we make short stops and cannot feed in the usual way. We also use them late, if needed, after it is too cold to feed syrup.

To secure a large crop of fall honey, Italian bees or the yellow races are the most suitable, as they work later in the season, and with more energy than black bees. To rouse them from the winter quiet—a state they are then approaching—part or all of the brood-combs are removed, and sheets of foundation put in their places. The desire for a winter's supply of honey, and the work on the foundation stimulates the bees' energies to the utmost, and as fast as the combs are drawn out and filled, they may be extracted and returned and again extracted as often as filled. By removing the honey often, the bees are kept at work as long as the flow continues. In this way 100 pounds per colony have been obtained where but a few hives are kept. As this draws on the vitality of a colony, and calls forth energy that would have been available in the spring, it may be wise to strengthen such colonies before wintering, unless they have an abundance of young bees.

In this location, this honey, as a rule, is not obtained except in brood-combs, and as it is excellent for winter stores, is allowed to remain. My Cook apiary is where there is much runout land grown up to weeds and brush. Here golden-rod and asters are very plenty. Being on a hill where it is rather bleak, a board fence was built on all sides; with this protection they venture out many times, when if the hives were exposed to the strong wind they would remain inside. It is also high and dry, and frosts hold off until late. Here bees have never failed to get enough late honey for winter stores.

At the beginning of the flow last fall, the colonies were almost without stores but very populous. All brood-combs not containing brood were removed, leaving from four to six combs two-thirds full of brood, nearly all of which was capped. The vacant space in the brood chambers was filled with dummies and surplus sections containing drawn out combs placed above, the hive covered with chaff cushions, and the entrance made rather small. After a hard frost I examined them and found that nearly all had from 12 to 20 pounds of honey in sections, two-thirds of which were nicely sealed, the remainder uncapped, and but partly filled. The brood-combs were solid with honey, with the exception of a space for bees to cluster in the center combs. The honey from golden-rod coming first, most of it was stored below in the room made by the fast hatching brood. The flow from asters came after, and as the space below was mostly filled, much was stored above.

The honey in some sections nearest to the center of the cluster was two-thirds golden-rod with aster honey about the edges, and was thick, well filled and finished; that further away was clear aster honey, nicely finished, and very clear and handsome; that furthest from the cluster was poorly filled, unsealed and thin. The wax cappings at this time are quite yellow from the pollen in the wax. Had I given less room in the brood-nest, and frequent attention, I should have secured less honey below and more above, but the colonies would have needed more stores for winter.

This result shows that the obstacles in the way of producing this honey in the comb may be overcome. It also shows what is possible in a better season, or in a still better locality. Although less in amount will be taken in boxes than in the extracted form, it will be worth more money.

If but one or two brood-frames of foundation are allowed below, and a few sections of drawn out comb above, and as fast as finished are removed and replaced by others, a large number may be secured. There is little danger of the queen laying in sections at this season. The proper amount of space below and above to get the best work and all the pollen below instead of above in boxes, will be learned by experience. At this season drawn-out combs should always be used instead of foundation in the sections.

A late-reared queen will have considerable brood late in the season, at a time when there is usually little or none. This is a great help to force the honey above, and if the bees of another colony are united to these, success will depend only upon the weather and the secretion of nectar. When the summer flow has yielded no surplus, I believe it will pay to secure this late crop in comb, even if all colonies have to be given sugar stores for winter. The latter should be stored and sealed in warm weather, and be ready to give when the other is removed. Instead of following this plan extensively, it may be best, in your locality, to try it the first season with but 1 or 2 colonies.

CANADA.

Report of the Brant Bee-Keepers' Association.

Written for the *American Bee Journal*
BY R. F. HOLTERMANN.

The Brant Bee Keepers' Association held their quarterly meeting at the Court House in Brantford, Ont., commencing at 2 p.m., on Aug. 11, 1888. In the absence of the President and Vice-President, Mr. T. Birkett, of Brantford, was elected to occupy the chair.

Reports of the Season of 1888.

The season's reports were then given as follows:

C. McNally, of Simcoe, said that fruit-bloom had yielded fairly well. They had but little clover, owing to last year's drouth. Linden yielded but little. They have a great deal of buckwheat about them, and he expected quite a number of pounds of surplus from that source. It was yielding well at present, one colony having filled, without capping, an 8-frame Langstroth super in 1½ days. He had nearly doubled his colonies.

J. R. Howell reported up to the close of the linden about the same as had Mr. McNally; but he secured some linden honey. The Chapman honey-plant came into blossom, and the bees worked very well on it; from the colony that appeared to have the most honey from it he extracted, and had a sample of the honey present, which was first-class. His increase was 50 per cent. The Secretary reported that he had secured about 5 pounds per colony up to linden bloom, and had now from thistle, clover and linden, an average yield of about 20 pounds per colony, or 1,000 pounds; and he expected enough for winter. His increase was 10 per cent., and besides, he had formed nuclei and reared about 70 queens.

T. Birkett reported that his bees had done but little until within the last three weeks. He had secured from about 67 colonies, spring count, about 1,000 pounds of honey, besides comb honey, and plenty to winter them on. His increase was about 30 per cent. He had allowed several swarms to go together, and these were the colonies which gave him the increase.

C. McAllister said that he had put 20 colonies into winter quarters last winter, some of them being light. They had increased from 8 colonies. All but one colony wintered; 4 more were lost by spring dwindling, and the remainder had done well lately, but not before.

Feeding Bees for Winter.

W. Phelps, of Mt. Pleasant, asked: "Does it pay to feed for winter?" C. McNally said "No; I fed 64 colonies \$125 worth of sugar one fall. I feed some every year. Bees should be fed early."

The Secretary said that he did not want to feed, and he keeps two full combs for every hive, which, on an average, will be enough for winter stores, besides what is already in the brood-chamber. He finds that bees

gain but little more than half in weight compared with the heavy fed ones. He feeds rapidly, and if he must feed, he would feed sugar syrup in preference to honey. While he strongly condemned feeding at all, if bees had not enough stores for winter, he fed sugar syrup.

"Do you use feeders?" was asked. One bee-keeper fed by pouring the feed in the back of the hive; others fed in pans with floats of some kind.

It was then moved, and after discussion, carried, that the North American Bee Keepers' Society be invited to hold their annual meeting in 1889, at Brantford, Ont.; promising the Society a free hall to meet in, reduced hotel rates, and that this association would make every effort to make the meeting a pleasant one.

Difference in Worker-Bees' Energy.

J. R. Howell asked what could account for the difference in energy of worker-bees. C. McNally said that bee-keepers were running too much to color in bees. He found of his best looking bees the poorest workers. The writer thought there was a tendency in this direction; he did not mind a little black blood in the bees, in fact he preferred it, but wanted only a very little.

The Perforated Queen-Excluders.

A discussion took place upon the necessity of perforated queen-excluders in producing extracted honey. Messrs. Dickie, Birkett, Howell and Holtermann used them and liked them. Some complained now and then that a queen passed through. C. Culver, of Bloomsburg, pointed out that it was important to have a bee space on both sides of the board.

The convention then adjourned to meet in December.
Brantford, Ont.

FOUL BROOD.

Theories of the First Cause of the Disease.

Written for the American Bee Journal
BY JAMES A. GREEN.

As to what may be the first cause of foul brood I believe no theory has as yet been advanced that will satisfactorily cover all cases.

The theory of Cheshire, that it is caused by bacilli, or minute vegetable organisms, is the one generally held by those who have studied the disease. If we accept this, we must suppose that all cases of foul brood are traceable to infection from some first case or cases. Bacilli can no more grow without seeds than corn or wheat. It seems somewhat difficult to account for all cases on this supposition, although if Cheshire's theory be true, that the bacilli or spores may be deposited by the bees from infected hives on the blossoms they visit, to cling to and be carried away by other bees that visit the same flowers, we can easily see that the disease might be quickly spread over wide

reaches of territory. The intervening links might then be destroyed in some way, leaving cases of foul brood apparently many miles away from any source of contagion. Even without this way of spreading, the disease may be carried far and fast by swarms escaping to the woods, and by robbing.

The credence given to Cheshire's conclusions is no doubt largely because they are in accord with what is known as the "germ theory" of disease. This is very captivating, very plausible, and a very convenient pair of shoulders on which to lay the burden of most of the disease that afflict the inhabitants of this mundane sphere.

It is not my intention to attack this theory. Apparently it rests on too firm a foundation to be overthrown. The whisper, though, is not unheard in scientific circles, that over zealous investigators have sometimes mistaken effect for cause, in concluding that because bacilli accompany a disease they necessarily produce the disease.

There are objections to the bacillus theory in the case of foul brood. One is, that Cheshire declared himself unable to detect either bacilli or spores in honey, and gave it as his opinion that the disease was never, or at least but very seldom, transmitted by means of honey. So far as I know, no microscopist has had any better success in detecting either bacilli or spores in honey. Yet the almost uniform testimony of all who have had practical experience with it is, that it is through the medium of the honey that it is most frequently and surely transmitted. The most practical and successful methods of cure are based on this assumption, while those which ignore it have in practice proven uncertain and unreliable.

Starvation as a Foul Brood Cure.

Cheshire declares, furthermore, that foul brood is not simply a disease of the brood, but that *bacillus alvei* affects the mature bees, both workers and queen. If so, they are very easily disposed of, for I have repeatedly cured the worst cases of foul brood by simply confining the bees without food for 48 hours, then putting them into a clean hive, and still more simply by brushing them from their infected combs into a clean hive, where they were obliged to build comb before brood could be reared.

The plain inference is, that the contagion, whatever its nature, is contained in the honey, and that it is destroyed when the honey is digested. Possibly the digestion of the last particle of honey does away with the bacilli so numerous in the vitals of bees and queen; but many will be inclined to doubt.

All attempts to get rid of foul brood without boiling, or equivalent treatment for everything except the bees, have proven tedious, uncertain and unsafe. By "equivalent treatment," I mean a thorough washing or admixture with carbolic or salicylic acid. To spray the outside of an infected comb is useless. While it is possible that the fumes of sulphur may be a sufficient disinfectant—though I do not believe it—the process must be more thorough

than that recommended on page 539. To put infected hives and frames out of doors in the summer—exposed to the bees—as there recommended, and then depend upon scraping and sulphuring, is simply to invite destruction.

The correspondent on page 538, has very evidently had little experience with foul brood, or he would not venture so wild an opinion as, that it is caused by the larva getting reversed in the cell, and that the puncture in the cap of the cell is made by its "sharp end" in the effort to get out.

The fact is, that foul brood nearly always attacks the larva before it is old enough to be sealed up. Even when it is attacked after it is sealed, the cap is by no means invariably punctured nor perceptibly sunken.

Ropyness the Test of Foul Brood.

The best test of foul brood is the ropy, tenacious, slightly elastic condition that the diseased larva assumes. Do not expect, though, that it will "snap back into the cell like a piece of India rubber when you pull it out with a stick," as some have said. I was not in favor of this test once, simply because too much stress was laid on the elasticity of the diseased matter. Remembering that its elasticity is but slight, this feature becomes our best criterion.

Dayton, Ills.

FINDING HONEY.

Uncle True's Experience in Getting it Out of a Chimney.

Written for the Boston Traveller
BY H. P. BARNARD.

Uncle Joshua True and Solomon Baskins lived in a double house. It was Sunday, while the Baskins and Trues had gone to meeting, leaving Joshua at home alone.

Suddenly, something like a small black cloud came between him and the sun; Uncle True looked up and saw that it was a swarm of bees hovering directly over his bald pate, which he covered with both hands and fled to the house. Like a living ball they hung suspended a moment, then swept toward the house-top, alighting upon an unused chimney. Uncle True ventured out and eyed them wistfully.

"Why couldn't ye come a week day?" he growled. "Then I could a got Collins—he's a great bee-man—and we'd put ye into that empty hive. It's a pity it's the Sabbath; a clean ten dollars as good as throwed away."

But soon his face brightened. There was the skylight, he could put the hive out of that, perhaps they would take a notion to it.

A moment later Uncle True was puffing up the attic stairs. The nerves in his crown crawled, as he remembered how it had seemed to attract the insects; still he ventured a leg out upon the long sloping roof, and gently proffered a home to the rovers, muttering:

"There, ye can't do better'n that!"

They rose in a body, and with them Uncle True's hope; only to fall again, as they at their queen's behest went down into the Baskins' chimney!

"Pesky things!" he ejaculated. As the church-goers were returning he withdrew the hive, closed the skylight with a bang, and then appeared below just as Aunt True bustled in.

"Feel better, Joshua? Such a sermon as we had—you don't know what you missed."

"I'm alluz missing something!" Uncle True answered, crossly.

"Why, what's the matter?" Then he told her how the bees had come, and "every soul of 'em gone into Baskin's west chimney."

Aunt True sat right down, bonnet in hand, while Joshua enlarged upon the subject. He said he'd give anything if the bees had come to him; he would have planted buckwheat for them, and in the fall smoked them out, and gathered the honey.

Suddenly Aunt True spoke, "I don't care if them bees be in Baskin's chimney! You found them, and you've the fust right; besides it opens in our cellar, and that gives us some tittle to them."

"That's so!" cried Uncle True. "Of course they belong to me—no question but the law'd decide that! But Baskin's might not think so!"

"I don't s'pose he'd divide," said Aunt True, "them Baskins is bound to get all there is, every time! I shouldn't mention the bees; maybe they wouldn't find it out all summer."

"Fact is, it's alluz best to manage folks quietly," chimed in Uncle True.

Little did either dream what a part they would have to act; or how often be forced into untruths.

Never were there such active, hot-tempered insects—the young Baskinses were continually getting stung by what they called hornets.

"It is a powerful year for 'em; I've got stung myself?" said Uncle True.

"Must be there's a nest under the eaves," she said, as she applied saleratus water.

And Uncle True pretended to hunt for it. Then, when the garden blossomed to buckwheat alone, and Baskins was amazed, Uncle True explaining the unusual spectacle by saying he "liked to see it blow!"

Later in the summer Joshua could not forbear an inspection of the chimney, so he took cement with him that he might be able to say to the Baskinses that he was mending the chimney!

The buckwheat blossomed, and its sweetness was culled by the busy insects. "Reg'lar workers, they are," Uncle True often said, gleefully. "That chimney must be filling up fast. Things have gone along nicely. The Baskinses don't mistrust; just as soon as they start, we'll get the honey."

The buckwheat faded.

"When are the Baskinses going to the beach?" each asked the other.

The summer went, but alas, the Baskinses stayed; they "couldn't afford the seashore" that year! It began to look as if Uncle True would never get a chance at the colony. Fortunately, the fall was unusually long and warm, and the bees kept on working clear up to Thanksgiving. On the morning of

that day, Mr. Baskins started for his native town with his family.

"Calc'late to make a long stop, neighbor?" Uncle True spoke carelessly as possible.

Mrs. Baskins said, "Pa wouldn't hear to their coming home till the next afternoon."

"They've gone at last—coast's clear!"

Even that fact did not open the way for an immediate attack upon the bees. The Trues waited, fearing the Baskinses might return for some forgotten article; then company came and stayed all day. "They have spoiled our best chance!" Uncle True said dolefully.

"Never mind," said Aunt True. "We'll get everything ready for an early start to-morrow."

The Trues retired long before the usual time, and slept too soundly—for they did not hear the Baskinses return, about midnight. As Mrs. Baskins said "Pa's too full to accommodate us!" which might have been taken literally after "Pa's" hearty dinner, but what she meant was the ancestral bed-rooms were filled with relatives from a distance. As these were from a cyclone district, the young Baskinses heard a tale of horror that sank deep into their minds.

"No part of our country is safe these days," said Baskins.

"Out our way we're prepared," said the cyclone representative: "We have a cave in the cellar to run into; let the house sail off then, we're safe!"

"The wind's going to sweep us yet," said Baskins, rolling his big eyes prophetically; "what's to hinder? folks is cutting off trees, and leveling the hills as fast as they can. Some day they'll wake up and find themselves to the mercy o' the elements."

Under the circumstances, it is not surprising that the children and Mrs. Baskins dreamed of cyclones.

The Trues began operations at day-break. A smothered chip fire was lighted in the opening of the chimney to smother out the bees.

"I don't calc'late they're very far down," said Uncle True; "guess I can reach them with a long-handled spoon."

Then he equipped himself in a bat draped with mosquito netting to his waist, a long iron spoon and preserving kettle, and started skyward. Mrs. True took a favorable sight-seeing position in the back-yard.

Uncle True peered cautiously into the chimney.

"It's jam full 'o suthi'," he told Aunt True; "must be a powerful big swarm."

"Sure, they are smoked out enough, Joshua?"

"Oh, yes, they're quiet; none o' them aint going out or coming in. There's a leetle buzzing, but that don't mount to nothing—no more'n a hen's flutterin' when her head's chopped off!"

While doing two things at once—speculating how much sweetness such a colony could procure, and thrusting in the spoon—Uncle True's elbow started a brick down the chimney. In an instant that "powerful swarm" darted up right into Uncle True's face, as he peeped intently over. With a howl of fright, he dropped the kettle.

It rolled and bumped the length of the roof, then bounded off, striking the ground just where Aunt True stood a moment before.

This woke the Baskinses like an electric shock. They sat up in bed bewildered and frightened. Then, hearing the clatter of Uncle True's boots down the slope of the roof, Baskins said:

"It's probably a cyclone; we haven't had the equinoctial yet! The only thing that'll save us is to get out of the house and away from the trees!"

As the Baskinses fled out of the back door, Uncle True, wishing only to distance the bees, suddenly dropped among them, in their back yard, and rolled over groaning. Perhaps they took him for some strange being, tipped off another planet by a freak of the cyclone; at any rate they did not recognize him in his "bee-protector," for as the figure flopped its hands wildly skyward, and gasped for speech, Baskins shouted:

"Run, all on ye? Make for the open field!"

"Run" they did, fast and far, screaming till the neighborhood was aroused.

As the Baskinses crowded through the gate that opened into a large field, the elder Baskins looked back to see if the house had gone over. To his surprise, it remained apparently firm, not even the chimneys had started. He noted also how still the trees were, and what a perfect morning it was.

"Surely, this is no cyclone," he said, and at once ordered a halt, while he went back to reconnoitre. His attention was at once called to the groans of Uncle True, who was being helped over the fence by his wife. The former, seeing through his thick veil that it was Mr. Baskins, called out:

"I've had a terrible fall, neighbor Baskins; I think I've broke my back. I'll never fix a chimney again!" With that he was ushered into the house, and the door slammed behind him.

As Mr. Baskins gazed upon the roof of the house, and saw many bees flying angrily around the chimney, the absence of several bricks, a long spoon and iron kettle on the ground, a dilapidated patch of buckwheat in his neighbor's yard, the truth gradually dawned upon him.

"Come back!" he shouted to his family; "it's no cyclone—only one of old True's experiments."

As Joshua True sat bolstered up in his armchair before the fire, it seemed as if every one who passed the house looked at the chimney and smiled. Even the boys paused on their way to school, explaining to some new-comer: "O d True's home ruu down the roof." Bert also, although innocent, was punished for the sins of his parents, for his playmates called him "Honey."

This was more than Uncle True could bear; he decided to move away, and start anew among strangers. It was some days before his wife could be persuaded to go, but at last she said:

"We'll go, Joshua, but," shaking her long forefinger at him, which meant she was in earnest, "don't you let me hear anything more about catching a swarm of bees."

CONVENTION DIRECTORY.

1888 *Time and Place of Meeting.*

- Sept. 6.—Bees and Poultry, at New Brunswick, Ind.
Ora Knowlton, Sec., New Brunswick, Ind.
- Sept. 8.—Susquehanna County, at Montrose, Pa.
H. M. Seeley, Sec., Hartford, Pa.
- Oct. 3-5.—North American, at Columbus, O.
W. Z. Hutchinson, Sec., Flint, Mich.
- Dec. —Michigan State, at Jackson, Mich.
H. D. Cutting, Sec., Clinton, Mich.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

 SELECTIONS FROM
OUR LETTER BOX

Limit Commission Men.—B. H. Standish, Evansville, Wis., on Aug. 22, 1888, writes thus:

I wish to caution beginners and all others who need it, to fix the price at which honey may be sold, when sending to commission men. If this price were fixed by supply and demand, it would now be quoted at 25 cents instead of 16 cents per pound. Who has produced honey at a cost less than 25 cents per pound this year? I think no one, and it ought to be quoted at that, and will be if producers limit salesmen to that price. It is an injustice to every brother bee-keeper, when one puts honey on the market which may be sold at half the cost of production.

Large Honey-Flow—Pure Italians.—R. H. Campbell, Madison, Ga., on Aug. 18, 1888, writes:

I have in my apiary four or five different kinds of hives, and among them 32 Heddon hives. I like them, and I believe that more extracted honey can be procured with them than with any other. Besides, they are light and nice to handle. We are having the largest flow of honey for August that I have ever seen; my hives are all loaded down. The honey is of fine flavor, and perfectly white, being gathered from cotton and field-peas. I have now 90 strong colonies ready for winter quarters. In this locality and county, hybrid and black bees have swarmed continually, while my Italians have swarmed but little, and had their hives full of honey. The pure Italians are the best bees of all. I have tried all known races, and I now have the Italians, which I find to be superior to any.

Bees Not Busy.—Mr. D. J. Winney, Schuylerville, N. Y., on Aug. 16, 1888, writes:

I notice by reports from various parts of the country, that in general bee-keeping will not be profitable this year. This section is no exception to that rule. I wintered, or began the past winter, with 19 colonies, 9 colonies in the cellar, and 10 in a bee-house, with chaff cushions on top of the bees. I lost 3 colonies, 2 in the cellar and 1 in the bee-house. The causes were diarrhea and starvation. Two colonies were robbed after I put them out, that left 14, which I have built up to 27, but they are lying around with nothing to do. I do not think that I will get over 100 pounds of surplus honey, unless it is from buckwheat, and of that I never have had much. Some of my bees have taken honey out of the sections that were not sealed, so I infer that they hardly get enough for present use, which is rather discouraging.

The Yield from Basswood, etc.—B. D. Scott, Ovid Centre, N. Y., on Aug. 17, 1888, writes:

I commenced the season with 56 colonies, increased them to 90, and have taken 3,600 pounds of extracted, and 300 pounds of comb honey in one-pound sections. Basswood yielded but little honey, but lasted well. The first blossoms opened on June 27, and I found fresh ones July 29. I have one colony on the scales, and the best day's work on basswood was 17½ pounds; on July 29 it gained 13½ pounds on clover and basswood mixed. But little honey is the general complaint among bee-keepers.

How to Hold the Breath.—L. D. Cheasbro, Conway, Iowa, on Aug. 15, 1888, says:

I notice by the BEE JOURNAL for to-day, that J. H. Amos has been trying the experiment of holding his breath to prevent bees from stinging. He says that it will not prevent it, but I believe it will, by half filling the lungs, and then holding the breath. The first time I filled my lungs to the full capacity, and could not help but let a very little escape, and was stung. But after that I never received a sting.

Bees Breeding Heavily, etc.—S. Shoup, Coloma, Mich., on Aug. 20, 1888, writes:

The honey crop in this part of the State, so far as I can learn, will be very light—may average 10 pounds per colony. My bees are breeding heavily now, and are storing some honey from buckwheat; but the weather continues dry, and I fear it will hurt young white clover for another season. I think that bees are generally in better condition for winter than last year at this time, and if we get rain to keep up fall bloom, some may get a little surplus.

No Rain for Six Weeks.—I. R. Good, Nappanee, Ind., on Aug. 20, 1888, says:

This has been the poorest season for honey and for queen-rearing that we have had since I have kept bees. There will be no surplus secured in this section. Six weeks ago last night we had our last rain, and everything is drying up. The prospects for a fall flow of honey are poor. Many colonies are almost in a starving condition.

One-Third of a Crop—Albino Bees.—H. P. Deahl, Berryville, Va., on Aug. 17, 1888, says:

The honey-crop here this season will be about one-third of a crop. Last spring I had 200 colonies, and obtained 5,000 lbs. of honey in one pound sections. I expected to get about 16,000 pounds. I will begin the winter with about 250 colonies. My Albino bees stored most of the honey.

Very Wet Weather.—Mr. Ezra J. Cronkleton, Dunlap, Iowa, on Aug. 14, 1888, says:

The weather has been very wet here for the last eight days, and it is raining now. If we can get a few days of fine weather, it will make a big difference in our fall crop of honey. Corn is being injured very much. Oats is half a crop.

Figwort, Sweet Clover and Culver's Physic.—L. E. Waterman, of Moline, Ills., on Aug. 19, 1888, writes thus about these plants for honey production:

I send two plants for name, besides which there is little attraction for the bees except sweet clover. I think it will pay any bee-keeper to plant sweet clover. I have seen C. H. Dibbern's three-acre patch since it bloomed, and I am satisfied that it pays. In fact, I think he is the only person getting any amount of honey in this locality, during the sweet clover period. I think that if the old stalks were taken off now, and the ground well harrowed, that it would bloom again next season.

[The plant with the long racemes of flowers is *Leptandra Virginica*, or Culver's physic. The other is figwort, or Simpson's honey-plant. Both are excellent honey-producers.—ED.]

Honey Crop of New York.—R. Bacon, Verona, N. Y., on Aug. 13, 1888, says:

The honey crop in this part of the country is very light, and from what I can gather, this State will not be able to put as much honey on the market this year as it did last.

CONVENTION NOTICES.

☞ The Darke County Bee-Keepers' Society will hold a basket meeting on the Greenville Fair Grounds, on Friday, Sept. 7, 1888.
J. A. ROE, Sec.

☞ The North American Bee-Keepers' Society will meet at Columbus, O., on Wednesday, October 3, 1888, and continue as usual in session for three days.
W. Z. HUTCHINSON, Sec.

☞ The Cortland Union Bee-Keepers' Association will hold their fourth annual picnic at the Floral Tract Farms, in Cortland, N. Y., on August 30, 1888. Let all bee-keepers and their friends come and have a good time.
W. H. BEACH, Sec.

☞ The next semi-annual meeting of the Joint Bee and Poultry Keepers' Association of Boone and Hendricks counties will be held at the apiary of Wm. H. Higgins, 2½ miles south of east from New Brunswick, Ind., on Thursday, Sept. 6, 1888. All interested are cordially invited to attend.
O. L. A. KNOWLTON, Sec.

☞ The Susquehanna County Bee-Keepers' Association will meet in the Court House at Montrose, Pa., on Saturday, Sept. 8, 1888, at 10 a.m. Sharp. The following subjects will be considered: Preparing Bees for winter; Preparing for and Marketing Surplus Honey; Does the Raising of Small Fruit Conflict with Bee-keeping? All bee-keepers are cordially invited to attend.
H. M. SEELEY, Sec.

Can You Do Anything that will do more to advance and defend the pursuit of bee-keeping, than to aid its Weekly Exponent and Defender? The AMERICAN BEE JOURNAL is the pioneer bee-paper of America, and is fully entitled to the active support of every progressive apiarist, for it works constantly and faithfully for the best interests of the pursuit. We therefore specially request all our readers to use their influence to double our subscription list during the coming autumn. Reader, will you please send us a new subscription with your renewal or before that time? A good weekly at one dollar a year is surely cheap enough to command patronage.

New Subscribers can obtain the full numbers for 1887 and 1888, for \$1.75, while there are any sets of 1887 left.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4 1/4 x 4 1/4 and 5 1/4 x 5 1/4. Price, \$1.00 per 100, or \$8.50 per 1,000.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexations delay and trouble.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in Cheshire's pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being available; it must be sent by express.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 25
 " 200 colonies (420 pages)..... 1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

CLUBBING LIST.

We Club the American Bee Journal for a year, with any of the following papers or books, at the prices quoted in the LAST column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

Cork for Winter Packing.—Its advantages are that it never becomes musty, and it is odorless. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Red Labels for Pails.—We have three sizes of these Labels, ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1 50	\$2 00	\$2 25
500 Labels.....	2 00	3 00	3 50
1,000 Labels.....	3 00	4 00	5 00

☞ Samples mailed free, upon application.

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; 1/2 pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. It wanted by mail, add 18 cents per pound for bag and postage.

Conventions.—The time for holding Bee-Keepers' Conventions will soon be here, and we cannot give any better advice than this: Let each one attend who can do so, and take part in making these meetings interesting and instructive. If you have not already obtained the "Bee-Keeper's Convention Hand Book," do so at once to post yourself up on how to conduct such meetings correctly. It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for Discussion—List of Premiums for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents. We will club this book and the AMERICAN BEE JOURNAL for one year for \$1.25.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$3.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Sweet, or Melilot, Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the BEE JOURNAL, and will send two or more free of cost to any one who will use them, and try to get up a club.

Exchange.—We will accept Honey and Beeswax in exchange for Bee-Keepers' Supplies in any quantity. Those desiring to make a trade are invited to correspond with us, stating quantity, quality, and price, and the goods they want in exchange.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, Ills., is published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

Scatter the Leaflets.—Look at the list (with prices) on the second page.

Honey and Beeswax Market.

NEW YORK.

HONEY.—Market is bare of extracted, but choice white clover or basswood will bring from 7½¢ to 8¢. Southern extracted, 55¢ to 60¢, per gallon, as to quality.
BEEWAX.—Dull at 23¢.

HILDETH BROS. & SPOELKEN,
 Aug. 23. 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—We quote: White to extra white comb, 12½¢ to 15¢; amber, 8¢ to 11¢. Extracted, white to extra white, 5¼¢ to 6¢; amber, 4¼¢ to 5¢. Arrivals of the new crop are small, the estimates being an average crop.
BEEWAX.—20 to 24¢.

June 18. **O. B. SMITH & CO.,** 423 Front St.

DETROIT.

HONEY.—Best new white comb, 15¢ to 16¢, with little in sight and slow sales. Market is low, and bee-keepers will do better to hold honey until approach of cold weather.

BEEWAX.—21 to 22¢. Supply limited.
 Aug. 22. **M. H. HUNT,** Bell Branch, Mich.

CHICAGO.

HONEY.—New crop offered at 16¢ to 17¢, demand being very light yet. Extracted is not in much demand, and prices are nominal at 7¢ to 8¢, for the best grades.

BEEWAX.—22¢.
 Aug. 14. **R. A. BURNETT,** 181 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 12¢; fancy 2-lbs., 10¢ to 11¢; fair white 1-lbs., 10¢ to 11¢, and fair 2-lbs., 8¢ to 9¢. Buckwheat 1-lb., 7¢ to 8¢. The demand is dull for comb but fair for extracted, of which new from the South is arriving, and sells for 55¢ to 58¢, per gallon.

BEEWAX.—Dull at 23½¢ to 24¢.
 Jun. 15. **F. G. STROHMEYER & CO.,** 122 Water St.

CHICAGO.

HONEY.—None here, and market in good condition for new crop. There is some demand for the extracted.

BEEWAX.—22¢.
 Aug. 2. **S. T. FISH & CO.,** 189 S. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5¢ to 8¢, per lb., for which demand is fair. Comb honey, 12¢ to 16¢.—Supply in large of last year's comb honey, and for which the demand is slow.

BEEWAX.—Demand is good—20 to 22¢, per lb. for good to choice yellow, on arrival.
 Aug. 15. **C. F. MUTH & SON,** Freeman & Central Av.

MILWAUKEE.

HONEY.—Choice white one-lb. sections, 14¢ to 16¢; 2-lbs., 13¢ to 14¢; 3-lbs., 12¢ to 13¢. Extracted, white in kegs and ½-barrels, 8½¢; in tin and pails, 9½¢ to 10¢; dark in barrels and kegs, 6¢ to 6½¢. Demand good for extracted, but dull for comb.

BEEWAX.—22 to 25¢.
 July 2. **A. V. BISHOP,** 142 W. Water St.

DENVER.

HONEY.—Best white 1-lb. sections, 14¢ to 15¢; 2-lb. sections, 12¢. Extracted, 6¢ to 7¢.

BEEWAX.—20 to 23¢.
 Jun. 25. **J. M. CLARK & CO.,** 1409 Fifteenth St.

KANSAS CITY.

HONEY.—We quote: 1-lb. sections, not glazed, at 16¢; 2-lb. sections and dark ones, also extracted, is not in demand. New honey is arriving freely, with a fair demand. This part of the State is favored with half a crop.

BEEWAX.—None in market.
 July 20. **HAMBLIN & BEARSS,** 514 Walnut St.

BOSTON.

HONEY.—We quote: 1-lb. sections, 14¢ to 16¢; 2-lb. sections, 12¢ to 13¢. New Florida extracted, 8¢ to 8½¢. Sales are very dull.

BEEWAX.—25 cts. per lb.
 July 5. **BLAKE & RIPLEY,** 57 Chatham Street.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 5¼¢ to 6¢; light, 5¼¢; amber, 4½¢ to 5¢. Comb, 1-lb., 12¢ to 14¢; 2-lbs., 9¢ to 13¢, as to quality. Arrivals not large, and supplies held firmly.

BEEWAX.—Dull at 19¢ to 22¢.
 Aug. 20. **SCHACHT & LEMCKE,** 122-124 Davis St.

KANSAS CITY.

HONEY.—We quote: White 1-lb., unglazed, 18 to 20 cts.; 2-lb., 15¢ to 16¢. California white 1-lb., 18¢; 2-lb., 15¢; extracted, white, 8¢—amber, 7¢.

BEEWAX.—None on the market.
 Aug. 10. **CLEMONS, CLOON & CO.,** cor 4th & Walnut.

ST. LOUIS.

HONEY.—We quote: Extracted, dark, 4¢ to 4½¢; bright, 5¢ to 5½¢; in cans, 7¢ to 8¢. Comb white clover in prime condition, 13½¢ to 15¢; dark, 11¼¢ to 12½¢ cts.—Market quiet, demand good and receipts light.

BEEWAX.—22¢, for prime.
 Aug. 10. **D. G. TUTT & CO.,** Commercial St.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

We Want 20,000 subscribers. Out of the 300,000 bee-keepers in America, certainly this is not an extravagant desire! It is only one out of every fifteen! We confidently ask those who appreciate the AMERICAN BEE JOURNAL, to show it by sending us one or more new subscribers. We will give them full value for their money.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Carniolan Queens a Specialty.

ALL Queens bred from imported mothers. A Gentlest Bees known. No smoke needed. They cannot be surpassed as honey-gatherers. Never saw foul brood. Prices:

One Untested Queen \$1.00.
 6 " Queens 5 50.
 12 " " 10.00.
 1 Tested Queen 2.00.
 1 Select and Tested Queen 3.00.

Ninety per cent. will prove to be purely mated. Safe arrival guaranteed. All orders booked and filled in rotation. Address,

ANDREWS & LOCKHART,
 31D3t PATTEN'S MILLS, Wash. Co., N. Y.

EDITORIAL BUZZINGS.

But still the world goes round and round,
And the genial seasons run,
And ever the right comes uppermost,
And ever is justice done!

The British Bee-Keepers' Guide Book, by our friend T. W. Cowan, has been translated into Spanish, and republished at Barcelona, Spain. It was long since translated into French. It is a good and practical work, and richly deserves its popularity.

The Two Most Skillful Architects in all the world are the bee and the spider. The one puts up neat packages of sweets, and the other builds a slaughter-house for flies. Spiders are valuable, inasmuch as they destroy noxious insects. So says an exchange.

It is an Old Proverb, but a true one, that "The Gods give us no great good without labor." It is also true that the *hardest labor* is not always that which receives the greatest pay. Bees are the *greatest workers* in the world—resting not day or night—but in six or eight weeks they die, before having enjoyed any of the results of their labors—leaving to their progeny the wealth gathered. Then comes man, and often "robs" both parent and offspring of their hoarded treasures.

Germany still mourns her heroic Emperor Frederick, and few can read without interest the well-illustrated sketch which opens *Frank Leslie's Popular Monthly* for September, tracing his whole career. The number abounds in most attractive illustrations, the frontispiece being very taking.

The Silver Lining to the clouds is now becoming apparent. White clover is now giving second bloom in some localities, and the bees are gathering more honey from it, than at any time previous during this year. Fall flowers are coming in and present an excellent prospect. Sweet clover is rather late in blooming, still it is just commencing to show its flowers and spread its perfume. Mr. O. B. Barrows, of Marshalltown, Iowa, wrote us as follows on Aug. 30, 1888:

From the time basswood bloom failed until Aug. 18, bees lost in weight until they neared starvation, with the prospect of being obliged to buy barrels of sugar to keep them from starving next winter. On the 18th they commenced gaining in weight, and some that did not swarm and were full of bees, have gained 20 pounds, and the most of them are out of the woods, so far as winter stores are concerned; and the balance will be, if this flow holds out a few days longer. We can now see the silver lining to that cloud.

Shall it be Changed?—Several have advocated the changing of the time for the payment of dues and the election of officers of the National Bee-Keepers' Union, to January instead of July. Here is what Mr. E. France has to say on the subject:

The report of the Manager of the National Bee-Keepers' Union, with voting blanks, was brought to the house by some of the boys, but I have never seen it. I wish we could change the time from what it is to Jan. 1, to make these payments; then we would have more time to attend to it, and could take time to see other bee-keepers, and very likely get some of them to join the Union. As it is, the time for renewal comes at the most hurrying time of the bee-keepers' year. For my part I would be willing to pay another dollar on Jan. 1, if the matter could be changed.

Of course it can be changed, if there are enough in favor of it. Votes count. Will every member kindly send in a vote on the subject who is in favor of the change? In that way it can be settled by amending the constitution accordingly.

A New Edition of Cook's Manual is just published, and a copy is on our desk. This is the 15th thousand of the deservedly-popular Manual of the Professor. It is largely re-written, and much elaborated, containing over 100 pages more than the former edition, besides a large number of new engravings. On this account the price has been increased to \$1.50. It now contains 462 pages.

On the matter of bees injuring grapes, we find the following on page 337:

That bees ever tear the grapes is a question of which I have failed to receive any personal proof, though for years I have been carefully seeking it. . . . I feel very certain that bees never attack sound grapes. I judge not only from observation and inquiry, but from the habits of the bee. Bees never bore for nectar but seek, or even know only of that which is fully exposed.

We may give further extracts, as opportunity offers. It can be obtained at this office.

Not only do the bees gather the honey, but it seems that Nature intended that they should fructify the flowers, and in return for this valuable work, the flowers pay the bees in nectar, which they carry to their homes to sustain their lives and feed their insect progeny—the *surplus* only being taken for man's use to pay him for the necessary care and protection. An exchange puts it in these words:

The usefulness of the bee is not confined to the honey she produces. Her mission is more extended. Much of the fruitfulness of our orchards must be credited to her diligent going from blossom to blossom. In the spring, when the pollen is ripe, it is shaken down by her upon the inner part of the blossom, or carried from one flower to another, thus making them fruitful. Plants which have male and female flowers on separate stalks are almost altogether dependent upon insects like the bee for fructification.

Verbena and Cone Flowers.—J. O. Todd, Richmond, Iowa, on Aug. 25, 1888, writes as follows:

I send samples of flowers on which the bees are at work very industriously. No. 1 has a blue flower and No. 2 yellow flowers. Please answer in the BEE JOURNAL.

No. 1 is *Verbena hastata*, one of the numerous vervains. It has long been recognized as a good honey-producer.

No. 2 is the cone flower (*Rudbeckia*), which is another August flower, and yields considerable honey.

A Honeyed Man.—Recently a man down in Kennebunkport, Maine, says an exchange, captured 800 bees while they were swarming in the woods. He daubed himself with honey, the bees alighted thereupon, and in this way he transported them home without receiving a sting. There is nothing strange about that—still the newspapers are passing it around as if it was a great feat.

The Langstroth photograph, that is just gotten up by Mr. Thomas B. Reynolds, of Dayton, O., is on our desk (see page 590). It is a full-length one, and shows the general appearance and pleasant face of the "grand old man" which we all have learned to love. It is full cabinet size, 4x6 inches, and we do not know how 50 cents could be spent to better advantage, than by buying this photograph—for the owner will have the unspeakable pleasure of being able to look into that benevolent face, and then to feel that he has done a meritorious act by adding to the fund which is to provide for the necessities of the closing years of a life which has been spent for the good of an industrial pursuit, and who will long be held in "blessed memory."

Why Should Not the subject of bee-keeping be taught in all of the Agricultural Colleges, if it is properly a branch of practical agriculture?

GLEAMS OF NEWS.

Honey Candy.—A correspondent in the *Canadian Bee Journal* gives the following concerning sugar-ripened honey, which may interest our readers :

At our home we have had a coal-stove burning for over two months without interruption, keeping the temperature high, consequently very dry. Near the stove is a pantry with only a lath and plastered wall between.

In the pantry was a large fruit-dish containing several pounds of very fine, well-ripened honey. The dish had been setting on the shelf next to the wall for about a week, and when it was brought out the spoon was resting on the top, which was tough, and had a glassy appearance. When pressed with a spoon it seemed like a paper covering. We scratched a hole in it to ascertain the depth, and found it to be between $\frac{1}{4}$ and $\frac{1}{2}$ of an inch. When placed on paper it looked like soft wax, and one would hardly believe that honey, by a hot, dry atmosphere, would evaporate its moisture and become so thick. We thought this a good opportunity to test the difference in quality and flavor; taking some of the honey from a 60-pound tin and comparing it in texture, color, and flavor with this better ripened, it did not seem the same. The contents of the tin was specially selected, and we considered it as good as could be produced; but tests go to prove that the honey in the dish was so much superior that any one comparing them would not hesitate to give 2 or 3 cents a pound more for it.

We do not know how much loss there would be in evaporating honey to that extent; but we suppose the loss to be from 10 to 20 per cent. We believe this class of honey would find a market at a price sufficient to warrant the experiment. It would be necessary to place it in very shallow vessels, and subject it to a very low temperature, that the color might not be changed.

We fancy a room properly arranged, with coils of steam-pipes to raise the temperature to a desirable height, at the same time allowing a current of air to pass through, would soon reduce our ordinary honey to the consistency of jelly. It could then be placed in tumblers, or any kind of vessel; in fact, paper bags could be manufactured of a size and shape suitable to hold it, and sold in 5, 10, 15 and 20 cent packages. It might even be sold by the penny worth, which would increase its consumption.

What is It?—The Bee-Keepers' *Review* for Aug. 10, came duly to hand, and as usual is very interesting. On Wiley's confession, the editor remarks thus :

Prof. W. A. Wiley has received so vigorous a trouncing from the bee-journals, particularly from the *AMERICAN BEE JOURNAL*, that he has at last forsaken his dignified silence, and attempted—well, it is hard to say what. It is a mixture of defense, explanation and confession, in which the contradictions and inconsistencies are pitifully ludicrous. It seems that he lacks the manhood to come right out and own up without any quibble, and do what he can to repair the damage he has done. Such confessions as he has already made awaken only contempt and disgust.

And it may be also stated that he would never have departed from his rule of "dignified silence" but for the editorial rocks hurled at him by the *AMERICAN BEE JOURNAL*!

"Worthless Drones in the hive of Nature!" How often we hear that sentence applied to lazy men. We are usually inclined to dispute the matter because the drone bees are not a *worthless set*—they have duties to perform, and are useful in the line designed by Nature. But here is a little story, told by Anna B. Quillin, of Ipara, Wis., in *Gleanings*, which will be read with interest :

One morning, a year or more ago, my little friend Max came in to see me; and as he walked across the room I noticed that he held both his hands behind him. As he approached my couch he explained, "I've got something for you—just hear them sing!" and suddenly, before I realized what he was going to do, he was holding his hands up by my ears. And, oh such a *buzz, b-u-z-z, b-u-z-z-i-n-g* as I heard! I felt as though a whole swarm of bees had surrounded me. Glancing up at him I saw his eyes were twinkling, and he was shaking with suppressed laughter as he watched my astonished countenance.

"O Max!" I said, "are your hands full of bees, or what have you got in there? It sounds like a swarm of bees."

"Just five humble-bees," he replied, "but they can't hurt you, for they are nothing but drones."

"But, where did you get them, and how did you know they were 'nothing but drones?'" I questioned.

"Why, 'cause I found them on that old dead tree in the lane!" he replied.

"But, Max," said I, "how could that tell you they were drones?"

"Ho! he said, "don't you know how to tell a drone? Why, I'll tell you how you can tell them every time! The workers are too busy to lounge around and do nothing; and when they alight it is always on something they can work on; and when you see bees sitting around on dead wood, with nothing to do, you may be sure they are old lazy drones. Why, I have caught dozens of them, and they are *always* drones. I never caught a worker that wasn't at work, or else looking out for a job."

"Well, Max, that is a new idea to me," I said; "but if that is the case, the bees are very much like people, aren't they? For a man who spends his time sitting around on old store-boxes, and lounging about saloons is generally a drone in the human hive. Our workers in the world haven't much time to waste, for they can always find plenty to do, and take pleasure in being useful."

Sometime Ago items were going the rounds of the press, showing that bees were storm warners. Now, they are barometers which warn the denizens of Australia of coming hot weather. A Melbourne correspondent of the *Dundas Advertiser* narrates what he considers an interesting proof of this provident and far-seeing instinct of bees!

Turning from men to insects, a singular circumstance is reported from a hot, dry valley in New South Wales. Last year the drouth there was of long duration, and the denizens of the apiaries suffered much from it. This year the bees have made provision against a similar emergency. They have filled a large number of external cells in every hive with pure water instead of honey. It is thought that instinct leads them to anticipate a hot summer.

New Subscribers can obtain the full numbers for 1887 and 1888, for \$1.75, while there are any sets of 1887 left.

Seasonable Hints.—The following remarks about seasonable apiarian operations, is from the *American Agriculturist* for September. It is time now to be making calculations on the necessary work before us :

It is of vital importance that every colony of bees should have a thorough inspection at the end of the honey season. It would be very exceptional if some colonies were not found queenless, and robbing is sure to follow. Parent colonies that have cast swarms are generally the ones found wanting in this respect, and if attention is not given at the close of the honey-flow, the bees will get the start.

When the flow ceases, the bees with their powerful force of idlers hunt up and rob such defective colonies. It matters little whether such queenless colonies are weak or strong, they will not defend their stores. The mischief does not stop here; when robbing bees become aroused they will overpower and destroy colonies that may be in proper condition. It is of the utmost importance to see that every colony has a good fertile queen at this season.

The reason why colonies having cast swarms are often found queenless is, that at the time of maturing, they have but the one young queen; they have no brood to fall back upon, if the young queen becomes lost, when she issues alone into the open world to receive fertilization, surrounded by myriads of enemies. In returning she sometimes enters the wrong colony.

September is the proper month to feed all colonies that may lack in food, for winter bees cannot be fed successfully during freezing weather, and if fed early, they seal the honey over. Unsealed honey in the combs near the bees during cold weather becomes diluted with the moisture from them, and is unhealthful.

Caring for, handling and disposing of the honey crop also demand our attention during the latter part of the season. It has been too common to ship honey to distant markets at a low figure. No one can as successfully build up a demand for honey as the apiarist himself, and the business is far safer in his hands than in any other. The place to commence operations is at home, where we have the entire care and control of the matter. Several thousands of pounds of honey may be disposed of in almost any locality with much greater profits than by shipping. Build up a home market, and never drive business away that can be transacted at home.

A Lady, writing about small fruit and flowers in the *Indiana Farmer*, concludes thus :

We are largely creatures of education, and if we were educated to look upon the honey-producing weeds as something useful, would they not cease to be such an eyesore to the farmer as well as the passerby? Suppose the seeds from the fence-corners do get scattered over the field; it will only take more culture to keep out of growing crops, and most people will admit that they can hardly have too much culture. I think the beautiful asters and golden-rods are an ornament to the fence corners. But, advancement in knowledge usually makes us equal to any emergency, and what we have lost in the destruction of weeds and forest-trees, may be regained in the cultivation of plants, etc., which will not only furnish our tables with delicious fruits, but also the where-withal to sweeten them.

The culture of small fruits furnishes an abundant supply of bee-food, and where there are small fruits there ought to be bees to help fertilize the flowers, and so make them more productive.

The Crop and Honey Market.—

In the San Francisco *Chronicle* we find a recent article on the crop of honey, and the market values of the product from which we extract the following :

Reports from all over the State are to the effect that the honey crop is so short that it is no exaggeration to say that it is a total failure. There is hardly an apiary in any of the hitherto most prominent bee-keeping counties of the State which has this year produced surplus honey enough to pay interest on the capital invested therein. The same reports come from the East, and never since the care of bees attained the proportions of a regular industry has the honey yield of the United States been so limited as in the season now closing.

In conjunction with the limited output, however, has come a marked rise in prices, but these comparatively high figures are after all of little value to the bee-keeper, for of what use would it be to him were honey to be quoted at even a dollar a pound if his bees produced no surplus for sale ?

The experience of the present season is, after all, only a repetition, on a more extended scale, of what has been the uniform history of the industry ever since the first colonies of bees were brought around by the isthmus and sold here for \$200 apiece. First there has come a succession of good seasons; the stock of bees has largely increased; the price of honey has gradually lowered, and finally many have gone out of the business in disgust.

Then a bad season has come, or a succession of them; there have been no wild flowers, or the natural bloom has not contained the usual amount of nectar; the honey crop has been short; prices have risen, and a few, who were located in exceptionally favorable regions, have made large profits.

This has stimulated others to go into the business, and the result has been another period of heavy production, low prices and small profit. For those who have been able to secure anything like a fair crop, the present season will be a bonanza. And those who have been sufficiently far-sighted to provide their bees with an abundance of forage, without placing any dependence upon the natural bloom, will this season reap a good reward for their enterprise.

Those who have taken this precaution are few enough by the side of the many who are accustomed to "trust to luck;" but this lends emphasis to the general proposition that the bee-keeper who treats his colonies precisely as he would any other kind of animals upon which he placed dependence for an income, and sees that provision is made for a bad season, will come out ahead in the long run, while the one who trusts to nature will run behind.

The St. Louis Fair opens Monday, Oct. 1, and closes Saturday, Oct. 6. Seventy thousand dollars is offered in premiums. On Tuesday, Oct. 2, the grand annual nocturnal pageant of the Veiled Prophets will be given. The streets of the city will be illuminated by 500,000 gas jets, thus presenting one of the most realistic sights imaginable.

All railroad and steamboat companies have made a rate of one fare for the round trip, during the entire week.

Any of our subscribers desiring a copy of the Premium List will receive one free by addressing Arthur Uhl, Secretary, 718 Chestnut Street, St. Louis, Mo.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

Work in Surplus Stories.—Many letters are received from beginners asking why their bees do not work in the surplus story. A correspondent in the *Prairie Farmer* asked a similar question, and Mrs. L. Harrison answered it in this manner :

Bees would work in your surplus sections if they had anything to work with; they cannot make bricks without straw, or, in other words, cannot secrete wax and store honey when there is none to gather in the fields. The honey-flow has been very little last year and this, with few exceptional days. Let there be a flow of honey, and your surplus sections would soon be full of bees, hanging in webs, secreting wax to build comb, and loaded bees would drop at the entrance. This season they get just honey enough to keep them breeding, and the queen is not crowded for room to deposit her eggs. I looked into a hive to-day where bees had been bived in a hive full of combs. There was brood in all the combs, but not one cell of honey stored above it, as is their usual way of doing. If there should be no honey at all for a few days, these bees must starve, if not fed. All the surplus stored in our apiary this season is where two or three swarms clustered together and were put into a hive full of comb, and surplus boxes put right on to give them room, during the blooming of the linden.

I have heard of but one apiary in Illinois where there has been any surplus stored, up to Aug. 14. This one is located on the Illinois river bottom on the east side, and is surrounded with a great deal of low, swampy ground. The proprietor claims that the east side of the river is better for an apiary than the west side, as many bees are lost in the river while crossing it, on the approach of storms from the south and west; and the bee-pasture is better on the east side, as there is more low land. An apiary located opposite to him on the west side has no surplus, while he has secured 1,500 pounds from 50 colonies, spring count.

Well Expressed.—The *Rural Home*, an influential farm paper, thus notices the National Bee-Keepers' Union, and the work being done by it, through the pen of a valued correspondent :

Again the Manager of the Bee-Keepers' Union is out with his yearly report. This report shows that the Union has been successful in every case that it has undertaken to defend, and it is hoped that the ignorance and petty jealousy which prompts certain individuals to make war on the little busy bee, which is of much benefit to the farmer and fruit-grower, by way of the fertilizing of nearly all fruits and seeds, will cease.

Ignorance, only can accuse the bees of eating *peaches* and *young ducks*, as in the case of the Arkadelphia, Ark., suit, which has been in court for the past six months, and has caused one of our best bee-keepers much trouble, besides fines and imprisonment. The whole thing seems to have come out of the jealousy of a few individuals, and the Mayor of that city.

The Manager of the Union deserves great credit, in that he does not undertake to defend any bee-keeper who has not done all in his power to keep peace between his bees and their neighbors.

The *Rural Home* and its correspondent have the thanks of the Manager for these kind words. Peace is his ardent desire, even if he is compelled to *fight* for it!

Scatter the Leaflets.—Look at the list (with prices) on the second page.

Pure Bees are the Best.—On this subject a correspondent of the *Bee-Keepers' Magazine* says :

The honey-bee has been known—if history is correct—for many centuries; the traditions of the Bible show its great antiquity more strongly than does any other historical work, so we can safely assume that the apis is as old as man himself. When, however, we come to the question of which of the present known races was the original, or whether either of them was, for that matter, we are wholly in the dark. As well might we assume that the one or the other was the original race, and we may do so with impunity, as no one can bring forward any proofs to the contrary.

I do not propose now to attempt to prove an impossibility, or to assert anything as to priority, the question with me being simply, "Shall we receive greater benefits from keeping our Italians pure than by crossing them?" I claim, in answer, that we shall, and do, and offer the records of the past in proof of the correctness of that answer, while at the same time I will give my own experience during over twenty years past as a bee-keeper, in comparing the Italian and black and their crosses; as evidence to the same point.

Conventions.—The time for holding Bee-Keepers' Conventions has now arrived, and we cannot give any better advice than this: Let each one attend who can do so, and take part in making these meetings interesting and instructive. If you have not already obtained the "Bee-Keepers' Convention Haud-Book," do so at once to post yourself up on how to conduct such meetings correctly. It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for Discussion—List of Premiums for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents. We will club this book and the AMERICAN BEE JOURNAL for one year for \$1.25. It also contains a lot of blank leaves on which you can note important matters as they come up. Do not fail to send for a copy of it.

We Want 20,000 subscribers. Out of the 300,000 bee-keepers in America, certainly this is not an extravagant desire! It is only one out of every fifteen! We confidently ask those who appreciate the AMERICAN BEE JOURNAL, to show it by sending us one or more new subscribers. We will give them full value for their money.

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1, postpaid.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

QUERIES AND REPLIES.

Amount of Honey for Surplus and Brood-Rearing.

Written for the American Bee Journal

Query 572.—What proportion of the honey gathered from a "field" goes to rearing brood, and what part for surplus, on an average?—Michigan.

I do not know.—P. L. VIALLO.

I do not know.—H. D. CUTTING.

I do not know.—MRS. L. HARRISON.

All answers are guess-work, and much depends, at that.—J. P. H. BROWN.

I doubt whether any one knows. I am sure I do not.—M. MAHIN.

I do not know how to get at it.—J. M. HAMBAUGH.

That is hard to tell. I have not a well-defined idea on the subject.—EUGENE SECOR.

I can only guess. In an average season at least one-half is consumed in brood-rearing, and perhaps more.—C. H. DIBBERN.

In an average season, taking the year through, I "guess" the bees require two-thirds of the amount gathered.—R. L. TAYLOR.

I put it at about 9 to 10, this season; and about 2 to 1 in a good season.—J. O. SHEARMAN.

At a very rough guess, one-third for brood, one-third for support of old bees, and one-third for surplus.—C. C. MILLER.

From the way I have seen brood-rearing use up honey, I should say that more honey was consumed, one year with another, by the bees and their young, than by the owner and his customers.—JAMES HEDDON.

That is too hard a nut to crack. We should judge, however, than on an average three-fourths of the honey harvested is used up by the bees.—DADANT & SON.

This is a theoretical question that I am not only unable to answer, but give a guess even. I doubt if any one can give an answer that will be of value, owing to difficulty of obtaining data on which to base it.—J. E. POND.

I should say that in a good season about one-half of the honey goes to feed the brood. Such a season as this, 100 per cent. is thus used.—A. J. COOK.

It takes at least 60 pounds of good, thick honey to carry a colony one year. If more is obtained, we get a surplus; if less, we must feed. All depends upon the season, etc.—G. M. DOOLITTLE.

I do not know. Last year my bees gathered enough to last until they gathered last spring; but this year they lived from "hand to mouth" till sweet clover yielded honey.—A. B. MASON.

It depends entirely upon the management. A well-managed colony puts about 50 per cent. of the gather in the supers; about 30 per cent. for brood-rearing, and about 20 per cent. for winter stores.—J. M. SHUCK.

This is a hard question to answer, as there is really no uniformity as a basis on which to form an opinion. Bees will consume more or less honey, as they can or cannot get it. Some observations have led me to believe that a good, strong colony will consume at least 100 pounds of honey in a year, if they can get it; and they will get along with much less if they are compelled to do so. On an average of years, I have calculated that a colony of bees can furnish one pound of surplus against every pound they consume; but there is no certainty about it. This season only the very best colonies can gather enough honey to live on.—G. W. DEMAREE.

The answer can only be guess-work, and hence very indefinite. It is impossible to give an answer "on an average." It does not average. If there is only enough honey gathered for brood-rearing and food for the old bees, they take it all. If there is not enough for these, then the one or the other goes short. In any case, the apiarist gets no surplus until these necessities are provided for. In such a season as the present one, the amount used by the bees being barely provided for by Nature, the season and the honey-gatherers, the apiarist gets no surplus, or only what small amount may become a "surplus." In an ordinary season of plenty, perhaps it may be a tolerably good guess to say that the old bees consume one-third, and brood-rearing another third—leaving the remaining one-third for surplus, provided that more than 60 or 80 pounds of honey is gathered during the season, as it would certainly take that amount for the necessities of the bees, including the supply needed for the coming winter.—THE EDITOR.

Plan for a Bee-Cellar.

Written for the American Bee Journal

Query 573.—I am contemplating building a cellar for wintering bees in, and have settled on this one: I have a dry and somewhat steep bank, into which I propose to dig 20 feet in length, and 12 feet in width, and then dig a ditch 2 feet deep all around the outside, filling it with small stones, and then build a close wall 8 feet high. On the inside of the wall I will board it up, leaving a space of 4 inches or more all around to be filled with sawdust, and bank up the whole thing, all but the door, making it perfectly dark. On top of this, I propose to build a shop for the purpose of making hives and storing honey, etc. 1. Will such a bee-cellar do? 2. How many colonies will it winter? 3. What about the shop overhead?—New York.

1. It will. 2. About 100 colonies. 3. The shop would be objectionable if there is much machinery run by power.—J. P. H. BROWN.

Having never wintered bees except on the summer stands, I am unable to answer from experience.—J. E. POND.

1, Yes. 2. It depends upon the size of the hives, but it ought to contain 150. 3. It is O K.—DADANT & SON.

Yes, if it preserves the proper temperature from 38° to 45°, Fahr., as I think it would. 2. As many as desired—200 or 300 colonies. 3. The shop is all right.—A. J. COOK.

1. I should think so. 2. That will depend upon the size of the hive and the ventilation given. 3. It will do no harm.—MRS. L. HARRISON.

1. I should hesitate about putting in the sawdust. It will soon be rotten, will it not? Why is it not all right without it? 2. Probably 100. 3. It is no objection.—EUGENE SECOR.

1. Yes, if the banking up is sufficient in amount to exclude frost. 2. From 200 to 300. 3. It is all right, but pack the floor between it and the cellar with 5 or 6 inches of sawdust, to keep the frost out of the cellar.—R. L. TAYLOR.

Such a bee-cellar is all right, but if much pounding is to be done in the shop overhead, I should prefer it elsewhere in winter.—C. H. DIBBERN.

1. Yes. 2. As many as you can put into it. 3. If the hives do not touch the floor, all the noise you can make overhead will do no harm.—J. M. HAMBAUGH.

1. I think so; but you will be safe to go by Doolittle's answer. 2. Perhaps 150 to 200. 3. Lath and plaster the cellar overhead, and I think the shop will not trouble.—C. C. MILLER.

1. Yes. 2. No one can tell you how many colonies it will winter, but it will hold 150 colonies if you build it deep enough. 3. I do not like the shop overhead. I should prefer a separate building. Your cellar will make a good place to do all of your summer work in.—H. D. CUTTING.

1. It will work well. 2. All you can get in. 3. The shop will do no harm if the hives rest on the cellar-bottom, and the protection is thick enough between the two floors so that no frost gets through to the cellar.—G. M. DOOLITTLE.

1. There is nothing to hinder it from answering every purpose. 2. It would depend upon how the hives were placed in the cellar. 3. If the joist are well "bridged," I do not believe that the shop will interfere with the bees.—G. W. DEMAREE.

1. I think you will have a good cellar. 2. The number of hives the cellar will hold depends upon their size, and the closeness with which they are packed. 3. The shop overhead will do no harm if no machinery is used, provided the hives in the cellar do not touch any part of the building.—J. M. SHUCK.

1. I see no objection to it, except that the sawdust may gather too much dampness. I would prefer a 4-inch dead-air space. 2. I can make no estimate of the number of colonies that may be wintered without knowing the size and form of the hives. 3. The shop will do no harm.—M. MAHIN.

1. Such a cellar might do, but the sawdust will become damp and rot, and unless the shop is kept warm, the cellar will get pretty cold sometimes, unless there is a double floor, and filled between. 2. That will depend upon the size of the hives, and how they are put in. Do a little figuring and you will know. 3. Some say that disturbing the bees in winter does no harm; but I know that it harms mine.—A. B. MASON.

1. Yes, it will do about as well as any repository does. 2. I would say anywhere from 100 to 200, ventilating accordingly. 3. I should rather not pound or make any big noise or jars over the repository. Of course you want the floor filled with sawdust unless you keep a fire in it nearly all the time. You do anyway.—JAMES HEDDON.

1. Yes. 2. All that you can comfortably get into it, providing the ventilation is sufficient. 3. As the hives will rest on the bottom of the cellar, "the shop overhead" cannot disturb the bees. If they do not touch the sides of the building, they could not feel any vibration, even if "power" is used.—THE EDITOR.

CORRESPONDENCE.

LEGISLATION.

Which Shall it be Hereafter, Legislation or Litigation?

Written for the American Bee Journal
BY DR. C. C. MILLER.

In a recent number of the AMERICAN BEE JOURNAL, the editor refers to me a question which lack of time has prevented me from noticing earlier. It is a question as to what is to be done by one who is likely to be hindered in the prosecution of bee-keeping for lack of the full and free swing that most of us enjoy. This opens up a subject which I had considered laid on the shelf, and which I should not again open but for the implied wish of the editor, and the—as it seems to me—very great importance of the subject. Without considering the particular circumstances attaching to any one case, it will be sufficient to consider the ground in general.

I hardly know the best approach to make. True, I might present only such phases of the matter as are entirely new, and thus avoid awakening prejudice; but I am not sure that such a course would be entirely frank and open. Besides, I think the sober second thought of many, makes them coincide with my own views.

I may say, then, that the remedy lies in awakening in the minds of bee-keepers, a sense of the real need of taking such steps as shall result in putting their business on a footing as secure as that of others. At least some are awake to the necessity for some action, as evidenced by their becoming members of the "Bee-Keepers' Union." That this Union has accomplished good, perhaps no one will deny. Wisely conducted in the future as it has been in the past, the necessity for its existence may not cease for a long time to come, for all that the old rule holds good, that "An ounce of prevention is worth a pound of cure."

Take the case of Mr. Z. A. Clark, that has justly excited so much interest. Is it not possible that the same amount of effort, with possibly a less

expenditure of money, would have secured such statutes as to have made bee-keepers safe from annoyance, not only in Arkadelphia, but throughout the entire State? When the matter is fairly understood, litigation will certainly not be preferred to legislation.

So far, the only legislation attempted, relating at all to bee-keepers, if I am not mistaken, has been, not that instigated by themselves, but, like that in Michigan, such as went directly contrary to their interests. In the uncertainty which attends such things, have we any security that when next attempted, as it may be, in some other State, it may not succeed? Although it failed in Michigan, the leading bee-keepers in that State considered the danger so great as to need their most active opposition. Please look at the matter clearly.

As it now stands, any wily schemer, for the sake of gratifying some petty spite, may secure the passage of a law injurious to bee-keeping interests. We are likely to have legislation, for that which has been attempted is likely, under the same circumstances, to be attempted again. Is it not better for us to take the initiative, and secure such legislation in advance as shall best subserve the interests, not only of bee-keepers, but of the public at large? In other words, will it not be better and easier to labor for good legislation than to labor against bad legislation after it is effected? In the one case, we have a fair field, for in most cases, at least prejudice is not aroused, as it is when some case of strife occurs.

It is a hopeful sign that some are beginning to consider what is the best legislation needed, and devising plans for the same. To that part of the subject I have given very little attention. I am hardly competent to decide what laws are needed, and it is hardly worth while to give very much attention to it, so long as the mass of bee-keepers are not awake to the importance of doing anything. The number of members in the "Bee-Keepers' Union" shows that. However liberal they may be in their desire to have every one a bee-keeper, and in wanting nothing done that may in any way prevent it at any time and in any place, they are nevertheless by no means liberal in helping to sustain them in the ranks after they get them there. To those, however, who are interested enough to join the Union, I respectfully submit whether it is not cheaper and better to have legislation than litigation.

Worker-Brood in Drone-Cells.

In reply to a query in a recent number of the AMERICAN BEE JOURNAL, one of the correspondents seems somewhat to call in question the possibility of workers being reared in drone cells. Although I may have seen more than one case, there is one case which I distinctly recall. In 1876, Mr. R. R. Murphy sent to the AMERICAN BEE JOURNAL "a piece of drone-comb with worker-brood in." It was reported on page 250 of Vol. XI. This remark was made by the editor: "This was a very clear case. Cells four to the inch, flat caps, out of which hatched nice young

workers." There was no mistake in the case. Mr. Murphy was too experienced to be deceived, and besides, as I was living in Chicago at the time, friend Newman handed the comb to me, and I saw the workers hatch out of it, with my own eyes.

It is not a very uncommon thing to see drone-cells where drone-comb abounds, having the mouths of the cells contracted by a heavy rim of wax. Is it not likely that in such cases the bees conclude there is an unnecessary amount of drone-comb, and that after being thus contracted these cells are to all intents and purposes worker-cells? Marengo, Ills.

APIARY WORK.

Honey Shower, Balled Queen, Giving Frames of Brood, etc.

Written for the Prairie Farmer
BY MRS. L. HARRISON.

There was a shower of honey in this locality from the basswood; something unusual, but like a thunder-shower, heavy and soon over. Those colonies that were in good condition—had their dishes right side up to catch it—are no longer poor, but rich in choice stores.

The change from poverty to riches was so sudden, that the bees had not wax scales secreted with which to build comb, but filled every empty cell. In order to have a share of this sweetness, as it were to take toll, I extracted combs where there were no brood before it was sealed. It was of course unripe, but sufficiently evaporated, and I put it out in the sun to boil, with the thermometer playing around the hundred. What I have is in vessels of tin or glass, with cheese-cloth tied over the top to keep out insects, and allow the moisture to pass off. When it is sufficiently ripened, it can be stored away, and will keep for all time free from souring.

Balling the Queen.

In looking after a swarm that had just issued, I found the queen balled in front of a hive near by. Now in releasing a queen thus balled, if the bees are picked off she is apt to be stung to death in the operation, but when the ball is thrown into water, then every fellow is for himself. Life-preservation is the first law of nature, and the queen is no longer thought of, and when the queen is released she can be taken from the water and secured. When I threw this ball into the water the bees swam away from her, but the poor thing was already dead.

