10 ¢ cent.; 8 times, 15 ¢ cent.; 13 times, 20 ¢ cent.;
26 times, 30 ¢ cent.; 52 times, 40 ¢ cent.

On 20 lines, or more, 4 times, 15 per cent.; 8
times, 20 ¢ cent.; 13 times, 25 ¢ cent.; 26 times,
40 ¢ cent.; 52 times, 50 ¢ cent.

On 30 lines, or more, 4 times, 20 per cent.; 8
times, 25 ¢ cent.; 13 times, 30 ¢ cent.; 26 times,
50 ¢ cent.; 52 times, 60 ¢ cent.

On larger Advertisements discounts will
be stated, on application.

Advertisements for the next BEE JOURNAL
must reach this office by the Saturday of the
previous week.

Make all Money Orders Payable at
Chicago, Ills.—Some postmasters in the
country insist on making such payable at some
sub-station of Chicago, but we want them drawn
on the main office.

Topics Presented in This Number.

Added many dollars to his income, etc.....	13
Alfalfa as a honey-plant in Colorado	8

Please to get your Neighbor who keeps
bees, to also take the AMERICAN BEE JOURNAL.
It is now SO CHEAP that no one can afford to
do without it.

Entered at P.O. as Second-class matter.

TO CORRESPONDENTS.

Our Club Rates are: \$1.90 for two copies
to the same or different post-offices; and for
THREE or more copies, 90 cents each.

The Bee Journal is sent to subscribers
until an explicit order is received by the
publishers for its discontinuance, and the
payment of all arrearages is made.

Foreign Postage.—To all countries in the
Universal Postal Union, 50 cents extra. To all
countries NOT in the Universal Postal Union,
\$1.00 more than the subscription price.

How to Send Money.—Remit by Express,
Post-Office Money Order, or Bank Draft on New
York or Chicago. If none of these can be had,
Register your Letter, affixing stamps both for
postage and registry, and take a receipt for it.
Money sent thus, IS AT OUR RISK; otherwise
it is not. Do not send Checks on Local Banks,
for they cost us 25 cents each, at the Banks here,
to get them cashed.

Postage Stamps of any denomination may
be sent for any fraction of a dollar; or where
Money Orders cannot be obtained, stamps for
any amount may be sent.

Subscription Credits.—The receipt for
money sent us will be given on the address-label
of every paper. If not given within two weeks
after sending the money, write to us, for there
must be something wrong. Do not wait months
or years, and then claim a mistake. The
subscription is paid to the END OF THE
MONTH indicated on the wrapper-label. This
is a continual statement of account.

We will take Canadian paper money for
subscription or books; and Canadian postage
stamps may be sent for fractions of a dollar.

Do not Write anything for publication on
the same sheet of paper with business matters,
unless it can be torn apart without interfering
with either part of the letter. Both may be sent
in one envelope, but must be on separate pieces
of paper.

Never Send Silver in letters. It will wear
holes in the envelope, or may be stolen.

Emerson Binders, made especially for the
AMERICAN BEE JOURNAL, are lettered in gold
on the back, and make a very convenient way of
preserving the BEE JOURNAL as fast as received.
They will be sent, postpaid, for 60 cents each.
They cannot be sent by mail to Canada.

Lost Numbers.—We carefully mail the BEE
JOURNAL to every subscriber, but should any be
lost in the mails, we will cheerfully replace them
if notified before all the edition is exhausted.

Always Give the Name of the Post-Office
to which your paper is addressed. Your name
cannot be found on our List, unless this is done.

Issued every Wednesday by

THOMAS G. NEWMAN & SON,
PROPRIETORS.

923 & 925 WEST MADISON ST., CHICAGO ILL.
At One Dollar a Year.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Special Notices.

We Club the AMERICAN BEE JOURNAL and the "Bee-Keepers' Magazine" for one year for \$1.40; or with "Gleanings in Bee-Culture" for \$1.75; or with the "Apiculturist" for \$1.80; or the "Canadian Honey-Producer" for \$1.30; or all five for \$3.50.

As Bread is the Staff of Life, so is judicious advertising the staff of business! You may as reasonably expect one "good square meal" to suffice for three months, as to expect one advertisement to bring in business for that length of time! Many persons cannot remember anything longer than about seven days. To stop advertising in a dull season, is like tearing out a dam because the water is low—either plan can but result in disaster.

Enterprising queen-breeders and supply-dealers know the value of advertising "all the year round." Persistently keeping their name and business continuously before buyers, will eventually place them on the successful side, if they have a valuable article to sell.

A "sign" is a mute invitation to those who may pass a man's place of business; a "circular" will only reach the one to whom it is personally addressed; but an "advertisement" in a well-conducted and widely-circulated paper (like the AMERICAN BEE JOURNAL) has an influence "far and wide;" it finds customers, and almost compels them to consider the claims of the wide-awake advertiser. To yearly advertisers the AMERICAN BEE JOURNAL offers special inducements. This is just the time to make a contract for the coming year.

A Favorable Word from any of our readers, who speak from experience, has more weight with friends than anything we might say. Every one of our readers can lend us a helping hand, in this way, without much trouble, and at the same time help to scatter apicultural knowledge and promote the welfare of our pursuit.

A Valuable Book Given Away.—We have made arrangements by which we can supply the AMERICAN BEE JOURNAL and the New York World—both weekly—for one year, for \$2.10, and present the subscriber with one of these books, bound in Leatherette Tree Calf:

HISTORY OF THE UNITED STATES—from 432 to 1887.—320 pages.—Price, \$2.00.

HISTORY OF ENGLAND—from before the Christian era to 1887.—Price, \$2.00.

EVERYBODY'S BOOK—a treasury of useful knowledge.—410 pages.—Price, \$2.00.

The extra 10 cents is for postage on the book, which must be selected by the subscriber at the time of sending the subscription, and cannot be afterwards exchanged.

The book selected will be mailed in a cardboard case, at the subscriber's risk; if lost it cannot be replaced. Be sure to write your name, post-office, county and State plainly, and then the risk of loss is very small. The subscriptions can commence at any time.

Remember, the amount is \$2.10 for both papers, and the Book and postage.

To create Honey Markets in every village, town and city, wide-awake honey producers should get the Leaflets "Why Eat Honey" (only 50 cents per 100), or else the pamphlets on "Honey as Food and Medicine," and scatter them plentifully, and the result will be a DEMAND for all of their crops at remunerative prices. "Honey as Food and Medicine" are sold at the following prices:

Single copy, 5 cts.; per doz., 40 cts.; per hundred, \$2.50. Five hundred will be sent postpaid for \$10.00; or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc. (giving the name and address of the bee-keeper who scatters them).

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell lots of it.

Don't do it!—Notwithstanding our many cautions, some persons still persist in sending silver in letters. In nine cases out of ten it will break the envelope and be either lost or stolen. Cases come to light nearly every day, showing that silver sent in letters stops somewhere on the way. It is an invitation to the thief—a regular temptation! If you wish to safely send money, get a Post-Office Money Order, Express Order, or Bank Draft on Chicago or New York. When money is sent in either of the above-named ways, it is at our risk. In any other manner, it is at the risk of the sender.

We are sometimes asked who our authorized agents are. Every subscriber is such an agent; we have no others, and we greatly desire that each one would at least send in the name of one new subscriber with his own renewal for 1888. The next few weeks is the time to do this. We hope every subscriber will do his or her best to double our list of subscribers.

Simmins' Non-Swarming System.—We have received another shipment of these books, and have made such favorable terms, that we will now club them with the BEE JOURNAL for one year, both postpaid, for \$1.25. We can supply all orders by return mail.

To Correspondents.—It would save us much trouble, if all would be particular to give their P. O. address and name, when writing to this office. We receive letters (some inclosing money) that have no name; many others having no Post-Office, County or State. Also, if you live near one post-office and get your mail at another, be sure to give the address we have on our list.

As there is Another firm in Chicago by the name of "Newman & Son," we wish our correspondents would write "American Bee Journal" on the envelope when writing to this office. Several letters of ours have already gone to the other firm (a commission house), causing vexatious delay and trouble.

Sample Copies of the BEE JOURNAL will be sent FREE upon application. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office or we will send them all to the agent.

Money Orders can now be obtained at the Post Offices at reduced rates. Five dollars and under costs now only 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them, and are in no way safe.

Photographs of Bee-Keepers.—We have purchased a lot of the "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a photographic sketch of each one, and will send it and the BEE JOURNAL for one year for \$1.75, or will present it free by mail to any one for a club of three subscribers and \$3.

Should any Subscriber receive this paper any longer than it is desired, or is willing to pay for it, please send us a postal card asking to have it stopped. Be sure to write your name and address plainly. LOOK AT YOUR WRAPPER LABEL.

New Subscribers can obtain the full numbers for 1887 and 1888 for \$1.80, as long as we have any sets of 1887 left. There are only a few, and to get them an early application will be necessary.

All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and commence to use it. The prices are reduced, as follows:

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable.

We have a few Sets of the BEE JOURNAL for the present year, and can fill orders until further notice, for all the numbers from the first of last January. New subscribers desiring these back numbers, will please to state it plainly, or they will not be sent.

THOMAS G. NEWMAN, Editor.

Vol. XXIV. Jan. 4, 1888. No. 1.

EDITORIAL BUZZINGS.

Past and Present mingle strangely.

While the next world borders this ;
Open doors at hour of midnight
Usher in a year of bliss.

Last year's record, good and evil,
Close another page of life ;
While the angels whisper promptings
For the New Year's coming strife.

Look Over last year's numbers of the BEE JOURNAL, and if any are missing, send for them at once, as we have but few left now, and they are daily becoming less.

Mr. John M. Rey, a bee-keeper of East Saginaw, Mich., has just been elected an officer by the "Knights of Honor" of that city. He will be installed to-morrow. There may he be a "RAY of light."

Mr. Jesse White, Perry, Iowa, had a letter printed on page 700 of last year. By an oversight the name "White" was omitted. Of course that was not treating him WHITE, and so we make this correction.

Only a Few complete volumes of the BEE JOURNAL for 1887 are left, and those of our new subscribers who want to secure them should send for them at once. We supply the numbers for 1887 and 1888 for \$1.75 until all of the former are gone.

The Apiculturist for January came in good time, and is as usual full of good things of interest to every apiarist. "Prevention of Increase" is the chief topic in this number, and it contains three good articles on that subject. The BEE JOURNAL and the "Apiculturist" for 1888 can be obtained for \$1.80.

To-Day we enter upon another year's work—creating another volume of the AMERICAN BEE JOURNAL—rearing another monument to progressive apiculture !

The present issue is nearly all printed from new type, with a clean and clear face, which can easily be read, and contains some two pages more reading of matter than heretofore. It is printed on thick white paper, and is a grand improvement, as a work of art. We trust all our readers will appreciate this, and regard it as an earnest of our determination that the AMERICAN BEE JOURNAL shall hold its place in the front rank, as the "leader" of all apicultural publications, leaving them to FOLLOW in the path we have marked out, prepared and tried in the van-guard.

It is quite unnecessary to state that we shall in the future, as in the past, endeavor to "keep abreast of the times," and place before our readers all the new things in our ever-advancing pursuit, as soon as they come to light.

With these few words we enter upon the fifteenth year since the BEE JOURNAL came into our hands, with full confidence that our labors are fully appreciated.

500 Queries were printed and nearly 6,000 replies given to them in the AMERICAN BEE JOURNAL up to the end of the volume just closed. To-day we give 501 and 502, with more numerous replies than ever. We have engaged several more persons to answer the questions propounded, and their replies will appear in addition to those of former years.

Our Desk Calendar for 1888 is the Columbia Bicycle Calendar and Stand, just issued by the Pope Manufacturing Company of Boston, Mass. The calendar proper is in the form of a pad, containing 366 leaves, one for each day in the year, to be torn off daily. A portion of each leaf is left blank for memoranda, so arranged that the memorandum blank for any coming day can be turned to immediately at any time.

Beeswax and its Utilization, by Mr. J. Denmler, has been translated into the French language by Mr. J. B. Leriche. A copy is on our desk, and as soon as we can give it space, we will publish a translation of it in the AMERICAN BEE JOURNAL. Mr. Leriche is the editor of "Le Bulletin Agricole" at Amiens, France.

The Apicultural Department of the "Indiana Farmer" has passed into new hands. Our friend, G. K. Hubbard, now becomes the editor of it. The Apiary Department of the "Indiana Farmer," under the management of Mr. Dougherty, has long been a credit to the pursuit, and as Mr. Hubbard is one of the BEE JOURNAL family, we may naturally expect it to be fully as good, if not better than ever before. We wish him much success.

World Wide.—Kindly take another look at the engraving at the head of this page. It is a work of art, and tells its own story, for the AMERICAN BEE JOURNAL to-day enjoys a reputation and influence second to none in the world of apiculture ! Its weekly visits to thousands of homes all over the world is greeted with an enthusiastic WELCOME ! Its apicultural instruction and record of improved methods in our pursuit have been as anxiously looked for as they have been essentially adopted by apiarists not only in every State, Territory and Province in North America—but also in Australia, Europe, Asia, and Africa !

We have adopted this design because it is so suggestive as well as comprehensive, and surely we may have a pardonable pride in its ELEGANCE. Some time since Mr. Baldrige, of St. Charles, Ills., sent us the following from a metropolitan daily paper :

It has become the custom of late for a railroad to adopt some distinctive design for posters, letter-heads, etc. Thus the Pennsylvania has its key-stone, and the Bee-Line its "honey-bee." The Lake Shore passenger department has just adopted a mail pouch as its trade-mark, emblematic of rapid transit.

This "hint" suggested to us the appropriateness of adopting the superb emblem at the head of this column.

The New Constitution and By-Laws which we presented at the late convention in this city, meets with the general approval of the "Canadian Honey Producer," but in its last issue it asks us to comment upon and discuss its merits more fully in the AMERICAN BEE JOURNAL. We gave weeks of valuable time and very careful consideration to every point, and when it was presented to the convention we considered it as nearly perfect as we could make it. Now, if any one sees a point in it open for improvement, let it be presented, and we will cheerfully either defend it as it is, or adopt the amendment. We desire to have it fully discussed, and improvements made where possible.

Robert's Rules of Order for deliberative assemblies, published by S. C. Griggs & Co., Chicago, is "a gem" in appearance, and an invaluable guide for those who are called to preside over conventions of bee-keepers and others. It has a table, covering two pages, which will aid a chairman to decide 200 questions of importance, without turning a leaf. Price 75 cents.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Cold Weather is reported everywhere.

GLEAMS OF NEWS.

What Ails Tin? asks one of our exchanges. A California Trade Journal answers the question in this way:

Tin is now selling at higher prices than ever before. The reason for this is that a syndicate of French merchants have gained control of the tin market, and are conducting a corner in that commodity all over the world. Mr. S. Mendel represents the syndicate in New York. The combination was made in Paris last April, with a capital of about \$50,000,000. They sent their agents to the London market and bought up in spot and futures more than the estimated supply of tin in the world. Since then the price of tin has advanced from 22 to 35 cents a pound, or from \$5 to \$8 a ton, and the limit has probably not been reached. The agents have also gone to the mines in the East Indies and in China, and secured their future output. They have likewise made purchases in the New York market, and now control everything in sight.

Bee-keepers are very much interested in the market value of tin. It is extensively used for honey and wax extractors, as well as for putting up extracted honey. The advance in prices will enhance the value of these necessary articles, and our best advice is to lay in a stock of such as are needed before a further advance in price is announced.

Mr. John L. Wolcott, of Bloomington, Ills., an apiarist widely known and much respected, died at his home on Dec. 19, from a disease of the liver. A widow and seven children are left to mourn his loss. He was 79 years of age on Aug. 30, 1887. Two years ago we called upon him at his place of business in Bloomington. He was then quite unwell, and we are not surprised to hear of his death. He had been in business in that city for over forty years. The BEE JOURNAL condoles with the mourning family.

The "Rich" Lawsuit is now being appealed, but the expenses are heavy. So far they have amounted to \$468.04. To appeal the case will cost \$500 more; and in the interest of the pursuit it should be done. The Bee-Keepers' Union is now only able to offer Mr. Rich \$200 to help his appeal. Now it is a shame that with 300,000 bee-keepers in the United States, that so few are willing to join the Union to defend the pursuit against its enemies.

Last July the members voted to put the fees down to an even dollar a year, and this amendment took effect on Jan. 1, 1888. Now let us see if this will not raise at least \$1,000 so as to defend the three or four cases now on hand. We await the decisive action of bee-keepers. What say you, reader, will you not become a member?

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents.

The Cranky Council in Arkansas, which has made a crusade against honey-bees, is nicely "dished up" by the "Southern Cultivator," a wide-awake farm paper. It says:

Out in Arkadelphia, Ark., the City Council lately declared bees to be a nuisance, some crank charging the bees with eating up his young ducks, as well as eating up the peaches! A fine of not less than \$5, nor more than \$25, was fixed for each day the bees were left in the city after the passage of the ordinance. Mr. Z. A. Clark, an influential apiarist of that place, backed up by the National Bee-Keepers' Union, proposes to fight the case on its merits, and it is reckoned he will conquer the cranky Council.

Ireland is likely to be a prominent European topic in 1888 as in 1887. To most readers a bright article describing the Parliament as that island once possessed it, will be something acceptable. The opening article of "Frank Leslie's Popular Monthly" for January, will give general pleasure. The House, the Halls of each House, the prominent men who figured on the floor, are all drawn graphically with pen and pencil.

Convention City.—Since it was decided that the next annual meeting of the North American Bee-Keepers' Society should be held at Toledo, there has been several protests. Mr. J. E. Shaver, of North River, Va., on Dec. 21, 1887, writes thus:

Could not a change be made yet, and hold the next convention in Cincinnati instead of Toledo? I think it certainly should be in Cincinnati next year. Have it there, if possible.

Our only reply to this is that we will print the request, and respectfully refer it to the executive committee. Their decision must be final. We have nothing to do with the matter.

Dr. A. B. Mason, President of the North American Bee-Keepers' Society, is on the programme of the Southeastern Michigan Farmers' Club, for an address, at their meeting to be held at Monroe, Mich., on Jan. 19, 1888. The Doctor will be sure to put in a good word for bees and bee-keeping. He is just the man for the occasion, and will do credit to the fraternity and pursuit of apiculture.

New Catalogues for 1888 are on our desk from the following persons:

A. F. Stauffer, Sterling, Ills.—16 pages—Bees, Queens, and Bee-Keepers' Supplies in general.

P. L. Viallon, Bayou Goula, La.—24 pages—Implements in Bee-Culture, Bees, Queens, etc.

W. D. Soper (successor to A. D. D. Wood), Jackson, Mich.—2 pages—Bee-Keepers' Supplies.

Wm. Hoyt, Ripley, Maine—4 pages—Bees and Queens.

Landreth's Vegetable Garden Seeds, Philadelphia, Pa.—33 pages—Garden Seeds.

Aaron Hunt, Gordon, O.—24 pages—Apiarian Supplies and "Guide to Bee-Keeping."

STATE CONVENTIONS.

Ohio State Convention.

The fifth annual Ohio State Bee-keepers' Convention will be held in the United States Hotel, on the corner of High and Town Sts., Columbus, O., on Jan. 10 and 11, 1888. An interesting programme will be arranged. Reduced rates at the hotel are \$1.50 for each person, double, or \$2.00 per day if single. There will be reduced rates of travel, particulars of which will be given later. It is desirable to know who can be present. Will you kindly notify me by postal card, at Bluffton, Ohio. The following is the programme:

TUESDAY, 9 A. M.—Reading the minutes of last meeting. Receiving members and collecting dues. Reports of the Secretary and Treasurer, and standing committees.

Bee conventions, how to make them a success, and their value to bee-keepers.—A. I. Root. Discussion on the Sectional Brood Chamber and its advantages.—Led by Dr. G. L. Tinker. Reversing, and has it come to stay?—C. M. Kingsbury.

TUESDAY, 1 P. M.—Discussion on Bee-keeping in connection with other pursuits.—Led by F. A. Eaton.

Bee-keeping for women.—Mrs. Jennie Culp. Bee-keeping as an exclusive pursuit.—Dr. C. C. Miller.

TUESDAY, 7 P. M.—Wood vs. tin separators: is it profitable to dispense with either?—Dr. Bease. T-sups and other surplus arrangements in connection with bee-spaces.—E. R. Root.

Discussion on, *Resolved*, That bee-keeping as a business is more profitable than farming. Opening of the question-box.—S. R. Morris.

WEDNESDAY, 9 A. M.—Extracted honey: its production, and the best method of marketing it.—Dr. A. B. Mason.

The commission man and his relation to the honey producer, as affecting the sale and price of honey.—Chas. F. Muth.

WEDNESDAY, 1 P. M.—Tiering-up: its advantages.—J. W. Newlove.

Freezing bees.—C. E. Jones. In-door vs. out-door wintering of bees, and the advantages of the former.—H. R. Boardman.

Election of officers for the ensuing year.

FRANK A. EATON, Sec.

Nebraska State Convention.

The next meeting of the Nebraska State Bee-Keepers' Association will be held on Jan. 11, 12, and 13, 1888, in Red Ribbon Hall, at Lincoln, Nebr. The Lindell Hotel will give reduced rates to members. Those who come should get a receipt from their home railroad agents on starting to Lincoln, as railroad companies require fifty receipts to entitle members to reduced rates. President Ryan requests all members to have questions ready for the first evening, so that they can be arranged in order. The programme is as follows:

What are the essential points in locating an apiary?—J. G. Hodges and J. L. Blanchard.

Apiculture as a profitable and permanent occupation.—A. D. Keller and C. Cealey.

How does bee-keeping pay compared with other occupations?—R. E. Leach and J. Rodgers. How to obtain the most honey in the best marketable shape.—Mrs. J. N. Heater and M. Tower.

How much, if any, comb foundation should be used?—E. Kretzmer and E. Tower.

Diseases of bees, their causes and remedies.—E. M. Hayhurst.

Is spring stimulating advisable? If so, with what?—T. L. Von Dorn and W. J. Lynch.

How best to prepare honey to exhibit for sale or for show.—Mrs. J. N. Heater and E. W. Whitcomb.

Which is more profitable, comb or extracted honey?—A. Johnson and M. D. Abbott.

Increase, natural or artificial?—R. V. Muir and J. F. Polk.

Should bees be frequently examined? and at what temperature should the atmosphere be?—Mrs. L. Marshall and Jas. Jardine.

Spring work with bees.—E. M. Hayhurst.

Fall breeding and spring dwindling.—J. N. Heater and E. Kretzmer.

Honey-plants of Nebraska.—Professor C. E. Bessey, of the State University.

Rearing queens and clipping their wings.—J. M. Young. H. N. PATTERSON, Sec.

BIOGRAPHICAL.

GEO. E. HILTON'S APIARY. AND BIOGRAPHY.

The illustration in the next column shows the apiary of Mr. Geo. E. Hilton, of Fremont, Mich., which contains about 90 colonies of bees. The octagonal building in the centre is the honey house and extracting room. The little piece of walk at the right leads to the dining-room door, and the walk running to the honey-house runs close to the dwelling, which is just cut off at the right of the picture.

The tallest person in the foreground is Mr. Hilton with his favorite hiving basket in his hand. The boy at his right is his little nephew and namesake, Geo. D. Hilton, while Mrs. Hilton stands on the walk further back. A new factory now stands to the right of the buildings, at the back of the lot, and has been built since the picture was taken.

The hives are painted, and so arranged that there is first a red, then a white, then a blue one in every direction, the rows running straight east and west, and north and south; the hives facing the east.

Mr. Geo. E. Hilton is an energetic and progressive apiarist, and we present an

GEORGE E. HILTON.

Illustration to show his personal appearance, and have secured a biographical sketch from which we extract as follows:

Mr. Geo. E. Hilton was born Aug. 25, 1846, in Bedfordshire, England, near the spot where John Bunyan wrote the world-inspiring book, "The Pilgrim's Progress," while incarcerated in Bedford jail. His parents moved to America when he was between 5 and 6 years old.

He says that he was always attracted to bees, and was never afraid of them from his earliest remembrances, and that he "lined" a bee-tree from bees working near the kitchen, when only 12 years of age, and the cutting of that tree resulted in his having all the honey he wanted for the first time in his life. He often said that when he became a man he would keep bees. He often sat by the side of an old log-gum watching the "tireless little workers," and enjoyed it much better than the sports usually indulged in by other boys.

His first colony of bees was a present from his wife; the parties of whom she bought it had another, and he bought that.

This was in the summer of 1877; the 2 were increased to 4 colonies, but being on odd sized frames they were soon transferred to

the American frame, and increased to 6 colonies; but finding too much honey along the top-bars, and learning of the Lang-

stroth frame, they were again transferred, and from that time until the present, his success has been very gratifying. His honey crop was largely in the comb, and for the past 8 years his average per colony has been about 75 pounds. The past season was the poorest one.

Mr. Hilton has a good library of books by the best authors on bee-culture, and takes nearly all the bee-periodicals. He put the first sections of comb honey on his home market which were ever seen there, and now has a large trade with surrounding towns, seldom having to ship to the large cities. He has helped many to start in the business, and Newaygo county is fast coming to the front as a honey-producing county.

A local organization called "The Fremont Progressive Bee-Keepers' Association" exists, of which Mr. Hilton is President. He has always taken great interest in convention work, believing it to be one of the best sources through which to receive and impart knowledge. He has attended the "North American" whenever it has been within his reach, and has never missed a meeting of the Michigan State Convention since his first attendance in 1881. He was elected President of that body in 1886, and re-elected in 1887.

Mr. Hilton, in the Fremont "Indicator," remarks as follows concerning East Saginaw, where the last Michigan State Convention was held:

Space will not permit me to speak of all the favors shown us while there. For cleanliness of streets East Saginaw is next to Detroit. For modern architecture in public and private buildings, taste and ornamentation, certainly she stands at the head. The newspapers, too, gave us every attention, devoting nearly a column morning and evening to the proceedings, and none but favorable comments appeared on their pages, which showed their reporters to be gentlemen in their profession, whether we deserved it or not.

The bee-keepers of Michigan will long remember their visit to East Saginaw. The address of welcome by Mayor H. M. Youmans was enough to make every one happy all through the session. But, not satisfied with this, he invited us in a body to look over the fire department. Here an alarm of fire was sounded two and a half miles away, and in the twinkling of an eye the gas lighted, the horses attached to the hose cart, the doors flew open, and away they went—the whole thing, except the muscles of the men and horses, being moved by electricity.

The Earliest January number of a bee-paper on our desk is the "Canadian Honey Producer," edited by our friend, Mr. R. F. Holtermann. Mentioning his visit to Chicago, and the late convention, he says:

It was pleasing to meet with so many bee-keepers—some old and some new faces. Thanks to Mr. Newman, the editor of the AMERICAN BEE JOURNAL, of Chicago, the accommodation was all that could be desired. The second morning of the convention a party of us paid a flying visit to the office of the AMERICAN BEE JOURNAL, also the Museum of bee-keepers' supplies and curiosities, and went through the factory and ware-rooms of Mr. Newman's supply business. Time would not permit the party to examine all of interest to the bee-keeper and supply dealer, but we felt amply repaid in the information we gained by the inspection of the Museum. Mr. Newman was in very poor health at the time of the convention. His numerous friends will be pleased to hear that he is regaining strength.

QUERIES AND REPLIES.

MOVING BEES IN WINTER.

Written for the American Bee Journal

Query 501.—My apiary is too near the highway, and it is desirable to move the bees a few rods. Can it be done this winter, without danger of loss when they come out for a flight in the spring?—New York.

Yes.—W. Z. HUTCHINSON.

Yes.—JAMES HEDDON.

Yes. The loss in the spring will be insignificant.—J. P. H. BROWN.

Yes, if a board is so placed over the entrance as to make them re-mark their location.—A. B. MASON.

Yes; it can be done on any day when not extremely cold. Bees appear to mark their location during their first flight in the spring.—MRS. L. HARRISON.

Yes. Not a bee need be lost. Remove as far as possible all familiar objects from the old location.—M. MAHIN.

Yes, I have several times moved bees in December, from 1 to 100 rods, with no bad results.—G. M. DOOLITTLE.

Yes, they may be moved now or in the spring, before they have had a flight, without loss from change of location.—G. L. TINKER.

*Yes, if you place some obstruction leaned against the hive, over the entrance, so that they will mark their location.—H. D. CUTTING.

I should prefer to wait till spring, and then move them a few feet at a time till the new location was gained. In any other way I think that some losses must occur.—J. E. POND.

Yes, the loss would be very slight if any at all. Leaning a board against the front of each hive before the first spring flight, might assist in preventing loss.—R. L. TAYLOR.

It can be done at any time if all are moved. The danger from loss by bees losing their bearings is not so great as some think. I have quite often moved colonies only a few feet, with no bad results.—EUGENE SECOR.

I would remove them as early as January, or before they have a chance to fly much. They can be removed at any time by using broad boards to shade the entrances, and thus induce the bees to mark their new locations.—C. H. DIBBERN.

Usually there is no trouble at all in doing this. If anxious, turn the hive about and place a board against the hive so that it will lean over the entrance.—A. J. COOK.

Move them just before flying in the spring, and make their old ground look as different as possible. A board put up in front of each hive after moving will help.—C. C. MILLER.

There will be a little loss even then. When you move them, place a slanting board in front of the entrance, to show them a change of position at their exit. If there is any danger of spring dwindling, do not move them at that time. We have once suffered a severe loss for just such a reason.—DADANT & SON.

Yes, your hives can be moved back as far as you want them without any perceptible loss of bees. Several years ago I was situated exactly as you describe; my apiary was too close to the highway, and people passing were afraid of the bees. I staked off the new yard, and got everything ready so as to place the hives as nearly in their old position relative to each other as was practicable. I then had a man to help me, and each hive was borne between us so steadily that the bees were not aroused in the least. After the hives were all placed in their new location, we cleaned up the old yard of all land-marks as much as possible; and the first warm day thereafter I made some smothered fires of damp straw on the old site, and kept them going till the bees had marked their new location. Some boards or shingles were placed in front of each hive.—G. W. DEMAREE.

Yes; it will be very EASY as well as very "desirable" to move the bees during the winter repose, if they are too near the highway. It is very important that the apiary should be located at a SAFE distance from highways, pathways, and places where damage may result from such location; and if any others are so located, let there be no delay in making the removal. The bees will re-locate the location on their first appearance in spring, especially if a board or bough be placed over the entrance.—THE EDITOR.

PREVENTING QUEENS FROM LAYING IN SECTIONS.

Written for the American Bee Journal

Query 502.—If I have a prime swarm on eight standard Langstroth frames, with starters one inch wide, and transfer the supers from the old to the new hive, will a slatted break-joint honey-board keep the queen from laying eggs in the sections?—Illinois.

It will, if accurately constructed.—J. P. H. BROWN.

Yes.—MRS. L. HARRISON.

I have never tried it, but I should think not.—A. B. MASON.

I think that it would usually, but I have not had experience.—C. C. MILLER.

Not in every case, but if they are good to work in the sections, the queen will seldom go there.—H. D. CUTTING.

It may have a tendency in that direction, but to make a sure thing, it

should be queen-excluding.—W. Z. HUTCHINSON.

Most likely, if the supers are well filled with honey; otherwise we would advise a delay of one or two days.—DADANT & SON.

I have never tried it, but I should say that it would be doubtful, especially if starters used were comb foundation; if of comb, the queen would be less liable to go into the sections.—G. M. DOOLITTLE.

Sometimes yes, and sometimes no. It will depend upon your management otherwise. A queen-excluder is the only safe and sure remedy.—J. E. POND.

Usually, but not always. Why not use a queen-excluder, then assurance is made not only doubly but wholly sure.—A. J. COOK.

No, not in every case. A queen-excluding honey-board, or some comb in the brood-chamber, would be necessary in order to keep the queen out of the sections.—R. L. TAYLOR.

I should prefer, in that case, a queen-excluding honey-board. If supers were put on at once, I should fear that the queen would go into the sections.—EUGENE SECOR.

If the sections transferred from the old hive are nearly ready to seal up, it will; otherwise the queen would be almost certain to lay eggs in the sections.—C. H. DIBBERN.

That will depend upon circumstances. If there are empty combs in the super, and the flow of honey should fail for a day or two, I would expect the queen to enter it and turn it into a brood-chamber. I would prefer to wait before putting on the super, until the bees had got started below.—M. MAHIN.

The slatted break-joint honey-board always has a tendency to keep the queen below, and I have never been troubled with brood or pollen in the surplus department whether these honey-boards were made queen-excluding or not. I am wondering if your fear of getting brood in the sections under the circumstances you mention, is the result of experience or theory. I have practiced this placing over the surplus on swarms, for over 15 years, and I have never been troubled with brood in that way; and I used to do it before we had foundation to put in empty frames. At this season of the year all combs are filled with honey as fast as built, whether built from foundation or otherwise, and there is no chance for the queen to lay in them.—JAMES HEDDON.

No. The habit of bees inclines them to ascend to the highest point in the hive, and when a hive is arranged as described by you, the queen is likely to go into the surplus cases at

the start, and if she finds empty combs of the proper depth of cells for breeding, she will commence business at once, and you will see your plan defeated. Unless you use perforated zinc queen-excluders, you had better defer putting on the surplus cases from the old hive for 4 or 5 days, or until the queen has commenced laying in the newly-built combs below. After that she is not liable to leave the brood-nest with or without a honey-board, as long as she finds room to carry on house-work below.—G. W. DEMAREE.

If the supers are not put on for three days after hiving, the queen is not apt to go above the honey-board to lay eggs in the sections. A great deal depends upon the size of the brood-chamber given. If it has a capacity for less than 800 square inches of comb surface, the honey-board should certainly be queen-excluding. Queens are more apt to enter the sections just before than after swarming, if they have access to them.—G. L. TINKER.]

No; it could not be depended upon to keep the queen from laying in the sections—that can be prevented by using a zinc queen-excluding honey-board. Inch starters in the brood-frames are too small to be satisfactory to the great majority of bee-keepers, who usually prefer either much larger pieces or full sheets.—THE EDITOR.

BEE CONVENTION.

Report of the Southeastern Michigan Annual Meeting.

Written for the American Bee Journal
BY A. M. GANDER.

The annual meeting of the Southeastern Michigan Bee-Keepers' Association was held in the Supervisors' Room of the Court House at Adrian, Mich., on Dec. 15, 1887.

The meeting was called to order by President Howes. The Secretary's report was read and approved, as was also that of the Treasurer. The report of the standing committee to confer with the executive committee of the County Agricultural Society was given by Mr. D. G. Edmiston, who reported that the Apiarian Department of the premium list of the Agricultural Society had been placed in the control of the Bee-Keepers' Association, and that a fairly liberal amount had been allowed the department, which had been arranged in a suitable list for the department.

Some discussions followed the report relative to striking out the part of the foot-note referring to bee-hives, feeders, queen-cages, and to honey being produced in the county, which resulted in a motion for a committee to be appointed to revise the premium list of the department, and to make necessary arrangements with the Fair Society. It was also voted that the portion of the foot-note mentioned above should be stricken out.

The committee as above mentioned is composed of the following: H. D. Cutting, of Clinton; A. M. Gander, of Adrian; and D. G. Edmiston, of Adrian.

The annual membership fees having been raised from 25 cents to 50 cents, at the last meeting, were voted back to the former amount, and 15 members then paid their dues.

Only a partial statistical report for 1887 was secured, being as follows: Number of colonies in the spring of 1887, 307; number of colonies in the fall, 377; number of pounds of wax produced, 173; number of pounds of comb honey produced, 2,515; number of pounds of extracted honey produced, 5,405; and the average price obtained per pound, 14 cents. The average yield per colony, spring count, was 25 $\frac{3}{4}$ pounds, and the number of queens sold was 91.

A committee of three on exhibits was then appointed, and the convention adjourned until 1 p.m.

The convention was called to order at 1 p.m., with President Howes in the chair. There was considerable dis-

cussion on the subject of producing both comb and extracted honey in the same apiary, it being generally thought that the extractor could be used to good advantage in an apiary where comb honey was produced; but not to obtain both extracted and comb honey from the same colony, at the same time.

Mr. Edmiston gave the method practiced by W. Z. Hutchinson, for getting the bees to work in surplus sections, and storing the honey in them.

Mr. Cleghorn gets the bees to enter and work in the surplus chamber, by raising a frame of brood to the surplus chamber for a short time, till the bees get well at work; then he removes the frame, extracts the honey, and returns the frame to the brood-chamber.

The election of officers resulted as follows: President, Dr. Samuel Stevenson, of Mornci; Vice-President, one for each county in the district of the association, as follows: Washtenaw county, Dr. C. F. Ashley, of Ypsilanti; Jackson county, Mr. F. Wilcox, of Jackson; Livingston county, F. L. Wright, of Plainfield; Hillsdale county, E. Goodrich, of Hudson; Oakland county, J. J. McWhorter, of South Lyons; Lenawee county, D. G. Edmiston, of Adrian; Wayne county, M. H. Hunt, of Bell Branch; and for Monroe county, M. Fleming, of Dundee; Secretary, A. M. Gander, of Adrian; and Treasurer, D. G. Edmiston, of Adrian, Mich.

The place for holding the next meeting was decided in favor of Jackson, and it was voted to meet jointly with the State Bee-Keepers' Society. The time for meeting of that society is to be fixed by the executive committee.

Bee-Keeping with Other Pursuits.

Mr. Deer combines poultry with bee-keeping, and find that it works very well. It keeps him busy, as there is plenty of work to do, but he can manage them quite satisfactorily. Horticulture was found to work quite well in connection with bee-keeping, if strawberries be excluded, as they ripen at the busiest time with the bees.

Wintering Bees.

Proper protection on the summer stands seemed to be the preferable way for wintering, but a proper cellar was not without its advantages. Changeable weather in the spring, after the bees are put out, was the main objection to cellar-wintering. If wintered in a cellar, the bees should be kept there as late as possible without injury to them (or as long as they can be kept quiet), to avoid chilling of the brood by early spring changes. All agreed that protection was necessary.

The New Year's Open Door.

MRS. A. GIDDINGS PARK.

Like one who turns some magic key
That holds from his wonderlog sight,
In close shut casket, the choicest gifts
Of gems and jewels bright,—
With eager hand on the portal key
Of the unknown corridor,
And the song of hope in our hearts, we stand
At the New Year's open door.

And we say: "What hast thou in trust for us
That we crave, O glad New Year?
Will your white-robed Winter, your smiling Spring,
Your rose-crowned Summer fair,
Your Autumn bright, bring joy or grief?
Hope's fulfillment, or hope deferred?"
And we eagerly listen, and anxiously seek
For some token seen or heard.

But silence alone gives answer. (Nay,
We ever would have it so.)
And nought is heard in that corridor dim
But the echoes of long-ago!
It is well. It is well that each flitting day
Reveals but its secrets alone,
And the future, though pleadingly importuned,
Withholds from each heart its own.

Ah, enough for us if duty be done
With a brave and honest heart;
Though adversity frown or prosperity smile,
To nobly perform our part.
So keep your counsel, O glad New Year,
Whether good or ill be in store;
May Heaven guide us and guard us e'er—
This we ask and we crave no more.

—The *Etna*.

Mr. Edmiston and Mr. Deer favored the chaff hive, and said that bees wintered as well, or better, in them as any other way.

Mr. Stevenson gave his method of preparation for winter, which was to thoroughly protect the bees on all sides and on top by an outer box with a cover, allowing a space for dry packing-material, and fix them up early or before cold weather sets in.

The Marketing of Honey.

Mr. Deer stated that he had bought honey that was in good condition for market, and on the market in his place, at a much less price than honey could be bought of posted bee-men. He bought of store-keepers at their price, and shipped to other markets at a good profit, showing that the honey was sold by the producer at a far less price than it was worth; thus his local market was rid of the surplus honey, that the unposted bee-keeper had parted with, unconscious or regardless of its value, and at the same time it opened a way for his own product at something near its value.

Mr. Cleghorn favored the appointment of a good business man to look the markets over, and open up avenues by which the honey in the district might be disposed of. Mr. Armstrong also favored Mr. Cleghorn's idea.

Mr. Howes illustrated how certain parties, not posted, brought their honey to market, selling it at less than its value, and when asked why they sell at less than what it is worth, and told what can be obtained for such honey, seemed surprised, and want to know where they can get such prices, or its value. He also stated that such persons will not take a bee-paper and keep posted, as that would cost something, and every penny saved is so much clear gain; but they go on losing dollars and tens of dollars, all for the lack of a little extra energy, and to save the small sum that it would cost to keep posted; yet the same thing happens year after year. The opinion seemed to prevail that those interested should use every influence possible to inform and induce such parties to keep posted.

Miscellaneous Business.

The committee on exhibits then made an enumeration of the various articles on exhibition.

A vote of thanks was tendered for the use of the room in the Court House, and for janitor's services. It was voted not to hold an evening session.

The convention then adjourned to meet at Jackson, Mich., in conjunction with the State Bee-Keepers' Association.

Adrian, Mich.

CORRESPONDENCE.

BEES IN COLORADO.

Alfalfa as a Honey-Plant, the Drouth, etc.

Written for the American Bee Journal
BY WILLIAM WILLIS.

As a partial answer to the questions of Mary A. Goodale, on page 792 of the BEE JOURNAL for 1887, I will give a brief sketch of my experience: In the month of June, 1876, I sent 2 colonies in box-hives without frames or comb foundation, and they filled these hives and stored 30 pounds of surplus comb honey per colony. Last June I sent 8 colonies more that had been threatening to swarm, but were too poor, and I got to this country on June 11, just as the alfalfa was getting in full bloom. I found bees working finely, and was expecting that they would soon send out several swarms; but in this I was disappointed, as I soon found that they had crowded the hive with honey so that the queen could not do her work; so the result was only 3 late swarms, and 50 lbs. per colony, of comb honey. Bees gather honey from alfalfa here, and I think they will wherever it is irrigated. We think here that we are not dependent upon the showers for our honey crop, as the best honey was gathered in June and July, before the rains began; but my bees continued to fill the sections till Oct. 10.

Montrose ♀, Colo., Dec. 20, 1887.

FIRE INSURANCE.

Wintering Bees and Insuring them against loss by fire,

Written for the American Bee Journal
BY A. C. WALDRON.

My bees are in the cellar on a platform raised about 3 feet from the cellar bottom, with the entrances wide open, and with a cover and blanket on, the same as when on the summer stands. They have natural stores, mostly gathered from fall flowers and buckwheat. I keep the temperature about 34° Fahr., as near as I can. I have a ventilator connected with the chimney, and when it is too warm I open that, and when it is cool I close it; if too warm, I put a piece of ice in the cellar. My bees are quiet, and there are but few dead ones. They do not seem to be disturbed by any one entering the cellar for vegetables, unless they are jarred.

I tried to insure my bees against loss by fire while in the cellar, but the company rejected that clause, saying that they did not insure bees. Has any one had any experience in that line? I would like to hear from some of the many bee-keepers as to their method of wintering bees. Will Mr. Powell or Mr. Lee describe their method in the AMERICAN BEE JOURNAL? Will the editor please give the size of the standard Langstroth brood-frame?

Buffalo, ♂, Minn.

[The size of the standard Langstroth frame is $9\frac{1}{8} \times 17\frac{1}{8}$ inches, outside measure.—Ed.]

WINTER WORK.

Feeding in Winter—Workshop—Hives, Frames, Crates, &c.

BY GEO. A. STOCKWELL.

Very little can be done with the bees in winter, in fact nothing in zero weather, but on warm, sunny days they may be fed, if in danger of starving; and bees in-doors may be placed on out-door stands, that they may have opportunity to fly and void excreta, an act never committed in the hive by bees in health, though they may remain in confinement from November to April. A "purifying flight" is a great help.

Winter Feeding.

If feeding be necessary, place warm food in a wide-mouth bottle, tie strainer-cloth over the mouth, and invert on the top of the frames. The bees will take the food as it drips, even faster, running their tongues through the cloth. That they may have access to the full width of the mouth of the bottle, place wire cloth between the frames and the bottle. The honey, or whatever is fed, will grow lower in the bottle rapidly. The feeding must be done on warm days, and in the middle of the day an entrance feeder may be used. This permits the bees to enter from the hive, and excludes outside bees.

Making Hives and Frames.

This is all that can be done with the bees themselves, but there is a great variety of other work in their behalf that can be, and ought to be done now. One of the attendant attractions of bee-keeping is its mechanical requirements.

Implanted and firmly rooted in many a Yankee is the desire to whittle, to play with sharp-edged tools, to spoil good lumber, "to make something." To such persons bee-keeping is adapted. The making of hives and frames, and a dozen other things needed in

the apiary, is simply pastime. Hives and frames may be bought in the flat, but their nailing is recreation. What man with a mechanical twist in his mind, does not like to drive nails, especially the clean, cleaving, clinching wire nails? With the hives and frames in holders, how merrily the bee-keeper sends them home (to the tune of a whistled melody) with a hammer of the right "heft!"

Apiarian Work-Shop.

The bee-keeper's work-shop is an institution by itself. Let us suppose that it is down under somewhere in a sheltered, cosy nook; that there is a good stove in it, or better, a big chimney with wide fire-place mouth. What a place to work, to whistle and to whistle, to sing the song of the saw, and to make that measured rub-a-dub with the playful hammer! And what satisfaction there is in the possession of a few good tools kept bright and sharp! If every farmer's boy had a place like this to attract his wandering wits, he would be less eager to fly to the city.

But there are 50 colonies of bees out in the orchard snugly packed in saw-dust, and tucked in by a snow-comforter. In May or June they will swarm, and 50 hives must be ready. No time then to hunt up a hive. As soon as spring has come to stay, place the empty hives where they are to stand, each with full equipment.

Painting the Hives.

The hives should be painted. We depend upon the eye for a great deal of enjoyment. Get a pot of red paint, and a pot of white paint. After one hive is painted red, pour in enough white to fill the red pot again. The next hive will be a little lighter, and by the time the paint is all used, the last hive will be nearly white. Any man with an appreciative eye will say that the row of hives from bright red to white is an attractive feature in the landscape. Many a man will say, "I have not time for such nonsense," but he ought to have time to paint his hives, and it costs no more time or money to make hives attractive. If it should cost a little more, it pays—it pays to make things cheerful. I believe it pays to paint a hive two colors, if the bee-keeper wishes to sell bees—if he wishes to interest others in apiculture. Bright colored hives will win a customer where the old weather-stained boxes will make no impression.

Nailing Frames, Crates, etc.

The 50 new hives must have 10 frames each, or 500 in all. With a nailing block, a man may nail two a minute. Then they must be wired, and then the foundation put in—500 sheets—a hundred pounds. No small

job is either, but only play in the sunny work-shop. If comb honey is the object, 50 crates will be required; a hundred had better be on hand, and 300 separators; or you may use wide frames, 6 in a hive, or 300 in all. Then the section boxes—1,500 for the first honey catch, in each of which is a starter, or a full sheet of foundation.

All this appears to provide for a mountain of work, but it is merely by-play between chores—between milking and feeding times.—*Country Gent.*

N. A. B. K. SOCIETY.

Some Opinions of its President on Several Subjects.

Written for the American Bee Journal

BY DR. A. B. MASON.

Mr. C. F. Muth, on page 787 of the BEE JOURNAL for 1887, says that he is "sorry that Toledo was selected for the next place of meeting of the North American Bee-Keepers' Society, and not Cincinnati." Such an expression would naturally be expected from a selfish person, but we all know that Mr. Muth does *not* belong to that class. He has the interest of the Society at heart, and had I known as much of the matter at the time Toledo was selected, as I do now, I should have worked hard, if necessary, to have had Columbus, O., selected. I did not make the motion, or even invite the Society, to meet here, but was certainly in favor of it, believing it to be the most acceptable place for those usually in attendance, being as it is midway between the East and the West, and *very* convenient for Canadian delegates.

As to the time, I was not aware of the time and place of holding the Ohio Centennial Exposition next year. It is to be held at Columbus, commencing Sept. 4, and continuing until Oct. 19, making 40 days, and not at Cincinnati, as would seem to be indicated by Mr. Muth; and I believe there are to be reduced railroad rates on all articles intended for the Exposition, for three months previous to Sept. 4, the time of the beginning of the Exposition, and I presume there will be reduced passenger rates on most, if not all railroads in the United States and Canada during the forty days of the Exposition, and for several days previous to and after, so that it will probably be cheaper to get a railroad ticket to Columbus and return, than it would be to Toledo and return, except for those living near Toledo; and notwithstanding my desire to have the meeting here, I am decidedly in favor, if it is possible to make the change, to have it held at Columbus during the Centennial Exposition.

Cincinnati is 116 miles, and Toledo 124 miles from Columbus, and as a larger number of bee-keepers attend the annual convention from the North than from the South, it seems to me that Toledo, at any time, is a more desirable place to meet than at Cincinnati, and especially so for those wishing to attend the Centennial Exposition; but if it can be changed, it will be better for all except those living near Toledo who do not care to visit the Centennial, for reduced rates can be taken advantage of to a greater extent than was possible to the Fat Stock Show at Chicago, and it is hardly probable that reduced rates can be had for Toledo.

It is not probable that any plan could be suggested for making the change, that would meet with universal approval, but I would suggest that we vote upon the matter, and that each member of the Society be requested to send a postal card to the President or Secretary, giving his vote for or against the change.

The only ones that can have a "reasonable excuse" against the change, except as above stated, will be the Michigan and Canadian members, and we all know they are wide-awake and always in favor of "good thing" when they see it.

The New Constitution and By-Laws.

I have this morning re-read for the third time the "Constitution and By-Laws" that the editor of the AMERICAN BEE JOURNAL presented to the convention at Chicago last November, with which to organize "The Inter-National American Bee-Association;" and each time I read it I was more and more thoroughly surprised that the committee to which it was referred, on my motion, composed as it was of such men as Prof. Cook, W. Z. Hutchinson, and A. I. Root, should "recommend that the consideration of the matter be postponed for one year."

I will admit that I have always been opposed to the converting of the present organization into one composed of delegates from "affiliated local associations," for fear it could not be made a success; but had I read what Mr. Newman had prepared, and which was referred to the above committee, I should, with some slight alterations, have moved its adoption. It seems to me that to have adopted it would have been making quite a step towards a thorough organization of the bee-keepers of the Continent, and I hope that this or some similar plan will be adopted at the next meeting.

Auburndale, Ohio.

[We think that the change suggested can very easily be made, and it should be done. The Executive Committee

should confer by letter, and, if they deem the change desirable, they have full power under the Constitution to make it, and the members of the Society will thank them for doing their duty promptly and efficiently.

As to the new Constitution and By-Laws we presented at the Convention, nothing will be lost by a full discussion of each important feature before its adoption.—Ed.]

THE PAST SEASON.

Results of the Year in an Apiary of 50 Colonies.

Written for the American Bee Journal
BY J. F. LATHAM.

In the spring of 1887 I had 50 colonies of flying bees, the number of colonies that I put into winter quarters the fall previous. After they had become well advanced in brood-rearing, 2 colonies became queenless, and their bees and brood were given to other colonies. I sold 2 colonies, leaving 46 with which to commence the season's operations.

For a week after the willow bloom had become abundant, my bees never displayed more energy in building up. Inclement weather followed, and its consequent, dwindling. Soft maples yielded considerable nectar, and the bees worked on their bloom quite freely; but the apple bloom was a failure, its nectar being absorbed by a ten-days' rain-storm. As there is but little bloom during the interval from fruit-bloom to that of wild raspberries and white clover, constant nursing was required to get the bees in proper condition for the surplus season of about 35 days, which is about the average length in this vicinity.

A week of very fine weather during the first part of June inaugurated swarming with a rush; but a week of cold rain following, put a "dampener" on active operations for awhile; then followed intervals of rain and sunshine, until July 7, when swarming closed with 13 new colonies from 18 swarms, thus increasing my apiary to 59 colonies.

During the remainder of July the rainy weather retarded the storing of surplus, but 5 of the new colonies stored sufficient honey for winter use. By Aug. 20, I had removed the surplus fixtures. The fall bloom was abundant, and the weather was favorable, so that all of the colonies, with the aid of a distribution of 275 pounds of granulated sugar made into syrup, obtained enough for winter stores.

I have sold, so far, 753 pounds of honey in the comb, and have, at a safe estimate, 500 pounds on hand; not a very favorable showing in favor of a "specialty" in bee-keeping, with the production of "comb honey" for a basis. About 500 sections of my crop this year was filled and finished to the perfection desirable in a first-class article; the balance of the sections will weigh about $\frac{3}{4}$ of a pound each.

I have now 59 colonies packed on the summer stands for wintering, and, from outward appearance, they are enjoying the quietude desirable for safety.

Cumberland, 9 Me., Dec. 19, 1887.

ALSIKE CLOVER.

Directing When and How to Sow the Seed.

Written for the American Bee Journal
BY M. M. BALDRIDGE.

The time is close at hand when honey-producers should see to it that their neighborhoods are supplied with the seed of Alsike clover—the best honey-plant, on many accounts, now known

ALSIKE CLOVER.

in the United States. The following has just been received by the writer from a honey-producer near Terre Haute, Ind.:

"Having read several articles from your pen in regard to Alsike clover, I now desire to ask you for some advice. I have now located my apiary of 96 colonies upon a 30-acre farm, close to the limits of this city. Some 10 acres of this land were seeded down two years ago the coming spring, with timothy and red clover. The crop

then growing was oats, and the summer being dry, the grass seed did not make a good catch. It was, therefore, re-seeded last spring with timothy and red clover, where necessary, and a pretty fair crop of hay was secured; but, in many places, owing to the severe drouth, the grass is once more badly injured. In general, however, the seeding is in good condition. Now I wish to seed this land with Alsike clover. Would it do to sow the Alsike upon it, and without any special preparation, say in February? If so, how much seed would you advise to the acre?"

In reply I would say, that no special preparation of the land is necessary for Alsike. Yes, sow the Alsike in February, or at any other time the present winter, or very early in the spring. The snow and spring rains will then drive the Alsike seed into the ground, and will insure its certain and early germination. And, besides, you will stand a good chance to get more or less honey from the Alsike blossoms the present year.

Two pounds of the Alsike seed will be plenty for an acre when thus mixed with red clover and timothy—and this is the proper way to grow Alsike successfully in a climate subject to drouth. The red clover is needed for shade during a dry spell of weather, and the timothy is also needed to hold it up and away from the ground. When thus grown, the Alsike will grow and produce honey in case the red clover grows. If wanted for seed, never mind the timothy nor the red clover. If wanted free from timothy seed, you can cradle off the heads of the timothy before you cut the Alsike, and this will secure that result.

It is not very generally known that pastures and meadows can be supplied with Alsike, at pleasure, but such is the fact. And a very good time to seed them is also in July or August. If we then have plenty of rain, the Alsike will make such a growth during the autumn, as to insure a crop of both hay and honey the following season.

It will pay honey-producers generally, wherever red clover and timothy can be grown, to give Alsike clover a thorough and immediate trial as herein indicated. And whether you have or have not land of your own to give it a trial upon, it will also pay you handsomely to induce all your neighbors, within bee-flight of your apiary, to give it a trial for simply its hay and pasture. One of the very best and most successful ways to do this is to place the "Alsike Clover Leaflets" in their hands, so they can acquaint themselves with its value to them as a hay and pasture plant. The Leaflets are by no means expensive, and they can be

had at the office of the AMERICAN BEE JOURNAL. Please give them a trial. St. Charles, 8 Ills.

PACKING BEES.

Some Practical Advantages of the System.

Written for the American Bee Journal
BY SAMUEL RAU.

On page 788 of the BEE JOURNAL for 1887, is an article on the above subject by Mr. J. A. Buchanan, with which I cannot quite agree. This may not seem altogether strange, as we have long since heard that doctors will disagree.

Mr. B. commences by asking, "What is there in the idea of packing bees for winter?" and says that he voices the answers of a great many bee-keepers in his locality when he says, "Nothing at all." Astonishing revelation!

Then to clinch the argument on both sides of the problem, he asks: Why is it that we see, after a terrible, long, cold winter, so many reports like the following? "I put a splendid apiary into winter quarters; the hives were thoroughly packed after the most approved manner, but there are only a few feeble colonies left to tell the story;" and thereupon concludes within himself that, "when I see such frequent reports like the above, it is 'giving away' the packing system without reserve."

He then attempts to account for the bees dying in packed hives, during long and severe winters, by saying that the sun cannot revive them sufficiently during "let up" weather to make cleansing flights. Well, that would depend upon how much of a "let up" there was, whether bees in a packed hive could make a cleansing flight or not.

I do not want my bees to fly out every time a little sunshine strikes the hives, or I might get too much of a good thing; and just here is where the packing serves a good purpose—there is a more uniform temperature in a packed hive, independent of surrounding circumstances. But, if my bees are very much in need of a cleansing flight, I remove the covers, during "let up" weather, and allow the sun to shine upon them, and I assure you that they wake up soon enough for all practical purposes.

Bees in a single-walled hive must consume more food to enable them to keep up enough animal heat to keep from perishing in severe weather, and consequently they need more cleansing flights. Then if Old Sol's smiles are too long deferred, it plays sad havoc with the poor bees that are domiciled

with but $\frac{1}{2}$ of an inch between them and Boreas' chilling frowns.

It seems to me that it would be just as reasonable to argue that a house without lining would be as comfortable during winter in our climate, as one that was duly lathed and plastered, because perchance a few rays of the sun would have a more animating influence upon it than if the walls were thicker. But I think that most reasoning people would at once conclude that the cold would influence it as readily, and as there would be a great preponderance of cold weather, the bad results would out-weigh the good a thousand fold.

I think that it is not best to jump so suddenly into extreme conclusions, if disaster has at times befallen bees in our extreme climate, that were duly packed, for there are other factors than this one of packing, in the wintering problem, which it is not necessary to enumerate here.

I have had all the experience that I want, in trying to winter bees in single-walled hives. I have lost hundreds of dollars worth of precious bees in that way, and I want "no more in mine," of that thing. More than 20 years of sad experience in that line, confirms me in the belief that trying to winter bees, unprotected, on the summer stands, is no paying business in this section of the country, to say the best for it.

I want the brood-chamber contracted according to the size of the colony, with a Hill's device and a good cushion on top, and 3 or 4 inches of good, dry packing around the outside of the hive, using an outer case for that purpose, with a water-proof roof and a proper entrance; then, for some reason or other, I can sleep much better at night, when the cold winds howl about my windows, and the mercury goes below zero. More than that, I want the packing left on until warm weather has come to stay, which is about the time I begin to think of making preparations for putting on the surplus arrangements.

After several years' experience, I find that spring packing serves a very useful purpose during brood-rearing, and I believe that Mr. Hutchinson is right in recommending spring packing for colonies that have been wintered in the cellar. It makes a good deal of labor, but it will pay well in dollars and cents for the time spent. Our changeable climate often seriously interferes with successful brood-rearing, but by this kind of protection we can, in a measure, counteract these untoward circumstances; and more, where this is done there will be less occasion to talk about spring dwindling.

Columbiana, 8 Ohio.

BEE CELLAR.

Great Mortality among Bees. What is the cause of it?

Written for the American Bee Journal
BY A. PINKERTON.

I put 156 colonies into the cellar last winter, and I think that I carried out between 2 and 3 bushels of dead bees during the winter and spring. Some of the hives seemed to have ten times as many dead bees in front of them as others. Will some one please tell me the cause for this great mortality of bees in my cellar?

I will give a description of my bee-cellar: The size is 17x24 feet, and 7 feet high. It is divided into three rooms, with building paper, but I leave the doors open between them, except when I am carrying bees in and out. I have one under-ground ventilator entering the south room; it is made of 4-inch tiling. Each of the two north rooms has a ventilator put in through the window; these are made of boards, and are 4 inches square inside. Then there is one of the same kind on the east side. I put one down on the outside, with an elbow on it, and run it under the wall; it comes about 4 feet inside the wall in the bottom of the cellar. In very cold weather I partly close, and sometimes entirely close, both of the north ventilators, but leave the others open. The mercury ranges from 38° to 54°, but generally it is about 44°. Is such ventilation injurious to bees if the cellar is kept at the right temperature? I have 122 colonies in the cellar now, that I put in on Nov. 17 and 18. They are very quiet, but there are many dead bees in front of some of the hives.

Marshalltown, © Iowa.

[No; such ventilation ought not to be injurious to the bees.—Ed.]

POOR SEASON.

White Clover Killed and Bass-wood Becoming Scarce.

Written for the American Bee Journal
BY L. G. REED.

My 45 colonies of bees are packed on the summer stands. My surplus for the past season was 237 pounds from 37 colonies, spring count; the poorest season ever known in this section; but my enthusiasm is not chilled any yet, and I shall try and make up next season what I have lost this season; although I do not look for big results any more in this vicinity, until there is a change in the climate. The long, dry summer and cold, snowless winters

have nearly annihilated the white clover; this being our main source for surplus honey.

There used to be large quantities of basswood abounding on the bottoms of our streams, but that is a thing of the past, and what little there is left does not seem to yield any nectar, for I have watched them closely for the past five years, during its bloom, and I have not found bees working on it to any extent during that time. I can well remember, when a boy, of going among the basswood and finding them just roaring or swarming with bees.

I am well satisfied that our farmers ought to take hold of this thing, and plant for honey, the same as for other crops, and thus make bee-keeping much more profitable.

Kent, O., Dec. 24, 1887.

BEEES AND GRAPES.

The Grape Industry in Ohio, and the Baltimore Oriole.

Written for the American Bee Journal

BY G. A. ADAMS.