I see it stated by a late writer, that when a queen gets separated from her colony, she returns to the place from where she went forth on her bridal tour. If this is so, it accounts for the reason why queens are so often found at the entrance of other colonies. When this swarm missed its queen its returned sad and disconsolate to its former home; no more swarming now until another queen can be reared. I shall watch this colony with interest.

In nine days all queen-cells are removed but one, so there will be no further swarming. Managing in this way, the colony is kept very strong during the honey flow, to gather surplus honey, and will go into winter quarters with a young, vigorous queen. Where no increase is desired, this is certainly a good way to do.

Giving Frames of Brood.

There has been much rain of late, and it is reasonable to expect a fair flow of honey. In order to profit by it, bees must be in good condition to gather it. After the hurry of swarming is over, it is well to look after the colonies that have cast swarms. I have sometimes found such hives to be almost entirely filled with honey, and a handful of bees with a laying queen, and a small patch of brood. I would take all the combs free from brood, and extract them, confining the bees with their brood to one side of their hive by a division-board. Then I would open a large colony, and take out a frame of sealed brood, brush off the bees, and give it to the little colony, placing one of the empty combs in its place. When enough of the young bees had emerged to cover the comb given to the small colony, I would give it another in the same way, and in about ten days it would be a strong colony, fully equipped for business. If it had been left alone, it would have perished the following winter, although surrounded with honey, having too few bees to keep up the necessary warmth. It is sometimes also a benefit to large colonies to have a frame which is partially filled with brood removed, and an empty comb put in its place, for I have seen every cell in such filled with brood. But if a frame filled with brood and honey is removed from a strong colony, and an empty frame put in its place, it will almost surely be filled with drone-brood.

Bees Clustering Outside of the Hive.

I do not desire more than one swarm from a colony, but if I am very busy, they get beyond my control. If I see a "cast," I cut out the queen-cells and return it, or a "maiden," which, by the way, is a swarm that casts one.

No bee-master allows his bees to cluster on the outside of a hive for want of storage room. And the farmer who waits until after harvest before he gets time to put on surplus boxes, may go without honey on his cakes another winter. When the combs are built out white, is a good time to put on receptacles for honey. What kind these should be, depends largely upon the way it is to be disposed of. Bees will, no doubt, build as much in starch boxes as in the whitest sections, but there will be a great difference in the returns, if it is to be marketed. City trade demands one and two pound sections. These can be bought by the thousand cheaply, and any child can put them together, and the cases to hold them. York State bee-keepers put one-pound sections for market into paper boxes, with highly colored lithographs on them, but our Western consumers do not demand all this "fuss and feathers."

Peoria, Ills.

The Prodigal—that Didn't Return.

Written for the American Bee Journal

BY EUGENE SECOR.

A silly bee got on a spree,
Out in a field of clover,
"I'll drink," said she, "my fill, te-he,
And play the merry rover."

"Now what's the use to be a goose,
And all the time be giving,
When life is short and made for sport,
And all we get's a living?"

"So I for one will have some fun,
And live a life of pleasure.
Who said I ought to work for naught,
And carry home the treasure?"

The day was fair. The balmy air
Played gently with the flowers.
By some strange spell, sweet hydromel
Distilled in nect'rous showers.

She frisked about, now in, now out,
From every flow'ret drinking;
Played in the sun till day was done.
With no thought worth the thinking.

When night drew nigh she heaved a sigh,
Half sorry for her folly;
But stubborn Pride, that prublid guide,
Soon banished melancholy.

Just underneath a plantain leaf
Retired she in the gloaming.
A nimble toad spied her abode;
A wink—she ceased her roaming.
Forest City, Iowa.

GOOD REPORT.

Steady Honey-Flow—Queen-Excluding Honey-Boards.

Written for the American Bee Journal

BY H. O. KRUSCHKE.

I thought that I would throw a little bright sunshine in among so many dark reports. I am having a great honey season; not as much per colony as is often reported, for I never look for more than one-half as much—when I get that I rejoice. We never look for surplus till after July 1, or basswood bloom, and this was after July 10 this year. From then on it has been a continuous flow, not in torrents, but a steady gain.

My best colony has 140 one-pound sections full; and some are sealing 40, 50, and 70 pounds each. I tired-up some for extracting three full stories high. They had brood in all the stories, and some of them have a bushel basket full of bees. I took off the boxes yesterday, and left them on the hives till I went through the apiary, but no robber bees appeared. I could not coax them to lick out the comb-carriers. This will continue for ten days or two weeks, if no frost appears. If I had white clover I would be in a regular "Eden."

I have never used queen-excluding honey-boards, but I have yet to find the first bit of pollen or brood in the sections. Large hives is the remedy. I had 38 colonies in good condition in the middle of May, and I have increased them to 58, and stocked the woods for miles around with runaway swarms; but they will soon wish they had stayed

at home, when Jack Frost lets the mercury down out of sight. It looks now as if I would have 3,000 pounds of surplus, one-half of it comb honey in sections, and the rest extracted.

My apiary is 18 miles away, and my cranberries require a great deal of attention, so that I cannot plan very scientific management for the bees, but I do the best I can for them. The result is perfectly satisfactory.

Duester, Wis., Aug. 28, 1888.

ON THE SCALES.

Testing the Storing Qualities of the Bees for Years.

Written for the Farmer and Dairyman

BY D. KAUFFMAN.

I have had one of the best colonies in my apiary on a scale during the last six years, and in 1886 I marked down the amount gained for the day every night, and also kept a close watch on the amount of surplus honey stored, and from this I found that when bees gain from one to three pounds, about one-quarter of the gain is stored as surplus honey, and when the gain is from 3 to 8 pounds, about one-half is stored as surplus honey, and from the record kept for this season, about two-thirds was stored as surplus honey. These experiments were all made for extracted honey.

But it seems to me that the rearing of brood would not have anything to do with the gain of a colony of bees, for if the bees did not feed the brood it would not gain in weight, and if they take the feed from within the hive, it would not get any heavier on account of the brood; but it would make a difference in the amount of surplus honey stored, and when bees gain from 10 to 16 pounds per day they will lose from 3 to 5 pounds during the night; and should the next two or three days be cool or rainy, so that the bees could not fly, the bees would lose about 3 pounds in the first 24 hours, 2 pounds in the second, 1 pound in the third, and ½ pound in the fourth day.

This loss is caused by the evaporation of the honey, and I think it is nearly as great when bees gather honey as it is when they do not, so that this would make the actual weight carried in by the bees during one day from 3 to 5 pounds more than the scales would show by weighing the hive in the morning and again in the evening; and I believe that when bees gain at such rates the old ones wear out as fast as the young ones come on, for they fill up the brood-combs with honey as fast as the young bees hatch, so that the queen will not be able to find any empty cells to put any eggs in, especially when running for comb honey.

I believe there were one-fourth less flying, or working bees in my apiary, at the close of the honey season than there were when I first put the scales under the hive on July 28, and three-fourths less brood.

I think that it is a great help to have a hive placed on a scale during the

honey season, for you can tell just what your bees are doing, and how fast you will have to get your sections ready to put on, how much more room they need, etc., from two to five days sooner than you would if you had no scales, and these few days would amount to several hundred pounds of honey for each day in an apiary of from 50 to 100 hives.

GEORGIA HONEY.

"Pleasantries" About the Production of Honey.

Written for the American Bee Journal
BY W. H. PRIOR.

An item on "Honey in Georgia," has been going the rounds of late through the secular press, and has been copied by some bee-papers. I also notice on page 460 of the AMERICAN BEE JOURNAL, the management of an apiary by Ben Foggy, of Iowa, who makes honey, according to his fancy, by "moon-shine."

Now I cannot produce honey like Ben Foggy, or my Georgia neighbor who has a grove of trees which he taps and gets the honey by the barrel. Certainly the Iowa man, as well as my Georgia friend, were out of employment, and acting up the old adage, that when you tell one, tell a big one, they indulged their imaginary genius in fabricating these sweet pleasantries—like the "Wily scientific pleasantry" in fabrication, but unlike that pleasantry in that they were not intended for the purpose of, nor could in any way injure apiculture in the least.

But laying all jest and pleasantry aside, Georgia (especially middle Georgia) is as well adapted to apiculture and the production of honey, as any country in the world, Italy not excepted. Our climate is almost the counterpart of that salubrious climate so much admired by travelers, and so beautifully described by writers of both prose and poetry.

The cultivation of "king cotton" has so absorbed the minds and energies of the yeomanry of the Sunny South for several generations past, that they have neglected and almost ignored every other rural industry; and this has been to the detriment of themselves and families, and almost to the irreparable ruin of this Heavenly favored Sunny South land of ours, by making barren wastes and gapping gullies on almost every hillside.

Once these fields were as fertile (and the most of them are still capable of as high a state of cultivation) as any land North, East or West. This has been demonstrated and proved beyond a doubt, not only by special tests, but by numerous and extensive experiments. The people are awaking to their best interests, and diversified farming—the dairy and other industries—are springing up on every hand. Northern capital is fast seeking investment with us, opening up industries which of course will give us a better home market for our honey, butter, fruits, vegetables

and the like. The want of a home market, and the lack of railroad facilities has been a great drawback in the production of these things. The opening of new lines of railway, a great deal of which has been done within the past few years, the reduction of freight, the preparation of refrigerator cars, etc., is working a revolution in this respect.

Middle Georgia as a Honey Country.

Middle Georgia is specially adapted to apiculture. Our winters are comparatively short and mild. The mercury rarely ever reaching zero. We hardly know what it is for it to go below zero, and the cold spells are generally of but short duration, there being scarcely a week during winter but that the bees can have a cleansing, sunny flight if they so desire.

We have no need of a cellar, house or even chaff hives; all that is needed for safe wintering is a good colony with enough honey to last them from November to March 1. By feeding the last of February and the first of March, for stimulating brood-rearing, one can have full colonies ready for work as early as from the first to the middle of April. My first swarm came out and was hived on Saturday, April 7. With empty frames to start with, in ten days they had the frames below filled with brood and honey, and were working in the upper sections.

Our honey harvest is during the months of April, May and June, although the bees can live by foraging from March to November. Thus it will be seen that we could save the cream of our honey harvest, and then sell and ship some colonies to the North in time for the beginning of the honey harvest there.

Honey-Yielding Plants of Georgia.

While I suppose we have nothing equal to the basswood of the North and Northwest, yet we have the great advantage of a greater length of time for the honey-flow, and a greater variety of honey-producing plants. Our poplar is almost as good as basswood. We have willow, besides other swamp growth and wild flowers that furnish the precious nectar. These come along in April and May. Apples, pears, plums and the like bloom in March. Later on we have the field pea—almost as good as red clover—being of the clover family a leguminous plant, which grows to perfection with but little labor, and is a fine stock feed, both pea and vine, besides the best renovator of worn soil, red clover not excepted.

Then red clover will also grow well here, if properly managed and fertilized. I have had it to grow from 2 to 3 feet high, and yield from 3 to 5 tons of good hay per acre. I shall sow more this fall than ever, and mix Alsike clover with it. Alsike is said to be better for bees than the red, and that Alsike will grow anywhere that the red will. I shall give it a trial anyway.

We have a little white clover that grows wild, to be found almost anywhere, that furnishes considerable honey during the month of June. Our cotton—and we have thousands of acres

in full bloom from the middle of July to the middle of October—furnishes enough for the bees to live on during this time. It is very light in color, and finely flavored. The meagre supply scattered over so large a territory gives but little surplus, but enough to keep the bees from consuming their already garnered winter supply. If the second crop of Alsike and red clover blossoms should prove with us what is claimed for it in the North and Northwest, we can have a July crop of honey that would make our honey harvest last from April 1 to Aug. 1. I shall sow at least ten acres of the two mixed this fall, and give it a fair test.

There are but few apiarists in this country, but quite a number of bee-keepers using the old-fashioned box-gum, not knowing a queen from a king bee. Dr. J. P. H. Brown, of Augusta, Ga., one of the most noted apiarists of the South, has already taken, this season, 125 pounds of surplus honey from one Italian colony. Of course this is a phenomenal yield for one colony, but from 75 to 100 pounds have been frequently obtained in Georgia. Of course, with us as at the North, every year is not a honey year, but we never have an entire failure, always having some surplus.

With our natural advantages of climate, and many honey-producing plants, with practical and scientific knowledge of apiculture, producing artificial pasturage for bees, combining the business with stock husbandry—certainly Georgia could be made a land that would with "milk and honey flow."

Madison, Ga., Aug. 1, 1888.

IN COUNCIL.

The N. W. Illinois and S. W. Wisconsin Convention.

Written for the Forrester, Ills., Herald
BY THE SECRETARY.

The bee-keepers of Northwestern Illinois and Southwestern Wisconsin met by appointment at Leaf River, Ills., on Tuesday, Aug. 21, 1888, the President, L. Highbarger, in the chair.

It being a very busy season among the farmers, there was not a very large attendance. A few of the most prominent men of the association were present, and their able discussions made it a very pleasant meeting.

Some time was spent by the visitors in examining the methods and looking over the well-kept apiary of the President of the association, Mr. Highbarger. His colony of newly-imported bees elicited the admiration of all present, and the queens of this species will be at a premium among the members in the future.

Bee conventions are modern societies, and bee-culture is a modern science. Thirty years ago a bee keepers' association was never thought of; to-day they are found in every progressive country of the globe. The person who will take the time to look over the records of the past thirty years, will

discover some of the benefits derived from these associations. No single individual has been able to discover all the intricacies concerning any one thing of the method of the bee. So the benefits of sociability and meeting with friends and neighbors, and the exchange of discoveries that have been made by the members are appreciated in this organization as well as in any other.

The questions for discussion before the society were:

1. "Which is more preferable for the bee-master, to supersede the old queen, or let the bees do it?" It was decided in favor of the master doing it.

2. "Can a queen that produces all three-handed bees be a hybrid?" Answer: No; by a letter read from the *Bee Journal*, by Frank Benton.

3. "Will mixed bees work better than bees all from one colony?"

4. "Do bees do better in hives faced in one direction than another?"

These questions were ably discussed by the members, after which the meeting adjourned, to be called in May, 1889.

SWARMING.

Do Bees Select a Habitation Before Swarming?

Written for the *American Bee Journal*
BY JAMES F. WOOD.

I have read the articles on the above subject with much interest, and as far as my observation has gone, I think that each writer has been partially right. I will give my experience with a few of the most striking cases that I have personally witnessed.

When a boy of about 16 years of age, I had a great desire to learn all I could concerning bees and their habits, and after reading and re-reading all the books until I knew them nearly by heart, I concluded to stock an apiary with Italian bees. Not having the funds to purchase bees, I set out to get my bees from the woods, and at that time there were many of my neighbors who kept bees, and many swarms escaped to the woods. Now for the facts:

A neighbor had a swarm that clustered where they could not be reached, and I was informed of this fact, and directly went to the place to watch the swarm and chase them to the tree when they left. I did not have to wait long before they started, and with some difficulty I managed to keep in sight of the bees until I saw them enter the tree about a mile distant. This was in 1875. The same year I followed the lines that several swarms had been known to have gone, but I never found but one more by following the direction they started from the hive.

But on this side of the question I have still the best evidence that I have yet seen printed. It occurred this season in a neighboring town. I went to purchase some bees of a friend, and while looking at the bees, a large swarm issued, and without alighting it went about 15 rods *directly* to an old hive, where a colony had died the win-

ter before. This swarm did not fly around after it issued, but as soon as it got out, it went direct to this hive, and nearly half of them were in the hive when we went to it. But this by no means proves that bees "pick out" a home before leaving the parent hive. But it looks pretty clear that the last-mentioned swarm knew where they were going before leaving the hive; and that the first-mentioned swarm knew where they were going before leaving the limb where they had clustered.

I might add that the scouts sent out, and those that returned, seemed to nearly all go and come from the direction of this tree that the bees selected for their home. I noticed this to such an extent that I remarked to several that I was pretty sure the bees would go in that direction, as they afterward did.

One writer has said that bees sometimes will fly for days and keep alighting and searching for a home. This is true also, as I can testify. I knew a small swarm to issue and fly off about two miles before alighting. Here they hung for two days on a limb, and flew about a mile and alighted again. They kept flying around for a week in the neighborhood, and finally settled in a tree not 20 rods from where they started. This was late in the season (the latter part of August). This swarm was not kept in sight all the time, but owing to the fact that it is rare that swarms issue so late in this locality, the size of the swarm, and that it was seen by many people flying back and forth, I think there is little doubt that it was all one and the same swarm.

I have several times found swarms clustered miles away from where any bees were kept, and have several times chased swarms until they finally lighted on some tree or bush instead of going to a tree. My conclusion of the whole is this: Bees sometimes go direct to the new home without alighting, but not often; and that others will alight and then send out scouts; then, if successful, they will go direct to the new home. But the majority of swarms that escape, fly and alight several times before they find a home; and I have the best of reasons to believe that they often get ten, and even twenty, miles from the parent hive before they settle in their new home.

North Prescott, Mass.

RIGHTS OF BEES.

Have the Bees a Right to the Nectar of the Raspberries?

Written for the *American Bee Journal*
BY JAMES M'NEILL.

I have been a member of the Bee-Keepers' Union since its inception, and have paid my dues each year without any thought that I should be obliged to invoke the aid of the Union in the defense of my rights, as I had kept bees for a number of years without any serious complaint from my neighbors. But the situation is changed now at my

out apiary, and one of my neighbors declares that it is his purpose to collect damage for the injury which our bees have done his raspberries.

Three years ago he set out about half an acre of raspberries of the red Antwerp variety. He made no serious complaint about the bees during the first two years; but the present season, toward the close of the raspberry harvest, a severe dry spell left the bees without any forage, and the same cause, I suppose, tended to ripen the berries faster than the owner could take care of them. The result was that the bees worked upon his raspberry patch, as he says; not only destroying his fruit, but stinging the pickers, so that many of them refused to pick, and he could not get pickers to take care of the fruit.

He claims that our bees have done him \$150 worth of damage during the past three seasons. He made no serious complaint to me during the first two years, simply asking once in awhile, as I supposed in a half joking way, what we were going to pay him for bee-pasturage. Nor during the greater portion of his berry harvest this year did he make any complaint about the bees, though we passed by when he was picking every day. But meeting him on July 31, he declared that the bees had become an intolerable nuisance—that they were eating his berries up and driving his pickers away, and that even after the berries were in the baskets, they stuck at them and destroyed many.

We drove down the same day to look over the berry patch, and we found, as we supposed we should, that the berry season was about over, and great quantities of over-ripe and dried-up berries hanging on the bushes. Of course the bees were on them, but wasps and hornets were there as well. Certainly no one but those who had a senseless fear of bees, need have been afraid to go among the bushes, as a slight jar would cause the bees to fly away.

There were a couple of crates of berries standing at the ends of the rows, and the women of the household were crying out that the bees would eat them up if they were not taken away. We opened the crates, and found perhaps 6 to 10 bees in each basket; but a slight jar would cause them to fly harmlessly away.

We called upon a neighbor of this man who has berries of the same variety, to find out if the bees troubled his patch, and he made no complaint. He said if the berries were not allowed to get over-ripe, the bees were not troublesome, and if they were upon a bush, a slight jar would cause them to fly harmlessly away. On the other hand, the man who works the farm where our bees are, and who has a patch of the same kind of berries, said that while he had no cause for complaint last year, this year he found the bees very troublesome.

The fact in this man's case we knew was, that he had so much to do that he neglected his berries until they were over-ripe. When we told these men that if they picked their berries when they should be picked, they would have

no trouble with the bees, they replied that they had the right to pick their berries when they saw fit to do so. But it seems to me that they have not ethically such a complete control of their possessions against bees as they have against domestic stock.

If my cattle break down my fence and get into my neighbor's fields, I am justly liable for any damage that they may do, for it is my business to keep my fence in good repair. But bees cannot be thus restrained. They roam at will, and however much we would like to prevent them from visiting our neighbors' berries and fruit, we are powerless in the matter.

Now bee-keeping being a highly useful industry, its peculiarities should be recognized in the laws of the land. The greatest good to the greatest number should control here as elsewhere in society; and if the fruit-grower can be as exacting in his rights and privileges against bees as against other forms of trespass, the effect would be to drive bee-keepers out of the business.

The "greatest good to the greatest number" would not be conserved by such a policy, for it is even better for the community that the fruit-grower should suffer than that the industry of bee-keeping should be proscribed.

When the fruit-grower claims the right of planting anything that he likes, and gathering his crop whenever it suits his convenience, law should step in and say: that is your undoubted right to the extent that it does not conflict with the higher law of "the greatest good to the greatest number," but when it does so conflict, individual rights must give way to the best interest of the community. I am not posted in the law as regards this matter, but it seems to me that this is a common-sense view of it.

It is decidedly disagreeable to me to have any difficulty with my neighbor. I would much prefer to pay a reasonable claim for damages than to sustain a suit at law, but I foresee that if I recognize this man's claim for damages, I will have to recognize his neighbor's claims also, and if I pay damages this year, I may have to do the same for years to come, and with such a prospect before me, I should certainly be compelled to give up the business, for in its present status, it would not stand such a tax.

Hudson, N. Y.

[It is true that the bees and their keepers have rights, and it is equally true that the owners of surrounding lands have rights. To get at, and carry out to their legitimate result these rights all around, is the difficulty. As General Manager of the National Bee-Keepers' Union, we have advised Mr. McNeill as to what course to pursue, and we have no doubt that the whole affair will be amicably settled—at least we hope so.

The thoughtful reader will find much to interest him in the article from Dr. Miller, on page 583 of this issue, on this important subject.—Ed.

EXTRACTED HONEY.

Its Purity, Granulation, Uses, and Production.

Written for the American Agriculturist
BY A. H. DUFF.

Extracted honey is coming into general favor. The fear of adulteration has been the great obstacle to its sale, but this is now largely dispelled, and people are taking hold of the article with more confidence. It is only necessary for consumers to consider a moment to convince themselves that at the present prices for which extracted honey is sold, it would be impossible to produce any substitute that would cost less. In earlier times, when honey would bring from 25 to 35 cents per pound, there was an inducement to adulterate; but when honey brings only 10 or 12 cents it is impossible to substitute any article with a salable appearance except at a cost that would not exceed the price. Every bee-keeper well knows that adulteration is a death blow to his own industry, and when adulteration was common, it was doubtless safe to lay the blame upon the middleman and not on the producer.

It has been asserted that adulteration is brought about by the bee-keeper feeding sugar and syrup to the bees. This is impossible, for the reason that sugar and syrup feeding will never produce honey. It will simply be sugar syrup stored in the combs, and will not be changed in flavor. The fact that bee-keepers feed sugar to their bees creates misapprehension among the inexperienced. It is of the utmost importance at certain seasons of the year to feed bees, but it is only to maintain life, or to stimulate brood-rearing, and it is done late in the fall and early in the spring.

The cost of feed brings this to an end as soon as the colony is in a fair condition. This feed is all consumed in the brood-nest, and not a particle of it ever reaches the surplus boxes. When honey is abundant in the flowers, and the bees have access to it, they cannot be led away by any cheap sugars or syrups. It would be folly to furnish food at a high rate, when honey-producing flowers are supplying the real nectar in excessive quantities.

Extracted honey can be secured in greater quantities than comb honey under the same conditions, and at a much less cost. The saving of comb is quite an item, for to produce wax involves the consumption of large quantities of honey. It has been estimated that 20 pounds of honey are sacrificed in producing one pound of wax or comb. The convenience of handling extracted honey, and the ease with which it can be kept any length of time in good condition, are greatly in its favor.

The granulation of extracted honey has heretofore interfered with its sale and use, but it is now pretty well understood that all pure honey will granulate, and in this condition it is preferred by many to the liquid form.

In extracting, the different varieties of honey produced from different blos-

soms can be kept separate, and the entire crop graded. Most people think there is but one kind of honey, and when they see two different colors they conclude one of them is not right. It is impossible to enumerate the different varieties, flavors and shades of honey, but we may safely say that in any one locality there may be twenty different kinds, at least as many as we have different genera of flowers.

All honey when taken from the hives should be stored away high and dry in buildings. Never use a cellar nor any damp place for this purpose. Dampness will spoil honey, but heat never will.

Creighton, Ohio.

COMB HONEY.

My Favorite Management, and How to Obtain It.

Written for the American Bee Journal
BY WESLEY DIBBLE.

I commenced using the new Heddon hive in 1886, which was considered a poor season here. I obtained more finished and marketable honey with it than with the hive I had used for 7 years previous, and I may add, more honey than any other bee-man with any hive in this territory produced, to my knowledge. I used it according to directions given by its inventor, which was a box on a single story. I, of course, was well pleased with the result the first summer.

I neglected to feed my bees in the fall, and put the bees into the cellar on Nov. 14, 1886, which were in the reversible and the Langstroth hives. The result on May 1, 1887, was that I had lost 50 colonies in the reversible hive, while those in the Langstroth wintered well.

I will say here that I had always wintered bees perfectly before, and the bees consumed so little honey that I did not see the necessity of feeding those in the reversible hives in the fall. The colonies in reversible hives went into the cellar very light, while those in Langstroth hives were heavy. In view of all of the above loss, I was not discouraged with the hive.

In 1887 I filled the hives again with bees, and used them mostly with both stories the second season. About June 1, 1887, I commenced to change the lower section or half-hive to the top, and the top one below. I practiced this once in seven or eight days, for four times, and some of them oftener. When the upper story was loaded with honey, I put it below as late as Aug. 1.

I did not get a natural swarm from the reversible hive in 1887. I put them into the cellar again on Nov. 19, 1887, with both chambers of the hives well filled with bees and honey. The bees wintered perfectly, and now, on July 27, 1888, with the same management as last summer, the colonies in these hives are ahead of anything I know of in this part of the country, in storing honey in sections; and I have had one swarm from 50 colonies.

About finding the queen: I am not telling what I can do, but what I have done. My wife and myself clipped the wings of 50 queens in reversible hives in less than two hours, in my home yard. I have another yard seven miles from here, with 73 colonies, spring count, and it required 1½ days to accomplish the clipping. The wings of the queens of both yards ought to have been clipped sooner, or before the hives were so full of bees; but I care but little about the quantity of bees with the reversible hive—I can find the queen 19 times in 20 almost instantly, while I have searched one hour for a queen in the other hives, and then shut them up till some other time, without finding her, especially a black queen. Middleburgh, N. Y.

CONVENTION DIRECTORY.

1888 *Time and Place of Meeting.*

- Sept. 6.—Bees and Poultry, at New Brunswick, Ind. Ora Knowlton, Sec., New Brunswick, Ind.
 Sept. 8.—Susquehanna County, at Montrose, Pa. H. M. Seeley, Sec., Harford, Pa.
 Oct. 3-5.—North American, at Columbus, O. W. Z. Hutchinson, Sec., Flint, Mich.
 Dec. —Michigan State, at Jackson, Mich. H. D. Cutting, Sec., Clinton, Mich.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

SELECTIONS FROM OUR LETTER BOX

Bees Doing Well.—L. Highbarger, Leaf River, Ills., on Aug. 23, 1888, says:

Bees are doing well at present on asters and heart's-ease. If it so continues I expect to get some surplus honey besides my increase of bees. I increased my apiary from 18 colonies to 50.

Bees Making a Living.—M. O. Tuttle, Osage, Iowa, on Aug. 28, 1888, says:

Bees in this section are going to make a living for themselves, but not for their keepers, unless we rob them. During the last of June and all of July, there was just honey enough to stimulate swarming, but not enough to get any surplus. There will not be comb honey here to one-tenth part supply our home market. Perhaps we can get the people educated to use extracted honey, while they can get nothing else. Honey from buckwheat, golden-rod and other fall flowers is as plenty now as any time this season.

The Ignorant Bee-Keepers.—J. W. Tefft, Collamer, N. Y., writes:

That class of bee-keepers who do not take good bee-papers—who read no books on honey-bees—have no business with bees, as bees have no business with them. They abuse the profession. No argument can convince them. They are so habituated to intrigue and mystery, and are prone to accept a plain fact, but will dodge the road to common-sense. They will not pause to deliberate upon and minutely scrutinize divers errors committed, and op-

portunities neglected, whereby he would wish to account for the total failure of his enterprise. After they have lost there bees, and are "upset," they will whine, and say that it all happened because of other's business, and that the weather was very heavy; when in fact the waters were very deep, the night very dark, and the intellect very muddy. Such condemn reversible frames, not knowing what they are talking about.

The plain fact of the business is, all such cases are unfortunate. Bee-keeping can only be achieved by those who, like Dzierzon of old, "pay the costly price for the brilliant meed of honor," by discipline, self-control, and a boundless enthusiasm for the art.

Working on Heart's-Ease.—W. H. Martin, Falls City, Nebr., on Aug. 25, 1888, says:

We have had plenty of rain in this vicinity this summer, and bees are working on heart's-ease, which is abundant in nearly all stubble fields.

Make Our Cause Strong.—J. W. Winder, New Orleans, La., on Aug. 28, 1888, writes:

The honey crop is short again in this portion of the State. Too much rain has not been conducive to the usual yield, so dollars for the "Union" will be scarce from this source. But as our pursuit must be defended against ignorance and wrong, I send in my dollar, to help make our cause strong.

Wet Summer and Small Crop.—Wm. B. McCormick, Uniontown, Pa., on Aug. 28, 1888, writes:

I had my back badly strained some three weeks ago, by being thrown from a wagon. I am now able to walk about again, but I have not sufficient strength to attend to my bees. Our prospects for a good crop of honey in the spring were very bright, as the bees all came through the winter in prime condition, with abundance of honey. Fruit bloom, etc., was good, as well as the weather, and nearly all of my 40 colonies commenced working in the sections; but, alas, alas, our hopes were all blasted, for the white clover (our main and only source for surplus) was a perfect failure, and since July 1, our bees have scarcely made a living. My crop will amount to about 1,000 pounds of comb honey, most of it being dark, and the sections not very well filled. We have had a very wet summer.

Pleased with the Union's Success.—D. Millard, Mendon, Mich., on Aug. 25, 1888, writes:

I am much pleased with Z. A. Clark's success, and I sincerely hope that he will come out ahead in the final contest. I am, however, much opposed to keeping large apiaries in thickly settled corporations; for if they are not a great public nuisance, they are often a source of great annoyance to one's nearest neighbors—the very ones with whom we should sustain the most amicable relations. I joined the Union, and gave my first dollar to assist in squelching the absurd idea that bees ever annoyed sheep. My second dollar went to assist in proving that bees of themselves never destroy grapes. I now send another dollar hoping that it will aid in "pushing to the wall" any would-be scientific professor, clergyman, idiots, or those who will persist in vilifying honey-producers. There is no more positive evidence of ignorance or dis-

honesty than to be persistently accusing others.

The season is a failure here with us. There is very little or no white clover, only a light bloom of linden, and the weather is too dry for buckwheat and fall bloom. I have no honey to sell, and but little increase.

Honey and Beeswax Market.

NEW YORK.

HONEY.—Market is bare of extracted, but choice white clover or basswood will bring from 7½@8c. Southern extracted, 55@60c. per gallon, as to quality.
BEEWAX.—Dull at 23c.
 HILDRETH BROS. & SEGELKEN,
 Aug. 23. 28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—White 1-lb. sections, 12@15c.; 2-lbs., 11 to 14 cts.; amber, 7@9c. Extracted, white, 5½@6c.; light amber, 5@5¼c.; amber and candied, 4¼@4¾c. Receipts light and market firm for best qualities.
BEEWAX.—17@21c.
 Aug. 25. O. B. SMITH & CO., 423 Front St.

DETROIT.

HONEY.—Best new white comb, 15@16c., with little in sight and slow sales. Market is low, and beekeepers will do better to hold honey until approach of cold weather.
BEEWAX.—21@22c. Supply limited.
 Aug. 22. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—New crop offered at 16@17c., demand being very light yet. Extracted is not in much demand, and prices are nominal at 7@8c. for the best grades.
BEEWAX.—22c.
 Aug. 14. R. A. BURNETT, 161 South Water St.

CHICAGO.

HONEY.—None here, and market in good condition for new crop. There is some demand for the extracted.
BEEWAX.—22c.
 Aug. 2. S. T. FISH & CO., 189 S. Water St.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb., for which demand is fair. Comb honey, 12@15c. Some small lots have sold at 14@16c. Market quiet.
BEEWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
 Aug. 24. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—Choice 1-lb. sections, 18c.; dark 1-lb., 14c.; 2-lbs., 16c.; dark, 13c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices firm, and stock light.
BEEWAX.—None in market.
 Aug. 29. HAMLIN & BEARSS, 514 Walnut St.

NEW YORK.

HONEY.—The market is not yet established, and very little new honey has arrived. From the crop reports, prices will be as high, and perhaps may be somewhat higher than last year. Reliable quotations cannot be given yet, but there is good demand for extracted. We quote choice white clover and basswood extracted at 7½@8½c.
 Aug. 29. F. G. STROHMAYER & CO., 122 Water St.

BOSTON.

HONEY.—We quote: New 1-lb. sections, 18@20c.; 2-lbs., 14@16c. New extracted, 8@10c.
BEEWAX.—25 cts. per lb.
 Aug. 24. BLAKE & RIPLEY, 57 Chatham Street.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 5½ cents; light, 5¼c.; amber, 4½@5c. 1-lb., 12@14c.; 2-lbs., 9@13c. as to quality. Arrivals not large, and supplies held firmly.
BEEWAX.—Dull at 19@22c.
 Aug. 20. SCHACHT & LEMCKE, 122-124 Davis St.

KANSAS CITY.

HONEY.—We quote: White 1-lb., unglazed, 18 to 20 cts.; 2-lbs., 15@16c. California white 1-lb., 18c.; 2-lbs., 15c.; extracted, white, 8c.—amber, 7c.
BEEWAX.—None on the market.
 Aug. 10. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—We quote: Extracted, dark, 4@4½c.; bright, 5@5½c.; in cans, 7@8c. Comb, white clover in prime condition, 13½@15c.; dark, 11½@12½ cts.—Market quiet, demand good and receipts light.
BEEWAX.—22c. for orime.
 Aug. 10. D. G. TUTT & CO., Commercial St.

MILWAUKEE.

HONEY.—New white 1-lb. sections 18c., and very fine, 20c.; 1-lb., 15@18c.; old 2 and 3 lbs., not salable, 1½@1¾c.; dark 1-lb., old or new, 12@13c. Extracted, 7½c. white in kegs and ¼-barrels, 8@9c.; old, in same packages, 7@8c.; in tin, 8@9c.; dark in barrels or ¼-barrels, 6@6½c. Arrivals of new crop small; demand not urgent, and only very moderate trade.
BEEWAX.—22@25c.
 Aug. 31. A. V. BISHOP, 142 W. Water St.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections $4\frac{1}{2} \times 4\frac{1}{2}$ and $5\frac{1}{4} \times 5\frac{1}{4}$. Price, \$1.00 per 100, or \$8.50 per 1,000.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in *Cheshire's* pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being available, it must be sent by express.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages)..... \$1 00
 " 100 colonies (220 pages)..... 1 25
 " 200 colonies (420 pages)..... 1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the *American Bee Journal* must be sent with each order for another paper or book:

	Price of both.	Club

Hastings' Perfection Feeder.—

This Feeder (illustrated) will hold 2 quarts, and the letting down of the feed is regulated

by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for \$3.50, and it can be obtained at this office. Postage 10 cents extra.

Cork for Winter Packing.—

Its advantages are that it never becomes *musty*, and it is *odorless*. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Can You Do Anything that will do more to advance and defend the pursuit of bee-keeping, than to aid its Weekly Exponent and Defender? The AMERICAN BEE JOURNAL is the pioneer bee-paper of America, and is fully entitled to the active support of every progressive apiarist, for it works constantly and faithfully for the best interests of the pursuit. We therefore specially request all our readers to use their influence to double our subscription list during the coming autumn. Reader, will you please send us a new subscription with your renewal or before that time? A good weekly at one dollar a year is surely cheap enough to command patronage.

Red Labels for Pails.—

We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities, according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2 00	3 00	3 50
1,000 Labels.....	3 00	4 00	5 00.

☛ Samples mailed free, upon application.

Clover Seeds.—

We are selling *Alsike Clover Seed* at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Sweet, or Melilot, Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Exchange.—

We will accept Honey and Beeswax in exchange for Bee-Keepers' Supplies in any quantity. Those desiring to make a trade are invited to correspond with us, stating quantity, quality, and price, and the goods they want in exchange.

Alfalfa Clover.—

For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 10 cents per pound for bag and postage.

We Supply Chapman Honey-Plant

SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; $\frac{1}{2}$ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and reset.

The Convention.—

The pamphlet containing the report of the proceedings of the Union Convention in Chicago, Ills., is published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Convention Notices.

The Darke County Bee-Keepers' Society will hold a basket meeting on the Greenville Fair Grounds, on Friday, Sept. 7, 1888.. J. A. ROE, Sec.

The North American Bee-Keepers' Society will meet at Columbus, O., on Wednesday, October 3, 1888, and continue as usual in session for three days. W. Z. HUTCHINSON, Sec.

The next semi-annual meeting of the Joint Bee and Poultry Keepers' Association of Boone and Hendricks counties will be held at the apiary of Wm. H. Higgins, 2 1/4 miles south of east from New Brunswick, Ind., on Thursday, Sept. 6, 1888. All interested are cordially invited to attend. ORA KNOWLTON, Sec.

The Susquehanna County Bee-Keepers' Association will meet in the Court House at Montrose, Pa., on Saturday, Sept. 8, 1888, at 10 a.m., Sharp. The following subjects will be considered: Preparing Bees for winter; Preparing for, and Marketing, Surplus Honey; Does the Raising of Small Fruit Conflict with Bee-Keeping? All bee-keepers are cordially invited to attend. H. M. SEELEY, Sec.

We will Present a Pocket Dictionary for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

Advertisements.

LANGSTROTH FUND.

A GOOD full-length PHOTOGRAPH of Rev. L. L. Langstroth, mounted on cabinet card, will be sent to any address for 50 cts.—one-half to go to the "Langstroth Fund." Address,

THOMAS B. REYNOLDS,

36A21 Box 356, DAYTON, OHIO. Mention the American Bee Journal.

BEES FOR SALE. — 24 COLONIES in improved movable-frame hives. For terms and particulars, write to

REV. J. D. GEHRING,

36A2t PARKVILLE, Platte Co., MO. Mention the American Bee Journal.

TESTED GOLDEN ITALIAN QUEENS.

ONE Queen, \$1.00; 2 Queens, \$1.80; three Queens, \$2.60; one-half dozen, \$5.00. By Return Mail. HENRY ALLEY,

36A3t WENHAM, MASS.

Mention the American Bee Journal.

GREAT BARGAIN!

ONLY \$2.50 per Colony—10-frame hives. For particulars address,

36A1t J. J. ROE, Buchanan, Mich.

Mention the American Bee Journal.

HONEY.

WE advise Bee-Keepers not to sell before getting our high prices.

State quality, quantity and style of packages; send samples of Extracted, with the sender's name marked on the same.

The Original BINGHAM Bee Smoker

Patented, 1878.

ADDITION, Vt.—Have one of your smokers good yet—used 6 years. E. J. SMITH. F. M. TAINOR. ROBORO, N. Y. Aug. 15, 1882.—All summer long has been "with me and the Egyptian colony of bees I have—but at last, I am boss—Bingham's Conqueror Smoker did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham. G. M. DOOLITTLE.

Bingham & Hetherington Uncapping Knife

Patented May 20, 1879.

BINGHAM SMOKERS and KNIVES have Revolutionized the Smoker and Knife Trade, and have made bee-keeping a pleasure and a success. They are the only lasting and satisfactory Smokers and Knives now used by experienced bee-keepers in Europe, Australia, Cuba, and America. They are covered by patents, and while they are always the best that can be made, they are also the lowest priced.

Prices, by mail, post-paid.

EDITORIAL BUZZINGS.

"There is a language in each flower
That opens to the eye;
A voiceless but a magic power
Doth in earth's blossoms lie."

A Dark, Warm Room is the best place in which to keep comb honey, in order to preserve its whiteness, and keep it from "gathering moisture." The temperature should be kept from 80 to 85 degrees.

Home-Made is the term claimed by two bee-papers. The editor of the *Review* is its compositor, foreman, "devil" and proof-reader in his own office, and his wife and children assist in getting the papers into the mails. The editor of the *Bee-Hive* fills all the offices mentioned, and does all the mechanical work as well. The work of each one reflects credit upon these brother editors. We wish them both success.

Mr. R. J. Kendall, with whose communications from Texas our readers were familiar 2 or 3 years ago, went to New Zealand and now has gone to Australia. His departure is thus noticed by the August number of the *Australasian Bee Journal*:

We are sorry to state that our friend and contributor, Mr. Kendall, has left for fresh fields. He has for some time contemplated returning to the United States, but finally made up his mind to try Victoria first, and left for Melbourne last month. Feeling very unsettled of late prevented him contributing to the *Journal* regularly, but he has promised to take up the running again as soon as he gets settled and has had time to see how things in the bee line are moving in Victoria. We shall be very pleased when that time comes, for Mr. Kendall is a very pleasant and amusing writer. We wish him every success.

Feeding Back, so called, is feeding the bees with extracted honey in sufficient quantity to induce them to finish up incomplete sections, in order to make them marketable. This has often been tried, but the loss of honey is so great that it is quickly given up in disgust.

The Virginia champion of "the Wiley lie" is persistent in his assertions that beekeepers are feeding glucose to the bees for the purpose of having them deposit it in the combs and seal it up, so that the bee-men may put upon the market a fraudulent article of comb honey, and thus accommodate Wiley, Evans & Co., by giving them a shadow of excuse for their *cheap* but untruthful assertions concerning the existence of adulterated comb honey and of its being found upon the markets in large cities.

The price of the pure article of extracted honey and the best glucose is now very nearly the same, and for that reason it will not pay to adulterate extracted honey. As Wiley, Evans & Co. are driven from that position, they now want to find some glucose comb honey on the market. But if the feeding back of pure extracted honey to make comb honey is an unprofitable business, the substitution of glucose (which is of about equal value) will not help the case! Both are alike unprofitable! Both are, therefore, commercially impracticable and financially impossible! Both "horns of the dilemma" refuse to support, or even to give color to the "vain imaginations" of these deluded mortals!

Commenting upon the experience of Mr. W. Z. Hutchinson in "Feeding Back," as given in the *Review*, of recent date, the *British Bee Journal* for Aug. 23, remarks as follows:

Ten or twelve years ago we experimented on feeding extracted honey to complete sections, but we soon found out that such a practice *would not pay at all*, and that it could only be done by an enormous waste of honey.

The experience of the most successful bee-keepers in America corresponds with that of our British cousins, and the uniform verdict is that *it will not pay to do so!*

Thus are the enemies of the pursuit of bee-keeping again beaten back! again made to "bite the dust"! again proven to be making cheap assertions concerning that of which they are in entire ignorance!—again exposed to public gaze as villifiers and traducers of an honest pursuit! and again and again we demand that they shall produce a sample crate of the article—or else acknowledge that their assertions are *falschoods*, without excuse and without the least shadow of proof.

A Carton—which is a cover for a one-pound package of comb honey, is received from Mr. J. B. Hains, Bedford, O. It has a neat front, and on the back is a view of his apiary, and a selection from our Leaflet entitled "Why Eat Honey?" It is neat, attractive and withal inviting and instructive.

That New Invention a Failure.

—On page 148 an announcement was made that Mr. Koerbs, a German, had invented a new comb; and on page 244 we stated that it was merely comb foundation "made on glass, wood, tin, card-board or other material, with the impression of cells in wax on one side, the other being left smooth." The intention is to have the cells of double length, the mid-rib or foundation being at one side.

Notwithstanding the fact that several beekeepers of Germany had stated that they approved the invention, and our friend, C. J. H. Gravenhorst, editor of the *Bienen Zeitung*, had seen the combs "completed by the bees," and predicted a "revolution" in the matter of bee-comb, "even if the invention accomplishes but one-half of what is claimed by Mr. Koerbs"—still we made these remarks:

A great "splurge" was made at its announcement. There was a great ringing of the bell to announce the advent of the locomotive, but, alas, the coming of the engine created no enthusiasm. It is almost a useless affair, if not absolutely so. Here in America, at least, we have no use for such an invention! We can secure longer cells by simply spreading the combs, but even that is undesirable, because of the slower ripening of the honey, and the consequent hindrance to the bees.

We shall watch this matter closely, and keep our readers posted concerning its advent and revelation—and ring the bell just in time for all to witness the arrival of the locomotive!

Now comes this "conclusion," in a letter from Mr. H. Stallhammar, of Sweden, to the *Canadian Bee Journal*:

As regards the Koerb comb foundation (one-sided, with cells of double-depth), this Summer it has proven itself a failure, the queen filling the cells with eggs before the bees had drawn the cells out long enough; and, furthermore, when fastened on the one edge of the frame, the bees are inclined to build a new comb on the other edge of the same frame.

We had no confidence whatever in the invention, and so stated it at the time of its very peculiar announcement. Nothing else than a complete failure ought to have been expected by its friends.

The Honey Crop in California has been misrepresented by the *Commercial Bulletin*. It stated that "the yield in San Bernardino and San Diego counties will be the heaviest ever gathered." This does not conform with advices received in San Francisco, and the *Country Merchant* says that a local dealer who has just returned from a trip to Southern California, after making a careful canvass of the field in person, reports the yield of the counties in question will be, from present prospects, only about half that realized in 1886, and that in other sections of the State indications are that the proportion will be no greater.

The fact is, somebody has been trying to bear the market. But in spite of all such work the prices of both comb and extracted honey will *go up!*

GLEAMS OF NEWS.

Bees as Educators.—Mrs. L. Harrison, in the *Prairie Farmer* of last week, gives the following very interesting article on the above subject:

EDUCATED EYES.—No sooner does a person become the owner of a colony of bees than he looks around to see what are the prospects of future gain. Heretofore he drove or rode along the highways, noticing the ruts, bridges, fences and houses, but now his vision takes in a wider range. His observation is quickened, and trees, shrubs and plants have put on new life, as it were, to his enlivened faculties. From the first opening buds in spring, until the last rustling leaf has fallen, his interest never lags, as he constantly watches the opening flowers, and notes with pleasure the busy workers roaming over them in quest of treasure to store in their hives.

NECTAR IN WEEDS.—What was to him once a useless weed, to be cut down with the scythe, or whacked off with a hoe, is clothed in beauty, and becomes a priceless treasure. Whoever saw any beauty in the figwort, or watched for the appearance of its tiny cupbowl, looked down into their depths for the first appearance of sparkling nectar, but a bee-keeper? Or whoever saw any utility in Spanish-needles, or beggarticks? There is a bond of friendship existing between the bee-keeper and nectar-bearing plants, and they appear to spring up to greet him wherever he goes. The Indian calls white clover "The White Man's Foot," and well he may, for its modest flower soon appears as the harbinger of peace and plenty.

SOILS.—The interest thus awakened in plants, soon takes on a wider range, and extends to the soil. Seeds of sweet clover (melilot) are scattered on gravelly soil, take root, penetrating deeply, keep it from washing and dying and add to its fertility. Dreary wastes thus become clothed with verdure, adding to the beauty of the landscape and yielding choice nectar, fit food for gods. On a recent trip of a dozen miles on a railroad leading out from this city, we were agreeably surprised to find this plant growing luxuriantly nearly the whole distance, and some deep cuts were so covered with it that the soil couldn't be seen. It is to be hoped that the officers of railroads will appreciate the utility of this plant in keeping the soil from washing away and preventing damage and danger thereby, and foster its growth. I have seen the yellow variety of this plant growing on the borders of salt marshes on the shores of Long Island Sound.

MOISTURE.—Marshes and wet lands along rivers and water courses, come in for a share of attention by the bee-keeper. His eye quickly detects anything in the interest of his winged stock. If by digging a ditch and running off water the growth of favorite bee-plants is promoted, it is done. He then benefits his neighbors as well as himself, for, as the ground becomes dry, blue-grass and the clovers will take root, thus promoting grazing for stock, and malaria will disappear. New plants will spring up as if by magic, the button-bush (*Cephalanthus occidentalis*) growing in water. It seems as if the seeds of honey-plants rattled from the bee-keeper's clothes. The seed of many honey-plants is food for birds, which are our friends and co-workers in destroying many noxious insects.

EDUCATED EARS.—As seeing is cultivated by bee-culture, so is hearing—even all the senses are quickened, much better than they can be in a kindergarten. How soon the trained ear discovers the note of the robber, the sound of swarming, the piping of queens, and the happy hum of plenty, or

the sorrowful moan, when the queen is lost. The sense of smell reveals the blooming of apples, as also the opening of the fragrant basswood, buckwheat, etc., and reveals the presence of that dire calamity, foul brood.

Bee-keeping is, therefore, not only a pleasant and profitable employment, but it tends to lift up and exalt the intellect, and educate the human senses.

Pleasantries.—Prof. Cook, on page 602 of this issue says that "the Wiley lie" was not a "scientific pleasantry"—there was nothing scientific about it. Instead of that, it was only a "glaring, mischievous error," clothed in "the garb of science!" The Professor is evidently correct. It is a libel to call it "scientific."

The Professor also gives some very emphatic decisions on honey being "digested nectar," and Mr. Paul L. Viallon, Bayou Goula, La., has sent us these criticisms on the matter, which came to hand since the page was "made up," which contains the Professor's article. He says:

I think Mr. Demaree gives us a pretty good "pleasantry" when he says on page 568: "Pure honey is nectar of flowers gathered by bees and reduced to proper consistency by the internal heat of the bee-hive. That's the whole of it." Will friend Demaree please to theorize on that question, and not let it remain in that crude state? As for the other part of the subject, he hits the nail pretty well.

Chapman Honey-Plant.—Mr. R. Bacon, Verona, N. Y., on Aug. 31, 1888, asks the following questions about the seed of the above-named plant:

Please inform me as to when is the best time to gather the seed from the Chapman honey-plant, and how to clean it. I obtained a small package of the seed, which I planted, and I find it to be one of the best—if not the best—of honey-plants. I believe that if bee-keepers would club together, and plant a large area with it, it would add immensely to our annual honey crop. I say "club together," for it will hardly pay one bee-keeper to plant it for all the surrounding apiarists, but all should help in bearing the expense, as all would reap the benefits.

We refer this question to Mr. H. Chapman for reply, which will probably appear in our next issue. Seed can be obtained at this office.

Another Bee Story.—The following is taken from the *Chicago Daily News*, and was sent to it by telegraph from Martin's Ferry, O., on Sept. 4, 1888. The bees must have been very numerous down there to have done so much cleaning up in so short a time. It says:

Mr. G. N. W. Stringer, a well-known and reliable farmer on Deep run, was in town to-day and told this wonderful bee story: Yesterday Mrs. Stringer boiled down forty gallons of cider to ten gallons, put it in four tin pans, and set them on a table out-of-doors to cool, covering the pans with a table-cloth. Five hours later she went to the table to take the cider in, and, much to her surprise, discovered that the bees had emptied every pan, sipping the cider through the table-cloth.

A Peculiar method of dispensing sweetness has been discovered by Mr. J. W. Tefft of New York, as will be seen by the following "notice" from the *East Syracuse, News* of Sept. 1, 1888. It says:

Mr. J. W. Tefft of Collamer will please accept our thanks for his liberal donation of several sections of honey last week. Among the number was one marked "For the Office Devil," with Mr. Tefft's compliments. Upon receiving the gift and immediately after testing the quality, the devil enquired as to the geographical position of Mr. Tefft's residence upon the globe. Our devil is quite an ingenious chap and we would not be surprised if he should invent a device to make honey for the girls, as they were among his most frequent callers during the past week.

The Northwestern Bee-Keepers' Society is usually held in Chicago during the last week of the Exposition. This year the North American Convention is to be held at Columbus, Ohio, on Oct. 3 to 5, and thus comes so close to the time for holding the one at Chicago, that it is, by some, thought best to omit it altogether. So many of the members feel unlike making the outlay for attending it, after three years of failure of the honey crop. If it is held at all, the better time would be at the time of the Fat Stock Show. The officers would like to hear from the members on this point.

Mr. F. Cheshire says that the rearing of a bee, from the egg to maturity, costs a colony the equivalent of four cells of honey; and it is only because a bee, in a fair yield, is able to require the colony with many times its cost, that a large population means surplus; but if this population is brought upon the stage after the harvest is over, it becomes a consuming instead of a producing population. Hence the importance of having the brood-rearing about over when the honey-flow is at its best.—*Exchange.*

How to Test Drinking Water.—One of the simplest ways of testing drinking water is to purchase a small quantity of saturated solution of permanganate of potassium from the druggist and put a few drops of it into a bottle of drinking water. This will turn the water a beautiful rose color, but if the water contains any dangerous amount of organic matter, in a few hours the water will change to a dirty reddish-brown. If the color of the water remains unchanged at the end of twelve hours it may be considered comparatively pure. A yet simpler way of testing the water is to put a half teaspoonful of pure sugar into a clean pint bottle, three-quarters full of water, cork the bottle, set it where it is warm for two or three days and where it will not be disturbed. If, during this time, the water becomes cloudy or milky, it is unfit for household use. If it remains perfectly clear, it is safe.—*N. Y. Tribune.*

Convention Notices.

The North American Bee-Keepers' Society will meet at Columbus, O., on Wednesday, October 3, 1888, and continue as usual in session for three days.
W. Z. HUTCHINSON, Sec.

The next meeting of the Union Bee-Keepers' Association will be held at Clayton, Ills., on Thursday and Friday, October 11 and 12, 1888, in the Town Hall at 10:30 a.m. The Park Hotel will charge \$1.00 per day; the restaurants 25 cts. per meal. We expect Messrs. Dadant, Hambaugh, Camm and other prominent bee-keepers to be present.
S. N. BLACK, Pres.

Honey Locust.—We have just received from Mr. Norman J. Coleman, Commissioner of Agriculture, the "Annual Report of Forestry for 1887," issued by the Department at Washington. It contains many things of interest concerning the forest trees, etc., of America. Concerning the Honey Locust it gives these interesting particulars and description:

Distribution.—From the Brazos River, eastern Texas, northward to eastern Nebraska and eastward throughout the entire region to the Atlantic, but in the latter States chiefly introduced. It is mostly associated with other trees, elm, walnut, hickory, and ash, though sometimes becoming the predominant species, and in a few cases, in small areas, excluding all other species. Outside of its natural range it has been quite generally cultivated as a shade and ornamental tree, and in a few of the Western States successfully grown in forest plantations. It is well fitted to replace the Black Locust in the southern half of the United States, where it can undoubtedly be more successfully grown as a forest tree.

In 1700 it was introduced into England, but cultivated only as an ornamental tree, and somewhat unsuccessfully as a hedge-plant, as it was also upon the Continent. Subsequently it became known in south-western Europe, especially in France, Austria, and Italy, where fertile seeds are easily matured.

Growth.—The Honey Locust grows rapidly during its early life in favorable situations, making from 2 to 3 feet annually in height growth, and nearly three-fourths of an inch in diameter for the first ten years. Although not as extensively tried as a forest tree as the Black Locust, yet so far as known it is generally far less liable to the attacks of insects than the latter. Commonly about 50 to sometimes 90 feet in height and 1½ to 3 feet in diameter. Grown in the open it usually produces a short trunk and a broad, much-branched crown, while closely grown with other heavy-foliated companions it develops a taller trunk and smaller crown.

Soil and Site.—The Honey Locust is found growing almost entirely in low, rich bottom-lands and in sheltered valleys, where the soil is deep and loose, rarely of its own accord taking to the poorer and drier uplands. In such favorable locations it produces its finest timber value. The moderately rich, but loose, sandy, or gravelly soils of highlands and slopes produce desirable timber, though not as quickly as the lower and richer soils. The growth in stiff damp soils is apparently a healthy one, but slow and undesirable for timber; it will not endure an undrained soil.

Propagation.—It does not sprout from the stump nor grow from cuttings, and is therefore propagated entirely from the seed, which will sometimes retain their vitality for three years, even out of the pods. The fresh seed procured in the fall grow most readily if planted immediately, but if kept dry for a season or more and then planted they germinate very slowly, often not at all, or "lie over." The young plants of the first year are not quite as hardy as those of the Black Locust of the same age, but are equal to them in this respect at any time afterwards. They can be transplanted to their permanent sites when one year old and will bear the transplanting well, but are on the whole, perhaps, best kept in the nursery rows till the fall or spring following the second year.

Quality of Wood and Economic Uses.—The wood is heavy, hard, strong, and durable in contact with the soil or when exposed to the weather (equal to that of Red Mulberry). It splits somewhat more readily than that of the Black Locust, and the grain is considerably coarser as well as being more porous. It seems not to have attracted

much attention for its economic value, but where available is employed considerably for fence-posts, rails, in turnery for heavy spoke-timber, and is much esteemed for fuel. It is adapted to other purposes in construction, and will undoubtedly come into more general use in the absence of other heavy-wooded but much slower-growing kinds.

The Honey Locust Tree.

Descriptive Characters.—Leaves compound, composed of small, lance-shaped, oblong leaflets. Pods large, flat, shiny brown, 9 to sometimes 18 inches long and about 1½ inches broad, with a sweetish hard pulp between the seeds—often eaten by children. Armed with clusters of long keen spines, generally three together, a central or main one with smaller lateral ones; often attached to the trunks of young trees, but absent from older stems. The

Honey Locust Limb, Seed and Pod.

bark of young trees (ten to fifteen years) is mostly smooth and unbroken; but very old trees have rough and much furrowed bark, rendering the tree quite a different one in appearance. Varieties of this species are without thorns, or sometimes with small thorns.

The locusts are excellent honey-producers and should not be overlooked in the selection of shade trees. Although the duration of bloom is but limited, they yield a bountiful

supply of rich nectar, and bees will literally swarm among the highly-perfumed blossoms. Mr. G. W. Demaree, of Kentucky, writes as follows regarding the locust:

"The time of year in which it blooms nearly filling the interval between the late fruit bloom and the white clover, makes it an exceedingly valuable auxiliary to the honey harvest in the middle states, if not elsewhere. It is a most profuse honey bearer, rivalling the famous linden in quality, and only inferior to the product of the latter in color. Locust honey cannot be said to be dark in color. It is of a rich pale-red color, when in a liquid state; but when in the shape of comb honey, its appearance, if removed from the hive when first finished, is but little inferior to our superior clover honey. It becomes exceedingly thick, if left with the bees till the cells are thoroughly sealed, and its keeping qualities are therefore most excellent. The trees are planted by the side of fences, in waste places, and on poor, worn-out lands. They may be propagated from the seeds, or by transplanting the young trees from one to three years old. If the ground is plowed in the spring, and the locust seeds planted on the hills with corn, or with other hill crops, and cultivated the first year, the young trees will grow with great rapidity, even on very poor lands. In this way beautiful groves can be started, making the land, in process of time, very valuable, in locations where timber is an object, besides giving a perfect sea of bloom, laden with precious nectar."

The Honey Crop is very small this season, especially the white honey. More honey is now being gathered than at any time before, this year. Mr. Geo. H. Knickerbocker of Pine Plains, N.Y., remarks thus:

With these conditions a good quality of honey must, of necessity, bring a good price, unless the market is demoralized. I already hear of some who live in favored localities, and have a fair crop of honey, who are making the mistake so common among bee-keepers, viz: being in such a hurry to dispose of their honey as soon as gathered (before someone else can get theirs ready for market), they offer nice comb honey for 10 or 12 cts. per pound, and by so doing help to establish a low price, even when honey is a short crop and should bring a good price, in order to fairly remunerate the producer for his labor and investment.

The foolishness of such proceedings cannot be too severely condemned. If honey does not bring an extra good price this year, it is the fault of the producers themselves. Even those who may have some of last years' crop of comb honey are to be congratulated, for it will also find a market at good prices.

We Have some copies of the old edition of Cook's Manual left, which we will sell at the old price, \$1.25. The price of the new edition is \$1.50 per copy: a notice of which may be found on page 579.

We Want 20,000 subscribers. Out of the 300,000 bee-keepers in America, certainly this is not an extravagant desire! It is only one out of every fifteen! We confidently ask those who appreciate the AMERICAN BEE JOURNAL, to show it by sending us one or more new subscribers. We will give them full value for their money.

QUERIES AND REPLIES.

Why Queen-Cells do Not Hatch.

Written for the American Bee Journal

Query 574.—My bees came out of winter quarters in very good condition, with the exception of one colony that starved to death, and another that was queenless. I have had 3 very good swarms, the first on June 9. To the queenless colony I gave a comb of eggs and brood, and they made two queen-cells, but neither of them hatched. From the colonies that swarmed first, I took a comb and adhering bees containing a nice, sealed queen-cell; but it never hatched. I have given them another comb containing two queen-cells; they have now had time to hatch, but I have not examined them. What do you suppose is the reason that queen-cells do not hatch there? I have kept them well supplied with bees from other colonies.—Iowa.

Candidly, I do not know.—G. M. DOOLITTLE.

The most probable cause of the trouble was that the brood got chilled.—J. P. H. BROWN.

I can offer no explanation that would be of use.—A. J. COOK.

I do not know; perhaps they got chilled.—C. H. DIBBERN.

I think there was not a sufficient number of bees to keep the cells warm.—R. L. TAYLOR.

It is impossible to give a correct answer without knowing all the circumstances.—P. L. VIALLO.

Laying workers probably infested the hive, which are at times very hard to dethrone.—J. M. HANBAUGH.

Why do you not see if the last cells have a queen or not? If not, break up the colony and unite it with others.—H. D. CUTTING.

You leave too many things in the dark. Did the queens die in the cells? Did the bees destroy the cells? I can give no opinion in the absence of fuller information.—M. MAHIN.

I cannot say, unless they got chilled. The position of queen-cells is usually the coldest part of the hive, and unless the weather is warm, or the colony strong, that may often happen in such cool summers as this.—EUGENE SECOR.

From the data given, I am unable to answer. There are so many reasons that might be given, none of which might be right, that it is useless to attempt to make a reply.—J. E. POND.

Possibly they were chilled, but I have found dead grubs in queen-cells when I thought they had hardly been chilled, and I did not know the cause of death.—C. C. MILLER.

Such colonies are often infested with laying workers, and the young queens are destroyed on their return from their bridal tour. Are you positive that the queens died in the cells?—MRS. L. HARRISON.

There are various reasons why queen-cells do not hatch. Not knowing more of the conditions, I cannot answer in your case. There is no certainty of any queen-cell hatching; that is the reason why all those who used to advocate clipping all the queen-cells but

one to prevent after-swarming, were writing a great deal more than they practically understood.—JAMES HEDDON.

Possibly the queen-cells were not handled carefully. I think that many queens, just after the cells have been sealed, may be entirely destroyed by shaking the frames, as we do when clearing them of bees. In this case the queen brood must either have been defective or destroyed by bad handling.—J. M. SHUCK.

No reason can be given why the cells did not hatch if the bees did not abandon them, and leave them to be chilled and destroyed by a too low temperature. I am inclined to think that the cells hatched, and the young queens were destroyed by the bees. Bees that have been queenless a long time are liable to act as though they had laying workers among them, whether you see any signs of these pests or not. This peculiar abnormality among bees is the prevailing cause of the loss of young queens at the time, and before their wedding flight.—G. W. DEMAREE.

In the absence of fuller details, it would be almost impossible to state the cause for the queen-cells not hatching. They may have been chilled, or laying workers might have interfered, or something else may have been the cause.—THE EDITOR.

Bees Stinging the Capping of Cells.

Written for the American Bee Journal

Query 575.—I notice that Mr. L. B. Clifton, in the *Southern Farm*, gives it as his idea that bees, after filling their cells with honey and capping them, insert their sting in the center and deposit some formic acid to protect the honey from fermenting. Now my idea was, that they left it uncapped until all the water evaporated, thereby keeping it from fermenting. What is your idea? I want to hear from older bee-men than I am. I ask this for information.—Georgia.

I more than doubt Mr. Clifton's theory.—M. MAHIN.

Stinging the honey is all "bosh."—R. L. TAYLOR.

I think your idea is as good as any.—H. D. CUTTING.

In my opinion, the *sting* performs no part in ripening honey.—G. M. DOOLITTLE.

My opinion is the same as your own.—J. M. HANBAUGH.

I have heard this assertion years ago, but I have failed yet to see anything of the kind.—P. L. VIALLO.

I do not believe that formic acid is deposited in it. If that is so, why does extracted honey that has never been capped not ferment when evaporated artificially?—MRS. L. HARRISON.

I think that the formic acid theory, put in the honey by the bees using their sting, is a grand humbug. Your idea is the better of the two.—EUGENE SECOR.

We think that Mr. L. B. Clifton is fond of wild theories. They do not

always leave it until evaporated, and that is why some honey bursts the cappings.—DADANT & SON.

I do not know, but I am somewhat skeptical about bees ever using their stings for any other purpose than as weapons of war.—C. C. MILLER.

We have no proof that bees *insert their sting* and deposit formic acid in the honey, although there is some formic acid present in nearly all honey.—J. P. H. BROWN.

The above idea is all theory, and to my mind utter nonsense; at any rate, it is all guess-work, and almost any Yankee could guess better.—J. E. POND.

I do not believe in the formic acid idea. I believe that the only use the bee makes of its sting is for defense. Bees do not generally cap the cells till the honey is sufficiently evaporated to keep.—C. H. DIBBERN.

Well, I am quite an old bee-man, and have put in most of my time studying apicultural queries that came rather closer to my dollar-and-cent success, so I will not try to give instruction about what I do not understand.—JAMES HEDDON.

I think that idea is a myth. There is formic acid in the honey, which is doubtless the result of digestion. How do the stingless bees of hot climates acidulate their honey?—A. J. COOK.

My "idea" is, that I never saw it done, and that I do not believe it is done. At our county horticultural meeting last week, a bee-keeper made the same statement, and also that the bees did the capping "with their stingers." I think that he never subscribed for a bee-periodical. If formic acid has to be put into honey to prevent its fermenting, when is it put in honey that is extracted before being capped?—A. B. MASON.

I believe it has been established that there is formic acid in honey. I incline to the believe that the acid formed in honey is developed and incorporated with the honey in the honey-stomach, and tends to preserve the nectar till it ripens, rather than to preserve it after it has been evaporated and sealed.—J. M. SHUCK.

When Mr. Clifton writes in that way he is simply repeating one of the many "scientific pleasantries" with which our bee-literature abounds. There is not a shadow of truth about it. Honey contains more or less of formic acid, but it gets there by absorption from the effluvium rising from the heated cluster of bees. Perhaps this is a wise provision of nature—certainly it is the most natural process by which such an end could be accomplished.—G. W. DEMAREE.

Formic acid is found in the honey, no matter whether it is capped by the bees or extracted before being capped—therefore the "theory" advocated by Mr. Clifton is without foundation. He is not the author of the theory, however. Our friend, the Rev. W. F. Clarke, is its sponsor, and if he finds it possible to further defend it, we should like to hear the arguments.—THE EDITOR.

CORRESPONDENCE.

QUEEN-REARING.

In full Colonies, without First Removing the Brood.

Written for the American Bee Journal
BY HENRY ALLEY.

It is supposed that queens reared at swarming-time are superior to those reared by what is called "artificial methods." This point I will not discuss at this time, but will give the results of some experiments which have been conducted in my apiary the present season, in order to induce a colony of bees to build queen-cells without first removing the queen or any of the brood.

On August 15, several of the best colonies in my apiary were put in order, to test this matter of rearing queens in full colonies the same as the bees would do if about to cast a swarm. When it was ready, I found the bees were ready also, and they built the cells just as I expected they would. I must say that I was as much surprised as delighted at the result, to see that my first attempt was a success.

The cells thus built were very large, and the young queens from them are fine and equal to those reared by any method, or by any one. I intend to present several of them to prominent bee-keepers in this country, and have them tested with those reared at swarming-time; others will be placed in my own colonies.

If this new method for rearing queens works as well as it now promises, it will most likely be adopted by nearly all who rear queens in large numbers, as it is the most practical as well as the most economical method yet devised by any one. There is no doubt in my mind, that one colony of bees can be kept at work building queen-cells from May 20 to September 20. There is one colony in my apiary that is now (Aug. 29) at work on the fourth set of cells, and the bees seem to take as much interest, and work on them with the same vigor, as they did on the first lot of eggs given them.

One of the best features about this new method is the fact that the bees build no cells except from the eggs given them; therefore, it will not be necessary to hunt the other combs over, when one set of cells are removed.

It must be evident to all, that this method has a marked advantage over others so long in use, one of the most important of which is in the immense saving in bees, time and honey, as by this method queens are reared, and in so doing the colony need not be disturbed, except when one frame is put in, and removed at the time the cells are capped.

Some one will say, "I thought you did not approve of having one colony build but one set of queen-cells." Well, I do not in cases where the bees are deprived of the queen and all the brood. You must remember that with the new

plan the bees are kept at all times in the same condition that they are in when a swarm issues. Now, if bees are kept in that condition, why are they not ready to rear as fine queens as they would if they had intended to swarm? The queen has the freedom of all the combs, and brood-rearing is not stopped for a moment, and thus the colony is kept up to the highest point of activity at all times.

So far as I have any knowledge, no one has ever reared, or has attempted to rear, queens by not depriving the bees of their queen. I am not quite ready to make public the details of this method of rearing queens, but I shall probably do so at the proper time, and in season for those who desire to test it another year.

Wenham, Mass.

THE A B C.

Early Instruction for Beginners
—Things Worth Knowing.

Written for the Youths' Companion
BY DR. C. C. MILLER.

"What a beautiful piece of honey! I wonder if it is artificial, or genuine comb-honey made by the bees."

Such remarks as this may often be heard from those who have read the statement which has been going the rounds of the papers, that comb-honey is made by machinery entirely independent of the labor of the honey bees. The story was first started by Professor Wiley who says he meant it as a scientific pleasantry; but error travels faster than truth, and may not be overtaken by it for years.

The truth is that no such thing has ever been accomplished, and I doubt if it has ever been attempted. Mr. A. I. Root made an offer of one thousand dollars for a single pound of honey so made, and although the offer has been standing, if I am not mistaken, for several years, no one has yet called for the money.

When you examine the wonderful workmanship in a piece of honey-comb and observe its great regularity, it seems that there must be some master-builder among the many thousands, whose province it is to direct the acts of the others that the work may go on as one harmonious whole. But if you watch the bees at work you will see nothing of the kind. True, there is a bee called a queen, but the bees do their work without any control on her part. Each bee seems to be working according to its own sweet will, one putting on a bit of wax, another giving it a push here, another there, and the only wonder is, that where so little order or system appears, such wondrously regular workmanship is done.

It is interesting to watch a young worker gnaw its way out of its cell, and become a member of the commonwealth. No mother, nurse nor tutor is on hand to instruct it as to what its duties are to be, and yet that mysterious something, that we call *instinct*, which is born with the bee, seems to tell it exactly what to do, so that the same perfection

of workmanship is found in the hive now as thousands of years ago, no improvement from practice. The bee does not seem to learn to do its work, it *knows* without learning.

The first sixteen days of the young worker's life are spent indoors doing house-work and tending baby, and during the rest of its life it is a field worker, bringing in nectar and pollen from the flowers, also water and propolis. During the busy gathering season, the life of a worker is not more than six weeks, and it seems to wear itself out with work, for the old bees are distinguished by their ragged wings.

The name queen is misleading. The queen is not a ruler, she is simply an egg-layer, and is said sometimes to lay her own weight of eggs in twenty-four hours, that is, about three thousand eggs. She does this, however, only when all conditions are most favorable, surrounded by a populous colony, with a copious harvest, for at such times she is bountifully fed by the workers, that can be seen every few minutes offering food to her.

Under ordinary circumstances a queen is doing pretty good work to lay one or two thousand eggs a day, or rather in a day and night, for work in the hive goes on day and night. The workers rather than the queen seem to control the rate at which eggs are laid, for at some seasons of the year, particularly in autumn and winter, the queen is left to forage for herself, and few or no eggs are laid.

The cells in honey-comb are six-sided and of two sizes, one size, worker, measuring five to the inch, and the other, drone, four. If an egg is laid in a small cell it produces a worker, if in a large cell a drone. At certain times a third kind of cell is built, a queen cell. When a colony becomes very populous and contemplates swarming, a number of queen-cells are built, looking not unlike so many peanuts, each queen-cell taking as much wax in its construction as would make a great many drone or worker cells. A queen-cell is not six-sided but round, and the young queen, while in it, has several times as much room as the other young bees.

About ten days before the young queens are old enough to emerge from their cells, the swarm issues. The old queen goes off with the swarm, and when the first young queen hatches, a second swarm is likely to issue, to be sometimes followed in two or three days by a third, and not rarely by a fourth and even a fifth.

The young queens seem to have a mortal antipathy to each other, and as soon as one such queen hatches, her first business is to proceed, if allowed, to destroy her unhatched royal sisters. This she does by digging a hole in the side of a queen-cell, and stinging the inmate in its cradle. If further swarming is contemplated by the workers, they defend the unhatched queens from the attack of the one at liberty, which goes off with the swarm. Previous to going off, however, this young queen may be heard, especially in the still of the evening, uttering a shrill cry, "Pe-e-p, peep, peep," replied to by the

young queens in their cells, "Quabk, quabk."

When no further swarming is intended, all the young queens who are sufficiently matured are allowed to emerge from their cells, and when two of these meet, a deadly combat ensues. One of them stings the other to death, and strangely enough the victor is never injured in the struggle, for neither one stings till she gets in a position to deal a death thrust without danger to herself. In this way the conflict continues till all the queens but one are killed, and those remaining unhatched are despatched in their cradles.

These queen-cells, of which I have been speaking, are usually found on the edges of the comb, and sometimes even on the wood that surrounds the comb. If a hole happens to be in any part of a comb the bees are likely to make use of the space for a queen-cell. If the queen is at any time lost, when no previous preparation has been made for rearing a young queen, a different course is pursued.

The bees select a young larva in a worker-cell, which, under ordinary circumstances, would have produced a worker, enlarge its cell greatly, destroying, if necessary, the adjacent cells for that purpose, feed it lavishly so that the little grub is literally swimming in a sea of food, and in due time it emerges a perfect queen.

If it should happen that nothing but drone eggs are in the hive, the poor bees will try their best to rear a queen from one of these, but it never grows into anything but a drone, and, I think, always dies in the cell. The fact is, there are only two kinds of eggs, drone and worker or queen, for any and every worker egg with the right kind of food and treatment will produce a queen.

The young worker has its rations very accurately dealt out, just enough, and not a particle is left over; but there is no stint in feeding the young queen, and when she hatches out of her cell there is usually enough food (or royal jelly, as it is called) left to make one think another queen might have been reared on it.

The time required for hatching out the perfect bee from the laying of the egg is, for the drone twenty-four days, for the worker twenty-one, and for the queen sixteen. Curiously enough, the one that matures the soonest lives the longest, for the queen attains the age of two, three and sometimes five years.

The life of the worker seems to depend on the amount of work it does, in the honey harvest living only about six weeks; but those which are hatched late in summer live over till the next spring. It is hard to tell just how long the drone would live if let alone, for when forage in the fields become scarce he is mercilessly driven from the hive to perish.

The drone is the male and is a lazy scamp, for he not only does nothing toward laying up stores in the hive, but does not even visit the flowers for his own food. He helps himself to the stores gathered by the workers, then flies about for exercise, and comes back with a good appetite for more.

There seems to be a popular impression that a queen is surrounded by a

body-guard or a number of courtiers always accompanying her, and ready to attend to her every want, while some have the notion that the queen-cell is a kind of throne where the queen holds court and may be found at all times.

So far is this from being true, the queen-cell is torn down shortly after the young queen hatches out, and before she is two weeks old she commences laying and may be found in any part of the hive.

No bee accompanies her, but if at any time she stops at any point, the workers near her form a circle about her, all facing the queen as if to do her honor. Presently the queen moves on, and the retinue is broken up, to be formed again when she next makes a halt, but the retinue is formed by a fresh lot of workers each time.

Within the past fifty years great progress has been made in bee-culture. Some men take as much pride in their stock of bees as others do in their stock of cattle, and fresh importations are constantly made from other lands, Egypt, Palestine, the Isle of Cyprus, but chiefly from Italy. The Italian bee is distinguished from the common black bee by having three yellow bands upon its abdomen, being more beautiful in appearance and more industrious in character.

I have only touched upon a few points of interest relating to the honey-bee. That the subject is a large one may be judged from the fact that there are published in the English language three weekly periodicals devoted entirely to bee-culture, besides a number published monthly and semi-monthly.

Marengo, Ill.

POOR SEASON.

Some Good Advice about the Fall Care of Bees.

Written for the American Bee Journal
BY CHARLES F. MUTH.

It requires but a small amount of skill and experience to produce a large amount of honey in bee-hives or nail-kegs when the season and surroundings are favorable; we all know that some of our brethren going in favored localities have their egotism tickled more than is necessary when a large crop is realized. Their celebrated hives, inventions of their own; their celebrated methods of manipulation, their fine theories and never-ending arguments, would all drop out of sight with themselves, if they were living in a locality like we "poor chaps" who have had four poor honey seasons in succession.

The season of 1888 is as bad as any we have had, and although I never experienced or heard of a colony of bees starving in the month of August, such things are possible, and it is the object of this article to put my neighbors on their guard.

My bees had, during this season, 8 acres of Alsike clover in their immediate vicinity, and I extracted 150 lbs. from about 20 colonies, which should not have been done, judging by present

appearances. I examined my colonies about Aug. 20, and found all strong in bees and brood, but, with a small amount of stores. A June swarm, hived on 10 full combs, had every comb filled with brood in all stages and not a drop of honey. I supplied them at once, as a matter of course. It is a peculiar fact that Italian bees, with a vigorous queen, will fill their combs with brood during a dearth, when with blacks, as a rule, almost all breeding would cease.

My colony referred to above, is now one of the best in my apiary, but would have starved to death in less than 3 days, as a cool, rainy spell set in while the food was still on their hive, lasting for three days or more. There are 20 acres of buckwheat in full bloom, and in view of the apiary, which would not have saved it from starvation.

There are hundreds of colonies of bees in Ohio, Indiana and Kentucky, in a worse condition than mine, which may starve to death between now and the beginning of winter, unless they are provided promptly.

Cincinnati, O., Aug. 30, 1888.

ORIGIN OF HONEY.

Where does the Honey come from?

Written for the American Bee Journal
BY JAMES HEDDON.

There have been many interesting articles written under the title of "Where honey comes from," and after reading them all, I can think of no heading more appropriate to my understanding of the matter, than "Where does honey come from?" After last season's severe drought, we had something less than half the usual white clover bloom, and the basswood bloom was an average one. From all I know after twenty years' experience, I should not have had much if any different weather during the above blooming, could I have fixed it my own way. But now, strange to say, of white clover honey we get almost none, and no more than one-sixth of the crop of basswood, nearly all of which was taken in the extracted form.

For the last four years we have secured but little amber honey which comes from buckwheat and weeds, during the months of August and September, and we credited the failure to the droughts which occurred each year. Now this year we have the same August drought as bad as ever, and we have almost an average yield of this so-called "fall honey." Buckwheat yielded well, right in the drought. Now I am non-plussed; my observations would lead me to say to a novice who might ask me where honey comes from, that "it just comes out of the air;" and if he asked me under what conditions, I might say, "when it wants to."

The pleurisy-root which I have written about, as the best honey-plant I am acquainted with, actually shared the fate of the clover and buckwheat of this season, at least to a certain extent. Certainly the bees worked on it, con-

stantly, never leaving it for basswood, but it was exceptional rather than in all blossoms, as heretofore, where you could see the drops of honey standing.

Poor Seasons are Blessings.

The last two very poor honey seasons, will, I am confident, prove a blessing to bee-keepers. It has given us old veterans a splendid education; it has taught us how to make the most of disaster; it is a valuable acquisition to know how to make the most out of our business when good luck favors us, and it is also equally valuable to know how to make the most during disastrous seasons. Besides this, the markets are cleared out, consumers are getting the habit of paying a little more for their honey, and better than all, producers as well as consumers, are finding out that bees do not "work for nothing and board themselves," but that intelligent labor and capital are needed to make our business remunerative.

The quality of honey in this section is some better than that of last year. We shall strive to winter our bees to the best of our ability, believing that honey-production offers more inducements at the present time, than at any time during the past few years.

Dowagiac, Mich.

TIERING UP.

My Method while Working for Comb Honey.

Written for Gleanings in Bee-Culture

BY G. M. DOOLITTLE.

The usual plan of working for comb honey is what is known as the tiering up system, and without doubt there are more who use this system than there are of those who use all other systems combined; yet this does not certainly make it true that this plan is the best one there is, by any means. It often happens that the majority is not in the right, and so, after I had proven to my entire satisfaction, that there was a better plan to work on, in producing comb honey, than the tiering-up system, I forsook the same and turned my attention to other plans. My chief objection to the tiering-up plan was that not so much honey could be obtained by using it; and, worse than all the rest, if the utmost care was not used, the result would be lots of unfinished sections in the fall. These unfinished sections have been an eye-sore to all the users of this plan, as the immediate past will testify, for many are so disgusted with them that they recommend that they be burned up, while a whole issue of one of our bee-periodicals, is used in telling how to save them by way of feeding back extracted honey, in order to get them filled.

The next system most in use is what is termed the "side and top storing plan combined," which I adopted upon leaving the tiering-up plan. By the use of this plan, more honey can be obtained than by any other plan I know of, except by using the lateral plan, of which I shall soon speak. The trouble with

the side and top storing plan was, that it required much work; yet, as I go over the results of the past while using it, I am convinced that the extra amount of honey obtained by it more than paid me for all the extra work the plan required, over the tiering up plan. An average yield of over 80 lbs. of comb honey per colony, for a period of 15 years, is a record never attained by any of the advocates of that plan.

A few years ago D. A. Jones came out with a wholly side-storing plan, the young brood to be kept in the center of the hive by means of perforated zinc, while the sections were to be placed between that and the older brood, which was to be kept on the outside. One trial of this proved, so far as I was concerned, that the plan was fallacious; and although he told us he would explain, some years ago, I have never seen a word from him on the subject since; hence I have not enumerated this in the above three plans at all.

While working with the side and top storing plan I left a passageway under the side sections, so that any bees which might be scattered around over the top and side of the hive, after any manipulation, could get back to the cluster, instead of dying there, as is the case where no means of outlet is provided. This caused many to write me, asking if I meant to have this so; "for," said they, "the bees will go around under these side sections, up into the cap over them, and build comb there, which they fill with honey." I told them that this was as I wanted it, giving the reasons for so leaving it, and telling them if any colony so persisted in doing, to give more room by adding sections at the sides.

Well, I often got caught in this same fix myself, when I would be a little tardy in keeping up with the bees, so that I have often had from 5 to 15 pounds of honey built in the cap of the hive, the bees having to travel from 25 to 30 inches entirely away from the brood to get there. This leaving the brood and storing honey in such amounts in the cap, led me to adopt what I term the lateral plan of obtaining section honey, which plan gives me fully as much honey as could be obtained by the side and top box plan, with as little work as is required when using the tiering-up plan.

The larger part of my hives are of the kind known as the "chaff hive," which gives plenty of space on top for all the room required by the largest colony, without tiering up. Over the top of these hives I have placed a queen-excluding honey-board, the queen-excluding part going over only the brood apartment to the hive, the rest being a thin board to cover up the chaff. When the honey season arrives this is put on (quilts being used, together with sawdust cushions up to this time), and from three to five wide frames, holding four 1½-pound sections each, are placed directly over the brood. As soon as these are well occupied with bees at work, I add one or two wide frames at each side; and when these are satisfactorily occupied I add enough more to cover the top of the hive if so much room is needed. In this way I accommodate the size of the colony with the

needed room, neither giving too much nor too little, as must of necessity occur where the T super and others of a set capacity are used.

As soon as the first that were put on are filled, they are taken off (handling by the wide frame only, so five pounds are handled instead of single boxes), when the partly filled sections at each side are slid along on the honey-board till they come together in the center, when the empty ones are placed at the sides.

As the honey season draws to a close no more empty sections are put on, so that, when the season is over, I often have but one or two wide frames or sections on the hive, thus doing away with more partly filled sections than I really need for bait sections the following season.

Borodino, N. Y.

FOUL BROOD CURE.

The Sulphuric Acid and other Methods of Cure.

Written for the American Bee Journal

BY GERD WENDELKEN.

Many substances can be used as a remedy for foul brood, but the question is, which is the best? Salicylic acid and carbolic acid, associated with borax and alcohol, is recommended by Mr. Muth and Mr. Kohnke, as the best remedy, but some other beekeepers have found them of no use. The failures, I think, are caused by wrong methods which they pursued. The attempt to cure foul brood by spraying the infected hive and combs with diluted salicylic or carbolic acid is uncertain, because we may spray too much or not enough; and in addition to this it is very troublesome to apply it, besides having a chilling effect on the colonies, and is often a mischief instead of a benefit. The worst of all is the fact, that when applied to hives and combs, we start robbing, and bees from other hives visit the combs under treatment, and take the spores home with them, and by the time one colony is cured, some of the others are infected; therefore I always have been in favor of the remedy being given in the food, and provide the bees with the drug, and the bees will give it to the larvæ.

Methods of Curing Foul Brood.

Mr. Stachelhausen recommends carbolic acid, mixed with wood-coal and tar. He puts this on felt paper in the hive on the bottom-board, and moistens the front at the entrance with it about twice a week. He disinfects every hive in the yard whether diseased or not diseased. The vapor of this stuff, he says will prevent the spread of the disease from four to six months. After this is done, he commences to cure the diseased colonies, by feeding every diseased one with medicated syrup, as Mr. Muth has recommended.

Mr. Cheshire recommends carbolic acid, 1 part to 500 parts of syrup, and he has cured foul brood by feeding it to diseased bees.

I prefer sulphuric acid when mixed 1 part to 700 parts of syrup, and fed to the bees; because the cure is easier, quicker and cheaper. The price of one ounce of salicylic acid is 50 cts., one pint of the best quality of alcohol cost 90 cts.—in all \$1.40. Now one ounce sulphuric acid costs only from 5 to 10 cents, and the curative effect will go as far as the other acids do. With little expense and little labor, I cured my foul broody bees in Germany in 1838 (50 years ago), and I think that I can do it yet; because there is no difference between foul brood in Germany and in America.

Several prominent beekeepers have recommended to give the foul bees a new, clean hive with foundation; treat them as a new swarm, and burn the combs of the foul brood. I have no doubt that foul brood can be cured by this method, but it seems to me unnecessary, and it is doubtful to me that the cures by burning, spraying, and starvation would pay.

Marietta, O., Sept. 1, 1888.

SCIENCE.

Indefensibility of Criticising True Science.

Written for the American Bee Journal
BY PROF. A. J. COOK.

I was surprised and as deeply pained, to read the article from our friend, Mr. G. W. Demaree, on page 568. Prof. Wiley's article in the *Popular Science Monthly* was not science. It was worthy censure, for it taught glaring mischievous error, and dressed this in science's garb. But to censure or ridicule true science is like discourtesy or rudeness to one's mother—utterly indefensible. Science has been one of the most potent factors in the Nineteenth Century civilization. To it we are all indebted more than we can tell. What base ingratitude, then, to defame it. "How worse than an aching tooth is a thankless child."

Honey is "Digested Nectar."

I was also surprised that the same gentleman should contradict one of the demonstrated facts of science—that honey is digested nectar. "No uncrazed thinker on the earth possessing brains enough to frame a thought could believe such an impossibility." That is a strong sentence for a man of Mr. Demaree's intelligence. He might as well say the same of the belief that I can talk with, and recognize the voice of, a friend 200 miles distant. Oh, friend Demaree! "There are more things in heaven and earth than are dreamt of in your philosophy." Nectar is neutral; honey is acid. Nectar is cane-sugar; nectar invert sugar. *They are not the same.*

That all honey is equally digested is very likely not true; but that honey is more or less perfectly digested nectar is as certain as that the world is round. To proclaim truth, should do injury to no man or industry; if it does, all the worse for the man or the industry.

Agricultural College, Mich.

QUEENLESSNESS.

Removing Queens from Colonies to Save Honey.

Written for the American Bee Journal
BY ALEX. W. STITH.

On page 504, is an article from my pen, on removing queens to save honey, and I will say, in "justice" to myself, that it was meant for surplus alone; I produce only extracted honey, and to this only, I intended the rule to apply.

On page 521, appears an article by W. Z. Hutchinson, embodying nearly the same principles, yet differing somewhat in its practicability, both he and I seemingly unaware of each other's production, as they were published on nearly the same date, and the reader will be left to solve the problem.

But lo, there ariseth the "wise man of the East"—Mr. Friedemann Greiner, who has an article on page 538. He is probably not as well known to the readers of the BEE JOURNAL as Baron Von Berlepsh, Dzierzon and others, to whom he refers so much. Mr. G. seems free to let Mr. Hutchinson alone, but perhaps Mr. H. is too good authority to tackle, if he does not "cage the queen." But Mr. G. seems ready to correct one whom he may consider a "mossbacked Kentuckian," with the experience and conclusions of Dzierzon, Hilbert, and Pollmann, but at the same time disregarding the advice of the great Baron Von Berlepsh, whose untiring investigations I have no reason to disregard; and with due justice to the above distinguished apiarists, I will say that if the idea originated with Berlepsh, or any one else, why, Mr. G. will please flatter the right one (or himself, as the dictates of his conscience will permit).

I have been a reader of the BEE JOURNAL, if I mistake not, for the past eight years, and I had not seen in print, prior to my article alluded to, the method I described, and I am not so desirous of notoriety as to state anything but facts which developed under my own observation, Mr. G.'s article on page 538, to the contrary notwithstanding.

I am aware that myself or Mr. G.'s writing the experiences and conclusions of others will not interest the reader; if it would, why need we go to Europe or South America? Have we no practical or scientific bee-keepers in the United States, to test the method described? Where are our Cooks, Newmans, Heddons, Doolittles, Secors, Abbots, Demarees, and many others whose names are so familiar, and whose scientific researches and practical experiences have been of so much benefit to the agricultural world—perhaps as much as those renowned pioneers of Europe, whose talent no one appreciates more than I?

What I may write on bee-keeping is for the sole purpose of benefiting beekeepers in general (especially the novice), and it is from my own experience in managing an apiary, consisting of from 50 to 100 colonies each year, for the past ten years—in Kentucky, not Germany, or South America, or in the

State of New York. I write of what I have tested to my own satisfaction in my own apiary, and I will practically answer all of Mr. G.'s criticisms, but respectfully request him, to describe his own experience in detail, of "caging queens" in full colonies, to be smothered by her own bees in extreme hot weather, such as we have in the months of July and August. Probably such procedure may do in New York, but not in Kentucky.

In conclusion I will add that no one enjoys a friendly discussion more than I, for in a diversity of opinion the reader is most likely to be enlightened. So my thanks are hereby tendered to Mr. G., not for his practical method of "caging queens," but for criticizing my error, if it is one.

Portland, Ky.

OLD COMBS.

The Condition of the Bees in Northern Iowa.

Written for the American Bee Journal
BY WILLIAM CLEARY.

Generally speaking, bees wintered well here last winter, but got very weak in the Spring, and some dwindled. It was so wet until the middle of June, that they did not get enough to keep up breeding. We got no honey from white clover, and very little from Basswood. There was no surplus, and on August 1, half the bees in the county did not average two lbs. per colony. We were "blue," but with buckwheat and fall flowers they have stored about 20 lbs per colony so far this month. Some of my neighbor's bees have been swarming continually for the last three weeks, and he has cut out all the queen-cells several times, but they would swarm the next day, and every fine day. I increased my bees one-third by dividing. They have not swarmed, but are in good working condition now—about as they should be in June in a favorable season. We expect very little surplus unless the fall is extra good and late. I want to ask a few questions:

1. Would you use old black comb that the bees died in, or empty frames, if the combs were straight and otherwise good? Last year and this I hived most of my new swarms on old comb, and a neighbor put his on new empty frames, and he got the most honey. I have almost lost faith in saving old combs.

2. Some say that you can keep the bees from swarming by cutting out queen-cells; but my neighbor cannot. Why is it?

3. Is it advisable to keep putting bees back, where they persist in swarming in June and the first of July?

4. I noticed a great many small shiny bees, and my neighbor spoke of the same thing. What were they, and what caused them? They were mostly among weak colonies. They died, or were killed off, as they are all gone.

5. I also noticed that when there was no honey coming in for several days, the bees left some brood they did not cap over, and I found dead brood in

some hives. Was this caused by the lack of honey? They had plenty of pollen all summer, but there was no honey in the bloom until now.

We are having a dry spell; the bass-wood yielded very little, as it was very late and lasted only a few days.

6. What way should the wind prevail, to have the best honey-flow?

Algona, Iowa, Aug. 30, 1888.

[1. We prefer to use comb foundation, rather than any "old black combs." It is false economy.

2. That is the usual method of the prevention of swarming—but when the "swarming fever" is on them it is difficult to control them.

3. To persist in putting the bees back, sometimes results in the loss of the swarm, by their going to the woods without alighting.

4. They are old bees and are often found in strong colonies, but soon disappear—dying of old age.

5. During a dearth of honey, the bees sometimes not only leave the brood uncapped but actually put it out and destroy it—thereby preventing any increase to consume the failing stores in the hive.

6. We have often noticed that no honey is gathered unless the wind comes from the south, southeast or southwest.—ED.]

FUMIGATION.

Bi-Sulphide of Carbon for Comb Fumigation.

Written for the American Bee Journal

BY G. R. PIERCE.

While looking over some of the back numbers of the AMERICAN BEE JOURNAL a short time ago, I noticed a query in regard to the best method of protecting spare combs, as well as surplus honey, from the ravages of the larvæ of the bee-moth. The reply to the question, describes the method usually adopted by bee-keepers to accomplish this purpose, *i. e.*, to expose the combs to the fumes of burning sulphur, in a closed room.

In my experience I have found the above method to be crude, more or less troublesome, and by no means reliable, unless the bee-keeper has an apartment that is suited to the purpose; and even then, if the worms have obtained a *foot-hold*, or if the quantity of comb to be fumigated is small, the trouble and labor expended by this method is greater than the benefit derived from the comb.

The principal objection to sulphur fumigation is, that combustion cannot be well regulated. If a small quantity is used, it is soon consumed, and the effect is not lasting enough; but, if on the other hand a larger quantity is used, care must be taken lest a conflagration be the result.

Another objection is, that sulphur will not burn readily except in connection with substances that are rich in carbon, *i. e.*, dry wood, resin, charcoal, lycopodium, etc.; and, as these substances are not chemically united with the former, when the oxygen of the air is insufficient in quantity to oxidize both elements, the carbon will take the most, leaving little or none to unite with the sulphur, to form sulphurous acid gas—the larvæ destroying agent.

As has been intimated above, the object of burning sulphur is to generate sulphurous acid gas, a most potent agent for destroying parasitical life, both animal and vegetable. It is true that there are other substances which would prove equally efficacious, as far as merely destroying the larvæ is concerned, but they are not available; either on the score of economy, or because they would render the combs unfit for the further use of the bee.

A few years ago, having occasion to fumigate some spare combs, and not being satisfied with the methods described in the different works on bee-keeping, I conducted a series of experiments with a view to find some simple and more reliable way to accomplish the object sought. After many trials with different substances—the details of which is not necessary to consider—I decided that the most satisfactory results were obtained by the combustion of bi sulphide of carbon.

As I have stated, the main objection to sulphur is, that its combustion cannot readily be regulated. The first step, therefore, was to obtain a solution containing sulphur which might be burned in a lamp; this would enable the operator to continue the fumigating process at will, as well as to confine the sulphurous acid evolved, to a very small space if desirable—as it would be when the quantity of comb to be exposed was small.

At first thought, sulphuretted oil (Sulphuretted oil is made by dissolving sulphur in hot oil. As the latter cools, most of the sulphur is precipitated. It is sometimes called "balsam of sulphur") would seem to have a composition that would burn readily in a lamp, and so, indeed, it would when in a free circulation of air, but when ignited in an enclosed space, the products of combustion were mainly carbonic acid gas, sulphur soot, etc. The trouble in this case also was, that the oil was too rich in carbon, especially when the lamp was burned in an enclosed space, the carbon appropriating nearly all of the oxygen, leaving very little to unite with the sulphur.

The foregoing experiments not being successful, I now turned my attention to bi-sulphide of carbon, to consider its possibilities as a fumigating agent. This substance is a clear, colorless liquid, with a peculiar fetid odor; volatilizes quite rapidly at ordinary temperatures if exposed to the air; and boils at about 118.5 per cent. Fahr. Its chemical formula is $C S_2$; contains 15.78 per cent. of carbon, and 84.21 per cent. of sulphur. It should be kept in a cool place, and under no circumstances should the container be opened near a flame.

The main difficulty experienced in using bi-sulphide of carbon as a fumigating agent was, to devise a lamp in which it would burn safely, for it is so inflammable that in one of ordinary construction the liquid in the fount would surely ignite from the flame of the wick; this trouble being overcome, the trial was a success in every particular.

I have no hesitation in saying that fumigation with bi-sulphide of carbon will commend itself to every enterprising apiarist who will give it a fair trial; a careless man, however, should never handle it, as it is a bad thing to play with, but with care it is as safe as kerosene or any other illuminating oil.

The price of bi-sulphide of carbon varies according to the quantity purchased. The quotations are from 20 to 30 cents per pound, wholesale. I have seen it quoted at 15 cts. per lb. in 5 lb. bottles, the price of the bottles added. It is only persons in the wholesale trade who can buy at these prices, but if the bee-keeper will buy the article in unbroken packages, he can probably obtain it from the local druggist at a comparatively small advance.

Blairstown, Iowa.

WINTER FOOD.

The Relation of Food to the Wintering of Bees.

Written for the Bee-Keepers' Review

BY W. Z. HUTCHINSON.

All are agreed that for the successful wintering of bees in our Northern States, good food is of the first importance; but as to how this shall be best secured, there is some difference of opinion. Pure cane-sugar properly prepared, or fed early enough to give the bees time to prepare it, stands unrivalled as a winter food for bees.

Dr. Miller says his bees made a "poor stagger" in wintering upon sugar last winter, but admits that the same might have been the case had honey been fed instead of sugar, and that sugar fed in the right time and in the right place is probably a safe food. The Doctor asks, who has practiced taking away all natural stores and feeding sugar, and met with unfeigned success? I have, Mr. Heddon says, many others have; in fact we feel like asking the Doctor who has not, when the bees are wintered in a temperature ranging from 35° to 50°?

When I was at Mr. Heddon's last spring, he read a letter just received from Mr. C. E. Boyer, of Ainger, Ohio, in which he recounted heavy losses of sugar-fed colonies that had been kept in a warm cellar. It was the first instance of the kind that had come to our knowledge. It was a puzzle to us, and is yet; that is, if the sugar was pure. As a general thing, I think it better that the sugar be fed early, but it can be given late and yet have the bees winter well.

It was Mr. E. J. Oatman, I believe, who once fed sugar so late, to 200 colonies, that it was not sealed over at all, yet they wintered well in a cellar. If fed early the bees have an opportunity

to handle it over, and in this hauling, its character is somewhat changed by the addition of the secretions from their glands. There is also an opportunity of sealing over the syrup, when it is less likely to be injured by changes in temperature, moisture, etc. If fed late, the syrup must be made thick, as the bees have no time to evaporate it; and there must be something added to prevent the syrup from crystallizing. After repeated trials I give my preference to honey. From ten to twenty per cent. of honey is sufficient. I never want to be put to the trouble of extracting the honey in the fall before feeding sugar, and, if contraction of the brood-nest is properly managed, the combs will be perfectly free from honey at the end of the honey harvest; when, with Heddon feeders, oil-stoves to prepare the syrup, and the proper utensils, feeding is never dreaded in this "family."

Two or three years ago I experimented by feeding and preparing for winter a few colonies each day. I began the latter part of August and continued feeding a few colonies each day until nearly the middle of October. All wintered equally well, except the last few colonies that were fed. I think that September is early enough to feed. When feeding has been neglected until it is so late, and the weather so cool that the bees will not leave the cluster and go up into a feeder, it may be managed by filling the feeder with hot syrup and placing it *under* the hive. The heat from the syrup will warm up and arouse the bees, when they will come down and carry up the feed.

But all cannot, or may not wish to, use sugar for a winter food, and I have done my best to help them. I especially recommend the views of Mr. O. O. Poppleton. According to his idea, those who have been so successful by saving out combs of early-gathered honey upon which to winter their bees, may attribute their success to the fact that the early honey harvests were very abundant, while the fall flow was scanty. Mr. J. H. Martin unconsciously voices that idea when he says: "I find that good buckwheat honey will winter bees better than honey from a great variety of fall flowers." Possibly the honey, in a slight flow, becomes more heavily charged with pollen. Candied honey or thin, watery honey is an unfit food for bees long confined by cold. As a rule, honey-dew furnishes a poor winter food. To those whose management is such that their bees must winter upon natural stores, we would say, see to it that the stores are from the most bountiful flow, well ripened and sealed, and you have done all that you can do.

Dr. Miller asks for an explanation of why bees have starved with an abundance of pollen within easy access, and yet showed no signs of diarrhoea. I would say that I suppose bees can live but a short time without honey, that upon pollen alone they would soon starve—before enough would be consumed to overload the intestines. In other words, if bees had access to pollen only, they would eat but very little of it, and the result would be starvation rather than overloading the intestines. Flint, Mich., Sept. 1, 1888.

CONVENTION DIRECTORY.

1888 *Time and Place of Meeting.*
 Oct. 3-5.—North American, at Columbus, O.
 W. Z. Hutchinson, Sec., Flint, Mich.
 Oct. 11, 12.—Union, at Clayton, Ills.
 S. N. Black, Pres., Clayton, Ills.
 Dec. —Michigan State, at Jackson, Mich.
 H. D. Cutting, Sec., Clinton, Mich.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

SELECTIONS FROM OUR LETTER BOX

Plan for a Bee-House.—Chas. D. Barber, Stockton, N. Y., on Aug. 31, 1888, says:

I want to build a bee-house. Will some one who has one, or who knows, please give a description of it in the BEE JOURNAL? How high, wide and long should it be? I want it for 20 to 30 colonies. Honey is selling here for from 12 to 15 cents per pound.

Protectors of the Bees.—F. M. Herrick, Woodstock, N. Y., on Sept. 2, 1888, writes:

I desire to become a member of the National Bee-Keepers' Union, as I fully indorse all its principles, and realize that in union only is there strength to protect an honest industry. I do not think that I shall ever have any trouble myself, but others may, and I wish to cast my lot with the protectors of the bee. The proceedings of the city authorities in the Arkadelphia case, brings to my mind amusing thoughts, and begging clemency with hope of escaping immediate execution (from the editor) I will submit the following:

Some folks there are with critic spleen
 Like dogs, who bark at things unseen;
 Not knowing what the bee was made for,
 From whence it came, or what it staid for;
 They think some enemy hath sent it,—
 Thus take occasion to resent it.

How to Control Swarming, etc.

—J. F. Eikenberry, Green, Iowa, on Aug. 3, 1888, says:

I took out of my out-door cellar, 27 colonies in good condition in the spring, and lost 6 colonies by spring dwindling. It was very cold and wet so long, that bees could not do anything until June. They commenced to swarm the first of July, and have kept it up until now, a swarm having issued yesterday. I wish that some one would tell me how to control swarming. My bees have done well the last month, and are still working faithfully in the sections. I have now 37 colonies all doing well.

Virgin Queens—Fall Prospects.

—G. W. Demaree, Christiansburg, Ky., on August 31, 1888, says:

In answer to query 511, on page 566, I wished to say, "the virgin queen lays no eggs until her amatorial period has passed." The omission of the word "no" changes my meaning to the reverse of what I intended to say. We have had an abundance of rain since Aug. 16, and there is now fair prospects of fall honey for winter stores, to say the least. The young white clover is partially saved.

Working on Buckwheat, etc.—I. N. Rogers, Jackson, Mich., on Aug. 31, 1888, writes:

So far this has been a very poor honey year for this (Jackson) county. But very few had any white clover honey stored in the sections, and the present indications are that but little fall honey will be obtained. I have 5 colonies that have given me 24 pounds each, gathered from buckwheat, for which I readily obtained 20 cts. per pound. My bees are still working lively on a piece of buckwheat, sown late expressly for them. I would say in regard to bees working on buckwheat, that I have grown it for several years (as much for the bees as for the seed), and have observed that, on a hot, sunny day, bees work on it only in the forenoon; but if the day be cloudy and warm, they will work on it the greater part of the day. Only about one-fourth of the bees put into winter quarters last fall, were alive when fruit trees commenced to bloom last spring, and the most of them were very weak. I put 25 colonies into the cellar; I had 19 in chaff hives, and had but 9 colonies to commence the season with—the first loss of any consequence, that I ever met with. Everything is drying up, not having had any rain to speak of, in this immediate vicinity, since early in June.

Bees are Busy.—Geo. G. Scott, Wadena, Iowa, on Sept. 4, 1888, says:

My bees have gathered about 20 lbs. of honey per colony, spring count. The season's yield in this section may be estimated at about half a crop. Fall flowers are yielding well, and bees are very busy.

Small Average per Colony.—D. L. Shapley, Randallsville, N. Y., on Aug. 6, 1888, says:

Bees have got through putting the honey into the sections for this season. It is the poorest season I have seen in six years. I shall not have over 50 lbs. of surplus honey from 6 colonies, spring count; and my bees have done as well as any in this vicinity. There is no honey here to speak of, this year. The average per colony is only about 5 pounds of surplus, and of poor quality at that.

Blessing in Disguise—Increase.

—E. B. Morgan, Cleveland, Iowa, on Aug. 31, 1888, writes:

The honey crop in this locality (southern Iowa) is very poor. Different bee-men have told me that they have no honey. The spring was too wet and cold, and the white clover yielded but little; the heads being so loose and straggly; they had lost that symmetrical shape, but I see that the fall clover, or the clover now in bloom, has resumed the old shape. Quite a number of the bee-men feel despondent, and I think I will class myself among them. Still, we had better look upon the bright side, as Dr. Mason says "that two poor seasons may be a blessing in disguise." One thing is sure, that quite a number of our farmer bee-keepers that kept from 10 to 20 colonies are swept out of existence, and have their ill-shaped hives for sale. My 50 colonies are in good condition for winter. The question of preventing increase, that has caused so much study and anxiety to many will, I think, soon be settled. I think that the principle is already discovered, but not being quite sure as to its results, having had such poor season, we must wait; but one thing is sure, it will not be caging old queens and keeping them over from year to year. Young queens for fertility, hence strength of colonies and honey; old queens for drones and swarming.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4½x4½ and 5½x5½. Price, \$1.00 per 100, or \$8.50 per 1,000.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in *Cheshire's* pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being mailable, it must be sent by express.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the *Apiary Register* and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 25
 " 200 colonies (420 pages)..... 1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the *American Bee Journal* must be sent with each order for another paper or book:

Hastings' Perfection Feeder.

This Feeder (illustrated) will hold 2 quarts, and the letting down of the feed is regulated

Patented Oct. 18, 1887.

by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for \$3.50, and it can be obtained at this office. Postage 10 cents extra.

Cork for Winter Packing.—Its advantages are that it never becomes *musty*, and it is *odorless*. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Can You Do Anything that will do more to advance and defend the pursuit of bee-keeping, than to aid its Weekly Exponent and Defender? The AMERICAN BEE JOURNAL is the pioneer bee-paper of America, and is fully entitled to the active support of every progressive apiarist, for it works constantly and faithfully for the best interests of the pursuit. We therefore specially request all our readers to use their influence to double our subscription list, during the coming autumn. Reader, will you please send us a new subscription with your renewal or before that time? A good weekly at one dollar a year is surely cheap enough to command patronage.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities, according to size, as follows:

	Size A.....	Size B.....	Size C.....
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2 00	3 00	3 50
1,000 Labels.....	3 00	4 00	5 00

Samples mailed free, upon application.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Sweet, or Melilot, Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Exchange.—We will accept Honey and Beeswax in exchange for Bee-Keepers' Supplies in any quantity. Those desiring to make a trade are invited to correspond with us, stating quantity, quality, and price, and the goods they want in exchange.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 10 cents per pound for bag and postage.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, Ills., is published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Honey and Beeswax Market.

NEW YORK.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 13@14c. Fair white 1-lbs., 15@16c.; 2-lbs., 11 to 12c. Extracted, white, 7½@8c.
THURBER, WEYLAND & CO.
 Sep. 5.

NEW YORK.

HONEY.—Fancy white 1-lbs., 17@18c.; off grades, 15@16c. Fancy white 2-lbs., 13@14c.; off grades, 12c. Extracted, white, 7½@8c. New crop is arriving and demand is good.
BEEWAX.—23@23½c.
HILDRETH BROS. & SEELKEN,
 28 & 30 W. Broadway, near Duane St.
 Sep. 5.

SAN FRANCISCO.

HONEY.—White 1-lb. sections, 12@15c.; 2-lbs., 11 to 14 cts.; amber, 7@9c. Extracted, white, 5½@6c.; light amber, 5@5½c.; amber and candied, 4¼@4¾c. Receipts light and market firm for best qualities.
BEEWAX.—17@21c.
O. B. SMITH & CO., 423 Front St.
 Aug. 25.

DETROIT.

HONEY.—Best new white comb, 15@16c., with 1½-lb. in sight and slow sales. Market is low, and beekeepers will do better to hold honey until approach of cold weather.
BEEWAX.—21@22c. Supply limited.

 Aug. 22.

CHICAGO.

HONEY.—New crop offered at 16@17c., demand being very light. New extracted is not in much demand, and prices are nominal at 7@8c. for the best grades.
BEEWAX.—22c.
R. A. BURNETT,
 161 South Water St.
 Aug. 14.

CHICAGO.

HONEY.—None here, and market in good condition for new crop. There is some demand for the extracted.
BEEWAX.—22c.
S. T. FISH & CO., 189 S. Water St.
 Aug. 2.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb., for which demand is fair. Comb honey, 12@15c. Some small lots have sold at 14@16c. Market quiet.
BEEWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
AUG. 24. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—Choice 1-lb. sections, 18c.; dark 1-lbs., 14c.; 2-lbs., 12c.; dark, 13c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices firm, and stock light.
BEEWAX.—None in market.
AUG. 29. HAMLIN & BEARSS, 514 Walnut St.

NEW YORK.

HONEY.—We quote: Choice white clover and basswood extracted, 7½@8½c.
AUG. 29. F. G. STROHMAYER & CO., 122 Water St.

BOSTON.

HONEY.—We quote: New 1-lb. sections, 18@20c.; 2-lbs., 14@16c. New extracted, 8@10c.
BEEWAX.—25 cts.
AUG. 24. BLAKE & RIPLEY, 57 Chatham Street.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 5½ cents; light, 5¼c.; amber, 4½@5c. Comb, 1-lbs., 12@14c.; 2-lbs., 9@13c., as to quality. Arrivals not large, and supplies held firmly.
BEEWAX.—Dull at 19@22c.
AUG. 20. SCHAUCHT & LEMCKE, 122-124 Davis St.

KANSAS CITY.

HONEY.—We quote: New white 1-lbs., 18c.; light 1-lbs., 16c. California white 1-lbs., 18c.; light 1-lbs., 16c.; white 2-lbs., 16c.; light 2-lbs., 14c. Extracted, white, 8c.; amber, 7c.
BEEWAX.—18@20c.
SEP. 5. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—We quote: Extracted, 4½@5½c.; if in cans, 3@9c. White clover comb, 14@15c. Market is steady and receipts light.
BEEWAX.—21c. for prime.
SEP. 6. D. G. TUTT & CO., Commercial St.

MILWAUKEE.

HONEY.—New white 1-lb. sections 18c., and very fine, 2½c.; 1-lbs., 15@18c.; old 2 and 3 lbs., not salable, 1½@14c.; dark 1-lbs., old or new, 12@13c. Extracted, new white in kegs and ½-barrels, 8@9c.; old, in same packages, 7@8c.; in tin, 8@9c.; dark in barrels or ½-barrels, 6@6½c. Arrivals of new crop small; demand not urgent, and only very moderate trade.
BEEWAX.—22@25c.
AUG. 31. A. V. BISHOP, 142 W. Water St.

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Conventions.—The time for holding Bee-Keepers' Conventions has now arrived, and we cannot give any better advice than this: Let each one attend who can do so, and take part in making these meetings interesting and instructive. If you have not already obtained the "Bee-Keeper's Convention Hand-Book," do so at once to post yourself up on how to conduct such meetings correctly. It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for Discussion—List of Premiums for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents. We will club this book and the AMERICAN BEE JOURNAL for one year for \$1.25. It also contains a lot of blank leaves on which you can note important matters as they come up. Do not fail to send for a copy of it.

Simmins' Non-Swarming System.—We have a few of these books left, and we will club them with the AMERICAN BEE JOURNAL for one year, both postpaid, for \$1.25. The subscription to the BEE JOURNAL can be for next year, this year, or may begin anew at any time.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the BEE JOURNAL, and will send two or more free of cost to any one who will use them, and try to get up a club. Sample copies will be sent free upon application.

We will Present a Pocket Dictionary for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

New Subscribers can obtain the full numbers for 1887 and 1888, for \$1.75, while there are any sets of 1887 left.

Advertisements.

WANTED.—Situation. I can manage, or assist in, a practical apiary, can give good references. Please address me, **HARRY GALEY,** 37A2t GRANBY, PROV. QUE., CANADA.
 Mention the American Bee Journal.

WORK FOR ALL \$30 a week and expenses paid. Samples worth \$5 and particulars free. **P. O. Vickery, Augusta, Me.**
 37A13t
 Mention the American Bee Journal.

LANGSTROTH FUND.

A GOOD full length PHOTOGRAPH of Rev. L. L. Langstroth, mounted on cabinet card, will be sent to any address for 50 cts.—one-half to go to the "Langstroth Fund." Address,
THOMAS B. REYNOLDS,
 36A2t Box 356, DAYTON, OHIO.
 Mention the American Bee Journal.

WEBSTER

3000 more Words and nearly 2000 more Illustrations than any other American Dictionary.

Among the supplementary features, unequalled for concise and trustworthy information, are

A Biographical Dictionary giving brief facts concerning 9,700 Noted Persons of ancient and modern times,

A Gazetteer of the World locating and describing 25,000 Places; and a Vocabulary of the names of Noted

Fictitious Persons and Places

The latter is not found in any other Dictionary. Webster excels in SYNONYMS which are appropriately found in the body of the work.

Sold by all Booksellers. Pamphlet free.
G. & C. MERRIAM & CO., Pub'rs, Springfield, Mass.

Mention the American Bee Journal.

We have some **ELEGANT RIBBON BADGES**, having a rosette and gold Bee, for bee-keepers' use at Fairs, Conventions, etc. Price

50 cents each, by mail, postpaid.

THOS. G. NEWMAN & SON,
 923 & 925 West Madison-Street, - CHICAGO, ILLS.

Are You Going to the Fair?

IF so, read **THE BEE-KEEPERS' REVIEW** for August. It is especially devoted to Apian Exhibitions at Fairs, and is contributed to by H. D. Cutting, Prof. A. J. Cook, James Heddon, M. M. Baldridge, M. H. Hunt, R. F. Holtermann, Dr. A. B. Mason and J. H. Martin.

The September Number will be devoted to "Food, and its Relation to the Wintering of Bees."

Price of the REVIEW, 50 cents a year. Samples free. Back Numbers can be furnished.

The Production of Comb Honey,

A neat little Book of 45 pages, price 25 cents. The REVIEW and this book for 65 cents. Stamps taken, either U. S. or Canadian.

Address, **W. Z. HUTCHINSON,**
 35D1f 613 Wood St., FLINT, MICHIGAN.
 Mention the American Bee Journal.

HANDSOME

ONE - PIECE SECTIONS.

WE have a limited quantity of One-Pound Sections, 4¼x4¼, a trifle less than two inches wide, with narrow tops, in packages of 1,000 each. They are manufactured from extra white lumber planed on both sides, making them the finest and most attractive honey-section in the world. Price, \$4.00 per package.

THOS. G. NEWMAN & SON,
 923 & 925 West Madison-Street, - CHICAGO, ILLS.

BEES FOR SALE.—24 COLONIES in improved movable-frame hives. For terms and particulars, write to

REV. J. D. GEHRING,
 36A2t PARKVILLE, Platte Co., MO.
 Mention the American Bee Journal.

TESTED GOLDEN ITALIAN QUEENS.

ONE Queen, \$1.00; 2 Queens, \$1.80; 3 Queens, \$2.60; one-half dozen, \$5.00. By Return Mail. **HENRY ALLEY,**
 36A3t WENHAM, MASS.

Mention the American Bee Journal.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. Sept. 19, 1888. No. 38.

EDITORIAL BUZZINGS.

•• **Though** the mills of God grind slowly,
Yet they grind exceeding small;
Though with patience he stands waiting,
With exactness grinds he all."

Our Query Department is not conducted for the purpose of answering catch-questions or puzzling conundrums. It is solely intended to aid earnest seekers after knowledge in our pursuit.

The Indiana State Fair commenced on Monday. We learn that there is a creditable display of honey among the exhibits.

In France, the month of August has been better for honey-production than July. The honey crop is less than the average, and in some parts the amount of white honey is exceedingly small.

Line Fences divide property, and keep cattle and horses on their owner's land, but bees pay no attention to such divisional lines. The air is their highway, the sunshine their invitation to roam, and the towers their banqueting halls. Happy, basking, smiling, buzzing, frugal bee! Cunning, stinging, robbing bee!

We have Received a copy of a pamphlet issued by The St. Louis Academy of Sciences, on the Pollination and Perforation of flowers. It is written by Mr. L. H. Pammel (who is well known as a correspondent of the AMERICAN BEE JOURNAL), as a contribution from the "Shaw School of Botany." It is very interesting, and we will make some extracts from it in our next issue.

Hotel Arrangements at Columbus.—Concerning these, Dr. A. B. Mason wrote us from the Centennial Exposition Grounds at Columbus, O., on Sept. 13, 1888, asking us to publish the following notice to bee-keepers who intend to be present at the convention:

If those in attendance at the next meeting of the North American Bee-Keepers' Society will report to me at the place of meeting in the hall of the House of Representatives at any time after 10 a.m., Oct. 3, I will try and be able to tell them where to obtain such entertainment as they may wish. As yet I have not been able to obtain reduced rates at hotels, but may succeed in doing so. Let those coming to the convention take advantage of the reduced railroad rates to the Centennial at Columbus.

An effort has been made to secure reduced rates through the Traffic Associations, but without success.

It is a Poor Economist, says an exchange, who lets surrounding available treasures go to waste. What would you think of the farmer who would not gather the golden grain when it was ripe and waving in the field? Or what would you think of the man who would harvest the new crop and let the old crop go to waste? The man of thrift gathers and saves from every possible source. He lets nothing go to waste. He gathers in his corn and his wheat, his rye and his barley, and he gathers also the honey from the flowers of his fields. It is his, he pays nothing for it. Genial nature plants the flowers and fills their cups with honey, and all he has to do is to get the bees and care for them, to save what would otherwise be lost.

Bees Imprison a Rattler.—The Atlanta Constitution relates that a party of men cut a bee-tree near Trompsville, Ga. The hollow was found to be filled with honey and comb for a distance of 15 feet. After securing the honey, one of the boys cut into the tree above the portion used by the bees, and found a rattlesnake 3 feet long. As there was no hole in the tree, except the one which contained the honey, the supposition is that the snake crawled up the hollow before the bees began to hive, and the honey-comb had blocked its exit.]

Orange Judd, so well known as an agricultural editor, has purchased the Farmer of St. Paul, Minn.; has moved it to Chicago, and the first number is on our desk, the name changed to *Orange Judd Farmer*, and making a very creditable appearance. We wish it a very prosperous career, and extend to friend Judd the right-hand of fellowship. With such a manager and editor it must succeed.

A Neat Pamphlet of 32 pages is on our desk, from the St. Joseph Apiary, Missouri. It is written by the Rev. Emerson T. Abbott, and is intended for distribution at the coming fair in that city.

Bee-Stings.—In an exchange Prof. A. J. Cook is credited with the following advice as to what to use for relief from the effects of the stings of bees:

I have ammonia, or hartshorn as it is usually called, always about our apiary, and have found nothing better for bee-stings. This is correct in theory as well as in practice; the active poison of the bee is or contains formic acid; ammonia is an alkali, and neutralizes the acid and so the poison. Dashing the part stung into ice water also gives partial relief; it stops the circulation, and so prevents absorption of the venom. A strong extract of cheap tobacco, made by turning hot water on a cheap cigar is also a partial alleviative. Some regard it superior to ammonia. It is a well-known fact that the bee-poison is itself a kind of vaccine; the more one is stung the less is he affected.

The Old Story about bees puncturing grapes and other fruits, says an exchange, to suck the juice therefrom is pretty well exploded. That they will suck the sweets from any of these fruits that they may find already broken, is true; and seeing them doing this, unthinking persons have jumped to the conclusion that the bee was the original trespasser. A little study of the organism of the bee will show that it has no tools wherewith to commit such depredations. Nature took care of the fruit as far as the bees are concerned, by incapacitating the bees from cutting or boring into it.

We had a Call from Mr. Herbert Brown, who has been sent to the Eastern States from Ventura county, Calif., to "place" several carloads of extracted honey. He reports the California honey crop as larger than it has heretofore been estimated. He says that some of the bee-keepers there have "bought up" all the honey on the market, and "hold it" to "stiffen the prices," as well as to judiciously place it upon the market; thus reducing to a minimum the damage usually done by small producers whose impecuniosity leads them to sacrifice their honey crop by accepting the first and lowest amount offered.

One-Third of a Crop.—A. Reusch, of Chariton, Iowa, says he expects to obtain only $\frac{1}{3}$ of a crop of honey this year. He writes us thus on Sept. 13, 1888:

The bees in this locality have done but little until Aug. 20. They had been doing well up to last Monday, Sept. 10, when it turned cold, and the wind was in the North. I expect to get a third of a crop of fall honey.

Frank Leslie's Sunday Magazine for October contains many interesting and valuable articles, all freshly written and brightly illustrated. The continued story, "Genevieve," opens the number. It is a story of the Huguenot troubles in France. The poems and short articles are numerous and good, and there are a number of full-page engravings of much beauty. It is a specially good number of this favorite family magazine.

GLEAMS OF NEWS.

Preparing Bees for Winter.—

Mr. H. E. Hill gives this description of his method of preparing bees for winter, in the *Farm and Home* :

Below I give a brief description of a plan of preparation that, notwithstanding the pollen, hibernation and other theories, has served me in the wintering of hundreds of colonies with a loss not exceeding two per cent. The method being simple, as it is effectual, is especially recommended to those who have but few colonies to care for :

Procure a box (such as may be had at any dry-goods store) from 12 to 24 inches larger than the hive to be packed. After cutting an entrance 6 inches in length by 1½ inches high in one side at equal distances from the sides, I place the box on the summer stand of the hive, and put the hive inside, supported on pieces of wood, at a height that brings the bottom-board to correspond with the entrance.

Then place strips 1½ inches high on either side of the entrance from the hive to the inside of the packing case, resting on the projecting bottom-board, and place a snug-fitting piece of stuff over these, thus forming a passage for the bees from the hive to the open air, and excusing the sawdust or planer shavings which are used for packing. Being now packed snugly beneath and on all sides of the hive, I use no honey-board, but simply cover the frames with a quilt of cotton cloth and a cushion of sawdust, which acts as an absorbent, and may be easily replaced with a dry one if it becomes damp from the escaping moisture of the colony during winter. Over this I put the usual six inches of shavings—or even 24 inches—filling the box. Now place a good roof over them, and all is complete.

Try it, and report your success next May. If by mild, sunny weather the bees are inclined to fly oftener than is desirable, place a short board in front over the entrance, with the bottom resting on the ground, a foot from the box, and over this an armful of straw. This box will darken the entrance, and tend greatly to equalize the temperature inside.

This Dialogue is published in a late number of the *Western Christian Advocate*. The answers to the questions are supposed to be given by one of the disgusted purchasers of some of the patent moth-trap bee-hives which abound in doors, hinges, drawers, corners, etc. :

What is the chief end of bees? To get out patent hives.

What is the best patent hive? The best hive is not patented.

But don't some of these patent hives fool the moth? No; they fool the men who buy them.

What patent hive is the most useful? The new one in the barn with a hen's nest in.

But is there not more money in patent hives than in bees? Yes; but that time is almost over.

But how are we to know a poor hive? It has a great many doors, drawers, hinges, cracks, crevices, nooks and corners which look like conveniences, but in which the bees stick fast.

Who are the great bee-savants of this country? The men who don't use patent hives.

Are bees profitable? Not to those who buy patent hives.

Sense Organs in bees and other insects are worthy of considerable study, and will repay a thorough investigation. In *Murray's Magazine* we find the following very interesting remarks on the subject :

In the matter of sense organs we are met by serious difficulties of interpretation, and this difficulty is the more keenly felt in studying creatures so widely different from ourselves as the bee. Such an insect would seem at first sight to be about as susceptible to the delicacies of touch as an ancient armor-sheathed knight. Head, thorax, abdomen, limbs, all are ensheathed in chitinous armor. The bee has his skeleton outside. The question is, how can delicate impressions of touch be transmitted through the tough, dense skin so as to affect the sensitive "squash" within? If you will examine one of the feelers of the bee you will see that the surface is richly supplied with hairs. It is by means of such sense hairs that the bee experiences a sensation of touch. Each touch hair is hollow, and within it is a protoplasmic filament containing, it would seem, the delicate terminal threadlet of a nerve. A curious modification of the touch hair is found on the last joint of the antennæ. They are here bent sharply at right angles, so as to form rectangular hooklets.

Shipping Colonies of Bees.—The following concerning the shipment of full colonies of bees is from the *Indiana Farmer* :

A great many people seem to think it is next to impossible to ship full colonies of bees by cars, without running a risk that makes it well-nigh out of the question. This is a mistake. Bees properly prepared may be shipped several hundred miles. The frames must be secured in some way so that they will not shake about the hive, and the bees fastened in with wire-screen, so that they can have plenty of fresh air. We usually tack screen over the entrance and over the brood-frames, and ship them with the cover off, and mark them "This side up, with care. Do not cover up. Do not leave in the sun." We also recommend that, where the route is known, they be shipped so that the greater part of the journey may be made at night. Timid express agents are apt to become greatly alarmed at a few robber bees that may hover about, and conclude at once that the bees are escaping. There is no danger of robber bees at night, and it is the coolest part of the day.

The North American Convention at Columbus, O., will soon convene, and all who intend to go should soon be making the arrangements. The following from the Secretary will explain about the railroad fare to and from the Convention :

The North American Bee-Keepers' Society will hold its annual meeting on Oct. 3, 4 and 5, 1888, in Representatives' Hall at the capitol in Columbus, Ohio. The Passenger Traffic Associations will grant reduced rates only when 100 persons are present, holding railroad certificates. Owing to the short honey crop it is feared that a sufficient number of persons will not be present holding certificates, and that an attempt on the part of the Society to avail itself of the reduced rates offered by the Passenger Traffic Associations will only result in disappointment; hence it has been decided that the only course open will be to allow each member to shift for himself, or herself, to either take advantage of such excursion rates as may be available in his or her vicinity, buy round-trip tickets, or do something of the sort.

W. Z. HUTCHINSON, Secretary.

September Hints.—Mr. C. H. Dibbern, in the *Western Plowman*, gives the following hints about seasonable work in the apiary :

This is the last month that bees can be reasonably expected to gather any honey. Usually about the 20th of the month we, in this latitude, have a frost that kills the flowers, but if not, the last series of flowers are done blooming, and there is nothing more for the bees to do.

Early this month is the time to know the exact condition of each colony.

While honey is yet coming in is the time to take out the frames and examine them. To guess they are all right, won't do, if you wish to winter them over.

In some localities, feeding will again have to be resorted to. This should be done now, before the nights become too cool, and robbing is more difficult to guard against.

As soon as the gathering season is over, remove all the surplus arrangements and put the bees in condition for winter. Many, especially those who have had two seasons of failure, will become discouraged and careless, and will let the bees shift for themselves, with perhaps not enough honey to carry them to January. That such persons will ever have "no luck" with bees is certain, and perhaps the sooner the bees come out dead, the better. The persevering, intelligent bee-keeper, however, will only strive the more when others around him are giving up, and my experience is that such only will win in any pursuit.

This season has been a peculiar one, in regard to swarming. Usually, in this locality, the bees commence swarming in June and end up early in July. This year they commenced in May, and are swarming some yet. Heretofore, we used to return second, or very late, undesirable swarms by looking over the combs of the swarming colony and removing all the queen-cells and giving the swarm back in the old hive. We lately hit upon a new wrinkle with the new hive. Now when a late swarm comes out that we do not want to hive separately, or have any weak or queenless colonies to boom up, we simply invert the hive that casts the swarm, and return the bees by shaking them on the sheet in front of the hive. So far this has worked nicely, and not one has made a second attempt to swarm. This process, of course, turns the queen-cells (the cause of the bees swarming) wrong side up, and the bees immediately tear them out. If this proves to be the invariable result of inverting, this is another point in favor of invertible hives.

We lately broke up a case of robbing in a very neat way. Going out into the apiary quite early one morning we noticed a colony that seemed to be working with unusual energy. In looking around a little further we soon discovered another colony that was evidently being robbed. Concluding that this last one had lost their queen, we removed it to the shop and examined them, and soon found that to be the fact. We now procured the comb from a nucleus (it is well to have a few such at all times) containing bees, brood and a queen. We exchanged this frame for one of the queenless hives. We now returned this hive to the place of the one doing the robbing, which was removed to the stand of the one that was being robbed. This, of course, threw the robbing business into great confusion. Those trying to rob would simply go into their own hives; if any returned, they only carried the honey back to the hive they had previously robbed. An hour afterwards, all was quiet, and the robbing was completely stopped, and both colonies resumed their honest toils.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

Doctors Disagree.—Mr. G. K. Hubbard has this criticism to make on one of our Queries. It appeared in the *Indiana Farmer* recently. Variety is the spice of life. If we all thought and spoke alike there would be no diversity of opinion—no spiky discussions—no progress from the “old ruts” and well-beaten paths of our forefathers. The fact that we disagree on every conceivable subject is the “bulwark of our freedom,” and the glory of the nineteenth century. But here is the item:

In the question department of the AMERICAN BEE JOURNAL, the question, “Are eggs ever put into the royal cell?” is answered by a large number of prominent apiarists, and it is actually surprising to see how many answer the question negatively, or in a manner expressing doubt. We do not understand why this should be. We have frequently seen eggs in queen-cells, and in fact have seen it so often that we wonder at our experience being different from so many who are more experienced. We imply that those who express doubt on the subject, think that young larvae are always used for the purpose. Clearly they are mistaken, as we have often seen eggs in queen-cells appearing to have been deposited as naturally as any in regular worker or drone cells. The question is not one carrying with it facts of much importance, but it makes a splendid illustration of how “doctors disagree” on questions that seem as plain as the alphabet to others.

An Eye Opener.—One of our exchanges contains the following showing that a poor honey crop may be a blessing in disguise:

I think it is not hard to see that this poor season may be a blessing in disguise, and may work for the good of our business. Our large markets have got overstocked with honey, prices had been knocked down by shipping honey into the already overstocked markets, until honey was selling at ruinous prices. The Wiley lie was floating over the country, that there were numerous manufactories where bee-comb was manufactured and filled with glucose syrup, and sealed over with hot irons. The newspapers wafted this story along, and thousands believed the story, although it was so inconsistent.

This failure of honey from the flowers has cleared out the honey markets so that commission men have been calling loudly for honey, at good prices. Where are these glucose manufactories all this time, that they allow the markets to become so bare of honey even at doubled-up prices? This ought to open the eyes of the community on this subject, and strike a death-blow to that infamous lie.

Stinging Bees.—A correspondent from Iowa sends us the following dialogue concerning educating the bees to hold their breath and thus suspend their stinging propensities. Here is the dialogue:

“What have you found to be the best remedy for a bee-sting?” said the reporter.

“Bee-sting! I haven’t had an opportunity to use a remedy for years.”

“How then, Mr. Foggy, do you manage; or don’t your bees sting?”

“Yes, my bees are capable of stinging, but they have had good training. You probably have noticed in some of the bee-literature of the day, a novel way of escaping the sting of a bee by holding your breath.”

“Now that idea never occurred to me, but

sometime ago I commenced training my bees to hold their breath as soon as they felt like stinging, thus preventing the sting, and if you don’t believe it, I have them well trained, and you can try it.”

Alsike Clover.—In the report of the United States Botanist just issued, in the report of the Commissioner of Agriculture, a copy of which we have received from N. J. Coleman, Esq., we find the following on page 304, concerning the history, development and characteristics of Alsike clover, which will interest our readers:

This differs from common red clover in being later, taller, more slender and succulent. The flower heads are upon long pedi-

Alsike Clover Bloom.

cells, and are intermediate in size and color between those of white and red clover. Its botanical name was so given from its being supposed by Linnæus to be a hybrid between those clovers, but it is now known to be a distinct species. It is found native over a large part of Europe, and was first cultivated in Sweden, deriving its common name from the village of Syke in that country. In 1834 it was taken to England, and in 1854 to Germany, where it is largely grown, not only for its excellent forage, but also for its seed, which commands a high price. In France it is little grown as yet, and is frequently confounded with the less productive *Trifolium elegans*.

The following is condensed from “Les Prairies Artificielles,” by Ed. Vianne, of Paris: “Alsike does not attain its full development under two or three years, and should therefore be mixed with some other plant for permanent meadows. It is best adapted to cool, damp, calcareous soil, and gives good results upon reclaimed marshes. It is adapted neither to very dry soils, nor to those where there is stagnant water. Being of slender growth, rye-grass, rye, or oats, are often sown with it, when it is to be mowed. In fertile ground weeds are apt to diminish the yield after a few years, so that it requires to be broken up. It is generally sown in May, at the rate of 6 to 7 pounds of the clean seed per acre. Sometimes it is sown in the pods at the rate of 50 to 100 pounds per acre, either in spring or in autumn after the cereals are harvested.

“Alsike sprouts but little after cutting, and therefore produces but one crop and

one pasturage. The yield of seed is usually 130 to 170 pounds per acre. The seed separates more easily from the pods than that of ordinary clover, and as the heads easily break off when dry, care is required in harvesting.

“It does not endure drouth as well as the common red clover, but will grow on more damp and heavy soils, and it is said that it can be grown on land which, through long cultivation of the common clover, has become ‘clover sick.’”

Absconding Swarm.—I desire to know the cause of a swarm of bees leaving. It was a very large swarm, which I had tried to prevent swarming, by cutting out queen-cells. I examined each one of the ten brood frames carefully, and cut out eleven cells in different stages of construction. On the second day after this they swarmed. I hived them and gave them a frame of brood, and set the hive on the old stand. They stayed until the next day, when they came out, and, without alighting, went straight to a tree about half a mile away. They had built two large pieces of comb, one on each side of the frame of brood, which contained a small quantity of honey and some eggs. Can you give any reason why they left in this ungrateful manner? The frame of brood which I gave them I took from a hive that had swarmed a few days before, and I thought perhaps the unsealed larvae were too large.—L. B. Post.