One can but laugh at the poor old man, mentioned on page 803 of the BEE JOURNAL for 1887, who "lost the entire products for two years of fifty vines taken by the bees!" and who conceived "that the entire grape industry has been almost entirely killed in Ohio" by the bees. We must laugh, for we cannot help it. Such credulity, such alarm, and such a mighty crop of grapes! Fifty vines! Now the bees must go!

I wonder what the writer of the above quotations would think, if he were to be taken into a township east of Cleveland, in which are more than 2,000 acres of grapes being planted. South of here, on the Maumee river, is one farm that has 20 acres; another that has 12, and dozens that have from 1 to 6 acres; and then the islands near Sandusky, O., send grapes to Toledo every fall by the steamboat load.

The Ohio State Horticultural Society has just held its annual meeting at Toledo. The opinions of such observers as Geo. W. Campbell, the Secretary, and other close observers, was declared to be, that the "Baltimore oriole" is the "chap" that opens the most of the grapes, doing it before such wisecracks, as the Iowa man, are out of bed.

I have a little vineyard of about an acre, and though there were 50 colonies of bees within 20 rods of it, they opened not a grape, nor troubled me in the least. The oriole had begun its work before I began picking, and of course the bees followed it. But the

oriole disappeared as soon as picking commenced, and I sold over a ton of grapes from the vineyard.

That does not look as if the industry was destroyed, or even injured by my neighbor's bees. Do send the Iowa man the facts, before he gets himself into a world of trouble, for not using his eyes before he "jumped."

Perrysburg, Ohio.

[Quite often the "ignorant ranting" of such scribblers as the one referred to by us on page 803, gets men into trouble. Such stupid "blunders" have made whole cities blaze from the torch, have put men and women to the "rack," have set armies to fighting, and have often done untold mischief. It is deplorable, that under the full blaze of the light of a nearly-completed "nineteenth century," such opinions and advice should find place in a public journal. The *Messenger* should take care and see that its "advice" is not "carried out," or there may be more "trouble" for it than it expects.—Ed.]

HIVES AND FRAMES.

Points in Favor of the Large Hives and Frames.

Written for the American Bee Journal

BY A. L. LEACH.

Mr. J. M. Hambaugh, in his article on page 804 of the BEE JOURNAL for 1887, makes some points in regard to large frames, to which I wish to add a little. Large hives and frames have their advantages over small ones, in most good honey-producing localities. I have been able to get larger returns from them, and with less labor.

In Mr. Quinby's book, in 1865, he referred to large hives, non-swarmers, etc. In 1883 I made four different sizes of frames from the Langstroth size up to $9\frac{3}{4} \times 20\frac{1}{4}$, of which size I can use the same number as of the standard Langstroth, without getting too much stores lodged in the brood-nest, in the way I use them. I like this one better than a deep, square frame which I have used in the same yard, and which is of about the same capacity.

I also think that the sectional brood-chamber is a good small-frame hive, which I believe will be best in some localities, especially where one gets his returns from a large number of colonies.

In reply to a question which appeared in the AMERICAN BEE JOURNAL about last February, in regard to non-

swarming hives, Dr. Miller said that it was for me to demonstrate. I am not quite ready to say that I have found it, but I expect to do so soon. No doubt there are many who would like to know the advantages they have missed by not knowing all they could do with a large frame. Let us hear more from those using large brood-chambers.

Dwight, Ills.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*
 Jan. 7.—Susquehanna County, at New Milford, Pa.
 H. M. Seeley, Sec., Harford, Pa.
 Jan. 10.—Cortland Union, at Cortland, N. Y.
 R. L. Weaver, Sec., Dryden, N. Y.
 Jan. 10, 11.—Ontario, at Woodstock, Ont.
 W. Couse, Sec.
 Jan. 10, 11.—Ohio State, at Columbus, Ohio.
 Frank A. Eaton, Sec., Bluffton, O.
 Jan. 11.—Nebraska State, at Lincoln, Nebr.
 Henry Patterson, Sec., Humboldt, Nebr.
 Jan. 17, 18.—N. W. Ills. & S. W. Wis., at Rockford, Ill.
 D. A. Fuller, Sec., Cherry Valley, Ills.
 Jan. 18, 19.—Vermont State, at Burlington, Vt.
 R. H. Holmes, Sec., Shoreham, Vt.
 Jan. 17-19.—New York State, at Utica, N. Y.
 G. H. Knickerbocker, Sec., Pine Plains, N. Y.
 Jan. 20.—Haldimand, at Cayuga, Ontario.
 E. C. Campbell, Sec., Cayuga, Ont.
 Jan. 25, 26.—N. E. Ohio, Northern Pa. and W. New York, at Meadville, Pa.
 C. H. Coon, Sec., New Lyme, O.
 Apr. 24.—Des Moines County, at Burlington, Iowa.
 John Nau, Sec., Middletown, Iowa.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

SELECTIONS FROM OUR LETTER BOX

Bees Wintering Well.—Chas. D. Barber, Stockton, N. Y., on Dec. 22, 1887, writes:

My bees are wintering well, and have plenty of honey. I have them in the cellar, and a few bees crawled out of the hives and sipped some cider for 3 or 4 days.

Temperature in a Bee-Cellar.

—H. Hastings, Willapa, Wash. Ter., on Dec. 14, 1887, writes:

Bees did splendidly here the latter part of the season, several of my colonies storing over 100 pounds of honey in the sections, and nearly all have stored honey since July. They have plenty of stores for winter. I have 57 colonies in a bee-house, double-walled and packed with sawdust, and it is too warm for the bees. It is difficult to keep the temperature below 50° above zero. I open the door every evening and leave it open all night, and in the morning the temperature is about 45°. The weather is so warm that it is difficult to keep the tempera-

ture low enough. Every evening I find it 50°, and sometimes above that. I have the house well ventilated, but the weather is so warm that it is difficult to control the temperature. What shall I do? I think I will put the bees out, if the weather does not change soon.

[Either the cellar may be cooled by placing some ice in it, or the bees may be placed on the summer stands.—Ed.]

Added many Dollars to his Income, etc.—C. Theilmann, Theilmanton, Minn., on Dec. 19, 1887, writes thus, when renewing his subscription for 1888:

I never paid a dollar more cheerfully, as you have put many dollars into my pocket, by advising bee-keepers to wait for good prices for the past crop. I would probably have sold one-half of my crop at about 12½ cents per pound, but I held it, on the strength of your advice, and sold it for from 15 to 20 cents per pound. Please accept my thanks.

So far we have had nice weather, excepting a couple of cold spells, with 33° below zero on one of them, and about 4 inches of snow; but the last 24 hours it has been snowing, and is still at it. The snow is about one foot deep, and 28° above zero.

An Apicultural Treasure.—Geo. McCormick, Russell, Iowa, on Dec. 26, 1887, says:

I disposed of my bees two years ago, but I cannot afford to do without the AMERICAN BEE JOURNAL. Its attractive and convenient form, its able editorials, and its vigorous defense of bee-keeping against the enemy, together with the masterly discussions of its excellent correspondents, all go to make up a paper that is a treasure to progressive apiarists, and can be read with profit by all lovers of progress.

How the Bees are Wintering.—John Nebel & Son, High Hill, Mo., on Dec. 28, 1887, writes:

At this date our bees are quietly resting in the cellar; they seem to be in almost a dormant state. The temperature in the cellar has ranged from 35° to 40° in the past two weeks; the temperature out-doors this morning is 6° below zero. The mercury fell 40° in 12 hours. We think that bees wintering in the cellar will get through this winter in a fair condition. The past season has been so poor that bees did not make enough to winter on,

especially to winter out-of-doors, with so few bees and insufficient stores, in which condition all the colonies were, that were not heavily fed during August.

Fully three-fourths of the bees in this county died during October and November, long before cold weather began. When inquiry is made now as to how the bees were getting along the last time when examined, we get the pitiful answer that they are all dead—starved! With a great deal of extra work and feeding we have now 200 colonies (100 in each cellar) wintering, that we think will come out in the spring in good condition. Has the loss in bees been as great everywhere? Will bee-keepers, when sending a report, also please state about what the losses of bees are in their vicinity?

Well Provided with Food.—W. Addenbrooke, North Prairie, Wis., on Dec. 29, 1887, writes:

I wintered 130 colonies without the loss of a single colony, and in the spring I sold 22 colonies, which left 108. These I increased to 120, which are now wintering in the cellar, all well provided with stores from buckwheat. They were only able to make a fair living until buckwheat blossomed, so that alone saved me a large amount of feeding. My bees stored only 200 pounds of white clover honey in sections. I hope for a better season the coming year.

Fastening Foundation.—E. F. Rowe, Granite Falls, Minn., on Dec. 23, 1887, writes:

To fasten foundation in sections I cut it the size wanted, fold the section, place the foundation in it from left to right about ¼-inch beyond the saw cut, and hold it firmly with the left hand. I fasten it with a putty chisel, or any round, smooth instrument dipped into a saucer of extracted honey, and rub lightly at first over the foundation, and increase the pressure, rubbing the foundation down, up to and a little beyond the saw cut. I then bend the foundation to an upright position. I think this way is as quick, and will give as satisfactory results as any.

Raspberries for Bees.—Walter Harmer, Manistee, Mich., writes:

In reply to the query of C. A. Bunch about raspberries, on page 735 of the BEE JOURNAL for 1887, I would say that I have cultivated the "Philadelphia" for about 5 years, and they have only winter-killed a little one winter,

and that was the last one. It is a large purple berry when well ripened, and for a local market I think it cannot be surpassed. Bees work on them in season, and by placing the hives between them on low stands, they afford considerable shade.

Bee-Keeping in Texas, etc.—

B. F. Carroll, Dresden, Texas, on Dec. 20, 1887, writes:

Last year the drouth cut short all crops, but we got half a crop of honey, and bees went into winter in good condition. In April I had 50 full colonies of pure Cyprian bees, and as it was very dry, I fed a barrel of sugar. The drouth continued until Aug. 27, when the great flood of 18 inches of water fell in eight hours. By this time my bees were very weak, many queenless, no drones, and not 5 pounds of honey per colony. Many colonies dwindled away, and now I have 30 colonies.

I sold 4 colonies for \$40, and for 10 queens, \$10. I fed 300 pounds of sugar at 7 cents a pound, \$21, and I will have to feed 300 pounds more as soon as Jan. 15. Corn averaged 10 bushels per acre; wheat 5 bushels; oats 10 bushels, and cotton one-sixth of a bale. I have lived here for 40 years, and this year has been nearer a complete failure than any other. It will be "nip and tuck" for many of us farmers to make another crop.

CONVENTION NOTICES.

☞ The Des Moines County Bee-Keepers' Association will hold its next meeting on April 24, 1888, at Burlington, Iowa. JOHN NAU, Sec.

☞ The annual convention of the Vermont State Bee-Keepers' Association will be held at the Van Ness House, in Burlington, Vt., on the Jan. 18 and 19, 1888. R. H. HOLMES, Sec.

☞ The Ontario Bee-Keepers' Association will hold its annual meeting at Woodstock, Ontario, on Tuesday and Wednesday, Jan. 10 and 11, 1888. W. COUSE, Sec.

☞ The Hardin County Bee-Keepers' Association will meet at the Court House in Eldora, Iowa, on the second Saturday in each month, at noon (12 o'clock), until further notice. J. W. BUCHANAN, Sec.

☞ The Cortland Union Bee-Keepers' Association will hold their annual meeting at Cortland, N. Y., on Tuesday, Jan. 10, 1888, for the election of officers and to transact such business as may come before the meeting. All bee-keepers are invited. R. L. WEAVER, Sec.

☞ The Susquehanna County Bee-Keepers' Association will meet at New Milford, Pa., on Jan. 7, 1888. Subjects for discussion: "The Best Way to Prevent Swarming" and "Is it Advisable to Italianize Colonies?" All bee-keepers are cordially invited. H. M. SEELEY, Sec.

☞ The annual meeting of the Northwestern Illinois and Southeastern Wisconsin Bee-Keepers' Association will be held in G. A. R. Hall, corner of State & North Main Sts., in Rockford, Ills., on Jan. 17 and 18, 1888. Dr. Miller will be present, and a good programme is in course of preparation. D. A. FULLER, Sec.

☞ The Northeastern Ohio, Northern Pennsylvania and Western New York Bee-Keepers' Association will hold its ninth annual convention in the Commercial House Parlor, in Meadville, Penn., on Wednesday and Thursday, January 25 and 26, 1888. Reduced hotel rates have been secured. C. H. COON, Sec.

Business Notices.

OUR CLUBBING LIST.

We supply the **American Bee Journal** one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

	Price of both.	Club
The American Bee Journal	1 00.	1 00.
and Cleanings in Bee-Culture	2 00.	1 75
Bee-Keepers' Magazine	1 50.	1 40
Bee-Keepers' Guide	1 50.	1 40
The Apiculturist	2 00.	1 80
Canadian Bee Journal	2 00.	1 80
Canadian Honey Producer	1 40.	1 30
The 7 above-named papers	5 40.	5 50
and Cook's Manual	2 25.	2 00
Bees and Honey (Newman)	2 00.	1 75
Binder for Am. Bee Journal	1 60.	1 50
Dzierzon's Bee-Book (cloth)	3 00.	2 00
Root's A B C of Bee-Culture	2 25.	2 10
Farmer's Account Book	4 00.	2 20
Simmons' Non-Swarming	1 50.	1 25
Western World Guide	1 50.	1 30
Hedden's book, "Success,"	1 50.	1 40
A Year Among the Bees	1 75.	1 50
Convention Hand-Book	1 50.	1 30
Weekly Inter-Ocean	2 00.	1 75
Iowa Homestead	2 00.	1 90

One yearly subscription for the **AMERICAN BEE JOURNAL** must be ordered with each paper or book, in order to take advantage of the prices named in the last column.

We pay 20 cents per pound, delivered here, for good Yellow Beeswax. To avoid mistakes, the shipper's name should always be on each package.

We Supply Chapman Honey-Plant seed at the following prices: One ounce, 40 cts; 4 ounces, \$1; 1/2 pound, \$1.75; 1 lb., \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Sweet Clover, (*Melilotus alba*), furnishes the most reliable crop of honey from July until frost, and at the same time it furnishes the most delicious honey, light in color, and thick in body. It may be sown in waste places, fence corners, or on the roadside, at any time of the year.

Sow two years running, on the same land, and the honey crop will be without intermission. Money invested in Sweet Clover Seed will prove a good investment. The Seed may be obtained at this office at the following prices: \$6.00 per bushel (60 lbs.); \$1.75 per peck, or 20 cents per pound.

Yucca Brushes are employed for removing bees from the combs. They are a soft, vegetable fiber, and do not irritate the bees. We can supply them at 5 cents each, or 50 cents a dozen; if sent, by mail, add 1 cent each for postage.

Red Labels for one-pound pails of honey, size 3x4 1/4 inches.—We have now gotten up a lot of these Labels, and can supply them at the following prices: 100 for \$1.00; 250 for \$1.50; 500 for \$2.00; 1,000 for \$3.00; all with name and address of apiculturist printed on them—by mail, postpaid.

Honey and Beeswax Market.

CHICAGO.

HONEY.—We quote: White clover 1-lb. sections 18@20c.; 2-lbs., 16@18c.; dark 1-lb., 17@18c.; 2-lbs., 15@16c. Extracted, firm at 7@10c. depending upon the quality, and style of package. Dark, 2 or 3 cts. below above quotations. Receipts light and demand fair.

BEEWAX.—22@23c.

Dec. 20. S. T. FISH & CO., 189 S. Water St.

CHICAGO.

HONEY.—Prices range from 18@20c. for best grades, with light demand; 2-lb. sections, 15@16c. Dark is not wanted. Extracted is steady at 7@10c., according to style of package.

BEEWAX.—20@23c. R. A. BURNETT,

Dec. 7. 161 South Water St.

DETROIT.

HONEY.—Best white in 1-lb. sections, 19@20c. Extracted, 11@12c. Demand brisk

BEEWAX.—21@23c.

Dec. 15. M. H. HUNT, Bell Branch, Mich.

CLEVELAND.

HONEY.—Best white 1-lb. sections sell at 19@20c. cts. Extracted, 7@8c. Demand small.

BEEWAX.—22@23c.

Dec. 15 A. C. KENDEL, 115 Ontario St.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 16@19c.; the same in 2-lbs., 14@16c.; buckwheat 1-lbs., 11@12c.; 2-lbs., 10@11c. Off grades 1@2c. per lb. less. White extracted, 8@9c. Market dull.

BEEWAX.—22@23c.

McCaul & Hildreth Bros.,

Dec. 20. 28 & 30 W. Broadway, near Duane St.

KANSAS CITY.

HONEY.—We quote: Choice white 1-lbs., 18@20c.; dark, 16@18c.; choice white 2-lbs., 18c.; dark, 15 to 16c. Extracted, white, in 60-lb. tin cans, 9c.; in barrels, 8c.; dark, in barrels, 5@6c. California 2-lb. white comb, 18c.; dark, 16c. Extracted, white, in 60-lb. cans, 8@9c.; amber, 8c.

BEEWAX.—No. 1, 20c.; No. 2, 16@18c.

Dec. 19. CLEMONS, CLOON & CO., cor 4th & Walnut

ST. LOUIS.

HONEY.—Choice comb, 18@20c.; latter price for choice white clover in good condition. Strained, in barrels, 5@6c. Extra fancy, of bright color and in No. 1 packages, 1/4-cent advance on above. Extracted, in 55-lb., 8 1/2@7c.; in cans, 7 to 9c.—Short crop indicates further advance in prices.

BEEWAX.—20c. for prime.

Dec. 19. D. G. TUTT & CO., Commercial St.

CINCINNATI.

HONEY.—We quote extracted at 4@9c. per lb. Choice comb, 16@20c., in the jobbing way. The demand for extracted exceeds arrivals, and for comb the demand is tame.

BEEWAX.—Demand good—20@22c. per lb. for good to choice yellow, on arrival.

Dec. 12. C. F. MUTH & SON, Freeman & Central Av.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 17@19c.; fancy 2-lbs., 15@16c. Lower grades 1@2c. per lb. less. Buckwheat 1-lb., 11@12c.; 2-lbs., 10@11c. Extracted, white, 9@10c.; buckwheat, 6@7c.

Demand has slackened some, and to make sales we must shade above prices. About Jan. 15 we expect a more active demand.

Dec. 31. F. G. STROHMEYER & CO., 122 Water St

PHILADELPHIA.

HONEY.—Fancy white 1-lbs., 18@19c.; fair 1-lbs 17c.; dark 1-lbs. are slow sale at 14@15c.; fancy 2-lbs., white, 15@16c.; buckwheat fancy 1-lbs., 13@14 cts.; common, 12c. Prices tend downward.

BEEWAX.—23@24c.

Dec. 11. ARTHUR TODD, 2122 N. Front St.

MILWAUKEE.

HONEY.—Choice white 1-lbs., 20c.; fair, 19@20c.; 2-lbs., 18@19c.; 3-lbs., 16@18c. White extracted in kegs or half-barrels, 9 1/2@9 3/4c.; in pails or cans, 9 1/2 to 10c.; amber, in 1/2-barrels, 9 1/2@9 3/4c.; dark in kegs and barrels, 7@7 1/2c. Demand good, supply fair.

BEEWAX.—22@25c.

Dec. 15. A. V. BISHOP, 142 W. Water St.

SAN FRANCISCO.

HONEY.—We quote: White to extra, 15@18c.; amber, 10@13c. Extracted, white liquid, 7@7 1/2c.; amber and candied, 5 1/2@5 3/4c. Market quiet.

BEEWAX.—21@24c.

Dec. 24. SCHACHT & LEMCKE, 122-124 Davis St

BOSTON.

HONEY.—New crop, 1-lb. sections, 18@20c.; 2-lb. sections, 17@18c. Extracted, 6@8c. The market is not very brisk and sales are only fair.

BEEWAX.—25 cts. per lb.

Dec. 10. BLAKE & RIPLEY, 57 Chatham Street.

SAN FRANCISCO.

HONEY.—We quote: White comb, 17@19c.; amber, 12 1/2@15c. Light amber to white extracted, 7 1/2@8c.; amber, dark and candied, 6 1/2@7 1/4c. Market firm and stocks light.

BEEWAX.—22@23c.

Dec. 12. O. B. SMITH & CO., 423 Front St.

Only One Book of History with every club subscription to the **AMERICAN BEE JOURNAL** and *New York World*, is all that we can offer. The book is worth the whole money to be sent, and then you may consider the other two papers as a free gift.

THE BEE-KEEPERS' REVIEW.

ABOUT Jan. 10, 1888, we shall begin the publication of a 16-page monthly having the above title.

As indicated by its name, one of its distinctive features will be the reviewing of current apicultural literature. Errors and fallacious ideas will be faithfully but courteously pointed out, while nothing valuable will be passed unnoticed. But few articles will be copied entire, but the ideas will be extracted, given in the fewest words possible, and commented upon when thought advisable.

Another feature will be that of making each number, to a certain extent, what might be termed a "special" number. For instance a large share of the correspondence, editorials and extracts of the first number will be devoted to the subject of, "Disturbing Bees in Winter."

Our own apiary will, hereafter, be largely experimental, and of this our readers will have the benefit.

The price of the **REVIEW** will be 50 cts. per year; and while we have not the slightest objection to receiving subscriptions in advance, our only request is, that each one interested will send his address, and allow Uncle Sam to hand him a copy of the first issue as soon as it is printed.

The Production of Comb Honey,

A neat little book of 45 pages, price 25 cts. The **Review** and this book 10 65 cents. Stamps taken, either U. S. or Canadian.

Address, W. Z. HUTCHINSON, 50Atf FLINT, MICHIGAN.

SELF-INKING RUBBER-STAMP. 2,000

Impressions for 10 cts. Will last a life-time. It prints Envelopes, Letter-Heads, Postal Cards, Sections, Clothing—everything Your name, occupation and address, with the machine and a bottle of ink, by mail, for \$1.00. Extra 1/2 bottles of ink for 12 cts. Show this ad to your friends. Send me an order for 10 Stamps, and get your own free. Read what Editor Newman says of this Stamp on page 547. Agents wanted. Send for Catalogue and terms. Address,

Geo. T. Hammond, BROCKPORT, Monroe Co., N. Y. 26Atf

Warranted Seed.

I have founded my business on the belief that the public are anxious to get their seed directly from the grower. Raising a large proportion of my seed enables me to warrant its freshness and purity, as see my Vegetable and Flower Seed Catalogue for 1888, FREE for every son and daughter of Adam. It is liberally illustrated with engravings made directly from photographs of vegetables grown on my seed farms. Besides an immense variety of standard seed, you will find in it some valuable new vegetables not found in any other catalogue. As the original introducer of the Eolpae Beet, Burbank and Early Ohio Potatoes, Hubbard Squash, Deephead Cabbage, Cory Corn, and a score of other valuable vegetables. I invite the patronage of the public.

JAMES J. H. GREGORY, Marblehead, Mass.

THOMAS G. NEWMAN, Editor.

Vol. XXIV. Jan. 11, 1888. No. 2.

EDITORIAL BUZZINGS.

Flowers.—Just as the cold wave struck Chicago last week, we received by mail a nice bouquet of flowers from Louisiana—from our friend J. W. Winder, we expect. He usually does some such things. Welcome.

“Are the Bees our Friends?”

This is the subject assigned to Mr. Eugene Secor, for discussion at the annual meeting of the Iowa Horticultural Society at Des Moines, on Thursday of next week. We all expect something good from our friend Secor, and we have no doubt this will be “extra good.” We shall present it to our readers as soon as that meeting is over.

Only a few complete volumes of the BEE JOURNAL for 1887 are left, and those of our new subscribers who want to secure them should send for them at once. We supply the numbers for 1887 and 1888 for \$1.75 until all of the former are gone.

Foul Brood is a dire calamity wherever it makes its appearance. Our friend, Mr. A. I. Root, says he has spent nearly a thousand dollars in experimenting in order to eradicate it. He admits that what we have often advised (viz: a total destruction of the hives, bees, etc.) would have been cheaper and more satisfactory. Many others have found out by experience that this would have saved them money as well as much annoyance. If the larva is elastic and rosy it is a sure indication of foul brood. This is a sure test, but the odor is not to be relied upon, for there is one kind of the disease that is known as “odorless foul brood.”

Mr. T. W. Cowan, in a recent letter to us from Switzerland, his winter residence, remarks as follows concerning the weather there:

We are in the midst of winter, but as yet we have had no snow, and the temperature is very mild, and more like spring than winter. I am afraid our Canadian toboggans will not be of much use here, but the children go half-an-hour's walk from here, up on higher ground, where there is plenty of snow and skating.

Then, in reference to the re-organization of the “North American Bee-Keepers' Society,” and of his being elected a member thereof, he adds:

I see that you brought up the question of organization at the convention, and that you have proposed to organize your Society on the same lines as ours, and that the “rules” you propose are a modification of ours. We have found them to work well, and at the present time we could not better them. If there is any information you wish at any time about them, I shall be pleased to give it.

I have also seen the resolution passed by your Society, making me an honorary member. I am very much obliged to the members for doing so, and have written to Dr. Mason, asking him to convey my thanks, as he is the newly elected President.

The official notification sent by the Secretary, Mr. W. Z. Hutchinson, had not reached Mr. Cowan when he wrote the above. The letters passed one another in the mails. The cordial feeling existing between the apiarists of the two Continents, is a matter for congratulation, and we trust it may long continue. We have a lively interest in both Continents—being born in one and reared in the other.

We Understand that an effort is being made to have the United States Government include in its free distribution of seeds, the celebrated Chapman Honey Plant. Certainly bee-keepers should reap some benefit in this way as well as other avocations. We hope to hear of the success of the effort. Mr. Chapman has harvested 28 bushels of the seed, and the Government should scatter at least that much, and thus assist the pursuit, the same as it does others.

Horticulture and Bees.—At the recent meeting of the Ohio State Horticultural Society there was nothing in the programme about bees, and Dr. A. B. Mason gave them a good stirring up about it, by calling attention to the benefit “our pets” are to the horticulturist. We shall have proper recognition at the next annual meeting. Dr. Mason enjoys the “stirring up of their minds” to the importance of the industry.

Meadville, Pa.—The committee appointed at the last convention of the Eastern Ohio, Western Pennsylvania and Western New York Bee-Keepers' Association, which met at Andover, Ohio, last January, met and arranged to have the ninth annual convention held in Meadville, Pa., on the 25th and 26th of this month.

The Krainer Bees.—The “Bienen Zeitung” contains an article from Herr Michael Ambrozic, of Moistrana, Krain, Austria, on the Krainer bees. The writer is a very enthusiastic admirer of that variety, and gives some information concerning it in its native home. From his article we give the following extract:

The profits of the apiary in Germany and Austria, are estimated to be 45 per cent. on the capital invested. But bee-culture depends largely upon the hardness of the race of bees, and their propensity to gather honey. Krainer bees, in these respects, must be preferred. The rough climate of our mountainous country has made our bees a hardy race, for they have been hemmed in by mountains for centuries. Our bees fly in dark and cool weather, and suffer very little from diarrhea and other spring maladies. The rich mountain meadows and forests of Krain, with their profusion of bloom, animate our bees in the spring, and we often find them flourishing in March and April, breeding early, and beginning early to swarm.

My apiary is situated but $1\frac{1}{2}$ miles from the mountain Triglav, which is 9,000 feet above the level of the sea, and its north side is covered with eternal fields of ice, but for all that my hardy Krainer bees visit the herbs on the rocks in March and April, showing that they will succeed in any country, for they are used to rapid changes of temperature, and I can recommend them for importation to any country. Our bees are proverbially kind and gentle.

A correspondent who received a colony direct from Herr M. Ambrozic, says that “these bees are great beauties, being nearly black, with white stripes—the white being probably due to hairs, as they all seem to be young bees.” About the hive in which they came from Krain, he says:

The hive to me is a curiosity, being made of tough, hard, rough boards, about 24 inches long inside, 14 inches wide, and 5 inches deep; top and bottom nailed with odd-looking hand-made nails, wooden pegs and wire nails; no frames inside; combs had been built diagonally, and were filled with dark-colored, thick, rich honey, about 20 pounds. It was quite a task to open this hive, but I did it, and found the Krainers lively, good natured, and so fond of honey that they all soon had their fill.

Their flight seems to be very strong, and I am inclined to think them large as compared with the Italians. It seemed odd enough to see these mountain bees flying very freely, with the mercury at 45°, when not a wing was to be seen about my other hives.

Concerning Books for bee-keepers, the “Southern Farm” remarks as follows about two books published at this office:

“Bees and Honey,” by Thos. G. Newman, well-nigh embraces every particular about bee-keeping, which, if followed out, cannot fail to lead to great success in the apiary.

“A Year Among the Bees,” by Dr. C. C. Miller, is one of those pleasant books that often go further to help to attain to success than a more complete manual. This work is replete with information regarding the necessary implements, plans, etc., of a complete apiary, and gives the results of 25 years' experience in bee-keeping.

Look Over last year's numbers of the BEE JOURNAL, and if any are missing, send for them at once, as we have but few left now, and they are daily becoming less.

GLEAMS OF NEWS.

THOMAS W. COWAN, ESQ.

Dr. A. B. Mason, President of the North American Bee-Keepers' Society, wrote us as follows on Jan. 3, 1888: "Yesterday I received the following from Mr. Thos. W. Cowan. Please insert in the AMERICAN BEE JOURNAL."

8 Avenue de la Gare, Lausanne, Switzerland, Dec. 17, 1887.

DEAR SIR:—I see by the AMERICAN BEE JOURNAL that your Association has elected me an honorary member; therefore, I should be glad if you, as President, would convey from me the message that "I am extremely obliged for the honor conferred upon me by the North American Bee-Keepers' Society, in electing me, by an unanimous vote, an honorary member of the Society. I shall henceforth as a member take even a more lively interest in the welfare and progress of the Society than formerly, and more particularly as I have become personally acquainted with some of its leading members."... I read with much interest the proceedings at your convention, and regretted not being able to be present.

Yours truly, THOS. W. COWAN.
To Dr. A. B. Mason.

President Mason has sent us the following responsive letter for publication:

I am sure we all feel that in honoring Mr. Cowan by electing him as an honorary member of our Society, we honored ourselves, and were glad of so good an opportunity to show him, in a feeble measure, the high esteem in which he is held by the bee-keepers of America.

We should have been glad to have had Mr. Cowan with us at the annual convention at Chicago, so that we could have had the opportunity, in a more demonstrative way, to have shown him what a cordial greeting we could have given him. It would have been a rare treat to have had him, in his pleasant and inimitable way describe to us the wonderful things his powerful microscope would have shown us. The brief, but enjoyable visit I had with him, is set down as one of the bright spots in my life; and the very fine photograph of himself that was enclosed in his letter, will be a constant reminder of the visit to our land, of one of England's best and noblest men.