[Your bees had picked out their hollow tree, and got it cleaned out and already fixed up for house-keeping before they swarmed at all. Under such circumstances you could not well induce them to give up their project, especially if you let them remain on the old stand, and this is one very good argument in favor of hiving at some little distance from where the parent colony stood. Where they pick out the location before swarming, they are pretty sure to move to it, sooner or later.—*Gleanings.*]

For the Sixteenth consecutive year Chicago opened up its great Inter-State Industrial Exposition, replete with the best products of science, industry and art, on Wednesday, Sept. 5, and will close Saturday, Oct. 20. The immense structure is now laden to its fullest capacity with the finest and most magnificent exhibits ever displayed; from almost every quarter of the civilized world, illustrating as it does every avenue of human industry in its most complete form, it is almost a necessity that they who would keep abreast of our most advanced ideas in both industry, science and art, should not fail to visit this great Exposition. Every railroad and transportation line running into the city have made reduced rates, and there is every indication that a much larger attendance will follow than any year that has preceded.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the BEE JOURNAL, and will send two or more free of cost to any one who will use them, and try to get up a club. Sample copies will be sent free upon application.

Golden-Rod.

Written for Our Little Men and Women
BY CLARA DOTY BATES.

An idle Breeze strayed up and down
The rusty fields and meadows brown,
Sighing a grievous sigh, "Ah, me!
Where can the summer blossoms be?"
When suddenly a glorious face
Shone on him from a weedy space,
And with an airy, plummy nod,
"Good afternoon!" said Golden-Rod.

The Breeze received her courtesy
And then came hurrying home to me,
And eagerly this story told:
"I've seen a lady dressed in gold,
So shining that the very light
That touches her is doubly bright—
She nodded, too, a royal nod."
"Why, that," I said, "is Golden-Rod."

"Come out and see her where she stands,
Gold on her head and in her hands,"
He cried; and I without delay
Went after where he led the way;
And there she stood, all light, all grace,
Illuming that weedy place,
And to us both, with airy nod,
"Good afternoon!" said Golden-Rod.

QUERIES AND REPLIES.**Tiering-Up when Working for Extracted Honey.**

Written for the American Bee Journal

Query 576.—When extracted honey is desired, is it not preferable to tier up, that is, to use extra stories above instead of taking from the brood-chamber?—N.

Yes.—DADANT & SON.

Certainly.—MRS. L. HARRISON.

Yes.—H. D. CUTTING.

Certainly.—R. L. TAYLOR.

Yes.—J. M. HAMBAUGH.

I think so, decidedly.—A. J. COOK.

Yes.—G. M. DOOLITTLE.

Yes, every time.—EUGENE SECOR.

In most of the cases it is.—J. P. H. BROWN.

Yes, every time.—C. H. DIBBERN.

Opinions differ. I think that I should prefer tiering.—C. C. MILLER.

Yes, sir. It is better if those extra stories above are half-depth. I have used both full and half depth supers for more than fifteen years.—JAMES HEDDON.

If the tiering-up plan is followed, and plenty of room given, it will seldom be necessary to extract from the brood-chamber.—A. B. MASON.

I consider that the best way to gather extracted honey is by tiering-up. I am of this opinion both from experience and observation.—J. E. POND.

Extract from an upper story, as a rule. Sometimes the brood-chamber has too much honey. In that case it should be extracted, or full combs exchanged for empty ones.—M. MAHIN.

Ideal extracted honey can only be had from supers where there can be no suspicion of the juices of brood, and the taste of pollen.—J. M. SHUCK.

Most assuredly it is. To take honey from the brood-nest is a slipshod, slouchy way of taking surplus. It is but a little better than the old foggy plan of "robbing bees."—G. W. DEMAREE.

I use a two-story hive, and extract as often as I find the honey about two-thirds capped over. It is necessary to occasionally extract from the brood-chamber, so as not to allow the queen to be over-crowded, etc.—P. L. VIALLO

While it is sometimes necessary to extract from the brood-combs, in order to give the queen room to lay, still with proper management and the judicious tiering-up of supers, it will not generally become a necessity. Our ideal extracted honey is always taken from the virgin comb in the supers—not from the breeding apartment.—THE EDITOR.

Number of Frames Used when Tiering-Up.

Written for the American Bee Journal

Query 577.—1. Are not 12 or 13 frames too many for the brood-chamber, when tiering up? 2. How many would you use below? 3. Would you use the same number above as below, when tiering up?—New York.

1. More than are necessary. 2. Eight. 3. One less.—R. L. TAYLOR.

1. No. 2. Eight Langstroth frames. 3. Yes.—MRS. L. HARRISON.

1 and 2. Nine Langstroth frames are sufficient. 3. I would.—J. P. H. BROWN.

I use nine Gallup frames in the brood-chamber when working for extracted honey.—G. M. DOOLITTLE.

1. Yes. 2. Ten. 3. Yes.—J. M. HAMBAUGH.

1 and 2. That depends upon the size of the frames. 3. Yes.—C. H. DIBBERN.

1. Yes. 2. Seven to eight. 3. Use 8 to 10 above.—H. D. CUTTING.

1. Yes, unless very small. 2. I am not fully settled on that point.—C. C. MILLER.

1. That depends upon the size of the frame. Ten Langstroth frames are not too many, unless the surplus is all wanted in the supers. 3. If for extracting, yes.—A. B. MASON.

1. No, not of the Langstroth size or smaller. 2. We use half-depth frames above, or rather 6 inches deep.—DADANT & SON.

1. Much will depend upon the size of the frame. Ten Langstroth frames or equivalent are, in my opinion, about right, both in the brood-chamber and in the surplus apartments.—J. E. POND.

You do not give the name of your frame. If Langstroth, I would not use more than ten below, and the same size of hive above with one frame less.—EUGENE SECOR.

1. Ten frames are enough. 2. Ten, if for extracted honey; 8 if for comb honey. 3. I use 10 frames in the brood-chamber and 9 above.—P. L. VIALLO.

That depends upon the size of the frames. I have used 12 Gallup frames with success. This leaves plenty in the lower hive for winter.—A. J. COOK.

1. Much depends upon the size of the frames, and something upon the locality and the season. I use in that way from 8 to 11 frames of nearly the Gallup pattern. 3. Yes.—M. MAHIN.

I do not understand the question. If the querist desires comb honey, 12 to 13 Langstroth frames are too many. If he desires extracted honey, 12 to 13 frames may not be too many.—J. M. SHUCK.

1. It depends upon the size of the frames used. 2. In my locality I use 10 Langstroth frames in the brood-chamber. 3. When I use full-depth supers above, I use but 9 frames. In fact, I use but 9 frames in the surplus apartment whether I am using full-depth or half-depth cases. Placing the frames a little wider apart in the surplus cases makes the sealed combs full and plump, and they uncap nicely.—G. W. DEMAREE.

Yes, too many for any brood-chamber, provided they are the size of the Langstroth frame. Never use more than 10 Langstroth frames' capacity in the brood-chamber, and never more than 7 or 8, unless you are practicing contraction at the proper season of the year. The rest of your query is answered in my reply to Query 576.—JAMES HEDDON.

1. That largely depends upon the size of the frames used. 2. I prefer the 10-frame Langstroth hive for all purposes, but would contract the brood-chamber by reducing the number of frames when working for surplus honey. 3. In order to obtain all the surplus in the supers, I should use less frames below, graded by the circumstances.—THE EDITOR.

Query 575.—The answer to this query, by Mr. J. M. Shuck, in last week's BEE JOURNAL, should have read as follows:

I believe it has been established that there is formic acid in honey. I incline to the belief that the acid found in the honey is developed and incorporated with the honey in the honey-stomach, and tends to preserve the nectar till it ripens, rather than to preserve it after it has been evaporated and sealed.—J. M. SHUCK.

The two italic words in the above answer, by an oversight, were printed incorrectly, and the error was not discovered until after the "forms" were printed.

Convention Notices.

The next meeting of the Union Bee-Keepers' Association will be held at Clayton, Ill., on Thursday and Friday, October 11 and 12, 1888, in the Town Hall at 10:30 a. m. The Park Hotel will charge \$1.00 per day; the restaurants 25 cts. per meal. We expect Messrs. Dadant, Hambaugh, Cumm and other prominent bee-keepers to be present.

S. N. BLACK, Pres.

The Ohio State Bee-Keepers' Association will hold its 6th annual meeting in joint convention with the North American Bee-Keepers' Society at Columbus, O., on Oct. 3, 4 and 5, 1888. A special business session of the Ohio State Bee-Keepers' Association will be held on Oct. 4, to elect officers for the coming year, and for the transaction of other business. This business meeting will not interfere with the regular programme of the National convention of the same day.

FRANK A. EATON, Sec.

CORRESPONDENCE.

PLEASANTRIES.

Time of Buckwheat and White Clover Bloom.

Written for the American Bee Journal
BY DR. C. C. MILLER.

In response to the request of the editor on page 563, I reply that in this locality, and I think it is the general rule in all localities, the nectar disappears from buckwheat bloom by the middle of the day, so that whereas there is no trouble from robbing in the forenoon when buckwheat is yielding, care must be taken to avoid everything like exposure of combs or honey in the afternoon. Something, however, depends upon the weather, for if the morning is cold or rainy, the forenoon of buckwheat bloom may be extended into the afternoon.

It is well to be somewhat familiar with the habits of flowers as to blooming, although buckwheat is the most notable exception to the general rule that flowers yield nectar all day long.

White Clover Blooming and Not Yielding Nectar.

Considerable apprehension was felt in this locality about the crop of white clover this summer. The summer of 1887 was so very dry that white clover seemed to be burnt up, root and branch, and the question was whether the summer of 1888 would see any white clover, and if some did come from seed, whether it would be forward enough to bloom. I never watched more closely in the spring for the first appearance of growth. Contrary to my expectation, I think that I never saw so much white clover starting. I cannot say, although I should like to know, whether it came from the roots of last year or from the seeds.

Then I watched to see whether it would bloom. Soon the blossom buds appeared in profusion, and my fears for the season subsided. I awaited with confidence the gathering of a bountiful harvest, for I feel sure I never before saw the ground more white with clover bloom, and I think that I never saw any thing to equal it. But the flood of nectar seemed slow about coming, and after the time for it was all over, I was obliged to confess that I was a "false prophet," and that very little honey was gathered from white clover.

Now what was the trouble? Is it true that white clover, as some have stated, produces no nectar the first summer it comes from seed? It certainly looked a little that way this year, providing the clover all came from seed this spring or last fall; and yet I can hardly believe there is any difference between a blossom on a plant a few weeks old, and one on a plant a year older. If the blossom needs nectar to call insects to fertilize it, will not the young plant produce it just as well as

the old one? I really would like some one who can speak with authority, to tell us more about this plant and its habits.

That Honeyed-Man.

This man was mentioned on page 579, and I agree with the editor that it was nothing strange that the man received no stings from the bees alighting upon the honey daubed on him. But I suspect there is very little foundation—very likely no foundation whatever—for the whole story. Let us look at it.

A man daubed himself with honey, 800 bees that were swarming in the woods alighted on him and stayed there until he transported them home. In the first place, when bees are swarming, they are very intent upon the one thing—swarming. I very much doubt if you could get 800, or 80 bees, of a swarming colony to alight upon a man daubed with honey for the sake of getting the honey. They are not just then in the honey-gathering business. But suppose you could get them to depart from their usual habit, and forsaking the cluster or the swarm in the air, settle upon the man, how long would they stay there? Just long enough to load up with honey and then off they would fly, and no bee would come back for a second load to the man unless he stood still at the spot where the bee left him.

You may bid defiance to the worst robbers by simply keeping on the move anything you want to protect from them. So I suspect that the whole thing originated in the brain of some one anxious to get up a sensational item for the newspapers. Sensational items are in demand, and we can expect nothing different so long as the truth is not more highly valued than sensations.

The Wiley Pleasantry.

This "pleasantry" owed its popularity and its successful run to the fact that it was sensational. It is not that newspapers or reporters so much prefer the false to the true. A true sensation is preferable to one that is false, but there is a lamentable absence of care as to whether truth or falsehood is promulgated, providing only that it is sensational. Get up a contradiction of the Wiley statement that shall be equally sensational, and it will promptly go the rounds. But no matter how strong may be Prof. Wiley's retraction, it will not be likely to find currency anywhere except in the columns of those papers specially devoted to the interests of bee-keepers. The retraction may be very true, but it is not sensational.

The holding the breath to prevent stinging goes the rounds for the same reason, and the bee-periodicals are not altogether guiltless, because at least two of them have published it with no word as to its truth or falsity. We hardly ought to blame other papers for neglecting to inquire closely into the truth of every item admitted to their columns, if the same thing is done right in our own ranks. A notable instance of this is in the following:

The Sting-Trowel Theory.

That bees ever use their stings to work wax, I believe is just as untrue as that artificial comb honey is made, and yet this error had its origin entirely among bee-keepers. It is true that it is not like the Wiley affair in mischievous tendency, and I do not suppose Mr. Clarke would have made the statement he did, if he had supposed mischief would arise from it; still he was far from warranted in putting forth as an ascertained fact, that which was a mere play of his imagination. I do not believe he ever had any proof that his fancy was a fact, and I confess I would very much like to see Mr. Clarke himself the first one to give the "sting-trowel" its quietus. I would like this for the sake of the truth, and also for the sake of Mr. Clarke as well. Marengo, Ills.

FALL FLOWERS.

The Autumn Honey-Flow in the Middle States.

Written for the Grange Bulletin
BY H. B. GEER.

After the heat of the summer has passed, and the first fall rains begin, then spring into life and beauty the autumn flowers that are usually loaded with delicious nectar—resorts of pleasure and profit for the millions of honey-bees, that, after some weeks of idleness and inactivity, are only too glad to again return to the fields and their duties.

During the spring and early part of last summer the flowers, such as struggled into existence despite the drouth—were nearly or entirely fruitless, and the sources of honey very limited indeed. But after the rain had come again, it brought out the autumn flowers here in Tennessee, and also, as I learn, in Missouri, and the honey-flow during the month of September was better and more of it than during all the previous months of the year.

Chief among the fall honey-plants of Tennessee, is the golden-rod. Here it blooms in great profusion, and its bright golden plumes may be seen nodding and waving in nearly every field and meadow—especially in the waste places or fallow land, and in the fence corners. It yields honey of a rich yellow color which has a very pleasant flavor. In fact I think it the finest honey that our bees can obtain from any source in the fall of the year.

In Missouri, where the writer is interested in apiculture, the asters are our chief reliance for fall honey. There they bloom in great profusion from about the first of September until frost. There are a great many varieties of asters, and they all yield a fair grade of honey, which every bee-keeper is glad to receive. After the spring and summer supply has proven a failure, as was the case last season.

Honey partakes of the nature of the flowers from which it is gathered, more perhaps than one would suppose. For

instance, in the spring of the year when the flowers are fragrant and loaded with perfume, the nectar gathered from them is likewise fragrant and delightful, and seems to emit the sweetness of the fields, and the wild flowers themselves. The delicate fragrance of the white clover bloom is well-known, and, as if in keeping with its delicate nature, the honey it yields surpasses all others in flavor and pleasurable taste.

On the other hand, the honey from the fall flowers, while equally sweet and pure, is devoid of the fragrance and pleasant smell that the early season honey possesses. Likewise the autumn flowers seldom emit a pleasant perfume, although they rival in beauty their kindred of the springtime.

CANADA.

Report of the Haldimand, Ont., Convention.

Written for the American Bee Journal
BY E. C. CAMPBELL, Sec.

A meeting of the Haldimand Bee-keepers' Association was held at Fisherville, Ont., on Saturday, Sept. 1, 1888. The minutes of the previous meeting were read and confirmed.

How and What to Feed Bees.

The President said that granulated sugar should be fed, as it was safer than to risk feeding cheap sugar. He made a thick syrup by putting the granulated sugar into boiling water, and stirring it frequently to keep it from burning. He exhibited a Canadian feeder, showing how it worked, and urged early feeding, so that the bees could cap their stores before cold weather. It was also necessary to feed in the evening, so as to avoid robbing.

Mr. W. Kindree's plan was the same as the President's, only that he boiled the sugar a little more than Mr. Armstrong. He thought that by doing so the syrup was not so apt to granulate.

Mr. Mehlenbacher described his plan of feeding, which was by tipping the hive up in front, and pouring the syrup behind the division-board.

Mr. Overholt used a similar feeder to the Canadian, and found it ahead of any other.

Mr. Best had always used honey, but this year he would have to try sugar, as he had no honey. He had wintered a colony on 15 pounds of honey, and it had wintered all right.

Mr. Atkinson made syrup the same as described by Mr. Armstrong, and used inverted glass jars as feeders.

How to Unite Colonies of Bees.

The President gave his plan of uniting colonies, which was to gradually move the colonies to be united, towards each other until they were close together, and then spreading the frames apart, and putting in frames alternately; he then gives the bees a good smoking, and the work is done.

Thirteen members reported 252 colonies, spring count, and 375 colonies, fall

count; from which it is seen that the increase has been very small, besides no surplus honey taken; and what is worse, the bees have not stores enough to winter on, and will have to be fed.

The next meeting of the association will be held at Cayuga, at the call of the President.

HONEY-JUMBLES

Of the North American Convention of 1887.

Written for the American Bee Journal
BY A COUNTRY BEE.

"All N. A. B. K's (wrote H., the recorder) were Summoned to appear before the President Miller, Each bringing one dollar in paper or silver; And at the Commercial Hotel please register, In Chicago, Ills., the 16th of November."

A No. 1 Root responded with his "A B C's;" Armstrong came on with his hive and T-supers; And a spinwall wrote that if we'd organize, All delegates should receive that "Magazine" of his— "Life ne'er exulted in so rich a prize."

Bees (*Genus Homo*) were Baldrige, Baldwin, Barber, Boardman, Miss Bennett, T. F. Bingham, the smoker, Betsinger, T. S. and Joshua Bull (not Johnny), Bedell, and Burnett, who is not a B(ur)master, Although he well knows how to handle the honey.

"We may live without friends, we may live without books— But this Society "cannot live without A. J. Cook," Completion, of Glenwood, Crocker, Cummins and Comstock. Were very modest, and did not give us much talk, But the deficiency was made up by Mr. Wilcox.

"While a-gathering of bee-bread for their living," Hubbard, whose ancestor "went to the cupboard," and Found Hopkins, of O. (kin of Hop-'o-my-thumb). Speaking of H's, Lemmer see; Dr. Haskin, Hutchin-son, Hilton and Heddon—the "hanner" goes to Michigan.

Lyman, Forncrook, and Thornton, no doubt ought to be, "I the man in the moon, this thornbush, my thorn-bush;" D. G. and G. W. Webster (descendants of Daniel and Noah); Hear our Betsinger, "Oh, velvet bee you're a dusty fellow. You've powdered your legs with gold," all yellow.

"O Woodman spare that (Dahl linden honey) tree," Cried Funk, Staininger, "mid the trees, where humming-bees" Extract the nectar from the bright flowers. Here the Redmond, who once chased Reynolds, the fox. Now extracts the "extracted honey" with the extractor.

Beside our President, were B. J. and M. M. Miller, Gilson who sent to fetch a pail of (Mc) Whorter; That reminds us of that young "Tribune" reporter, Who thought our "conflicted look peculiar;" If he'd seen one buzzing drone, he'd not have been so joacular.

Mrs. Seartes—"hark to the music, the drum and the life." A Taylor, Cummins, Davenport with his wife, Jones, Esher, Marphi, and Gander, Dethloff—my life, Neimetz! I'm Fullmer than Hawks, when chickens are rife. Another room for exhibits, would lessen the strife.

I hear the bees swarming, and while watching for the queen, Oh, Gould, I see the one who sang, "Keep our Graves, Green." "I Lovett, (Sweet, Hart), or Stanton, in the Parks. With Wilson, Thompson, Robertson, or even the Holtermann.

When the Outman was Stow (ed) in the hopper, With Newman, Secor, and McLain the Professor, By the hardest of Davis work our Strong Miller, Turned us out a gist of very Good flower. "And here by thee, will hum the bee, forever and forever."

The flower was left with the Cook, by Chapman; Who turned it over to the ladies and gentlemen. Some Marvin that the flavor was equal to linden—"Excuse me, but will our Good friend, Dr. Mason, Be so kind as to see to the ventilation?"

Our hearts went out to Father Langstroth, With the hope that his remaining days on earth, May be filled with sweetness around his hearth, And the conscious thought of the good he has wrought. For the bee-keeping people, bring joy to his heart.

Thanks were tendered to Mr. Thomas W. Cowan, Who, being such an able "microscopian," Gave pleasure and profit to all who met him; While regretting his absence, at Prof. Cook's suggestion, He was made honorary member of this Convention.

Thanks to Thomas G. Newman again and again, For his excellent arrangements with the hotel-man, For his thoughtful good-will shown on every hand; To mention this Society, is to think of his name. "He has served thee as none would," still sounds the refrain.

For President, the genial Dr. A. B. Mason, For Secretary, the efficient W. Z. Hutchinson, For Treasurer, Mrs. Harrison, who uses no deception, They were Secor (ed) officers at the election, Without a Wakeman's or Woodman's dissension.

"We may learn of the bee, the wise man's lore, The hand of the diligent gathereth store," At Columbus, Ohio, "If this life be not o'er," On the 3rd of October, "May we meet once more," 'Till then, success to you all, *Au revoir*.

MAPLE TREES.

Insect Enemies Mowing Them Down—Plant Lindens.

From the Detroit, Mich., Tribune
SEPTEMBER 3, 1888.

Dr. W. C. Stevens of Fourteenth avenue has devoted considerable attention to the destructive insects from whose ravages the maple trees are suffering so severely. He expresses the belief that there is not one sound maple tree in a hundred under five years old in Detroit. On some whole streets he has been unable to find a single tree unaffected by the pest. The same state of affairs seems to prevail among the shade trees throughout the country east of Detroit.

Dr. Stevens recently wrote to Prof. Cook of the Agricultural college relative to the matter. The professor in his reply says that the same destruction of maples in Detroit referred to by the Doctor is noticeable in Lansing and in every other city in the state. He pronounces a specimen insect, which Dr. Stevens sent him, the grub of a common maple tree borer, *Plagionotus speciosus*, which is very harmful to trees all over Michigan. They attack large, thrifty trees and have destroyed many maples in Jackson, Lansing and other places. The beetle, which appears in July and August, is a large, handsome longicorn, black in color and striped with a rich yellow.

The pupa case which the Doctor sent is pronounced by the professor that of a caterpillar, *Egeria aceris*. This beautiful moth lays her eggs in July, and the caterpillars feed on the inner bark for one year. It is black, striped with yellow and orange. This insect, Prof. Cook says, is also doing much to destroy the maples.

More harmful than either of these varieties is the big-headed apple tree borer, which is a very serious enemy of the maples, especially young or newly transplanted trees. This beetle attacks trees whose vigor has been checked. Thus it is that it is so destructive to trees recently transplanted. Prof. Cook

recommends that the trunks of trees be washed early in June and July with a strong solution of soap, to which one-tenth of its volume of crude carbolic acid has been added, especially for two or three years after setting. Still better is good care—spading about the trees and adding a generous mulch every spring for five or six years after planting.

"Why do we plant so many maples?" is a conundrum propounded by the professor in his reply. He estimates that throughout the state ten maples are planted to one of any other species. He refers to the elm as a beautiful tree, and one, which, in this locality, is yet free from serious attack. Still the elm-leaf beetle in the East is moving West rapidly, and the canker worm is a fatal enemy of the tree. The basswood or linden is a handsome tree, a more vigorous grower than either maple or elm, and is comparatively free from insect enemies. With the same care five, and the professor guesses ten, lindens survive to one maple. It is also an admirable honey-tree, and so has much economic value.

"If we must plant maples," concludes the professor, "give them the best of care and wash them with the solution mentioned each June and July for some years after planting, but it is far better to plant the beautiful linden, which with half a chance, if stock is kept away, will live, thrive and mature."

STINGING BEES.

Something in the Honey Causes Bees to Sting.

Written for the American Bee Journal
BY SOLOMON W. JEWETT.

No pure honey can be found in America in any quantity or in any condition, that has not gone through the chemical laboratory of the honey-bee, or some other insect that stores this peculiar sweet, which has properties as food and medicinal, that cannot be found outside of its deposits in the comb by some insect. Most people have yet to learn this, and many other simple things in nature not yet learned.

There are other matters relating to bees that I find many apiarists have not discovered, namely, in the working of the bees among some flowers, they become more irritable, and more liable to use their simple weapons of warfare, than they do when gathering sweets, and the pollen, or anything which they are seeking to convey to their rural home. Some wild flowers, and the buckwheat flower, contain more poison, and is more virulent than clover, or from the willow, etc.

When working on the flower of buckwheat, sometimes they are so overcharged with poison, that they are quite inclined to sting man and animals, seemingly to relieve themselves of this surfeit; and we find it in the honey sometimes, by partaking of a little fresh honey (gathered and stored by these arch chemists, as deposited in the comb), which will give griping pains; and this poison is in less quan-

ties in the seed. By continuing along for sometime, daily partaking of buckwheat cakes, it shows the effects on the cuticle or skin of the body, and even the scalp may feel this dry roughness, and an itching sensation when nothing of the kind had been felt before.

We have some people who keep fowls, that speak in favor of buckwheat to make hens lay; but that is a mistake; they may lay in their seasons because it is their nature, but if one will only observe how dry and dead their feathers become, and stand out as though they were suffering pain, they might desist from putting before these birds buckwheat as food.

Simple Remedy for Bee-Stings.

There is a simple remedy at hand, for those afflicted with pain from eating too freely of this honey gathered from buckwheat. It is simply to take a swallow of the weak solution of soda and water, and it is one among the best remedies to apply wherever the bee, the wasp, or the snake has inserted its venom through the sting into man or animal flesh.

But there is another remedy that will draw out poison from the snake bite. Kill and open the body of a hen or bird, and lay it on the stung place; it will extract the poison, reduce the swelling, and remove the pain. At the usual swarming season, should one have the solution of common baking soda, or saleratus, on hand, it will destroy the effects of the bee-sting at once, if applied.

Rutland, Vt.

MARKETING.

Disposing of the Honey Crop to Commission Men, etc.

Written for the American Bee Journal
BY REV. J. D. GEHRING.

It is easier to learn the bee-business so as to know how to produce nice comb honey, than it is to learn how to dispose of it to the best advantage.

Last year I had no trouble to dispose of all I had at 20 cents a pound. This year I cannot sell a pound to the same grocerymen in Kansas City. When I called on them the other day, I asked, "Can I sell you some nice, white clover honey?" One answered: "No, sir! We have more honey now than we can sell. Nobody wants honey." Another, "Is it nice and white? Sections well filled out and unbroken?" To which I could promptly reply in the affirmative. "How much do you want for it?" Eighteen cents, net.

"Don't want it!"

And 18 cents a pound is 2 cents less than the quoted market price! These same men are retailing it at 25 cents. Something is wrong somewhere. What is it?

We have two firms in Kansas City who make comb honey a specialty. They now quote 18 and 20 cents for first-class comb honey. I presume they sell to retailers at those prices. I do

not know how they sell it in large lots; but I know that they have a "buying price" and a "selling price," for when I ask, "What is the price of the best comb honey?" they will cast upon me a look peculiar to a Kansas City commission man, and answer my question "Yankee fashion," thus: "Do you want to buy or sell?"

I have a few hundred pounds to sell at 18 cents.

"Don't want it! Piles of it on hand now."

Who is glutting (?) the Kansas City market *this year*. I wonder? Some "big bee-men in the East," I am told!

What a queer state of affairs! The bee-papers inform the anxious, tired and disgusted *small* bee-man that there is a very light honey crop in the country. He can say "amen" to the statement, for he is *one* of them. But New York bee-keepers send honey by the carload (?) all the way to our own market; and our commission men cannot be convinced that honey is scarce.

"If you want to consign your honey, we'll take it and sell it for you. But we can't guarantee any particular price, as the demand is light."

"You see?" No, some bee-keepers don't "see" that they are helping a syndicate of commission sharpers to control the honey market, and that they are making it easy for those men to treat us poor, small struggling fellows with haughty contempt.

I tell you, Mr. Editor, we ought not to stand such an outrage! I am only a small "Dutchman," and have no great amount of "stock" invested in bees and honey; but, sir, I am big with indignation! Even a Dutchman will find out a thing or two when he is exasperated. Let me tell you what I mean:

Not many years ago a man, whom I know quite well, had some honey to sell. He was a "poor preacher," and needed money, so he sent it to a commission man who said he could probably (?) get 17 cents for it. But when the preacher collected for his honey, he got only 15 cents minus the "commission"—because "we couldn't get 17 cents."

Well, one day, sometime after the transaction with the commission man, the preacher saw some honey in a grocery store which he thought looked exactly like his 1½-pound sections. He asked the price, and found they were retailing it at 25 cents a pound. He asked where they got it, and was told at—commission house. It was his honey, no doubt. But as it was a delicate question to ask the merchant what price he paid for the honey, this preacher sent a man (who didn't want to buy honey) to inquire the price, and was told that, as that was "particularly nice honey," they had to ask 18 cents (!) for it.

That Dutchman has ever since been a little careful about accepting the gift of a "stencil plate," ready for use, from a commission house.

Hadn't we better form a "honey trust?"

Parkville, Mo.

[We trust that the last sentence is a joke, Bro. Gehring. The word itself is distasteful to us. We have trusted so

much in our business career, that we are now mourning the loss of many thousands of dollars *trusted!* Then about "honey trusts," it was only a few months ago that the papers would have it that the New York bee-keepers were to hold a meeting to form a "honey trust," which was to accomplish *wonders!* But there was no truth in it. Two years ago a Honey Producers' Association was talked of when the honey crop was of fair proportions, and if such a plan as then presented could be carried out, it would be productive of much good. Such an association would practically put an end to the swindling done by *dishonorable* commission men (for there are such, though there are also many honorable ones) who sell at one price, and report to producers at another and lower one. There are *sharppers* and swindlers in all occupations, and honey commission men are no exception to the rule.—Ed.]

NEW YORK.

An Average Honey Crop of 30 lbs. per Colony.

Written for the American Bee Journal
BY H. J. ROGERS.

The season for surplus has closed here, and the result is not very encouraging; however, we have some honey, and are thankful.

My 80 colonies were put into winter quarters last fall with plenty of bees and honey, and came out in the spring without any loss; but five colonies were rather weak, and I lost 3 out of the 5 by spring dwindling.

The cold, backward spring kept the brood from spreading very fast, so that when apple blossoms appeared, most colonies were not very strong. For the first season here since I have kept bees, apple blossoms yielded no nectar, and I soon found some of my colonies on the verge of starvation; especially those that I had transferred. I fed all the honey I had on hand, and also considerable sugar syrup.

About June 1 raspberries opened, and about four-fifths of my colonies commenced work in the sections, and I secured about 2,000 lbs. of very nice honey, all in the comb. At this time we were getting copious rains, and it looked as if clover would be a fine harvest, but it yielded very little, scarcely more than last season.

This section is always favored with lots of buckwheat, and when I found that the basswood was a total failure, I hoped we would get a "big run" from buckwheat. This, too, has failed on account of a frost, which has ended all work in the sections for this season.

It is well known that bees do not work on buckwheat except a few hours in the early part of the day—sometimes

they cease work at 11 o'clock, but generally as soon as 1 o'clock. I think I have never seen a bee work as late as 3 p. m. on buckwheat.

I have not had any increase this season, mainly, I think, on account of the large, roomy hives which I use. They take 10 frames of the Langstroth size, and hold 40 sections $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$ 15-16, in each super. I think they are as good non-swarming hives as there are in existence, not excepting the "Cotton Hive."

If my bees had swarmed, I should not have a pound of surplus: as it is, I have 30 lbs. per colony. We will now commence to prophesy concerning the crop of 1889, which *surely* ought to be very large.

Stannard's Cor., N. Y., Sept. 3, 1888.

THE FAIRS.

Will it Pay to Exhibit Bees and Honey?

Written for *Gleanings in Bee-Culture*
BY DR. A. B. MASON.

Agricultural fairs set in motion the best elements of farm life, and stir up the ambition of those interested, and all are interested in the success of the undertaking. It is an advertisement for the community and for persons interested; and if the display is good it gives a good reputation to the exhibitor.

"Like other productive industries, bee-keeping is not exempt from uncertainties as to results, and few things bring to the bee keeper so many pleasant and profitable things as does a display of bees, honey, and apiarian appliances," at the annual and other State, county, and district fairs and expositions. Wherever such an exhibit is made it is a nucleus around which beekeepers gather, and in a quiet, pleasant, and profitable way exchange ideas and discuss matters "new and old." An incident at the Tri-State Fair held here two years ago made a more lasting impression on me than hours of ordinary talking or pages of reading-matter might have done. An elderly farmer, some would have called him an "old codger," wanted to buy some bees of me. We talked over prices, etc., and I thought a bargain was about made, when he asked me if I used the extractor. When I told him I did, it would have done any melancholy dyspeptic good to see the expression of disgust that spread over his face as he said, "I don't want any of *your* bees." Strange as it may seem, I had to laugh in spite of all my efforts to the contrary, and I saw that this oracle knew that the extractor is responsible for the great winter mortality among bees, for he afterwards told me so. I believe he tried to purchase bees of every beekeeper there, and with the same result.

If there is a business that requires a man who can express in his face, at one and the same time, disgust, contempt, and anywhere from ten to ten thousand other kinds of expressions, I would most earnestly recommend that gentle-

man as the best-qualified man to run that business that I ever met.

These exhibits aid us in our efforts to popularize the use of honey as food and medicine. They will also help to raise the standard of excellence, both quality and attractiveness of honey put upon the market. New ideas will be disseminated, new methods will be learned, and old ones discarded.

Bees and honey are always great attractions at fairs; and to hear the "fat" expressions and quaint sayings of "smart" country people and city "dudenes" is enough to add years of happy life to the average age of those who enjoy such things. To listen to fond papas and doting mammas as they explain to their children, who are all eyes and ears at such times, the mysteries of the hive, and how the bees "make honey" while they are shut in the hive at the fair, and how a honey-extractor works either as a washing-machine, an ice-cream freezer, or a churn, will cause a change in the facial expression of such stoics as Mr. Hutchinson and a score or more others whom I might name, but space forbids; and such matter-of-fact men as our friend A. I. Root gather new enthusiasm and energy from such displays of sweetness, and the consequent contact with wise and otherwise people.

The first year I lived here, the premium offered by the Tri-State Fair was five dollars "for the best show of honey." I found the "show" set away on a high shelf among other things, and where it was seen by but few. It consisted of a rough box, holding about twenty pounds of comb honey, with glass in one end of the box. I spoke to officers of the society about the matter, and the result was the offering of over \$100 the next year as premiums, and the next year \$208. For six years the Bee and Honey Department has been a "fixture," and, like other departments, has a superintendent, etc.; and last fall it was said to be "the most attractive exhibit on the grounds." The exhibit in 1882 was small compared to what it has since become, and was described in the AMERICAN BEE JOURNAL by the editor, who assisted in awarding the premiums, as a "grand success. The small corner set apart for the bee and honey show was so crammed all the time that it was with great difficulty any one could get through the crowd, and utterly impossible for many who desired to examine the exhibits to even get within a stone's throw of them."

I want to say a few kind words about friend T. G. Newman. When we first started out to make an exhibition of honey, etc., at the Tri-State Fair in 1882 and also in 1883, he kindly consented to help us, and came from Chicago to Toledo and spent three days each year, without "fee or reward," in aiding in judging, and starting us off in good shape. A. I. Root and C. F. Muth and others helped us in 1883, and we have tried each year to improve on the previous one.

The exhibit at the St. Joseph, Mo., fair has become one of its most attractive features; and for five or six years past the Michigan bee-keepers have made a large and attractive display at

their State Fair, and have a separate building for their exhibit, and the premium-list was gradually worked up by Mr. Cutting, Prof. Cook, and others, from next to nothing to over \$300. At Toronto, Canada, have been made some of the largest (if not *the* largest) and most attractive exhibitions of honey and apianian appliances ever made on this continent.

I believe honey should be made the main attraction. A display of bees and queens is always "in order," and calls forth more quaint and original expressions from the crowd of sight-seers than even the extractor does. Many an old "residenter" has taken pains to put on the second pair of eyes to see "the king-bee who bosses all the other bees, and tells them what to do," and then, after being told it is a queen, and the mother of the bees, hurries off to hunt up some friend or member of the family to show them "the mother of all the bees."

Supplies are viewed with curiosity; but honey, that "sweetest of sweets, excepting the lasses that we all love to greet," is the great attraction, and creates a desire to *taste* that which to many is so irresistible that a purchase has to be made before the visitor is satisfied, and then, when leaving, frequently turns and casts longing glances at the tempting display of luscious sweetness.

The skill displayed in making honey exhibits in some of the countries of Europe is so great, and the display so attractive, that it is not a rare thing to have them visited by common people, as well as by kings and queens; and it is largely the fault of the bee-keepers themselves if like attractive and instructive displays are not made at the different fairs throughout this country; and I have yet to learn that the managers of any fair have regretted having done what they could to call forth an exhibit of honey, but all have been surprised at the beauty and attractiveness of a well-prepared display.

The Stark Co., O., Agricultural Society, at the solicitation of the Stark Co. Bee-Keeper's Society, last year appropriated \$100, to be given, as premiums for bees and honey, etc. and \$150 for the erection of a building for the display of things pertaining to the apiary.

If all county and State agricultural societies cannot be induced to give fair premiums for the products of the apiary, without doubt enough can be secured to more than pay expenses; but some one or more bee-keepers must look after the matter, and be sure that it is attended to. It will *not* take care of itself.

The question with us all very properly arises, "Does it pay to be to all this expense and trouble?" The same question very naturally arises, also, in regard to any kind of an exhibit at fairs, and each will have to answer the question for himself.

On page 221 of *Gleanings* for 1887, J. H. Martin puts this matter before us very nicely. He says, "Does it *pay* to spend time and money to advertise the honey business? If we look around us, we see every trade making strenuous efforts to get ahead. Take up the

most obscure county paper, and every trade is represented in its columns. Our most successful merchants are the ones who 'catch on' to every advertising novelty to be used in the extension of their business. Our fairs are the red-hot centers of attraction and advertising, through all lines of business, with the exception, perhaps, of bee-keeping.

"Probably the hardest thing for a spirited bee-keeper to bear, at the present time, is the general belief that bee-keeping is a small business, and that any ninny who knows just enough to chew gum, can successfully produce honey; and bee-keepers, as a rule, are following a course of action to confirm people in that belief; for if a business is not worth a little advertising effort, it is not much of a business."

It seems to me that a few bee-keepers in each county where honey is produced can make it *pay* to be to the necessary expense and trouble of making a nice and attractive exhibit. To be sure, it has to be "mixed with taste and brains," and that is just what every successful bee-keeper, or his wife, has a supply of. See that the premiums are enough to *pay expenses* (which need not be heavy), and trust to sales, etc., for the "net proceeds."

One thing has been fully demonstrated by the exhibits of honey at fairs, and that is, that bee-keeping is fully abreast of other productive industries; and when compared with some, is much ahead in attractiveness and value.

The honey exhibition at the Ohio Centennial Exposition at Columbus, from Sept. 4 to Oct. 9, is not to be made just for the money there is in it, but to show the progress in bee-culture during the last hundred years; and it is hoped that it will be the largest and most attractive that has ever been held in this country; and, so far as I know, those engaged in the matter have the vim and push to do credit to the fraternity. Just think of a building 36x80 filled with the luscious God-given sweet! I have seen tons of honey piled up at fairs that did not make as much show as one-fourth the amount might have been made to do.

Anburndale, O.

FOUL BROOD.

What Produces It?—Sulphuric Acid Treatment.

Written for the American Bee Journal
BY WILLIAM KLINTWORTH.

It is easier to ask a question than to answer it. We may have theories upon certain things, but if our theories are not founded upon facts that corroborate our ideas, our theories have no foundation, and are not worth much. What creates foul brood? We might ask, what creates sickness, such as typhoid fever, yellow fever, and other diseases that occur more in some localities than others?

If we could see atmosphere, or the production of decayed vegetation, in

its true light, we would know more about diseases than we do now. But we know those things only in part. It is clear to my mind that the same cause produces chills and fever, yellow fever and typhoid, and some other diseases; but how much of that substance it takes to create a certain disease, cannot be stated with any certainty. But after it is developed it is not merely a dead substance, but has life in itself, and takes possession of its victim. Then the question comes to us, what can we do to kill that, and not hurt the bees and brood?

There are several things that will destroy foul brood, but we cannot apply them. When a colony of bees has foul brood, it not only affects the brood, but bees and queen also, and consequently they should then be fed, or we will not always accomplish our object. If I found foul brood among my bees, I would feed them all, for it would be hard to tell how soon it would develop in those that I could not discern anything wrong, and at the same time were diseased.

How to Feed Sulphuric Acid.

I will now describe how to feed sulphuric acid: Take 60 drops of sulphuric acid to one pint of water, and add one pint of honey. Mix it thoroughly, and that will do to feed. I prefer to feed from beneath, but if I could not do so, I would take the bees and frames out of the box. I would then take 60 drops of sulphuric acid to one pint of water, and wash the inside of the box thoroughly with it, and then put the bees back into the box, and feed the best way I could with the preparation. I have fed one quart of it to one colony of bees inside of 24 hours.

The Fire Treatment of Foul Brood.

I know that some who have had experience with foul brood, recommend burning the bees, but I must confess that I have failed to see it in that way. Suppose I had only 3 or 4 colonies of bees, and had discovered that they were foul, I would then take them and burn them, hives, bees, and all. The question comes to me, what have I gained by doing so?

But suppose I had a larger number, and find that some of them are foul, and burn them; and in a few days I find some more, and do the same with them, and I do so until I have burned them all—where are my profits? I keep bees for pleasure and profit. As long as everything goes all right, I get plenty of honey—I think much of my bees. But when they get diseased, I burn them alive! Does that not look hard?

But we say, "It can't be cured with any certainty." How do we know? Have we tried everything that we can? If I had foul brood among my bees, and I had no other remedy, before I would burn them, I would take the bees and brush them off the comb into a box, as if I would ship them. I would take box, frames and all, except the bees, and put them into a bleach box, or a big dry-goods box. I would take a half pound of sulphur, put it into an

iron kettle or something fire-proof, and place it in the box with the hive. Then set the sulphur afire. After it had burned, put the hive on the old stand, and put the bees into it. That will kill the brood and eggs, and save the hive, frame and bees. Has any one ever tried it?

Marietta, Ohio.

CONVENTION DIRECTORY.

1888	<i>Time and Place of Meeting.</i>
Sept. 25, 26.	—Cedar Valley, at Cedar Falls, Iowa. J. J. Owens, Sec., Waterloo, Iowa.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Yield of Fall Honey.—Jno. A. Thornton, Lima, Ills, on Sept. 5, 1888, says:

The yield of fall honey will be good. I will have an average surplus of about 85 lbs. per colony. The quality is equal to clover, as some of it was from red clover. The largest yield is from smart-weed. My 200 colonies have gathered a good supply for winter besides the above amount of surplus.

A Blooming Curiosity.—J. C. Bell, Belton, Tex., on Aug. 31, 1888, writes:

I send a blossom that made its appearance about April 1, from which the bees gathered quite a quantity of honey for 60 days. Since the rains set in on Aug. 18, it is blooming again. What is it? Bees have done finely in Texas this year.

[This is not yet identified. It is a curiosity, and I should much like to have a pressed specimen showing more of the plant. Please address it to T. J. Burrill, Champaign, Ills.]

Chapman Honey-Plant Seed.—H. Chapman, of Versailles, N. Y., on Sept. 10, 1888, gives the following information in reply to a question by Mr. R. Bacon, on page 596:

The seed of the Chapman honey-plant should be collected as soon as the balls commence to turn brown; the balls should be spread upon platforms until thoroughly cured, when the seed can be easily shaken from the heads. But to separate the seed from the capsule, requires more labor. I accomplish this with a machine devised by myself, and which consists of a cylinder thickly studded with steel teeth, and which is made to revolve within another cylinder, from the inner sides of which project steel teeth. It is unnecessary to remove the capsules from seed used at home, but I have always cleaned that which I sold.

Heart's-Ease Honey.—John Has-kins, Empire Prairie, Mo., on Sept. 7, 1888, writes:

Three to four weeks ago it seemed as though I should have had another failure with my bees; but about the middle of August they commenced to swarm, and no person that has not seen bees working on the heart's-ease can form but little idea how fast they will gather honey. The colonies that three weeks ago I did not know would gather enough honey to winter on, will probably give me in comb honey from 100 to 150 pounds each. There are thousands of acres of heart's-ease here.

Gay Feather.—D. W. McDaniel, of Hamilton, Ills., on Sept. 3, 1888, says:

I send a specimen of a honey-plant to be named. It grows on thin clay soil, and from 2 to 4 feet in height. Bees work on the blossoms all day. The bloom commences at the top of the spike, and blossoms downward. Please give its name in the "old reliable" AMERICAN BEE JOURNAL.

[This is "gay feather" (*Liatris scariosa*); not known to be specially valuable for honey; but like other "compound" flowers, it is a great pollen producer.—T. J. BURRILL.]

No Swarms or Honey.—Mr. John Boerstler, Vashon, Wash. Ter., on Sept. 7, 1888, says:

I am not discouraged yet, although the bees did not swarm or store one pound of surplus honey this year. In the spring it was too wet, and after that they secured a good supply of stores, and will have plenty to winter on; but not a pound for me. I will have to do without honey this year. All right; I guess I am not the only one in that "boat."

Hedge Hyssop, etc.—T. M. Coleman, Glendon, Iowa, on Aug. 28, 1888, writes:

I send you a part of a plant which grows in a corner of my lot, that I do not recollect of ever seeing before this season. It grows about 6 to 7 feet high, and the bees work on it as if they liked it. Will you please state, in the BEE JOURNAL, what it is.

Bees are doing nothing as to surplus honey. My colonies have been strong all the season, and I have not had an ounce of honey and no swarms this season. The most of them stored in about enough to winter on, from the linden trees, of which I have a good bee-range.

[This is "hedge hyssop" (*Lophanthus scrophularifolius*); like most of the mint family, it is an excellent honey-plant.—T. J. BURRILL.]

Excessive Swarming, etc.—Mr. Franklin Witcox, Mauston, Wis., on Sept. 10, 1888, writes:

The bees have not worked "according to rule" this season. They wintered fairly well, but dwindled very badly in the spring. I had 3 swarms in June; they swarmed almost every day from the middle of July to Sept. 4. I have kept bees for 20 years, and I have never had so much swarming as this year. I lived nearly all the first swarms on full combs on the old stands, cut

out queen-cells, and hived back after-swarms; in this way all colonies have been kept strong. The crop of honey is better than last season, though rather below an average. The honey season usually ends by Aug. 20, but this year it continued good till Sept. 4, since which time only the buds of black-oak have yielded a clear, fine-flavored nectar. From sunrise till 9 o'clock it may be seen in drops on the ends of dark-colored, shining buds. It is no honey-dew. It has lasted a week or more. I never saw it before, and may never see it again.

Happily Disappointed.—Rev. S. Roese, Maiden Rock, Wis., on September 1, 1888, says:

The very heavy rains have ceased here, and we have now had 10 days' fair weather, after the winter wheat in shocks was nearly spoiled, and all other crops but corn (so far) a total failure. We have had for the last week or so, a fair honey-flow, and I feel happily disappointed. The bees are taking advantage of this opportunity. Since my last report I have extracted over 400 lbs. of honey, and take off about the same number of pounds of comb honey, for which I feel thankful.

Honey Coming in Freely.—J. E. Pryor, Dexter, Iowa, on Sept. 13, 1888, writes:

Up to Aug. 1 our bees scarcely stored enough honey to keep them from starving; in fact, in June we had to feed to keep them breeding. But since Aug. 15 I think I never saw bees do any better. I have had 10 or 12 swarms since Aug. 22, all of which will have considerable surplus honey. Swarms that were hived on full frames of foundation, had their hives filled with honey to the exclusion of the queens, in from 4 to 6 days. The honey is of the finest quality of fall honey, very thick and heavy, and is still coming in quite freely. Our bees will be in splendid condition for winter. I increased my apiary from 48 to 76 colonies, by natural swarming.

Bee-Keepers' Union.—Dr. H. J. Scoles, Knoxville, Iowa, on Sept. 10, 1888, says:

As to the change of time of election of officers and payment of dues to the Bee-Keepers' Union, I vote "No!" I think that it would be a detriment to the Union, and decrease the membership instead of increasing it. It would bring the election and renewal of membership at a time when the bees are in winter quarters, and there is no fear or talk of the bees interfering with any one; and all would rest content, and be more likely to forget, than they would if it came at a time when it required attention.

☞ The 6th annual meeting, and basket picnic, of the Progressive Bee-Keepers' Association will be held on Wednesday, Sept. 26, 1888, at the residence of Mr. W. S. Wait, in Newburg, Geauga Co., Ohio. All are invited to be present. DEMA BENNETT, Sec.

☞ The Cedar Valley Bee-Keepers' Association will hold its annual meeting at the Council Rooms, Cedar Falls, Iowa, on Sept. 25 and 26, 1888. All who are interested in bees and honey are cordially invited to be present. J. J. OWENS, Sec.

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1, postpaid.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4 1/4 x 4 1/4 and 5 1/4 x 5 1/4. Price, \$1.00 per 100, or \$8.50 per 1,000.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in *Cheshire's* pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being mailable, it must be sent by express.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the *Apiary Register* and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the *American Bee Journal* must be sent with each order for another paper or book:

Hastings' Perfection Feeder.

This Feeder (illustrated) will hold 2 quarts, and the letting down of the feed is regulated

Patented Oct. 18, 1887.

by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for \$3.50, and it can be obtained at this office. Postage 10 cents extra.

Cork for Winter Packing.

Its advantages are that it never becomes *musty*, and it is *odorless*. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Can You Do Anything that will do more to advance and defend the pursuit of bee-keeping, than to aid its Weekly Exponent and Defender? The AMERICAN BEE JOURNAL is the pioneer bee-paper of America, and is fully entitled to the active support of every progressive apiarist, for it works constantly and faithfully for the best interests of the pursuit. We therefore specially request all our readers to use their influence to double our subscription list during the coming autumn. Reader, will you please send us a new subscription with your renewal or before that time? A good weekly at one dollar a year is surely cheap enough to command patronage.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2 00	3 00	3 50
1,000 Labels.....	3 00	4 00	5 00

Samples mailed free, upon application.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$3.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Sweet, or Melilot, Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Exchange.—We will accept Honey and Beeswax in exchange for Bee-Keepers' Supplies in any quantity. Those desiring to make a trade are invited to correspond with us, stating quantity, quality, and price, and the goods they want in exchange.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 10 cents per pound for bag and postage.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; 1/2 pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, Ills., is published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Honey and Beeswax Market.**CHICAGO.**

HONEY.—New crop arriving slowly, but demand is limited. White clover comb, 17@18c. Extracted, 7@9c.

BEESWAX.—22c.
Sep. 12. S. T. FISH & CO., 189 S. Water St.

CHICAGO.

HONEY.—For white comb 1-lbs., 18c. Very little inquiry for anything outside of 1-lbs., and when it is wanted it is at a lower price. Extracted, the best grades, 7@8c., and some held higher. Offerings are small and demand slow.

BEESWAX.—22c.
Sep. 12. R. A. BURNETT,
161 South Water St.

DENVER.

HONEY.—Colorado, new 1-lb. sections., 13@15c. Extracted, 7@8c.

BEESWAX.—20@23c.
Sep. 7. J. M. CLARK & CO., 1409 Fifteenth St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 13@14c. Fair white 1-lbs., 15@16c.; 2-lbs., 11 to 12c. Extracted, white, 7@8c.

BEESWAX.—23@24c.
Sep. 5. THURBELL, WHYLAND & CO.

NEW YORK.

HONEY.—Fancy white 1-lbs., 17@18c.; off grades, 15@16c. Fancy white 2-lbs., 13@14c.; off grades, 12c. Extracted, white, 7@8c. New crop is arriving and demand is good.

BEESWAX.—23@23½c.
Sep. 5. HILDRETH BROS. & SEGELKEN,
28 & 30 W. Broadway, near Duane St.

SAN FRANCISCO.

HONEY.—White 1-lb. sections, 12@15c.; 2-lbs., 11 to 14 cts.; amber, 7@9c. Extracted, white, 5¼@6c.; light amber, 5@5¼c.; amber and candied, 4¼@4¾c. Receipts light and market firm for best qualities.

BEESWAX.—17@21c.
Aug. 25. O. B. SMITH & CO., 423 Front St.

DETROIT.

HONEY.—Best new white comb, 15@16c., with little in sight and slow sales. Market is low, and beekeepers will do better to hold honey until approach of cold weather.

BEESWAX.—21@22c. Supply limited.
Aug. 22. M. H. HUNT, Bell Branch, Mich.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb., for which demand is fair. Comb honey, 12@15c. Some small lots have sold at 14@16c. Market quiet.

BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Aug. 24. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—Choice 1-lb. sections, 18c.; dark 1-lbs., 14c.; 2-lbs., 15c.; dark, 13c. White extracted in 60 lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices firm, and stock light.

BEESWAX.—None in market.
Aug. 29. HAMBLIN & BEARSS, 514 Walnut St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 17@18c.; 2-lbs., 14@15½c. Fair 1-lbs., 14½@15½c.; 2-lbs., 11@12c. Extracted, fancy white clover, 7½@9½c.

BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Sep. 13. F. G. STROHMEYER & CO., 122 Water St.

BOSTON.

HONEY.—We quote: New 1-lb. sections, 18@20c.; 2-lbs., 14@16c. New extracted, 8@10c.

BEESWAX.—25 cts. per lb.
Aug. 24. BLAKE & RIPLEY, 57 Chatham Street.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 5½ cents; light, 5¼c.; amber, 4½@5c. Comb, 1-lbs., 12@14c.; 2-lbs., 9@13c., as to quality. Arrivals not large, and supplies held firmly.

BEESWAX.—Dull at 19@22c.
Aug. 20. SCHACHT & LEMCKE, 122-124 Davis St.

KANSAS CITY.

HONEY.—We quote: New white 1-lbs., 18c.; light 1-lbs., 16c. California white 1-lbs., 18c.; light 1-lbs., 16c.; white 2-lbs., 16c.; light 2-lbs., 14c. Extracted, white, 8c.; amber, 7c.

BEESWAX.—19@20c.
Sep. 5. CLEMENS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—We quote: Extracted, 4½@5½c.; if in cans, 8@9c. White clover comb, 14@15c. Market is steady and receipts light.

BEESWAX.—21c. for prime.
Sep. 6. D. G. TUTT & CO., Commercial St.

MILWAUKEE.

HONEY.—New white 1-lb. sections 18c., and very fine, 20c.; 1-lbs., 15@18c.; old 2 and 3 lbs., not salable, 12@14c.; dark 1-lbs., old or new, 12@13c. Extra-comb, new white in kegs and ½-barrels, 8@9c.; old, in ten, same packages, 7@8c.; in tin, 8@9c.; dark in barrels or ½-barrels, 6@6½c. Arrivals of new crop small; demand not urgent, and only very moderate trade.

BEESWAX.—22@25c.
Aug. 31. A. V. BISHOP, 142 W. Water St.

Conventions.—The time for holding Bee-Keepers' Conventions has now arrived, and we cannot give any better advice than this: Let each one attend who can do so, and take part in making these meetings interesting and instructive. If you have not already obtained the "Bee-Keepers' Convention Hand-Book," do so at once to post yourself up on how to conduct such meetings correctly. It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for Discussion—List of Premiums for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents. We will club this book and the AMERICAN BEE JOURNAL for one year for \$1.25. It also contains a lot of blank leaves on which you can note important matters as they come up. Do not fail to send for a copy of it.

We Want 20,000 subscribers. Out of the 300,000 bee-keepers in America, certainly this is not an extravagant desire! It is only one out of every fifteen! We confidently ask those who appreciate the AMERICAN BEE JOURNAL, to show it by sending us one or more new subscribers. We will give them full value for their money.

Simmins' Non-Swarming System.—We have a few of these books left, and we will club them with the AMERICAN BEE JOURNAL for one year, both postpaid, for \$1.25. The subscription to the BEE JOURNAL can be for next year, this year, or may begin anew at any time.

We Have some copies of the old edition of Cook's Manual left, which we will sell at the old price, \$1.25. The price of the new edition is \$1.50 per copy; a notice of which may be found on page 579.

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Queens.—We can mail a Tested Italian Queen (bred for the best results as well as for beauty) for \$2.00; Untested Queens \$1.00 each, or \$9.00 per dozen. Orders solicited.

We will Present a Pocket Dictionary for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Advertisements.

WANTED—Situation. I can manage, or assist in, a practical apiary; can give good references. Please address me, HARRY GAFFEY, 37A2t GRANBY, PROV. QUE., CANADA.

Mention the American Bee Journal.

BEE-KEEPERS, TAKE NOTICE!

TO INTRODUCE our SECTIONS we will from now until Jan. 1, 1889, sell A No. 1, all-white Sections at \$2.75 per M.; and second class at \$2.25 per M. All other Supplies at a corresponding low figure. Price-List and samples free. Address,

R. H. SCHMIDT & CO.,
38A1t NEW LONDON, WIS.

Mention the American Bee Journal.

HANDSOME ONE-PIECE SECTIONS.

WE have a limited quantity of One-Pound Sections, 4¼x4¼, a trifle less than two inches wide, with narrow tops, in packages of 1,000 each. They are manufactured from extra white lumber planed on both sides, making them the finest and most attractive honey-section in the world. Price, \$4.00 per package.

THOS. G. NEWMAN & SON,
923 & 925 West Madison-Street, - CHICAGO, ILLS.

The **BUYERS' GUIDE** is issued March and Sept., each year. It is an encyclopedia of useful information for all who purchase the luxuries or the necessities of life. We can clothe you and furnish you with all the necessary and unnecessary appliances to ride, walk, dance, sleep, eat, fish, hunt, work, go to church, or stay at home, and in various sizes, styles and quantities. Just figure out what is required to do all these things **COMFORTABLY**, and you can make a fair estimate of the value of the **BUYERS' GUIDE**, which will be sent upon receipt of 10 cents to pay postage, **MONTGOMERY WARD & CO.** 111-114 Michigan Avenue, Chicago, Ill.

38A13t
Mention the American Bee Journal.

Jones' Frame Pliers.

FOR taking frames out of hives, or moving them in any way desired. It is made of Japanned iron, and can be utilized in many ways. It has a long claw for loosening frames, and a hook which may be used for carrying other frames besides the one held by the Pliers. Price, 40 cents., by mail. By express, 30 cents.

THOS. G. NEWMAN & SON,
923 & 925 W. Madison St., - CHICAGO, ILL.

Vol. XXIV. Sept. 19, 1888. No. 38.

EDITORIAL BUZZINGS.

“Though the mills of God grind slowly,
Yet they grind exceeding small;
Though with patience he stands waiting,
With exactness grinds he all.”

Our Query Department is not conducted for the purpose of answering catch-questions or puzzling conundrums. It is solely intended to aid earnest seekers after knowledge in our pursuit.

The Indiana State Fair commenced on Monday. We learn that there is a creditable display of honey among the exhibits.

In France, the month of August has been better for honey-production than July. The honey crop is less than the average, and in some parts the amount of white honey is exceedingly small.

Line Fences divide property, and keep cattle and horses on their owner's land, but bees pay no attention to such divisional lines. The air is their highway, the sunshine their invitation to roam, and the flowers their banqueting halls. Happy, basking, smiling, buzzing, frugal bee! Cunning, stinging, robbing bee!

We have Received a copy of a pamphlet issued by The St. Louis Academy of Sciences, on the Pollination and Perforation of flowers. It is written by Mr. L. H. Pammel (who is well known as a correspondent of the AMERICAN BEE JOURNAL), as a contribution from the “Shaw School of Botany.” It is very interesting, and we will make some extracts from it in our next issue.

Hotel Arrangements at Columbus.—Concerning these, Dr. A. B. Mason wrote us from the Centennial Exposition Grounds at Columbus, O., on Sept. 13, 1888, asking us to publish the following notice to bee-keepers who intend to be present at the convention:

If those in attendance at the next meeting of the North American Bee-Keepers' Society will report to me at the place of meeting in the hall of the House of Representatives at any time after 10 a.m., Oct. 3, I will try and be able to tell them where to obtain such entertainment as they may wish. As yet I have not been able to obtain reduced rates at hotels, but may succeed in doing so. Let those coming to the convention take advantage of the reduced railroad rates to the Centennial at Columbus.

An effort has been made to secure reduced rates through the Traffic Associations, but without success.

It is a Poor Economist, says an exchange, who lets surrounding available treasures go to waste. What would you think of the farmer who would not gather the golden grain when it was ripe and waving in the field? Or what would you think of the man who would harvest the new crop and let the old crop go to waste? The man of thrift gathers and saves from every possible source. He lets nothing go to waste. He gathers in his corn and his wheat, his rye and his barley, and he gathers also the honey from the flowers of his fields. It is his, he pays nothing for it. Genial nature plants the flowers and fills their cups with honey, and all he has to do is to get the bees and care for them, to save what would otherwise be lost.

Bees Imprison a Rattler.—The Atlanta Constitution relates that a party of men cut a bee-tree near Trompsville, Ga. The hollow was found to be filled with honey and comb for a distance of 15 feet. After securing the honey, one of the boys cut into the tree above the portion used by the bees, and found a rattlesnake 3 feet long. As there was no hole in the tree, except the one which contained the honey, the supposition is that the snake crawled up the hollow before the bees began to hive, and the honey-comb had blocked its exit.]

Orange Judd, so well known as an agricultural editor, has purchased the Farmer of St. Paul, Minn.; has moved it to Chicago, and the first number is on our desk, the name changed to *Orange Judd Farmer*, and making a very creditable appearance. We wish it a very prosperous career, and extend to friend Judd the right-hand of fellowship. With such a manager and editor it must succeed.

A Neat Pamphlet of 32 pages is on our desk, from the St. Joseph Apiary, Missouri. It is written by the Rev. Emerson T. Abbott, and is intended for distribution at the coming fair in that city.

Bee-Stings.—In an exchange Prof. A. J. Cook is credited with the following advice as to what to use for relief from the effects of the stings of bees:

I have ammonia, or hartshorn as it is usually called, always about our apiary, and have found nothing better for bee-stings. This is correct in theory as well as in practice; the active poison of the bee is or contains formic acid; ammonia is an alkali, and neutralizes the acid and so the poison. Dashing the part stung into ice water also gives partial relief; it stops the circulation, and so prevents absorption of the venom. A strong extract of cheap tobacco, made by turning hot water on a cheap cigar is also a partial alleviative. Some regard it superior to ammonia. It is a well-known fact that the bee-poison is itself a kind of vaccine; the more one is stung the less is he affected.

The Old Story about bees puncturing grapes and other fruits, says an exchange, to suck the juice therefrom is pretty well exploded. That they will suck the sweets from any of these fruits that they may find already broken, is true; and seeing them doing this, unthinking persons have jumped to the conclusion that the bee was the original trespasser. A little study of the organism of the bee will show that it has no tools wherewith to commit such depredations. Nature took care of the fruit as far as the bees are concerned, by incapacitating the bees from cutting or boring into it.

We had a Call from Mr. Herbert Brown, who has been sent to the Eastern States from Ventura county, Calif., to “place” several carloads of extracted honey. He reports the California honey crop as larger than it has heretofore been estimated. He says that some of the bee-keepers there have “bought up” all the honey on the market, and “hold it” to “stiffen the prices,” as well as to judiciously place it upon the market; thus reducing to a minimum the damage usually done by small producers whose impecuniosity leads them to sacrifice their honey crop by accepting the first and lowest amount offered.

One-Third of a Crop.—A. Reusch, of Chariton, Iowa, says he expects to obtain only $\frac{1}{3}$ of a crop of honey this year. He writes us thus on Sept. 13, 1888:

The bees in this locality have done but little until Aug. 20. They had been doing well up to last Monday, Sept. 10, when it turned cold, and the wind was in the North. I expect to get a third of a crop of fall honey.

Frank Leslie's Sunday Magazine for October contains many interesting and valuable articles, all freshly written and brightly illustrated. The continued story, “Genevieve,” opens the number. It is a story of the Huguenot troubles in France. The poems and short articles are numerous and good, and there are a number of full-page engravings of much beauty. It is a specially good number of this favorite family magazine.

GLEAMS OF NEWS.

Preparing Bees for Winter.—

Mr. H. E. Hilf gives this description of his method of preparing bees for winter, in the *Farm and Home* :

Below I give a brief description of a plan of preparation that, notwithstanding the pollen, hibernation and other theories, has served me in the wintering of hundreds of colonies with a loss not exceeding two per cent. The method being simple, as it is effectual, is especially recommended to those who have but few colonies to care for :

Procure a box (such as may be had at any dry-goods store) from 12 to 24 inches larger than the hive to be packed. After cutting an entrance 6 inches in length by 1½ inches high in one side at equal distances from the sides, I place the box on the summer stand of the hive, and put the hive inside, supported on pieces of wood, at a height that brings the bottom-board to correspond with the entrance.

Then place strips 1½ inches high on either side of the entrance from the hive to the inside of the packing case, resting on the projecting bottom-board, and place a snug-fitting piece of stuff over these, thus forming a passage for the bees from the hive to the open air, and excluding the sawdust or planer shavings which are used for packing. Being now packed snugly beneath and on all sides of the hive, I use no honey-board, but simply cover the frames with a quilt of cotton cloth and a cushion of sawdust, which acts as an absorbent, and may be easily replaced with a dry one if it becomes damp from the escaping moisture of the colony during winter. Over this I put the usual six inches of shavings—or even 24 inches—filling the box. Now place a good roof over them, and all is complete.

Try it, and report your success next May. If by mild, sunny weather the bees are inclined to fly oftener than is desirable, place a short board in front over the entrance, with the bottom resting on the ground, a foot from the box, and over this an armful of straw. This box will darken the entrance, and tend greatly to equalize the temperature inside.

This Dialogue is published in a late number of the *Western Christian Advocate*. The answers to the questions are supposed to be given by one of the distinguished purchasers of some of the patent moth-trap bee-hives which abound in doors, hinges, drawers, corners, etc. :

What is the chief end of bees? To get out patent hives.

What is the best patent hive? The best hive is not patented.

But don't some of these patent hives fool the moth? No; they fool the men who buy them.

What patent hive is the most useful? The new one in the barn with a hen's nest in.

But is there not more money in patent hives than in bees? Yes; but that time is almost over.

But how are we to know a poor hive? It has a great many doors, drawers, hinges, cracks, crevices, nooks and corners which look like conveniences, but in which the bees stick fast.

Who are the great bee-savants of this country? The men who don't use patent hives.

Are bees profitable? Not to those who buy patent hives.

Sense Organs in bees and other insects are worthy of considerable study, and will repay a thorough investigation. In *Murray's Magazine* we find the following very interesting remarks on the subject :

In the matter of sense organs we are met by serious difficulties of interpretation, and this difficulty is the more keenly felt in studying creatures so widely different from ourselves as the bee. Such an insect would seem at first sight to be about as susceptible to the delicacies of touch as an ancient armor-sheathed knight. Head, thorax, abdomen, limbs, all are ensheathed in chitinous armor. The bee has his skeleton outside. The question is, how can delicate impressions of touch be transmitted through the tough, dense skin so as to affect the sensitive "squash" within? If you will examine one of the feelers of the bee you will see that the surface is richly supplied with hairs. It is by means of such sense hairs that the bee experiences a sensation of touch. Each touch hair is hollow, and within it is a protoplasmic filament containing, it would seem, the delicate terminal threadlet of a nerve. A curious modification of the touch hair is found on the last joint of the antennæ. They are here bent sharply at right angles, so as to form rectangular hooklets.

Shipping Colonies of Bees.—The following concerning the shipment of full colonies of bees is from the *Indiana Farmer* :

A great many people seem to think it is next to impossible to ship full colonies of bees by cars, without running a risk that makes it well-nigh out of the question. This is a mistake. Bees properly prepared may be shipped several hundred miles. The frames must be secured in some way so that they will not shake about the hive, and the bees fastened in with wire-screen, so that they can have plenty of fresh air. We usually tack screen over the entrance and over the brood-frames, and ship them with the cover off, and mark them "This side up, with care. Do not cover up. Do not leave in the sun." We also recommend that, where the route is known, they be shipped so that the greater part of the journey may be made at night. Timid express agents are apt to become greatly alarmed at a few robber bees that may hover about, and conclude at once that the bees are escaping. There is no danger of robber bees at night, and it is the coolest part of the day.