A. B. MASON,
Pres. N. A. B. K. Society.

P. S.—As the AMERICAN BEE JOURNAL and the "Canadian Bee Journal" are the only weekly bee-journals published, I send the above to them only, requesting other apicultural papers to copy same.—A. B. M.

From the handsome girl's head, lithographed in colors, nicely cut out, to the last slip of the pad, Hood's Household Calendar for 1888, is thoroughly artistic. Every month is beautifully engraved, and each slip as torn off presents a new and pleasing combination of color printing. Hood's Calendar easily leads the procession. It is nice enough for any parlor, and has so many excellent points in arrangement and convenience that it must be seen to be appreciated. Copies may be obtained at the drug stores, or by sending six cents in stamps to C. I. Hood & Co., Lowell, Mass.

Putting Bees into Cellars.—It has become quite common to give bees a flight during some warm spell in winter. To take them from the cellar and return them requires care, and some may inadvertently cause much damage by not knowing just how to do it. The "Canadian Bee Journal" gives these excellent suggestions about carrying the hives:

If the hives are carried in one at a time in your arms, the end of the frames should stand lengthwise from you, because if the frames stand sidewise, the sudden jar of moving causes them to oscillate, disturbing the bees, frequently breaking the clusters, causing them to gorge themselves with stores, and rendering the possibility of wintering more difficult, because of the fact that as it is usually warmer in the beehouse than out-doors at the time of carrying them in, they will not cluster again so tightly in the bee-house or cellar. If placed into winter quarters without being disturbed, they, of course, remain clustered in just that much more compact a form, and will not consume nearly so much food.

The same paper also gives these directions about how to prepare the hives for handling when first taking them in or when returning them to the cellar or bee-house:

Before we start to carry them in we close all the entrances, then if they should receive a slight jar that would otherwise disturb them, seeing no light they are not nearly as liable to become excited. The entrance-blocks are left on the hives in the bee-house until all are in. After making all dark inside, the entrance-blocks are removed, leaving the entrance full width.

Fire.—We are sorry to learn that Mr. S. H. Rickard, of West Bridgewater, Pa., has suffered a loss by fire. A local paper makes the following remarks concerning the misfortune:

Some time between 2 and 4 o'clock the residents of Bridgewater were awakened by the cry of fire, which was followed shortly after by the ringing of the foundry bell and the blowing of the Hob-Nail Works' whistle.

The residence of Mr. S. H. Rickard, on Water street, was burning, and the flames had already gained such headway that there was no thought of extinguishing it. The time in which to save the household goods was quite limited, and only a few of them were carried from the burning building, and many of these only in pieces, rendering them useless. In half an hour after the first alarm was heard, the house was a heap of smouldering ruins.

Fire caught in the kitchen, and is supposed to have been caused by the increase in the pressure of gas in the Heat and Light Company's main, from which gas was obtained.

The family was awakened by the noise made by the fire, and had barely time to escape. A domestic in the employ of the family ran in her night clothes to the stable, where she was compelled to remain until clothes were brought to her. Most of the clothing belonging to the members of the family was destroyed. The building and contents, together with the out-buildings, was insured in the Sun Fire Insurance Company, of London, England, for \$900. It was valued by Mr. Rickard at at least \$1,500.

In a letter Mr. Rickard recounts the loss in this language:

Besides the house and furniture, I lost several good colonies of bees, which took fire in the yard from the intense heat; and

many more of them would have been consumed but I moved them out into the street, and into the adjoining lot. My barn was saved only by the prompt attention of a good colored man, who got in the "mow" and kept the hay well-soaked with water. Although the barn was on fire for several minutes, and burnt nearly all weather-boarding off of that side, it was saved. Should it have burned I should have lost 18 colonies of bees that I have in the upper story of the barn, but luckily they were saved. I have lost all of my bee-fixtures and extra hives, and shall have to begin anew.

Moving Bees in Winter.—Mrs. L. Harrison, in the "Prairie Farmer" for last week, makes these remarks on the above subject:

As a rule it is not best to disturb bees during cold weather. It arouses them to activity, and some of them get away from the cluster, become chilled and perish. The combs are brittle and break loose easily when it is cold.

Before I became a bee-keeper I thought that bees could not be moved in any other way than on runners, and have learned no better way since, if they must be moved during cold weather. Place hay or straw in the bottom of the sled, and take every precaution against a jar. Two very careful persons working together, might lift them so easily they would never know it. Places should be fixed to stand the hives upon, and they should be removed from the sled at once. If they are left in the sled over night, and the next day prove warm, they might fly out and get mixed up, and then be materially damaged.

In moving bees at any time of the year, it is well to put something in front of the hive to obstruct their flight—to bump their heads, as it were. This causes them to stop and consider where they are, and take the points of the compass.

I once moved bees late in autumn, from one part of the apiary to another, and the first time they flew, which was six weeks afterwards, they went back to their old stand. The next day I gathered up handfuls of them clustered where the entrance of their hive had formerly been.

New Catalogues for 1888 are on our desk, from the following persons:

Christian Weckesser, Marshallville, O.—20 pages—Queen-Bees, Garden Seeds, etc.

A. I. Root, Medina, O.—40 pages—Apiculture and other implements.

M. H. Hunt, Bell Branch, Mich.—12 pages—Bee-Keepers' Supplies.

Jacob Alpaugh, St. Thomas, Ont., sends sample section and comb foundation.

Snow around the hives is no detriment. It is porous, and enough air can penetrate it for ventilation in winter. When it forms ice at the entrance, then it must be cleaned away. An examination during and after a thaw is very necessary.

The Couvention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

BIOGRAPHICAL.

Mr. T. F. BINGHAM, APIARIST AND INVENTOR.

Many desire to know something more concerning the principal apiarists and inventors of the world, than can be obtained in the current literature concerning the development of the industry. In most cases this can be obtained more correctly, and in better form from the persons themselves than from any others. In the case of our present sketch, we concluded that this was particularly the case, and so, at our request, Mr. Bingham has furnished the following concerning his life and inventions :

My father's as also my mother's ancestors emigrated from England early in Colonial history. My mother's name was Kent; her ancestors settled in Connecticut, while my father's settled in Massachusetts. My grandfather moved from Massachusetts to New Hampshire, where my father was born. My father, when a young man, moved to Vermont, where he married and became a farmer. My grandfather Kent was a farmer, and also kept bees, and made very handsome straw-hives—the time-honored kind now shown in print, to denote "industry." He gave my father a colony of bees in such a hive. Those bees and their progeny my father kept during the remainder of his life—about 50 years.

The subject of this sketch was born Jan. 22, 1830, in Woodstock, Vt., and early became accustomed to and familiar with the management of bees, and also the current bee-literature of the times. When 18 years of age I was invited by a watch-maker to learn the watch and jewelry business. Three years were so spent, and then being desirous of further perfecting my business, I accepted a position in a Boston house; after which I was employed as a watch-maker in New York, Petersburg, Va., Columbus, Ga., and Cincinnati, O. I then commenced the jewelry and watch business for myself in Gowanda, N. Y.

Thinking that some out-door employment might prove a recreation and a reward also, I bought 25 colonies of bees and transferred them to Langstroth hives. Soon after that I purchased 75 more in logs, barrels and boxes, which were also transferred at once to Langstroth hives, to work for comb honey, which then (three years after the American war began) was worth 40 cents per pound by the ton or car load, gross weight, without crating, in the bee-yard.

Invention of a Bee-Hive.

A few winters and summers led to the belief that bee-keepers had not yet all that was needed for the easy and successful production of comb honey, and the safe wintering of the bees.

Experiments had shown that a flat hive, having 4 inches of comb, and a large upper surface for supers realized much better results, but it was regarded impracticable to try to winter bees in such hives with or without protection.

I then decided to make a frame of triangular form, each of the three sides measuring 23 inches, two of the sides having a piece 1½ inches wide attached to hold the frame upright, and to furnish a shoulder, against which the surplus boxes should rest. This arrangement gave ample space for eight 6-pound boxes, in close proximity to the brood; while, at the same time, only eight large frames were required for honey for winter and other use. These frames were clamped together by a wire loop across the

wide ends of the frames, and the movable sides—the whole making a hive as compact as any box-hive, yet easy to manipulate under all circumstances. Either movable side had a long entrance (23 inches) and a portico. Around the whole was a bottomless box having a loose cover. This served as a cover to the surplus in season, and to hold chaff in winter. This hive was a radical affair, and attracted considerable comment among bee-keepers.

Many hives were brought out in different places embodying the same principles, but of different form. Among these may be mentioned the "Quincy improved," which had a series of large, rectangular, tight-end frames, clamped together and setting in a loose box, which served as a cover to the surplus in season, and to hold packing for winter.

The triangular frame, however, was soon abandoned, and at once remodeled, so as to use the same outside cover and front and rear sides. This was done by nailing the tight-ends to a strong top-bar 22¼ inches long, forming a rectangular frame holding a piece of comb 5x22¼ inches.

The above changes converted a hive made before the extractor became much used,

T. F. BINGHAM.

(having frames impractical for extracting purposes), into a hive peculiarly adapted to tiering-up—the extractor just then coming forward as an implement or machine of value to apiculture.

In conventions in Michigan and elsewhere this hive was much discussed, but was regarded as too flat for practical use. It has, however, held exclusive possession of my apiary for a period of 20 years, without a wish to change it. It embodies the principle in a high degree on which my first experiments were made; viz: large upper surface for surplus comb honey in close proximity to the brood.

Invention of a Smoker.

While the hive experiments were progressing, I was also trying various devices for the production and easy management of smoke, which experience had shown to be absolutely necessary to the easy and rapid handling of bees in movable-combs or otherwise.

My first experiments were the production of a light tin tube having a fire grate and two cork ends, in each of which was a small wooden-tube, to be held in the mouth and to direct the smoke. This proved to be very handy, as both bands remained free for use. They were used quite extensively. They were not, however, all that I desired, and continued experiments were persever-

ingly made. These experiments led to a comparatively handy smoker held in the hand, but operated by the mouth, through a small, flexible tube, one end of which was held in the mouth while the other furnished the smoke tube with air and blast. This was a great advance on any other mouth smoker, but the same old weakness clung to it, that had clung to the others—if you stopped blowing, the fire died out.

But this smoker demonstrated many fine points, as well as its own weaknesses—the latter of which proved the most valuable. They led to the establishment of the natural draft between the blast-pipe and the smoker-stove, continuous, unobstructed, reliable and direct. The principle was now a fixed and established reality—needing only a few ingenious experiments to render it what it has proven itself to be, viz: one of the greatest aids to easy practical apiculture in every country where enlightened methods prevail.

Had Father Langstroth possessed such an implement for managing bees, while his patent was in his own hands, it is safe to say that his hive and system of management would have been more easily introduced to bee-keepers, and that intelligent apiculture would have been very greatly promoted.

Invention of an Uncapping-Knife.

It has been said that "necessity is the mother of invention." The necessity of uncapping combs to extract the honey with unscientific uncapping knives, cheaply made of poor material, led to experiments which developed the peerless Uncapping Knife, now known as the Bingham & Hetherington Uncapping Knife, wherever the honey extractor is known.

Our family and the Hetherington family, if these inventions are of value to the bee-keepers and the world, have not lived entirely in vain. It has been claimed that bee-keeping to be a success must be the special pursuit. In answer, it will be borne in mind that in the Kent-Bingham family bees have been kept consecutively for at least one hundred years. Also that in no one case have they been other than a side issue or pursuit. If, then, the introduction of shallow, tight-end frames, the invention of the direct draft bee-smoker, and the single beveled uncapping-knife may be reasonably called successes, bee-keeping simply as a side-issue in our family, at least, may be regarded as a success.

Briefly yours, T. F. BINGHAM.
Abronja, Michigan.

Long Preservation.

A Case of remarkable preservation of apples comes to us from Pokeepsie, N. Y. The "Evening Enterprise" remarks thus concerning it:

We received to-day from the hands of Mr. George H. Knickerbocker, who keeps a beefarm in the town of Pine Plains, specimens of two varieties of apples—"russet" and "lady sweet"—that were grown on his farm in 1886. They are in an excellent state of preservation, and look as if they might be kept for an indefinite period of time. Mr. K. informed us that they were kept in a fruit cellar without any artificial means applied to preserve the fruit, and he attributes their remarkable preservation to the even temperature of his fruit cellar. It is certainly a remarkable showing, and is worthy the attention of all who are interested in the preservation of fruit in its natural state.

Mr. Knickerbocker is one of our advertisers, a progressive apiarist, and queen-rearer of prominence in New York.

QUERIES AND REPLIES.

THE ENTRANCES TO HIVES, AND VENTILATION.

Written for the *American Bee Journal*

Query 503.—1. What kind of hive entrance do you prefer—the dimensions, how contracted, etc.? 2. Does this entrance furnish all the ventilation necessary?—Goshen, N. Y.

1. I use an entrance $\frac{3}{4}$ x 14 inches, contracted by entrance-blocks. 2. Yes.—G. M. DOOLITTLE.

1. The full width of the hive and $\frac{3}{8}$ of an inch deep. 2. Yes.—C. H. DIBBERN.

1. The one usually made in the Langstroth hive— $\frac{1}{2}$ inch deep and the whole width of the hive, contracted by two 3-cornered entrance-blocks. 2. Yes, usually.—EUGENE SECOR.

1. Eight inches long, and $\frac{1}{2}$ inch high. Contract by the use of blocks similar to the entrance-blocks of the Langstroth hive. Contracting the entrance is seldom necessary. I leave them wide open in winter. 2. Yes.—M. MAHIN.

1. The full width of the front end of the hive, and $\frac{3}{8}$ of an inch high; contract it with entrance-blocks. 2. Usually it does, but not always.—A. B. MASON.

1. On the whole, I prefer it $\frac{1}{2}$ -inch by 8 or 10 inches, and contract the size by the Langstroth triangular blocks.—A. J. COOK.

1. One-half inch high and the full width of the hive, to be contracted as needed by a block or stick. 2. Yes.—C. C. MILLER.

The full width of the hive and $\frac{3}{8}$ of an inch wide. Contract it with right-angled blocks in the early spring. In the summer and winter have the full entrance open, and furnish necessary ventilation.—MRS. L. HARRISON.

One-half inch wide and the whole width of the front of the hive; contractions to be made with the Langstroth entrance-blocks. Such an entrance furnishes as much ventilation as is needed, so far as I know.—W. Z. HUTCHINSON.

Ten inches wide and 5-16 of an inch deep. Besides in the summer we raise the hive from the bottom and give as much as 2 inches room in depth, in front. We leave the back closed.—DADANT & SON.

1. I prefer the entrance 10 or 12 inches long, $\frac{1}{2}$ -inch wide, which I contract as occasion requires, either by slides or by triangular blocks. 2. It will, if the hive is properly shaded.—J. P. H. BROWN.

1. I prefer an entrance $\frac{1}{2}$ -inch by 11 inches, and to have it come beneath rather than at the ends of the brood-frames, as usually provided. This kind of an entrance is quite effectual against robber bees, and with full colonies it needs no contraction at any time of the year. 2. On very hot days I give further ventilation at the top of the hive.—G. L. TINKER.

1. I use the Langstroth hive 14 $\frac{1}{2}$ inches wide, and give an entrance the whole width of same. 2. Yes, ordinarily, if shade of some kind is used to guard against the sun.—J. E. POND.

The whole width of the hive, and $\frac{3}{8}$ of an inch deep, contracted by the entrance-blocks. 2. It will until it gets very warm, then I raise the hive up on little blocks $\frac{1}{2}$ inch by 1 inch, placed under each corner. That will raise the hive $\frac{1}{2}$ -inch from the bottom-board all around, except in front, which will be $\frac{1}{8}$ of an inch.—H. D. CUTTING.

1. I use and prefer the entrance to the hive to be on a level with the bottom-board of the hive. I prefer this style of entrance for too many reasons to be mentioned here. A slight pitch to the front will drain the bottom-board of all moisture. I make the entrance $\frac{3}{8}$ of an inch high, and full width of the hive. I contract it by means of two blocks that can be moved at will. I have had no trouble with this arrangement in any way. 2. The ventilation is ample except in excessively hot weather, at which time the hive-covers can be raised slightly, to the comfort of the bees.—G. W. DEMAREE.

I use, and prefer, an opening of from $\frac{1}{2}$ to $\frac{3}{8}$ of an inch, and clear across the end of my hive, which is 11 $\frac{1}{2}$ inches. I prefer the triangular Langstroth blocks to the many devices that I have tested, and all I have ever heard of. These entrances, with the aid of the bees, furnish all the ventilation needed; all upward ventilation in summer has proven worse than useless with me.—JAMES HEDDON.

I prefer an entrance made by cutting a piece $\frac{3}{8}$ of an inch deep out of the front end of the bottom-board, extending clear across the front end, and running to a point something like a V about 4 inches from the front end. Give a full entrance by pushing the hive even with the front end, which gives all necessary ventilation. The entrance is reduced by sliding the hive back.—R. L. TAYLOR.

1. The entrance should be the full width of the hive, and about $\frac{3}{8}$ of an inch deep. The triangular blocks of the Langstroth hive are about as good as we could wish. 2. The ventilation secured at the entrance of the hive is usually sufficient.—THE EDITOR.

EMPTY COMBS, OR WIRED FRAMES OF FOUNDATION?

Written for the *American Bee Journal*

Query 504.—If bees are all ready to begin work in the supers, which would be preferable, empty combs at \$12 per 100, or wired frames of foundation costing about \$9 per 100?—Sturgis, Mich.

Empty combs, every time, if you are producing extracted honey.—JAMES HEDDON.

Give me the wired frames at the figures named, every time.—C. H. DIBBERN.

I think that I should prefer the wired frames.—MRS. L. HARRISON.

If to be used for obtaining extracted honey, I think that the combs, if good ones, are preferable.—R. L. TAYLOR.

The wired frames of foundation, if you wish to get the surplus in the supers.—A. B. MASON.

At a rough guess I should not have much choice.—C. C. MILLER.

I would prefer the empty combs, if in good condition.—H. D. CUTTING.

If the combs are new, perfectly clean and straight, take them; but if they are old and dirty looking, take the foundation in preference.—J. P. H. BROWN.

If the honey is to come in "show-ers," the combs would be preferable; if otherwise, the foundation.—W. Z. HUTCHINSON.

I should prefer the empty combs, if they are clean and bright, and not filled with pollen.—J. E. POND.

I do not quite understand the question. If the combs and frames mentioned are for the brood-nest, I would take the empty combs.—M. MAHIN.

The empty combs, provided they are worker combs. We suppose you speak of producing extracted honey.—CHAS. DADANT & SON.

At the present prices of extracted honey, and given a prospective heavy flow from basswood, I should take the empty combs.—G. L. TINKER.

If by "super" you mean upper story for extracting, I would prefer the empty combs. If working for comb honey in sections, the foundation would be worth the most below. I fear that I do not fully understand the intent of the query.—EUGENE SECOR.

I should prefer the empty combs, if I understand the question rightly; but I would prefer to have the bees build them at times when it could be done at a less expense.—G. M. DOOLITTLE.

The question is not clear. If they are "all ready," they must have a set

of filled combs in the brood-chamber.
—A. J. COOK.

If the combs were good ones in every way, I would accept the combs without hesitation. It takes time for bees to draw out foundation, and they will not do it unless honey is coming in. I am quite sure that the empty combs would give a good profit over the frames of foundation, after accounting for the difference in the price. I would not have wire in my combs as long as I can get a good article of foundation suitable for combs without wire. I have a lot of wired combs, and they will never be increased in numbers in my apiary.—G. W. DEMAREE.

That depends upon the condition of the empty combs. If they are in good condition, they would perhaps be preferable, but there is but little difference.
—THE EDITOR.

SWARMS ALIGHTING HIGH.

Written for the American Bee Journal

Query 505.—Are not swarms that alight high, more likely to desert the premises?—E.

No.—MRS. L. HARRISON.

I do not know.—H. D. CUTTING.

I do not know.—W. Z. HUTCHINSON.

No.—DADANT & SON.

They usually are.—J. P. H. BROWN.

Not if the same care is exercised in hiving.—A. B. MASON.

No; it makes no difference where they alight.—C. H. DIBBERN.

I do not know why they should.—C. C. MILLER.

Yes, but only so far as I know for the reason that there is generally greater delay in recovering them.—R. L. TAYLOR.

Yes, if you cannot reach them. In fact, without joking, I believe there are more individual bees that desire to go right off to the woods in swarms that cluster high up.—JAMES HEDDON.

I think so, for the reason that they are more likely to have a young queen, and young queens are more likely to leave than old ones.—EUGENE SECOR.

I have not seen any difference, and I cannot imagine any reason why they should.—J. E. POND.

I have seen no difference. In fact I have never had a swarm to come out after I had hived it.—M. MAHIN.

Not in my experience. Bees are more apt to emigrate when located in the country near heavy timber. In villages and cities it is rare for a swarm to go away unless unearned for.

My bees often go to the tops of the highest apple-trees, but I have never had a swarm to go away, or desert a hive if properly shaded and ventilated.

—G. L. TINKER.

No swarms desert for me, as I keep the wings of the old queens clipped, and allow few if any second swarms. I think that the alighting has little to do with it.—G. M. DOOLITTLE.

I should say so, as the bee-keeper finds it difficult to capture them, and certainly will be more tardy in hiving such a swarm. Clip the queen's wing, and there will be no danger, in any event.—A. J. COOK.

I think not. I have seen swarms cluster so high that no ordinary means could reach them, and they would tarry as long in the cluster as other swarms that clustered near the ground. I am not a believer in the marvelous stories about bees "sending out scouts to look up a new home." People are fond of the marvelous, and are ready to believe anything, if it is a little out of the general order of things. I venture to assert that bees never know where they will stop when they leave the maternal roof. I have seen a swarm go straight to a tree and enter a hole in it; but that does not prove any thing, for I have seen them fail to do so, a great many more times than I have seen them do it.—G. W. DEMAREE.

Swarms that alight high usually, have young queens, and as it is more difficult to capture such swarms, and takes more time to accomplish it, they do more often get away than those which are more easily captured. If the queen's wing be clipped, as practiced by many of our best apiarists, there will be no danger of their going away.—THE EDITOR.

O Winter, We Greet Thee.

Written for Vick's Magazine

BY S. W. LLOYD.

We greet thee, Winter! We are glad
To see thy snowy mantle spread
O'er river, lake and hill;
We're glad to hear the merry sounds
That tell us happiness abounds
Among sleigh-riders still.

We love thee, Winter! Thou dost bring
Upon the cold and frosty wing
Much, much our hearts to glad;
And though thou'rt bleak, we'll not repine,
For springs of joyousness are thine
That Summer never had.

Then, hail thee, Winter! We will greet
Thy pleasures with a welcome meet,
And taste them while they stay;
And when thou'rt gone, and joyous Spring
Comes with her robes of blossoming,
We'll bid thee speed away.

CORRESPONDENCE.

FOUNDATION.

The Plan of Manufacturing it with the Use of Molds.

Written for the American Bee Journal

BY G. M. DOOLITTLE.

I was a little surprised to find that every one answering Query 500, on page 788 of the BEE JOURNAL for 1887, answered it in the negative, except myself. Can it be that few, if any, of our apiarists are using molds for making foundation? And if such is the case, why are they not using them? As my answer to the query above mentioned has caused quite an increase in my correspondence, I will try to answer some of the questions that have been asked.

I never was favorably impressed with any of the machines requiring dipping-boards, in the hands of the average bee-keeper, owing to its taking so much paraphernalia, and especially as so much wax was required; for when I sent wax off to be worked up, I was told that if I sent less than 50 pounds, I would get little, if any, of my own wax in the foundation that I would receive, as it took from 50 to 75 lbs. of wax in the dipping-tank to get the required depth of sheet. As soon as I understood this, I saw that it was of no use for me to think of making my own foundation, to carry on the few experiments which I wished to make. Therefore I then rested contentedly in purchasing the little foundation that I wished for experimental purposes, till about five or six years ago, when I saw an advertisement regarding "foundation-molds" for making small sheets of foundation for sections.

From the little information that I gained from the advertisement, I saw that I could use as small a quantity of wax as I wished in working the molds. I immediately procured the molds, and was soon making foundation running from 10 to 12 square feet to the pound, by simply pouring a large spoonful of melted wax into the molds, and quickly shutting them. With these little molds (about 6 inches square) I could easily make up 12 pounds of wax in a short winter's day, which gave me \$3 for my day's labor, as I must pay 50 cents per pound for foundation when wax was only worth 25 cents per pound.

After making all the wax I had into nice foundation, I lent the molds to a neighbor bee-keeper who left them at night while wet, when the plaster of Paris was frozen, thus ruining them, as

they all crumbled off in using afterward.

The next year I secured another mold 12x12 inches square, on which I can easily make from 40 to 50 pounds of wax into foundation in one day; and as these have been kept from frost, except when dry, they are now as good as ever, after having made considerable foundation on them for myself and neighbors.

How to Use Foundation Molds.

All that is necessary to do in making the foundation is, to have the extractor can filled with water, which is kept cold by ice, or allowing a stream of cold spring-water to run through it, on top of which (can) a rack is fixed similar to the one which goes over the Dadant uncapping can, upon which the molds rest. Having the can thus fixed, plunge the molds in the water an hour before you wish to commence work.

Now place a large pan filled with wax on the stove, having the can near by, or, what is preferable, if you have one, place an oil-stove beside the can, having a melting dish fixed for the purpose on the oil-stove. This dish should have an apron made of tin to extend from it to the can, so that all drippings will run either back into the melter, or over into the can, the former being preferred.

Being thus ready, raise the molds from the water, let them drain a second, and then place in position in the frame over the can, when with a small dipper, or the fount that comes with the molds, pour the required amount of melted wax on the lower plate of the mold. As soon as the wax is on, shut the mold with a steady hand, giving it as much of a pressure as is convenient by bearing down with the hand. In a few seconds open the molds, and remove the sheet of foundation, when you are ready to pour on melted wax again.

After about 5 or 6 sheets of foundation have been made, the molds will begin to get warm, when, if heavy foundation is to be made, they must be opened and put in the water again to cool off, leaving them in the water for about a minute. If thin foundation is desired, dip the molds in the water only enough to keep them so cool that they will not tear the foundation to pieces in opening them. I make the heavy foundation to run about 6 square feet to the pound, and the thin from 11 to 12 square feet; and I can make good wages doing it, if only 20 colonies were kept, and those to be furnished with nothing but starters; for I have my own wax, extractor can, dipper, stove, etc.

Now if Mr. Dadant or Mr. Van Deusen should see a sheet of this

foundation, they would doubtless say, "Doolittle, this does not compare with the foundation that we make;" when I would say, "By what authority do you decide?" expecting to be met with, "See, it does not look nearly so perfect as does ours." Then I should say, "Admitted;" but when the authority is the bees, they say: "Give us the molded foundation, and we will work it out just a little quicker than the other, and after it is completed you nor any other man can tell any difference."

From my experience with this and nearly all other kinds of comb foundation, I am convinced that this molded foundation is equally as good as any; is accepted by the bees just as soon as that made on the Given press, and a little sooner than that made on any of the roller mills; and the best of all is, that any one can make it at his leisure, use up his own wax, even down to the last ounce, thus being independent, and keeping his pennies at home to feed and clothe his family.

To anticipate an error regarding this article, I will say that I am in no way interested in the manufacture, or the sale, of the molds, any more than I am in all other bee-keeping appliances. I have written this article only for two reasons, viz: First, to tell my friends regarding what I believe is a good thing; and, second, to answer my numerous correspondents publicly, so as to avoid the strain on my time and health that a private answer to each would cause.

COUSINS TALK.

Putting Bee-Literature on its Proper Basis.

Written for the American Bee Journal
BY R. M'KNIGHT.

So, after all, Dr. Mason "has no unkindly feeling toward his cousins across the border." Well, I began to suspect as much, from his own utterances, as well as from the good character that has been given him by others who know him. When he administers the lash, it is for the sole object of correction, and not for the purpose of inflicting pain. He tells us so himself, and who has a better right to know? His dearest wish is to exercise a fatherly care over the erring. "All wayward people who go astray," are the especial objects of his care; and "to aid in getting them in the right way when they go astray," he feels to be a duty to which he has been called.

In pursuance of this self-imposed task, he tells us that he is not going to "confine himself" "to any one erroneous statement," but thinks he shall

"wander around after such bee-literature as gets off its base." I admire the Doctor's courage, for none but a courageous man would undertake such a Herculean task, and none but a hopeful one could expect to succeed in the undertaking. It would be a cruel thing to say or to do anything calculated to make rough the path of duty which the Doctor has mapped out for himself, however much we may doubt his ability to reach the goal of his ambition.

After this he may tell us as often as he may please, that we are a people given to "bombast;" we will remember that it is just a way he has of putting bee-literature on its proper basis. He may charge us with practicing "dishonesty and fraud," but we will know that these charges are only the hammer and the trowel that he employs in making the "crooked" things straight. He may say that we steal the name of your Linden honey, but he does not mean it, for he "has no objection to Canadians giving their products any name that they choose."

The Doctor says that he does not hate anybody. I sincerely believe that to be a fact, and regret having used the word in a way that he might think it was meant to have a personal application to himself. I am upon my knees in penitence, that I misunderstood his motives. I shall hereafter only think of him as one of America's greatest philanthropists. "A gude New Year to you," Doctor, "and many happy returns."

Owen Sound, Ont., Dec. 30, 1887.

UNFINISHED SECTIONS.

How Best to Utilize the Partly-Filled Sections.

Written for the American Bee Journal
BY C. THEILMANN.

In the report of the proceedings of the North American Bee-Keepers' Convention at Chicago, I find the discussion on the re-use of comb built in sections to be filled with honey the next season. It is gratifying to know that the great majority of bee-keepers consider these combs of great advantage, by which they can obtain larger crops of honey, and of just as good quality, as by the use of foundation. I can hardly understand why some bee-keepers cannot obtain good honey in nice, white combs built in sections the year previous.

Some years ago it was a real perplexity to me, to have a lot of unfinished sections in different states of completion, after the harvest was over, and I hardly knew what to do with them. I then tried in different ways to make use of them. Those nearly

completed I sold at about half the price of sealed honey, and the rest was given to the bees for completion the next season, and of which the bees made a bad job, as some of it was granulated, and some was sour, though they fixed it all up as well as they could, and finished them; but it was horrible looking honey, the sides of the comb was very uneven, besides being of different colors. I was almost ashamed to offer it for sale.

Using Partly-Filled Sections.

After experimenting two or three seasons more, I discovered the right way, though I think I had lost considerable before, by trying to make the bees finish nearly all the sections the same season, by changing them around among the hives. This was not only lost time for me, but also for the bees, or rather, less honey for me. I now allow my bees to go above toward the close of the honey season, and let them have their own way about finishing the sections; but as soon as the honey season is over, I extract every unfinished section that I have, and let the bees clean them out, when they are ready for the next season. By this method I secured just as fine honey as I do with foundation starters, and a great deal more of it; and the cases with the empty combs are nicely put away, where no mice or dust can get at them.