The North American Convention at Columbus, O., will soon convene, and all who intend to go should soon be making the arrangements. The following from the Secretary will explain about the railroad fare to and from the Convention :

The North American Bee-Keepers' Society will hold its annual meeting on Oct. 3, 4 and 5, 1888, in Representatives' Hall at the capitol in Columbus, Ohio. The Passenger Traffic Associations will grant reduced rates only when 100 persons are present, holding railroad certificates. Owing to the short honey crop it is feared that a sufficient number of persons will not be present holding certificates, and that an attempt on the part of the Society to avail itself of the reduced rates offered by the Passenger Traffic Associations will only result in disappointment; hence it has been decided that the only course open will be to allow each member to shift for himself, or herself, to either take advantage of such excursion rates as may be available in his or her vicinity, buy round-trip tickets, or do something of the sort.

W. Z. HUTCHINSON, Secretary.

September Hints.—Mr. C. H. Dibbern, in the *Western Plowman*, gives the following hints about seasonable work in the apiary :

This is the last month that bees can be reasonably expected to gather any honey. Usually about the 20th of the month we, in this latitude, have a frost that kills the flowers, but if not, the last series of flowers are done blooming, and there is nothing more for the bees to do.

Early this month is the time to know the exact condition of each colony.

While honey is yet coming in is the time to take out the frames and examine them. To guess they are all right, won't do, if you wish to winter them over.

In some localities, feeding will again have to be resorted to. This should be done now, before the nights become too cool, and robbing is more difficult to guard against.

As soon as the gathering season is over remove all the surplus arrangements and put the bees in condition for winter. Many, especially those who have had two seasons of failure, will become discouraged and careless, and will let the bees shift for themselves, with perhaps not enough honey to carry them to January. That such persons will ever have "no luck" with bees is certain, and perhaps the sooner the bees come out dead, the better. The persevering, intelligent bee-keeper, however, will only strive the more when others around him are giving up, and my experience is that such only will win in any pursuit.

This season has been a peculiar one, in regard to swarming. Usually, in this locality, the bees commence swarming in June and end up early in July. This year they commenced in May, and are swarming some yet. Heretofore, we used to return second, or very late, undesirable swarms by looking over the combs of the swarming colony and removing all the queen-cells and hiving the swarm back in the old hive. We lately bit upon a new wrinkle with the new hive. Now when a late swarm comes out that we do not want to hive separately, or have any weak or queenless colonies to boom up, we simply *invert* the hive that casts the swarm, and return the bees by shaking them on the sheet in front of the hive. So far this has worked nicely, and not one has made a second attempt to swarm. This process, of course, turns the queen-cells (the cause of the bees swarming) wrong side up, and the bees immediately tear them out. If this proves to be the invariable result of inverting, this is another point in favor of invertible hives.

We lately broke up a case of robbing in a very neat way. Going out into the apiary quite early one morning we noticed a colony that seemed to be working with unusual energy. In looking around a little further we soon discovered another colony that was evidently being robbed. Concluding that this last one had lost their queen, we removed it to the shop and examined them, and soon found that to be the fact. We now procured the comb from a nucleus (it is well to have a few such at all times) containing bees, brood and a queen. We exchanged this frame for one of the queenless hives. We now returned this hive to the place of the one doing the robbing, which was removed to the stand of the one that was being robbed. This, of course, threw the robbing business into great confusion. Those trying to rob would simply go into their own hives; if any returned, they only carried the honey back to the hive they had previously robbed. An hour afterwards, all was quiet, and the robbing was completely stopped, and both colonies resumed their honest toils.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

Doctors Disagree.—Mr. G. K. Hubbard has this criticism to make on one of our Queries. It appeared in the *Indiana Farmer* recently. Variety is the spice of life. If we all thought and spoke alike there would be no diversity of opinion—no spicy discussions—no progress from the “old ruts” and well-beaten paths of our forefathers. The fact that we disagree on every conceivable subject is the “bulwark of our freedom,” and the glory of the nineteenth century. But here is the item :

In the question department of the AMERICAN BEE JOURNAL, the question, “Are eggs ever put into the royal cell?” is answered by a large number of prominent apiarists, and it is actually surprising to see how many answer the question negatively, or in a manner expressing doubt. We do not understand why this should be. We have frequently seen eggs in queen-cells, and in fact have seen it so often that we wonder at our experience being different from so many who are more experienced. We imply that those who express doubt on the subject, think that young larvae are always used for the purpose. Clearly they are mistaken, as we have often seen eggs in queen-cells appearing to have been deposited as naturally as any in regular worker or drone-cells. The question is not one carrying with it facts of much importance, but it makes a splendid illustration of how “doctors disagree” on questions that seem as plain as the alphabet to others.

An Eye Opener.—One of our exchanges contains the following showing that a poor honey crop may be a blessing in disguise :

I think it is not hard to see that this poor season may be a blessing in disguise, and may work for the good of our business. Our large markets have got overstocked with honey, prices had been knocked down by shipping honey into the already overstocked markets, until honey was selling at ruinous prices. The Wiley lie was floating over the country, that there were numerous manufactories where bee-comb was manufactured and filled with glucose syrup, and sealed over with hot irons. The newspapers wafted this story along, and thousands believed the story, although it was so inconceivable.

This failure of honey from the flowers has cleared out the honey markets so that commission men have been calling loudly for honey, at good prices. Where are these glucose manufactories all this time, that they allow the markets to become so bare of honey even at doubled-up prices? This ought to open the eyes of the community on this subject, and strike a death-blow to that infamous lie.

Stinging Bees.—A correspondent from Iowa sends us the following dialogue concerning educating the bees to hold their breath and thus suspend their stinging propensities. Here is the dialogue :

“What have you found to be the best remedy for a bee-sting?” said the reporter. “Bee-sting! I haven’t had an opportunity to use a remedy for years.”

“How then, Mr. Foggy, do you manage; or don’t your bees sting?”

“Yes, my bees are capable of stinging, but they have had good training. You probably have noticed in some of the bee-literature of the day, a novel way of escaping the sting of a bee by holding your breath.”

“Now that idea never occurred to me, but

sometime ago I commenced training my bees to hold their breath as soon as they felt like stinging, thus preventing the sting, and if you don’t believe it, I have them well trained, and you can try it.”

Alsike Clover.—In the report of the United States Botanist just issued, in the report of the Commissioner of Agriculture, a copy of which we have received from N. J. Coleman, Esq., we find the following on page 304, concerning the history, development and characteristics of Alsike clover, which will interest our readers :

This differs from common red clover in being later, taller, more slender and succulent. The flower heads are upon long pedicels.

Alsike Clover Bloom.

cells, and are intermediate in size and color between those of white and red clover. Its botanical name was so given from its being supposed by Linnæus to be a hybrid between those clovers, but it is now known to be a distinct species. It is found native over a large part of Europe, and was first cultivated in Sweden, deriving its common name from the village of Syke in that country. In 1834 it was taken to England, and in 1854 to Germany, where it is largely grown, not only for its excellent forage, but also for its seed, which commands a high price. In France it is little grown as yet, and is frequently confounded with the less productive *Trifolium elegans*.

The following is condensed from “Les Prairies Artificielles,” by Ed. Vianne, of Paris: “Alsike does not attain its full development under two or three years, and should therefore be mixed with some other plant for permanent meadows. It is best adapted to cool, damp, calcareous soil, and gives good results upon reclaimed marshes. It is adapted neither to very dry soils, nor to those where there is stagnant water. Being of slender growth, rye-grass, rye, or oats, are often sown with it, when it is to be mowed. In fertile ground weeds are apt to diminish the yield after a few years, so that it requires to be broken up. It is generally sown in May, at the rate of 6 to 7 pounds of the clean seed per acre. Sometimes it is sown in the pods at the rate of 50 to 100 pounds per acre, either in spring or in autumn after the cereals are harvested.

“Alsike sprouts but little after cutting, and therefore produces but one crop and

one pasturage. The yield of seed is usually 130 to 170 pounds per acre. The seed separates more easily from the pods than that of ordinary clover, and as the heads easily break off when dry, care is required in harvesting.

“It does not endure drouth as well as the common red clover, but will grow on more damp and heavy soils, and it is said that it can be grown on land which, through long cultivation of the common clover, has become ‘clover sick.’”

Absconding Swarm.—I desire to know the cause of a swarm of bees leaving. It was a very large swarm, which I had tried to prevent swarming, by cutting out queen-cells. I examined each one of the ten brood frames carefully, and cut out eleven cells in different stages of construction. On the second day after this they swarmed. I lived them and gave them a frame of brood, and set the hive on the old stand. They stayed until the next day, when they came out, and, without alighting, went straight to a tree about half a mile away. They had built two large pieces of comb, one on each side of the frame of brood, which contained a small quantity of honey and some eggs. Can you give any reason why they left in this ungrateful manner? The frame of brood which I gave them I took from a hive that had swarmed a few days before, and I thought perhaps the unsealed larvae were too large.—L. B. POST.

[Your bees had picked out their hollow tree, and got it cleaned out and already fixed up for housekeeping before they swarmed at all. Under such circumstances you could not well induce them to give up their project, especially if you let them remain on the old stand, and this is one very good argument in favor of hiving at some little distance from where the parent colony stood. Where they pick out the location before swarming, they are pretty sure to move to it, sooner or later.—Gleanings.]

For the Sixteenth consecutive year Chicago opened up its great Inter-State Industrial Exposition, replete with the best products of science, industry and art, on Wednesday, Sept. 5, and will close Saturday, Oct. 20. The immense structure is now laden to its fullest capacity with the finest and most magnificent exhibits ever displayed; from almost every quarter of the civilized world, illustrating as it does every avenue of human industry in its most complete form, it is almost a necessity that they who would keep abreast of our most advanced ideas in both industry, science and art, should not fail to visit this great Exposition. Every railroad and transportation line running into the city have made reduced rates, and there is every indication that a much larger attendance will follow than any year that has preceded.

Colored Posters for putting up over honey exhibits at Fairs are quite attractive, as well as useful. We have prepared some for the BEE JOURNAL, and will send two or more free of cost to any one who will use them, and try to get up a club. Sample copies will be sent free upon application.

Golden-Rod.

Written for Our Little Men and Women
BY CLARA DOTY BATES.

An idle Breeze strayed up and down
The rusty fields and meadows brown,
Sighing a grievous sigh, "Ah, me!
Where can the summer blossoms be?"
When suddenly a glorious face
Shone on him from a weedy space,
And with an airy, plummy nod,
"Good afternoon!" said Golden-Rod.

The Breeze received her courtesy?
And then came hurrying home to me,
And eagerly this story told:
"I've seen a lady dressed in gold,
So shining that the very light
That touches her is doubly bright—
She nodded, too, a royal nod."
"Why, that," I said, "is Golden-Rod."

"Come out and see her where she stands,
Gold on her head and in her hands,"
He cried; and I without delay
Went after where he led the way;
And there she stood, all light, all grace,
Illuminating that weedy place,
And to us both, with airy nod,
"Good afternoon!" said Golden-Rod.

QUERIES AND REPLIES.**Tiering-Up when Working for Extracted Honey.**

Written for the American Bee Journal

Query 576.—When extracted honey is desired, is it not preferable to tier up, that is, to use extra stories above instead of taking from the brood-chamber?—N.

Yes.—DADANT & SON.

Certainly.—MRS. L. HARRISON.

Yes.—H. D. CUTTING.

Certainly.—R. L. TAYLOR.

Yes.—J. M. HANBAUGH.

I think so, decidedly.—A. J. COOK.

Yes.—G. M. DOOLITTLE.

Yes, every time.—EUGENE SECOR.

In most of the cases it is.—J. P. H. BROWN.

Yes, every time.—C. H. DIBBERN.

Opinions differ. I think that I should prefer tiering.—C. C. MILLER.

Yes, sir. It is better if those extra stories above are half-depth. I have used both full and half depth supers for more than fifteen years.—JAMES HEDDON.

If the tiering-up plan is followed, and plenty of room given, it will seldom be necessary to extract from the brood-chamber.—A. B. MASON.

I consider that the best way to gather extracted honey is by tiering-up. I am of this opinion both from experience and observation.—J. E. POND.

Extract from an upper story, as a rule. Sometimes the brood-chamber has too much honey. In that case it should be extracted, or full combs exchanged for empty ones.—M. MAHIN.

Ideal extracted honey can only be had from supers where there can be no suspicion of the juices of brood, and the taste of pollen.—J. M. SHUCK.

Most assuredly it is. To take honey from the brood-nest is a slipshod, slouchy way of taking surplus. It is but a little better than the old foggy plan of "robbing bees."—G. W. DEMAREE.

I use a two-story hive, and extract as often as I find the honey about two-thirds capped over. It is necessary to occasionally extract from the brood-chamber, so as not to allow the queen to be over-crowded, etc.—P. L. VIALLO

While it is sometimes necessary to extract from the brood-combs, in order to give the queen room to lay, still with proper management and the judicious tiering-up of supers, it will not generally become a necessity. Our ideal extracted honey is always taken from the virgin comb in the supers—not from the breeding apartment.—THE EDITOR.

Number of Frames Used when Tiering-Up.

Written for the American Bee Journal

Query 577.—1. Are not 12 or 13 frames too many for the brood-chamber, when tiering up? 2. How many would you use below? 3. Would you use the same number above as below, when tiering up?—New York.

1. More than are necessary. 2. Eight. 3. One less.—R. L. TAYLOR.

1. No. 2. Eight Langstroth frames. 3. Yes.—MRS. L. HARRISON.

1 and 2. Nine Langstroth frames are sufficient. 3. I would.—J. P. H. BROWN.

I use nine Gallup frames in the brood-chamber when working for extracted honey.—G. M. DOOLITTLE.

1. Yes. 2. Ten. 3. Yes.—J. M. HANBAUGH.

1 and 2. That depends upon the size of the frames. 3. Yes.—C. H. DIBBERN.

1. Yes. 2. Seven to eight. 3. Use 8 to 10 above.—H. D. CUTTING.

1. Yes, unless very small. 2. I am not fully settled on that point.—C. C. MILLER.

1. That depends upon the size of the frame. Ten Langstroth frames are not too many, unless the surplus is all wanted in the supers. 3. If for extracting, yes.—A. B. MASON.

1. No, not of the Langstroth size or smaller. 2. We use half-depth frames above, or rather 6 inches deep.—DADANT & SON.

1. Much will depend upon the size of the frame. Ten Langstroth frames or equivalent are, in my opinion, about right, both in the brood-chamber and in the surplus apartments.—J. E. POND.

You do not give the name of your frame. If Langstroth, I would not use more than ten below, and the same size of hive above with one frame less.—EUGENE SECOR.

1. Ten frames are enough. 2. Ten, if for extracted honey; 8 if for comb honey. 3. I use 10 frames in the brood-chamber and 9 above.—P. L. VIALLO.

That depends upon the size of the frames. I have used 12 Gallup frames with success. This leaves plenty in the lower hive for winter.—A. J. COOK.

1. Much depends upon the size of the frames, and something upon the locality and the season. I use in that way from 8 to 11 frames of nearly the Gallup pattern. 3. Yes.—M. MAHIN.

I do not understand the question. If the querist desires comb honey, 12 to 13 Langstroth frames are too many. If he desires extracted honey, 12 to 13 frames may not be too many.—J. M. SHUCK.

1. It depends upon the size of the frames used. 2. In my locality I use 10 Langstroth frames in the brood-chamber. 3. When I use full-depth supers above, I use but 9 frames. In fact, I use but 9 frames in the surplus apartment whether I am using full-depth or half-depth cases. Placing the frames a little wider apart in the surplus cases makes the sealed combs full and plump, and they uncapped nicely.—G. W. DEMAREE.

Yes, too many for any brood-chamber, provided they are the size of the Langstroth frame. Never use more than 10 Langstroth frames' capacity in the brood-chamber, and never more than 7 or 8, unless you are practicing contraction at the proper season of the year. The rest of your query is answered in my reply to Query 576.—JAMES HEDDON.

1. That largely depends upon the size of the frames used. 2. I prefer the 10-frame Langstroth hive for all purposes, but would contract the brood-chamber by reducing the number of frames when working for surplus honey. 3. In order to obtain all the surplus in the supers, I should use less frames below, graded by the circumstances.—THE EDITOR.

Query 575.—The answer to this query, by Mr. J. M. Shuck, in last week's BEE JOURNAL, should have read as follows:

I believe it has been established that there is formic acid in honey. I incline to the belief that the acid found in the honey is developed and incorporated with the honey in the honey-stomach, and tends to preserve the nectar till it ripens, rather than to preserve it after it has been evaporated and sealed.—J. M. SHUCK.

The two italic words in the above answer, by an oversight, were printed incorrectly, and the error was not discovered until after the "forms" were printed.

Convention Notices.

The next meeting of the Union Bee-Keepers' Association will be held at Clayton, Ills., on Thursday and Friday, October 11 and 12, 1888, in the Town Hall at 10:30 a.m. The Park Hotel will charge \$1.00 per day; the restaurants 25 cts. per meal. We expect Messrs. Dadant, Hanbaugh, Camm and other prominent bee-keepers to be present.

S. N. BLACK, Pres.

The Ohio State Bee-Keepers' Association will hold its 6th annual meeting in joint convention with the North American Bee-Keepers' Society at Columbus, O., on Oct. 3, 4 and 5, 1888. A special business session of the Ohio State Bee-Keepers' Association will be held on Oct. 4, to elect officers for the coming year, and for the transaction of other business. This business meeting will not interfere with the regular programme of the National convention of the same day.

FRANK A. EATON, Sec.

CORRESPONDENCE.

PLEASANTRIES.

Time of Buckwheat and White Clover Bloom.

Written for the American Bee Journal
BY DR. C. C. MILLER.

In response to the request of the editor on page 563, I reply that in this locality, and I think it is the general rule in all localities, the nectar disappears from buckwheat bloom by the middle of the day, so that whereas there is no trouble from robbing in the forenoon when buckwheat is yielding, care must be taken to avoid everything like exposure of combs or honey in the afternoon. Something, however, depends upon the weather, for if the morning is cold or rainy, the forenoon of buckwheat bloom may be extended into the afternoon.

It is well to be somewhat familiar with the habits of flowers as to blooming, although buckwheat is the most notable exception to the general rule that flowers yield nectar all day long.

White Clover Blooming and Not Yielding Nectar.

Considerable apprehension was felt in this locality about the crop of white clover this summer. The summer of 1887 was so very dry that white clover seemed to be burnt up, root and branch, and the question was whether the summer of 1888 would see any white clover, and if some did come from seed, whether it would be forward enough to bloom. I never watched more closely in the spring for the first appearance of growth. Contrary to my expectation, I think that I never saw so much white clover starting. I cannot say, although I should like to know, whether it came from the roots of last year or from the seeds.

Then I watched to see whether it would bloom. Soon the blossom buds appeared in profusion, and my fears for the season subsided. I awaited with confidence the gathering of a bountiful harvest, for I feel sure I never before saw the ground more white with clover bloom, and I think that I never saw any thing to equal it. But the flood of nectar seemed slow about coming, and after the time for it was all over, I was obliged to confess that I was a "false prophet," and that very little honey was gathered from white clover.

Now what was the trouble? Is it true that white clover, as some have stated, produces no nectar the first summer it comes from seed? It certainly looked a little that way this year, providing the clover all came from seed this spring or last fall; and yet I can hardly believe there is any difference between a blossom on a plant a few weeks old, and one on a plant a year older. If the blossom needs nectar to call insects to fertilize it, will not the young plant produce it just as well as

the old one? I really would like some one who can speak with authority, to tell us more about this plant and its habits.

That Honeyed-Man.

This man was mentioned on page 579, and I agree with the editor that it was nothing strange that the man received no stings from the bees alighting upon the honey daubed on him. But I suspect there is very little foundation—very likely no foundation whatever—for the whole story. Let us look at it.

A man daubed himself with honey, 800 bees that were swarming in the woods alighted on him and stayed there until he transported them home. In the first place, when bees are swarming, they are very intent upon the one thing—swarming. I very much doubt if you could get 800, or 80 bees, of a swarming colony to alight upon a man daubed with honey for the sake of getting the honey. They are not just then in the honey-gathering business. But suppose you could get them to depart from their usual habit, and forsaking the cluster or the swarm in the air, settle upon the man, how long would they stay there? Just long enough to load up with honey and then off they would fly, and no bee would come back for a second load to the man unless he stood still at the spot where the bee left him.

You may bid defiance to the worst robbers by simply keeping on the move anything you want to protect from them. So I suspect that the whole thing originated in the brain of some one anxious to get up a sensational item for the newspapers. Sensational items are in demand, and we can expect nothing different so long as the truth is not more highly valued than sensations.

The Wiley Pleasantry.

This "pleasantry" owed its popularity and its successful run to the fact that it was sensational. It is not that newspapers or reporters so much prefer the false to the true. A true sensation is preferable to one that is false, but there is a lamentable absence of care as to whether truth or falsehood is promulgated, providing only that it is sensational. Get up a contradiction of the Wiley statement that shall be equally sensational, and it will promptly go the rounds. But no matter how strong may be Prof. Wiley's retraction, it will not be likely to find currency anywhere except in the columns of those papers specially devoted to the interests of bee-keepers. The retraction may be very true, but it is not sensational.

The holding the breath to prevent stinging goes the rounds for the same reason, and the bee-periodicals are not altogether guiltless, because at least two of them have published it with no word as to its truth or falsity. We hardly ought to blame other papers for neglecting to inquire closely into the truth of every item admitted to their columns, if the same thing is done right in our own ranks. A notable instance of this is in the following:

The Sting-Trowel Theory.

That bees ever use their stings to work wax, I believe is just as untrue as that artificial comb honey is made, and yet this error had its origin entirely among bee-keepers. It is true that it is not like the Wiley affair in mischievous tendency, and I do not suppose Mr. Clarke would have made the statement he did, if he had supposed mischief would arise from it; still he was far from warranted in putting forth as an ascertained fact, that which was a mere play of his imagination. I do not believe he ever had any proof that his fancy was a fact, and I confess I would very much like to see Mr. Clarke himself the first one to give the "sting-trowel" its quietus. I would like this for the sake of the truth, and also for the sake of Mr. Clarke as well. Marengo, Ills.

FALL FLOWERS.

The Autumn Honey-Flow in the Middle States.

Written for the Grange Bulletin
BY H. B. GEER.

After the heat of the summer has passed, and the first fall rains begin, then spring into life and beauty the autumn flowers that are usually loaded with delicious nectar—resorts of pleasure and profit for the millions of honey-bees, that, after some weeks of idleness and inactivity, are only too glad to again return to the fields and their duties.

During the spring and early part of last summer the flowers, such as struggled into existence despite the drouth—were nearly or entirely fruitless, and the sources of honey very limited indeed. But after the rain had come again, it brought out the autumn flowers here in Tennessee, and also, as I learn, in Missouri, and the honey-flow during the month of September was better and more of it than during all the previous months of the year.

Chief among the fall honey-plants of Tennessee, is the golden-rod. Here it blooms in great profusion, and its bright golden plumes may be seen nodding and waving in nearly every field and meadow—especially in the waste places or fallow land, and in the fence corners. It yields honey of a rich yellow color which has a very pleasant flavor. In fact I think it the finest honey that our bees can obtain from any source in the fall of the year.

In Missouri, where the writer is interested in apiculture, the asters are our chief reliance for fall honey. There they bloom in great profusion from about the first of September until frost. There are a great many varieties of asters, and they all yield a fair grade of honey, which every bee-keeper is glad to receive, after the spring and summer supply has proven a failure, as was the case last season.

Honey partakes of the nature of the flowers from which it is gathered, more perhaps than one would suppose. For

instance, in the spring of the year when the flowers are fragrant and loaded with perfume, the nectar gathered from them is likewise fragrant and delightful, and seems to emit the sweetness of the fields, and the wild flowers themselves. The delicate fragrance of the white clover bloom is well-known, and, as if in keeping with its delicate nature, the honey it yields surpasses all others in flavor and pleasurable taste.

On the other hand, the honey from the fall flowers, while equally sweet and pure, is devoid of the fragrance and pleasant smell that the early season honey possesses. Likewise the autumn flowers seldom emit a pleasant perfume, although they rival in beauty their kindred of the springtime.

CANADA.

Report of the Haldimand, Ont., Convention.

Written for the American Bee Journal
BY E. C. CAMPBELL, Sec.

A meeting of the Haldimand Bee-Keepers' Association was held at Fisherville, Ont., on Saturday, Sept. 1, 1888. The minutes of the previous meeting were read and confirmed.

How and What to Feed Bees.

The President said that granulated sugar should be fed, as it was safer than to risk feeding cheap sugar. He made a thick syrup by putting the granulated sugar into boiling water, and stirring it frequently to keep it from burning. He exhibited a Canadian feeder, showing how it worked, and urged early feeding, so that the bees could cap their stores before cold weather. It was also necessary to feed in the evening, so as to avoid robbing.

Mr. W. Kindree's plan was the same as the President's, only that he boiled the sugar a little more than Mr. Armstrong. He thought that by doing so the syrup was not so apt to granulate.

Mr. Mehlenbacher described his plan of feeding, which was by tipping the hive up in front, and pouring the syrup behind the division-board.

Mr. Overholt used a similar feeder to the Canadian, and found it ahead of any other.

Mr. Best had always used honey, but this year he would have to try sugar, as he had no honey. He had wintered a colony on 15 pounds of honey, and it had wintered all right.

Mr. Atkinson made syrup the same as described by Mr. Armstrong, and used inverted glass jars as feeders.

How to Unite Colonies of Bees.

The President gave his plan of uniting colonies, which was to gradually move the colonies to be united, towards each other until they were close together, and then spreading the frames apart, and putting in frames alternately; he then gives the bees a good smoking, and the work is done.

Thirteen members reported 252 colonies, spring count, and 375 colonies, fall

count; from which it is seen that the increase has been very small, besides no surplus honey taken; and what is worse, the bees have not stores enough to winter on, and will have to be fed.

The next meeting of the association will be held at Cayuga, at the call of the President.

HONEY-JUMBLES

Of the North American Convention of 1887.

Written for the American Bee Journal
BY A COUNTRY BEE.

"All N. A. B. K's (wrote H., the recorder) were summoned to appear before the President Miller, each bringing one dollar in paper or silver; and at the Commercial Hotel please register, in Chicago, Ills., the 16th of November."

A No. 1 Root responded with his "A B C's;" Armstrong came on with his hive and T-supers; and Aspinwall wrote that if we'd organize, all delegates should receive that "Magazine" of his—
"Life ne'er exulted in so rich a prize."

Bees (*Genus Homo*) were Baldridge, Baldwin, Barber, Boardman, Miss Bennett, T. E. Brigham, the smoker, Betsinger, T. S. and Joshua Bull (not Johnny), Biell, and Burnett, who is not a *Burmester*, although he well knows how to handle the honey.

"We may live without friends, we may live without hooks"—

But this Society "cannot live without A. J. Cook." Compton, of Glenwood, Crocker, Cumins and Comstock.

Were very modest, and did not give us much talk, but the deficiency was made up by Mr. Wilcox.

"While a-gathering of bee-head for their living," Hubbard, whose ancestor "went to the cupboard," and

Found Hopkins, of O. (kin of Hop-o-my-thumb). Speaking of H's, Lemmer see; Dr. Haskin, Hutchinson,

Hilton and Heddon—the "hanner" goes to Michigan.

Lyman, Forncrook, and Thornton, no doubt ought to be,

"I the man in the moon, this thornbush, my thornbush."

D. G. and G. W. Webster (descendants of Daniel and Noah);

Hear our Betsinger, "Oh, velvet see you're a dusty fellow,

You've powdered your legs with gold," all yellow.

"O Woodman spare that (*Dahl* linden honey) tree," Cried Funk, Staininger, "mid the trees, where humming-bees"

Extract the nectar from the bright flowers. Here the Redmond, who once chased Reynolds, the fox,

Now extracts the "extracted honey" with the extractor.

Beside our President, were B. J. and M. M. Miller, Gilson who sent to fetch a pail of (*Me*) Whorter; That reminds us of that young "Tribune" reporter, Who thought our "contrived look peculiar;" If he'd seen one buzzing drone, he'd not have been so jocular.

Mrs. Searles—"hark to the music, the drum and the life."

A Taylor, Cumins, Davenport with his wife, Jones, Escher, Murphy, and Gander. Dethloff—my life,

Neimez! Im Fullmer than Hawks, when chickens are rife.

Another room for exhibits, would lessen the strife.

I hear the bees swarming, and while watching for the queen,

Oh, Gould, I see the one who sang, "Keep our Graves, Green."

"I Lovett, (*Sweet, Hart*), or Stanton, in the Parks, With Wilson, Thompson, Robertson, or even the Holtermann.

When the Oatman was Stow (ed) in the hopper, With Newman, Secor, and McLain the Professor,

By the hardest of Davis work our Strong Miller, Turned us out a crust of very Good flower.

"And here by thee, will him the bee, forever and forever."

The flower was left with the Cook, by Chapman; Who turned it over to the ladies and gentlemen.

Some Marvin that the flavor was equal to Linden— "Excuse me, but will our Good friend, Dr. Mason, Be so kind as to see to the ventilation?"

Our hearts went out to Father Langstroth, With the hope that his remaining days on earth, May be filled with sweetness around his hearth, And the conscious thought of the good he has wrought,
For the bee-keeping people, bring joy to his heart.

Thanks were tendered to Mr. Thomas W. Cowan, Who, being such an able "microscopian," Gave pleasure and profit to all who met him; While regretting his absence, at Prof. Cook's suggestion,
He was made honorary member of this Convention.

Thanks to Thomas G. Newman again and again, For his excellent arrangements with the hotel-man, For his thoughtful good-will shown on every hand; To mention this Society, is to think of his name.
"He has served thee as none would," still sounds the refrain.

For President, the genial Dr. A. B. Mason, For Secretary, the efficient W. Z. Hutchinson, For Treasurer, Mrs. Harrison, who uses no deception, They were Secor (ed) officers at the election, Without a Wakeman's or Woodman's discussion.

"We may learn of the bee, the wise man's lore, The hand of the diligent gathereth store," At Columbus, Ohio, "If this life be not o'er," On the 3rd of October, "May we meet unce more," Till then, success to you all, *Au revoir*.

MAPLE TREES.

Insect Enemies Mowing Them Down—Plant Lindens.

From the Detroit, Mich., Tribune
SEPTEMBER 3, 1888.

Dr. W. C. Stevens of Fourteenth avenue has devoted considerable attention to the destructive insects from whose ravages the maple trees are suffering so severely. He expresses the belief that there is not one sound maple tree in a hundred under five years old in Detroit. On some whole streets he has been unable to find a single tree unaffected by the pest. The same state of affairs seems to prevail among the shade trees throughout the country east of Detroit.

Dr. Stevens recently wrote to Prof. Cook of the Agricultural college relative to the matter. The professor in his reply says that the same destruction of maples in Detroit referred to by the Doctor is noticeable in Lansing and in every other city in the state. He pronounces a specimen insect, which Dr. Stevens sent him, the grub of a common maple tree borer, *Plagionotus speciosus*, which is very harmful to trees all over Michigan. They attack large, thrifty trees and have destroyed many maples in Jackson, Lansing and other places. The beetle, which appears in July and August, is a large, handsome longicorn, black in color and striped with a rich yellow.

The pupa case which the Doctor sent is pronounced by the professor that of a caterpillar, *Aegeria aceris*. This beautiful moth lays her eggs in July, and the caterpillars feed on the inner bark for one year. It is black, striped with yellow and orange. This insect, Prof. Cook says, is also doing much to destroy the maples.

More harmful than either of these varieties is the big-headed apple tree borer, which is a very serious enemy of the maples, especially young or newly transplanted trees. This beetle attacks trees whose vigor has been checked. Thus it is that it is so destructive to trees recently transplanted. Prof. Cook

recommends that the trunks of trees be washed early in June and July with a strong solution of soap, to which one-tenth of its volume of crude carbolic acid has been added, especially for two or three years after setting. Still better is good care—spading about the trees and adding a generous mulch every spring for five or six years after planting.

“Why do we plant so many maples?” is a conundrum propounded by the professor in his reply. He estimates that throughout the state ten maples are planted to one of any other species. He refers to the elm as a beautiful tree, and one, which, in this locality, is yet free from serious attack. Still the elm-leat beetle in the East is moving West rapidly, and the canker worm is a fatal enemy of the tree. The basswood or linden is a handsome tree, a more vigorous grower than either maple or elm, and is comparatively free from insect enemies. With the same care five, and the professor guesses ten, lindens survive to one maple. It is also an admirable honey-tree, and so has much economic value.

“If we must plant maples,” concludes the professor, “give them the best of care and wash them with the solution mentioned each June and July for some years after planting, but it is far better to plant the beautiful linden, which with half a chance, if stock is kept away, will live, thrive and mature.”

STINGING BEES.

Something in the Honey Causes Bees to Sting.

Written for the American Bee Journal
BY SOLOMON W. JEWETT.

No pure honey can be found in America in any quantity or in any condition, that has not gone through the chemical laboratory of the honey-bee, or some other insect that stores this peculiar sweet, which has properties as food and medicinal, that cannot be found outside of its deposits in the comb by some insect. Most people have yet to learn this, and many other simple things in nature not yet learned.

There are other matters relating to bees that I find many apiarists have not discovered, namely, in the working of the bees among some flowers, they become more irritable, and more liable to use their simple weapons of warfare, than they do when gathering sweets, and the pollen, or anything which they are seeking to convey to their rural home. Some wild flowers, and the buckwheat flower, contain more poison, and is more virulent than clover, or from the willow, etc.

When working on the flower of buckwheat, sometimes they are so overcharged with poison, that they are quite inclined to sting man and animals, seemingly to relieve themselves of this surfeit; and we find it in the honey sometimes, by partaking of a little fresh honey (gathered and stored by these arch chemists, as deposited in the comb), which will give griping pains; and this poison is in less quantities

in the seed. By continuing along for sometime, daily partaking of buckwheat cakes, it shows the effects on the cuticle or skin of the body, and even the scalp may feel this dry roughness, and an itching sensation when nothing of the kind had been felt before.

We have some people who keep fowls, that speak in favor of buckwheat to make hens lay; but that is a mistake; they may lay in their seasons because it is their nature, but if one will only observe how dry and dead their feathers become, and stand out as though they were suffering pain, they might desist from putting before these birds buckwheat as food.

Simple Remedy for Bee-Stings.

There is a simple remedy at hand, for those afflicted with pain from eating too freely of this honey gathered from buckwheat. It is simply to take a swallow of the weak solution of soda and water, and it is one among the best remedies to apply wherever the bee, the wasp, or the snake has inserted its venom through the sting into man or animal flesh.

But there is another remedy that will draw out poison from the snake bite. Kill and open the body of a hen or bird, and lay it on the stung place; it will extract the poison, reduce the swelling, and remove the pain. At the usual swarming season, should one have the solution of common baking soda, or saleratus, on hand, it will destroy the effects of the bee-sting at once, if applied.

Rutland, Vt.

MARKETING.

Disposing of the Honey Crop to Commission Men, etc.

Written for the American Bee Journal
BY REV. J. D. GEHRING.

It is easier to learn the bee-business so as to know how to produce nice comb honey, than it is to learn how to dispose of it to the best advantage.

Last year I had no trouble to dispose of all I had at 20 cents a pound. This year I cannot sell a pound to the same grocerymen in Kansas City. When I called on them the other day, I asked, “Can I sell you some nice, white clover honey?” One answered: “No, sir! We have more honey now than we can sell. Nobody wants honey.” Another, “Is it nice and white? Sections well filled out and unbroken?” To which I could promptly reply in the affirmative. “How much do you want for it?” Eighteen cents, net.

“Don't want it!”

And 18 cents a pound is 2 cents less than the quoted market price! These same men are retailing it at 25 cents. Something is wrong somewhere. What is it?

We have two firms in Kansas City who make comb honey a specialty. They now quote 18 and 20 cents for first-class comb honey. I presume they sell to retailers at those prices. I do

not know how they sell it in large lots; but I know that they have a “buying price” and a “selling price,” for when I ask, “What is the price of the best comb honey?” they will cast upon me a look peculiar to a Kansas City commission man, and answer my question “Yankee fashion,” thus: “Do you want to buy or sell?”

I have a few hundred pounds to sell at 18 cents.

“Don't want it! Piles of it on hand now.”

Who is glutting (?) the Kansas City market *this year*. I wonder? Some “big bee-men in the East,” I am told!

What a queer state of affairs! The bee-papers inform the anxious, tired and disgusted *small* bee-man that there is a very light honey crop in the country. He can say “amen” to the statement, for he is *one* of them. But New York bee-keepers send honey by the carload (?) all the way to our own market; and our commission men cannot be convinced that honey is scarce.

“If you want to consign your honey, we'll take it and sell it for you. But we can't guarantee any particular price, as the demand is light.”

“You see?” No, some bee-keepers don't “see” that they are helping a syndicate of commission sharpers to control the honey market, and that they are making it easy for those men to treat us poor, small struggling fellows with haughty contempt.

I tell you, Mr. Editor, we ought not to stand such an outrage! I am only a small “Dutchman,” and have no great amount of “stock” invested in bees and honey; but, sir, I am big with indignation! Even a Dutchman will find out a thing or two when he is exasperated. Let me tell you what I mean:

Not many years ago a man, whom I know quite well, had some honey to sell. He was a “poor preacher,” and needed money, so he sent it to a commission man who said he could probably (?) get 17 cents for it. But when the preacher collected for his honey, he got only 15 cents minus the “commission”—because “we couldn't get 17 cents.”

Well, one day, sometime after the transaction with the commission man, the preacher saw some honey in a grocery store which he thought looked exactly like his 1½-pound sections. He asked the price, and found they were retailing it at 25 cents a pound. He asked where they got it, and was told at—commission house. It was his honey, no doubt. But as it was a delicate question to ask the merchant what price he paid for the honey, this preacher sent a man (who didn't want to buy honey) to inquire the price, and was told that, as that was “particularly nice honey,” they had to ask 18 cents (1) for it.

That Dutchman has ever since been a little careful about accepting the gift of a “stencil plate,” ready for use, from a commission house.

Hadn't we better form a “honey trust?”

Parkville, Mo.

[We trust that the last sentence is a joke, Bro. Gehring. The word itself is distasteful to us. We have trusted so

much in our business career, that we are now mourning the loss of many thousands of dollars *trusted!* Then about "honey trusts," it was only a few months ago that the papers would have it that the New York bee-keepers were to hold a meeting to form a "honey trust," which was to accomplish *wonders!* But there was no truth in it. Two years ago a Honey Producers' Association was talked of when the honey crop was of fair proportions, and if such a plan as then presented could be carried out, it would be productive of much good. Such an association would practically put an end to the swindling done by *dishonorable* commission men (for there are such, though there are also many honorable ones) who sell at one price, and report to producers at another and lower one. There are *sharps* and swindlers in all occupations, and honey commission men are no exception to the rule.—ED.]

NEW YORK.

An Average Honey Crop of 30 lbs. per Colony.

Written for the American Bee Journal
BY H. J. ROGERS.

The season for surplus has closed here, and the result is not very encouraging; however, we have some honey, and are thankful.

My 80 colonies were put into winter quarters last fall with plenty of bees and honey, and came out in the spring without any loss; but five colonies were rather weak, and I lost 3 out of the 5 by spring dwindling.

The cold, backward spring kept the brood from spreading very fast, so that when apple blossoms appeared, most colonies were not very strong. For the first season here since I have kept bees, apple blossoms yielded no nectar, and I soon found some of my colonies on the verge of starvation; especially those that I had transferred. I fed all the honey I had on hand, and also considerable sugar syrup.

About June 1 raspberries opened, and about four-fifths of my colonies commenced work in the sections, and I secured about 2,000 lbs. of very nice honey, all in the comb. At this time we were getting copious rains, and it looked as if clover would be a fine harvest, but it yielded very little, scarcely more than last season.

This section is always favored with lots of buckwheat, and when I found that the basswood was a total failure, I hoped we would get a "big run" from buckwheat. This, too, has failed on account of a frost, which has ended all work in the sections for this season.

It is well known that bees do not work on buckwheat except a few hours in the early part of the day—sometimes

they cease work at 11 o'clock, but generally as soon as 1 o'clock. I think I have never seen a bee work as late as 3 p. m. on buckwheat.

I have not had any increase this season, mainly, I think, on account of the large, roomy hives which I use. They take 10 frames of the Langstroth size, and hold 40 sections $4\frac{1}{4} \times 4\frac{1}{4} \times 15-16$, in each super. I think they are as good non-swarmer hives as there are in existence, not excepting the "Cotton Hive."

If my bees had swarmed, I should not have a pound of surplus: as it is, I have 30 lbs. per colony. We will now commence to prophesy concerning the crop of 1889, which *surely* ought to be very large.

Stannard's Cor., N. Y., Sept. 3, 1888.

THE FAIRS.

Will it Pay to Exhibit Bees and Honey?

Written for Gleanings in Bee-Culture
BY DR. A. B. MASON.

Agricultural fairs set in motion the best elements of farm life, and stir up the ambition of those interested, and all are interested in the success of the undertaking. It is an advertisement for the community and for persons interested; and if the display is good it gives a good reputation to the exhibitor.

"Like other productive industries, bee-keeping is not exempt from uncertainties as to results, and few things bring to the bee-keeper so many pleasant and profitable things as does a display of bees, honey, and apiarian appliances," at the annual and other State, county, and district fairs and expositions. Wherever such an exhibit is made it is a nucleus around which beekeepers gather, and in a quiet, pleasant, and profitable way exchange ideas and discuss matters "new and old." An incident at the Tri-State Fair held here two years ago made a more lasting impression on me than hours of ordinary talking or pages of reading-matter might have done. An elderly farmer, some would have called him an "old codger," wanted to buy some bees of me. We talked over prices, etc., and I thought a bargain was about made, when he asked me if I used the extractor. When I told him I did, it would have done any melancholy dyspeptic good to see the expression of disgust that spread over his face as he said, "I don't want any of *your* bees." Strange as it may seem, I had to laugh in spite of all my efforts to the contrary, and I saw that this oracle knew that the extractor is responsible for the great winter mortality among bees, for he afterwards told me so. I believe he tried to purchase bees of every beekeeper there, and with the same result.

If there is a business that requires a man who can express in his face, at one and the same time, disgust, contempt, and anywhere from ten to ten thousand other kinds of expressions, I would most earnestly recommend that gentle-

man as the best-qualified man to run that business that I ever met.

These exhibits aid us in our efforts to popularize the use of honey as food and medicine. They will also help to raise the standard of excellence, both quality and attractiveness of honey put upon the market. New ideas will be disseminated, new methods will be learned, and old ones discarded.

Bees and honey are always great attractions at fairs; and to hear the "fat" expressions and quaint sayings of "smart" country people and city "dudenes" is enough to add years of happy life to the average age of those who enjoy such things. To listen to fond papas and doting mammas as they explain to their children, who are all eyes and ears at such times, the mysteries of the hive, and how the bees "make honey" while they are shut in the hive at the fair, and how a honey-extractor works either as a washing-machine, an ice-cream freezer, or a churn, will cause a change in the facial expression of such stoics as Mr. Hinchinson and a score or more others whom I might name, but space forbids; and such matter-of-fact men as our friend A. I Root gather new enthusiasm and energy from such displays of sweetness, and the consequent contact with wise and otherwise people.

The first year I lived here, the premium offered by the Tri-State Fair was five dollars "for the best show of honey." I found the "show" set away on a high shelf among other things, and where it was seen by but few. It consisted of a rough box, holding about twenty pounds of comb honey, with glass in one end of the box. I spoke to officers of the society about the matter, and the result was the offering of over \$100 the next year as premiums, and the next year \$208. For six years the Bee and Honey Department has been a "fixture," and, like other departments, has a superintendent, etc.; and last fall it was said to be "the most attractive exhibit on the grounds." The exhibit in 1882 was small compared to what it has since become, and was described in the AMERICAN BEE JOURNAL by the editor, who assisted in awarding the premiums, as a "grand success." The small corner set apart for the bee and honey show was so crammed all the time that it was with great difficulty any one could get through the crowd, and utterly impossible for many who desired to examine the exhibits to even get within a stone's throw of them."

I want to say a few kind words about friend T. G. Newman. When we first started out to make an exhibition of honey, etc., at the Tri-State Fair in 1882 and also in 1883, he kindly consented to help us, and came from Chicago to Toledo and spent three days each year, without "fee or reward," in aiding in judging, and starting us off in good shape. A. I. Root and C. F. Muth and others helped us in 1883, and we have tried each year to improve on the previous one.

The exhibit at the St. Joseph, Mo., fair has become one of its most attractive features; and for five or six years past the Michigan bee-keepers have made a large and attractive display at

their State Fair, and have a separate building for their exhibit, and the premium-list was gradually worked up by Mr. Cutting, Prof. Cook, and others, from next to nothing to over \$300. At Toronto, Canada, have been made some of the largest (if not the largest) and most attractive exhibitions of honey and apianian appliances ever made on this continent.

I believe honey should be made the main attraction. A display of bees and queens is always "in order," and calls forth more quaint and original expressions from the crowd of sight-seers than even the extractor does. Many an old "residenter" has taken pains to put on the second pair of eyes to see "the king-bee who bosses all the other bees, and tells them what to do," and then, after being told it is a queen, and the mother of the bees, hurries off to hunt up some friend or member of the family to show them "the mother of all the bees."

Supplies are viewed with curiosity; but honey, that "sweetest of sweets, excepting the lasses that we all love to greet," is the great attraction, and creates a desire to *taste* that which to many is so irresistible that a purchase has to be made before the visitor is satisfied, and then, when leaving, frequently turns and casts longing glances at the tempting display of luscious sweetness.

The skill displayed in making honey exhibits in some of the countries of Europe is so great, and the display so attractive, that it is not a rare thing to have them visited by common people, as well as by kings and queens; and it is largely the fault of the bee-keepers themselves if like attractive and instructive displays are not made at the different fairs throughout this country; and I have yet to learn that the managers of any fair have regretted having done what they could to call forth an exhibit of honey, but all have been surprised at the beauty and attractiveness of a well-prepared display.

The Stark Co., O., Agricultural Society, at the solicitation of the Stark Co. Bee-Keeper's Society, last year appropriated \$100, to be given, as premiums for bees and honey, etc. and \$150 for the erection of a building for the display of things pertaining to the apiary.

If all county and State agricultural societies cannot be induced to give fair premiums for the products of the apiary, without doubt enough can be secured to more than pay expenses; but some one or more bee-keepers must look after the matter, and be sure that it is attended to. It will *not* take care of itself.

The question with us all very properly arises, "Does it pay to be to all this expense and trouble?" The same question very naturally arises, also, in regard to any kind of an exhibit at fairs, and each will have to answer the question for himself.

On page 221 of *Gleanings* for 1887, J. H. Martin puts this matter before us very nicely. He says, "Does it *pay* to spend time and money to advertise the honey business? If we look around us, we see every trade making strenuous efforts to get ahead. Take up the

most obscure county paper, and every trade is represented in its columns. Our most successful merchants are the ones who 'catch on' to every advertising novelty to be used in the extension of their business. Our fairs are the red-hot centers of attraction and advertising, through all lines of business, with the exception, perhaps, of bee-keeping.

"Probably the hardest thing for a spirited bee-keeper to bear, at the present time, is the general belief that bee-keeping is a small business, and that any ninny who knows just enough to chew gum, can successfully produce honey; and bee-keepers, as a rule, are following a course of action to confirm people in that belief; for if a business is not worth a little advertising effort, it is not much of a business."

It seems to me that a few bee-keepers in each county where honey is produced can make it *pay* to be to the necessary expense and trouble of making a nice and attractive exhibit. To be sure, it has to be "mixed with taste and brains," and that is just what every successful bee-keeper, or his wife, has a supply of. See that the premiums are enough to *pay expenses* (which need not be heavy), and trust to sales, etc., for the "net proceeds."

One thing has been fully demonstrated by the exhibits of honey at fairs, and that is, that bee-keeping is fully abreast of other productive industries; and when compared with some, is much ahead in attractiveness and value.

The honey exhibition at the Ohio Centennial Exposition at Columbus, from Sept. 4 to Oct. 9, is not to be made just for the money there is in it, but to show the progress in bee-culture during the last hundred years; and it is hoped that it will be the largest and most attractive that has ever been held in this country; and, so far as I know, those engaged in the matter have the vim and push to do credit to the fraternity. Just think of a building 36x80 filled with the luscious God-given sweet! I have seen tons of honey piled up at fairs that did not make as much show as one-fourth the amount might have been made to do.

Auburndale, O.

FOUL BROOD.

What Produces It?—Sulphuric Acid Treatment.

Written for the *American Bee Journal*
BY WILLIAM KLINTWORTH.

It is easier to ask a question than to answer it. We may have theories upon certain things, but if our theories are not founded upon facts that corroborate our ideas, our theories have no foundation, and are not worth much. What creates foul brood? We might ask, what creates sickness, such as typhoid fever, yellow fever, and other diseases that occur more in some localities than others?

If we could see atmosphere, or the production of decayed vegetation, in

its true light, we would know more about diseases than we do now. But we know those things only in part. It is clear to my mind that the same cause produces chills and fever, yellow fever and typhoid, and some other diseases; but how much of that substance it takes to create a certain disease, cannot be stated with any certainty. But after it is developed it is not merely a dead substance, but has life in itself, and takes possession of its victim. Then the question comes to us, what can we do to kill that, and not hurt the bees and brood?

There are several things that will destroy foul brood, but we cannot apply them. When a colony of bees has foul brood, it not only affects the brood, but bees and queen also, and consequently they should then be fed, or we will not always accomplish our object. If I found foul brood among my bees, I would feed them all, for it would be hard to tell how soon it would develop in those that I could not discern anything wrong, and at the same time were diseased.

How to Feed Sulphuric Acid.

I will now describe how to feed sulphuric acid: Take 60 drops of sulphuric acid to one pint of water, and add one pint of honey. Mix it thoroughly, and that will do to feed. I prefer to feed from beneath, but if I could not do so, I would take the bees and frames out of the box. I would then take 60 drops of sulphuric acid to one pint of water, and wash the inside of the box thoroughly with it, and then put the bees back into the box, and feed the best way I could with the preparation. I have fed one quart of it to one colony of bees inside of 24 hours.

The Fire Treatment of Foul Brood.

I know that some who have had experience with foul brood, recommend burning the bees, but I must confess that I have failed to see it in that way. Suppose I had only 3 or 4 colonies of bees, and had discovered that they were foul, I would then take them and burn them, hives, bees, and all. The question comes to me, what have I gained by doing so?

But suppose I had a larger number, and find that some of them are foul, and burn them; and in a few days I find some more, and do the same with them, and I do so until I have burned them all—where are my profits? I keep bees for pleasure and profit. As long as everything goes all right, I get plenty of honey—I think much of my bees. But when they get diseased, I burn them alive! Does that not look hard?

But we say, "It can't be cured with any certainty." How do we know? Have we tried everything that we can? If I had foul brood among my bees, and I had no other remedy, before I would burn them, I would take the bees and brush them off the comb into a box, as if I would ship them. I would take box, frames and all, except the bees, and put them into a bleach box, or a big dry-goods box. I would take a half pound of sulphur, put it into an

iron kettle or something fire-proof, and place it in the box with the hive. Then set the sulphur afire. After it had burned, put the hive on the old stand, and put the bees into it. That will kill the brood and eggs, and save the hive, frame and bees. Has any one ever tried it?

Marietta, Ohio.

CONVENTION DIRECTORY.

- 1888 *Time and Place of Meeting.*
 Sept. 25, 26.—Cedar Valley, at Cedar Falls, Iowa.
 J. J. Owens, Sec., Waterloo, Iowa.
 Sept. 26.—Progressive, at Newburg, O.
 Miss Dema Bennett, Sec., Bedford, O.
 Oct. 3-5.—North American, at Columbus, O.
 W. Z. Hutchinson, Sec., Flint, Mich.
 Oct. 4.—Ohio State, at Columbus, O.
 Frank A. Eaton, Sec., Bluffton, O.
 Oct. 11, 12.—Union, at Clayton, Ills.
 S. N. Black, Pres., Clayton, Ills.
 Dec. —Michigan State, at Jackson, Mich.
 H. D. Cutting, Sec., Clinton, Mich.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Yield of Fall Honey.—Jno. A. Thornton, Lima, Ills, on Sept. 5, 1888, says:

The yield of fall honey will be good. I will have an average surplus of about 35 lbs. per colony. The quality is equal to clover, as some of it was from red clover. The largest yield is from smart-weed. My 200 colonies have gathered a good supply for winter besides the above amount of surplus.

A Blooming Curiosity.—J. C. Bell, Belton, Tex., on Aug. 31, 1888, writes:

I send a blossom that made its appearance about April 1, from which the bees gathered quite a quantity of honey for 60 days. Since the rains set in on Aug. 18, it is blooming again. What is it? Bees have done finely in Texas this year.

[This is not yet identified. It is a curiosity, and I should much like to have a pressed specimen showing more of the plant. Please address it to T. J. Burrill, Champaign, Ills.]

Chapman Honey-Plant Seed.—H. Chapman, of Versailles, N. Y., on Sept. 10, 1888, gives the following information in reply to a question by Mr. R. Bacon, on page 596:

The seed of the Chapman honey-plant should be collected as soon as the balls commence to turn brown; the balls should be spread upon platforms until thoroughly cured, when the seed can be easily shaken from the heads. But to separate the seed from the capsule, requires more labor. I accomplish this with a machine devised by myself, and which consists of a cylinder thickly studded with steel teeth, and which is made to revolve within another cylinder, from the inner sides of which project steel teeth. It is unnecessary to remove the capsules from seed used at home, but I have always cleaned that which I sold.

Heart's-Ease Honey.—John Haskins, Empire Prairie, Mo., on Sept. 7, 1888, writes:

Three to four weeks ago it seemed as though I should have had another failure with my bees; but about the middle of August they commenced to swarm, and no person that has not seen bees working on the heart's-ease can form but little idea how fast they will gather honey. The colonies that three weeks ago I did not know would gather enough honey to winter on, will probably give me in comb honey from 100 to 150 pounds each. There are thousands of acres of heart's-ease here.

Gay Feather.—D. W. McDaniel, of Hamilton, Ills., on Sept. 3, 1888, says:

I send a specimen of a honey-plant to be named. It grows on thin clay soil, and from 2 to 4 feet in height. Bees work on the blossoms all day. The bloom commences at the top of the spike, and blossoms downward. Please give its name in the "old reliable" AMERICAN BEE JOURNAL.

[This is "gay feather" (*Liatris scariosa*); not known to be specially valuable for honey; but like other "compound" flowers, it is a great pollen producer.—T. J. BURRILL.]

No Swarms or Honey.—Mr. John Boerstler, Vashon, Wash. Ter., on Sept. 7, 1888, says:

I am not discouraged yet, although the bees did not swarm or store one pound of surplus honey this year. In the spring it was too wet, and after that they secured a good supply of stores, and will have plenty to winter on; but not a pound for me. I will have to do without honey this year. All right; I guess I am not the only one in that "boat."

Hedge Hyssop, etc.—T. M. Coleman, Glendon, Iowa, on Aug. 28, 1888, writes:

I send you a part of a plant which grows in a corner of my lot, that I do not recollect of ever seeing before this season. It grows about 6 to 7 feet high, and the bees work on it as if they liked it. Will you please state, in the BEE JOURNAL, what it is.

Bees are doing nothing as to surplus honey. My colonies have been strong all the season, and I have not had an ounce of honey and no swarms this season. The most of them stored in about enough to winter on, from the linden trees, of which I have a good bee-range.

[This is "hedge hyssop" (*Lophanthus scrophularifolius*); like most of the mint family, it is an excellent honey-plant.—T. J. BURRILL.]

Excessive Swarming, etc.—Mr. Franklin Wilcox, Mauston, Wis., on Sept. 10, 1888, writes:

The bees have not worked "according to rule" this season. They wintered fairly well, but dwindled very badly in the spring. I had 3 swarms in June; they swarmed almost every day from the middle of July to Sept. 4. I have kept bees for 20 years, and I have never had so much swarming as this year. I hived nearly all the first swarms on full combs on the old stands, cut

out queen-cells, and hived back after-swarms; in this way all colonies have been kept strong. The crop of honey is better than last season, though rather below an average. The honey season usually ends by Aug. 20, but this year it continued good till Sept. 4, since which time only the buds of black-oak have yielded a clear, fine-flavored nectar. From sunrise till 9 o'clock it may be seen in drops on the ends of dark-colored, shining buds. It is no honey-dew. It has lasted a week or more. I never saw it before, and may never see it again.

Happily Disappointed.—Rev. S. Roese, Maiden Rock, Wis., on September 1, 1888, says:

The very heavy rains have ceased here, and we have now had 10 days' fair weather, after the winter wheat in shocks was nearly spoiled, and all other crops but corn (so far) a total failure. We have had for the last week or so, a fair honey-flow, and I feel happily disappointed. The bees are taking advantage of this opportunity. Since my last report I have extracted over 400 lbs. of honey, and take off about the same number of pounds of comb honey, for which I feel thankful.

Honey Coming in Freely.—J. E. Pryor, Dexter, Iowa, on Sept. 13, 1888, writes:

Up to Aug. 1 our bees scarcely stored enough honey to keep them from starving; in fact, in June we had to feed to keep them breeding. But since Aug. 15 I think I never saw bees do any better. I have had 10 or 12 swarms since Aug. 22, all of which will have considerable surplus honey. Swarms that were hived on full frames of foundation, had their nives filled with honey to the exclusion of the queens, in from 4 to 6 days. The honey is of the finest quality of fall honey, very thick and heavy, and is still coming in quite freely. Our bees will be in splendid condition for winter. I increased my apiary from 48 to 76 colonies, by natural swarming.

Bee-Keepers' Union.—Dr. H. J. Scoles, Knoxville, Iowa, on Sept. 10, 1888, says:

As to the change of time of election of officers and payment of dues to the Bee-Keepers' Union, I vote "No!" I think that it would be a detriment to the Union, and decrease the membership instead of increasing it. It would bring the election and renewal of membership at a time when the bees are in winter quarters, and there is no fear or talk of the bees interfering with any one; and all would rest content, and be more likely to forget, than they would if it came at a time when it required attention.

The 6th annual meeting, and basket picnic, of the Progressive Bee-Keepers' Association will be held on Wednesday, Sept. 26, 1888, at the residence of Mr. W. S. Wait, in Newburg, Geauga Co., Ohio. All are invited to be present. DEBA BENNETT, Sec.

The Cedar Valley Bee-Keepers' Association will hold its annual meeting at the Council Rooms, Cedar Falls, Iowa, on Sept. 25 and 26, 1888. All who are interested in bees and honey are cordially invited to be present. J. J. OWENS, Sec.

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmuns. For sale at this office. Price, \$1, postpaid.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections $4\frac{1}{4} \times 4\frac{1}{4}$ and $5\frac{1}{4} \times 5\frac{1}{4}$. Price, \$1.00 per 100, or \$8.50 per 1,000.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in *Cheshire's* pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being mailable, it must be sent by express.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

CLUBBING LIST.

We Club the American Bee Journal for a year, with any of the following papers or books, at the prices quoted in the LAST column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	Club

Hastings' Perfection Feeder.—

This Feeder (illustrated) will hold 2 quarts, and the letting down of the feed is regulated

by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for \$3.50, and it can be obtained at this office. Postage 10 cents extra.

Cork for Winter Packing.—Its advantages are that it never becomes musty, and it is odorless. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Can You Do Anything that will do more to advance and defend the pursuit of bee-keeping, than to aid its Weekly Exponent and Defender? The AMERICAN BEE JOURNAL is the pioneer bee-paper of America, and is fully entitled to the active support of every progressive apiarist, for it works constantly and faithfully for the best interests of the pursuit. We therefore specially request all our readers to use their influence to double our subscription list during the coming autumn. Reader, will you please send us a new subscription with your renewal or before that time? A good weekly at one dollar a year is surely cheap enough to command patronage.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2 00	3 00	3 50
1,000 Labels.....	3 00	4 00	5 00

☛ Samples mailed free, upon application.

Clover Seeds.—We are selling Alsike Clover Seed at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. White Clover Seed: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. Sweet, or Melilot, Clover Seed: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Exchange.—We will accept Honey and Beeswax in exchange for Bee-Keepers' Supplies in any quantity. Those desiring to make a trade are invited to correspond with us, stating quantity, quality, and price, and the goods they want in exchange.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 10 cents per pound for bag and postage.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; $\frac{1}{2}$ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, Ills., is published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Honey and Beeswax Market.**CHICAGO.**

HONEY.—New crop arriving slowly, but demand is limited. White clover comb, 17@18c. Extracted, 7@9c.

BEESWAX.—22c. S. T. FISH & CO., 189 S. Water St. Sep. 12.

CHICAGO.

HONEY.—For white comb 1-lbs., 18c. Very little inquiry for anything outside of 1-lb., and when it is wanted it is at a lower price. Extracted, the best grades, 7@8c., and some held higher. Offerings are small and demand slow.

BEESWAX.—22c. R. A. BURNETT, 181 South Water St. Sep. 12.

DENVER.

HONEY.—Colorado, new 1-lb. sections., 13@15c. Extracted, 7@8c.

BEESWAX.—20@23c. J. M. CLARK & CO., 1409 Fifteenth St. Sep. 7.

NEW YORK.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 13@14c. Fair white 1-lb., 15@16c.; 2-lbs., 11 to 12c. Extracted, white, 7½@8c.

BEESWAX.—17@21c. THURBER, WHYLAND & CO. Sep. 5.

NEW YORK.

HONEY.—Fancy white 1-lbs., 17@18c.; off grades, 15@16c. Fancy white 2-lbs., 13@14c.; off grades, 12c. Extracted, white, 7½@8c. New crop is arriving and demand is good.

BEESWAX.—23@25½c. HILDRETH BROS. & SEGELKEN, 28 & 30 W. Broadway, near Duane St. Sep. 5.

SAN FRANCISCO.

HONEY.—White 1-lb. sections, 12@15c.; 2-lbs., 11 to 14 cts.; amber, 7@9c. Extracted, white, 5¼@6c.; light amber, 5@5¼c.; amber and candied, 4¼@4¾c. Receipts light and market firm for best qualities.

BEESWAX.—17@21c. O. B. SMITH & CO., 423 Front St. Aug. 25.

DETROIT.

HONEY.—Best new white comb, 15@16c., with little in sight and slow sales. Market is low, and beekeepers will do better to hold honey until approach of cold weather.

BEESWAX.—21@22c. Supply limited. M. H. HUNT, Bell Branch, Mich. Aug. 22.

CINCINNATI.

HONEY.—We quote extracted at 5@8c. per lb., for which demand is fair. Comb honey, 12@15c. Some small lots have sold at 14@16c. Market quiet.

BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival. Aug. 24. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—Choice 1-lb. sections, 18c.; dark 1-lbs., 14c.; 2-lbs., 16c.; dark, 13c. White extracted in 60-lb. cans, 8c.; amber, 7c. in barrels and kegs, 5@8c. Demand good, prices firm, and stock light.

BEESWAX.—None in market. HAMLIN & BEARSS, 514 Walnut St. Aug. 29.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 17½@18c.; 2-lbs., 14½@15½c. Fair 1-lb., 14½@15½c.; 2-lbs., 11@12c. Extracted, fancy white clover, 7½@8c.

BEESWAX.—21@22c. F. G. STROHMAYER & CO., 122 Water St. Sep. 13.

BOSTON

HONEY.—We quote: New 1-lb. sections, 18@20c.; 2-lbs., 14@16c. New extracted, 8@10c.

BEESWAX.—25 cts. per lb. Aug. 24. BLAKE & RIPLEY, 57 Chatham Street.

SAN FRANCISCO.

HONEY.—We quote: Extracted, white, 5½ cents; light, 5¼c.; amber, 4¼@5c. Comb, 1-lbs., 12@14c.; 2-lbs., 9@13c., as to quality. Arrivals not large, and supplies held firmly.

BEESWAX.—Dull at 19@22c. Aug. 29. SCHACHT & LEMCKE, 122-124 Davis St.

KANSAS CITY.

HONEY.—We quote: New white 1-lb., 18c.; light 1-lbs., 16c. California white 1-lbs., 18c.; light 1-lb., 16c.; white 2-lbs., 16c.; light 2-lbs., 14c. Extracted, white, 8c.; amber, 7c.

BEESWAX.—18@20c. Sep. 5. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—We quote: Extracted, 4¼@5¼c. If in cans, 8@9c. White clover comb, 14@15c. Market is steady and receipts light.

BEESWAX.—21c. for prime. D. G. TUITT & CO., Commercial St. Sep. 6.

MILWAUKEE.

HONEY.—New white 1-lb. sections 18c., and very fine, 20c.; 1-lbs., 15@18c.; old 2 and 3 lbs., not salable, 12½@14c.; dark 1-lbs., old or new, 12@13c. Extracted, new white in kegs and ¼-barrels, 8@9c.; old, in same packages, 7@8c.; in tin, 8@9c.; dark in barrels or ¼-barrels, 6@8½c. Arrivals of new crop small; demand not urgent, and only very moderate trade.

BEESWAX.—22@25c. Aug. 31. A. V. BISHOP, 142 W. Water St.

Conventions.—The time for holding Bee-Keepers' Conventions has now arrived, and we cannot give any better advice than this: Let each one attend who can do so, and take part in making these meetings interesting and instructive. If you have not already obtained the "Bee-Keeper's Convention Hand-Book," do so at once to post yourself up on how to conduct such meetings correctly. It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for Discussion—List of Premiums for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents. We will club this book and the AMERICAN BEE JOURNAL for one year for \$1.25. It also contains a lot of blank leaves on which you can note important matters as they come up. Do not fail to send for a copy of it.

We Want 20,000 subscribers. Out of the 300,000 bee-keepers in America, certainly this is not an extravagant desire! It is only one out of every fifteen! We confidently ask those who appreciate the AMERICAN BEE JOURNAL, to show it by sending us one or more new subscribers. We will give them full value for their money.

Simmins' Non-Swarming System.—We have a few of these books left, and we will club them with the AMERICAN BEE JOURNAL for one year, both postpaid, for \$1.25. The subscription to the BEE JOURNAL can be for next year, this year, or may begin anew at any time.

We Have some copies of the old edition of Cook's Manual left, which we will sell at the old price, \$1.25. The price of the new edition is \$1.50 per copy; a notice of which may be found on page 579.

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Queens.—We can mail a Tested Italian Queen (bred for the best results as well as for beauty) for \$2.00; Untested Queens \$1.00 each, or \$9.00 per dozen. Orders solicited.

We will Present a Pocket Dictionary for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. Sept. 26, 1888. No. 39.

EDITORIAL BUZZINGS.

The Honey Exhibit at the St. Joseph, Mo., Fair was a very grand one, and exceeded in magnificence that of last year. The Rev. Emerson T. Abbott captured premiums amounting to \$110. Of the other premiums we are not yet advised.

Hon. A. B. Cheney, of Sparta, Mich., is running on one of the tickets as candidate for Governor of that State. Mr. Cheney is a very enthusiastic bee-keeper, as well as an influential and honored gentleman.

Feed the Bees in such a manner as to prevent robbing. A good feeder is worth many times its cost as a prevention of robbing. If there is danger of such, contract the entrance so that only a single bee can pass. This will enable the bees to defend their lives against intruders.

A Change of Time.—Owing to the Quincy celebration, the next meeting of the Union Bee-Keepers' Association will be held at the Town Hall in Clayton, Ills., on Tuesday and Wednesday, Oct. 16 and 17, commencing at 10:30 o'clock on Tuesday.

Susquehanna Co., Convention.—H. M. Sealey, of Harford, Pa., on Sept. 14, 1888, announces the following change in the date of meeting of this bee-convention:

Owing to the 8th day of September being a very wet day, the Susquehanna County Bee-Keepers' Association postponed their meeting until Oct. 6, 1888, when it will be held at Montrose, Pa., the same as before, with the same programme and at the same hour.

Not a "Corner!"—The daily papers are very fond of stating that there is a "corner on honey down in New York," and then they invent incredible stories about that "corner" or "trust." Mr. G. H. Knickerbocker, of Pine Plains, N. Y., writes us as follows on this subject:

I enclose a clipping credited to the *Farm, Field and Stockman* of Chicago. This is another illustration of the fact that some newspaper men get a "hint," and then build up a big lie, and the bigger the lie the faster they will copy it. I have written to the editor asking him to retract these statements, as they do our association great injustice by grossly misrepresenting our motives and intentions.

Will you please publish the clipping and also the enclosed circular letter, which will show how utterly false these charges are? We work only for the greatest good to the greatest number, and in the interest of dealers as well as producers.

Here is the item to which Mr. Knickerbocker alludes:

A MELLIFLUENT TRUST.—The latest thing in trusts reported is a combination of honey-producers, in session at Utica, N. Y. The producers present claim an annual output of over 5,000,000 pounds of comb honey, and 1,000,000 pounds of the extracted product. The large producers propose to establish uniformity of shape, size, and style of the packages for the coming year, the price to be charged to the wholesale dealers, and a plan for uniformity of action to prevent the cheapening competition which has marked the honey sale during the past. A trust to be composed of all the large producers in the State is proposed, nominally to regulate the size of combs, so as to unify the marketable packages, but actually to buy up all the surplus honey when there is a glut of production, so as to keep up the price and shut out competitors who might be willing to sell at a sacrifice.

It is hardly probable that this mellifluous syndicate will unify all, or even a majority of the bee-men of the United States, in a scheme to corner the honey-market, at least so long as honey remains as a high-priced luxury in the principal markets of the country.—*Farm, Field and Stockman.*

The following is the true account concerning the formation of the Honey-Producers' Exchange, being an official document from the Secretary:

PINE PLAINS, N. Y., April 26, 1888.
At the convention of the New York Bee-Keepers' Association, held at Utica, Jan. 17, 18 and 19, 1888, a committee composed of John Aspinwall, C. G. Dickinson, A. I. Root, and P. H. Elwood, was appointed to draft a scheme looking to the organization of an Inter-State Association, which should not be confined to any one section, but should, in the broadest sense, be a benefit to its reporters and members all over the United States.

This committee made the following report, which was adopted:

Your committee would suggest that this Association shall resolve itself into a Honey Producers' Exchange, for the purpose of gathering statistics of the wintering of bees and the honey crop throughout the United States.

Resolved, That the duties of the Secretary of this Association shall be the forwarding of suitable blanks to reporters, so that they shall report on the first day of May, June, July, August and September from every honey-producing State. No State to have more than six reporters, who shall fill them out and send by return mail to the Secretary. He shall have the reports

printed and mailed to members and reporters by the 10th of each month.

Resolved, That the Secretary keep account of his time involved in this work, and report the same at the next convention. He shall be empowered to draw upon the Treasurer for funds necessary to carry out the work.

This organization is to be a secret one, and the statistics obtained are not to be made public, but are for the exclusive use of the members and reporters of this Honey Producers' Exchange. To obtain reliable statistics (per centage of loss in wintering, honey crop, per centage of increase, quantity of honey on the market, prices offered, etc., etc.) will require the hearty co-operation of intelligent reporters throughout the United States. The advantages of these statistics are too plain to every honey-producer and dealer to require any elaboration here. We would only say that if you know the honey crop, the market is yours, and you can secure prices in keeping with the amount of honey which you know is on the market.

On the last of April, May, June, July and August postal-cards with a set of questions to be answered on them and returned at once, will be sent to each reporter, and the compiled report will be sent out by us on the 10th of each month.

Others who desire these reports can have them by sending us one dollar, which will make them members of the Exchange, and also of the New York State Bee-Keepers' Association.

G. H. KNICKERBOCKER, Sec.

All the newspaper sensations about "corners" and "trusts" having nothing else to rest upon than the above—which is only a system of "gathering statistics of the wintering of bees and the honey crop throughout the United States!" Just that and nothing more! Will the newspapers now as readily copy the facts as they did the falsehood?

Another Bee-Keeper Gone.—Mr. F. A. Snell, of Milledgeville, Ills., on Sept. 13, 1888, wrote as follows concerning the death of a lady bee-keeper:

Mrs. Catherine Hendrick departed this life on Sept. 13, 1888. She leaves a husband and four children to mourn her death. She was 44 years old, and her disease was cancer. Mrs. Hendrick, though not an extensive bee-keeper, was one of our most successful ones. In her well-managed apiary she kept only pure Italian bees. She used the modern improvements in hives and surplus receptacles, and was well informed, having read numerous work on bee-culture. Mrs. Hendrick was a true Christian, and was loved by all who knew her. She had kept bees for 10 years, and had resided here 31 years.

The Preserving qualities of honey are immense. The best hams are cured with honey, and pears and apples are often preserved in honey. In fact, honey has the quality of preserving for a long time in a fresh state anything that may be laid in it or mixed with it, and to prevent its corruption in a far superior manner to sugar; thus many species of fruit may be preserved by being laid in honey, and by this means will obtain a pleasant taste, and give to the stomach a healthy tone. One who has once tried it will not use sugar for preserving fruit.

GLEAMS OF NEWS.

Nebraska Bee and Honey Show.

—The bee-keepers of Nebraska are progressive and pushing—always in the lead in every enterprise which will do honor to the pursuit.

About a month ago Mr. J. N. Heater, Secretary of the State Association, sent out circulars to the bee-keepers of Nebraska, the first paragraph of which reads thus :

The Board of Managers of our State Fair Association have very generously appropriated \$600 to be used in erecting permanent quarters for the exhibition of bees, honey and apiary supplies at our State Fair, and in accordance it is expected that the bee men and women of the State will turn out and bring a liberal share of their product for exhibition until this new building shall be filled until we shall even surprise ourselves. Thousands of people from the East will visit our coming State Fair, and the light exhibit heretofore has impressed them with the idea that we were not producing much honey in this State, while the opposite has really been the fact, and it has only been our neglect to show this product that has caused this impression. Now that new and ample quarters are to be furnished us in which to make an exhibit, let us, as bee-keepers of the State, unite to see how well we can fill these new quarters, and show to those who visit our coming State Fair, what a lot of sweet things we are producing here in Nebraska.

The result of this appeal to the bee-keepers is thus stated by the *Lincoln Journal* in its report of the Fair :

When Supt. Whitcomb of the department of bees, honey and apiary goods asked the Board for a new building, he agreed that it should be filled the first year. The promise has been faithfully kept. The new structure is so full of exhibits that it is with difficulty that the spectators find room to stand while they are observing the many interesting features of the exhibit.

The present display, Mr. Whitcomb says, is larger than of all previous years combined, and Mr. Whitcomb ought to know. Cases and jars and vessels of all kinds are filled with the most luscious honey. There are cords of apiary goods with here and there an exhibition colony of bees, not including the seven hives out in the bee-yard.

The first display encountered on entering the building is that of Mrs. J. N. Heater, of Columbus. This exhibit includes comb honey to the amount of 500 pounds, and 200 pounds of extracted honey, bee-hives, extractors, plants and all kinds of bee-keepers' supplies. The exhibit occupies the front half of the building. It is tastefully arranged, and attracts no end of attention.

Special credit should be given this year to the bee-men of the State, who have sent in a large number of samples of their product. There is not so much from the vicinity of Lincoln as one would expect, but the remainder of the State has done well, and will do better in the future.

M. Tower, of Lincoln, shows one case of comb honey, two gallons of extracted honey, and one colony of bees.

Almon Tower, of Lincoln, shows the same amount, smokers, and 2 colonies of bees.

Geo. F. Warren has two cases of comb honey.

Henry Patterson, of Humboldt, exhibits two cases of comb honey, and 100 pounds of extracted honey.

Mrs. E. Whitcomb, of Friend, shows 20 pounds of fine granulated honey.

A. V. Kouba, of Crete, has a case of comb honey and 15 gallons of extracted honey, 2 nuclei colonies, queens, foundation mill, and foundation, and one colony of bees.

Ernest Bose, of Pleasant Dale, has a case of comb honey.

Mrs. E. J. Watterman, of Milford, has a case of comb honey.

Thos. Dobson, of Germantown, has extracted honey, one colony of bees.

W. P. Dakin, of Lincoln, shows one colony of bees.

J. E. Rose, of Friend, shows a case of comb honey and five gallons of extracted honey.

An exhibit that fills nearly half of the building is made by E. Kretschmer, of Coburg, Iowa. This is not a Nebraska exhibit, but Coburg is but a few miles from the border, and the State can almost claim the display, which includes 300 different articles in the line of bee-supplies alone, embracing everything relating to practical bee-culture; some 23 volumes on bees and honey, including nearly all the literature of the subject, two of the books being written by Mr. Kretschmer; a full colony of Italian bees in working order, and a colony of bees in a revolving observatory hive; 600 pounds of honey in jars, pails, bottles and receptacles of all kinds, and also in the comb.

The hives in the yard were weighed yesterday morning, and the increase for two weeks was found to be as follows: A. V. Kouba, 74 pounds; M. Tower, 65 pounds; A. Tower, 60 and 13, the bees from the latter hive having gone home; Thos. Dobson, 40 and 42 pounds; W. P. Dakin, 13 pounds, these bees also having returned to their old location.

The building—the exhibit—the honey—the implements—all are very creditable to the apiarists of that youthful State; and should stir up apiarists in older States to be "up and doing" something to their credit in the line of exhibiting their product.

Columbus.—We do not refer to the discoverer of America, but to the capital city of the State of Ohio, where the next meeting of the North American Bee-keepers' Society is to be held on Oct. 3 to 5—NEXT WEEK. Dr. Mason, writing from the grounds, has this to say to those intending to go to Columbus, which should be read by all who intend to go :

Most of those who will attend will be within the reach of reduced rates to the Ohio Centennial Exposition. Let each one intending to attend the convention inquire at his railroad station about rates to the Centennial; and if there is no reduction from that station, buy a round-trip ticket to the nearest large town or city, and there buy a round-trip ticket to the Centennial. Most if not all such tickets will have a ticket attached that will give one admission to the Centennial Grounds. If the holder does not care to use it, it can be disposed of for what it cost. I do not know the rates from New York, Toronto, St. Louis, Chicago, Louisville, etc., but excursions are coming every week. Fare from Toledo, to Columbus, O., (124 miles) is and will be \$2.50 round trip.

No reduced rates for board and lodging have been made as yet; but good meals can be had for 25 cents, and lodging for from 25 cents and up. It has been customary to get reduced rates at what are called first-class hotels, and the rates are frequently such that only a few take advantage of them, the remainder preferring to secure equally good accommodations at other hotels and boarding-houses at cheaper rates, so that the social part of the convention is divided.

The convention will meet in the State House, in the hall of the House of Repre-

sentatives, at 11 a.m., Oct. 3, and I shall try to be prepared to refer all delegates to good lodging and boarding places, at rates that will best suit their pocket-books, and then all can make the place of meeting "head-quarters" for the social part.

We have interviewed the Passenger Agent, at Chicago, of the Pennsylvania Lines (Pan Handle route), and he informs us that application has been made for reduced rates for the Bee-keepers' Convention, and a rate of 1½ fare has been granted. Tickets can be obtained at any station on that route, on Sept. 29 and 30, and Oct. 1 and 2, by purchasing a full-fare ticket to Columbus, O., and obtain with it a certificate from the agent of such purchase. This certificate must be counter-signed at the Convention by its Secretary, and upon presentation of this certificate, the ticket agent at Columbus, O., will sell the return ticket at one-third fare.

The fare from Chicago to Columbus is \$9.20, and trains leave Chicago at 10:30 a.m. and 8:30 p.m.

Read these particulars carefully, for if not strictly followed, no reduction can be obtained.

Fresh Viands or Hash!—The following is from a valued correspondent to the *AMERICAN BEE JOURNAL*, but as he did not indicate whether it was for publication, or only for the Editor's private reading, we omit his name. He wrote us something about the new edition of Prof. Cook's *Mannual*, and what it said about Mr. Cheshire and his book. Upon receiving our reply, he wrote us as follows :

Lest you may misunderstand me about the Cook and Cheshire controversy, I will just say that I am inclined to think that Prof. Cook is correct when he says Cheshire's *Bee-Keeping* is a "compilation." It is a magnificent compilation, however, and a most beautiful book.

I cannot help but meditate upon the destruction of idols. William Tell, whom boys have so often tried to imitate, has gone; Shakespeare is laid on the shelf; Pocahontas is no more; Captain John Smith and Miles Standish rest under suspicion; and now this atmosphere of doubt pervades the bee-keeper's sanctum, and clothes him with uncertainty as to whether he may be feasting on fresh viands, or only after all subsisting on hash.

As between Cook and Cheshire I shall tie to the American at all hazards, until proper treaties are established.

If authors and inventors could forget pecuniary interest, and seek only for that which is right, best, and true, the funeral expenses of jealousy could be well afforded.

That the beautiful volumes of Mr. Cheshire's "Bees and Bee-Keeping" are under ban, is true; but their elegance, like charity, covers a multitude of sins! As a work of art—as a triumph of the printer's art, both in "letter press" and engraving—as a full and complete treatise on the subject, the work is a master-piece, and stands unexcelled and unapproachable in any Country, clime or language. We admit that it is marred by jealous flings, inexcusable errors, and uncredited cullings, but these we charge up to human weakness and frailty.

CONVENTION DIRECTORY.

- 1888
Time and Place of Meeting.
 Sept. 25, 26.—Cedar Valley, at Cedar Falls, Iowa.
 J. J. O'Keefe, Sec., Waterloo, Iowa.
 Sept. 26.—Progressive, at Newburg, O.
 Miss Emma Bennett, Sec., Bedford, O.
 Oct. 3-5.—North American, at Columbus, O.
 W. Z. Hutchinson, Sec., Flint, Mich.
 Oct. 4.—Ohio State, at Columbus, O.
 Frank A. Eaton, Sec., Bluffton, O.
 Oct. 6.—Susquehanna County, at Montrose, Pa.
 H. M. Seeley, Sec., Harford, Pa.
 Oct. 10, 17.—Union, at Clayton, Ills.
 S. N. Black, Pres., Clayton, Ills.
 Nov. 21, 22.—Pan Handle, at Wheeling, W. Va.
 W. L. Kinsey, Sec., Blaine, O.
 Dec. —Michigan State, at Jackson, Mich.
 H. D. Cutting, Sec., Clinton, Mich.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

 SELECTIONS FROM
 OUR LETTER BOX
When Buckwheat Yields, etc.

—H. M. Seeley, Harford, Pa., on Sept. 14, 1888, writes :

I saw in the BEE JOURNAL a short time ago, the request to know if buckwheat yielded all day, or only in the morning. When we have a hot, damp and cloudy day, it yields nectar all day; all other times only in the morning. It has not yielded very much this season. My report for the season is as follows: From 7 colonies in the spring, I have taken 170 pounds of honey, and increased them to 12 colonies. I took 155 pounds of the honey from 2 colonies.

Bee-Keeping in Florida.—N. C.

Larsen, Cleveland, Fla., on Sept. 10, 1888, writes :

My 10 colonies of bees are in splendid condition, with plenty of stores. I am trying to learn the seasons and honey-flows here, and have not taken any more than about 10 gallons of honey in all, for home use. I expect to get considerable honey the coming winter and spring. Our main flow, I think, is from pennyroyal, which blooms during the winter, and saw palmetto, which blooms during the spring months. However, if I can have honey enough for home use, I will be satisfied, considering my outfit thus far.

Yellow Fever in Florida.—John

Craycraft, of Altoona, Fla., on Sept. 12, 1888, writes as follows concerning the trouble in Florida :

The orange crop is fine and large, and will be a great income to the people here. But we are all in prison, as it were. A guard is across the whole line of the State to keep us in like criminals. We can ship nothing out of the State, and our mail matter is all defaced and detained. We are in a part of the State where there has not been a case within 50 miles of us, and we are treated like criminals, if we attempt to leave the State. There is no objection to a strict quarantine on Jacksonville, but to treat us all alike, and for the authorities that be, to pen up in a camp, women and children with negroes and roughs, as is done, is more than is pleasant. Such outrages are far worse than the "fever." There

are a number of cities in the North that have offered their hospitality to the afflicted city of Jacksonville, and for its people to come to them, but the "powers that be" would not let them leave, but have kept them in pens "like thieves," to sicken and die, so that they could carry out their "theory," or kill in the attempt. We have plenty to eat, and things are allowed to come into the State, but nothing we have can go out in exchange but cash, and that will not last long. I cannot get along without the BEE JOURNAL, if our honey crop is small this year; we must know what others are doing.

Golden-Rod and Wild Asters.—

Rev. S. Roese, Maiden Rock, Wis., on Sept. 10, 1888, says :

We are having a nice flow of honey from golden-rod and wild asters. My bees are doing finely, and if frost holds off two weeks more, they will be in fine condition for wintering. I have extracted 1,400 pounds, and taken off 600 pounds of comb honey—a happy disappointment since my last report. The bees are still working lively, and all are equally strong for winter.

P. S.—Sept. 14.—We had a hard frost last night. I will prepare my bees for winter.

Buckwheat Yielding Honey.—

H. M. Moyer, Hill Church, Pa., on Sept. 15, 1888, says :

Mr. S. J. Youngman, on page 563, asks if buckwheat yields nectar all day, or only in the forenoon. In this locality (Berks Co.) the bees work only in the forenoon, and I think also in other places. Hardly a bee could be seen on it in the afternoon. My experience is with common Silverhull and Japanese buckwheat. The Silverhull has the most blossoms, and is longest in bloom, but the Japanese is a good yielder for grain.

Sweet Clover and Buckwheat.

—D. F. Park, Athens, Pa., on Sept. 13, 1888, writes :

The opening of white clover found my 80 colonies well stocked with bees, but nearly destitute of honey. The honey-flow was light, so that I took off only 12 cases of white honey. This was secured by taking out the outside frames and putting on cases with empty combs. By shaving the thickest edge with a hot knife, it was capped as white and even as from foundation. Sweet clover, of which we have a great abundance along our rivers, comes into blossom before the close of white clover, when bees forsook the latter, and filled the sections with the sweet clover honey, thus spoiling many cases that would otherwise have been white. I think that sweet clover is much overrated as a honey-plant. Buckwheat has yielded fairly, so that I shall have 40 cases of sweet clover and buckwheat honey combined. I have had but 4 swarms this season. Last season's average was 35 pounds per colony, which was small; however I shall realize more money this year, as I shall not repeat the experiment of sending my honey to a city commission house, getting returns of 6 cents per pound for nice buckwheat honey! It don't pay.

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1, postpaid.

Bees and Honey at the Woonsocket, R. I., Fair attracted considerable attention in the Harris Hall. The *Patriot* thus describes it :

Harris Hall looked quite gay at night when lighted, all the articles on all the tables showing up to good advantage.

One of the most attractive as well as instructive features of the hall display is that made in the Apiarian Department by Samuel Cushman, of Pawtucket. If any one desires to realize these lines of Watts, he or she would do well to visit the hall :

"How doth the little busy bee
 Improve each shing hour,
 And gather honey all the day
 From every opening flower."

There are collections of bees of the Syrian, Austrian and Italian species. The Italian-hybrids can be seen in a working glass-covered hive, "busy as bees," forming cells, storing honey, collecting pollen, spreading wax or carrying out dead bees. A wire work tube is connected with the hive and extends to an opening in a front window of the hall. Through this the bees pass out during the day for the purpose of collecting honey, and when loaded, will return and go through the process of storing what they have obtained, in doing so showing their art in the distribution of honey, wax and pollen. The queen-bees can be seen in the other hives producing eggs, while they are surrounded by hundreds of working bees, all busy, not one for an instant idle. There is certainly a grand lesson of industry, skill and perseverance to be learned from these bees. Their owner understands his business well, and knows all about bees.

Besides the bees, this gentleman also exhibits honey in the comb, extracted honey and winter hives.

Among other contributors C. F. Tarbell exhibits sixty varieties of asters.

Convention Notices.

The Pan-Handle Bee-Keepers' Association will hold its next meeting in the K. of P. Hall, on Main St., between 11th & 12th Streets, in Wheeling, W. Va., on Nov. 21 and 22, 1888. All bee-keepers are cordially invited. W. L. KINSEY, Sec.

The 6th annual meeting, and basket picnic, of the Progressive Bee-Keepers' Association will be held on Wednesday, Sept. 26, 1888, at the residence of Mr. W. S. Wait, in Newburg, Geauga Co., Ohio. All are invited to be present. DEMA BENNETT, Sec.

The Cedar Valley Bee-Keepers' Association will hold its annual meeting at the Council Rooms, Cedar Falls, Iowa, on Sept. 25 and 26, 1888. All who are interested in bees and honey are cordially invited to be present. J. J. OWENS, Sec.

The next meeting of the Union Bee-Keepers' Association will be held at Clayton, Ills., on Tuesday and Wednesday, Oct. 16 and 17, 1888, in the Town Hall at 10:30 a.m. The Park Hotel will charge \$1.00 per day; the restaurants 25 cts. per meal. We expect Messrs. Dabant, Hamburg, Cumm and other prominent bee-keepers to be present. S. N. BLACK, Pres.

The Ohio State Bee-Keepers' Association will hold its 6th annual meeting in joint connection with the North American Bee-Keepers' Society at Columbus, O., on Oct. 3, 4 and 5, 1888. A special business session of the Ohio State Bee-Keepers' Association will be held on Oct. 4, to elect officers for the coming year, and for the transaction of other business. This business meeting will not interfere with the regular programme of the National convention of the same day. FRANK A. EATON, Sec.

The North American Bee-Keepers' Society will hold its annual meeting on Oct. 3, 4 and 5, 1888, in Representatives' Hall at the capitol in Columbus, Ohio. The Passenger Traffic Associations will grant reduced rates only when 100 persons are present, holding railroad certificates. Owing to the short honey crop it is feared that a sufficient number of persons will not be present holding certificates, and that an attempt on the part of the Society to avail itself of the reduced rates offered by the Passenger Traffic Associations will only result in disappointment; hence it has been decided that the only course open will be to allow each member to shift for himself, or herself, to either take advantage of such excursion rates as may be available in his or her vicinity, buy round-trip tickets, or do something of the sort.

W. Z. HUTCHINSON, Secretary.

QUERIES AND REPLIES.

Desirability and Advantages of Reversing.

Written for the American Bee Journal

Query 578.—When is reversing desirable? and what are its advantages?—PENN.

With me, never.—M. MAHIN.

I do not practice it.—J. P. H. BROWN.

I have had no experience.—MRS. L. HARRISON.

I am not sure that it is ever desirable.—C. C. MILLER.

Never, unless you want to compel the bees to move their honey to the supers.—DADANT & SON.

I do not practice it, and cannot see its advantages.—H. D. CUTTING.

Never. It has no advantages except to get the combs fastened to the bottom-bars.—G. W. DEMAREE.

I have never practiced this method, hence I do not know.—J. M. HAMBROUGH.

When the bees are gathering honey to get the frames solid full of comb.—R. L. TAYLOR.

I do not know that I ever found it desirable at any time, nor of any advantage in practice.—P. L. VIALON.

It seems to be desirable to obtain well-filled frames. Beyond that I doubt if it gives permanent satisfaction.—EUGENE SECOR.

It is never desirable, except once, perhaps, to get the combs built out to the frames all around.—G. M. DOOLITTLE.

I do not think it desirable at any time. I have tested the matter somewhat, and base my opinion upon that experience.—J. E. POND.

1. To get combs fastened to the frames on all sides. 2. To insure against swarms; so my experience says. Others think not. 3. To get the bees into the sections at will, at the dawn of the harvest.—A. J. COOK.

It is desirable when you want the frames filled with comb, and also when the lower part of the combs are filled with brood, and the upper part with honey that you want put into the supers.—A. B. MASON.

After a good honey-flow, when the body of the hive has become too full of honey, the bees will then carry a part of it into the sections.—C. H. DIBBERN.

Oh, now this wants a whole article to answer it, and I have spoken my "piece" in several back numbers; but perhaps it is nearly time to repeat, as there are many new subscribers, and I guess I will do so before long, for reversing is a beneficial practice when properly understood and executed.—JAMES HEDDON.

It is desirable when preparing the bees for the honey harvest; desirable after the gathering begins, as it promotes the habit of carrying the honey to the supers, thus leaving the brood-

combs for the use of the queen. The invertible system gives us more bees from an 8-frame Langstroth brood-nest than we can get from a 12-frame non-invertible of the same size.—J. M. SHUCK.

In brief, it may be said to be desirable to *some* when they wish to give the queen the full capacity of the brood-chamber for laying purposes, and when they want to have the frames built out in full all around. These are the main reasons, but some can find no excuse for reversing frames. Like all other questions, this has two sides to it.—THE EDITOR.

Uncapping the Combs of Honey in Extracting.

Written for the American Bee Journal

Query 579.—When extracting, is it best to uncap both sides of the comb before you put it into the extractor? or do you first uncap one side, then extract, and then uncap the other side?—Q.

Uncap both sides.—MRS. L. HARRISON.

Both sides, of course.—R. L. TAYLOR.

Uncap both sides to save time.—DADANT & SON.

Uncap both sides before putting it into the extractor.—A. B. MASON.

Uncap both sides first, and save much time.—A. J. COOK.

Uncap both sides before you place it into the extractor.—J. P. H. BROWN.

I have always uncapped both sides first.—C. C. MILLER.

I uncap both sides before placing the combs in the extractor.—J. M. SHUCK.

Uncap both sides before putting the comb into the extractor.—M. MAHIN.

Uncap both sides always, as it saves extra work.—G. M. DOOLITTLE.

Uncap both sides before putting the comb into the extractor.—J. M. HAMBROUGH.

Uncap from each side before the frame is put into the extractor.—H. D. CUTTING.

I do that way myself. I think you can do it more rapidly that way.—EUGENE SECOR.

Yes, by all means uncap both sides before you put it into the extractor.—P. L. VIALON.

I always uncap both sides of the comb before I begin to extract either. It is only a matter of dispatch.—JAMES HEDDON.

I always uncap both sides. It is less work, owing to the fact that it will require less handling to do so.—J. E. POND.

Uncap only one side at a time; as the capping helps to strengthen the comb, and keeps it from breaking.—C. H. DIBBERN.

I shave the capping from both sides before the frame is placed in the extractor. It requires less handling of the frames to proceed in this way, and there is not the least inconvenience about it.—G. W. DEMAREE.

It makes a saving of time and trouble to uncap both sides before putting the frame into the extractor; though some uncap one at a time, the great majority uncap both at once.—THE EDITOR.

CORRESPONDENCE.

QUEEN-CELLS.

Do Queens Ever Lay Eggs in Royal Cells?

Written for the American Bee Journal

BY G. M. DOOLITTLE.

I see by the replies to Query 569, that some are still in doubt that a queen ever lays eggs in queen-cells. Formerly there used to be many such, but I had supposed that at this late day and age (after such men as Gallup, Grimm, Shuck and others had testified that they had seen queens deposit eggs in queen-cells), the doubting ones had given up the old theory of the queen hating a rival so badly that she would in no way contribute toward the getting of such an one; but in this I see that I am mistaken.

It seems to me that the way an egg is attached to a queen-cell should be enough to convince any one that none but a queen could so put the egg, occupying the same position that it occupies in a worker-cell.

I never saw a queen in the act of laying in a queen-cell, but my hired man did, which gave me positive proof that what I had long considered as a fact, was a literal truth. God said to all of his creation, after he had made it and pronounced it good, "Multiply and replenish the earth;" then why should not the queen perform her part of this work, as well as the mothers of all else living?

That one queen will kill another, when two come in contact, does not positively argue that the mother-bee should not do her part in keeping the colony provided with a means by which it could exist after she had left with a swarm. What difference could it make with her, after she had left, how many queens sprang up, so long as none of them could possibly harm her?

I am well aware that the workers do once in a great while carry eggs from an ordinary cell to an embryo queen-cell, still this is not done nearly so often as larvæ are so carried, and when eggs are so carried, it is very easily detected by the experienced eye, for they are placed in the cells in almost any shape, save the manner in which the queen does her work.

I once had a strong colony swarm, and before I could get around to do my part of the work, they returned, the queen having her wings clipped. Thinking that I would be all ready for them the next day, I did not try to divide them in the afternoon, as I sometimes do to save time for the swarms of the next day, but left them

as they were. The next day, when they came out again, I was on hand, but before they were fairly out of the hive, another swarm came tumbling out of a very populous hive and went with them.

No sooner were they all in the air, than the whole of them were re-enforced by another swarm from another hive, which I had said was not to swarm that year on account of their having a failing queen. This last hive had been opened a hour previous, and all queen-cells cut off, so as to keep them as I wished for a few days, till I could get some queens fertilized which I had under beadway; and one can imagine my surprise and chagrin, when, before this last swarm had got two-thirds out, the whole mass went piling into the hive of the colony that I had determined should not swarm. After a few moments' thought, I concluded to leave them as they were (only I put on section room to the capacity of 100 pounds, or over), to see what would become of it.

The next morning, before 8 o'clock, out they came, and were hived in an empty hive, after giving them one of the good queens which were kept back the day before. Having secured them, and having the old queen, that I had said should not swarm, in a cage, I went to the hive to inspect it before I let her go back in. Now came the greatest surprise of my life in the way of queen-cells, for by turning to my diary I see that by actual count there were 423, 276 of them having eggs and larvæ in, when less than 11 hours before there was not a queen-cell in the hive.

Here was where I first detected the difference between eggs carried to a queen-cell by the bees, and those placed in them by the queen. I decided that 188 eggs had been laid by the queen in these cells, by their being attached by the point to the bottom of the cells, and 17 were carried there by the bees, as they were in all positions in the cells; 71 cells had larvæ, which the bees must have carried there, of course. These larvæ were from two to three days old, as nearly as I could judge, and all of them were literally swimming in royal jelly, as much so as any I ever saw of that age in my life. Here is a point worthy of note for those who claim that no queen can be really good unless started from the egg and fed as a queen.

Since then I have a few times had eggs and larvæ removed from the comb I had given to a queenless colony, to a dry comb at its side; but in all these instances the queen-cells were built first, and the eggs or larvæ deposited in them, the position of the eggs resembling that which I have described above; but as I said near the beginning, the cases are quite rare where either eggs or larvæ are removed from one cell to another, and three larvæ are removed to where one egg is removed; for the bees can get a queen more quickly from the larvæ than from the egg.

The usual way of working in a queenless colony to secure a queen is, to float the royal larva when chosen, out to near the end of the worker-cell in which it is, and when there, turn a

queen-cell down over the ends of the cell. Nearly all writers tell us that the bees when made queenless tear down adjoining cells so as to build a queen-cell over the larva which they have selected for a queen; but this is not done once in one thousand times, according to my experience, and not then, unless the combs are new, not having any cocoons in them, or the selected larva is near a hole in the comb, or the edge thereof.

Borodino, N. Y.

GREAT BRITAIN.

No Honey Crop, and the Bees are Starving.

From the *British Bee Journal*
AUG. 30, 1888.

We think that the season of 1888 may be reckoned as the most disastrous that modern bee-keepers have ever experienced in the British Isles. Flowers have been plentiful, but when in bloom the weather prevented the bees leaving their hives, and also retarded the secretion of the necessary nectar in them. In consequence of this, many colonies at the present time are either starving or bordering on that condition.

Last week we "drove" (bumped) 7 colonies of bees in straw-skeps, the property of a cottager who, in other seasons, has averaged from 15 to 20 pounds of honey per colony. Although the hives were full to overflowing with bees—we took $4\frac{1}{2}$ pounds of bees from one having a super on—the total amount of honey obtained from the 7 colonies was just a trifle over 3 pounds; one of them had commenced to succumb, hundreds lying dead on the floor-board.

The foregoing we take as almost a general average, in our district, of the condition of colonies left entirely to their own resources. At the present time, therefore, the question left for consideration is, will it pay to feed the colonies the quantity of stores necessary for their winter's consumption? With the frame-hive bee-keeper his answer, given we should think without a moment's consideration, will be "yes." Of this there cannot be two opinions, but with the cottager an outlay of (say) four shillings per colony is a consideration; yet it will pay him. Many of these poor folks have all their work cut out for them to make two ends meet with their present earnings, but to expend four shillings per colony, money down, to keep the bees alive, is an impossibility, and so the dying out of such colonies during the coming winter will be most calamitous.

Having satisfied ourselves that "feeding up" is now the only and most remunerative course to pursue, the next question to arise is, What to feed? There is such a variety of sugars on the market that the novice scarcely knows which to choose, and even when he does know the description of sugar, the form in which it is to be given to the bees is a stumbling-block. "Dry sugar feeding," says one; "syrup," says another; "candy," another; "Good

candy," a fourth; "place the sugar in a dummy-board," advises a fifth; "No, don't; put it on top of the frames," chimes in a sixth. Well, between all these numerous words of advice he becomes bewildered, and gives the apparent enigma up in despair; and yet each of these advisers is giving sound advice in as far as the different requirements of a colony at a given time necessitate.

A little reflection on the part of the bee-keeper will prove to him that dry-sugar feeding alone during the coming season will be of no use whatever; the food given must be syrup—good, thick, cane-sugar syrup; no washy sugar-and-water—we might almost say, water and syrup. We have for some years tried dry-sugar feeding, and have found it in some cases very useful, but where a colony has little or no natural stores, it has invariably been a failure; times and times have we endeavored to rear condemned bees placed in fully-built combs upon dry sugar, but always failed. A colony at the commencement of winter having 6 or 7 pounds of stores, if fed on dry sugar will die out, or be of little use the next season, but where a colony has just a shortness of stores, barely enough to last it until the following spring, then dry sugar feeding will be invaluable, and so will candy, both ordinary and "Good."

Having then satisfied ourselves that for the present season, at least, syrup feeding is our only resource, it behooves us to consider what sugar to use, how to make the syrup, and how to feed. The first question is, perhaps, of the greatest importance, as the quality of—we cannot call it adulterated—unsuitable sugar for bee-feeding on the market is enormous.

Sugar at the present time is obtained commercially from a variety of vegetable substances; of course those yielding the greatest quantity are chosen before others, and as the beet-root yields 8 per cent. of cane-sugar, it is the principal (after the sugar-cane) vegetable requisitioned to supply the tea and breakfast table. Then again, cane (sugar-cane) sugars, when damaged, or of bad color, are after chemical treatment transformed into good colored and sound samples, and used for admixing with beet-sugar; this description of sugar can be mostly detected by the smell, by an adept by the sight, the chemicals used in the bleaching process, giving a most decided acid odor. The smell of beet-sugar to most people (for our own part, we should say to all people), is most nauseous, but when mixed with other sugars and refined, it loses to a great extent, but not entirely so, this unpleasant odor. Sugars of this description are known in the trade by the term "pieces." When feeding bees sugar should be avoided.

Any respectable grocer will give an applicant the information as to what is, or what is not "pieces." Loaf-sugar, best qualities, are almost free from beet, the best being "Tate's cubes" No. 1 quality, black brand, Martineau's cubes first quality; both of these are in hundredweight square, wood cases. Dutch crushed, sold now in large quantities for preserving purposes, is not to

be recommended, as frequently other than sugar-cane sugars are used in its manufacture. This sugar is packed in bags of about two hundredweight, mostly having a lead seal attached to the mouth of the bag. It is in irregular-shaped pieces of loaf-sugar, together with large quantities of the dust of the same; as its name denotes it is "crushed" loaf-sugar. Other descriptions of loaf-sugar we do not recommend.

Sugars Suited for Bee-Feeding.

We now come to a description of sugar which we have found eminently suited for bee-feeding, not only have we found it useful and suitable in this respect, but we never use any other description upon our table, as its clean sweetening properties are far before loaf and raw sugars. It is called "granulated." When this was first brought before the bee-keeping public, one manufacturer only produced it. Duncan; it then was known by the name of "Duncan's Pearl Sugar." This firm ceased refining, and certain manufacturers in America purchased the royalty, manufacturing and importing large quantities to England packed in barrels of about 238 pounds; unfortunately during the last few months no consignments of this sugar have been received in England. This sugar made a splendid, clear, thick syrup if half-a-pint of water was added to each pound of sugar, and made in the ordinary manner.

The foregoing sugar being now beyond our reach, we have found an excellent substitute for the same in granulated sugar manufactured by two firms, viz., Messrs. Geo. Crosfield & Co., of 6 Stanley Street, Liverpool (registered trade-mark C. in a diamond), and Messrs. Lyle, of Glasgow and London; both of these firms guarantee their granulated sugar as perfectly free from beet. These firms, being refiners, will not supply a private individual, but any respectable grocer will obtain the sugar for a consumer.

Raw sugars, such as Demerara, Barbadoes and Porto Rico, will make very good syrup, upon which the bees will successfully winter, but their color detracts from their merits, as such syrup will stain the combs; this, according to our experience, is the only objection. Demerara sugar is imitated by one firm who color a white crystallized sugar with some material (a trade secret); this sugar can easily be detected by placing a small quantity in the mouth. After sucking a short time, the remainder left in the mouth will be quite white, the act of sucking having removed the coloring matter, which is only superficial. As we do not know what the coloring matter is composed of, we object to its being used in the apiary.

Porto Rico sugar we find the most suitable for dry-sugar feeding, as it is very deliquescent; it also, for feeding on top of the frames, binds together with slight pressure, so forming itself into almost a solid cake. "Good" candy is made by mixing icing sugar with hot honey until of the consistency of putty; this is much too expensive, and on account of the same, suitable

only for the food used in queens' traveling cages.

The answer then to the question, What sugar to use in making syrup? will be found to be granulated, guaranteed by the makers to be free from beet. How to make the syrup is answered also in the above paragraph, and will also be found in any modern manual on bee-keeping.

How to Feed Sugar to Bees.

How to feed is then the next question. The ordinary regulating bottle-feeder will be of little service this season; a fast-feeder must be used. There are plenty of these to choose from, and where expense is of little object, any of the boxes with numerous divisions, upon the principle of which most fast-feeders now are made, can be used, but there are other and cheaper methods of making a fast-feeder, the following one we frequently use:

Obtain a tin dish, having almost perpendicular sides; into this place a wood float almost fitting the dish, and having a number of holes, freely dispersed, bored through. We place this on top of the frames, after filling it with syrup, and under the quilts, allowing, by laying pieces of wood across the tin dish, the bees to work up over the edge and take the syrup down. It is not what we call a tidy way of doing it, but it answers as well as the most expensive feeder.

The dish is refilled through the hole in the quilt, and will hold about four pounds of syrup. The quilts must be tucked down snugly all around. A good colony with this feeder can be fed up in about ten days or less, if the weather is warm.

It is very noticeable that beet-sugar is objected to by most bee-keepers, and rightly so. Although beet-sugar is, chemically speaking, cane-sugar, it is vastly inferior in its saccharine properties to sugar made from the sugar-cane. If we place a quantity equal in bulk to what we usually find with sugar-cane sugar sufficient for sweetening a cup of tea, it will be found quite unsuited to our taste, necessitating a further addition of at least one-fourth the original bulk. Bees fed on the same do not winter in at all a satisfactory manner, therefore we think that a knowledge as to where to get a sugar free from beet will be of great service to our readers, and likewise a comfort to the bees through the rigors of the winter of 1888-89.

CALIFORNIA.

The Season and the Sources of Honey.

Written for the American Bee Journal
BY S. L. WATKINS.

The honey crop in El Dorado county, this year, was an average one, being about 50 pounds per colony. The weather has been extremely warm the past month, at Placerville the mercury standing at 100° to 105° almost every day in August. This hot weather and

no honey coming in, caused the bees to dwindle down rapidly. At the Placerville apiary I lost 40 colonies out of 82.

The Carniolan bees have done the best at Placerville. It is true that they dwindled down considerably, but nothing at all in comparison with the Italians, hybrids and blacks. I have not lost a single colony of Carniolan bees. They are the best bees to defend their hives against robber bees, of any that I have ever seen. Next season I shall keep nothing but Carniolan bees in the Placerville apiary.

I have two apiaries located 14 miles above Placerville in the mountains. At these apiaries all kinds of bees do well. I do not see much difference in regard to the amount of honey stored by each race—black bees do as well as the Italians.

Bees gather the spring crop from alders, willows, maples, dogwood, wild cherry and plum, California lilac, manzanita, chaparral, flocio, pennyroyal, etc. The fall crop is the largest and best, being gathered mostly from the incense cedar, which is a wonderful yielder of honey. The spring crop averages about 30 pounds per colony, and the fall crop sometimes averages 100 pounds per colony.

Bees do not begin to gather honey from the incense cedar until October, and it usually lasts about six weeks. The honey gathered from this source is the thickest that I have ever seen. The bees cap the cells with a snowy whiteness, which gives it a very beautiful appearance. The incense cedar is rich in both pollen and honey, a single tree furnishing enough pollen for the wants of a whole colony.

Placerville, Calif., Sept. 10, 1888.

NECTAR.

Do Bees Hear?—Swarming and Science.

Written for the American Bee Journal
BY G. W. DEMAREE.

There are many questions pertaining to bee-culture that are not directly of practical utility, but interesting nevertheless.

Have Bees the Sense of Hearing?

This is a matter, it seems to me, capable of demonstration. That bees do hear in some sense which answers to the sense in which other animals hear. I have every reason to believe. That bees pay no attention to the ordinary din and clash of the outer world about them, proves nothing at all, for the same is true, in a limited sense, with all living creatures.

My grounds are bounded on the one side by a railroad, and from 10 to 14 trains pass by every day. My stock graze in the pasture undisturbed—they rarely ever raise their heads when a train thunders by. The same is true with my bees—they work right along as though all was silent. But if I drop some young bees on the ground, they will find the entrance to the hive if they are in hearing distance of the bees at the entrance; if not, they will wan-

der about, crawl into some other hive, or perish in their lost condition.

Sometimes when hiving a swarm, I dip up a cupful of bees and pour them into the prepared hive; they immediately set up a loud "roar," and the swarm promptly answer; and they rush into the hive with that joyous hum which thrills the heart of the true lover of bees with joy, that is difficult to describe. Do you say that *vibration* guides the bees, and not *sound*? What is "sound" but an impression made on the *subject* by concussion or vibration of the atmosphere?

To say that sound is not the same thing identically to the insect that it is to animals of higher order, proves nothing, because it cannot be proven that sound is precisely the same thing to the lower animal that it is to the intellectual being. Bees *hear* in a sense which answers all their purposes, and this is all that can be said of other animals.

Selecting a Home before Swarming.

This is an old doctrine. It has age on its side. It had its origin away back in the ages of bat-eyed foggism as pertains to bees. There is such a touching story here, about the sending out of "scouts" to locate a future home while the swarm waits with patience and hope. There are among these "scouts" some good Joshuas and Calebs—they will bring in a good report.

It is hopeless, perhaps, to try to be an educator along this line. Mr. Youngman, on page 567, publishes a case of "sending out scouts," which appears conclusive to him. But to me it is easy to see what attracted those bees which he took for scouts, "cleaning out a new home." The "chunks of propolis and fragments of comb" adhering to the hollow tree is what attracted the bees there. They were foraging for bee-glue, and doubtless they unwittingly answered as a decoy to the homeless swarm as it passed that way. I once saw a swarm enter an empty hive in my apiary, directed there by the same cause.

No evidence that will bear investigation has ever been published, to warrant the belief that bees locate and "clean up" a home in advance of their taking actual possession.

Honey is Not Digested Nectar.

Since writing the above items the BEE JOURNAL has come to hand, and Prof. Cook's reply to my article on page 568, has been noted. I am as much astonished, and grieved, at the Professor's reply, as he was surprised and pained because of my article. What have I said against "true science" that justifies the heated and spontaneous defense of Prof. Cook? No man has a higher appreciation for what "true science" has done for the "nineteenth century," than myself. But vagaries and absurd theories are not science. Against these (not true science) I hurl ridicule, because no other weapon can reach them. True science is not the child of one father nor of one "mother," hence the "base ingratitude" which so *stirs* the Professor is a thing of his imagination.

Yes, "there are more things in heaven and earth" than I ever dreamt of, and the remark is true when I apply it to my honored friend, Prof. Cook, or to any other living man; but I am pretty certain that no man can lift himself by the straps of his boots.

Our learned author says, "that honey is more or less perfectly—what words are these?—digested nectar is as certain as the world is round." This is at par with his dogmatic assertion that, "bees never hibernate." The one as well as the other rests alone on his *Ipsa dixit*.

"That all honey is equally digested is very likely not true." Yes, I should think so; and it is a thousand times more safe—more in accordance with the evidence, with reason and common observation—to say that it is not *digested* at all in the meaning of that word when applied to the assimilation of food in the stomach.

I have before me a fancy little card, "Why Eat Honey," sent me by that shrewd and practical apiarist and honey-dealer, Chas. F. Muth. I quote from it as a sample of good common-sense:

"What is honey? It is a vegetable product, not made, but gathered from the nectary of flowers, where it is secreted according to the rules of Nature's laboratory." These common-sense words whet the appetite for honey, while Prof. Cook's "more or less perfectly digested" vomit makes every fiber of my being recoil.

I am not able to make the large reports of great yields of honey as some bee-keepers seem able to do—perhaps my locality will not admit of it; but I had one colony of bees to gather and finish up 300 pounds of the finest quality of honey in less than 30 days. The density of raw nectar varies so much that it is hard to say how many pounds of raw nectar that 300 pounds of standard honey would represent, but certainly not less than 600 pounds of freshly-gathered nectar. Now I say that it would be as impossible for a colony of bees to digest (assimilate) in their stomachs 600, or even 300, pounds of raw nectar in less than 30 days, as it would be for Prof. Cook to lift himself by the straps of his boots.

The presence of invert sugar in honey argues nothing. Chemical changes going on during the process of evaporation is sufficient to account for that.

Christiansburg, Ky.

BOTANICAL.

The Pollination and Perforation of Flowers.

From the Shaw School of Botany,
BY L. H. PAMMEL.

Last spring my attention was drawn to a rather large and conspicuous cluster of *Phlomis tuberosa* growing in the Botanic Garden. The species is a native of Europe, and has become sparingly naturalized in the United States. The pollination of this species seems not to have been studied, although we

have an admirable account of the pollination of *Phlomis Russeliiana* by Loew. Our species, although agreeing in some important particulars with the Syrian, differs in color and some other minor points.

The structure of the flower clusters is that common to many of the Labiates, in that the flowers are borne in cymose axillary clusters; but in this case the clusters are very dense, so that the flowers are not separated readily. The tubular calyx is 10-ribbed, and terminates rather abruptly in 5 awns.

A plant when in flower is very conspicuous not only from the purple color of the corollas, but also from the number of flowers open at the same time, as there are often as many as six or eight in one cyme; and on going to the flower at any time of the day, one could see several species of *Bombus* and a *Xylocopa* collecting nectar, besides other small Hymenoptera which principally collected pollen. The corolla is decidedly two-lipped. The upper lip arches over the lower, and is slightly notched.

At the time of pollination the upper lip lies close to the lower, so that a humble-bee, on entering the flower, must force the former back, when its thorax is dusted with pollen from the anther cells which lie among the rather numerous hairs in the arched upper lip. This lip readily returns to its former position on account of the elastically-hinged arrangement to be found on its posterior part close to the tube of the corolla. This arrangement is also described by Loew, as occurring in *Phlomis Russeliiana*, and has been called by him "Charnier Gelenk"....

Insects, attracted by the clusters of bright purple flowers, find a landing-place on the lower lip of the corolla, and experience no trouble in finding the nectar, as there is a well marked groove in the middle and larger lobe of this lip, which diminishes in size downward till the nectary is reached, where it disappears. In addition to this groove there are some nectar marks: two on the middle lobe (one on each side of the groove), add one on each of the lateral lobes. These nectar marks are colored somewhat deeper than the rest of the corolla, and run to the groove, where they disappear.

There is an abundance of nectar, secreted from the well-developed nectar-gland situated immediately underneath the pistil, in the form of a fleshy outgrowth arising from the receptacle. This gland is usually somewhat angled, sending up one lobe between each of the lobes of the ovary.... The nectary occupies the lower part of the tube of the corolla, which is considerably enlarged above the nectary; this enlargement is not peculiar to this plant, but is also to be found in others. There is developed at this enlargement a ring of rather stiff hairs, which excludes small insects. The occurrence of a ring of hairs above the nectary is also common to other Labiates....

Pollination by Humble-Bees.

The flowers of *Phlomis tuberosa* are adapted to pollination by humble-bees, as has been shown, by the elastically hinged arrangement in the upper lip,

and the length of the tube of the corolla. Several of our species of *Bombus* must be able to do efficient work in their cross-pollination, as the measurements of their tongues indicate. Mr. Robertson, who has kindly identified the insects I sent him, gives me the following measurements:

The tongue of a female of *Bombus separatus* measured 11 mm., while that of *B. pennsylvanicus* was 16 mm. long. I frequently saw a large species of *Bombus*, probably *B. pennsylvanicus*, which entered the flowers in a normal way, and most of the flowers were pollinated by this insect. Besides this there was one other humble-bee, a worker of *B. vagans* (?), which visited the flowers, but mostly those which had previously been used by *B. pennsylvanicus*. The tongue of this insect measured 6.5 mm., so that it was hardly long enough to reach the nectar, and I doubt whether the insect is strong enough to push the upper lip back; as it regularly visited the older flowers, no doubt it may be of service to the plant.

Anthophora and *Melissodes*, which have longer tongues than those of *Bombus pennsylvanicus*, are frequent visitors to flowers with deep seated nectar, but they were not noticed on *Phlomis*; on the other hand *Xylocopa virginica* made perforations and used them exclusively.

The two species of *Phlomis* are much alike in the awn-pointed lobes of the calyx, the hinged arrangement in the upper lip, and the compactness of the flower-cluster. The flowers of *Ph. russelliana* are somewhat larger, and are therefore adapted only to long-tongued insects, since the tube of the corolla is 22.22 mm. long. But the tube of *Ph. tuberosa* is only 10 mm. long, so that it is adapted to a much larger range of insects. Accordingly Loew found *Ph. russelliana* visited in the Berlin Botanic Garden only by *Bombus hortorum*, and he says that *Anthophora pilipes* is the only other insect in North Germany which can do adequate service in its pollination.

In both of these species there is a beautiful contrivance for securing cross-pollination. But while the Syriau, according to Loew, is proof against such depredators as *Bombus terrestris*, which perforates many European flowers in order to get at their nectar, *Ph. tuberosa* is not proof against these unwelcome visitors. Notwithstanding that *Xylocopa* has a tongue of 7.5 mm., and can therefore get at a portion of the nectar in a normal way, it chooses rather to perforate the flowers, the awn-pointed calyx lobes offering no resistance.

The Colors of Flower Species.

But I think the most striking difference between the species is in color, and as this is such an interesting biological fact, I will summarize what Hermann Muller says about it in his classical work "Die Befruchtung der Alpenblumen."

Not only have Hymenoptera been most active in the development of such peculiar contrivances as the bell-shaped corollas of *Convallarias*, *Campanulas*, and *Gentians*; the funnel-shaped corollas of *Rhododendrons* and *Echinus*; the tubular corollas of *Loniceras*; the closed corollas of *Laurinus* and *Andrinhums*; the spurred flowers of *Aquilegias* and *Aconitums*; the

Salvias, *Melampyrum*, and *Pedicularis*; the inverted flowers with small openings of *Arctostaphylos* and *Vaccinium*; and the papilionaceous flowers of *Trifolium* and *Robinia*;—but they have also influenced the colors of flowers in a most marked degree. Flowers adapted to a large range of insects, like those of *Composita*, *Saxifraga*, *Valerianacea*, *Penttila*, and *Ranunculus*, are usually yellow or white. But in such highly modified flowers as *Lamiums*, *Salvias*, *Delphiniums*, *Aconitums*, and *Aquilegias*, the colors are generally violet, blue, pink, or purple. In these and other genera a change seems to have stepped in, especially where flowers have the same structure and are pollinated by the same class of insects.

Our species of *Monarda* show this color-range beautifully.... In Labiates the prevailing colors are blue, rose, lilac, and purple; album yellow or white. *Lanibum sibiricum*, however, is white, while *L. maculatum* is red. *Phlomis tuberosa* is purple, *Ph. russelliana* is yellow. *Salvia glutinosa* is yellow, *S. pratensis* blue. Why should we have changes in color of such closely related species?

Slight changes in color must therefore be of great use to an insect, just as changes in color of parts of a flower after pollination are of use to the insect by indicating that its services are no longer needed. Muller believes that the changes in color, in closely allied species, have been produced for reasons of this kind.

The Perforation of Flowers.

The perforation of flowers by insects, and in a few cases by birds, to get at the nectar by fraudulent means, is a matter of common observation; but in a few cases this is the normal way of procedure, as has been shown by Darwin and Muller, for insects are obliged to perforate the lax inner membrane of some orchids (nearly all of the British *Ophrea* according to Darwin) in order to get the nectar which lies within their tissues; and in the case of *Laburnum*, etc., Muller has shown that insects puncture the thickened bases of the standard petal in order to get nectar. I ought also to call attention to the destructive work of species of *Megachile*, which cut out parts of the petals of roses, pelargoniums, etc., and use them to line their nests.

A century ago, Sprengel noticed that flowers were perforated. Since his time many European as well as American observers have noticed perforations. Among them I may mention Darwin, Delpino, Ogle, Kerner, Loew, and Hermann Muller. To Loew, and especially Muller, are we greatly indebted for painstaking labor in giving lists of flowers and their visitors, and, with the exception of these and a few by other investigators, we have no statistical tables on the pollination of flowers and their insect visitors, so that we have little accurate information as to what insects perforate flowers.

It is of value to know not only that a given flower is perforated, but also what relation the insect bears to the flower which it perforates. It is, indeed, interesting to follow out these relations from Muller's tables....

Darwin, in his "Cross and Self-Fertilization," etc., states that out of many hundred specimens of red clover examined by him, nearly all were perforated, and he has even seen whole fields in the same condition. Thos. Belt and others have noticed the same thing. It is quite as common for red

clover to be perforated in this country as it is in Europe....

Italian Bees and the Red Clover.

In the summer of 1883, in the vicinity of La Crosse, Wis., I noticed large numbers of honey-bees on the flowers of red clover, and wondered whether they made perforations, or what they were doing. In some cases they obtained pollen, but in a vast majority of cases nectar was collected through perforations made by some other insect. Among bee-keepers there is a notion that the Italian bee is able to get nectar from red clover. I doubt whether this is true, for in my experience I never found them collecting nectar in the normal way; they seemed to collect only through perforations made by some other insect.

One thing will show, in part at least, why honey-bees go to the red clover at certain times and not on other occasions. It is a well-known fact that the amount of nectar secreted by a plant varies according to season and locality. There are periods, as I have had occasion repeatedly to observe, when hive-bees cannot collect enough to supply their young, and they then freely use the perforations made by *Bombus* and other insects; but when there is an abundance of nectar they pass over fields of red clover, and when *Monarda punctata* is in flower, and has a good supply of nectar, they will pass over fields of white clover, and fly some distance to fields of wild bergamot.

Although the rule seems to be that honey-bees do not perforate flowers, there seems to be exceptions, for no less an authority than Hermann Muller states that they perforate the flowers of *Erica tetralix*, using their mandibles to bite holes in the tube of the corolla. The tongue of the honey-bee is only 6 mm. long, so that it is not able to get the nectar otherwise in these early flowers. Later he found honey-bees collecting nectar in the normal way, but he failed to observe whether these late flowers were smaller or not....

It is not always an easy matter to tell whether an insect makes the perforations, especially when these are in the form of longitudinal slits, or whether it is merely looking for the perforations of some other insect. In flowers where the tissue is firm, these slits close over quite effectively, and are not readily seen. While the honey-bee makes, at most, few perforations, Muller records many cases in which it uses perforations made by other insects; but it is sufficient here to refer to his works for these.

In this country, Meehan believes that the honey-bee perforates the flowers of *Salvia splendens*. Delpino, Comes, and a few other observers, also state that the honey-bee perforates corollas. I think, however, that generally honey-bees only use the perforations made by other insects, and they are certainly quick to perceive these perforations. Muller records the most interesting case of *Salvia sclarea*, in which the tube of the corolla is so long that the honey-bee is not able to get the nectar in a normal way. It made several attempts, but did not try to perforate the corollas. When, finally, it found

several in which the corollas had just loosened, it immediately began to sip the little drops of nectar which still remained attached to the base of the corolla. It is certainly a clear case, for the insect tried in every way to get nectar, except by perforating the corolla.

The examples of flowers perforated by *Bombus terrestris* show that it mainly pierces those from which it cannot get nectar in a normal way. Muller has found this interesting difference between its visits to flowers on the plains and valleys, and to those of alpine and sub-alpine regions; that while in the lower regions it perforates many flowers where the nectar is in part accessible to it... others are visited in a normal way in alpine regions.

Muller also found a constant difference in the length of its tongue. In the Alps its tongue was usually 8-11 mm. long, while in the lowlands only 7-9 mm. long. *Bombus terrestris* is one of the most abundant of European humble-bees, and this is perhaps one reason why it uses these illegal means to get nectar. But *B. maculatus*, as Muller's investigation shows, is the worst enemy to alpine flowers. Notwithstanding that its tongue is of sufficient length to enable it to reach the nectar of some flowers... it perforates them, and only pollinates such flowers as... it could not well perforate unless it were to go to more trouble than getting the nectar in a normal way involves....

Carpenter Bees and Flowers.

The Carpenter bees, belonging to the genus *Xylocopa*, do considerable injury to flowers in more southern latitudes, where they abound.

Xylocopa Virginia, according to Cresson, is found in the middle, southern and western States, and of the 27 species of this genus mentioned in his catalogue, this is the most northern, and has the widest distribution. The species no doubt causes considerable annoyance, as Mann, Ryder, and Miss Murdfeldt have shown. Mr. Mann was the first to describe one method which it uses to perforate flowers, in which "the insect applies its sharp and wedge-shaped maxillæ to the grooved surface of the tube, and splits this open 3 or 4 mm. from the base."

Dr. Schneck and Mr. Van Ingen each record several cases in which the tube of the corolla had longitudinal slits, but as perforators they found humble-bees (*Bombus*?). As these slits correspond so well to the slits I found on the tube of the corolla of *Philomis*, I bring them up in this connection. I frequently found this *Xylocopa* in the act of making longitudinal slits in the tube of the corolla of *Philomis tuberosa*. The insect applies its powerful mandibles against the tube of the corolla until it gains entrance, then, thrusting its maxillæ in as far as it can in a longitudinal direction, the tissue yields easily, so that longitudinal slits are the result. At other times the mandibles are drawn backward and forward, thus causing longitudinal slits. The number of slits varied from one to three. The insect did not take much trouble to find the old slits, but went directly at making new ones, as it seemed to be

easier for it to do this than to waste time in looking for the old ones.

Wasps Perforating Flowers.

Wasps also perforate flowers, especially such as are adapted to this class of insects... Mr. Robertson has reported to me several interesting cases where wasps use perforations, and, at least in one instance, make them. At Orlando, Fla., he found five species of wasps, which sucked the flowers through perforations, which are at first very small, but finally large and irregular. At Clinton, Mo., he observed that *Odynerus Foraminatus* made perforations in the tube of the corolla of *Monarda Bradburiana*, which, as he thinks, were made by the wasp taking the tube between her jaws and cutting towards the mouth of the corolla, thus loosening a triangular piece which could be closed over the opening. In the Botanic Garden I frequently found the flowers of this species perforated, but the perforations were in the form of longitudinal slits.

While wasps do not generally perforate flowers, they are not above using those perforated by species of *Bombus* and other insects; for these, in their rapid visits to flowers, are certain to leave some nectar. Insects much lower in the scale than wasps, frequently use the perforations made by species of *Bombus*, as Muller has shown to be the case in a small Ichneumon fly which eagerly sought the nectar left in the flowers....

Ants and Beetles Gathering Honey.

Ants are especially fond of saccharine matter, and are frequent visitors to flowers, but only for nectar. Their visits are entirely injurious to the plant. They frequently gnaw parts of the flowers, and make irregular holes, thus gaining an entrance, or they use the perforations made by other insects.

Beetles, although not high in the scale of development, and certainly low as far as the adaptation of flowers and their pollination is concerned, show, in a few cases, some ingenuity in getting at nectar, as Muller found to be the case with *Cetonia Aurata*, which feeds on delicate parts of various flowers, is especially fond of nectar, and was found on the flowers of *Convallaria Polygonatum* eating its way from the top of the perianth to where the nectar is found at the base of the pistil, where it began to feed on the nectar-secreting gland until the wall of the ovary was reached, when it left the flower.

The acute observer Sprengel found that large numbers of the flowers of *Symphytum Officinale* were perforated by one of the flower-beetles, and that ants used these perforations. Mr. B. M. Vaughn, who found the flowers of *Corydalis Aurea* perforated at Madison, Wis., is of the opinion that these perforations were made by one of the flower-beetles.

Birds that Perforate Flowers.

It is not strange that birds should at times perforate flowers, since so many flowers are well adapted to pollination by them. Prof. Trelease mentions

that, according to Prof. W. A. Henry, the humming-bird probably perforated the flowers of *Tecoma Radicans*. Dr. Schneck and George Sprang have found these perforated, but the latter found ants gnawing through the corolla. In the Botanic Garden there was hardly a single fully opened flower of this species which did not have a few slits.

Prof. Beal reports that Mr. Hollingsworth found the flowers of *Fuchsia* pierced through at the base of the calyx-tube and robbed of their nectar. Mr. Robertson writes me that he has seen the humming-bird force its bill into a flower-bud, so that the lobes of the corolla had not been separated, but merely cut through. Prof. Beal watched carefully for two seasons the flowers of the Missouri Currant, seeing large numbers of bees collecting nectar from holes made in the calyx-tube; yet, after careful examination, he has never seen honey-bees make these holes, but several times noticed the Baltimore oriole passing over the bushes and giving each of the fresh flowers a prick with the tip of its beak. No other bird having been seen doing this, he concluded that it is the work of the Baltimore oriole, while the honey-bee takes the gleanings after the oriole.

How Flowers are Perforated.

I have alluded to the manner in which *Xylocopa* makes perforations; I must also describe how this is done by *Bombus* and *Apis*:

The mouth-parts are somewhat complex: the mandibles or upper jaws are developed for the purpose of biting; the maxillæ and labium are brought into use when the bee takes a liquid into its pharynx. The maxillæ are situated on each side of the labium, and consist of a flattened stipe at the base, then the rudimentary maxillary palpi, and from the stipe projects the triangular and deeply grooved lacinia. When the maxillæ are brought close together, a tube is formed which opens into the pharynx. The labium or lower lip consists of a central portion and two pairs of appendages, the paraglossæ and labial palpi. The central portion of the labium is divided into a basal portion, the mentum and a terminal portion, the ligula. "The mentum is hinged to the submentum, which in turn is hinged to the maxillæ by two chitinous rods." The labial palpi are deeply grooved, and when brought together form a tube.

In flying from flower to flower the insect carries its sucking apparatus stretched forward so that it is enabled to put it directly into the flower. The mouth-parts of the bee are held in a similar way when the tender cellular tissue is pierced with the tips of its maxillæ. While many humble-bees are addicted to boring the tubes of corollas, they also resort to biting the tissues of the flowers by the aid of their mandibles.

Fertility of Perforated Flowers.

The opinion is current that perforated flowers are not as productive as unperforated ones. Delpino has shown that some perforated flowers are absolutely sterile. Ogle states that many

flowers of *Phaseolus multiflorus* fail to produce seed because of perforations.

I doubt whether there are many flowers in which one can find more perforations than in *Symphytum Officinale*. In stocks which have several thousand flowers, hardly one can be found which is not perforated. Several stocks in the Botanic Garden gave me ample opportunity of seeing the results from perforated flowers. I did not undertake to count the ripened fruits, but the greater number of flowers developed some nutlets. At this time I had not seen Loew's experiments on this plant. His results are so striking and conclusive that I give them somewhat in detail:

On the 11th of June, 1885, he took several branches which had passed anthesis. On these he had 73 flowers, and was careful to remove later flowers; on the 4th of August, 46 flowers were dry, while the remaining 27 flowers had matured 51 nutlets, so that 37 per cent. of the flowers were more or less fertile.

The full fertility of many plants, as Darwin has shown, depends largely upon cross-pollination. Insects do not commonly visit flowers unless they get nectar or pollen in return, so that, when a flower is constantly robbed, the regular pollinators do not receive their due share of nectar or pollen, their visits are fewer, and consequently there is less chance for cross-pollination. If the plant is capable of self-pollination, seeds may be developed, and often in great abundance, yet Darwin has shown that the progeny of self-fertilized flowers is less vigorous than from cross-fertilized flowers.

If the structure of a flower is such that self-fertilization is prevented, and insects do not go to it in the regular way, sterility may result. But in most of the flowers perforated there is an abundance of nectar, and insects which perforate flowers are very hasty in their visits, and therefore always leave some nectar, as can be seen in many cases where the perforator first robs the flowers, after which numerous other insects use the perforations to get nectar, while others again visit the flowers in a normal way. On the whole, I am inclined to think that sterility results more from the disharmonic action of perforating insects than is usually supposed....

Insects certainly show considerable intelligence in making perforations, or using those made by other insects. One of the most remarkable cases is that observed by Francis Darwin, in a cultivated variety of the everlasting pea, where the nectar is enclosed within a tube formed by the united stamens, at the base of which are two natural openings, one on each side, the left being a little the larger. Humble-bees which bite holes through the standard petal, always operated on the left-hand side, so as to reach the larger passage....

Muller records an interesting case where a female of *Bombus terrestris* entered a flower of *Vicia Faba* in the normal way. Being unable to get the nectar, the insect forced its head under the banner, and stretched its tongue as much as possible, but, being still unable to reach the nectar, it withdrew

its head from the flower, and after cleaning its tongue with its forelegs, flew to another flower, where the same performances were repeated; but in the fourth she bit a hole in the corolla above the calyx....

Humble-bees show preferences in the flowers they perforate. Dr. Wm. Ogle states that in Switzerland he collected 100 flower-stems of a blue variety of *Aconitum Napellus* without finding a single flower perforated, while on 100 stems of the white variety, growing near by, every one of the open flowers had been perforated. This difference, Darwin thinks, may be due to different amounts of acrid matter contained in the flowers, the blue variety being distasteful to bees....

Why should insects perforate flowers? Darwin believes that, as a general rule, flowers are only perforated when they grow in large quantities close together.... Flowers grown in large masses are conspicuous, and therefore attract many insects; and, as the perforated flowers usually contain considerable nectar, the number of insects visiting the flowers at any one time is very large, and, as Darwin has shown, some of the nectaries are sucked dry; now, in order to save time, for the flowers would have to be probed for their nectar, the insect makes perforations. To this rule there are exceptions, as has been shown in some of the cases cited, where an insect, unable to get the nectar in a normal way, takes to perforating flowers. Muller, Loew, and others, have shown that there is a certain correlation between the length of the tongues of Hymenoptera and the flowers they perforate, as can be seen by consulting their tables on flowers and their visitors....