I am glad that there are more bee-keepers who can secure nice honey with these combs, as was shown at the late convention in Chicago; that Mr. Hutchinson had the nicest lot of honey in Chicago; and that he, as we understand, uses the empty combs.

When I was ready to sell my honey, I have never been asked, "Are your crates and sections clean?" or, "Are the combs from last year?" etc. No, not any of these questions have ever been asked, but invariably, "Is your honey white?" and on this *white* the whole question turns, in selling and buying.

If I have my dark honey in ever so nice combs, crates and sections, it is slow sale, and at a far lower price than white honey; even if the latter is less attractively put up. Of course it is best to have the honey in the best marketable shape, and everything else clean, and in its proper place.

Report for 1887.

I commenced with 145 colonies, increasing them to 217, by natural swarming. I obtained 7,000 pounds of comb honey, and 1,000 pounds of extracted honey. The whole crop realized for me about \$1,300. I also sold bees enough to pay nearly all the expenses of the apiary.

Theilmanton, O. Minn.

BEE CELLAR.

The Proper Temperature and Ventilation of a Bee-Cellar.

Written for the American Bee Journal

BY A. C. TYRREL.

So much has been written on this subject, that the heading of this article may prevent an impartial perusal thereof, by those who consider that they long ere this learned *all* there is to be known about wintering bees successfully in caves or cellars. But I opine that many decades will elapse ere the "A B C class" in apiculture graduate.

What I am about to advocate, I am well aware will not meet with a "second" from the majority of bee-keepers throughout the country, for my experiments (not assumptions or mere theories) will not comport with what they term "reason" or common sense, but *audi alteram partem* (hear the other side), and then condemn, or award the full measure of praise if the *proof* herein presented for consideration sustains my assertions.

In the matter of temperature and ventilation, I have endeavored to thoroughly post myself, for they are the most important factors—all others are of minor importance, as matters over which we have no control, such as honey-dew, improper food, etc., speculative fancies, formative hypothesis, to meet the exigency of exceptional cases. Whenever it has been my good fortune to make a discovery, seemingly outside of the usual order of things, it has been the practice with me to patiently watch and experiment for at least *three* seasons before acquainting the public with the result of my observations—so often do our fondest hopes and brightest dreams prove to be chimerical. And of those composing the great fraternity of bee-keepers, from the Orient to the Occident, having many a pet theory and hobby-horse to ride, when asked to give "a reason for the hope that is within them," at once "trot out" *Experience*, of longer or shorter duration, in accordance with the importance of the case, or amount of pressure brought to bear by adherents of the opposite side of the question.

For a long time I was of the opinion that my bee-cellar was *too warm*, but as so many of my fellow-apiarists said 41° to 45°, and some have said 52°, Fahr., I endeavored to so regulate the cellar that the temperature would not fall below 45°, but I signally failed to exclude frost; and it was well for me in a financial point of view, and certainly better for the bees, that I did fail.

During the winter of 1885, and the following winter, the thermometer in my cellar, after the cold weather set in (say about half of the winter), registered 30°, occasionally dropping down to 28°, but, strange (?) to say, the bees, without any exception, wintered perfectly.

Last winter the cellar was made much warmer than ever before, the mercury indicating 45° (often higher), but the loss of bees was *much greater* than the preceding winters. Was this phenomenal, or the legitimate result of cause and effect? On Nov. 22, 1887, my bees were put into the cellar, having previously provided tight outside and inner doors, and stopping all crevices, besides making ample provisions for ventilation. The weather has been, with one exception, unusually warm, and in consequence the thermometer in the cellar has registered, nearly every day, 50°, until night before last, when I succeeded (by opening wide all outside doors, and raising the curtain used for darkening the apartment) in lowering the temperature to 42°, and last night to 32°.

Up to this time the stronger colonies have been very restless, necessitating the use of wire-cloth to confine them to their respective hives. Night and day it was distressing to hear them "roar," so different from the low, gentle hum of contentment that there is no mistaking the cause, or sound. Although there were no symptoms of diarrhea, the death-rate was fearful, and would soon have depleted the colonies had it not been checked.

When the mercury dropped to 42°, the change inside the hives was apparent at once, but when it reached 32° the bees went into the hives and remained perfectly quiet and contented.

Whenever the temperature rises above 42°, Fahr., in my cellar, the bees become restive, and boil out of the hives as if in the act of attacking marauders; hence I say that from 32° to 38° is the proper temperature for a bee-cellar or cave; and I do not fear for the safety of *my* bees if it drops occasionally to 28°.

If I could regulate the temperature at all times I would not allow it to rise above 40°, for I am satisfied that "heat" is more injurious to bees in "confinement" than cold, provided the cellar is dry and well ventilated.

How many, if any of the bee-keepers who have written on the subject, have tested the condition of a *strong* colony as to bodily heat generated? How do they know that 45° or 50° is "about right?" that if the temperature falls below those figures, the bees become restless, exercise violently to keep warm, consume more honey than is

necessary to sustain life, and diarrhea is the result? Do their assumptions comport with scientific investigations? That theory is fallacious, and has no foundation in fact, so far as my observation has extended; for we have occupied a room above the bee-cellar for four winters, and cannot subscribe to that hypothesis.

By repeated trials I have satisfied myself in regard to degrees of heat engendered by a large colony. For instance, when the temperature of the cellar 3 feet from the hive is 32°, inside (not among the cluster), a thermometer laid lengthwise on top of the brood-frames registers 78°, a difference of 46°, with the hive raised from the bottom-board a bee-space, and burlap on the hive slightly raised. If the same rule applied to a higher (outside) temperature, it would be as follows: At 35° on the outside, inside of the hive it would be 81°; 40° outside, 86° inside; 45° outside, 91° inside; 48° outside, 94° inside; and 52° outside, 98° inside the hive.

My bees on the summer stands, whenever the mercury reaches 90° in the shade, either loaf idly around the throne (bee-throne) or hang outside the hives, and I feel like following their example. If the degrees of heat was maintained in proportion to the scale above given, the heat inside the hives would be unendurable, but at 41° outside, the bees begin to break cluster, and at 45° the cluster is broken up, and they manifest a very restless disposition, traveling swiftly to and fro, trying to get out of the hives, and on such occasions the loudest "roaring" is heard. This fact cannot be gainsaid, for inside of the experimental hive the thermometer registered but 76°, proving conclusively to me, that the bees endeavor to keep the temperature at from 76° to 78°, the proper condition for successful wintering.

High temperature, in my opinion, is the cause of bee-diarrhea, not improper stores, as my weak colonies have never shown symptoms of that disease. Again, hives packed full of bees, as many of mine are, with the mercury ranging from 45° to 50°, sweat profusely, and the combs in consequence soon become moldy, the honey unfit for use, the entire colony perish, and in the spring, when the hives are opened, to our astonishment we find a putrid mess of bees, and the cause is attributed to pollen, honey-dew, or poor honey, jumping at conclusions. While it is a fact that our stronger colonies cannot be wintered successfully in a cellar wherein the temperature rises so high as to cause the trouble indicated, weak colonies will remain perfectly quiet, and winter well in an

atmosphere deterring to the majority of large colonies.

As all colonies are not of uniform size, we must make the conditions alike for both large and small ones, which can be done by dividing the larger, and contracting the smaller colonies, by using division-boards, thereby compelling them to cluster as desired. I prefer medium-sized colonies, but "men and mice go oft agley," men especially, if as in my case the elements combine to frustrate all our well-laid plans.

In this article I have been actuated by a desire to help solve the problem of wintering bees, "under the ground;" and as an "ounce of preventive is worth a pound of cure," so is one practical scientific fact of more value than volumes of theoretical asseverations. I have been careful not to submit "positive assumptions upon the tottering platform of unverified theories."

Madison, ♀ Nebr., Dec. 16, 1887.

SPECIALISTS.

Can a Specialist produce Honey cheaper and in better shape than others? If so, why?

Read at the Ontario Bee-Keepers' Convention,

BY DR. C. C. MILLER.

By *specialist*, in this case, I suppose is meant one who keeps a number of colonies and makes bee-keeping at least a principal part of his business. Just where is the dividing line between one who is, and who is not a specialist may not be so easily determined. I suppose all would agree that a man who keeps a thousand colonies and devotes his whole time and thought to bee-keeping is a specialist, and one who owns a single colony which is left to take care of itself without the owner's knowing whether the king or the drones lay the eggs, is not a specialist. Somewhere between these two lies a ground where it might be hard to tell whether a man were a specialist or not. Without any hair-splitting, however, we may all agree that the specialist in bee-keeping devotes a considerable portion of his time and thought to the care of his bees, and has enough colonies so that their failure or success may be a matter of serious concern to him.

I may as well frankly avow myself as a believer in specialties, but it is well to look at both sides. The general tendency is toward specializing in all departments. Our great grandmothers cut the wool from the sheep's backs, and without passing from their hands the wool was fashioned into stockings or coats. Now all that is changed. At least half a dozen persons take the place

of the one great grandmother, each one pursuing his specialty, and so it is everywhere.

In an age so keen to the pursuit of wealth, there is no evading the conclusion that there must be money in settling down into specialists, or it would not be done. There are, however, exceptions to general rules. Take the two cases we have supposed, one man with a thousand colonies, another with one. The 1,000-colonies man cannot produce honey for nothing, that is clear. He must have something to buy his bread. The 1-colony man attaches little or no value to his bees. They cost him nothing, and in the event of a failure of the honey crop, he counts upon no loss for he has bestowed no labor on his bees, no study or thought. If they give him a crop, it is so much clear gain. He divides with his neighbor, or takes his honey in a pail to the nearest store, and accepts whatever price is offered, as he is not particular what he gets for that which has cost him nothing. He counts it about the same as the wild grapes which grow in his fence-rows, and which any one can have for the gathering. Looking at it in this light, as between the man with 1,000 colonies and the man with one, does it not look as if the latter has the best of it in point of cheapness? Looking at it no further than this, I do not wonder that some hold the view that every one should be encouraged to keep bees, and that to have honey plenty and cheap, all that is necessary is to have a bee-hive at every man's door.

But let us see what is the result of this happy-go-lucky state of affairs. Has not this system been tried? I think that close observation will bear me out in saying that before the days of specialists in bee-keeping, when honey "cost nothing," not one family had honey to eat where three now have it. Please do not forget that the plan of having bees kept 1 or 10 colonies in a place, is exactly the system that was in vogue 50 years ago, and is no new thing. Is the system practiced as much now as then? Look around you and see. People are not apt to give up that which is profitable. If the man with one colony can produce honey for nothing, does he follow it up year after year? Very seldom. The fact is, take a series of years and he cannot produce his honey as cheaply as he can buy it of the specialist, and the strongest proof is his own actions.

I have just been looking over a list of bee-keepers of ten years ago, and of those who were specialists not one in ten has left the ranks. On the other hand I recall to mind those who were non-specialists living about me ten years ago, and not one in ten of them to-day owns a bee, although some of them had as many as 20 colonies. Put-

ting these two facts together, do they not show that the specialist can produce honey more cheaply than others? Else why does he keep at it, and others give it up. The fact is, the latter consider it a matter of luck. If, walking along the road, I find a silver dollar and pick it up, it costs me nothing, but I would hardly argue from that, that finding silver dollars in the road is the cheapest way of getting them as a steady business.

Very strong proof, then, that the specialist can produce honey more cheaply than others is the simple fact that he persists in the business when others give it up. Now why can he produce it more cheaply? Why can you buy your coats and pants at the clothier's more cheaply than your wife can make them? Because the clothier has the proper appliances, and knows his business. Just so with the specialist in any line. The man who makes a specialty of bee-keeping is provided with books and papers. He studies his business, and is thus less liable to make disastrous mistakes. Keeping a large number of colonies, he can afford to be supplied with the best implements and labor-saving appliances. Above and beyond everything else, however, is the one reason, that the specialist knows his business. Can you expect anything else in any line of business than that the man who gives his best thoughts and energies to that business will succeed better than he who knows nothing about it?

To take the middle part of the subject last, the specialist will produce honey in better shape, for the same reason that he can produce it more cheaply, simply because he has better facilities, and because he *knows how*.

Marengo, 8 Ills.

SEASON OF 1887.

Comparing Farmers with Apiculturists in a Poor Season.

Written for the American Bee Journal
BY DR. H. J. SCOLES.

I commenced the season of 1887 with 44 colonies, 40 of them being in good condition, and the other 4 were quite weak. When the white clover began to bloom, the 40 colonies were ready for it, but there was but a small bloom, and of what there was the heads were small and yielded but little nectar. The clover looked sickly, and appeared to be dying out; then the drouth set in, and it appeared to be about all dead.

The linden bloom was early, and it yielded but little, so that from my 44 colonies I got but 4 swarms, and some of the weak colonies dwindled away

until I have but 43, which I put into the cellar on Nov. 18, 1887. About one-third of them were rather light, but had stores enough, I think, to keep them until they are put out in the spring.

I secured but 185 pounds of honey, all in the comb. But few of the colonies that I had set apart for extracting, had any surplus, and that I saved to give to those that were short of stores. In this part of the country the blacker the bee, the less stores they gathered.

I have been handling bees for about 15 years, and the one just past was the poorest season for honey that I have ever experienced. A great many have become discouraged, and were trying to dispose of their apiaries the past fall. What folly! If a farmer loses all of his hogs by cholera, he does not stop trying to raise more; or, if the chinch-bug or grasshopper destroys his crops, he does not cease sowing and planting; but it makes him the more careful. Why should it not be the same with apiculturists, and thus make us the more careful, so that we may be ready to take advantage of a good season when it does come?

Knoxville, 9 Iowa, Jan. 2, 1888.

STARTERS.

Suggestions about Fastening Foundation in Sections.

Written for the American Bee Journal
BY ED. S. EDEN.

After reading Mr. Fox's article, on page 823 of the BEE JOURNAL for 1887, I fail to see that his method of fastening foundation in sections would be very satisfactory, especially to me. I fancy that if Mr. Fox would use a foundation starter that would reach across the section, he would find that his method would prove very unsatisfactory. Very few bee-keepers use as small a starter as does Mr. Fox, 1-inch square.

We will suppose that Mr. Fox uses a starter that is 2 inches deep. I presume that it would require $\frac{1}{4}$ of an inch to be pressed on to the section, as a means of fastening it. Now $\frac{1}{4}$ of an inch is $\frac{1}{8}$ of 2 inches. We will suppose again that Mr. Fox invests \$100 in foundation; $\frac{1}{8}$ of 100 is \$12.50; which would be very unsatisfactory to me. In Mr. F's case, his loss is \$25, for he uses just one-half the width, and consequently loses one-fourth of the whole amount.

Another objection to fastening foundation by pressure is, that if the sections are allowed to stand any length of time after the starters have been

fastened in them, the foundation will curl out to one side; and if placed on the hive in this shape, the bees will fasten the sides of the foundation to the section in a great many cases, so that it is impossible to get straight combs without separators.

My bees have consumed very little honey so far this winter.

Eastwood, Ont., Jan. 2, 1888.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*
Jan. 17, 18.—N. W. Ills. & S. W. Wis., at Rockford, Ill.
D. A. Fuller, Sec., Cherry Valley, Ills.
Jan. 18, 19.—Vermont State, at Burlington, Vt.
R. H. Holmes, Sec., Shoreham, Vt.
Jan. 17-19.—New York State, at Utica, N. Y.
G. H. Knickerbocker, Sec., Pine Plains, N. Y.
Jan. 20.—Haldimand, at Cayuga, Ontario.
E. C. Campbell, Sec., Cayuga, Ont.
Jan. 25, 26.—N. E. Ohio, Northern Pa. and W. New York, at Meadville, Pa.
C. H. Coon, Sec., New Lyme, O.
Apr. 24.—Des Moines County, at Burlington, Iowa.
John Nau, Sec., Middletown, Iowa.
Jan. 24-26.—Eastern New York, at Albany, N. Y.
John Aspinwall, Sec., Barrytown, N. Y.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

SELECTIONS FROM OUR LETTER BOX

Sweet Clover for Bees, etc.—

Nathan Davis, Emporia, Kans., on Dec. 28, 1887, writes:

The bees are wintering well. I commenced the season of 1887 with 25 colonies, and I have increased them to 30 colonies. Bees have done nothing here for two years, on account of the drouths. There has been nothing raised the past year. I have been in Kansas 28 years, and I have never seen times as hard as they are at present. I think that it would pay to sow sweet clover for the bees. I had two acres that bloomed this year, and the bees did well on it. I saved 16 bushels of the seed. I have no trouble to get it to grow.

Honey for the Liver.—Mr. W. H.

Smith, Mount Salem, Ont., on Jan. 3, 1888, writes:

I have been a careful reader of the AMERICAN BEE JOURNAL for several years, and I have frequently realized more value from one copy, than the cost of a whole year's subscription. There is one item to which I wish to call the attention of the readers, which I read in the spring of 1886, and that treated of honey as a medicine for the liver. My wife, having for years been a sufferer from liver trouble, concluded

to give honey a thorough trial. At the time she commenced taking the honey, she was very thin in flesh, and a great sufferer, weighing about 100 pounds. In a few weeks she was materially better, and found that she had increased 13 pounds in weight. During the season she regained her health completely, and weighed 142 pounds. She is now a picture of health. I shall be pleased to reply to any one desiring further particulars. It would be quite impossible for me to mention here all the benefits that I have realized from reading the very valuable AMERICAN BEE JOURNAL.

Varieties of Hardy Raspberries, etc.—L. C. Woodman, of Grand Rapids, Mich., on Jan. 2, 1888, says:

Mr. C. A. Bunch, in a recent number of the BEE JOURNAL, asked that some Michigan bee-keeper should give some information in regard to hardy raspberries. As I have 10 acres in cultivation, I will try to answer. I would put the Cuthbert, a red variety, at the head for bee-keepers; and then the Souhegan, Tyler and the Ohio, of the black-cap varieties, next to the head.

My bees are in the cellar, and seem to be wintering nicely. My chaff-hive apiary, 3 miles from home, seems to be wintering equally as well.

Large Crop of Honey, etc.—J. E. Cady, Medford, Minn., Dec. 31, 1887, writes:

My crop statement for 1887 is as follows: Number of colonies in the spring, 109, which I increased to 118 colonies. I took 8,575 pounds of honey, nearly 600 pounds of it being comb honey, and the balance extracted; 2,635 pounds was from buckwheat and fall weeds. It has been storming for the last three days, and the snow is getting quite deep. Bees in the cellar seem to be quiet and comfortable at a temperature of 48°.

To the Mountains.—J. F. Flory, Lemoore, Calif., on Dec. 10, 1887, writes:

Bees have not stored a full crop of honey here; in some places they stored less, and in others more than half a crop, so that on an average it has been about half a crop. We have about 500 colonies, 300 colonies here, and the others some 8 miles away. We shall move them next spring about 50 miles west, up the mountains. I have 25 acres in fruit, and 18 acres in raisins. We have so many yellow-jackets, or wasps, that cut open the fruit, and then the bees suck out the juice. I am

an enthusiastic bee-man, have been such for over 30 years, and so dislike moving my bees from this place; but I see no other remedy at present. I think of keeping perhaps some 20 or 30 colonies here, but the rest I will move.

But Little Honey Obtained.—A. H. Thorne, Fountain City, Ind., on Dec. 27, 1887, says:

I started last spring with 22 colonies of bees, bought 6 more Italian colonies, and increased them to 40 good colonies, and introduced eight Carniolan queens successfully, which I will try the coming year. I had to feed my bees for winter, and I did not get honey enough for use in my own home. The name, "extracted honey" is good enough for me.

Carrying out Brood, &c.—J. M. Doudna, Alexandria, Minn., on Dec. 29, 1887, writes:

The honey season was very short, only lasting 8 days, from July 4 to 12. Early in June the bees began to carry out brood. I had read that the cause was "no honey," and so it proved. I immediately commenced to feed them, and continued until the linden bloom, and then I obtained 2,700 pounds from 68 colonies. All of it has been sold at good prices. Bee-keeping has paid me better this year than ever before. To me the BEE JOURNAL is worth ten times its cost every year.

Hardy Raspberries and Bees.—J. H. Newman, Charlevoix, Mich., on Dec. 26, 1887, writes:

Mr. C. A. Bunch (on page 795 of the BEE JOURNAL for 1887) asks about hardy raspberries, and in reply I would say that the red raspberries are nearly all hardy here, with the temperature sometimes 30° below zero. The best we have are the Cuthbert, Turner, and Shaffer's Colossal, of the red berries. Of the black raspberries we raise the Ohio, Tyler, and Souhegan, which are good and hardy, but not so hardy as the red kinds. The bees seem to work well on all the raspberries, both wild and tame; and they work on the berries as well as the blossoms.

Expericnee with Bees, etc.—A. B. Congdon, South Hadley Falls, Mass., on Dec. 24, 1887, writes:

In the spring of 1886 I bought 2 colonies of bees in box-hives, and not knowing how to transfer them, it was not done until the next spring, so the first year was wasted, just because I

did not post myself before beginning with bees. This year I transferred them into movable frame hives, and doubled them up, as it was a very poor year for honey here also. I did not get any honey, but I am not discouraged, and I think, and know, that if there will be any honey taken in this vicinity next year, that I shall have my share of it.

I have put my bees into the barn in a comfortable place. I had to feed them some sugar syrup before putting them away. I have looked at them, and they are as quiet as can be, and I think they will come out in the spring as bright as need be. They are hybrids, but I intend to Italianize them in the spring.

Bees did Poorly.—Wm. Robson, Rolla, Mo., on Jan. 2, 1888, writes:

Buoyant with flattering prospects in the spring of 1887, the supers were arranged, new hives prepared, and every thing made ready for the harvest of 1887, when along came storms from all directions, for a change. Did I get any honey? Yes, but allow me to explain: I left a few cases of honey on the hives over winter, that was gathered during the summer of 1886, but not being filled with comb and honey as desired, they remained until white clover began to bloom. I then removed them, and for the first time in my life I had the pleasure of tasting honey from the bloom of the apple trees. I placed other cases on the hives and awaited results. The "result" is an empty pocket-book, for want of honey to sell. Since I can remember, which is 40 years ago, I have no knowledge of bees doing as poorly as they did the past season. I have spoken to several about their bees, how they were doing, etc.; their reply is, "no good; all dead."

A Puzzling Colony, etc.—R. J. Mathews, Riverton, Miss., on Dec. 18, 1887, writes:

I commenced the season with 9 colonies, increased them to 19, and took one from a tree in the woods, so I now have 20 colonies in good condition. I obtained 1,040 one-pound sections of honey, and 250 pounds of extracted honey, of which about 75 pounds was of very poor quality, and the rest was fair. I consider that pretty good for a bad season generally.

To-day it is clear and warm, the temperature is up to 65° out-doors in the shade, and I see from one colony of hybrid bees a large number of drones flying. I have another colony that puzzles me. On Sept. 2 I took its queen (a black one) from them, and

gave it to another queenless colony belonging to my little son, a colony that he got from the woods. In a few days I examined the little boy's colony, and again found it queenless, so I went to my black colony where the queen came from, and found that they had a queen laying, and so I supposed that she had gone back home; but now the bees are nearly all nice Italians, and no young black bees in the hive. Can any one account for this?

Properly Attending to Bees.—

F. H. McDonald, Star, Idaho, on Dec. 26, 1887, says:

Those who attended properly to their bees have reaped a bountiful crop of honey in this neighborhood. Some late swarms have but little food. One of my neighbors put his bees into the cellar last month, and in a few days he had to take them out again, as they had the diarrhea. He will winter part of them in the cellar, and part on the summer stands. Nearly all the bees kept in this valley are, and have been so far, wintered on the summer stands without any protection, and also with scarcely any loss.

Half an Average Crop, etc.—

George Spittler, Mosiertown, Pa., on Dec. 26, 1887, writes:

The honey crop in this part of the State is not more than half an average crop, being about 20 pounds per colony, spring count. I started in the fall of 1886 with 20 good colonies, and 3 weak nuclei; in the spring of 1887 I had 18 colonies, 3 queenless ones and 2 nuclei. I had them packed in chaff. Those that were weakest in the fall came through in the best condition. I have 23 colonies packed as they were last year, out-doors, and 11 colonies in the cellar. One colony out-doors and 3 in the cellar are very weak—nothing but nuclei. There was but very little swarming the past season.

Good Winter for Bees, etc.—

Joshua Bull, Seymour, Wis., on Jan. 5, 1888, writes:

On page 823 of the BEE JOURNAL for 1887, I am made to say that basswood yielded continually "from July 4 to July 27 inclusive," which is not according to the facts in the case. I intended to say, "from July 4 to July 7" (not 27).

My bees were in excellent condition last fall to enter their long winter repose, the colonies being very populous, with an abundance of stores. The weather, during November and December, was unusually mild for that

time of the year in this latitude; and although the mercury was below zero several times, it was for a few hours only. The year 1887 closed with a driving snow-storm, which continued into the beginning of the New Year. When the storm cleared away, it turned cold, and on the morning of Jan. 3 the thermometer indicated 24° below zero. But it is quite mild again to-day, being 22° above zero. Somehow I feel a sort of premonition that this is going to be a favorable winter for bees, and I sincerely hope that the results next spring will be such as will justify that feeling.

BEE CONVENTIONS.

Nebraska State Convention.

The next meeting of the Nebraska State Bee-keepers' Association will be held on Jan. 11, 12, and 13, 1888, in Red Ribbon Hall, at Lincoln, Nebr. The Lindell Hotel will give reduced rates to members. Those who come should get a receipt from their home railroad agents on starting to Lincoln, as railroad companies require fifty receipts to entitle members to reduced rates. President Ryan requests all members to have questions ready for the first evening, so that they can be arranged in order. The programme is as follows:

What are the essential points in locating an apiary?—J. G. Hodges and J. L. Blanchard. Apiculture as a profitable and permanent occupation.—A. D. Keller and C. Cealay. How does bee-keeping pay compared with other occupations?—R. E. Leach and J. Rodgers. How to obtain the most honey in the best marketable shape.—Mrs. J. N. Heater and M. Tower.

How much, if any, comb foundation should be used?—E. Kretschmer and E. Tower. Diseases of bees, their causes and remedies.—E. M. Hayhurst. Is spring stimulation advisable? If so, with what?—T. L. Von Dorn and W. J. Lynch. How best to prepare honey to exhibit for sale or for show.—Mrs. J. N. Heater and E. W. Whitcomb.

Which is more profitable, comb or extracted honey?—A. Johnson and M. D. Abbott. Increase, natural or artificial?—R. V. Muir and J. F. Polk. Should bees be frequently examined? and at what temperature should the atmosphere be?—Mrs. L. Marshall and Jas. Jardine. Spring work with bees.—E. M. Hayhurst. Fall breeding and spring dwindling.—J. N. Heater and E. Kretschmer. Honey-plants of Nebraska.—Professor C. E. Bessey, of the State University. Rearing queens and clipping their wings.—J. M. Young. H. N. PATTERSON, Sec.

Vermont State Convention.

The 14th annual convention of the Vermont Bee-keepers' Association will be held at the Van Ness House at Burlington, Vt., on Wednesday and Thursday, Jan. 18 and 19, 1888. The order of exercises is as follows:

WEDNESDAY EVENING, 1:30 P. M.—Convention called to order by the President. Reading of the minutes of the last meeting. Reading of the Constitution, etc. At 2:15.—A paper by W. H. Wheatley, St. Johnsbury, on "Vermont Bees." Followed by discussion of the subject by the convention. At 2:45—"Experience of Fifteen Years in Bee-Keeping" by H. B. Isham, New Haven. At 3:00—Discussion: "Is it advisable to insert empty combs in the centre of brood-

nests for the purpose of spreading brood in the spring?" Opened by E. M. Wright. At 3:30—Discussion: "What is the best method to prevent an increase in colonies?" Led by J. E. Crane.

WEDNESDAY EVENING, 6:45—Appointment of committees.

At 7:00—Discussion: "Bee-keeping in Vermont; does it pay?" "Its hindrances," N. G. Webster, Bakersfield, "Its Expenses," J. H. Larabee, Larabee's Point. "Its profits," Geo. Beecher, Essex. "As a business," H. L. Leonard, Brandon.

At 1:15—Essay: "The pleasure and difficulties of bee-keeping;" by a lady bee-keeper.

At 8:15—Essay: "Should women keep bees and join the Bee-keepers' Association?" by a lady bee-keeper.

THURSDAY FORENOON, 9:00—Reports of the Secretary and Treasurer. Reports of committees, organization, etc.

At 10:15—Discussion: "Is it profitable to use full sheets of foundation in the brood-chamber?" Opened by F. H. McFarland, St. Albans.

At 10:45—Question Drawer. A. E. Manum, Bristol.

At 11:15—Discussion: "Marketing honey." Led by J. E. Crane.

Adjournment. R. H. HOLMES, Sec.

The Vermont Association are to be congratulated upon the nice programme of 12 pages which they have issued.

Ohio State Convention.

The fifth annual Ohio State Bee-keepers' Convention will be held in the United States Hotel, on the corner of High and Town Sts., Columbus, O., on Jan. 10 and 11, 1888. An interesting programme will be arranged. Reduced rates at the hotel are \$1.50 for each person, double, or \$2.00 per day if single. There will be reduced rates of travel, particulars of which will be given later. It is desirable to know who can be present. Will you kindly notify me by postal card, at Bluffton, Ohio. The following is the programme:

TUESDAY, 9 A. M.—Reading the minutes of last meeting. Receiving members and collecting dues. Reports of the Secretary and Treasurer, and standing committees.

Bee-conventions, how to make them a success, and their value to bee-keepers.—A. I. Root.

Discussion on the Sectional Brood Chamber and its advantages.—Led by Dr. G. L. Tinker.

Reversing, and has it come to stay?—C. M. Kingsbury.

TUESDAY, 1 P. M.—Discussion on Bee-keeping in connection with other pursuits.—Led by F. A. Eaton.

Bee-keeping for women.—Mrs. Jennie Culp.

Bee-keeping as an exclusive pursuit.—Dr. C. C. Miller.

TUESDAY, 7 P. M.—Wood vs. tin separators: Is it profitable to dispense with either?—Dr. Bessey and other surplus arrangements in connection with bee-spaces.—E. R. Root. Discussion on, *Resolved*, That bee-keeping as a business is more profitable than farming. Opening of the question-box.—S. R. Morris.

WEDNESDAY, 9 A. M.—Extracted honey: its production, and the best method of marketing it.—Dr. A. B. Macon.

The commission man and his relation to the honey producer, as affecting the sale and price of honey.—Chas. F. Muth.

WEDNESDAY, 1 P. M.—Flaring-up: its advantages.—J. W. Newlove.

Freezing bees.—C. E. Jones.

In-door vs. out-door wintering of bees, and the advantages of the former.—H. R. Boardman.

Election of officers for the ensuing year.

FRANK A. EATON, Sec.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

CONVENTION NOTICES.

The Eastern New York Bee-Keepers' Association will meet on Jan. 24, 25 and 26, 1888, in Agricultural Hall, at Albany, N. Y. Every one is welcome. We are sure to have a pleasant and profitable time.
JOHN ASPINWALL, Sec.

The Des Moines County Bee-Keepers' Association will hold its next meeting on April 24, 1888, at Burlington, Iowa.
JOHN NAU, Sec.

The annual convention of the Vermont State Bee-Keepers' Association will be held at the Van Ness House, in Burlington, Vt., on the Jan. 18 and 19, 1888.
R. H. HOLMES, Sec.

The Ontario Bee-Keepers' Association will hold its annual meeting at Woodstock, Ontario, on Tuesday and Wednesday, Jan. 10 and 11, 1888.
W. COURSE, Sec.

The Hardin County Bee-Keepers' Association will meet at the Court House in Eldora, Iowa, on the second Saturday in each month, at noon (12 o'clock), until further notice.
J. W. BUCHANAN, Sec.

The Cortland Union Bee-Keepers' Association will hold their annual meeting at Cortland, N. Y., on Tuesday, Jan. 10, 1888, for the election of officers and to transact such business as may come before the meeting. All bee-keepers are invited.
R. L. WEAVER, Sec.

The annual meeting of the Northwestern Illinois and Southeastern Wisconsin Bee-Keepers' Association will be held in G. A. R. Hall, corner of State & North Main Sts., in Rockford, Ills., on Jan. 17 and 18, 1888. Dr. Miller will be present, and a good programme is in course of preparation.
D. A. FULLER, Sec.

The Northeastern Ohio, Northern Pennsylvania and Western New York Bee-Keepers' Association will hold its ninth annual convention in the Commercial House Parlor, in Meadville, Penn., on Wednesday and Thursday, January 25 and 26, 1888. Reduced hotel rates have been secured.
C. H. COON, Sec.

Robert's Rules of Order for deliberative assemblies, published by S. C. Griggs & Co., Chicago, is "a gem" in appearance, and an invaluable guide for those who are called to preside over conventions of bee-keepers and others. It has a table, covering two pages, which will aid a chairman to decide 200 questions of importance, without turning a leaf. Price 75 cents.

The Apiculturist for January came in good time, and is as usual full of good things of interest to every apiarist. "Prevention of Increase" is the chief topic in this number, and it contains three good articles on that subject. The BEE JOURNAL and the "Apiculturist" for 1888 can be obtained for \$1.80.

Please to get your Neighbor who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now SO CHEAP that no one can afford to do without it.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell lots of it.

Business Notices.

OUR CLUBBING LIST.

We supply the American Bee Journal one year, and any of the following publications, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

	Price of both.	Club
The American Bee Journal	1 00.	
and Gleanings in Bee-Culture	2 00.	1 75
Bee-Keepers' Magazine	1 50.	1 40
Bee-Keepers' Guide	1 50.	1 40
The Apiculturist	2 00.	1 80
Canadian Bee Journal	2 00.	1 80
Canadian Honey Producer	1 40.	1 30
The 7 above-named papers	5 40.	5 00
and Cook's Manual	2 25.	2 00
Bees and Honey (Newman)	2 00.	1 75
Binder for Am. Bee Journal	1 60.	1 50
Dzierzon's Bee-Book (cloth)	3 00.	2 00
Root's A B C of Bee-Culture	2 25.	2 10
Farmer's Account Book	4 00.	2 20
Simmons' Non-Swarming	1 50.	1 25
Western World Guide	1 50.	1 30
Heddon's book, "Success"	1 50.	1 40
A Year Among the Bees	1 75.	1 50
Convention Hand-Book	1 50.	1 30
Weekly Inter-Ocean	2 00.	1 75
Iowa Homestead	2 00.	1 90

One yearly subscription for the AMERICAN BEE JOURNAL must be ordered with each paper or book, in order to take advantage of the prices named in the last column.

We pay 20 cents per pound, delivered here, for good Yellow Beeswax. To avoid mistakes, the shipper's name should always be on each package.

We Supply Chapman Honey-Plant seed at the following prices: One ounce, 40 cts; 4 ounces, \$1; ½ pound, \$1.75; 1 lb., \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Sweet Clover, (*Melilotus alba*), furnishes the most reliable crop of honey from July until frost, and at the same time it furnishes the most delicious honey, light in color, and thick in body. It may be sown in waste places, fence corners, or on the roadside, at any time of the year.

Now two years running, on the same land, and the honey crop will be without intermission. Money invested in Sweet Clover Seed will prove a good investment. The Seed may be obtained at this office at the following prices: \$6.00 per bushel (60 lbs.); \$1.75 per peck, or 20 cents per pound.

Yucca Brushes are employed for removing bees from the combs. They are a soft, vegetable fiber, and do not irritate the bees. We can supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Red Labels for one-pound pails of honey, size 3x4½ inches.—We have now gotten up a lot of these Labels, and can supply them at the following prices: 100 for \$1.00; 250 for \$1.50; 500 for \$2.00; 1,000 for \$3.00; all with name and address of a printer printed on them—by mail, postpaid.

Honey and Beeswax Market.

CHICAGO.

HONEY.—We quote: White clover 1-lb. sections 18@20c; 2-lbs., 16@18c; dark 1-lb. 17@18c; 2-lbs. 15@16c. Extracted, firm at 7@10c, depending upon the quality, and style of package. Dark, 2 or 3 cts. below above quotations. Receipts light and demand fair.
BEEWAX.—22@23c.
Dec. 20. S. T. FISH & CO., 189 S. Water St.

CHICAGO.

HONEY.—Prices range from 18@20c. for best grades, with light demand; 2-lb. sections, 15@16c. Dark is not wanted. Extracted is steady at 7@10c., according to style of package.
BEEWAX.—20@23c. R. A. BURNETT, Dec. 7. 161 South Water St.

DETROIT.

HONEY.—Best white in 1-lb. sections, 19@20c. Extracted, 11@12c. Demand brisk.
BEEWAX.—21@23c.
Dec. 15. M. H. HUNT, Bell Branch, Mich.

CLEVELAND.

HONEY.—Best white 1-lb. sections sell at 19@20 cts. Extracted, 7@8c. Demand small.
BEEWAX.—22@25c.
Dec. 15. A. C. KENDEL, 115 Ontario St.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 16@18c; the same in 2-lbs., 14@16c; buckwheat 1-lb., 11@12c; 2-lbs., 10@11c. Off grades 1@2c. per lb. less. White extracted, 8@9c. Market dull.
BEEWAX.—22@23c.
Dec. 20. MCCAUL & HILDRETH BROS., 28 & 30 W. Broadway, near Duane St.

KANSAS CITY.

HONEY.—We quote: Choice white 1-lb., 16@20c; dark, 16@18c; choice white 2-lb., 15c; dark, 15 to 16c. Extracted, white, in 60-lb. tin cans, 9c; in barrels, 8c; dark, in barrels, 5@6c. California 2-lb. white comb, 18c; dark, 15c. Extracted, white, in 90-lb. cans, 8@9c; amber, 8c.
BEEWAX.—No. 1, 20c; No. 2, 16@18c.
Dec. 18. CLEMONS, CLOON & CO., cor 4th & Walnut

ST. LOUIS.

HONEY.—Choice comb, 19@20c; latter price for choice white clover in good condition. Strained, in barrels, 5@6c. Extra fancy of bright color and in No. 1 packages, 4¢ advance on above. Extracted, in bbls., 6¼@7c; in cans, 7 to 9c.—Short crop indicates further advance in prices.
BEEWAX.—20c for prime.
Dec. 19. D. G. TUTT & CO., Commercial St.

CINCINNATI.

HONEY.—We quote extracted at 4@9c. per lb. Choice comb, 18@20c, in the jobbing way. The demand for extracted exceeds arrivals, and for comb the demand is tame.
BEEWAX.—Demand good—20@22c. per lb. for good to choice yellow, on arrival.
Dec. 12. C. F. MUTH & SON, Freeman & Central Av.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 17@19c; fancy 2-lbs., 15@18c. Lower grades 1@2c. per lb. less. Buckwheat 1-lb., 11@12c; 2-lb., 10@11c. Extracted, white, 9@10c; buckwheat, 6@7c. Demand has slackened some, and to make sales we must shade above prices. About Jan. 15 we expect a more active demand.
Dec. 31. F. G. STROHMAYER & CO., 122 Water St

PHILADELPHIA.

HONEY.—Fancy white 1-lb., 18@19c; fair 1-lb. 17c; dark 1-lb. are slow sale at 14@15c; fancy 2 lbs., white, 15@18c; buckwheat fancy 1-lb., 13@14 cts.; common, 12c. Prices tend downward.
BEEWAX.—23@24c.
Dec. 11. ARTHUR TODD, 2122 N. Front St.

MILWAUKEE.

HONEY.—Choice white 1-lb., 20c; fair, 19@20c; 2-lb., 18@19c; 3-lb., 16@18c. White extracted in kegs or half-barrels, 9¼@9½c; in pails or cans, 8¼ to 10c; amber, in ½-barrels, 9¼@9½c; dark in kegs and barrels, 7@7½c. Demand good, supply fair.
BEEWAX.—22@25c.
Dec. 15. A. V. BISHOP, 142 W. Water St.

SAN FRANCISCO.

HONEY.—We quote: White to extra, 15@18c; amber, 10@13c. Extracted, white liquid, 7@7½c; amber and candied, 5¼@6¼c. Market quiet.
BEEWAX.—20@24c.
Dec. 31. SCHACHT & LEMCKE, 122-124 Davis St

BOSTON.

HONEY.—New crop, 1-lb. sections, 18@20c; 2-lb. sections, 17@18c. Extracted, 6@8c. The market is not very brisk and sales are only fair.
BEEWAX.—25 cts. per lb.
Dec. 10. BLAKE & RIPLEY, 57 Chatham Street.

SAN FRANCISCO.

HONEY.—We quote: White comb, 17@19c; amber, 12¼@15c. Light amber to white extracted, 7½@8c; amber, dark and candied, 6¼@7¼c. Market firm and stocks light.
BEEWAX.—22@23c.
Dec. 12. O. B. SMITH & CO., 423 Front St.

THOMAS G. NEWMAN, Editor.

Vol. XXIV. Jan. 18, 1888. No. 3.

EDITORIAL BUZZINGS.

So Far, the general report is that the bees are wintering well. We have had many cold spells, but such have been of short duration, and the bees have not suffered any inconvenience on that score. What the rest of the winter may be, is as yet an uncertainty.

New Patents.—Two new patents on bee-hives were granted on Dec. 30, 1887. One to T. M. Cobb and the other to F. Danzenbaker. The number of the former being 375,261; and the latter 875,269. What the special features are we know not.

The Ontario bee-keepers met in convention at Woodstock last week, and had an interesting meeting. Martin Emigh was elected President, and J. B. Hall Vice-President. We expect to publish a report of the proceedings next week.

The New York Bee-Keepers are now in session. The nineteenth State Convention met on Tuesday of this week for a three days' session at Utica. We are sorry we did not get the programme until our last week's issue was on the press, or we should have published it entire. We hope that the meeting will be one of great interest and enthusiasm.

Father Laugstroth is again heard from, and our readers may expect an article from his pen in next week's BEE JOURNAL. He intends to go to Cincinnati this week to obtain medical treatment to relieve him from his distressing "head troubles," which is promised by the physician he intends to visit. We hope he will succeed in obtaining a cure.

Drunken Loafers.—That is what the New Orleans *Picayune* calls the bees. It says:

A lady living in Rappahannock County, Va., had 12 colonies of bees, which were very valuable until a distillery was started in the neighborhood. Since it was started, however, the bees pay frequent visits to the still, get very drunk, and are of little profit.

The Chicago *Herald* commenting upon this circumstance, gets off the following, calling them "boozy bees:"

A lady in Virginia has a colony of bees that go to a neighboring distillery and get tipsy. This is a sad revelation for the moralist who is fond of holding up the bee as a bright and shining model for thrift, sobriety and industry. The didactic poetry regarding the little boozy bee seems to be in need of revision.

Mrs. Mahala B. Chaddock remarks very pointedly on the above in the *Farm, Field and Stockman* as follows:

Bees never work on grapes or peaches, neither do they frequent cider-mills or distilleries, except when there is no honey in the flowers. At such times there is no honey coming in, or not enough for the bees to store it.

No one need have the least fear of contracting the taste for whisky from eating honey, as there never was anything more true than this. If bees are gathering honey, they do not trouble distilleries; if they go to the stills they are not gathering honey.

The Reaction Comes, as well to the grape-bees controversy as to many other things. We find the following item now "going the rounds" in the political papers, and such will do much to dispel the prejudices of grape-growers to the bees. Here is the item:

BEES INJURING GRAPES.—The Columbus Horticultural Society reports to the *Country Gentleman* an experiment performed by Mr. McLain, of Aurora, Ills. In a grape-house well ventilated, but bee-proof, he places grapes and other ripe fruits sound as well as imperfect. Three colonies of hungry bees, hived on empty combs, were placed within. They visited the fruit in great numbers, and took advantage of every crack or opening or accidental puncture. They never molested sound fruit. If the skin of a grape was broken or burst from over-ripeness, the bees sucked the exposed juices. They did not attempt to break the skin. The experiment was continued 30 days, with 20 sorts of grapes, with the same result. When grapes were punctured with needles, the bees sucked the juice out only so far as they could reach.

W. R. Graham, Greenville, Texas, on Jan. 10, 1888, writes his congratulations on the BEE JOURNAL for 1888, and adds:

I obtained nine cash premiums at the Texas State Fair and Dallas Exposition, on bees, honey, and bee-fixtures.

"Up to this Time I think bees are wintering good. The weather has been favorable; not much zero weather." So writes M. L. Spencer, of Little Genesee, N. Y. He then adds: "I congratulate you on the appearance of the AMERICAN BEE JOURNAL. I think it much improved for 1888."

Bees from Carniola or Krain, in Austria, are generally known in Europe as Krainer bees; in America as Carniolan bees. Many of these queens are now sent across the ocean by mail, every year, by Mr. Benton, of Munich. Mr. B. is an American, and used to attend the Mich. Agricultural College.

Carniola is a province of Austria, just south of Vienna, and nearly borders Italy on the northeast—the Adriatic intervening. A continuation of the Alpine Mountain range runs through the province—and hence the hardihood of the bees from that mountainous region.

Cabbage and Celery Plants.—A guide to their successful propagation. A new manual of instruction by Isaac F. Tillinghast. Seed and plant grower, and editor of *Seed Time and Harvest*, LaPlume, Pa., 32 pages. Illustrated. Price 25 cents.

This little volume relates in an interesting manner how two farmer's boys started a vegetable plant trade, on a farm in the country, which developed into a large seed and plant business, which now reaches into every corner and section of the Union. It gives modern plans for constructing low-cost hot-beds and greenhouses, to be heated by fermenting manure, fire flues, and hot water. Also, how to successfully grow cabbage and celery plants in the open ground, with certain methods of protecting them from destructive insects and diseases, which have not heretofore been given to the public.

There are no doubt thousands of locations in which, with the aid of this little instructor, an active farmer's boy, or established market gardener, might work up a very remunerative plant business with very little expense or trouble.

✂ We will send the above and the BEE JOURNAL for one year, for \$1.15.

Every One having a garden, or even a shrub, should own and study Vick's Floral Guide, published at Rochester, N. Y., price 10 cents, and a due-bill for 10 cents worth of seeds accompanies the Guide.

Interesting Library.—Mr. S. B. Brillhart, of Kendallville, Ind., writes thus:

For the past five years I have had the AMERICAN BEE JOURNAL bound, and it is beginning to make a very interesting library on "the bee." The BEE JOURNAL is just what every one who owns bees ought to take. It *pays*, and that is a good reason. I usually keep about 25 colonies of bees.

New Catalogues for 1888 are on our desk, from the following persons:

J. D. Goodrich, East Hardwick, Vt.—16 pages—Apian Supplies.

H. G. Frame, North Manchester, Ind.—4 pages—Bees, Queens, etc.

Geo. H. Kirkpatrick, New Paris, O.—16 pages—Bees and Supplies.

A. D. Hale, Deer Lodge, Tenn.—20 pages—Poultry.

GLEAMS OF NEWS.

The Next Convention, etc.—Concerning the re-location of the next annual meeting of the North American Bee-Keepers' Society, and other subjects, Prof. A. J. Cook writes as follows:

AGRICULTURAL COLLEGE, MICH.,
Jan. 12, 1888.

DEAR MR. EDITOR:—Dr. Mason is, as usual, wise in his suggestions. Our calamity is our "magnificent distances." It costs so much to attend our meetings! This is why we cannot hope to equal Europe. Whatever, then, will lessen expense is to be advocated. If the Centennial will give reduced rates to Columbus, O., then I vote for Columbus. Again, it would be nearer the South; and as I remember the cordial greeting that we received at Louisville some years since, I feel desirous to meet the Southern bee-keepers again. I vote for Columbus.

Ohio Horticulturists and Bees.

I am glad that Dr. Mason is stirring up the Ohio horticulturists on the bee-question. I had the honor of addressing that Association a year ago, at their annual meeting, and I told plain truths about bees. The truth is, the value of bees, aside from the honey which they gather, is so important that all, especially farmers and horticulturists, should know of it. Therefore I lose no suitable occasion to spread this knowledge. I think that all bee-keepers should be equally ready. We can thus create right views where ignorance and prejudice now reign.

Fraternal Good-Will.

The words from our good friend, Mr. McKnight, are good reading. Who could imagine Dr. Mason with malice in his heart? If any man in America has "good-will to man" written all over his face, that man is our big, fat, jolly friend of Toledo. I could but think, as I read Mr. McKnight's article, how the bee-periodicals had changed in the past few years. In the olden time, quarrels, invective and vindictive thrusts were all too common. Now everybody is kindly disposed, and a good brotherly temper pervades every page of all our bee-papers. That this spirit will never be replaced, is my hope, as it is my belief.

As to changing the location of the next meeting, the executive committee have full power under the Constitution to make the change, if they are satisfied of its desirability. The points of advantage mentioned by Dr. Mason are ample, in our opinion, and the change should be decided upon, and notice given as soon as possible.

The location of the "Centennial Exposition of the Ohio Valley and Central States" is at Cincinnati, O., and the time of holding it is from July 4 to Oct. 27, 1887. As Brother Muth was the first to suggest the holding of the next meeting of the North American Bee-Keepers' Society at Cincinnati because of this Centennial Exposition, cheap fares, etc., and as he is "a host" to make good arrangements for such a meeting—we vote for Cincinnati.

The Centennial Exposition in Columbus, O., is to be held in September, a trifle too early for a successful bee-meeting.

As to the fraternal and friendly feeling mentioned by Prof. Cook, no one rejoices,

more in its "exhibition" than do we; indeed it is our opinion that no one should attempt to write on matters apicultural, with any other intent or purpose; in its absence, let the pen be dropped, and not resumed until such a disposition is in full possession.

Experiment in Freezing Bees.—

Mr. J. C. Haines, of Herkimer County, N. Y., writes to *Gleanings in Bee-Culture*, in relation to an experiment in freezing bees, to find if they might again be revived, as follows:

I got a pan of clean, dry snow, just after it had fallen, set it in the barn to keep it soft and light, and on Nov. 30, about 3 p.m., I opened a strong colony, smoked slightly. In a little while I took a small handful and dropped them in the pan of snow. As soon as they were chilled, I put some in a dry paper box, and set them in a small open building. Next morning we brought two of each lot into the house, put them on the mantel near the kitchen stove, where it was nice and warm (not hot), but they showed no signs of life. We left them in all day, and got more of each lot, but they showed no signs of life at all. To-day I brought more in, but could not see any signs of life. They are quite dead. We opened some and they seemed to be filled with honey.

At the time when we put the bees in the snow in the first place, it thawed some on the south side of the house, and the bees were bright and active, and seemed quite strong; but it was very cold that night. Next morning the thermometer was down to 5° below zero, and the next day was very cold. The thermometer was at zero. So you see if there is anything in its being cold, they had the benefit of it.

Neat as Wax.—Mr. J. M. Shuck, of Des Moines, Iowa, writes us as follows:

No. 1, Vol. XXIV, of the AMERICAN BEE JOURNAL is received, and in a new dress, greatly improved in appearance. It looks like the baby's first tooth, neat as wax. It is certainly equipped for a trip "all around the world."

Succeeded Grandly.—The *Republican Standard*, published at New Bedford, Mass., gives us this unsolicited notice, for which it has our thanks:

When the AMERICAN BEE JOURNAL commenced its appearance as a weekly, it was prophesied that it would not succeed, but it has grandly. Every number is full of useful information.

The *Journal of Lewiston, Maine*, remarks as follows on the same topic:

The AMERICAN BEE JOURNAL is the oldest bee-paper in America, but that isn't all; it stands at the head in bee-literature, giving from week to week the best thought and practice in apiculture. No one who keeps bees can expend a dollar to better advantage than to subscribe for this JOURNAL.

The Canadian Bee Journal is a year behind the times. It apologized on the first page for having "1887" on the cover, and just above the apology is the date in black-faced type, "Jan. 4, 1887." In this case "two wrongs will not make one right." But mistakes will happen in the best regulated families.

The *Review* came promptly to our desk, and is very attractive in appearance. Its reading matter is much superior to the ordinary "run" of such, in the various new bee-papers. The complete list of contents may be found on page 47.

The principal topic in this first number is "Disturbing bees in winter," which the editor "sums up" in these words:

What bee-keeper that does not delight, in winter, when the mercury is coquetting with zero, to enter a comfortable bee-cellar, in which the hives stand in long rows, tier above tier, and peep into their entrances and see the bees hanging from the combs in golden-brown clusters? And how many in making these visits have not, sometimes, felt that they were trespassing upon forbidden ground; that the price of these admiring glances might be disease and death to the admired? We have often had such thoughts; have felt that a visit in winter to the bee-cellar, or a peep into a live out-of-doors, was something like a stolen pleasure; but these thoughts will come no more, for we are thoroughly convinced that such examinations do no harm. That bees can be moved in winter, or the hives opened, combs taken out, bees examined, etc., and no injurious results ever follow, we are not so certain; but that such treatment seldom results in harm, we are well satisfied. We recollect reading a report of some bee-keeper who lost part of his bees from starvation in the cellar. He knew they were short of stores, but feared to disturb them, lest it should result in greater loss than would starvation. Had we colonies of bees that we thought might be lacking in stores, we should unhesitatingly examine them, and feed them, too, if we found them in need.

The frequent and extensive handling of bees during winter, indulged in by some of our correspondents, might, perhaps, have had less happy closing chapters, had the food been of a different character; in fact, all are quite well agreed that frequent disturbance may aggravate the evils arising from unsuitable food; and, as the years roll by, we are becoming more and more convinced that food is the pivotal point upon which turns the question of wintering bees in a Northern climate. Our faith in the popular belief that disturbing bees in winter is necessarily injurious has been entirely destroyed; and our advice would be: If you wish to know how your bees are wintering, go and examine them—quietly and carefully, and if you think they need food, or any other attention, make the necessary examination and give the required care with but little fear that the disturbance will cause injury.

We wish the *Review* a long and prosperous career, and its editor all the success he could wish for himself. No. 1 is excellent, and should please the most fastidious.

We are Sorry to learn that our friend Paul L. Viallon, of Bayou Goula, La., has been quite ill for some time. Bronchitis is the cause of the trouble. He is now recovering, and this will be good news to our readers, as he is to give us answers to queries hereafter. The first answers from him appear in this number of the BEE JOURNAL. In reference to moving an apiary, he remarks as follows:

A few years since I moved my apiary about 5 acres, during a cold day. I placed a slanting board in front of each hive, as advised by Mr. Dadant, and I do not think that a handful of bees returned to the old location.

The School of Sorrow.

BY J. K. LUDLUM.

The mills of God grind slowly;
They grind exceedingly small,
For whoso' the Father loveth
He chasteneth, one and all.

Sunlight will ripen harvest,
But without clouds and rain
The seeds in spring-time scattered
Could never grow into grain.

Smiles are soothing and pleasant,
Happiness good to behold,
But without the fire refining
How could we test the gold?

If we should suffer no sorrow,
How could we count the cost?
Would not our hearts grow careless?
All our sympathies lost?

"Sorrow makes all men brothers,"
Sorrows our hearts refine;
The whirlwind smiting the forest
Tests the strength of the pine.

Aye, bitter the school of sorrow,
Bitter the cross and pain;
But trial worketh patience,
And loss is followed by gain.

—Written for the *Ætna*.**BIOGRAPHICAL.****MR. IVAR S. YOUNG, OUR VISITOR FROM NORWAY.**

We have received the following letter from Mr. Young, and in order that our readers may get an idea of his personal appearance, we have prepared an engraving from the photograph which he presented to us for our Bee-Keepers' album. Mr. Young's letter reads thus:

MESSRS. THOS. G. NEWMAN & SON:—Will you kindly allow me to express, through the AMERICAN BEE JOURNAL, my most cordial thanks for all the friendliness and affability which were so profusely shown to me during my memorable visit amongst the bee-friends of the United States and Canada. I will, as long as I live, take delight in thinking of my trip, and never! no never! forget the World's most able bee-keepers, nor their exceeding hospitality towards me, as a stranger.

I only regret, that my time was so limited, that I had no opportunity of personally calling on the many more, whose names were so well known and dear to me from the bee-periodicals.

Respectfully yours,

IVAR S. YOUNG.

The apiarists of America will appreciate Mr. Young's expressions of kind feeling and regard, and duly reciprocate them, for he may very properly be called "the father of modern bee-keeping in Norway."

Mr. Young's visit to America was at the instigation of the Norwegian Government, and at its expense; and his mission was to gather up all the information possible to be obtained in reference to modern and progressive apiculture in America, together with details of methods and samples of implements. Such will be used in the interest of "apiculture as an industry" in Norway.

The Norwegian Bee-Keepers' Society was organized in 1884, and has about 1,500 members. It also publishes a monthly bee-paper, entitled *Tidsskrift for biskjotsel* at Christiania, Norway, of which Mr. Young is the editor, and every member receives a copy free.

Mr. Young has also published a book on apiculture, entitled "Praktisk lommebog i tidsmæssig biskjotsel," which is well printed and illustrated.

Mr. Young has "written up" his trip in America, and it is published in his paper. We cannot read it, but expect to have it translated, and in a future number we shall present the salient points to our readers. When Mr. Young was visiting Mr. Holter-

MR. IVAR S. YOUNG.

mann, editor of the *Canadian Honey Producer*, he obtained and published the following facts concerning

Bee-Keeping in Norway.

We had a very pleasant and instructive conversation with Mr. Young, and, of course, made all possible inquiries about the state of bee-keeping in Norway.

Bees can be kept very well as far north as Drontheim. In Norway, as here, there is no method by which the number of colonies can be ascertained, but the number of colonies kept are estimated at about 40,000; of these about 2,000 are kept in the movable-frame hive, the balance in straw skeps.

Wintering is done very successfully in some of the old straw-skep hives. Many think the bees in the movable-frame hive do not winter as well, but such is not the case; on the contrary, the honey taken by means of the movable-frame hive is mostly extracted. On account of so few frame hives, and but little comb foundation being used, the average yield per colony for the country is not great, but he thinks if properly conducted it would be 70 pounds to 100 pounds per colony.

The chief sources of honey are clover, basswood, and heather. The clover is mostly Alsike; there is but little white.

Health and Home Library.—The first number of this periodical is on our desk. It contains 100 pages of the most interesting articles concerning *health* and *home* life. It should be read by every parent, and especially mothers. It is to be published quarterly at \$1 a year, at Chicago, Ills.

COMMENDATIONS.

Clean as a New Pin.—Mr. Geo. E. Hilton, Fremont, Mich., expresses himself thus:

The first number of the AMERICAN BEE JOURNAL for the new year is at hand, bright, spicy and clean as a new pin, in its new attire. I want to congratulate you on the cut you have made of my apiary. It has been published several times in different forms, but I have not seen a picture that pleased me as well as the one you produced.

How Can it be Done?—Mr. J. M. Hicks, Battle Ground, Ind., on Jan. 12, 1888, wrote us as follows:

This morning finds me at home, but not very well. I am suffering from a severe cold; I hope to be out in a few days again. I see you are out on time with the good old reliable AMERICAN BEE JOURNAL. The great wonder to me is, how ON EARTH you can afford so good a journal, 52 times a year, for so little pay as \$1? Yet I trust it pays you to do so.

Never Lost a Copy.—Mr. A. B. Bray, Bois D'Arc, Mo., on Jan. 9, 1888, writes thus:

When I opened the BEE JOURNAL for Jan. 4, 1888, I scarcely knew what it was; a change had been made in appearance from beginning to end. I do not see how you could have made such improvements every year since 1874 as you have. I have been taking the BEE JOURNAL for years, and I have yet my first paper to lose. I have received three times the value of the JOURNAL in information every year. It will richly repay any bee-keeper's faithful perusal.

Much Pleased.—Mr. Charles Solve-son, of Nashotah, Wis., on Jan. 5, 1888, wrote thus of his surprise and pleasure upon receiving the first number of our paper for this year:

I have just received No. 1 of the AMERICAN BEE JOURNAL for 1888, and to say that I am pleased with its new appearance, is but stating it mildly; it appeared so clean and white that I involuntarily got up and washed my hands (they were not dirty) ere I allowed myself to feast on its many good things. May you long live to lead the fraternity in its progressive march!

Not Stuck Up!—Dr. A. B. Mason, of Auburndale, O., upon receiving the first number of the BEE JOURNAL for this year, wrote us as follows:

FRIEND NEWMAN:—What have you "been up to?" "What for have you gone and spoiled the old reliable AMERICAN BEE JOURNAL for?" I missed its old familiar face this week, but in its place came a "spic, span" new and fresh one, but "awfully stuck up." As it don't "slop over" as "stuck up" arrangements usually do, I guess I can get used to it. It looks nice with its new heading. You know it is "my first love" in the line of bee-periodicals. I began taking it when the lamented Samuel Wagner was its editor. I like the other bee-papers, but none of them can take its place. Its make-up and matter are very good.

QUERIES AND REPLIES.

DO SWARMS LEAVE HIVES WITH TWO QUEENS?

Written for the American Bee Journal

Query 506.—Is there such a thing as a swarm leaving a hive with two queens?—R.

Yes.—J. P. H. BROWN.

Yes.—W. Z. HUTCHINSON.

Yes, or a dozen.—C. C. MILLER.

Yes; I have known them to leave with 8, but there were none left in the hive.—A. B. MASON.

Yes; an after-swarm sometimes has 5 or 6.—MRS. L. HARRISON.

Yes, why not, if it happens to be an after-swarm?—EUGENE SECOR.

Yes. Nearly all swarms except the first have two or more queens.—M. MAHIN.

Yes, whether the querist means going with two queens or leaving two queens in the hive; it is not uncommon.—R. L. TAYLOR.