To summarize:—It has been shown that flowers with deep-seated nectar are often perforated, and that in most cases the perforations are made by insects which are unable to get at the nectar in a normal way; that *Bombus maurus* is more addicted to this habit than any other European humble-bee; that there is a certain correlation in the length of the tongues of Apidae and the flowers they visit in a normal way, but when this limit is reached, flowers are often perforated; that conspicuousness of plants may account for some of the perforations, but most of them are attributable to the non-adaptability of the insect to the flower; that the insect uses considerable ingenuity in perforating flowers, attacking them in close proximity to the nectary; that this is individual experience, and not inheritance on the part of insects; and that perforated flowers are not necessarily sterile, but are often quite productive.

St. Louis, Mo.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

HONEY PRICES.

Criticisms on the Quotations of Commission Men.

Written for the American Bee Journal
BY C. F. MUTH & SON.

The Editor has kindly sent us the letter of a correspondent to answer, to which we have no objection whatever, as the question has been asked us many times. The correspondent says:

"I would like to see an explanation of the quotations given in the AMERICAN BEE JOURNAL. For instance, Messrs. Muth & Son quote extracted honey at 5 to 8 cents per pound; but upon writing to them, they sent quotations asking about 10 to 12 cents for extracted clover honey. Now, why do they not quote correctly, 5 to 12 cents per pound? I do not mean Messrs. Muth & Son alone, but simply suppose it were they, or any other commission house. Why do they do it?"

Our quotations in the AMERICAN BEE JOURNAL and other bee-papers quote extracted honey at 5 to 8 cents on arrival. This means that we buy honey at that range; i. e., good standard qualities, for which we have a pretty steady demand. Those quotations are known to our customers as, L L (a certain grade of Southern honey), tall honey, basswood, mangrove, clover and belle-flower honey, the last being from Cuba. It has a peculiar flavor of its own, but is a nice article, and having sold about 40,000 pounds since last spring, we believe to have created a demand for it. When re-ordering, the majority of our customers call for honey by the above names.

The above are our buying prices, but they do not hinder us from buying occasionally at 4 cents a pound, or even for less; or at 9 cents a pound, as the case may be. Our range of prices is from 5 to 12 cents a pound when selling. It would not have been proper to say, from 5 to 15 cents, although we do sell a single pound of the best clover honey at 15 cents, ½ pound at 8 cents. Our conscience does not trouble us any when we sell to one party a pound of honey at 15 cents, to another a barrel of the same quality at the rate of 10 cents, or five barrels at 9 cents a pound; and to another party 50 pounds in a tin can and crate for \$7.00. We make no secret of our prices, because we prefer, at any time, to sell a barrel of honey instead of a pound. Most of our customers are manufacturers or dealers, and unless we give them a margin, we cannot expect to make the sale. It is our business to sell, and we are sorry to refuse the purchase of a lot because our stock on hand is too large. At our farm we have one class of customers only, and one price for all. There we do as other producers do, or should do, and dispose of all we can.

Cincinnati, O.

[The quotation of a certain sum "on arrival," is understood to mean that the persons so quoting it, pay that amount on arrival, and take all that arrives. That phrase is misunderstood, and should not be used, for Brother Muth has no intention of conveying that idea.

Of course the prices quoted in our Honey and Beeswax Market must be understood to indicate the prices that honey brings for the producer—not the prices at which the dealers sell it at retail.—Ed.]

Scatter the Leaflets.—Look at the list (with prices) on the second page.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4 1/4 x 4 1/4 and 5 1/4 x 5 1/4. Price, \$1.00 per 100, or \$8.50 per 1,000.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in *Cheshire's* pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being available, it must be sent by express.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the *Apiary Register* and begin to use it. The prices are as follows:

For 50 colonies (120 pages) \$1 00
 " 100 colonies (220 pages) 1 25
 " 200 colonies (420 pages) 1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

CLUBBING LIST.

We Club the American Bee Journal for a year, with any of the following papers or books, at the prices quoted in the LAST column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	Club
The American Bee Journal	1 00	...
and Gleanings in Bee-Culture	2 00	1 75
Bee-Keepers' Magazine	1 50	1 40

History of National Society	1 50	1 25

Hastings' Perfection Feeder.—This Feeder (illustrated) will hold 2 quarts, and the letting down of the feed is regulated

by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for \$3.50, and it can be obtained at this office. Postage 10 cents extra.

Cork for Winter Packing.—Its advantages are that it never becomes musty, and it is odorless. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Can You Do Anything that will do more to advance and defend the pursuit of bee-keeping, than to aid its Weekly Exponent and Defender? The AMERICAN BEE JOURNAL is the pioneer bee-paper of America, and is fully entitled to the active support of every progressive apiarist, for it works constantly and faithfully for the best interests of the pursuit. We therefore specially request all our readers to use their influence to double our subscription list during the coming autumn. Reader, will you please send us a new subscription with your renewal or before that time? A good weekly at one dollar a year is surely cheap enough to command patronage.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels	\$1.50	\$2.00	\$2.25
500 Labels	2 00	3 00	3 50
1,000 Labels	3 00	4 00	5 00

Samples mailed free, upon application.

Clover Seeds.—We are selling Alsike Clover Seed at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. White Clover Seed: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. Sweet, or Melilot, Clover Seed: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Exchange.—We will accept Honey and Beeswax in exchange for Bee-Keepers' Supplies in any quantity. Those desiring to make a trade are invited to correspond with us, stating quantity, quality, and price, and the goods they want in exchange.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 10 cents per pound for bag and postage.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; 1/2 pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, Ills., is published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Honey and Beeswax Market.**CHICAGO.**

HONEY.—New crop arriving slowly, but demand is limited. White clover comb, 17@18c. Extracted, 7@9c.

BEESWAX.—22c.

HONEY.—New white 1-lb. sections, 18c., and very fine, 20c.; 1-lbs., 15@18c.; old 2 and 3 lbs., not salable, 12½@14c.; dark 1-lb., old or new, 12@13c. Extracted, new white in kegs and ¼-barrels, 8@9c.; old, in same packages, 7@8c.; in tin, 8@9c.; dark in barrels or ¼-barrels, 6@6½c. Arrivals of new crop small; demand not urgent, and only very moderate trade.

BEESWAX.—22@25c.
A. V. BISHOP, 142 W. Water St.
Aug. 31.

Conventions.—The time for holding Bee-Keepers' Conventions has now arrived, and we cannot give any better advice than this: Let each one attend who can do so, and take part in making these meetings interesting and instructive. If you have not already obtained the "Bee-Keeper's Convention Hand-Book," do so at once to post yourself up on how to conduct such meetings correctly. It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for Discussion—List of Premiums for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents. We will club this book and the AMERICAN BEE JOURNAL for one year for \$1.25. It also contains a lot of blank leaves on which you can note important matters as they come up. Do not fail to send for a copy of it.

We Want 20,000 subscribers. Out of the 300,000 bee-keepers in America, certainly this is not an extravagant desire! It is only one out of every fifteen! We confidently ask those who appreciate the AMERICAN BEE JOURNAL, to show it by sending us one or more new subscribers. We will give them full value for their money.

Simmins' Non-Swarming System.—We have a few of these books left, and we will club them with the AMERICAN BEE JOURNAL for one year, both postpaid, for \$1.25. The subscription to the BEE JOURNAL can be for next year, this year, or may begin anew at any time.

We Have some copies of the old edition of Cook's Manual left, which we will sell at the old price, \$1.25. The price of the new edition is \$1.50 per copy; a notice of which may be found on page 579.

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Queens.—We can mail a Tested Italian Queen (bred for the best results as well as for beauty) for \$2.00; Untested Queens \$1.00 each, or \$9.00 per dozen. Orders solicited.

We will Present a Pocket Dictionary for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

The Institution which has done so much to foster art in America, "The National Academy of Design," has its history well told by A. S. Southworth, in the opening article of *Frank Leslie's Popular Monthly* for October. It is illustrated with views of the building, and portraits of its Presidents. The stories and adventures in the number are all attractive and well illustrated, and some, like "Venezuela and Great Britain," by Almont Barnes, of no little value.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

Advertisements.

Pure Italian Bees,
ONLY \$3.00 per Colony QUEENS, \$1.00.
Address, S. F. REED,
39A3t NORTH DORCHESTER, N. H.
Mention the American Bee Journal.

Jones' Frame Pliers.

FOR taking frames out of hives, or moving them in any way desired. It is made of Japanned iron, and can be utilized in many ways. It has a long claw for loosening frames, and a hook which may be used for carrying other frames besides the one held by the Pliers. Price, 40 cents., by mail. By express, 30 cents.

THOS. G. NEWMAN & SON,

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. Oct. 3, 1888. No. 40.

EDITORIAL BUZZINGS.

The "North American" Convention will be in session by the time this paper is in the hands of its readers. We expect to give a report of the proceedings in our next issue.

We Regret to learn that Mr. W. Z. Hutchinson has been "on the sick list" again. He is now improving, however, and hopes to have fully recovered in a few days.

The Appeal of the Arkadelphia case is to come before the Supreme Court at Little Rock, Ark., this month. The Hon. S. W. Williams has the case in charge for the Union, and we confidently hope that it will sustain the verdict of the lower court, and declare that the pursuit of bee-keeping is *not a nuisance*. Thousands anxiously await the result of the trial.

Dr. Morrison, of Oxford, Pa., was very successful at the late Pennsylvania State Fair, in his competition in the Apiarian Department, having secured five first prizes on his bees. First on Carniolan and Italian bees, and on queens, queen-rearing and queen-cells.

The Wintering of Bees is the most important subject now before us—it is thoroughly a reasonable topic, because a plan must be decided upon and put into practice in a very short time. We advise every bee-keeper to read carefully the article on pages 647 and 648, written by Mr. G. R. Pierce, entitled, "The Result of Experiments Made to Discover the Cause of Bee-Diarrhea." Its careful perusal will pay for the time devoted to it, even though you may not agree with all its conclusions.

Pleurisy Root.—Mr. James Heddon, on page 600, mentions the fact that this plant had "shared the fate" of the clover and buckwheat of this season, at least to a certain extent. Now in *Gleanings* we find, as a later report, the following, stating that it has yielded better than any other plant:

This year the pleurisy plant is the best honey-yielder of them all. It has spread until there is no dearth and robbing, when basswood closes. We see that the quality of the honey is excellent, and the color about the same as white clover. It is standing full of seeds this season, and we believe that in the near future, it will be the best surplus honey-producing plant we have in this locality, basswood and clover not excepted.

A Change of Time for the payment of dues and the election of officers of the National Bee-Keepers' Union was proposed on page 579. It was thought that it would be a much better time to have it come in January instead of July, and as we have several cases on hand with a call for money to carry them to a successful issue, it was further proposed that the next annual dues be called for next January, for the year 1889. Several have voted, and all so far have been in favor of the change. Let every member of the Union send a postal card to the Manager, and say whether he favors the change or not. Be free to vote, and *vote at once*.

If you Have Surplus Honey ready to take off from the hive, do so at once. Honey is much better looking when just completed than it will ever be after. By leaving it on the hive the bees thicken the cappings, and by traveling over the dark brood-combs and then over the honey, it becomes soiled, and has a darker appearance. The propolis nuisance should also be remembered. The sooner the honey is removed the less of this will there be to scrape off from the sections.—*Colman's Rural*.

At the Indiana State Fair Mr. G. K. Hubbard captured all the premiums but one; the exception being that of a collection of honey plants, which was awarded to Mr. J. S. Russell, of Zionsville, Ind. Mr. Hubbard took the other eight premiums as follows: On queens, apiarian supplies; comb foundation for brood-chamber and surplus, honey and wax extractors, sections, and crates for honey. By the report we should think that no honey was exhibited.

When we Consider that pure honey is the very essence of flowers and plants, in which, we are told, there is a remedy for every disease, surely we cannot doubt the bappy combination of honey as medicine. The Scripture tells us, in many passages, of the wonderful efficacy of honey as food and medicine. As the treatment of disease becomes more and more rational so will the value of honey as a medicine become more and more apparent.—*Exchange*.

Uncle Sam's National Flower.—Upon the selection of this, the Lewiston, Maine, *Journal* remarks as follows:

What shall be the National flower of the United States? This question was first brought before the public at the recent session of the Society of American Florists in New York. Some one proposes that the golden-rod shall be the chosen emblem of nationality. The claims made for this flower are that it is national in the wide range of its growth, accommodating itself to almost any circumstances, in the pasture, in the meadow, in the roadside, or by the stream.

Mr. Turner's "Outline Studies in the History of the Northwest," (Charles H. Kerr & Co., Chicago), is a timely publication in this anniversary year of the settlement of the Northwest. It is prepared for the uses of study clubs, and arranged to occupy fifteen meetings, each meeting being devoted to a particular division of the study, and three special topics being provided for each. Mailed to any address for 10 cents by the publishers.

Reproduction in the Honey Bee is the title of a pamphlet just received. It is an address delivered before the Pennsylvania State Board of Agriculture, by Prof. G. G. Groff, acting President of the Bucknell University, and apiarist of the State Board of Agriculture. It is a very interesting address, and we shall copy a portion of it as soon as we can find room for it.

Nature's Way.—This is the title of a 15-cent pamphlet entitled, "G. M. Doolittle's Method of Rearing Queens"—which is called "The nearest approach to Nature's way yet devised." It describes his method, and points out its advantages. For sale at this office.

Wax is a substance secreted by the bees, and is analogous to the fat of higher animals. To produce a single pound of wax, bees must consume from 15 to 20 pounds of honey. The expensive substance is used by the thrifty little insects with the greatest economy. The thickness of the cell-walls in a new comb is said to be only 1-180th of an inch.—*The Millstone*.

Saved by Bees.—An exchange says: "Once when the Turks had begun to scale the wall of a church in Transylvania, a girl's wit saved the people from capture and death. Behind the church was a little garden, and in it a dozen bee-hives which it was the girl's duty to care for. Seizing a hive she ran up on the fortress wall and hurled it down among the enemy. Again and again she repeated the process until ten or more swarms of maddened bees were stinging the Turks. They were blinded and dismayed, and, unable to cope with the insect foe, beat a hasty retreat. They had been discomfited by a girl's device."

GLEAMS OF NEWS.

That Silver Lining to the clouds which have hung like a pall over the pursuit of bee-keeping for the past few years, is thus commented upon in last week's *Prairie Farmer* by Mrs. L. Harrison:

Bee-stock has been below par for a couple of years, but, as every cloud has a silver lining, let all engaged in the fascinating pursuit, keep up their courage, hoping for a prosperous season in the near future. There is one happy coincidence, however, to console us over the flabby condition of our purses, that if we have no honey to sell to fill them up, bees generally winter well after a poor season. The queen has plenty of room to deposit eggs, and vigorous young bees to act as nurses, for they have no secreting of wax or building of comb to attend to. When there is an abundance of honey, all hands are pressed into service, and the queen is neglected, so that when the season closes the bees are mostly old, with little vitality to withstand the winter's cold; then we hear of diarrhea, spring-dwindling, and kindred ills; but now our colonies are strong, with queens doing their level best, and at the approach of cold weather will be full of vigorous workers, hardy as a nut.

Cross bees at this season! Yes, indeed; some of them are hot as a streak of lightning. The best way is to feed them a little for a few days, before disturbing them, especially if they have no unsealed honey. A well-fed colony is as good-natured as a fat alderman after dinner, but paupers are very different.

Feeding Back.—This is relied upon by the cranks, who persist in claiming that comb honey is adulterated, to prove their point. We have repeatedly asserted that such is not practiced to any extent—is not profitable—and therefore does not in the slightest degree uphold or sustain the assertion of Wiley, Evans & Co.—still they repeat the story over and over again. The last issue of the *Rural Canadian* contains this corroboration of our statement:

Mr. S. T. Pettit, for two years President of the Ontario Bee-Keepers' Association, says that a few years ago some one gave a plan of securing lots of comb honey by the use of the extractor; throwing out the nectar green, as fast as it came in, thus exciting the bees to gather all they possibly could, and then when the honey season was past, just feeding it back, thus securing big crops of comb honey. Well, the plan looked reasonable on paper, but in actual practice it looks very different to me. Of course, I waited until the gathering season was past, and then went enthusiastically to work giving unfinished sections, mostly, to work upon. Well, the amount they managed to cram away in the brood-chamber before starting at all in the sections, took a good deal of the enthusiasm out of me; but at length they went reluctantly, tardily, at work in the sections. But the sections were not as nice as those built by the same bees during the honey-flow.

Another set-back to the scheme was found in the great loss of weight during the feeding-back process. I did not keep an accurate account, but I believe it to be 40 to 50 per cent.

Another serious objection that presented itself consisted in the fact that all the bees used for feeding back died outright or

dwindled badly. Too much honey in the brood-chamber I think was the cause.

My opinion is, that it will not pay to feed back, even to complete sections that are nearly finished, much less for the building of whole sections.

Extracting the Wax.—This is very often a great nuisance in a house, and many family jars have resulted from the process of rendering beeswax. In the *Western Plowman*, Mr. C. H. Dibbern gives some of his experience in these words:

I have lately experimented a good deal in rendering the wax from old brood-combs. In my experiments I have used about all known methods. I have boiled it and strained it; I dipped it from the top; I have steamed it and melted it in the sun extractors, but all with about the same result, not nearly all the wax would be secured.

Lately I had a pile of refuse from which I extracted all the wax I could get, but upon examination with a microscope I became convinced that a good deal of wax still remained. I filled a wash boiler full of it and boiled it until all the lumps separated. I had rigged up a box with a false slatted bottom in it. I poured the contents of the boiler into a strong burlap sack, placed it in the box after tying securely, placed a piece of plank on the sack, and a square block on top of that. I took a long plank to use as a lever, placing one end under a cleat nailed to the building, and commenced pressing the contents of the sack, gradually adding more weight till the pressure was about as great as the sack would stand without bursting. Leaving the weight on for an hour or more, the last drop of wax seemed to have separated from the mass in the sack. The wax and dirty water will be caught in the bottom of the box where it will readily cool.

After cleaning up this run I found we had seven pounds of nice, bright yellow wax, worth at least \$1.40, and much more to make into foundation. This experiment has convinced me that many thousands of dollars are annually lost by the imperfect methods of securing beeswax. When the comb is new or from cappings, it is easy enough to get all the wax, but old, dirty pieces of drone comb, or odds and ends, mixed with propolis, and what not, it is quite another matter. I am now convinced that the only way to get nearly all the wax from such comb, is to submit it, as hot as possible, to a high pressure.

Bee-Keeping was one of the most rural occupations. At the time when man first commenced to stir the soil for his daily bread, bees were managed for domestic use, to furnish the only product then known and used exclusively as a sweet. The discovery of sugar-making supplied a cheaper staple, which placed honey among the luxuries. For hundreds of years such has been the state of the honey trade. Now we see advanced bee-keeping increasing the production to an extent which will place honey on regular bill of fare of the most unpretentious hotels. Indeed, we should see it there today.—*Exchange*.

A Home Market for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Figwort.—On page 649, will be found an article on this honey-producing plant, by R. S. Russell, committee on Honey Plants at the Indiana State Bee-Keepers' Association, at Zionsville, Ind. Mrs. L. Harrison makes the following additional remarks on the same plant in the *Prairie Farmer*:

The Simpson honey-plant was brought to notice by Mr. Simpson, of Warren county, Ills. It is often called rattle-weed, as the seeds will rattle in the pod, and Carpenter's square, as it has a square stalk. It belongs to the figwort family, the botanical name *Scrophularia nodosa*, from its being a supposed remedy for scrofula. It delights in damp, shady ground, and grows wild over a large extent of country along hedges, old rail fences, stumps, etc. Willows are all good honey-plants. One tree bears all pistillate flowers; another all staminate. The pistillate yield honey, and the staminate pollen, and the bees act as marriage priests carrying the fertilizing powder from one to another.

There has been more honey gathered in one day from basswood than from any other source. Many persons learning this, planted out orchards, but were sadly disappointed in the yield. Plants do not yield honey in the same amount in different localities. While basswood yields largely in Canada, Vermont, Michigan, etc., it is worth but little for that purpose in Illinois.

The Season in Canada is thus described in the last issue of the *Rural Canadian*: "The past season has been a very poor one for bee-keepers. Last summer (1887) the drouth prevented clover from seeding, and this prevented the usual flora of this nectar-secreting plant, one upon which the bee-keeper depends so much for his profits. Linden yielded but little, and our only hope was thistle and fall flowers. Heavy and frequent showers have given a yield sufficient for winter, and perhaps an average of 15 pounds to the colony surplus. Of course it will be necessary to distribute this evenly between those colonies which have gathered insufficient."

Irresponsible.—In *Gleanings* for Sept. 1, 1888, we find this brief "puff":

We have for some time past had complaint from different parties in regard to Mr. F. J. Crowley, dealer in apian supplies, Batavia, Genesee county, N. Y. We are now informed that he is in Batavia only a part of the time, and is no way responsible.

He has also been owing us for several years, but we can get nothing from him. There are many more very much like Crowley, whose transactions ought to be published for the benefit of honest men. We are considering the matter of publishing a black list, and we may have to do it yet.

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1, postpaid.

Look at Your Wrapper Label.

—The date there indicates the end of the month and year to which your subscription is paid. If that date is past, we hope you will sit down at once and send us the necessary dollar to move the date a year ahead. The following incident, from the *Breeder's Journal*, illustrates the danger of procrastination in this matter of punctually paying subscription for your paper:

Not long since, says a writer, I dropped into a prominent newspaper office, and, while chatting with the editor, a well-to-do stock-raiser of that county dropped in and planked down the necessary amount for two years' subscription in advance for the paper, and at the same time remarked:

"I want the tag on my paper to be in such a shape that I need not be ashamed, when a friend calls at my house, to let him see it. You may believe me or not, but it is a fact all the same," he continued, "that a little matter like that has already saved me considerable money; and one particular instance I want to tell you about. I had some dealings with a certain man," said he, "and one day, while at his house for the purpose of selling him some sheep, I chanced to pick up his newspaper. I observed by the tag upon the margin that he was terribly in arrears for it. The fact that a man would allow his newspaper account to run on, year after year, to such an extent, set me to thinking, and I resolved that should he ask me for credit—he already owed me for fifty head of fine sheep—I would respectfully decline his request. As I had anticipated, he did ask for time, which I not only refused him, but demanded the amount already due me. He was unable to meet the obligation just then, he said, but would do so very soon. I sold my stock elsewhere, but I never got the money out of the man for the sheep I had previously sold him, nor do I expect to. Had I not seen that tell-tale newspaper tag he might have stuck me still further. Now, when I am in doubt as to a man's responsibility, all I want to enable me to accurately size him up is, to get my optics on his newspaper tag, and in nine cases out of ten I will never be mistaken in my estimate of him."

We commend this item to the careful perusal of all those who are in arrears for their reading matter. Good credit is better than a fortune—nay, it is a fortune itself.

Rustic Superstitions about the Bees.—We clip the following from the *Scottish Farming World*:

Many curious and quaint traditions, dating from a remote past, still linger around the venerable straw hive, and upon which we may dwell more at length on some future occasion. Not a few cottage bee-keepers of the old school still devoutly believe in the efficacy of adhering to old customs to the very letter, absurd and amusing as they appear to outsiders. It is considered indispensable at the outset that the swarm be paid for in gold; silver coin is supposed to be "unlucky," and, accordingly, the lesser gold coin is tendered almost invariably in payment. It is just possible, however, that this tradition may have originated on the part of some shrewd bee-keeper anxious to keep up the price at a time when swarms were many and sales few. In some places it is the practice to put a little sugar at the hive-entrance on Christmas Eve, and at the stroke of midnight the bees are believed to come down and eat it. If a death occurs in a family, the hives must be draped with the insignia of mourning, and at night the bees are "woken up" by sharply rapping the hives with the knuckles, and each is then

informed of the event; the sound caused by the humming of the bees inside the hives, alarmed at being "woken up" in such a manner, is considered to be their response to the communication. A generation ago this belief was very general, and it has still many adherents.

Quite recently a couple of old bee-keepers, Sam Goodheve and Phil. Hacksles, characteristic representatives of the old school, discussed the topic, happily unconscious of a "chil" standing by "taking notes." We subjoin it verbatim:

"Our Joe tells me that poor old Tom Hedgestake's heeves be all dead arter all," said Sam, "and he fed 'em too, all the time he could still get about."

"What else could 'ees widder expect," replied Phil. "She ne'er woke 'em up when the old man died, and ne'er put one of 'em in mourning."

"Well, I told how't would be," Sam rejoined; "and now she sees plain enough how my words become true. But there be a many people that'll ne'er be told nothing, and so she must put up with consequences."

"Bees be curis things now," observes Sam musingly, after lighting a fresh pipe; "and I well mind how, when Uncle Jim died—that was in the 'ear '60—his heeves all perished the followin' winter, as there was not a scrap o' black put on any on 'em. Now when my feyther died, and that nigh on thirty 'ear ago, I took care to wake the bees up and put all the heeves in mournin'. I cut up his old black weskit on purpose, and not one on 'em perished; and they was the forridest too swarm of anybody's round about that spring. What a whoppin' lot o' honey I had that 'ear surely! I sold £6 worth, 'sides what we ate inside, and brewed a big barrel o' mayde in t' bargain."

CONVENTION DIRECTORY.

1888	Time and Place of Meeting.
Oct. 3-5.	North American, at Columbus, O. W. Z. Hutchinson, Sec., Flint, Mich.
Oct. 4.	Ohio State, at Columbus, O. Frauk A. Eaton, Sec., Bluffton, O.
Oct. 6.	Susquehanna County, at Montrose, Pa. H. M. Seeley, Sec., Harford, Pa.
Oct. 16, 17.	Union, at Clayton, Ills. S. N. Black, Pres., Clayton, Ills.
Nov. 21, 22.	Pan-Handle, at Wheeling, W. Va. W. L. Kinsey, Sec., Blaine, O.
Dec. —.	Michigan State, at Jackson, Mich. H. D. Cutting, Sec., Clinton, Mich.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Results of the Season.—J. E. Boyles, Nelsonville, O., on Sept. 17, 1888, writes:

I wintered 30 colonies, spring count, on the summer stands. I have always wintered my bees that way, and generally with success, but not always. They came through in nice condition, and all bred up early except one which was queenless. I gave them brood with adhering bees, and a queen-cell, and they soon became strong, but too late to store surplus. I have five new colonies by natural swarming. The last one on June 18 was a large one, and became very strong, but too late also for surplus. All of the 33 colonies stored more or less honey in the sections, amounting to about 1,000 pounds, although a portion of

the sections were unfinished. I sell in my home market, and mostly at the stores where I sell garden stuff, as I am in the garden business. I get 16 cents per pound for honey, in cash, or 20 cents in merchandise. I could always sell more if I had it. The present crop is about two-thirds gone, and I could have sold all of it by this time, had I not been crowded with my other work. Our honey harvest was ended by July 5. We never look for a fall crop here; yet the bees have had much better late forage than usual, as we have had plenty of rain.

Decidedly the Best Season.—N. C. Clayton, Central, S. C., on Sept. 19, 1888, says:

I have been a bee-keeper several years in a locality that, years ago, was exceedingly good for bees, but of late it has been the reverse, some years having no surplus at all. But since applying modern improvements I get some honey every year, and my report for this year is decidedly the best it ever has been. I began in the spring with 31 colonies, controlled swarming pretty well by extracting, and took about 75 gallons of honey. There is not much market for honey here.

What a Woman Can Do.—Mrs. Harriet A. Gale, Shelby, Lake Co., Ind., thus writes of her season's work and the cash results:

My bees have done well for the past season. I have 18 colonies now with honey-boxes on the hives. When those on are finished, my crop will amount to over a thousand pounds, which I have already sold for 18 cents per pound, and a part of it is already shipped.

Determining the Sex of Bee Eggs.—M. S. Morgan, South Elgin, Ills., on Sept. 27, 1888, writes:

I am obliged to dissent from the commonly received theory that the volition of the queen determines the sex of her eggs. In my opinion, after her fertilization any one of her eggs will produce a worker, a queen, or a drone, according to the purpose and manipulation of the workers. A proof that a worker-egg may be made to produce a drone, may be obtained in this way: Divide a colony, giving to the new hive, bees with sealed worker-brood only, together with a queen-cell. Be sure that there are no drones in the new hive. Now from a colony that have killed off their drones, select any one frame of entire worker brood having a few unhatched eggs; place this frame in the new hive; and I will guarantee that upon this frame will be found the elongated cells of drones, whilst in the colony from which it was taken, there will be workers only. The egg with the sperm attached produces a worker; the same egg with the sperm detached, produces a drone; the separation being made by the volition of the worker, and not by the volition of the queen.

We will Present a Pocket Dictionary for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

QUERIES AND REPLIES.

Handling Bees with Veil and Gloves.

Written for the American Bee Journal

Query 580.—Is it desirable to use a veil or gloves, when handling bees?—Kentucky.

Veil, yes; gloves, no.—G. M. DOOLITTLE.

A veil almost always, but gloves never.—JAMES HEDDON.

Yes, a veil, but no gloves.—J. P. H. BROWN.

A veil, but no gloves.—C. C. MILLER.

Yes, a veil, but not gloves.—R. L. TAYLOR.

I use a veil, but no gloves.—J. M. HAMBAUGH.

If the bees are disposed to sting, yes. If not, no.—M. MAHIN.

Yes, a veil, when necessary to prevent stings. Gloves never, say I.—A. J. COOK.

A veil, yes; but not gloves, unless you cut off the finger tips.—DADANT & SON.

A veil is very desirable at times. I never handle bees with gloves.—H. D. CUTTING.

I prefer to. You cannot always or sometimes tell how bees are going to act.—MRS. L. HARRISON.

Sometimes it is best to use both, and "Kentucky" is not much of a bee-keeper if he cannot tell *when*.—A. B. MASON.

Sometimes it is well to use a veil, but gloves of any kind are useless.—C. H. DIBBERN.

It will depend wholly upon the individual, and on the bees. There have been times with myself, where both were absolutely necessary.—J. E. POND.

It is desirable to have a veil ready for use, and to use it when you feel like it. Gloves are seldom needed. Bees usually strike "above the belt." Singe the long hairs off the back of the hands, and do not jerk back if a bee darts at the hand. Keep your nerves steady and—*hold your breath!*—EUGENE SECOR

There are times that bees can be handled with impunity without a veil, but after one gets stung on the bridge of the nose, or other tender spots on the face, he will always think of having a veil when handling bees. Gloves are a nuisance, and not desirable.—P. L. VIALLO.

It is very desirable to me on some occasions. I do not often wear gloves, but I would use them oftener if I could get gloves that would not be in the way of nimble fingering. A bee-veil is among the essential devices in apiary work. I frequently hear people say that they have no use for a veil or gloves. It is evident that such people know but little about handling bees. When taking honey, tiering-up, etc., during the honey flow, I rarely ever use a veil; but I frequently go through hybrid colonies to remove queen-cells

and such-like operations, and I know that I have met with cases where an unprotected person would get a sting in every square inch of his hide.—G. W. DEMAREE.

I use a veil, but no gloves. I am not often stung, but the chance of a sting in the eye, or a bee in the ear, causes me to wear a veil.—J. M. SHUCK.

When honey is coming in, there is but little reason for wearing a veil, but a good smoker should always be at hand, for use in case of an emergency—an accident, for instance. Gloves are of use, to protect the hands, when the finger tips are cut off, in times when the bees are cross, or there is a dearth of honey.—THE EDITOR.

Bee-Sting Remedies.

Written for the American Bee Journal

Query 581.—Are the so-called bee-sting remedies of any value for curing bee-stings? Iowa.

I think not.—R. L. TAYLOR.

They are of very little value.—J. P. H. BROWN.

I think not.—J. M. HAMBAUGH.

None that I have used, and I have tried many.—JAMES HEDDON.

Yes, a little. I think that ammonia is the best.—A. J. COOK.

We tried them, and think nothing of any of them, except cold water.—DADANT & SON.

Some of them are. The oils of cinnamon and cloves have been of real value to us this season.—A. B. MASON.

Very little, if any. The best remedy I have found is saliva from my own mouth.—M. MAHIN.

I do not know from experience, but my faith in them is not very strong.—C. C. MILLER.

From experience and reading on the subject, I am of the opinion that no remedy of value has as yet been found.—J. E. POND.

Simple pure ammonia is the best of anything I have used, but of late years I have not used anything.—H. D. CUTTING.

Not any that I have ever tried. If a person belonging to my family were stung badly, I should put them in a wet sheet pack. If an animal, in like manner.—MRS. L. HARRISON.

I never use any. Years ago, when I first commenced, few suffered more from stings than I did. Now they affect me but little more than an insect bite.—G. M. DOOLITTLE.

They have proven worthless so far as I have experimented with them. It is proper to say, however, that a bee-sting amounts to very little with me, anyway.—G. W. DEMAREE.

They will alleviate the pain and lessen the swelling on persons not used to stings. The professional bee-keeper has little use for them.—C. H. DIBBERN.

I have not tried everything, but nothing that I ever did try did any good, so far as I could discover. Stings

do not swell on me any more. If I get stung on the end of the nose, my friends do not notice any difference.—EUGENE SECOR.

The absorption of the poison is immediate, and no local application is of any value. I would like to have Prof. Cook give us an article on the subject, and bring in the action of the hypodermic syringe to fully demonstrate this.—P. L. VIALLO.

I think not. A sting in the hand, where I always get it, if at all, can be instantly rubbed out on the clothing, and, many times, the poison will not reach the blood at all. The bee will often be crushed in this way before it has pushed its lance into the skin.—J. M. SHUCK.

Our British friends are very enthusiastic in their praise of the use of apifuge for the prevention of being stung by bees. When Mr. Cowan was here he spoke very highly of it—though some have condemned it, or stated that they did not think it of value as a preventive. When stung some use ammonia to advantage to allay the pain; others apply smoke for the same purpose. The poison acid may be neutralized by an alkali; saltpetre for instance. Ice cold water, if applied at once, will drive the blood back, and quite often affords relief.—THE EDITOR

Convention Notices.

☞ The Pan-Handle Bee-Keepers' Association will hold its next meeting in the K. of P. Hall on Main St., between 11th & 12th Streets, in Wheeling, W. Va., on Nov. 21 and 22, 1888. All bee-keepers are cordially invited. W. L. KINSEY, Sec.

☞ The next meeting of the Union Bee-Keepers' Association will be held at Clayton, Ills., on Tuesday and Wednesday, Oct. 16 and 17, 1888, in the Town Hall at 10:30 a.m. The Park Hotel will charge \$1.00 per day; the restaurants 25 cts. per meal. We expect Messrs Dadant, Hambaugh, Camm and other prominent bee-keepers to be present. S. N. BLACK, Pres.

☞ The Ohio State Bee-Keepers' Association will hold its 6th annual meeting in joint convention with the North American Bee-Keepers' Society at Columbus, O., on Oct. 3, 4 and 5, 1888. A special session of the Ohio State Bee-Keepers' Association will be held on Oct. 4, to elect officers for the coming year, and for the transaction of other business. This business meeting will not interfere with the regular programme of the National convention of the same day. FRANK A. EATON, Sec.

☞ The North American Bee-Keepers' Society will hold its annual meeting on Oct. 3, 4 and 5, 1888, in Representatives' Hall at the capitol in Columbus, Ohio. The Passenger Traffic Associations will grant reduced rates only when 100 persons are present, holding railroad certificates. Owing to the short money crop it is feared that a sufficient number of persons will not be present holding certificates, and that an attempt on the part of the Society to avail itself of the reduced rates offered by the Passenger Traffic Associations will only result in disappointment; hence it has been decided that the only course open will be to allow each member to shift for himself, or herself, to either take advantage of such excursion rates as may be available in his or her vicinity, buy round-trip tickets, or do something of the sort. W. Z. HUTCHINSON, Secretary.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Scatter the Leaflets.—Look at the list (with prices) on the second page.

CORRESPONDENCE.

The Battle-Bees.

Were you there when the columns swirled about,
Did you hear the cannons' rattle?
Did you hear the regiments' lusty shout,
And the hum of the Bees of Battle?

The bees that hummed in the air were of lead;
How they sang through the leafy bowers!
And the juice of the flowers which they drank was
red—
How the Battle-Bees fed on flowers!

Were you there when the bees came humming
through,
Were you there when they so beset us,
When the honey they made with so much ado
Was sweeter than that of Hymettus?

Was it sweet? Ah, it was! So I say again:
Its sweetness is told in story—
It was deadly sweet to the armies twain—
But the honey was only glory.

—Selected.

BEE-DIARRHEA.

The Result of Experiments Made to Discover the Cause of It.

Written for the American Bee Journal
BY G. R. PIERCE.

Query 564 reads thus: "During December, January and February of the winter of 1884-85 I lost 700 full colonies out of 900 located in five apiaries.... The frames and combs were badly smeared with excreta where there were a few bees and queen left.... The winter of 1885-86 was the same with 600 colonies. The winter of 1886-87 all of 400 colonies came through to February. They commenced dwindling then, and went down one-third.... The past winter has been the same. I have some 15 or 20 colonies that have withstood all these winters, and have come out good every time under the same conditions. 1. Have you had this experience? 2. What is it? 3. How can I stop it?—Illinois."

The above is the substance of Query 564, on page 502. It was accompanied by the opinions of some twelve experienced apiarists as to the cause of the disease in question, and how to prevent it—a few to whom the query had evidently been submitted, not expressing any decided view on the subject. All who expressed any opinion were united in referring the trouble to bee-diarrhea, and the cause to improper food, but disagreed as to the manner of prevention. Some advise "Illinois" to feed pure cane-sugar; some to keep the bees in a warm cellar; to deprive them of pollen, etc.

Doubtful Cause of Bee-Diarrhea.

I believe but very few persons who have kept bees in the Northern States will hesitate in naming the disease referred to in the Query as bee-diarrhea; but as to the cause—that is the rub! That is the winter problem which has been discoursed upon in all the bee-periodicals of the land during the past twenty years, and if there has ever been a clear, rational explanation given of the cause of this disease—the dread of the Northern bee-keeper—it is not

yet manifest to the mental vision of the fraternity. The hypothesis of to-day does not become a theory to-morrow, but is kicked out to give place to the next plausible explanation that may be offered; in the meantime, the disease "gets there just the same," as sure as the winters come on—at least it does with the majority of bee-keepers.

Facts Discovered in Experimenting.

I do not propose, in this article, to advance any explanation as to the cause of the trouble under consideration—this would require more time than I have at present at my command—but rather to bring forward some facts which I think have escaped the attention of some of the prominent writers on this question. I have indeed an hypothesis—as every bee-keeper must have—to explain the cause of winter losses in the apiary, but for the present I must try to confine my remarks to certain facts which I have noticed while conducting a series of experiments undertaken with a view to discover some practical method by which bees could be carried through the winter with as little risk as is incurred by the stockman in wintering his horses, cattle, sheep or hogs.

We may boast to our heart's content of the great advance made in bee-keeping; of our extractors, comb foundation machines, and the superiority of the improved hives now in use, over the bee gums of our daddies, but after all the fact remains that the average winter mortality among bees is quite as high now as it was 25 years ago.

The winter of 1879-80 was very cold, all through the northwest, and the losses among bee-keepers were very extensive, especially among those who practiced out-door wintering. My own losses were so severe that I resolved to conduct a series of experiments with a view to arrive at some definite idea as to what was the cause of winter mortality among bees. I had for years taken much interest in this question; had read everything available on the subject; had tried nearly all methods and devices recommended in the bee-papers and books devoted to the industry; and had seen more or less of my bees die every winter and spring without being able to afford them any relief. I do not mean by saying this, that my losses were more than that of the average of bee-keepers in the North—I do not think they were as high as the average; but I was losing more bees than I thought necessary to lose if the proper conditions of wintering were understood.

Different Phases of Bee-Diarrhea.

The solution of the subject under consideration naturally leads along three lines of thought, viz:

1. What is it?
2. What causes it?
3. What will prevent it?

It might be supposed that the first question was known from the start, but this idea is an error, arising from the notion that diarrhea is a specific disease, whereas it may be simply a corroborative symptom of some organic or constitutional derangement. Simple

diarrhea is generally caused by a sudden change in food or drink, or by the introduction of improper or vitiated alimentary substances; but it often occurs when the cause has not the remotest relation to food or drink. Medical writers recognize this distinction by treating of the subject under different heads—usually three—but as my education has been confined mainly to chemistry and *Materia Medica*, I shall not attempt to explain all the different phases of the disease.

The Quality of Winter Bee-Food.

Now to return to the Query, the question arises, did those bees have the diarrhea in its simplest form, or was it exhibited in connection with some derangement of the bee-system? If the former supposition is correct, then we may properly look to the food for the cause. If the latter, then the cause must be sought elsewhere. My opinion is that the disease, which is usually termed bee-diarrhea, is the out-growth of another disorder, and the cause of this is seldom, if ever, to be referred to the quality of the food. I do not wish to be understood as saying, that if bees were fed impure food they would not have the diarrhea, for they probably would. What I mean to assert is, that the quality of honey has nothing to do, in ninety-nine cases out of a hundred, with the bringing about of the disease in question. I am forced to this conclusion not only from experimental experience—which I have not time to set forth—but also from the following reasons:

First, when animals are afflicted with simple diarrhea, the organs of the system are in a relaxed condition; there is no distention or inflammation. In bee-diarrhea—so-called—there is unmistakable evidence of congestion and inflammation. The bloated appearance evidently does not result from the accumulation of fecal matter, for it does not disappear after evacuation. It might be urged that the retention of the feces in the intestines for an unusual time would cause irritation which would evidently produce inflammation in the surrounding membranes. This argument seems very reasonable, but I am disposed to believe that it is not applicable to this case for the following reasons:

1. It has been proven repeatedly by direct experiment, that bees can be kept housed for six months or more, on stores of honey and pollen, without any injurious effect. 2. Bees often become diseased within two or three days after having had a cleansing flight. 3. The disease usually makes itself manifest within a short period of time. I have repeatedly seen colonies become badly sickened within 10 or 12 hours after a previous examination, when, to all outward appearance, they were in perfect health. The second and third reasons, by themselves, prove nothing, but when taken together, tend to disprove the hypothesis that the disease is caused by fecal accumulation.

The Impure-Food Theory.

Second, I disbelieve in the "impure food" theory because, when improper substances are taken into the animal

system, nature acts *ab initio*—from the beginning. When a young man commences to use tobacco, he does not smoke a box of cigars before feeling the unpleasant effects of the weed; the first cigar or pipe generally "lays him out" limp and pale, with his whole internal apparatus in open rebellion and spasmodic eruption. The farmer understands that, if he feeds green food exclusively to animals, that have been fed upon hay, they will, for a time, "have the scours." These are only a few of the many examples that might be cited to illustrate that wise provision of the Creative Power, by which all animals are warned against partaking of substances which would cause the system to become deranged, even if the derangement is only temporary, as in the case of a sudden change of feed.

Third. There is still another objection to the "impure food" argument. Even when the adult members of a species of animals are enabled, by virtue of their superior physical power, to eat food which may not be best for them, if the same food be consumed by the same species of immature growth, the evil effects will very soon become apparent.

Now in the case of bee-diarrhea, neither the young bee, just emerging from its cell, nor the one that has nearly completed its course of life, exhibit any indications of disease until nearly the middle of the winter, and very often not until the month of March.

To still further show the fallacy of the prevalent idea that winter mortality of bees is caused by improper food, let me illustrate by the following facts that have come under my notice while studying this question:

Experiments in Wintering Bees.

Suppose we take ten hives containing colonies of normal strength, both as to bees and honey. Let these colonies be left on the summer stands and protected from the weather in any manner that the experimenter may see fit, provided it is so arranged that the clustered bees may be examined from the top, with as little disturbance as possible.

Now if we examine these colonies, say on Dec. 1, we shall find—if the weather is cold—the bees closely clustered in the front-center of the hive, with the top part of the living sphere from 3 to 5 inches below the top-bars of the brood-frames—the distance below will vary according to the disposition of the honey stores and the depth of the frame. If the weather continues cold, the motion of the cluster will be upward, and in time the bees at the top will be in close proximity to the honey-board or quilt, whichever may be used to cover the hive.

Suppose these 10 colonies are closely watched, and it is found that on Jan. 1, 4 colonies are so clustered as to reach over the frame tops; this interval of time—December to January—we will designate *a*. On Feb. 1, two more are in the same position, interval of time called *b*; still two more reach this position on Feb. 15, interval of time *c*, and

the last two on March 1, interval of time *d*.

Now what I wish to bring to the notice of the reader is, that during the interval of time *a*, there will be no danger of any of these 10 colonies becoming diseased. During the interval *b*, if there is disease it will be among the first 4 colonies named; during interval *c* only among six; during interval *d*, only among eight. After March 1, if very cold weather is experienced, or if the hives are not properly protected, all of the 10 colonies are liable to become diseased; but the chances of escape are in favor of those which were last to reach the top-bars, and against the first.

The question arises, what has the position of the clustered bees to do with the bringing on of the disease, if the cause is to be referred to improper food? If the honey in the upper region of the hive is unfit for bee-food, why is not that below?

But let us try another experiment. Take a good, strong colony—it is no matter about the quantity of stores—and in place of the honey-board place over it an empty hive, or a box, without top or bottom, of the same dimensions as the hive. To prevent its being moved, light cleats should be nailed on the lower edge, or straw may be piled around on all sides except the entrance. Now lay a piece of oil-cloth on the frames, and over this tuck snugly a piece of heavy blanket or quilt. Cover with a heavy board to keep out rain or snow. As soon as the clustered bees reach the top-bars, take six one-pound sections of sealed honey, cut out entrance-ways in the sides, and lay them close together, side downward, in such a manner that the center of the clustered bees will be directly under the general center of the sections. Replace the coverings, and do not disturb them until about the time they will have consumed most of the honey in the sections, when another course must be laid on, and so continue as long as the bees approach the coverings.

The result of this experiment will be, that the colony operated upon will be alive and in good health on the first day of April, or thereabouts, no matter whether there is pollen in the honey or not; no matter what kind of honey is used—only that it must be sealed—whether from white clover or buckwheat; gathered in the spring or fall, it makes no difference in the result. If any one doubts this, it may be verified or disproved during the coming winter.

What the Experiments Prove.

These experiments, together with others not mentioned, prove conclusively to me that *quality* of food has seldom, if ever, any part in producing diarrhea—so called; and acting upon this theory, I have been enabled to so prepare my bees that I have had no losses from this cause during the past five winters, and shall prepare my colonies for the coming winter with perfect confidence that they will pass that heretofore critical period in vigorous health.

If the reader of this article desires to know what name I would give the disease, I would say that I am not an ex-

pert at clinical diagnosis, therefore I have not unlimited confidence in my conclusions; but if he will, for the time being, throw aside all preconceived notions about ventilation, absorption, hibernation, pollen consumption, etc., watch his bees and read some standard work on catarrh, he may, or may not, come to the conclusion to name it *intestinal catarrh*.

How to Prevent Winter Losses.

The main point, however, is to know how to prevent this trouble, and this can be done by the following:

1. Never stinting the bees in their supply of honey.

2. Keeping the hives so protected that the heat generated by the bees will be retained as long as possible *within the hive*.

I have no confidence in any system of wintering bees which does away with *hive protection*, not even when wintered in a cellar. The first cost is an item, but it pays well in the end.

AUTUMN.

Suggestions about the Necessary Fall Work.

Written for the *Farmers' Advocate*

BY R. F. HOLTERMANN.

As the honey-flow has been so very short this season, bee-keepers will be inclined to take away more honey from their bees than good judgment should allow, and as a natural result the bees will starve before spring. If an upper story is put upon a hive, and this is called the surplus arrangement, it does not mean that the bees can spare all they put in a jar from it; of extracted honey, especially, the bees rarely have enough in the lower combs for winter. So many bees are lost by starvation, and so much has been said upon this subject that it would seem almost as if there was no use in writing upon this subject.

Get your bees ready for winter early—in fact, in summer it should commence, and as the brood will often not permit the storing of sufficient honey below, reserve two or three combs of good honey well capped, and have these to fall back on in every hive, if they do not have the requisite quantity of honey on Oct. 1. Take out combs free from brood and with the least honey, and put in the combs of sealed honey.

It is a very bad plan to feed—time is taken up. The bees rob if they get the least chance; it wears the bees of the hive out as a honey-flow does, and leaves them aged for winter; and there is a great, actual waste by the bees in placing their stores in the hive, to say nothing of the bad impression that your neighbors get to see you haul home sugar and feed it to the bees; they of course at once say you are "making honey." See, then, that your bees have 30 pounds of feed, an average hive with combs and bees weighing 20 pounds. Have this feeding done before Oct. 1.

Winter-Passages n Brood-Combs.

These enable the bees to pass from comb to comb without having to pass under them or around the sides, and the desirability of such passages will be better understood when it is remembered that the lower part of the hive is colder than the upper. The bees cluster on the combs in a ball-shape, for instance, the center combs have the largest number of bees, and the outside combs the least of any. The size of this cluster depends upon the temperature of the hive, and the higher the temperature the more the bees spread over the frames; the colder, the more compactly they cluster. Then as they cluster in a ball shape, when the cluster contracts they can contract on each comb, but not towards the center of the cluster unless they go down or outside and pass around the comb, which is a movement just opposite to the natural, and those on the outside combs become isolated and perish. If there was a passage through each comb, where the center of the cluster on the comb would be, the bees could pass through and join the cluster on the other side. The best position for the passage would be in the center of the upper two-thirds of the comb, above rather than below.

There are many contrivances for cutting or punching these holes. Perhaps the best is a cone-shaped piece of tin, growing in diameter, as it recedes from the cutting end. This can cut a round hole through the comb, allowing the piece of comb removed to slide out on the wide end of the cone. Another plan resorted to is, to lay a bridge over the top boxes. This bridge is constructed simply of sticks, so made as to allow the bees to pass from comb to over the top boxes. If you winter your bees outside, it is particularly desirable to make these passages for the bees. In a warm cellar it is less necessary.

Old and Worn-Out Queens.

Many colonies perish in winter or early spring because their queens are old and worn-out, and perish at this season of the year. A queen will sometimes be vigorous and prolific when five years old, but much oftener a queen will be in that condition in which she should be replaced by a young and vigorous queen, at three years of age.

The question naturally follows, how shall we know the age of a queen? This is a somewhat difficult matter, and a careful record of each hive, which should be numbered, is a good way. Bear in mind that the old queen issues with the swarm, and you must transfer the record with the swarm. If queens' wings are clipped, the front right wing may be clipped the first year, the rear right the second year, and the left, next in order. If you have only a few colonies you should have no trouble to tell the age, and should know all your queens by sight.

If you have old queens replace them before fall; this may be done by taking out the queen and placing a queen-cell in the hive which you know is about ready to hatch. Use good stock, and now and then purchase a "dollar

queen" from some one whose bees you know have blood different from your own bees. In bees, as in other stock, new blood of the right kind gives vigor and energy—very desirable qualities in bees.

BEE-PASTURAGE.**Figwort, or Simpson Honey-Plant, for Honey.**

Read at the Indiana State Convention

BY R. S. RUSSELL.

Where is there one who has handled bees and made them his associates, who doubts for a moment that these industrious little misers will appreciate any improvement in their homes and plantation, and doubly repay any judicious outlay toward supplying them suitable plants from which to extract the honey?

We believe that a bee is not happy except when employed gathering the sweets which Nature stores in certain plants. Now is the time to lay the foundation for an abundant honey harvest.

If you have no bee-willow near your apiary, procure a few roots or cuttings, and plant in low land near the apiary.

Simpson Honey-Plant—Figwort.

This will bring the earliest pollen, which is the most useful. The bark will crack late in the fall and furnish a harvest of honey after frost has killed all flowers. Also set out a few soft and hard maples, and tap lightly in two or three places early in the spring. Set these trees near the beehouse, as many bees are chilled and lost in rambling for the early sweets.

Be sure and save all the basswood on your farm, and plant a few more in old pastures for shade. Plant catnip, the more the better, near the apiary; it is fine for the young bees. Spare all the golden-rod when mowing the fence-corners, also all asters. The bees will tell you what they are when in bloom, if you do not recognize your friends.

Sow a patch of buckwheat on July 1 and 20; and also on Aug. 10 and Sept. 1. Last but not least, procure a supply of Simpson's honey-plant seed from some reliable apiarist or seedsman. It can be sown in hot-beds, and trans-

planted the same as cabbage, or sown in open ground. It will grow anywhere, in fence-corners or waste ground, in shade or cultivated fields, planted 2½ feet apart. It is a certain grower, and will "get there" whether cultivated or not.

This is, beyond doubt, by far the best honey-plant of all, giving a steady flow of good honey from the middle of July until killed by frost. The honey accumulates in the cup-shaped flowers, and if all removed will almost immediately fill up again, thus affording an inexhaustible supply faster than the busy workers can remove and store it.

I have noticed no disease in my apiary since I have raised this honey-plant. I think that the secret is, it keeps the bees employed gathering good, healthy honey, instead of trying to extract it from decaying fruits and vegetables in the fall months, which they are sure to do unless they can work on something better.

It is a medicinal plant, but is not eaten or disturbed by stock of any kind, and will take care of itself after the first year. It is not a noxious weed which will take possession of your farm, but is easily exterminated.

Brother apiarists, I can imagine no lovelier stroll than through my woods in August and September. This honey-plant is in full bloom, and the beautiful Italian bees make the woods musical from daylight until dark. I will not speak of the merits of the different varieties of clover, as of necessity they will be sown, and help to round out a season for the most industrious creature of God's creation.

GRAPE BLOOM.**Bees Gathering Honey from Grape-Blossoms.**

Written for the American Bee Journal

BY PROF. A. J. COOK.

"Do men gather grapes from thistles?" No, but bees gather honey or nectar from grapes.

A few days since a gentleman from Texas sent me what he thought was a kind of sarsaparilla, with the statement that bees were collecting much honey from it. He was a subscriber to *Gleanings*, and at his request I named the plant for that paper.

Now our friend C. F. Muth, sends me the same plant with the following: "Our friend J. W. Park sends the enclosed plant and blossom from Columbia, Texas. He calls it 'cow-itch,' and says that it grows profusely in his neighborhood, and yields very abundantly of a superior quality of honey."

Right here we see the mischief of common names, and the necessity of scientific ones. One calls this "sarsaparilla," and one "cow-itch," and it is really one of the very reputable grape family. It is *Vitis bipinnata*. It is a bushy, low, climbing vine, with fruit about the size of a pea, but not eatable.

As will be seen, it belongs to the same genus—*Vitis*—that includes all our grapes. *Vitis vinifera* is the Euro-

pean grape; *Vitis lobrusca* is the northern fox grape; *Vitis æstivalis*, the summer grape; *Vitis cordifolia*, winter or frost grape; and *Vitis vulpina*, the southern fox grape. *V. indivisa* is more closely related to the one in question, as its berries are not edible.

BABY BEES.

A Few Thoughts for Children About Young Bees.

Written for the *Prairie Farmer*

BY MRS. L. HARRISON.

There is a good deal more in a colony of bees than the honey and wax they produce. They are models of industry, neatness and order. About the first lines engraved on the plastic clay of my memory, are these of Watts:

How doth the little busy bee
Improve each shining hour,
And gather honey all the day,
From every opening flower.

How skillfully she builds her cell,
How neat she spreads the wax,
And labors hard to store it well
With the sweet food she makes.

Children should be taught to watch the bees as they go in and out of their hives, and, particularly, notice that each individual bee has a duty to perform for which it is accountable. The guards protect the entrance against all intruders, and no enemy is allowed to pass without resistance. It is amusing to watch a bumble-bee as it tries to evade the guards and gain access to the rich stores within. How soon his back is mounted, and "policemen" at his side bring him forth, as he loudly buzzes and struggles for freedom. Bees from neighboring hives are not allowed to enter without showing their passport, which is a well-filled sac of nectar, while all paupers are denied entrance. Woe betide the moth that has the presumption to knock at the door of a strong colony of Italians, for it will never try that game again.

When the young drone bee emerges from the cell, he looks around for something good to eat. If he is not fed by the field workers, he goes to a cell and helps himself. This he is allowed to do *ad libitum*, until his duties commence, which, in his case, is to fertilize a queen. He daily sallies forth in quest of her, to perform the task for which was the purpose of his creation, and in the performance yields up his life. If he is not needed for this duty, he must "walk the plank," for no needless members are allowed, but all must succumb to the good of the commonwealth.

The young worker is allowed a few days to eat and digest food, when her duties as nurse to the larvæ and queen commence.

The duties of the queen are so onerous, in the production of so many eggs, that her system is not capable of sustaining the draught, unless her food is given her in a half-digested state, so that it readily assimilates. The queen, even, is not allowed in the hive, if she does not perform her duties properly.

She must not "skip any stitches," but go round and round in a circle, using every cell; and her progeny must be able to perform their duties, or she is ejected. Woe betide her, if she rears all "boys" and no "girls," and her owner finds it out.

When the worker's duties of a nurse are completed, she takes a rest in secreting wax and building comb, and is allowed a play spell after dinner, that she may learn the location of her hive. Perhaps she is given a lesson now and then in stinging, as she is always an adept at it, and ready, on the least provocation, to "curl her tail." We see more of her in her capacity as guard and field-worker than in any other.

She attends strictly to business, and, when gathering clover honey, does not stop to smell the fragrance of roses, pinks and posies, but goes quickly from one clover blossom to another. There is harmony in Nature, and she must carry the fertilizing powder from flower to flower, so that the seed will germinate, and the plant be perpetuated.

Peoria, Ills.

IOWA.

Report of the Iowa State Bee-Keepers' Convention.

Written for the *American Bee Journal*

BY JOS. NYSEWANDER.

The Iowa State Bee-Keepers' Association met in their commodious tent on the Fair Grounds during the State Fair, on Sept. 4 and 5, 1888. In the absence of President Spaulding, Joseph Nysewander acted as temporary chairman at the opening of the meeting. In the election of officers the following were chosen for the ensuing year:

President, Mrs. O. F. Jackson, of Sigourney, Iowa; Vice-President, Eugene Secor, of Forest City; Secretary, J. W. Moore, of Des Moines; and Treasurer, Jos. Nysewander, of Des Moines.

The subjects discussed were appropriate to the season, which, being a peculiar one, brought new experiences to many. Much swarming and little surplus honey is the exception to the rule in Iowa. There seemed to be just enough honey gathered to engender much swarming, while with fewer swarms fair returns could have been secured in the way of surplus honey.

How to Control Swarming.

Several plans were presented that had been successfully employed by different members present. It was conceded that a single swarm from one colony was rather an advantage than a disadvantage, as it was possible to have the benefit of 2 colonies instead of one when the real harvest came. Upon this theory Mr. Chantry suggested that it was his method to work for increase until July, and then have the several colonies, instead of one, ready for the fall flowers; it being understood, however, that he is entirely dependent upon the fall bloom for his

honey crop. Ordinarily, or in most locations, this method was deemed impracticable.

Mr. Kimble said he thought that he could secure the best results by having about one-third increase; and in response to a number asking the question as to whether it was possible to confine his colonies to a certain number, he thought that he would have to depend on at least that much increase.

Mr. Secor stated that he practiced having the first swarms on the old stand, and removing the parent colony to a new location. He found that this in most cases brought about the desired result. Others suggested cutting out queen-cells, etc., which they found quite satisfactory, although it required more labor.

It was found that even this season, that those who were able to control swarming, had a fair yield of honey to report. Mr. Secor stated that up to that date, which did not include the fall honey, or at least very little of it, that his colonies averaged about 40 pounds each, of comb honey. He believed that bees should be made to pay their way in any season.

Honey from Different Flowers.

In discussing this subject, Mr. Bittenbender stated that it was his observation that bees never gathered nectar from different kinds of flowers in a single trip.

Mr. Secor said that he noticed at different times that some of his colonies would be storing one kind of honey, while others in the same apiary would be storing another kind.

The question arising that different kinds of honey were noticeable in the same comb, was explained by the fact that different flowers would secrete nectar at different times in the same day, and in such cases bees, unlike some human beings, would not lie idle for a favorite job; or, in other words, would not wait for a favorite flower to secrete honey.

The Use of Honey-Boards.

All that were present favored the use of honey-boards, whether working for comb or extracted honey. While poor queens will sometimes lay in the sections, and very little in the brood-chamber, such cases were more frequently the result of not using the honey-board. One of some description was highly indorsed, whether it was queen-excluding or not. Even if not queen-excluding, it would largely prevent this difficulty when working for comb honey. Queen-excluding boards were recommended where extracting was done, and many favored them in any case.

Danger to Bees in Extracting Late.

In reference to this subject, it was seen by a number of reports to have been the cause of heavy winter losses. It was conceded that a reserved store of honey should be preserved where close extracting was practiced. A sufficient number of sealed combs of honey, and of a good quality too, should be put away for this purpose; and after the honey season was over, it

should be placed in the center of the brood-chamber for the winter supply of food for the colony.

A committee was selected for arranging a programme for the next meeting. It is proposed to make that meeting one of the grandest in the history of the Association, and it cannot fail in its aims, having as co-operative workers the most enthusiastic, practical and able apiarists in the country. An announcement of the programme and time of meeting will be made in due time, in the different bee-papers.

Des Moines, Iowa.

FUMIGATION

With Sulphur—Sting-Trowel Theory.

Written for the American Bee Journal
BY DR. C. C. MILLER.

I was a little surprised, on reading page 603, to find that one who appears to be so close an observer as Mr. Pierce, should hold views concerning sulphur, that, according to my experience, are erroneous. He is entirely right in saying what is not generally said (and perhaps it is not generally known), that after worms have obtained a good foothold, it is very difficult to kill them with sulphur.

I have had combs in which the worms have abounded, from those of small size to those of full grown, and after subjecting them to a very dense smoke of sulphur for a long time, the "fat old chaps" seemed to be none the worse for their smoking. Such combs, I think, I would not try to cure with sulphur. The cheapest and easiest way, probably, to dispose of them is to give them to the bees to clean out.

If it is not at a time when it is warm enough for bees to fly, the worms will not make much headway, and as soon as the worms are frozen, that is the last of them. If only a few worms are in a comb, and they are half-grown or larger, it is no very difficult matter to pick them out with a wire nail. But for the worms that are very small—and we never need wait for them to get large—the fumes of burning sulphur are very effective.

My experience has been almost entirely in fumigating comb honey in sections, and for that purpose sulphur may almost be said to be preventive, rather than curative, for the worms should be killed when they are hardly large enough to be seen by the naked eye. If a section be fumigated within two weeks after its removal from the bees, and then two weeks later, I think there need be little anxiety about the worms.

Having used a good many pounds of sulphur during a number of years, I think I may speak with some authority upon the subject, and I trust that Mr. Pierce will take it kindly when I say that I think he is mistaken on two points: first, as to the difficulty of regulating the combustion of sulphur, and second, as to the necessity for burning sulphur in connection with some car-

bonaceous substance. With regard to the latter, I may say that I never burn anything in connection with sulphur, simply lay a lighted match upon the sulphur, and there is no difficulty about the dim, blue blaze continuing as long as a grain of sulphur remains.

As to the difficulty of regulating, especially when a large amount is used, let me give a bit of my experience in a previous year:

I had a lot of sections piled in a room about 15 feet square, and concluded to smoke the whole room. So I lighted 5 pounds of sulphur early enough in the day so that I thought it would all burn before night, and kept occasional watch of it through a window. At dark it was burning apparently the same as when first lighted, and at bedtime the same. Although I thought it entirely safe, I never feel that I can be too careful about fire, so I concluded to sit up with it until it expired. I did not get to bed until after 1 o'clock.

My method of using was this: The sulphur was put in an iron kettle holding about a gallon. A common kettle holding 3 or 4 gallons was partly filled with ashes, and in this the smaller kettle containing the sulphur was placed, and over all a tin cover that did not fit closely. I suppose this cover allowed plenty of air to enter to keep up combustion, but made it burn slower than if entirely uncovered. Previous to covering, a lighted match was laid on the sulphur, and that was all the attention it received except the watching, and no doubt it would have burned just the same if I had been a mile away.

I do not think that roll brimstone would act just the same, but I suspect a part of it mixed with the powdered sulphur might answer. The cost is so little that I have always used it in the powdered form.

Bees Stinging the Capping of Cells.

Referring to "replies" on page 598, allow me to correct Dr. Mason and the Editor. Dr. Mason thinks that the man who believed that the bees did the capping with their stingers, never subscribed for a bee-periodical. Now Doctor, that idea originated with the Rev. W. F. Clarke, and was first promulgated in the bee-papers and his book, unless I am very much mistaken, and your man's believing it, was just so much proof that he had been reading the bee papers. The Doctor may be surprised at the man's belief, but a little thought will convince him that there is nothing surprising in it.

The statement was given in all soberness in the columns of our bee-papers, and coming from a respectable source, why should it not be believed? If I remember rightly, it passed entirely unchallenged for a considerable length of time, and to this day I think not more than three individuals ever denied its truth, and not a single one of our editors ever said he thought it was not true. Why shouldn't the man believe it?

If the Doctor refers, not to the sting-trowel, but to the injection of formic acid after the cell was filled with honey, the case is not different, but still stronger, for I do not remember to

have seen that stated elsewhere than in the bee papers. The last place I remember seeing anything of the kind was in the *British Bee Journal* for Aug. 23, where, on page 409, Dr. A. von Planta quotes approvingly Dr. Muellenhoff in No. 6 of the *Eichstaedt Bienenzeitung*, where he says, on page 61, "When the cell is nearly filled, and the honey is not intended for immediate consumption, the bees add a drop of the secretion of their poison gland." Now we ought to know positively whether this is true or false. Somewhere, lately, Prof. Cook has called it in question—I mean aside from his answer in the present case—but I do not remember whether he says positively it is false, or simply that he does not believe it.

The Editor is in error, I think, in attributing the sting-acid theory to Rev. W. F. Clarke. I think it came from a number of sources, and it might be difficult now to determine who first started it. Mr. Clarke is "sponsor" for the "sting-trowel" theory—at least I do not know that any one else in this country has said he knew it was true, unless it be Dr. Mason's friend, although I have been told that the idea first had birth in France. Mr. Clarke, however, says he became satisfied of its truth as the result of observations. I seriously question whether Mr. Clarke ever made any observations that warranted him in giving utterance to the sting-trowel theory as a positively ascertained fact.

Marengo, Ills.

[If the editor was in error in the statement made on page 598 in answer to Query 575, our friend, the Rev. W. F. Clarke, will be very ready to show it. Editors are not always right, especially when they try to find "fathers" for waifs, or the offspring of fertile brains.—ED.]

CALIFORNIA.

Honey Production on the Pacific Coast.

Written for the Riverside Press
BY FRED. L. ALLES.

Throughout Southern California, for a distance of 300 miles, the Coast Range of Mountains is spotted with little canyons upon whose sides may be found a hundred varieties of wild flowers. Here and there rises an occasional live-oak or a clump of low growing pines. The body of this living carpet, covering the acclivity of the Temescal range, the San Jacinto mountains and the lower edges of the Sierra Madres, is composed of all the colors of the rainbow, and varies with the months and seasons, while heaps of gray old boulders, jutting clumps of sandstone and granite, and masses of chaparral, grease-wood and mesquite, with their neutral tints, give the eye relief from the too brilliant color surrounding them.

These canyons are the sources of the water supply for the valley vineyards

and orchards, and are the homes of the bee-masters of a land literally "flowing with honey."

Bee-farming in California bears little resemblance to the same industry elsewhere, on account of the novel difference in the seasons. Instead of making provision for long and cold winters, the bees are able here to gather nectar from New Year's Day to Christmas, and the bee-master takes out honey during eight months of the year. During January, February and March the orange and lemon trees of the valley orchards, and the wild acacia and eucalyptus (Australian blue-gum) are all in bloom, and furnish a fair quantity of nectar, but the larger part of this is consumed by the bees, and it is not the custom to take this from the hives. The so-called "orange-blossom honey" sometimes seen on the market, is not made from orange-blossom nectar at all, and is so labeled with intent to deceive.

Early in February the native sheep-grass, alfilerilla, furnishes an abundance of bloom, which makes a good honey of amber color, but not so good as that made from black sage, which blossoms later in the same month. This sage grows in the lowest valleys, and on the side of the mountain ranges in all parts of California, and is the best plant for bees, because its nectar gives them heart and vitality at a season when they most need it. The honey from it is of a fine color and strong body.