Yes; second and third swarms often have several queens. First swarms I believe never do.—C. H. DIBBERN.

Yes. You will often find second swarms with 2 queens; and with Syrians, 3 or more queens.—H. D. CUTTING.

Second swarms will often do so. I never saw a first swarm do so, unless it had been retarded until a young queen was ready to hatch, etc.—P. L. VIALLO.

Yes, with as high as 12 to 20, and often from 2 to 5.—G. M. DOOLITTLE.

Certainly there is. After-swarms or first swarms that leave the hive with young, unfertile queens, often have two or perhaps a dozen queens each.—JAMES HEDDON.

The question has two meanings, and we would answer yes to both. Both the swarm and the old colony may have 2 queens.—DADANT & SON.

Yes, with 4 or 5. This is never true of first swarms, but frequently it is true of after swarms.—A. J. COOK.

From one to half-a-dozen virgin queens may go out with a swarm, but I have never known two laying queens to lead a swarm.—G. L. TINKER.

I never heard of such a case. This is one of those theoretical questions that no one can answer without an experience of the kind mentioned.—J. E. POND.

I do not know that I catch the idea that was in your mind when you wrote the query. If you mean a prime or first swarm, there is never but one queen with them, unless another queen

happens to be in the air at the time and joins the swarm. It is possible for a swarm to be delayed by rainy weather until the first young queen hatches, in which case she might go with the swarm if she was old enough to fly. This would give the swarm 2 queens—the mother and her virgin daughter. I have seen this state of things once or twice. In case an old queen is superseded, or dies just before a prime swarm was to issue, there will be delay until several of the young queens hatch; and when the swarm issues, there may be more than one queen with the swarm. I have seen a half dozen or more virgin queens with an "after swarm."—G. W. DEMAREE.

The old queen goes with the first swarm—that swarm will have but one accompanying queen; but with "after-swarms" (either second or third) there are often more than one, and sometimes several young queens.—THE EDITOR.

THE CAUSE OF ABNORMAL SWARMING.

Written for the American Bee Journal

Query 507.—What would be the cause of a colony leaving a hive early in the spring, with plenty of honey in store, and otherwise all right?—N.

Too few bees.—J. P. H. BROWN.

I do not know. Possibly old bees have died off, leaving more brood than can be covered.—C. C. MILLER.

I could not give a correct reply unless I knew more about the circumstances.—H. D. CUTTING.

Weak colonies sometimes "swarm out" in the spring, when everything is apparently all right.—W. Z. HUTCHINSON.

Lack of pollen. There might be other causes, but then they would not be, as in the question, "all right."—DADANT & SON.

It is unknown to me. I have had several do so during my 18 years' experience.—G. M. DOOLITTLE.

I never had such a case. I do not think that we have such a case in the South.—P. L. VIALLO.

If there are plenty of stores, "and otherwise all right," it would not leave. Something is wrong when it leaves.—A. B. MASON.

If they are "otherwise all right," I do not believe they will desert the hive. They do so because something is wrong.—EUGENE SECOR.

I do not think that they leave when "otherwise all right." This is proof that they are not all right. There is likely some hidden cause, probably not understood.—MRS. L. HARRISON.

When a colony of bees having plenty of honey leaves the hive early in the spring, it is not "otherwise all right." Generally only small colonies desert the hive, and those that are more or less diseased.—M. MAHIN.

Taking the statement literally, there would be no cause; but bees sometimes vacate their hive on account of discontent, arising from some inscrutable cause.—R. L. TAYLOR.

Sometimes a colony will leave when it is hopelessly weak, and other bees commence robbing them. In case of a strong colony deserting thus, there is some dissatisfaction either with the stores, the hive, or the surroundings.—C. H. DIBBERN.

I should say all is not right. There must be something amiss, even though not patent to the bee-keeper.—A. J. COOK.

A colony will never leave the hive in the spring, if *everything* is all right. The hive and its contents, all but the bees, may be all right, and yet they leave; but in that case the bees are diseased. Such things usually result from the notorious bee-diarrhea.—JAMES HEDDON.

The most common cause is too few bees. If weak colonies are placed in warm quarters on cool nights in the spring, I think that it would be rare to have them swarm out with plenty of honey in store.—G. L. TINKER.

I cannot imagine such a case. If querists would state actual occurrences, with all the facts connected therewith, answers of value could be given thereto. To cause a colony to leave, something *must* be wrong.—J. E. POND.

In the early spring there are but few young bees in the hive; and when the bees take a general flight, as they frequently do on warm days in the spring, the queen finds herself nearly deserted, and under her excitement she takes wing with the frolicking workers. Generally they return all right, but if the excitement runs high on account of the presence of the queen in the aerial flight, it results in a case of "swarming out." This state of things becomes habitual with some weak colonies in early spring, and sometimes in the fall. The remedy is, to put a queen-excluder over the entrance of the hive; this will prevent the queen from taking wing when the workers take an airing. The above is the "cause," though there may be exceptions to the rule, as in most other rules.—G. W. DEMAREE.

If bees leave their hive in a body in the spring-time it shows that they are dissatisfied with something in the hive, or its surroundings, or else the bees are diseased. They often leave

when short of stores, or lacking in bees.—THE EDITOR.

COLONIES BUILDING UP IN REVERSIBLE HIVES.

Written for the American Bee Journal

Query 508.—Will bees build up as strong in numbers by the use of sectional brood-chambers of the Heddon reversible pattern, as they will upon combs of as large size as the Simplicity or Quinby pattern?—H.

Most certainly.—W. Z. HUTCHINSON.

I should not expect much difference.—C. C. MILLER.

I think that there is no doubt of it.—A. J. COOK.

I think so, but my experience is limited.—G. M. DOOLITTLE.

Yes, if proper care is given them.—A. B. MASON.

I think there will be little if any difference.—M. MAHIN.

I have had no experience, but I think that they will.—MRS. L. HARRISON.

I do not know, as I have never used a Heddon hive, but I do not think there would be much difference.—C. H. DIBBERN.

If you give them sectional brood-chambers as they require, I have no doubt that they will.—P. L. VIALON.

I do not know. I have never used the Heddon hive; only by experiments can the matter be proved.—J. E. POND.

As this is a hot question, we would say, try it with 2 or 3 colonies. We have tried it, and do not want any sectional hives.—DADANT & SON.

They will build up as strong, but not so soon. However, if the hives are packed in chaff, the difference is not great.—G. L. TINKER.

I have had no experience with the Heddon reversible hive; but as I understand the question, they will not.—H. D. CUTTING.

I object to all cross sticks, or objects of like nature in frames. I prefer a regular Langstroth frame.—J. P. H. BROWN.

Yes, sir. The past season I had one colony in the new Heddon hive that produced of comb honey five times the average of my apiary, and about twice as much as the best of my colonies on Simplicity frames, and it was because of their numbers that they did it.—R. L. TAYLOR.

That would depend upon the management. If 10 frames were left in the Simplicity, or an equal space in any other hive in the spring, they ought to build up faster in the Heddon sectional brood-chamber if only one were used at first, because that is con-

traction. Contraction can be practiced with any hive. Therefore answering the query in one word, *yes*.—EUGENE SECOR.

Yes, faster. I am now answering from four years' experience. With the new hive, with the divisible brood-chamber, in two sections, bees breed up stronger and earlier, and finally produce more in the same capacity, than can be obtained in any other style of brood-chamber, provided the same is properly manipulated. No style of brood-chamber is its superior, if the divisible brood-chamber is not manipulated at all.—JAMES HEDDON.

I have used the half-depth-frame cases for over eight years, and I have used them for all purposes. When used for brood-rearing in this climate where the 'springs are early and changeable, the colonies in them do not breed up rapidly like they do when in the standard Langstroth hives. But when the weather becomes warm, there is little difference to be seen in the amount of brood reared. The shallow sectional-frame cases are at their best when used for the purposes for which they were first devised, viz: to take honey on the tiering-up plan.—G. W. DEMAREE.

With judicious management, we do not think that there will be much difference.—THE EDITOR.

CORRESPONDENCE.

BROOD-FRAMES.

Deep Frames vs. Shallow Ones, and Sectional Hives.

Written for the American Bee Journal
BY W. J. CULLINAN.

This afternoon, as I was enjoying the New-Year holiday (by "minding the baby" while my wife went shopping), I thought that I could not better improve the spare time than by writing to my favorite bee-paper; and suiting the action to the thought, I will begin.

About ten weeks ago I tore myself from the town of my birth and the scenes of my youth, and hied me to this great "Chicago of the southwest," better known as Kansas City.

I left home with the intention of going to California, and may still reach that "land of sun and flowers," if the accounts I get of fleas, poison-oaks and hostile reptiles of the sea do not cause my courage to fail me. Let this suffice as a preface, for I started out to answer an article on page 804 of the

AMERICAN BEE JOURNAL for 1887, wherein Mr. J. M. Hambaugh enters "a plea for large frames."

It is well enough to analyze and discuss every phase of apiculture, and when we have stumbled upon anything (be it new or old) that will facilitate the labors, or add to the profits of bee-keeping, lay it before the great brotherhood and sisterhood, who in the pursuit of this noble calling are yearly adding to our national wealth, and contributing to the comfort, health, happiness and luxury of their fellowmen. Mr. Hambaugh does not claim that he has anything new to offer in the shape of a hive, but is simply commending that which is old, or giving his preference, as it were.

Mr. H. says, that in transferring bees "from nail-kegs, log-hives, beehives, etc., he has found the same principle to govern all, *i. e.*, large, deep, roomy combs, with stores above, brood beneath, and combs spaced from 1½ to 2 inches from centre to centre." I would ask, did he not find those combs of all shapes and sizes, made, and shaped more with a view to filling the repository in which they were built, than to honor any whim or requirement of the queen-mother? For it is well known that bees in their wild or natural state inhabit caves, built under ledges of rocks, in the sides of houses, in chimney-flues, and in all manner of places, and as they show an utter abhorrence to a vacuum (when they have honey to fill it), they always fill the particular space, be it round, square or oblong, thus forcing the queen to deviate from her characteristic circular movements, suiting them to her particular surroundings. I have frequently seen Langstroth frames filled completely full of brood; and again, I have seen a patch of eggs in one corner of a frame, while the other three were empty—showing that the queen does not always move in a circuit, but readily adapts herself to her surroundings.

The Quinby frame, which is the frame Mr. H. alludes to, is too large and unwieldy for extracting, as well as slower of manipulation at all times. I think that Mr. H. forgets himself when he says, "We should imitate nature in the construction of our hives." Does he go to an old hollow-tree or cave for measurements when he wishes to begin the construction of his Simplicity or Quinby hives? No; he will consult his table of measurements on paper, which, by the way, contain not one single feature of the hollow-tree intact. He and others have changed, altered and improved upon the pioneer homes of the honey-bee to such an extent that the one resembles the other only in the form and construction of

the cells; and had we the power, we would doubtless have changed these.

As to the queen losing time in "passing over bars and bee-spaces," etc., I think amounts to nothing; for any one who knows anything about the inside workings of the bee-hive, knows that when the queen begins her work of reproduction, her starting-point is the centre of one of the central combs—be they large or small; here she deposits in the neighborhood of a dozen eggs, then passing to the other side of the comb, she deposits a like number; then passing back she enlarges upon the first, and so on until she has a patch of eggs as large as a man's hand, when she begins depositing in the adjoining frames successively, then back to the centre, and so on, taking in more territory at the side as she enlarges her circle in the centre, thus keeping her bunch of brood nearly in the form of a globe—this, of course, being done to accord with a natural instinct or trait of the bees to cluster in a ball, so that in the event of cool weather the brood is all well protected and kept from chilling.

Now it is but reasonable to suppose that if we have large, deep frames, as Mr. H. suggests, the queen will lose a great deal more time in passing from side to side, and from frame to frame, than if the frames are shallow, or have horizontal bee-spaces in the centre. And by this line of reasoning I contend that horizontal bars and bee-spaces, instead of being detrimental and forming an obstruction to the movements of the queen, facilitate the same and become a help. If I were to tolerate large, deep frames, such as the Quinby, at all, it would be in the brood-chamber only, with a shallow-frame above for extracting, *ala* Dadant, or a single-tier crate for comb honey. But this I do not consider feasible in the production of extracted honey, for the combs are not interchangeable, which I believe to be an important aid in forcing the bees upward in the fore-part of the season.

Then again, in the production of comb honey I believe the contraction of the brood-nest to be essential to the best success. I consider it a great advantage to have the brood distributed over the whole under-surface of the surplus cases—a condition which can only be secured by dividing the brood-chamber horizontally, by the use of the shallow brood-frame.

Mr. H. is running his apiaries nearly altogether for extracted honey, and for this purpose his large and deep brood-chamber hives may answer very well; but should he turn his attention to the production of comb honey, he would soon adopt a frame much shallower

than the Quinby, if not a horizontally-divisible brood-chamber.

However, I should be pleased to hear from such as have used the sectional brood-chamber hive in the production of either comb or extracted honey, and with what success. Mr. Heddon might favor us with an account of his successes with the sectional brood-chamber hive; for if they do possess advantages over other hives, I am sure that all, like Mr. H., would like to know it.

Kansas City, Mo.

FUMIGATION.

Report for 1887, Fumigating Combs and Poisoning Bees.

Written for the American Bee Journal
BY P. LATTNER.

The last was the poorest honey season that I have experienced in 28 years. I lost 50 per cent. of my bees last winter, by their having honey-dew, or bug-juice, for winter stores; all that had none, or did not live on that stuff, wintered well.

I commenced the season with 49 colonies, spring count. Four swarms issued, but one of them left after being bived. I increased my apiary to 80 colonies, by the nucleus method, and took 1,200 pounds of extracted honey. This was the result of having plenty of combs.

We had good fall pasturage, and all the bees were put into winter quarters in good condition. One-half of them are on the summer stands in chaff hives, and the other half are in a beecellar under the bee-house. The cellar is 16x22 feet, and 6½ feet high, with the ceiling lathed and plastered, the floor cemented, ventilation from the floor into the chimney, opposite the entrance, and a stove to regulate the temperature completes the cellar.

Fumigating Empty Combs and Honey.

I use the stove in summer to fumigate empty and full surplus combs. It is placed in the bee-house, in one corner, which is partitioned off and arranged right above the stove for that purpose. One-half pound of pulverized brimstone, saturated with alcohol, is placed in an iron kettle inside of the stove, with the stove-pipe directed toward the combs; then a lighted match is dropped into the kettle, and the work is done.

About Poisoning the Bees.

I was glad that the editor reprimanded the correspondent of the *Messenger*, at Atlantic, Iowa, in the *BEE JOURNAL* of Dec. 21, 1887; but I am sorry that the good State of Iowa has

among her people such a villain. I think that the public would be more benefited by feeding such an ignorant, dastardly adviser on the same stuff that he recommends for the destruction of the honey-bee. That article contains ignorance, falsehood and malice combined.

Worthington, Iowa, Dec. 24, 1887.

BEES AND FRUIT.

The Mistaken Idea that Bees Injure Fruit.

Written for the American Bee Journal
BY ALLEN BARTOW.

I have just read, on page 803 of the *BEE JOURNAL* for 1887, an article in regard to poisoning bees, being a few quotations from a paper called the *Messenger*, which asserts that there has been great destruction of grapes here by bees. Now that is not the fact. That bees do not injure sound grapes, or fruit of any kind, is admitted by all intelligent fruit-growers and bee-keepers. But some years ago it was thought that bees did injure fruit, but thanks to Prof. Cook for dispelling that mistaken idea from the minds of both parties on that question. It came about in this wise:

We had an agricultural meeting at Sandusky, O., and Prof. Cook attended and lectured on entomology, and the anatomy of the bee was part of his subject. At the close of his lecture the Professor was subpoenaed, and gave evidence in a case then being tried in the County Court at Sandusky, and the writer heard him being catechised for about two hours by four lawyers. He made it plain that bees could not puncture sound fruit—so plain that the suits were withdrawn. The facts were as follows:

The bees were poisoned by one party, in the vineyard, and the party owning the bees traced the poison, by following the bees from the hives to the vineyard, when he found great numbers on the route, dead and falling all the way from the hive entrances to the poison in the vineyard. The owner of the bees sued the grape-grower, and the latter brought counter suit for damages done to grapes.

Now the point I wish to make is this: It caused both bee-keepers and fruit-men to investigate, and they found that the facts exonerated the bees from blame. We found other causes that opened the fruit. First, grapes when over-ripe will crack open; again, birds and other insects destroy them. We have a small bird about the size of a brown ground-bird, that gets on a bunch of grapes, and pecks them open as fast as one could count.

This bird did not seem to eat the grapes, but simply tore the skins open. I then shot the birds, and as some grapes were fully ripe, I gathered the remainingsound grapes and left those that were opened, on the vines. The bees of course sucked these dry. But the strange part is, the same birds (the live ones of the same kind), came and ate the seeds of the dry grapes that remained on the vines.

I venture to say, that whoever will spend the same time in investigation, that he does in blaming, will be satisfied that the bees are innocent of opening fruit.

Milan, 3 O.

BEE-CELLAR.

How to Build a Good Cellar for Bees or Kitchen Use.

Written for the Western Plowman
BY C. H. DIBBERN.

Not only is a cellar a good thing for the bee-keeper and farmer, but with many an absolute necessity. Now by a cellar I do not mean a hole in the ground under the house, filled with decaying vegetables. I maintain that the cellar should be the "best room in the house," as well as the most useful. To build a cellar right requires a good deal of care and expense. The bottom should be cemented with a hard cement that will not sweep off and crumble away. The walls should be back-lathed, and plastered with cement. If it is plastered directly on the wall it is apt to "sweat" in the spring and become moldy. The ceiling should also be plastered with cement at least an inch thick. Windows should be made on opposite sides so as to allow a free circulation of air. If bees are to be wintered there, it should be divided by a partition into two parts, so as to keep them entirely apart from the vegetables. There should be at least two general clearings out of the cellar, in the spring and fall, when the walls, floor and all should be thoroughly whitewashed. The boxes, barrels, etc., that have been in the cellar, should be exposed for a few days to the sun and air at such times. Now if ordinary care is used in the meantime to keep everything clean and sweet, and ventilated as much as possible, my word for it, such a cellar is a blessing.

Snow Around the Hives.

"In wintering out-of-doors is it necessary to sweep the snow from the top and front of the hive?" No. It is often an advantage to leave it on, and even in front of the entrance to keep the bees from flying and getting lost in a light snow. Should the snow,

however, become deep, I think it advisable to shovel the snow from the front and open the entrance.

Milan, Ills.

ALSIKE CLOVER.

How to Induce Neighboring Farmers to Plant it.

Written for the American Bee Journal
BY M. M. BALDRIDGE.

Joshua Bull, one of the delegates to the last Inter-National meeting of bee-keepers in Chicago, informs me that he succeeded very nicely last spring in securing the distribution of about 15 bushels of Alsike clover seed, among his neighbors; by simply leaving with a local dealer a small package of

Alsike Clover Root and Crown,
average size, a year old.

Red Clover Root
and Crown,
average size, a year old.

Alsike Clover Leaflets, obtained through the office of the AMERICAN BEE JOURNAL, with instructions to place them in the hands of parties who came to him after grass-seed. He thought it better to do thus than to distribute the Leaflets himself, lest his being interested in honey-production might create the impression that he was personally interested in the sale of the seed, or otherwise; that is, speaking "one word for his neighbor and two for himself!"

As non-producers of honey are often both jealous and suspicious of the bee-keeping fraternity, the plan pursued by Mr. Bull may be just the one for others to adopt, and so I thought it best, thus early, to call special atten-

tion to it. But I will now suggest another plan which I know will also be a success, and will, as must be obvious, have its advantages:

Besides supplying all local dealers in grass-seeds with the Leaflets, just drop one in the Post-office, in a sealed envelope, to each and every farmer living within a radius of three miles of your apiary, and do this the present winter, and before the general time for sowing grass-seeds, and in the quietest manner possible! This plan will give the farmers, who really should be the parties most interested, ample opportunity to study the subject, through inquiries and otherwise; and then, when they have occasion to visit the grass-seed dealers, they will be better prepared to decide what they should and ought to do.

If we can induce the farmers to grow Alsike, mixed with other grasses, we will then solve the problem of good bee-pasturage, and an abundance of it; and, besides, we will be doing to the farmers, as well as ourselves, an immense amount of good. For my part I would rather have one acre of Alsike clover, mixed with timothy and red clover, and within bee-flight of my apiary, than the best ten acres of the common white I ever saw; and so will others when they give the mixing plan I advise a fair and extensive trial. Alsike will, when mixed as stated, never disappoint the farmer, nor the apiarist, in case its partnership neighbors make a satisfactory growth; for it is a fact, though not generally known, that Alsike will do well wherever and whenever the common red can be grown with success. Try it, ye doubting Thomases, and then report.

St. Charles, Ills.

BEEES IN COLORADO.

Experience in Bee-Keeping in Colorado—Alfalfa, etc.

Written for the American Bee Journal
BY DANIEL WESTOVER.

I have read Mary A. Goodale's communication on page 792 of the BEE JOURNAL for 1887, and in reply to her questions I will give my experience of three years.

I started with 3 colonies, and have sold \$100 worth of bees, and over 1,000 pounds of comb honey the past fall. I sold some bees the past season at \$8 per colony. I have wintered my bees on the summer stands for three winters without any loss; and I now have packed in chaff 45 colonies in good condition. They had a splendid flight to-day. Here they have two or three cleansing flights during the win-

ter months, and they are not troubled by moths or diarrhea.

Alfalfa is being raised here in abundance, and is considered splendid bee-food. There are but few bees in the southern portion of the State as yet, but I am sure that they would do well there. I am located on the Platte river, 47 miles from Denver, and four miles from Greeley. I have never sold first-class comb honey for less than 20 cents per pound.

It would not pay to ship bees from Indiana to Colorado. The Italians take the lead here, as compared with any other race of bees. I kept bees in Indiana 30 years ago, when we sawed off hollow-logs, bored holes and drove cross-pins in them, and stood them up on a puncheon. They then were considered second to none, as were also the black bees that we handled without a smoker or veil.

Evans, ♂ Colo.

CAVE-WINTERING.

The Drouth Causes Poor Results —A Cave for Bees in Winter.

Written for the American Bee Journal
BY P. L. GIBSON.

My bee and honey report for 1887 is as follows: I put 40 colonies in the cellar on Dec. 8, 1886, and took them out on March 8, 1887, all being in fine condition. They stored a little honey in June, from white clover, but consumed it all and the greater part of their stores by July 15.

As we had no rain in June and July, the result was that from 40 colonies I received no surplus honey, no swarms, and lost by starvation 10 of my old colonies, and 5 more will have to be fed in order to survive the winter. I am not discouraged, however, for I have the beggar's consolation, namely, "There are many more in the same fix;" but I still hope for better returns the coming summer.

Wintering Bees in Caves.

I am a strong advocate of cellar-wintering of bees, and I would winter them in this way if I had to make a new cellar or cave every year. My present depository is a cave, dug 4 feet deep, with posts set around the sides 7 feet above the bottom of the cave. This is sided and covered with punch-ions split from green oak timber. A passage-way 3 feet wide and 4 feet long is lined and covered with the same material. This passage-way admits of two doors, one on the inside, and one on the outside of the cave when needed. The total cost of the whole was 3 days' work.

I remove the caps, sections, and honey-boards from the hives, and place any kind of a cloth over the brood-chamber, and then tier them up, with one-inch strips between them. In this way I never lose any bees, by keeping the cave dry, and at a temperature of 42°. I find the BEE JOURNAL a great help, and a welcome visitor. Every one having a colony of bees, or expecting to get a colony, should read it.

Illinois City, ♂ Ills., Dec. 30, 1887.

DISCUSSION.

Some Questions which all are Invited to Answer.

Written for the American Bee Journal
BY C. P. HEWETT.

1. How many keep a daily record of the temperature and degrees which they prefer in their depositories?
2. How many believe in hibernation?
3. How many can winter colonies on from 3 to 6 pounds of stores?
4. How many have had bees steal eggs, and from them make queens?
5. How many have had queens fertilized that did not leave the hive?
6. How many have had queens become re-fertilized?
7. How many have had queens die with the drones, on their bridal trip?
8. How many have had bees hibernated, and remain so until taken out in the spring?
9. How many can tell that they have a queenless colony in their apiaries, by seeing bees trying to steal eggs, before they notice the colony which is queenless?
10. How many know that there is no vitalization in some queens' eggs, when they first commence laying in the spring, and the bees have no regard for her, more than any other bee, and swarm out?

The above questions are open to all.
Kingston, ♂ Wis.

STARTERS.

How I Fasten Foundation in Grooved Sections.

Written for the American Bee Journal
BY HENRY W. HAAG.

It seems from Mr. Fox's remarks on page 823 of the BEE JOURNAL for 1887, that his is the only satisfactory method for fastening foundation in sections. I have tried several methods, and I find none that suits me but the following:

I use only grooved sections, and cut the starters $\frac{1}{2}$ -inch shorter than the section is wide, and about $1\frac{1}{2}$ inches

deep. Then I put the section on a table, with the grooved side down, take a starter in my left hand, insert it in the groove, and then run melted beeswax along the side of the starter, which holds it securely; no matter how many bees get on the foundation, it will not drop off.

I formerly used Mr. Fox's method, but I did not like it, as so many starters dropped off; and then they would ruin some honey by causing the bees to build the combs crooked.

I would not have sections without grooves for foundation, for in any other it cannot be securely fastened. Not one starter in five hundred will drop off if the above plan is used, and the sections are grooved.

Pettit, ♂ Ind.

WINTERING.

Results of the Season, and How I Winter my Bees.

Written for the American Bee Journal
BY E. HENKLE.

I started last May with 44 colonies of bees, two-thirds of them being in splendid condition. I lost 4 colonies during the summer, by moths getting the advantage of them before I discovered it. I had one swarm, which leaves me with 41 at present, and not a pound of surplus honey.

On Sept. 1, I found one-third of them nearly starving. I bought \$20 worth of sugar, and fed it to them, which fixed them up nicely for winter. They are all well packed on the summer stands, with cushions of chaff and forest-leaves on top and around them. I use the Mitchell hive, in which the frames hang crosswise, with two division-boards, one at each end. I place the bees in the centre on eight frames in winter, and put one cushion at each end and one on top. I have always wintered my bees very successfully in that way. I never allow snow or sleet to fall on the hives. I have three sheds that are 50 feet long and 6 feet wide, boarded up on the back to keep off the cold winds.

I do not think that I am in a very good part of the State for bee-keeping. I have never been able to get more than from 25 to 40 pounds of honey per colony. We have to depend entirely upon white clover for surplus. There is no basswood within five miles of this place. I have about half an acre of sweet clover; but what is half an acre of sweet clover for 40 colonies of bees? But I have been sowing considerable more this fall, and will sow more next fall, so as to let it take the place of basswood.

Washington C. H., ♀ O., Dec. 23, 1887

BEES AND GRAPES.

Another Proof that Bees do not Puncture Grapes.

Written for the American Bee Journal
BY H. W. LACY.

On page 805 of the BEE JOURNAL for 1887, I saw a statement supposed to be made by Secretary Garfield, wherein he states that the Secretary of the Eaton County Horticultural Society said that there is no use talking, bees do open grapes, and that he has seen them where there was no crack or anything of the kind. I, for one, flatly and positively contradict that statement. I am willing to bet five of the best queens in my apiary, that no Italian bee ever punctured a sound grape-skin. I tried it the last season in different ways, for my own benefit, as I have heard it discussed by different ones, and as some of my neighbors thought that their crop of grapes would be small on account of my bees.

As I have quite a large vineyard of my own, with some twelve different kinds of grapes, I placed 6 colonies amongst them in such a way that the bees were all amongst the grapes; in fact it was hard work to open the hives, as the fruit hung so clustered about them, and right before the entrances of three of the hives. I had large clusters of grapes hang in such a way that the bees had to work around them to get in and out of the hives. I do not think that there was one grape injured by a bee. Then on the nearest bunches I caused a small scratch to be made with a pin, just through the skin on a few of the grapes, and they were immediately sucked out by the bees. Therefore, I say that a bee will not injure grapes unless the skin is first cracked in some other way.

Results of the Past Season.

The past season was the poorest that I ever experienced in bee-keeping; yet I think that my bees did as well as any in this State. I commenced the season with 27 colonies, spring count, in a fair condition. I sold 12 colonies, and had one colony stolen. I bought 14, had 9 swarms, and then doubled-up my number of colonies to 30, which I put into winter quarters. I had 103 pounds of comb honey, and 227 pounds of extracted.

To those colonies which I thought had not enough for winter stores, I fed some granulated sugar, and so far they seem to be doing well. Up to Dec. 20 there had not been more than five days that they were not on the wing. I winter my bees packed on the summer stands in chaff hives.

Mansfield, Mass., Dec. 30, 1887.

WATER.

The Bees Need Water for Winter Use.

Written for the American Bee Journal
BY T. S. BULL.

Having a colony of bees in my cellar that showed signs of uneasiness and wanting to fly out whenever the door was opened, and Dec. 18, 1887, being a warm day, I decided to carry them out and put them on the summer stand. By the time I had them on the stand, there was a good many bees on the alighting-board. They had not been on the ground (I had placed them on the ground) a minute, before they were crawling out on the ground and sipping water. They did not all fly. They crawled until they came to water.

I wet a cloth and laid it on the alighting-board, and it was soon covered with bees. There was no sign of any disease whatever. There was no brood in the hive. They were as healthy as bees in June. Now that was conclusive evidence, to my mind at least, that that colony wanted water at that time. I came to the same conclusion a number of years ago. I have given the bees water in the cellar a number of times, in years past, in order to keep them quiet. The front end of the hives have been covered with bees in the cellar sipping water. I never saw any bad effect from it.

I never give the bees any water in the cellar before February or March. I put them into the cellar on Nov. 10 to Nov. 14. The mercury is from 50° to 52°. My cellar is very dry. The next day I removed them in the cellar, but before putting them back, I poured about a gill of water in a division-board feeder that was next to the cluster, on Jan. 2, 1888. I examined them to-day, and the feeder was dry. I never saw bees more quiet than they are. I also gave them some more water.

Valparaiso, Ind., Jan. 7, 1888.

BEES AND BIRDS.

Shoot the Birds, and the Bees will not be Blamed.

Written for the American Bee Journal
BY O. B. BARROWS.

I live within four blocks of the business centre of a town containing about 9,000 people, and I have five rows of Concord grape-vines, each row being about 70 feet long, and about 6 feet apart. Between these rows of grape-vines I keep from 50 to 100 colonies of bees—usually about 80 colonies—which makes them quite crowded, and in

many cases the vines hang down on the hives. These vines bear grapes which ripen, and some of them frequently hang on until they are spoiled by freezing, and yet I very seldom see bees on the grapes; while at the outskirts of the town they complain of their grape crop being almost entirely destroyed by bees.