Early in June appears the best of all honey-producing plants—the white and silver sages. No flower in the world produces a clearer white, pure nectar than California silver sage. Eastern white clover and basswood (American linden) are splendid honey-producers, but both are inferior to the silver sage in making an article of delicious flavor, good body, and clear as pure water. These sages bloom usually during the entire month of June, and then comes the wild buckwheat, which has a blossom resembling the cultivated plant, and furnishes a honey of good quality and rich, amber color.

Early in July the wild alfalfa appears, and soon after the wild sumac opens its large clusters of creamy-white flowers, and both are exceedingly rich in a delicious nectar. The wild mignonette is in bloom during the same period, and the bees never seem to tire of hovering over its perfumed flowers during their short period of bloom.

The golden-rod throws up its brilliant yellow flower spikes in July and August, and continues in blossom until Christmas. It is similar to the plant of the same name growing in the Eastern States, and is one of the most valuable of California's long list of honey-producing plants.

This list includes nearly 200 plants, but many of them bloom for only a short period, every fortnight showing a new combination of colors on the hill-sides. The nectar gathered from all the different flowers is not separated by the bee-master. The aim is only to keep the light, silver-sage honey apart from that of darker color gathered earlier in the season from the alfilerilla

and black sage, and afterward again from the amber honey of the wild buckwheat, sumac and golden-rod.

The process of preventing the mixing of the honey by the bees is very simple, the bee-master watching the season of the different flavors, and taking the honey from the combs as the season progresses.

California liquid honey, as it leaves the bee-master, is always pure. Sugar, glucose, and all other possible adulterations cost more per pound than the pure honey is worth on the ranch.

TIERING-UP.

Results of the Season—Doubling Up Swarms.

Written for the American Bee Journal

BY H. C. GIFFORD.

I will now give a statement of my summer's work and the results. About July 1 my 20 colonies of bees had not 5 pounds of honey to the hive. I have practiced the tiering-up plan, some of them 3 tiers high, making 81 one-pound sections per hive. I have taken off 1,350 pounds of honey, and have about 450 or 500 pounds yet to take off, or about 1,800 pounds from 20 colonies, besides increasing them to 27 colonies. At the present time all are in good condition, and the hives well filled with honey. I have doubled up some swarms, returned some second swarms, and have had no trouble with their coming out the second time.

My bees never did as well as they have since July 5. I have read very many big stories in the BEE JOURNAL, and some of them I rather doubted, so I need not be surprised if some doubt what I may say about one of my new swarms; but it is true, and I think it has been of great benefit to me, for I intend to practice it next summer, if I live.

Experience with Two Swarms.

About Aug. 5, a large swarm came out, and settled on the grape-vines near the hives. I hived them, but when about three-fourths of them were in the hive, another swarm issued, and came right to the hive where I was working. I let it stay until about one-half of them had settled in my new hive, which I immediately carried to a stand; the rest flew around awhile, and then went back to their old home.

It seemed that all the bees could not get into the hive, so I put 48 sections on top, and they all went in. After awhile I put on 24 more sections, and on Sept. 15, I took off the three tiers, which weighed 78 pounds, and the hive is now full from top to bottom, which cannot be less than 60 pounds, and perhaps 80. This was all stored in about 40 days.

The above statements are facts, and I intend after this to put two swarms together whenever I can. One strong colony is worth three small ones, and is not so much trouble or expense.

My neighbors call me an "expert" in the bee-business, but this summer's

experience teaches me that I am only in my A B C's. What I have learned I have gotten from the AMERICAN BEE JOURNAL. My neighbors have no honey to speak of, except Wm. Johnson, who works by the same method that I do. I sell my honey at the stores, at 18 cents per pound, and I tell them to sell it at 20 cents. I will have no trouble to sell my crop, although some who have a little honey bring it in and sell it for what they can get, which ranges from 12½ to 16 cents per pound.

I send my membership fee for the "Union." It would look selfish to me not to belong to the Bee-Keepers' Union, when I have received so much benefit from the experience of those who do belong to it; but I have such good luck with wintering my bees on the summer stands, that I shall not try the cellar yet. I box up the hives and pack them with straw, leaving an opening in front 6 inches long and 3 inches high, which I can close up at any time. I pack the caps with straw, and cover them well on top to keep them dry.

Morris, Ills., Sept. 24, 1888.

CLUBBING LIST.

We Club the American Bee Journal for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	Club

Can You Do Anything that will do more to advance and defend the pursuit of bee-keeping, than to aid its Weekly Exponent and Defender? The AMERICAN BEE JOURNAL is the pioneer bee-paper of America, and is fully entitled to the active support of every progressive apiarist, for it works constantly and faithfully for the best interests of the pursuit. We therefore specially request all our readers to use their influence to double our subscription list during the coming autumn. Reader, will you please send us a new subscription with your renewal or before that time? A good weekly at one dollar a year is surely cheap enough to command patronage.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, \$1.00 per 100, or \$8.50 per 1,000.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Pure Phenol for Foul Brood.—Calvert's No. 1 phenol, mentioned in Cheshire's pamphlet on pages 16 and 17, can be procured at this office at 25 cents per ounce. Not being available, it must be sent by express.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 25
 " 200 colonies (420 pages)..... 1 50

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

Hastings' Perfection Feeder.—This excellent Feeder will hold 2 quarts and the letting down of the feed is regulated by a thumb-screw. The cap screws securely on. It is easy to regulate—either a spoonful or a quart—and that amount can be given in an hour or a day, as desired. By it the food can be given where it is most needed—just over the cluster. Not a drop need be lost, and no robber bees can get at it. A single one can be had for 40 cents, or a dozen for \$3.50, and it can be obtained at this office. Postage 10 cents extra.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2 00	3 00	3 50
1,000 Labels.....	3 00	4 00	5 00

Samples mailed free, upon application.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, Ills., is published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$3.75 per peck; 30 cents per lb. *Sweet, or Melilot, Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Cork for Winter Packing.—Its advantages are that it never becomes *musty*, and it is *odorless*. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Exchange.—We will accept Honey and Beeswax in exchange for Bee-Keepers' Supplies in any quantity. Those desiring to make a trade are invited to correspond with us, stating quantity, quality, and price, and the goods they want in exchange.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 10 cents per pound for bag and postage.

Honey and Beeswax Market.

CHICAGO.

HONEY.—New crop arriving slowly, but demand limited. White clover comb, 17@18c. Extracted, 7@9c.

BEESWAX.—23½c. THURBER, WHYLAND & CO. Sep. 17.

NEW YORK.

HONEY.—We quote: Fancy white 1-lbs., 17@18c.; 2-lbs., 13@14c. Fair white 1-lba., 15@16c.; 2-lbs., 12c. Buckwheat 1-lba., 11@12c.; 2-lbs., 10@11c. White extracted, 7½@8½c.; buckwheat, 5½@6½c.; California extracted, white sage, 7½@7¾c.; amber, 7¼@7½c. Demand good and prices firm. New comb honey in arriving quite freely.

BEESWAX.—23@23½c. HILDRETH BROS. & SEGELKEN, 28 & 30 W. Broadway, near Duane St. Sep. 26.

SAN FRANCISCO.

HONEY.—White 1-lb. sections, 11@12½c.; 2-lbs., 12½@1 c.; amber, 8@10c. Extracted, white, 5¼@6c.; light amber, 5¼@5½c.; amber and candied, 4¼@5c. Receipts light and market firm for best qualities.

BEESWAX.—Dull at 19½@22½c. O. B. SMITH & CO., 423 Front St. Sep. 22.

DETROIT.

HONEY.—Best white comb, 17@18c.; dark, 16c.—Extracted, 8@10c. Market bare of all kinds.

BEESWAX.—21@22c. M. H. HUNT, Bell Branch, Mich. Sep. 24.

CINCINNATI.

HONEY.—We quote extracted at 4¼@8c. per lb. Comb honey, 12@16c. Demand slow.

BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival. Sep. 18. C. F. MUTH & SON, Freeman & Central Av.

KANSAS CITY.

HONEY.—Choice 1-lb. sections, 18c.; dark 1-lba., 14c.; 2-lbs., 16c.; dark, 13c. White extracted in 60-lb. cans, 8c.; amber, 7c.; in barrels and kegs, 5@8c. Demand good, prices firm, and stock light.

BEESWAX.—None in market. HAMBLIN & BEARSS, 514 Walnut St. Aug. 29.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 17½@18c.; 2-lbs., 14@15c. Fair 1-lbs., 14½@15½c.; 2-lbs., 11@12c. Extracted, fancy white clover, 7¼@7½c. California white in 60-lb. cans, 8c.; light amber, in same cans, 7¼c.; amber, 7¼c. Buckwheat in kegs and barrels, 5½@6. Cuban, in barrels and ½-barrels, 65c. per gallon.

BEESWAX.—21c. F. G. STROLMAYER & CO., 122 Water St. Sep. 26.

BOSTON.

HONEY.—We quote New 1-lb. sections, 18@20c.; 2-lbs., 14@16c. New extracted, 8@10c.

BEESWAX.—25 cts. per lb. BLAKE & RIPLEY, 57 Chatam Street. Aug. 24.

KANSAS CITY.

HONEY.—We quote: New white 1-lba., 18c.; light 1-lbs., 16c. California white 1-lbs., 18c.; light 1-lba., 16c.; white 2-lbs., 16c.; light 2-lbs., 14c. Extracted, white, 8c.; amber, 7c.

BEESWAX.—18@20c. CLEMONS, CLOON & CO., cor 4th & Walnut. Sep. 5.

ST. LOUIS.

HONEY.—We quote: Extracted, 4½@5½c.; 1½ in cans, 8@9c. White clover comb, 14@15c. Market is steady and receipts light.

BEESWAX.—21c. for prime. D. G. TUTT & CO., Commercial St. Sep. 6.

MILWAUKEE.

HONEY.—New white 1-lb. sections 18c., and very fine, 20c.; 1-lbs., 15@18c.; old 2 and 3 lbs., not salable, 12½@14c.; dark 1-lbs., old or new, 12@13c. Extracted, new white in kegs and ½-barrels, 8@9c.; old, in same packages, 7@8c. In tin, 8@9c.; dark in barrels or ½-barrels, 6@6½c. Arrivals of new crop small; demand not urgent, and only very moderate trade.

BEESWAX.—22@25c. A. V. BISHOP, 142 W. Water St. Aug. 31.

Conventions.—The time for holding Bee-Keepers' Conventions has now arrived, and we cannot give any better advice than this: Let each one attend who can do so, and take part in making these meetings interesting and instructive. If you have not already obtained the "Bee-Keeper's Convention Hand-Book," do so at once to post yourself up on how to conduct such meetings correctly. It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for Discussion—List of Premiums for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents. We will club this book and the AMERICAN BEE JOURNAL for one year for \$1.25. It also contains a lot of blank leaves on which you can note important matters as they come up. Do not fail to send for a copy of it.

Simmins' Non-Swarming System.—We have a few of these books left, and we will club them with the AMERICAN BEE JOURNAL for one year, both postpaid, for \$1.25. The subscription to the BEE JOURNAL can be for next year, this year, or may begin anew at any time.

We Have some copies of the old edition of Cook's Manual left, which we will sell at the old price, \$1.25. The price of the new edition is \$1.50 per copy; a notice of which may be found on page 579.

Queens.—We can mail a Tested Italian Queen (bred for the best results as well as for beauty) for \$2.00; Untested Queens \$1.00 each, or \$9.00 per dozen. Orders solicited.

The Latest catalogue for this year is that of T. S. Sanford, New Castle, Pa. It has 4 pages, and includes bees and supplies.

Dr. Miller's Book, "A Year Among the Bees," and the AMERICAN BEE JOURNAL for one year—we send both for \$1.50.

New Subscribers can obtain the full numbers for 1887 and 1888, for \$1.75, while there are any sets of 1887 left.

Advertisements.

BEEES to Give Away.—75 Colonies of hybrid Bees in Langstroth hives. Plenty of honey for winter. Will sell the lot for what the hives and honey are worth. Address,

I. W. ROLLINS, Elgin, Wabasha Co., Minn.

CONVENTION BUZZINGS

The Earnest Man of the Convention was the son of friend A. I. Root.

The "Bees and Honey" Building on the Centennial grounds was a great attraction on Friday.

The Next Session of the International is to be held in Brantford, Ont., and Mr. Holtermann, editor of the *Honey Producer* of that place, is the Secretary.

Father Langstroth has taken a severe cold, and is again unable to leave home. For that reason his promised essay for the North American Convention was among the missing.

The New Constitution of the International Society was adopted on Thursday evening, as laid over for consideration at the last meeting. We hope that it will be a means of increasing its usefulness.

Mr. J. Y. Detwiler, from Florida, had some very fine samples of mangrove honey at the convention. It was fully equal to white clover honey, and we do not wonder why he objects to its being quoted in the honey markets as "Southern honey," and priced by the gallon. It should be quoted separately as mangrove extracted honey, and priced by the pound, like other kinds of equal quality and value. Mr. Detwiler was not located in the yellow fever district, but he found it difficult to leave the "stricken State." He will spend a few months in Toledo, O., where he formerly resided. He is an enthusiastic apiarist.

The North American Convention at Columbus, O., was a small but a very enthusiastic annual gathering of the bee-keepers of the Continent. Some seven States were represented, and our friend Holtermann, of Brantford, Ont., represented the Province of Ontario, Canada. It convened last Wednesday morning, and held six sessions. Then, as it was generally desired by those present to visit the Centennial grounds to view the attractions there presented, including the bee and honey show, the last day was spent on those grounds in social and fraternal intercourse, while examining and commenting upon the exhibits of bees, honey, and apiarian supplies.

Some of the principal exhibitors were A. I. Root, Dr. A. B. Mason, Dr. H. Besse, Dr. G. L. Tiuker, Mr. McPherson, etc.

The honey exhibit was very fine, and conferred credit upon all the exhibitors, many of whose names we cannot now recall.

Mr. Root's exhibit of apiarian implements was large and varied, covering almost everything used advantageously in apiculture. In the "Power Hall" Mr. Root had his machinery running which makes one-piece sections complete, from the wood in the rough. The saws make such fine work that the sections looked as though they had been sand-papered. It is a triumph in the art of making sections to have them beautiful as well as useful. To say that in workmanship they were fully equal to those four-piece sections made by Dr. G. L. Tinker, is no small praise, for the Doctor's work has heretofore excelled almost everything presented in that line.

The magnificent coliseum building on the grounds is a marvel. It is said to hold ten thousand persons, and seat about six thousand. The speaker can be distinctly heard anywhere in the hall, so perfect are the acoustics thereof. It is about 250 feet across, and 100 feet in height.

Our visiting company consisting of Mr. A. I. Root, Dr. Miller, Mr. McLain, Dr. A. B. Mason and ourself. We prevailed upon Dr. Miller to play the organ and sing several pieces, accompanied by the rest of the party. We went to the further side of the hall, and we could hear the words distinctly—but we cannot enumerate all the things which were very attractive to us.

Mr. Ernest Root, son of A. I. Root, an estimable young man, was accompanied by his charming and affable wife. He had with him his instrument for taking instantaneous photographic views, and it was well employed. He "took" the members of the convention, the bee and honey building on the grounds, and several views of the exhibits.

Lady Members to the number of a dozen were in attendance at the Convention at Columbus. We will give the list next week. We regret to say that Mrs. L. Harrison was absent on account of poor health.

The Horticultural Society was in session at Columbus at the same time, and in the same building as the Bee-Convention, and we record the fact with pleasure that both societies worked very harmoniously. Mr. Devol, Secretary of the Ohio State Horticultural Society, was introduced to the Bee-keepers' Convention by the Editor of the AMERICAN BEE JOURNAL, and in behalf of the horticulturists, he extended an invitation to all the bee-keepers to attend a meeting of the Horticultural Society, which was then in session in the Senate Chamber. The Convention received Mr. Devol with much applause, and by vote thanked the horticulturists, and accepted their fraternal invitation.

Upon entering the Senate Chamber we found the horticulturists engaged in a discussion concerning the fructification of fruit-bloom by insects. The bee-men were invited to take part, and they did so. The result is that it was generally agreed that the bees and other insects performed very valuable work upon the flowers, by fertilizing them, and thus increasing the fruit.

Several of the horticulturists mentioned the fact that the bees were often heard "roaring" over the bloom of the strawberries. Upon being asked if there was any noticeable difference between their "roaring" over the Crescent and Wilson varieties, it was answered in the negative. Some people had "notions" about their being a difference, but none were discovered upon close examination.

We are glad to note a growing friendliness among fruit-growers towards their special friends—the bees. We shall do all we can to foster and encourage such a desirable result.

Eight States were represented at the Inter-National Convention. The following are the officers elected for the ensuing year:

PRESIDENT—Dr. A. B. Mason, Abundale, O.
VICE-PRESIDENTS—Thos. G. Newman, Chicago, Ill.
Prof. G. W. Webster, Lake Helen, Fla.
Joseph Nyaewander, Des Moines, Iowa.
R. L. Taylor, Lapeer, Mich.
O. L. Herahiser, Jamestown, N. Y.
Martin Emigh, Holbrook, Ont.
Frank A. Eaton, Bluffton, Ohio.
F. Minnick, Bessemer, Wis.

SECRETARY—R. F. Holtermann, Brantford, Ont.
TREASURER—Dr. C. C. Miller, Marengo, Ills.

Singing was made a feature of the convention in Columbus, O. Dr. Miller is an organist, and had composed the music for two bee-keepers' songs, which were written by that poet-laureate of bee-men—Mr. Eugene Secor. Mr. A. I. Root, of Medina, O., had them printed and freely scattered on the convention. The result was some lively singing to introduce the work of each session. We think that no vote of thanks was offered to these gentlemen—wholly due to thoughtlessness, not to ingratitude—and we now propose such a hearty vote by the larger convention made up of absentees. That all may vote understandingly, we hope to publish both the music and words of one song in our next issue.

GLEAMS OF NEWS.

Uses of Honey.—In the *Orange Judd Farmer* we find the following interesting item on the uses to which honey is now frequently put. The superior value of honey in the "sweet manufactures" of the day is just beginning to be appreciated; and when consumers once realize its excellence as a substitute for sugar, and its comparative inexpensiveness, honey will then occupy its proper position—not only in medicine and the culinary art, where its use would bring health and happiness to all, but also in the manufacture of luxurious confections. The item referred to reads thus:

In all ages honey has been used for many purposes. The Ancient Britons used it to make mead, and this drink continued to be much used hundreds of years after them. When malt liquors became popular, and when sugar was introduced, the uses of honey went down for a time, but of late years it has gone up again with a bound. Honey is largely used in the manufacture of honey chocolate creams and honey chocolate tablets. There is a delicious taste of the honey in these articles, but they are so judiciously blended with the other materials that they are not too sweet. Honey is also now largely used by the confectioners in the place of sugar in many kinds of lozenges, cough drops and other sweetmeats. Glycerine and honey jujubes for the throat; corn and honey food; herbal tablets, etc., are only a few of the many things which might be mentioned. The toilet is not left out, as it is used in soap and dentifrice. Doctors use it very largely for many purposes, and many doctors are amongst our most successful bee-keepers, and thus the purity of their medicines may be guaranteed. There are many persons who are not allowed to use sugar at all; to these honey comes as a boon. It is a curious thing to note that even the angler now uses honey, and natural honey fish bait is put down in the list of necessities for the modern complete angler. What would old Isaac Walton say to this?

Prof. N. W. McLain, of the Government Experiment Station at Hinsdale, Ill., has been appointed superintendent of the Apianian Exhibit of the Paris Exposition to be held in April, 1889, and he is now making preparations to gather together the largest and best exhibit of bees, honey, apianian supplies, implements, and their processes of manufacture, that has ever been made. Let us all help him to make up the exhibit, and thus show the world what we can do.

Winnebago County, Iowa, held its first fair the last week of September, and it was a success, the display in every department exceeding all expectations. Mr. Eugene Secor—one of our valued correspondents—is the President of the Agricultural Society, which fact of itself should have insured a successful outcome of the fair. Mr. Secor and W. W. Wright made a fine display of honey, which attracted a good deal of attention, and Mrs. Secor made a good showing of canned fruit.

Mr. R. McKnight, of Owen Sound, Ont., on Sept. 29, 1888, writes as follows concerning the exhibit of honey which he made at the Toronto Industrial Exhibition:

I send you a photograph of my honey exhibit as shown at the Industrial Exhibition at Toronto recently. It took the special prize of \$50 for its general "get up," apart from the quality and quantity of the honey.

My aggregate prizes on this exhibit amounted to \$87—the most taken for honey alone, by any one here, up till the present time.

The photograph shows the end and one side of the exhibit. The extent of space it covers is 16x4 feet, rising to 4½ feet from the stage at the back end, with a uniform ascent from front to rear.

The photograph referred to by Mr. McKnight is an excellent one, showing a very creditable and finely-arranged exhibit of honey, both comb and extracted. Among the numerous nicely-labeled glass cans and jars of honey are placed a number of pots of beautiful flowers, which adds much to the attractiveness of the display. Such exhibits of the products of the apiary will do a great deal toward familiarizing the general public with the results of the labors of the bees and their keepers, and also bring to the attention of interested spectators this unexcelled food product—honey—in its various forms. Thus will the apiarists not only develop a good home market for their production, but at the same time they will contribute no little to the health and happiness of others.

A Young but promising apiarist of Virginia has passed away. We refer to Mr. Samuel B. Wood, eldest son of Mr. Daniel T. Wood, aged 23 years. He died at his father's residence after a lingering illness of consumption, on Monday, Sept. 9, 1888.

When at College his health became impaired, and three years ago he relinquished his studies, left College, and commenced to keep bees. He was very successful, and would have become a distinguished apiarist in time. The *Winchester Times* says:

He was an exemplary young man, and had won the esteem and admiration of many friends by his Christian demeanor and attractive manners. His death is deplored by all who knew him. To the sorely bereaved parents and family we tender our sympathies.

He was buried on Sept. 12, from his father's residence at Mount Hebron, three miles south of Jordan's Springs. The funeral procession was a very long one, showing that he had many friends.

Mr. T. B. Blow, one of the most progressive apiarists of England, is now in America, on a visit. He sailed on Sept. 19 from Liverpool to New York, in the steamship "City of Rome." He intends to visit some of our principal bee-keepers. As Mr. Blow is well acquainted with the portions of Europe and Asia from which we obtain the Eastern races of bees, his company will be very entertaining.

Farmer De Forest's Birthday Bees.—Cyrus De Forest owns a farm in North Wilton, on the Danbury branch of the Housatonic railway. On his birthday every May a swarm of bees come to his place and take refuge between the floor and the ceiling of his house. All efforts to keep them out have failed, and it has not yet been discovered how they gain an entrance. At the end of the season the floor is taken up and the honey is gathered. Last year Mr. De Forest got 94 pounds, and this year his crop was 76 pounds. The remarkable facts of the case are the regularity of the appearance of the bees. Last year was the one exception in several years, they coming one day earlier than usual. The bees are killed every year, but a swarm takes their place the next season.

A correspondent sends us the above for publication. It is evidently one of the "yarns" now going the rounds. It is very unlikely they should come "every May," on his birthday, even if it did once happen.

The Toronto Honey Exhibit.

In the *Canadian Honey Producer* for October is given a list of the exhibitors and their exhibits, with the amounts secured in premiums, besides diplomas. From that list we glean the following, the judges being J. F. Dunn, Allen Pringle and W. McEvoy:

For various exhibits R. McKnight, of Owen Sound, secured \$37 in premiums; R. F. Holtermann, of Brantford, \$42.50; R. H. Smith, of Bracebridge, \$30.50; E. L. Gould & Co., of Brantford, \$23; Will Ellis, of St. Davids, \$8; Mrs. John Wilson, \$2; and J. Spence, of Toronto, a silver medal. Mr. R. McKnight received, in addition to the premiums, \$50 "for the most tasty, attractive and neatly-arranged exhibit of honey in the apianian department, all the honey the production of the exhibitor." Half of the prize was given by the Ontario Bee-Keepers' Association. Although the season had proved disastrous to the bee-keeper, the exhibit on the whole was very creditable, indeed.

The Rhode Island Bee and Honey Exhibit

is thus mentioned by the *Providence Journal* of Sept. 26:

There are six entries, the largest of which is by Samuel Cushman, of Pawtucket. He has six hives of bees, showing strong colonies of the best working strains of Italian, Syrian, Carniolans and natives. He has also an exhibit of hives, winter hives, comb honey hives, and hives for extracting the honey. He has also a large cage showing a swarm clustered in their natural state.

In this exhibit there are 1,200 pounds of the best Vermont comb honey, and 200 pounds of extracted honey, extracted by centrifugal force, with an extractor on view.

A. C. Miller, of Drownville, ex-Secretary of the Rhode Island Bee-Keepers' Association, has an exhibition of comb honey, extracted honey, honey vinegar, and observatory hive of bees, light comb foundation, a machine for placing the foundation in the supers, and specimen hives for the production of comb honey.

Mrs. S. M. Lackey, of Providence, shows observatory hives, samples of wax, comb honey, extracted honey, and an extractor.

Sam Warren Lewis shows 200 pounds of extracted honey in glass, 10 pounds of comb honey, and the largest display of beeswax, one cake of which was made 31 years ago.

S. A. Dexter shows an observatory hive, showing the production of comb honey.

QUERIES REPLIES.

Breeding so as to Eradicate the Swarming Propensity.

Written for the American Bee Journal

Query 582.—Can a strain of bees be improved by careful breeding, which will have bred out the propensity to swarm?—Ohio.

I doubt it.—EUGENE SECOR.

We think not.—DADANT & SON.

I think so, most assuredly.—A. J. COOK.

I think so, to some extent.—J. M. HAMBAUGH.

Possibly, but I think that it would be a long job.—C. C. MILLER.

I do not think that the swarming propensity can ever be bred out.—J. P. H. BROWN.

It is possible to improve bees by careful breeding.—H. D. CUTTING.

I think so, but it would take a very long time.—R. L. TAYLOR.

I do not know; but I would like such bees if as good in other respects.—C. H. DIBBERN.

Oh, yes. You can breed toward almost any desired mental or physical standard, but practically I think you had not better spend much of your time trying to breed out the propensity to swarm.—JAMES HEDDON.

By careful selection of breeding-stock, the propensity to swarm can be diminished.—M. MAHIN.

They may, but I think it is doubtful; hens have been bred that lose the propensity to set.—MRS. L. HARRISON.

No doubt of it. Chas. Dadant & Son have nearly accomplished it, aided by their large hives.—J. M. SHUCK.

No one can tell. Theoretically it can, but I think that it would cause injury to so breed. See *Glennings* of 1883, for an article on that subject.—J. E. POND.

I live in Ohio, but I do not know of any such bees in the State, and I do not believe that there ever will be any such here, or elsewhere, for that matter.—A. B. MASON.

No. I have had colonies of bees that did not swarm for four years, but after carefully experimenting without avail, I adhered to my convictions, that it is useless to try to work to change natural laws.—P. L. VIALON.

I think not. If the desire to swarm under favorable conditions could be bred out of bees, it could only be done at a sacrifice of valuable qualities. I think the only way to breed out of bees the desire to fulfill this mission in the earth, would be to breed down-

ward until no energy was left. I will suggest that if you can breed a strain of bees that always have *young queens*, healthy and strong, you will have a non-swarving strain. But if the queens are to get old, like all other living creatures, you will make a failure.—G. W. DEMAREE.

To the first half of the question, yes; to the other part, I will say that when working for comb honey, you will be apt to get swarms after "careful breeding" for a thousand years.—G. M. DOOLITTLE.

Careful selection, and breeding may very much improve bees, but swarming is their method of increase, and to "breed out the propensity to swarm" is more than one might hope for, or expect.—THE EDITOR.

The Annual Rent of an Apiary.

Written for the American Bee Journal

Query 583.—What annual rent could be profitably paid for an out-apiary of 100 colonies?—Nebraska.

All depends upon circumstances, and it is very hard to answer.—P. L. VIALON.

Last year and this, it would be the widow's mite.—MRS. L. HARRISON.

So much depends; that I will not try to shed any light.—JAMES HEDDON.

It would depend upon the location and the honey-crop prospects.—J. P. H. BROWN.

It is hard to say. This year, a "goose-egg," as the College boys say.—A. J. COOK.

Ten to fifteen dollars ought to pay the ground rent.—C. H. DIBBERN.

In this locality not a cent, unless the seasons change.—H. D. CUTTING.

Much depends. Lines should be very nicely drawn to decide.—J. M. HAMBAUGH.

I do not know. It will depend wholly on the locality and season, or more particularly on the crop of honey gathered.—J. E. POND.

So much depends upon varying circumstances that I cannot give an opinion.—M. MAHIN.

Annual interest at the current rates upon the cash value of the bees and hives.—J. M. SHUCK.

That depends upon so many minor considerations that I will not attempt a guess.—EUGENE SECOR.

No one could tell without knowing the average yield of the field, and other circumstances.—R. L. TAYLOR.

That depends upon the locality and season. Last year and this, in most localities, any rent would have been

too much. Last year Dr. Miller's surplus honey cost him over \$2.00 a pound.—A. B. MASON.

It depends upon the location. In a first-class place, say 1,500 pounds of extracted honey, or its equivalent. We would advise the renter, however, to give nothing but a *share of the crop*.—DADANT & SON.

I guess that would depend upon the season. Such seasons as the past two have been, give little margin to the apiarist who has no rent to pay.—G. M. DOOLITTLE.

In former years I would have answered that an annual rent equal to 20 per cent. on the investment could be safely and profitably paid; but with the experience of the last three years freshly in my mind, a man would have to pay me a *bonus* equal to 25 per cent. of his investment, to take his bees off of his hands for one year.—G. W. DEMAREE.

So much depends upon the locality, the pasturage near it, the kind of season, that it would be difficult to arrive at a correct way to answer the question. Ten dollars ought to pay the rent in an ordinary season, perhaps.—THE EDITOR.

Convention Notices.

The Pan-Handle Bee-Keepers' Association will hold its next meeting in the K. of P. Hall on Main St., between 11th & 12th Streets, in Wheeling, W. Va., on Nov. 21 and 22, 1888. All bee keepers are cordially invited. W. L. KINSEY, Sec.

The next meeting of the Union Bee-Keepers' Association will be held at Clayton, Ills., on Tuesday and Wednesday, Oct. 16 and 17, 1888, in the Town Hall at 10:30 a.m. The Park Hotel will charge \$1.00 per day; the restaurants 25 cts. per meal. We expect Messrs Dadant, Hambaugh, Camm and other prominent bee-keepers to be present. S. N. BLACK, Pres.

Can You Do Anything that will do more to advance and defend the pursuit of bee-keeping, than to aid its Weekly Exponent and Defender? The AMERICAN BEE JOURNAL is the pioneer bee-paper of America, and is fully entitled to the active support of every progressive apiarist, for it works constantly and faithfully for the best interests of the pursuit. We therefore specially request all our readers to use their influence to double our subscription list during the coming autumn. Reader, will you please send us a new subscription with your renewal or before that time? A good weekly at one dollar a year is surely cheap enough to command patronage.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

CORRESPONDENCE.

DO BEES HEAR?

Have Bees the Sense of Hearing? —Experiments.

Written for the American Bee Journal
BY S. A. SHUCK.

On page 567, I find this sentence: "Many seem to think that bees have the sense of hearing, but so far all of my experiments go to prove to the contrary."

I am very sorry that this statement comes from one whose teachings are so plain and practical, and his logical deductions so nearly without a fault, that it gives me a feeling of regret to believe that he is in error; and notwithstanding the fact that it makes no difference in dollars and cents, to scientific apiculture, whether bees hear or not; if they possess the sense of hearing, it must appear that any one of extensive experience with bees should have discovered this fact.

I am confident that bees possess the sense of hearing equal to that of sight, scent or taste; and if I fail to give satisfactory evidence in support of my position, will some one please to point out my error?

In July, 1882, I attached one end of a silken thread to the waist of a very active virgin queen. The other end of the thread was attached to a long pole, and this pole was held up in the apiary when the drones were flying freely. This queen flew as far as the thread would allow her to fly, and continued her efforts for some considerable time. Then after a short rest, renewed her efforts. This flying and resting by turns, was repeated many times. As long as she continued to fly, the drones pursued here in great numbers, but the instant she stopped to rest, the drones dashed away as if suddenly frightened, appearing again as soon as the queen put forth an effort to fly. Does it not appear that it was the sound produced by the queen's wings that attracted the drones?

Some four or six weeks ago I shook a large swarm from my hiving-box on the ground in front of a hive prepared for them. A few bees remained in the box, and instantly they commenced the "call" to their comrades that were scrambling in every direction to gain a footing. I placed the box under a large Russian sunflower, some 3 feet from the entrance of the hive. I saw the queen take wing from the bees on the ground, and not seeing her return to them, as soon as the

bees got started into the hive, I took up the box and found the queen in it.

I do not think that this box, with perhaps a hundred bees in it, smelled more of bees than the 6 or 8 pounds of bees on the ground; and not only this, but it is evident that this queen was attracted more by the humming noise of the few bees in the box, than she was by the scent or sight of the scrambling mass she deserted.

Just as I had shaken a swarm from this box in front of a hive, I discovered another swarm issuing from a hive only about 20 feet distant. The queen of the issuing swarm could not fly, so I knew that the bees would very soon return. I quickly gathered up some dry grass that had been cut from among the hives, and piled it in front, on the two sides and top of the hive the bees were entering, thus covering up the bees that I had just shaken from the box. In a few moments the bees in the air began to return, and just as I had anticipated, commenced tumbling down on this pile of grass, and started right down through it to the loud humming beneath. I picked up a small stick and commenced whipping this pile of grass. This put the bees to flight, and in another moment they were tumbling down at the entrance of their own hive.

The bees under the grass were entering the same hive they had issued from only 10 or 15 minutes before. No change had taken place in the surroundings except the bunch of grass over the hive. There were over a hundred hives in the apiary. The ground is level, and the hives are in rows about 11 feet apart, and 9 feet apart in the rows. One hive faces to the east, and the next one to the south, and I see no excuse whatever, for those bees trying to crawl down through this bunch of grass, except the loud humming noise beneath it.

I have given three examples, one each of drone, queen and worker-bees being attracted by sound. These three instances are only a few of many very similar instances that have come under my observation during the past twelve years. I will now offer some experiments that I am confident will enable any one to prove to his entire satisfaction that bees do hear.

Take a comb with adhering bees from any hive of gentle bees. Be careful not to excite or disturb the bees. Hold the comb before you. Now sing, whistle, hollow or blow a horn, so as to make any kind of a prolonged tone of a musical nature, and of a reasonable degree of loudness, and nearly every bee on the comb will stop to listen. The effect is so striking that no one can doubt it. Do not be afraid of being stung, unless you blow your

breath upon them. When the noise ceases, they resume business as if nothing had taken place. I have tried these experiments many times during the past ten years, and I know that the bees will listen while you sing.

I have observed the same effect from the piping of virgin queens, when nearly all the bees of a fair sized colony would listen, while the queen was piping. Please to test this matter, and report through the BEE JOURNAL.

Liverpool, Ills.

LEGISLATION.

A Canadian's Views About Nectar being Public Property.

Written for the American Bee Journal
BY DR. C. C. MILLER.

FRIEND NEWMAN:—I enclose a private letter from one of the prominent bee-keepers of Canada, and I think that I betray no confidence in allowing you to print that part of it which is of public interest, and shows some careful thinking. I am glad to know that I am not so entirely alone as I formerly considered myself, in thinking that *something* ought to be done. After reading the article of Mr. McNeill, on page 586, and the comments thereon, I am strongly impressed that bee-keepers will begin to see the possibility of conflict arising at any and all points, and that certain laws that might perhaps be easily had for the asking, would forever set them free from the danger of litigation that would come without the asking, and require heavy fees before its departure. But here is the letter from Canada:

"I fully believe in such legislation as will enable a bee-keeper, by paying a reasonable sum of money, to control a certain territory. It seems to me that it would be a great mistake, on your part, to admit that the nectar does not belong to the land-owner. The farmer owns the land, pays the taxes, cultivates it, fences it, and, in fact, he is the "lord" of the soil, and I know enough of farming to know that his labor is no mean task, and I confess it would be very difficult to convince me that the whole grass, or rather clover crop, including the roots, stalks, leaves, flowers—yea, and even the very nectar in the blossoms, do not belong to the owner of the soil.

"All and singular, most surely, are the personal property of the land-owner. But at the same time it is quite as clear to my mind that if all farmers or land-owners, if you please, should undertake to keep bees, and gather each his own share of that nectar, each and every one, or nearly so,

would make a miserable failure; and what little honey that might be secured, or should be secured in that way, all costs being computed, would cost very likely not less than one dollar per pound.

"Well, now, it appears to me that the most rational thing in the world would be, for these land-owners to simply sell their right for a term of years to a professional who would, in the most economical method possible, secure that honey, and thus be in a position to supply the people in nice shape, at a minimum price, one of the choicest gifts of a kind and benevolent Father.

"But how is all this to be accomplished, you ask? It is not a difficult matter, in my way of thinking. Simply get a permissive, local-option Bill through your Legislature, empowering the voters of a given locality, the size of which may be fixed by the bee-keeper who may wish to establish, or one who has already established an apiary in such a locality. Then after the necessary legal preliminaries are complied with (which need not be enumerated here), let the matter be decided in the same manner that many other public matters are decided, namely, by the ballot.

"I think that the money could be applied to educational matters or purposes with perfect satisfaction and equity to the people in that particular locality voted to the use of the bee-keeper in question. I believe this scheme would be just to all parties concerned.

"Every land-owner would be remunerated for his own nectar. The bee-keeper would feel that he was not stealing his living from some who think that they have a right to some fair consideration for the nectar that their own possessions produce. He would also rejoice in a sweet feeling of security, that some unwise person cannot now come along and ruin his prospects after he has gone to all the expense of establishing an apiary.

"There would be no difficulty in carrying such a by-law in almost any rural district. Do you not see that nine-tenths of the people never keep bees, nor have they any expectation of doing so? and they would be quite willing to dispose of their share of the nectar to any one who would in turn pay a reasonable sum into the common school fund. Almost any offer that promises to reduce the taxes without inflicting difficulties, will be accepted by the people. Of course some difficulties would have to be surmounted, and details adjusted, but I see no real serious objections to the scheme.

"But on the other hand, if you start out declaring that the nectar is

public property—belongs to everybody—I predict that in a short time you will have a lot of fellows pulling your hair in right lusty earnest."

REPRODUCTION

In the Honey-Bee—Interesting Facts About Bees.

Read before the Pa. State Board of Agriculture
BY PROF. GEO. G. GROFF, M.D.

To the naturalist the means by which living beings reproduce their kind is always a subject of interest. Indeed, of all the functions of life, that of reproduction is the most interesting, the most wonderful, and to each species, the most important. Some forms of insects seem to exist in the mature state only that they may perpetuate their kind, and this being accomplished, they perish; the males in the act of fertilizing the females, the female, at once, when the eggs are safely deposited, neither parent ever seeing their offspring.

In all the higher animals reproduction is accomplished through the intervention of the two sexes, the male and the female, but among many of the lower forms of life both male and female are frequently dispensed with. In some cases the offspring pass through so many and so great transformations that it has been exceedingly difficult to trace the whole life history of these strange beings. In some cases the germs of life are so small that their origin cannot easily be discovered, except with the most patient research. This is true of the honey-bee.

A knowledge of the modes of reproduction, and of the laws governing the same, is always of value to the agriculturist and to the naturalist, because in the case of the higher forms he may readily improve his cattle, grains, tubers and fruits by a careful study of and conformity to these laws, as is so well illustrated in the great number of valuable varieties introduced in late years. And also in the case of the lower forms of life, pests and all kinds of animals and vegetable parasites, if their habits, times and modes of reproduction be understood, we may often, with great ease, cut short the career of forms which, undisturbed, would have caused great losses. The different modes of reproduction in the organic world may be outlined as follows, viz:

1. Asexual, divided into Division and Budding, both of which are again divided into Continuous and Discontinuous.
2. Hermaphrodite, divided into close-fertilization and cross-fertilization.
3. True Sexual, divided into Oviparous, Ovoviviparous and Viviparous;

the last being again divided into Aplanental and Placental.

The minute animals called animalcules, which live in stagnant waters, in damp places, and in the sea, in many cases reproduce their kind in some "asexual way," *i. e.*, without the intervention of the sexes. Of these asexual methods there are two principal ones. In the first, the body of the parent splits into two or more pieces, which, by absorption of nutrition, rapidly grow into perfect animals. Sometimes the young remain attached to the parent germ, and then we have "continuous" division, and the resultant is a "colony," as is true of sponges, sea-mats and numerous other marine forms. In other cases the young are all set free from the parent organisms.

Budding differs from division, in that the young appear on the sides of the body of the parents as small buds or enlargements. They remain attached, growing larger and larger, until they become perfect animals in all their parts. When development is completed, they either remain attached to the parent or else are set free to live independent lives, in the first case forming "colonies," as in continuous division. Coral colonies are formed in this way. In some of these lowly asexual forms the young are entirely unlike their parents, and at no period of their lives resemble them. These beings of the second generation bring forth young, which return to the original type, that is, resemble the grandparents. This is called "alternation of generation." Jelly fish are such intermediate forms. Nearly all the lowest plants, as moulds, mildews, blights, etc., are asexual.

The next mode of reproduction is the "hermaphrodite." In this the sexes both exist in the same individual. This is the common mode in the higher plants, the male and the female elements being in the same flower. The common earth-worm is a true hermaphrodite, as is the tape-worm. In the earth-worm we have *cross-fertilization*, that is, two individuals reciprocally fertilize each other, while in the tape-worm, which fertilizes its own ova, it is called "close." Nature generally abhors close fertilization, or, at least, usually contrives that it shall not continue the permanent order of things with any group of beings. Thus, in plants, the fertilizing pollen is carried to distant plants of the same species, by the winds, or by honey-seeking insects.

The highest mode is the "true sexual," in which the sexes exist perfect in distinct individuals. To this group belong fish, reptiles, birds, mammals, and many insects. The lowest class here is the "oviparous," in which eggs

are laid by the female, and then hatched by heat applied externally, as in insects, fish, reptiles and birds.

"Ovoviviparous" animals produce eggs, but these are retained within the body of the female until hatched. This is true of some reptiles. In the "viviparous" mode the eggs exist, but are very minute, and development proceeds within the body of the female.

The "aplacental" animals, opossums and kangaroos, bring forth their young in a very imperfectly developed state, while in the "placental" animals the young are much further developed at the time of birth, as is true of all the domestic animals.

Bees are oviparous insects, in which an egg is laid, which in time hatches into a worm (grub, larva or caterpillar). This, after a time, spins a cocoon, and becomes the quiescent pupa, and after a variable time the pupa changes into the imago or perfect insect. The honey-bee has always passed through all the stages of the egg, the worm, the pupa, and the perfect insect.

In a perfect colony of honey-bees in the summer time we find one queen, a few hundred drones, and several thousand workers, of the last from 10,000 to 40,000. Now, that eggs and worms and young bees are found in bee-hives was long known, but by what means the eggs were laid for a long time baffled the most careful observers. The queen-bee was generally considered the ruler of the colony, and a *male*, hence, in Shakespeare, we read :

"They have a king and officers of state."

And in Virgil, the Latin poet,

"First of the throng and foremost of the whole
One stands confest, the sovereign and the soul."

The naturalist Aristotle has left a remark showing that some observers of his time, or possibly earlier, had a clue as to the origin of bees, for he says, "Some say that the rulers produce the young of the bees." About the time of Christ, Virgil, the poet already quoted, gave the following method for replenishing depleted bee-hives :

A young bullock is to be killed by being suffocated. His body is covered with flowers, and allowed to lie in a secluded place until it decomposes. Worms will appear in the putrid mass, which, in time, will hatch into bees, and then if empty hives are near, the new bees will enter the same. Virgil states, however, that this is the method *said to be practiced* in Egypt, but some early English writers gravely recommended the plan as the correct thing to do.

The earliest mention I find of any modern person knowing the true method of bee-reproduction is that of Joseph Warden, physician of Corydon,

England, who, in 1617, published a curious and interesting little book, entitled, "The Feminine Kingdom; or, the True Amazons." In this book he tells us that the queen is the one female in the colony, and that she is at once the ruler and mother of all within the hive.

Butler, an English bee-keeper of an earlier date, seems also to have had a correct view of the same matter. Recent students have cleared the matter all up, and we are now able to understand quite fully what so long puzzled our predecessors.

We will consider first the origin of the queen, then of the workers, and last of all, of the drones.

How the Queen-Bee is Produced.

The queen is produced by two methods, which may be termed the *ordinary* and the *extraordinary* methods. As to the ordinary way: In a strong colony of bees, in the months of May and June, and sometimes later (this is for the latitude of Pennsylvania), there will often be found large cells, which on the exterior much resemble ground-nuts or peanuts. These cells are generally at the sides of the combs, though they are sometimes found on the face of a comb. They have thick walls, and an internal cavity much greater than that found in either worker or drone cells.

A peculiarity of the queen-cells, for so there are called, is that *the mouth opens downward*, while all other cells in the hive are horizontal. This arrangement is doubtless made that more room may be secured for the cell, for naturally the combs are placed too close together to build the queen-cells in the ordinary horizontal position. At any rate, queens will hatch from cells placed horizontally. In these cells eggs are placed, by what member of the colony, is not certainly known.

A single egg is placed in each cell, some say by the queen, others think by the workers. A number of careful observers have declared that they have seen the queen in the very act of depositing eggs in these cells. No one doubts that the queen lays these eggs. In time, they hatch into young queens, if the colony is strong, and the weather is favorable; the young queens will be ready to emerge in 16 days from the time the egg becomes a worm. However, if the workers are not ready for the new queen, they will confine her in her cell, feeding and caring for her there.

Under favorable conditions, about eight days before any young queen will hatch out, the old queen leads off a portion of the bees to form a new colony, which, leaving the old home for the new queen, will, in a short time, fully replenish it with bees.

So soon as a young queen emerges from her cell, she makes a tour of the hive, and finding any queen-cells, unless prevented by the workers, proceeds to tear them open and destroy the immature queens. In case the workers prevent this destruction, a second swarm is given off, led by the newly hatched queen.

It is a curious fact, that the queen-bee does not spin a complete cocoon, but leaves one end open, which makes her destruction very easy to any rival. About the only use the queen makes of her sting, is to destroy her rivals with it.

If the weather becomes bad, and the honey-flow ceases, the workers frequently destroy all the queen-cells, thus preventing all swarming for the season. On this plan, modern bee-keepers prevent second swarms, by opening the hives and cutting out all queen-cells.

What we call the extraordinary method follows: Should the queen of a healthy colony be lost through any accident, there being in the colony *worker larvae* not over three days old, the workers will select some of these worms, destined in the ordinary course of things to become worker-bees, and by enlarging their cells, by assiduous attention, feeding them almost constantly upon a peculiar substance called "royal jelly," will produce, in due time, a number of healthy young queens, one of which, the first to hatch, becomes the leader of the colony. This important discovery, that the queen proceeds from a worker-egg, was first announced by Schirarch, a Saxon clergyman, in 1771. (It is an interesting fact that nearly all of the great discoveries in bee-production have been made by clergymen.)

On this discovery depends the modern methods of commercial queen-rearing, by which queens are now produced, in every modernized apiary the world over, many bee-keepers making queen-rearing an exclusive business. Though the queen hatches in *sixteen days*, the drone requires *nineteen*, and the workers *twenty-one days*. The shorter period is probably due to the much more abundant and the richer food supplied to the queens; also because she has a more roomy cell in which to develop. This is an excellent illustration of how much environment will do for a developing animal. On these influences, the Rev. L. L. Langstroth has written in his classic work on the "Hive and Honey-Bee." He says:

"The peculiar mode in which the worm designed to be reared as a queen is treated, causes it (1) to arrive at maturity almost one-third earlier than if it had been bred a worker. And

yet, as it has to be much more fully developed, according to ordinary analogy, it should have had a slower growth. (2.) Its organs of reproduction are completely developed, so that it is capable of fulfilling the office of a mother. (3.) Its size, shape and color are all greatly changed. Its lower jaws are shorter, its head rounder, its abdomen without a receptacle for secreting wax, and its legs have neither brushes nor baskets, while its sting is more curved, and one-third longer than that of the worker. (4.) Its instincts are entirely changed. Reared as a worker, it would have been ready to thrust out its sting at the least provocation; whereas, now, it may be pulled limb from limb, without attempting to sting. As a worker, it would have treated a queen with the greatest consideration; whereas, now, if brought into contact with another queen, it rushes forthwith to mortal combat with its rival. As a worker, it would frequently have left the hive, either for labor or exercise; as a queen it never leaves the hive after impregnation, except to accompany a new swarm. (5.) The term of its life is remarkably lengthened; as a worker, it would not have lived more than six or seven months; as a queen, it may live seven or eight times as long. All these wonders rest on the impregnable basis of complete demonstration, and instead of being witnessed only by a select few, may now be familiar sights to any bee-keeper who prefers to acquaint himself with the facts, rather than to cavil and sneer at the labors of others."

Of the anxiety of bees over the loss of their queen, and joy on finding her, the same writer says:

"A large hive standing at a distance from any other, was removed in the morning of a pleasant day, to a new place, and another hive, containing only comb, was placed in its stead. Thousands of workers, which were out in the fields, or which left the old hive after its removal, returned to the familiar spot. It was affecting to witness their grief and despair; they flew in restless circles about the place where once stood their happy home, entered and left the new hive, continually expressing in various ways their lamentations over so cruel a bereavement. Towards evening, they ceased to take wing, and roamed in restless platoons in and out of the hive, and over its surface, acting all the time, as though in search of some lost treasure.

"I now gave them a small piece of brood-comb, containing worker-eggs and worms. What followed the introduction of this brood-comb took place much quicker than it can be described.

The bees which first touched it raised a peculiar note, and in a moment the comb was covered with a dense mass; their restless motions and mournful noises ceased, and a cheerful buzz at once proclaimed their delight. Despair gave place to hope, as they recognized in this small piece of comb the means of their deliverance.

"Imagine a large building filled with thousands of persons, tearing their hair, beating their breasts, and by piteous cries, as well as by frantic gestures, giving vent to their despair; if some one should enter this house of mourning, and by a single word cause all these demonstrations of agony to give place to smiles and congratulations, the change would not be more instantaneous and wonderful than that produced when the bees received the brood-comb."

The Mating of Queens.

If the weather is favorable, on the third day from the cell, the young queen goes forth on her "bridal tour," and in a few hours, if she is successful, she returns, bearing with her the organs of the male, which has perished in the act of impregnation. If the third day is cloudy, or wet, she goes forth on the first favorable day, and she continues to go forth day after day until she is successful.

The queen is always (some object to this) fertilized in the open air, while on the wing, *and but once in her life*. This was first announced by the blind naturalist Huber, at the close of the last century. The fertilizing element received from the male is stored in a little receptacle, and a little of it ejected as the eggs pass down the oviduct, thus vitalizing them.

Average Age of Prolific Queens.

The queen in her prime may lay from 2,000 to 3,000 eggs in a single day. Her second year is generally thought to be the most prolific, and after that she gradually declines in value. The queen lays such large numbers of eggs, however, only during the busy season of the year, when honey is coming in rapidly. During the winter months, and during a sudden cessation of the honey-flow, she ceases to lay almost entirely, though I think a few eggs and worms will be found at most times in vigorous colonies. This is a wise provision to protect the colony from destruction through loss of the queen.

When a queen has grown old and is no longer very prolific, the workers see that a new one is reared, and the old one is then "superseded," though occasionally the old and the young queens have been seen living in harmony in the same hive, and actually at the same time, on the same comb.

Some bee-men think that the workers will, unaided, attend to the destruction of feeble queens, but at present a large number of the more progressive apiarists prefer to do this themselves, thus insuring at all times to all their colonies, young and vigorous queens. This is one important particular in which modern bee-keeping differs from the old.

How Bee-Eggs are Hatched.

The eggs of the bee are hatched by the united heat of the colony. The interior of a hive is always warm, even in the dead of winter, and hence, when the number of bees in a hive becomes small, the colony perishes, being unable to maintain the requisite degree of animal heat. Hence, also, the reason for increasing only by swarming.

The Progeny of Unfertilized Queens.

If the queen-bee fails to become fertilized before she is 21 days old, she remains through her life sterile. This was first observed by Huber. In 1845, Dzierzon, a Catholic clergyman of Germany, observed that young queens not fertilized, and old, nearly exhausted queens, alike laid eggs, all of which hatched only drone-bees. After repeated observations, Dzierzon announced the discoveries, and the theory of *parthenogenesis*, which, in short, is, that some animals have, under peculiar circumstances, the power of bringing forth young, without the intervention of the male. In the case of bees, these unfertilized eggs hatched only into drones.

Mr. Langstroth, about 1851, sent an old drone-laying queen to Dr. Joseph Leidy, the renowned scientist, who found that the receptacle in which the male element is stored, was entirely empty. The same observation has been made by competent persons on young drone-laying queens. It seems then, that a queen can lay eggs which will produce queens, workers or drones. That queens come from ordinary worker-eggs, laid in special cells, and attended with special care. The workers come from fertilized eggs, laid in ordinary cells, while the drones come from unfertilized eggs. It would seem that the queen can *will* whether she will have worker or drone progeny, she voluntarily discharging the male fluid upon the eggs as they pass down the oviduct, or withholding it. This point is, however, in dispute, some believing that the small worker-cell compresses the body of the queen, and that this pressure opens the mouth of the vessel containing the male fluid. Be that as it may, the queen can also lay drone-eggs in worker-cells, and worker-eggs in the cells which have only just been commenced, and where

this pressure cannot possibly be exerted.

The workers hatch in 21 days. A careful microscopic study of their sexual system (first made in the time of Huber, and for him), shows them to be partially developed females, the sexual organs being very rudimentary. Here rests the possibility of developing *any worker worm* into a queen, if it is only taken early enough, and subjected to lengthening to meet the needs of the larger occupants. All this shows the wonderful instincts of this wonderful insect.

Edenburg, Pa.

LARVAL FOOD.

The Quantity and Quality of the Food of Larval Bees.

Written for the Druggist Circular
FOR SEPTEMBER.

The bee has proven a sufficiently interesting study to engage the attention of many able observers, among the keenest of whom are Leuckart and Schonfeld, whose observations concerning the food of larval bees agree in the main, and are according to A. V. Planta (*Zeit. Physiol. Chem.*) substantially as follows:

1. The food of the queen-bee larvæ is the same during the whole of the larval period; it is free from pollen-grains, which have been reduced to a thickish but homogeneous juice by the digestive action of the stomach of bee.

2. The food of the larval drones is also, during the first four days of the larval period, free from pollen, and appears to have been completely digested previously. After four days their food is rich in pollen-grains, which have, however, undergone a certain amount of digestion. The food stuff of the larvæ is probably formed from bee-bread. The composition of the food of the queen-bee larvæ was water, 69.38; total solids, 30.62. In the solids the proportions were, nitrogenous material, 45.14; fat, 13.55; glucose, 20.39; ash, 4.06.

The composition of the food of the drone-larvæ and those of the working bees both differed from each other, and from that of the queen-bees. All kinds are rich in nitrogen; all were of a grayish white color; that of the queen-bee was the stickiest, that of the workers the most fluid. Peptone appeared to be absent; the greater part of the nitrogenous material present was proteid. The ethereal extract was in all cases acid, but formic acid was absent. The sugar present was, in all cases, invert sugar, whereas the

sugar in pollen-grains is invariably cane-sugar.

There are certain differences in the composition of the different kinds of larval food, more especially in the composition of the solids present. Its composition is, moreover, quite different from that of the bee's saliva, which contains no sugar. The difference between the proportional amount of the different solids present in the different forms of larval food is a constant one, and no doubt this variation has in view the particular requirements of the larvæ in question. Certain small but constant differences were also observed in the chemical composition of the food of the larval drones during the first four days, and at subsequent periods. Not only is there a difference in the quality, but there is also one in the quantity of the food supplied.

The juice from 100 queen-bee cells yielded 3.6028 grams of dry substance; that from 100 drones' cells, 0.2612 gram; that from 100 workers' cells, 0.0474 gram. The substance investigated was the juice of pap, the whitish sticky substance which the working bees store in the cells of the larvæ of the queens, drones and workers.

Leuckart regarded it as the product of the true stomach of the working bees, which they vomit into the cells, in the same way that honey is vomited from the honey-stomach. Fischer and others regarded it as the product of the salivary glands of the bees. Schonfeld, in numerous papers, has recently shown that Leuckart's original view is the correct one. He showed that the saliva can be easily obtained from the salivary glands of the head and thorax, and that it is very different from the food juice deposited in the cells of the bees; and that, moreover, the juice is similar, both chemically and microscopically, to the contents of the bee's true stomach; he showed also from the consideration of certain anatomical and physiological peculiarities of the bee, such as the position of the mouth, the inability of the bee to spit, etc., that the view of this substance being saliva, is quite untenable.

Certain observers have replied that a bee cannot vomit the contents of its true stomach, because of a valve which intervenes between it and the honey stomach; but Schonfeld has shown that the structure, mistaken by these observers for a valve, does not act as one, but is in reality an internal mouth, over which the animal has voluntary control, and by means of which it is able to eat and drink the contents of the honey-stomach when necessity or inclination arises. By light pressure on the stomach, and stretching out the animal's neck, the contents of the stomach can be easily

pressed out. Planta's investigations entirely confirm Schonfeld's view, that this substance comes from the bee's stomach.

REARING QUEENS

By the Swarming Impulse, Not in the Swarming Season.

Written for the American Bee Journal
BY A. N. CLARK.

Recently Mr. Alley stated that he had in August reared queen-cells in colonies having queens. I do not know his method, but a year ago last July I had cells built in a normal colony as follows:

I contracted the hive to 8 Langstroth frames, 2 of which were empty combs. There being but little nectar in the fields, I fed one pound of diluted honey each day; this stimulated breeding, and, being crowded for room in the course of a week, they commenced building cells preparatory to swarming. As soon as the cells were started, I removed the comb containing them, replacing it by a selected comb of hatching eggs in which the cell-walls were broken down in rows that were horizontal.

Upon examination a few days later, I found cells on the prepared comb. Just before the cells were ready to seal, the comb of cells was removed to a queenless colony. By thus removing cells, replacing with empty comb, and the discontinuance of feeding, swarming was prevented.

It is quite possible that one would not always be so successful. For instance, the bees might build cells of their own larvæ instead of from that given them; and frequently they might swarm before the cells were removed, or, even after their removal. In some cases the queenless colony might destroy the unsealed cells given them. Perhaps Mr. Alley's method overcomes these difficulties.

Although queens reared by the above method seem as good as any, I doubt their being *better* than those reared in queenless colonies, strong in young bees.

Why Bees Gather More Propolis in the State of Michigan.

Some apiarists have wondered why bees in Michigan use propolis more freely than they do in some other States. I think that it is due to the greater number of tamarack trees that grow here. The bees are now gathering large quantities of resin, which exudes from the cones on the tamarack and evergreen trees.

STRAIGHT COMBS.

Securing Straight Combs Without Comb Foundation.

Written for *Furn, Field and Stockman*
BY S. E. MILLER.

This is one of the first difficulties that the beginner in bee-culture will meet with, if he has not some good book to refer to, and even some of these only tell how to do it by using comb foundation. I believe I have never seen an article in any book or paper which told how straight combs could be secured without the use of foundation. Although it is the best and cheapest in the long run, it is not every beginner who has the money to invest, or wishes to purchase the article, therefore, the question arises how to get along without it.

The following plan was given to me by a brother bee-keeper, and I have since verified it to my satisfaction :

When hiving a swarm, if you have already a movable-frame hive containing straight combs, take out one, or better, two combs, replacing them with empty frames or division-boards. Insert these frames in the new hive which the swarm is to occupy, putting them near the centre, with an empty frame between them. The bees will cluster on these two frames of brood, and will be sure to commence work on the frame between them first, and having a straight wall on each side, will be almost certain to build it straight. If honey is plentiful, this frame will soon have a straight comb started all along its top-bar, but should they build any side-combs, remove them. Now part these frames and put two more empty frames between, leaving the frame with the newly-made comb in the centre, an empty one on each side of it, and the two finished frames containing full combs on the outside of these.

Continue in this way until all the frames have a small straight comb started along under their top-bars, after which very little attention will be necessary to insure straight combs. Until then, be ever attentive, not allowing them to work more than two or three days without examining them, and cutting off all combs that may be started where you do not want them. You can get along with one full frame of comb to start with, or even without any, but in that case you must be vigilant, and never allow the bees to start building the combs crosswise of the frames.

Some beginners seem to think that all they have to do is to put the bees into the hive, in the belief that the bees will know how to manage things. The

result is, the bee-keeper has a movable-frame hive in which the frames are not "movable" after being filled with combs. I know of a case of this kind just across the river from here. Bees, if allowed to have their own way in frames not having foundation starters, are, I think, just as likely to build crosswise as lengthwise of the frames.

With a little experience in this way, the beginner will soon have no trouble in securing combs as straight as can be secured with comb foundation.

I might add that I have had the best results in frames with a triangular strip of wood fastened to the underside of the top-bar, instead of the comb-guide in common use at the present day.

OLD QUEENS.

The Value of Queens After 2 or 3 Seasons.

Written for the *Prairie Farmer*
BY MRS. L. HARRISON.

Some prominent bee-culturists (among them Mr. Oatman, of Dundee, Ills., who counts his colonies by hundreds), do not keep a queen after she has laid for three seasons. They keep bees for the money there is in them, and claim they obtain the best returns by so doing, as an old queen, like an old hen, lays but few eggs, and that she is apt to fail when most needed. Nor if the colonies are not populous, at the right time, the more of them the owner has, the poorer he will be. Just before the honey seasons closes in the fall, is a good time for renewing queens, as then no time will be lost. If it is done in the spring, it may materially damage the honey crop for that season.

Those who desire to purchase queens can obtain them much cheaper in the fall, than at any other time of the year. It is better for all bee-keepers to introduce a little new blood among their bees now and then; following the example of breeders of fine horses, cattle, sheep and fowls, they should aim at excellence, and not be satisfied with any but the best. Queen-bees are now sent in the mails to all parts of our country, for a two-cent stamp, and even from Europe, with entire safety.

It is not necessary to purchase queens, except to introduce new blood now and then to build up an apiary to a high state of excellence. Every close observer will soon notice which are his best colonies, those that are most populous, and consequently gather the most honey. The best colonies generally swarm earliest, and if

all of the queen-cells are preserved, the bee-keeper will be master of the situation. These young queens can be kept during the busy season in a hive with two or three frames of comb, and are ready to be introduced to large colonies at the pleasure of their owner. Where after-swarms or "casts" have been hived in the hurry incident to swarming, and are being united in the fall, the good queens should be preserved; her bees will proclaim her character.

In the general overhauling of the apiary in the fall, some colonies will be generally found not up to the standard; bees very small, or else very dark, the queen having mated with a black drone. The queens removed while uniting could be introduced to such colonies. A general weeding-out should take place in the fall, of all undesirable stock.

Imported queens were for many years held at high figures, as so many died in transit. An Irishman once said to me: "Mr. Rogers once paid twenty dollars for a bay, a single bay, Madam." Since a better way of sending them has been discovered, few are lost, and they can be purchased at reasonable rates.

It is an easy matter to discern Italian queens. They stick to the comb, and their bright color attracts the eye; but with the dark or common bees, it is different. The bees run like a flock of sheep, and the queen hides among them, and cannot be discerned by her color. I have lifted the combs of a black colony two or three times, and failed to find her sable majesty. I now have a queen-excluder, which is a piece of zinc with holes in it, that admit workers, but not drones or queens, and put that against the entrance of a new hive. I remove the old one, putting this in its place. Then I remove the combs and brush off the bees, place them in the new hive, cover them up, and, if I am busy, retire to new duties and allow them to enter the hive at their own sweet will. The queen and drones will be found on the excluder. One time, in driving a colony in this way, I picked up the black queen, and immediately put an Italian in her place, and she was well received.

It should be borne in mind, that the old queen must first be removed before releasing a new one, or she will be destroyed. Then cage the queen, and release her in 48 hours, or, better still, let the bees do it. If a shipping-cage is fastened to the side of a comb with the tin points, the bees will eat away the comb and release her. I roll up wire-cloth over a little stick and wedge in the comb as stoppers, and let the bees release her from this.

Peoria, Ills.

CONVENTION DIRECTORY.

- 1888 *Time and Place of Meeting.*
 Oct. 16, 17.—Union, at Clayton, Ills.
 S. N. Black, Pres., Clayton, Ills.
 Oct. 20.—Wabash County, at Wabash, Ind.
 Henry Cripe, Sec., North Manchester, Ind.
 Nov. 21, 22.—Pan-Handle, at Wheeling, W. Va.
 W. L. Kinsey, Sec. Blaine, O.
 Dec. —Michigan State, at Jackson, Mich.
 H. D. Cutting, Sec., Clinton, Mich.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

A Power for Protection.—G. H. Ashby, Albion, N. Y., on Oct. 1, 1888, says :

I send my dues for the Bee Keepers' Union. The Union is doing wonders for the small amount expended. I do not believe that any bee-keeper, whether of few or many colonies, would miss one dollar per year—about 8 cents per month ; and if only one-half would "chip in" that amount, what a power for protection the Union would be.

Over One-Half a Crop.—C. Thielmann, Thielmanton, Minn., on Sept. 27, 1888, says :

Bees in this vicinity have had a good time for honey gathering for the past 5 or 6 weeks ; but for the past 2 weeks they have not done much in the sections on account of the cold nights, but they have filled the brood-chambers with honey. They have more than what they need for winter and spring. There are multitudes of flowers in bloom yet, but it has been too cold the past two days for the bees to work. The honey crop here is a little over one-half, and about one-third of it is white, but not as white as usual. I got about 7,000 pounds, 6,000 pounds of which is comb honey.

Bee-Keeping in Dakota.—Andrew Craig, Empire, Dakota, on Sept. 22, 1888, writes :

I have 3 colonies of bees, one of which stored 18 pounds of surplus honey in sections ; the other 2 did nothing. Settlers here are few and far between, and my bees have troubled nobody yet. My surplus was all gathered after Aug. 10, and is of light amber color. It was one-half granulated within a week after being taken off. Alsike clover sowed last spring blossomed some, and bees worked immensely on bee-balm. Buckwheat yielded no nectar this season. Golden-rod and asters are abundant.

Best Season for 5 Years.—K. A. Dyke, Effingham, Ills., on Sept. 27, 1888, writes :

Having seen so many discouraging reports in the bee-papers lately, I feel like giving mine for this season. I commenced the season with 12 colonies, increased them by manipulation to 23, and secured 1,100 pounds of honey, three-fourths of it extracted, and all from heart's-ease and Spanish-needle. I had to feed my bees during August until about the 16th, to keep them from starving, and to keep up brood-

rearing ; they used up the feed clean each day, and when the honey-flow came on Aug. 26, it was a refreshing sight to see them lay it away. From Aug. 26 to Sept. 9 the weather was cloudy, some rainy, and quite warm, but very little sunshine ; and with thousands of acres of bloom in sight and range, it is no wonder that the bees stored honey rapidly. Since that time it has not been so favorable, and only asters are yielding anything now. This has been the best season here for five years. Last year was considered a failure, yet I increased from 9 colonies to 12, and wintered all on the summer stands safely, and secured 350 pounds of surplus honey. I am disposing of my honey to the home markets, at 12½ to 18 cents per pound, wholesale ; and 15 to 20 cents retail. I have lots of competition in the way of broken honey and "squeezed stuff."

Frozen Foundation.—C. G. Ridout, of Hutchinson, Minn., asks the following question :

Will it in any way injure comb foundation to freeze, or be kept in a room all winter that does freeze hard ?