One of these grape-growers complained to a friend of mine, about it, and for a joke he told the man that they were Barrows' bees, and that he had them trained so that they would not touch a grape at home. I confess that I was puzzled about it, but upon appealing to another friend who raises grapes, but not bees, he said that where I lived a certain kind of bird did not frequent, that did frequent the other place, and that when the bees commenced on his grapes, he shot three or four of the birds, and the bees immediately stopped eating the grapes.

Marshalltown, Iowa.

[The bees are blamed wrongfully as well as persistently by those who will not think and experiment, and thereby be convinced. Birds, wasps and insects do the damage in every instance, and yet the poor bees are almost universally blamed for all the depredations. Why not be fair and reasonable, and do justice to the bees?—Ed.]

FOUL BROOD.

Keeping Bees in Texas, and Treating Foul Brood.

Written for the American Bee Journal
BY C. M. DAVIS.

I take great pleasure in reading the BEE JOURNAL. Bees have done fairly well in northern Texas the past season. I have been keeping a few colonies in this thriving city for three years, and the past season was the first that I have received a profit from them. I made about enough to pay for all previous expenses, and I think that if my bees had not been troubled with foul brood, I might have had much better results.

In the spring of 1886 I found that all of my bees had the foul brood. I tried phenol, but failed to cure it; after which I cleansed the hives, etc., and transferred all, which seemed to get rid of the disease, and they seemed to be all healthy last spring. But to my surprise, the last of July I found every colony affected, and very weak in bees. Some swarmed out, and what was left I have doubled up to 6 colonies. In August I had 18 colonies. I think that they got it from some neighbor's bees,

as I learn that they have foul-broody bees. I would like to ask the following questions :

1. How would it do to cleanse the hives by scalding them, and then get some fresh combs that are known to be free from foul brood taint ; then transfer the bees during the first flight in the spring, or before they commence to breed, and move them away from the district where the foul brood is ? When in August I found that they were foul broody, I got some phenol and thoroughly sprayed both combs and bees, so that there was not an empty cell ; but the liquid entered without effecting any cure or benefit.

2. Are the bees and ground impregnated with the germs that produces dead brood, where the stands were ? I think that I have seen some such ideas presented in the BEE JOURNAL ; if so, it would be very expedient to move the bees to some other location. I would increase my apiary to 30 colonies, if I thought I could get rid of the foul brood.

Denison, 6 Tex., Dec. 21, 1887.

[1. If the foul brood is fully developed, and of the disastrous kind, we think the only "cure" we would try, would be to burn up hives, bees, fixtures, etc. We have but little confidence in any of the so-called "cures."

2. Yes ; the trees, boards surrounding the apiary, and everything contiguous are liable to be harboring the germs of the disease, which are liable to develop at any time.—ED.]

ANATOMY.

Rudimentary Glands in Bees, and the Evolution Theory.

Written for the American Bee Journal

BY M. B. CHADDOCK.

I notice on page 809 of the BEE JOURNAL for 1887, that in Prof. A. J. Cook's lecture on the anatomy of the honey-bee, he described the glandular system in particular, and said : "One pair of glands furnishes the saliva ; another the food for the larvæ. Drones do not have this gland, and it is only rudimentary in the queen, which shows that she once nursed the larvæ as the queen bumble-bee now does in the spring. The change that has taken place in the honey-bee in this respect, is another proof of the correctness of the evolution theory."

Now I want to ask a few questions about those rudimentary glands. A queen is hatched from a worker egg, and that worker egg, if let alone, would

hatch out a worker bee. That worker egg is bound to contain *all the parts* that go to make a perfect worker-bee, does it not ? If it does contain all the parts, then it must contain the same thing that will develop into a food-gland in the worker-bee. But when by means of richer food, the worker egg is changed into a queen, the rudimentary food gland must remain there. There is no evolution about it ; it is in the egg, and must be in the queen, how can it help itself ?

Of course drones not being hatched from worker eggs, would not have "the rudimentary food glands ;" and as to its being deficient in old worker bees, any gland that is not used becomes deficient.

Do rudimentary glands prove that animals possessing them ever used them for the same purpose that the glands proper are used for now ? Do the rudimentary mammary glands in the male hog, prove that once upon a time the male hog suckled the litter of pigs ? And do the rudimentary mammary glands in man, prove that our baboon ancestors drew nourishment from the male and female parent, just as it happened, without any distinction of sex ?

Vermont, 6 Ills.

[Will Prof. Cook kindly reply to these queries ?—ED.]

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*

Jan. 20.—Haldimand, at Cayuga, Ontario.
E. C. Campbell, Sec., Cayuga, Ont.

Jan. 24-26.—Eastern New York, at Albany, N. Y.
John Aspinwall, Sec., Barrytown, N. Y.

Jan. 25, 26.—N. E. Ohio, Northern Pa. and W. New York, at Meadville, Pa.
C. H. Coon, Sec., New Lyme, O.

Feb. 4.—Stark County, at Canton, Ohio.
Mark Thomson, Sec., Canton, O.

Feb. 15, 16.—E. Iowa & W. Ills., at Davenport, Iowa.
H. S. Dibbern, Sec., Milan, Ills.

Apr. 24.—Des Moines County, at Burlington, Iowa.
John Nau, Sec., Middletown, Iowa.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Piling in the Pollen.—J. W. Winder, Carrollton, 6 La., on Jan. 8, 1888, writes :

Bees are piling in pollen now ; one colony to-day averaging 20 bees per minute, all heavily laden. Grasshoppers and butterflies are sporting in the sunshine, and the little pestiferous mosquito does not yet neglect his dainty bite, by day or night.

Bees Resting Quietly.—G. M. Whitford, Arlington, 6 Nebr., on Jan. 8, 1888, says :

The weather at present is very cold, the mercury going 20° below zero last night. Bees have not had a flight since Nov. 24. Those that were put in the cellar are resting quietly.

Bees are Quiet, etc.—S. J. Church & Son, Cedar Rapids, 6 Iowa, on Jan. 5, 1888, write :

On April 7, 1887, we took 120 colonies out of the cellar in good condition, and lost only 2 colonies by June 1 ; but we lost 18 colonies more, some by swarming out, 2 were queenless, some by robbing, and others by dwindling. So we had only 102 colonies left by the middle of June. The hives were full of bees and brood, but with little honey, except what we fed them, which was 500 pounds. On July 1 linden was in full bloom, and yielded well for 4 or 5 days. We had 4 natural swarms, made 4 by dividing colonies, and obtained 200 pounds of extracted honey and 100 pounds of comb honey in 1-pound sections ; and left 20 to 30 pounds for each colony for winter stores. We put them into the cellar on Dec. 1. They were very quiet with the temperature at 40° to 45°.

Sweet Clover the Best, etc.—

Peter Billing, Pawnee City, 6 Nebr., on Jan. 6, 1888, says :

The bee-keeping spirit is almost down at zero in this vicinity, as the bees scarcely stored any surplus at all the past year. I had 30 colonies in the spring, prevented increase, and obtained about 300 pounds of honey, which was mostly basswood and sweet clover. I believe that sweet clover is the best honey plant for this country, as I have never noticed it to fail.

Yield from Basswood, etc.—

Fayette Lee, Cokato, 6 Minn., on Dec. 20, 1887, writes :

I commenced the season of 1887 with 75 colonies of bees, being mostly weak colonies. I increased them to 95 colonies, and took 2,700 pounds of extracted honey, and 600 pounds of comb honey in 1-pound sections. I had to feed only 100 pounds in the fall. I never have failed to get a fair crop of honey here. In the fall I took eight empty combs without a bit of pollen in them, put them into an empty hive, and then shook a large swarm in front of the hive. They all went in, and I then fed them 15 pounds of fall honey, after heating it very hot, and then letting it cool. This will prove whether

it is pollen that causes bee-diarrhea or dampness; or whether sugar is better than honey to winter bees on. I shall not let them fly until they have been in the cellar 150 days or more. They were fed on Oct. 25, and put in the cellar on Nov. 5. There is a bee-keeper in Winona, Minn., who wants to know whether basswood yields honey well as far north as this place. Yes, it does; and I have never known it to fail. Sometimes it only lasts for ten days. I got a fine lot of golden-rod honey this fall. The best yield per day from basswood was 21 pounds per colony, gathered in 12 hours; and just at night they gained 3 pounds in one hour.

The Queen-Excluding Honey-Boards, etc.—E. H. Trumper, Hillsdale, ♀ Mich., on Jan. 7, 1888, says:

I have 74 colonies nicely packed in the cellar, where the temperature ranges from 41° to 45°, and most of the time the bees are very quiet. I started last spring with 28 colonies, increased them to 51, and took 2,000 pounds of honey, all in 1-pound sections except 150 pounds of extracted. That is the most honey that I have heard of any one getting here. I have sold about half of my honey. I bought 23 colonies of bees the past fall, and have fed about 2 barrels of sugar. I think that my bees are in good condition for winter. I use the Langstroth frame and hive, all new colonies being hived on 5 frames with starters. I use a queen-excluding honey-board, and thus I do not get any drone comb, and more of the honey is put into the sections.

Children Playing in the Apiary.

—Bradford Barlow, Toledo, ♀ Ohio, on Jan. 9, 1888, writes as follows when sending his dues for the Bee-Keepers' Union:

I keep bees on a city lot with a family on each adjoining lot. One of my neighbors has a large family of children, who play hide-and-seek in the apiary, when I am handling the bees. They stand by in perfect safety. The same neighbor has grapes, but he does not think the bees are destructive to them.

My Experience with Hives.

John Boerstler, of Vashon, ♀ Wash. Ter., writes as follows:

I began bee-keeping about 20 years ago, with a colony of black bees in a box-hive. I made boxes instead of hives for a long time. I next obtained a moth-proof patent hive, and thus spent about \$20 for kindling-wood, as

that was all it was good for. I afterward paid \$5 for the right to make, and \$25 for 5 hives of another patent moth-proof style, which I called the "humbug hive." It was not much better than the first, but I made a good hive out of it by making some alterations. After experimenting with several more styles of hives, and spending about \$100 more, I heard of and procured a two-story Langstroth hive, and that is, without doubt, the best hive for any bee-keeper. I want no better hive than that.

Before leaving the East, I had 85 colonies of bees, mostly Italians, and nearly all in Langstroth hives. I now am here in Washington Territory starting anew, by getting black bees in box-hives, and then transferring them into Langstroth hives.

If ever any bee-man gets up a gold medal for Father Langstroth, I will be only too glad to pay my share of its cost. It is what he ought to have had long ago, and I hope some one will soon begin to get it up.

Bees in Good Condition.—Mr. Henry Walsh, Sheboygan Falls, ♀ Wis., on Dec. 26, 1887, writes:

I have 42 colonies of bees in the cellar, that are in good condition, and which I think will winter all right. I commenced keeping bees four years ago next May, when I bought 4 colonies, which I increased to 9 colonies, and took enough honey for our own use. I did not lose any the following winter. The next year I increased them to 23 colonies, lost 2, and sold \$60 worth of honey. I began last spring with 21 colonies, increased them to 42, and took about 600 pounds of comb honey. My best colony stored 72 pounds of finished honey, and 29 pounds of partly finished sections; all white clover and linden.

Bees Dying in the Cellar.—E. T. Jordan, Harmony, ♀ Ind., on Jan. 5, 1888, writes:

I placed my bees in the cellar on Nov. 24, 1887, and they seem to be wasting away very fast. I cannot account for it. The temperature of the cellar has not been below 42°, but the most of the time it was at 48°. The ventilation is good. A pipe is connected with the stove-pipe above. The bees leave the hives and die on the cellar floor. I have taken nearly half a bushel of dead bees from 72 colonies. Can any one give some idea of what the trouble is; and suggest a probable remedy? The bees that leave the hives seem to be healthy, with no signs of diarrhea.

Not much Loss in Bees.—Abe Hoke, Union City, ♀ Ind., on Jan. 5, 1888, writes:

Bees seem to be very quiet, with not much loss so far. I have one colony that has lost, up to this time, not less than a quart of bees, and it lost heavily last winter; but it came through in pretty fair condition. The winter has not been very cold, 4° below zero being the coldest so far. I am getting ready for next season, and am making some changes. The BEE JOURNAL is a welcome visitor in everything that relates to bees.

Bee-Keepers' Union—Packing Bees.—L. C. Seabright, Blaine, ♀ O., on Jan. 7, 1888, writes:

The BEE JOURNAL comes to hand this week looking fresh and bright in its "new dress." I commenced the season of 1887 with 63 colonies, and got 60 pounds of surplus honey. Bees appear to be wintering well in this locality. They have had good flights the last two days. There has been but very little cold weather, and as yet we have had only about three cold days. On the coldest day the mercury was 6° above zero.

Mr. Samuel Rau, on page 11, speaks my sentiments exactly, in regard to packing bees for winter quarters.

I do not see why it is that the Bee-Keepers' Union has not the support of every bee-keeper in the land.

[The apathy of bee-keepers relative to their defensive society—the National Bee-Keepers' Union—is astounding. They *sleep* apparently, on a volcano, which may "belch out" in fury at any moment, judging from the "rumbles" heard but recently. Already the cry of "distress" is heard, but *where are the responsive voices* of "cheer" and "substantial help" which should greet them? Reader, will you reply?—ED.]

Building Drone-Comb, etc.—John G. Pursel, Round Plains, ♀ N. Y., on Dec. 12, 1887, writes:

I commenced the season with 10 colonies, and increased them to 30 colonies by natural swarming and dividing. I have read the BEE JOURNAL this year with pleasure. I think that it is a very valuable paper, and the price is nothing compared with the information which it contains. I hived my second swarms on foundation, using starters in the shape of a V, which partly filled the frame. The bees, after drawing them out, began to

build drone-comb all around them. 1. Why did these second swarms, having young queens, build drone-comb as soon as they had drawn out the foundation? 2. To secure brood-comb, must I cut the drone-comb out? 3. If so, when is the proper time to do it?

[1. Presumably because their queen had failed to become fertilized.

2. I do not see how you can secure worker-comb where the drone-comb is, unless you cut the latter out.

3. The best time to have bees build worker-comb is after all the swarming-fever is over, or when they have a young queen, or both; and of course when everything is favorable for the comb-building.—JAMES HEDDON.]

BEE CONVENTIONS.

Wisconsin State Convention.

The bee-keepers of Wisconsin meet in their fourth annual convention, at the Capitol in Madison, Feb. 8, 1888.

In consequence of the State Agricultural Convention being held in the same week, with its usually interesting essays, speeches, papers and discussions, the bee-convention will probably last but one day. Reduced rates can be secured on all railroads, thereby making the expense much less, and giving those who wish to do so, a chance to attend both conventions.

The following is the programme for the convention:

President's Address, C. A. Hatch, Ithaca
Notes from American Bee-keepers' Convention, Frank Wilcox, Mauston.

Relation of Producer to the Commission Merchant, A. V. Bishop, Commission Merchant, Milwaukee.

The Heddon Hive and How to Use it, W. H. Putnam, River Falls.

How to Build a Bee-Cellar, D. D. Danther, Madison.

How to Get the Best Extracted Honey, E. France, Platteville.

Comb or Extracted Honey; Which? F. Minnick, North Freedom.

C. A. Hatch, President, Ithaca, Wis.
Frank Wilcox, Secretary, Mauston, Wis.

Vermont State Convention.

The 14th annual convention of the Vermont Bee-keepers' Association will be held at the Van Ness House at Burlington, Vt., on Wednesday and Thursday, Jan. 18 and 19, 1888. The order of exercises is as follows:

WEDNESDAY EVENING, 1:30 P. M.—Convention called to order by the President. Reading of the minutes of the last meeting. Reading of the Constitution, etc.

At 2:15.—A paper by W. H. Wheatley, St. Johnsbury, on "Vermont Bees." Followed by discussion of the subject by the convention.

At 2:45—"Experience of Fifteen Years in Bee-Keeping," by H. B. Isham, New Haven.

At 3:00—Discussion: "Is it advisable to insert empty combs in the centre of brood-nests for the purpose of spreading brood in the spring?" Opened by F. M. Wright.

At 3:30—Discussion: "What is the best method to prevent an increase in colonies?" Led by J. E. Crane.

WEDNESDAY EVENING, 6:45—Appointment of committees.

At 7:00—Discussion: "Bee-keeping in Vermont; does it pay?" "Its hindrances," N. G. Webster, Bakersfield. "Its Expenses," J. H. Larabee, Larabee's Point. "Its profits," Geo. Beecher, Essex. "As a business," H. L. Leonard, Brandon.

At 1:15—Essay: "The pleasure and difficulties of bee-keeping;" by a lady bee-keeper.

At 8:15—Essay: "Should women keep bees and join the Bee-keepers' Association?" by a lady bee-keeper.

THURSDAY FORENOON, 9:00—Reports of the Secretary and Treasurer. Reports of committees, organization, etc.

At 10:15—Discussion: "Is it profitable to use full sheets of foundation in the brood-chamber?" Opened by F. H. McFarlaud, St. Albans.

At 10:45—Question Drawer. A. E. Manum, Bristol.

At 11:15—Discussion: "Marketing honey." Led by J. E. Crane.

Adjournment. R. H. HOLMES, Sec.

CONVENTION NOTICES.

☞ The Eastern New York Bee-keepers' Association will meet on Jan. 24, 25 and 26, 1888, in Agricultural Hall, at Albany, N. Y. Every one is welcome. We are sure to have a pleasant and profitable time.
JOHN ASPINWALL, Sec.

☞ The Des Moines County Bee-keepers' Association will hold its next meeting on April 24, 1888, at Burlington, Iowa.
JOHN NAU, Sec.

☞ The Hardin County Bee-keepers' Association will meet at the Court House in Eldora, Iowa, on the second Saturday in each month, at noon (12 o'clock), until further notice.
J. W. BUCHANAN, Sec.

☞ The next regular meeting of the Stark County Bee-keepers' Society will be held in Grange Hall at Canton, O., on Feb. 4, 1888. A full attendance is desired, as business of importance will be considered.
MARK THOMSON, Sec.

☞ The Eastern Iowa and Western Illinois Bee-keepers' Association will hold its sixth annual convention in Moore's Hall at Davenport, Iowa, on Feb. 15 and 16, 1888.
H. S. DIEBERN, Sec.

☞ The Northeastern Ohio, Northern Pennsylvania and Western New York Bee-keepers' Association will hold its ninth annual convention in the Commercial House Parlor, in Meadville, Penn., on Wednesday and Thursday, January 25 and 26, 1888. Reduced hotel rates have been secured.
C. H. COON, Sec.

☞ The annual convention of the Vermont Bee-keepers' Association will be held at the Van Ness House, in Burlington, Vt., on the Jan. 18 and 19, 1888.
R. H. HOLMES, Sec.

☞ The annual meeting of the Northwestern Illinois and Southeastern Wisconsin Bee-keepers' Association will be held in G. A. R. Hall, corner of State and North Main Sts., in Rockford, Ills., on Jan. 17 and 18, 1888. Dr. Miller will be present, and a good programme is in course of preparation.
D. A. FULLER, Sec.

Frank Leslie's Sunday Magazine for February contains an exceedingly interesting article by Lily Higgin, on "Modern English Artists," with portraits, giving just the information that all wish to have. "From the Suez Canal, Through Two Seas, to the Equator," is important, in view of the perennially interesting Eastern Question. The number closes, as usual, with a piece of sacred music.

Honey and Beeswax Market.

CHICAGO.

HONEY.—We quote: White clover 1-lb. sections 18@20c.; 2-lbs., 16@18c.; dark 1-lb. 17@18c.; 2-lbs. 15@16c. Extracted, 15 firm at 7@10c., depending upon the quality, and style of package. Dark, 2 or 3 cts. below above quotations. Receipts light and demand fair.
BEEWAX.—22@23c.
Dec. 20. S. T. FISH & CO., 189 S. Water St.

CHICAGO.

HONEY.—Prices range from 18@20c. for the best grades, with light demand; 2-lb. sections, 15@16c. Dark is not wanted. Extracted is steady at 7@10c., according to style of package.
BEEWAX.—20@23c.
Dec. 7. R. A. BURNETT, 161 South Water St.

DETROIT.

HONEY.—Best white in 1-pound sections, 19@20c. Extracted, 11@12c. Demand brisk.
BEEWAX.—21@23c.
Dec. 15. M. H. HUNT, Bell Branch, Mich.

CLEVELAND.

HONEY.—Best white 1-lb. sections sell at 19@20 cts. Extracted, 7@8c. Demand small.
BEEWAX.—22@25c.
Dec. 15. A. C. KENDEL, 115 Ontario St.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 16@19c.; the same in 2-lbs., 14@16c.; buckwheat 1-lb., 11@12c.; 2-lbs., 10@11c. Off grades 10@12c. per lb. less. White extracted, 8@9c. Market dull.
BEEWAX.—22@23c.

MCCAUL & HILDRETH BROS.,

Dec. 20. 28 & 30 W. Broadway, near Duane St.

KANSAS CITY.

HONEY.—We quote: Choice white 1-lb., 18@20c.; dark, 16@18c.; choice white 2-lbs., 18c.; dark, 15 to 16c. Extracted, white, in 60-lb. tin cans, 9c.; in barrels, 8c.; dark, in barrels, 6@6c. California 2-lb. white comb, 18c.; dark, 16c. Extracted, white, in 60-lb. cans, 8@9c.; amber, 8c.
BEEWAX.—No. 1, 20c.; No. 2, 16@18c.
Dec. 19. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—Choice comb, 18@20c.; latter price for choice white clover in good condition. Strained, in barrels, 5@6c. Extra fancy, and of bright color and in No. 1 packages, 1/4-cent advance on above. Extracted, in bbls., 6 1/2@7c.; in cans, 7 to 9 cents. Short crop indicates further advance in prices.
BEEWAX.—20c. for prime.
Dec. 19. D. G. TUTT & CO., Commercial St.

CINCINNATI

HONEY.—We quote extracted at 4@9c. per lb. Choice comb, 16@20c., in the jobbing way. The demand for extracted exceeds arrivals, and for comb the demand is tame.
BEEWAX.—Demand is good—20@23c. per lb. for good to choice yellow, on arrival.
Dec. 12. C. F. MUTH & SON, Freeman & Central Av.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 17@19c.; fancy 2-lbs., 15@16c. Lower grades 1@2c. per lb. less. Buckwheat 1-lb., 11@12c.; 2-lbs., 10@11c. Extracted, white, 9@10c.; buckwheat, 6@7c. Demand has slackened some, and to make sales we must shade above prices. About Jan. 15 we expect a more active demand.
Dec. 31. F. G. STROHMEYER & CO., 122 Water St.

PHILADELPHIA.

HONEY.—Fancy white 1-lb., 18@19c.; fair 1-lb 17c.; dark 1-lb. are slow sale at 14@15c.; fancy 2-lb. white 15@16c.; buckwheat fancy 1-lb., 13@14 cts.; common, 12c. Prices tend downward.
BEEWAX.—23@24c.
Dec. 11. ARTHUR TODD, 2122 N. Front St.

MILWAUKEE.

HONEY.—Choice white 1-lb., 20c.; fair, 19@20c.; 2-lbs., 18@19c.; 3-lbs., 16@18c. White extracted in kegs or half-barrels, 9 1/2@9 3/4c.; in pails or cans, 9 1/2 to 10c.; amber, in 1/2-barrels, 9 1/4@9 3/4c.; dark in kegs and barrels, 7@7 1/2c. Demand good, supply fair.
BEEWAX.—22@25c.
Dec. 15. A. V. BISHOP, 142 W. Water St.

SAN FRANCISCO.

HONEY.—We quote: White to extra, 15@18c.; amber, 10@13c. Extracted, white liquid, 7@7 1/2c.; amber and candied, 5 1/2@6 1/2c. Market quiet.
BEEWAX.—20@24c.
Jan. 7. SCHACHT & LEMCKE, 122-124 Davis St.

BOSTON.

HONEY.—We quote: 1-lb. sections, 16@17c.; 2-lb. sections, 14@15c. Extracted, 8@9c. The market is not very brisk and sales are slow.
BEEWAX.—25 cts. per lb.
Jan. 12. BLAKE & RIPLEY, 57 Chatham Street.

SAN FRANCISCO.

HONEY.—We quote: White comb, 17@19c.; amber, 12 1/2@15c. Light amber to white extracted, 7 1/2@8c.; amber, dark and candied, 6 1/4@7 1/4c. Market firm and stocks light.
BEEWAX.—22@23c.
Dec. 12. O. B. SMITH & CO., 423 Front St.

KANSAS CITY.

HONEY.—We quote: Choice white 2-lb. sections, 17@18c.; dark 2-lb., 14@15c.; choice white 1-lb., 18 to 20 cts.; dark 1-lb., 15@16c. White extracted, 7@8c.; dark 5@6c. Demand is light.
BEEWAX.—21 to 22c.
Jan. 10. HAMBLIN & BEARSS, 514 Walnut St.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. Jan. 25, 1888. No. 4.

EDITORIAL BUZZINGS.

Did you ever, since ever you ever were born,

Hear about little Miss May Unicorn,
Who spent all her money

For honey
(How funny !)

When she might have kept bees,
And obtained it from these,
And saved all the money

She spent for the honey

To send to the heathen way over the seas !

—*St. Nicholas Magazine.*

Prof. McLain is engaged to give a lecture on bee-keeping, at the Academy of Sciences on Adams street, in this city, on Feb. 27.

The Ohio State Convention, held last week at Columbus, O., was a decided success. Dr. Mason said that it was one of the best he ever attended. But a correspondent remarks that "the Doctor is a whole convention himself." We shall publish the proceedings as soon as received.

Bees in Manitoba.—A correspondent wants to know how bee-keeping would pay in southern Manitoba. It is too far north to expect much for bee-keeping. The winters are too long; making the "long confinement" disastrous. Perhaps some of our subscribers in that region can better answer the question.

An Honor.—Messrs. Chas. Dadant & Son, of Hamilton, Ills., write us as follows on Jan. 13, 1888 :

We extend our congratulations for the new and neat appearance of the old AMERICAN BEE JOURNAL. It is a pleasure to peruse such a well-printed paper, and it does honor to its publisher. Long may it live !

The Weather in England has been quite mild. The London *Journal of Horticulture*, in its issue of Jan. 5, 1888, remarks as follows concerning it and the bees :

During the months of November and December the weather has been changeable; frost, snow, and rain alternating with extreme mildness for the season, the temperature often being above 50° Fahr. The lowest temperature during November was on the 24th, the thermometer registering 19°, and the lowest during December was 10° on the 22d in North Britain.

On the last day of November and on the first day of December the thermometer stood above 50°, and the bees were alert, many of them on the wing, and a great number gathering water, evidence that, owing to the mildness, breeding had begun earlier than is usually the case.

One colony in particular was very busy, and killed the last of its drones on Dec. 1. This colony, I believe, had a young queen, which was fertilized as late as Oct. 27, but I have not sufficient data at present to confirm this, but a few weeks will prove it, as the bees were half-bred Syrians, and the drones living were Carniolan. In addition to the above, either two or three had preserved their drones until the two days mentioned.

The Canadian Bee Journal makes the following friendly allusion to us in its last issue :

The AMERICAN BEE JOURNAL comes to us in an entirely new dress of type, which makes a decided improvement in its appearance. In its articles, the AMERICAN BEE JOURNAL keeps abreast of the times, is a credit to its publishers, and worthy of patronage. We wish it every prosperity.

Our thanks are hereby extended to friends Jones and Macpherson. We also wish prosperity to the *Canadian Bee Journal*.

Mrs. L. Harrison, of Peoria, Ills., is to give an address on "The Apiary," before the Farmers' Institute, to be held at Peoria, Ills., on Feb. 1, 1888. The meeting will be held in Rouse's Hall.

Feeding Partly-Filled Combs.—A subscriber in Ontario, Canada, asks the following question :

I have some colonies that I fear have not enough food to carry them through the winter. I also have combs partly filled; will it do to put those light colonies over the frames that are partly filled with honey, and give them a passage way out of the bottom of the super containing the honey ?

If the supers with partly-filled combs are placed over the bees, they may go up and get the honey, but will not be likely to go down to it. There is danger, however, of letting the heat escape by having the super over the cluster.

If the partly-filled combs are placed at the side of the cluster (in place of empty ones), and holes made through the combs, the bees may take the honey if the weather is not too severe.

The St. Paul Ice Palace and winter carnival opens Jan. 25, and continues ten days. One fare for round trip on all railroads

Bees on Shares.—F. Richards, of northern New York, asks the following questions. As others may desire the information, we give it a place here :

Which is the proper way to take bees on shares? Must the taker feed them at his expense, if necessary? Must he furnish the honey-boxes and foundation, and give the owner of the bees back his original number and half of the increase ?

It is usual for one party to furnish bees, and the other party the care and labor. The expense of new hives, surplus-boxes, comb foundation and queens is usually divided equally, and at the end of the season the honey and increase of bees are equally divided—leaving each to take all chances of marketing, as well as wintering.

Make a written contract, stating the agreement in full, and then there will be less liability of a misunderstanding.

Pleasure and Profit.—S. T. Pettit, of Belmont, Ont., wrote as follows on Jan. 18, 1888, concerning our paper :

I am more than ever pleased with the good old AMERICAN BEE JOURNAL. Your staff of writers in the question drawer department are all so well qualified to give simple, plain, intelligent answers, that it is at once a pleasure and a profit to study these answers.

Postponed for One Year—that is what was decided to do, as will be seen by the following letter :

Please state in the next issue of the BEE JOURNAL, that the meeting of the "Eastern Iowa and Western Illinois Bee-Keepers' Association" has been postponed for one year, or until "called;" it being thought best to do so upon consultation of officers.

C. H. DIEBERN, Sec.

Cabbage and Celery Plants.—A guide to their successful propagation. A new manual of instruction by Isaac F. Tillinghast. Seed and plant grower, and editor of *Seed Time and Harvest*, LaPlume, Pa., 32 pages. Illustrated. Price 25 cents.

☞ We will send the above and the BEE JOURNAL for one year, for \$1.15.

A Favorable Word from any of our readers, who speak from experience, has more weight with friends than anything we might say. Every one of our readers can lend us a helping hand, in this way, without much trouble, and at the same time help to scatter apicultural knowledge and promote the welfare of our pursuit.

New Catalogues for 1888 are on our desk, from the following persons:

G. D. Black, Brandon, Iowa—8 pages—Bees, Queens, Honey, etc.

Iowa Seed Co., Des Moines, Iowa—48 pages—Vegetable and Garden Seeds.

Look Over last year's numbers of the BEE JOURNAL, and if any are missing, send for them at once, as we have but few left now, and they are daily becoming less.

GLEAMS OF NEWS.

A "CORNER" IN HONEY.

Mr. Albert H. Lind, of Fond du Lac Co., Wis., has sent us the following item taken from the New York *World* of Dec. 21, 1887:

KANSAS CITY, Mo., Dec. 19.—A "corner" on honey exists in this section; one firm here holding nearly all of the product that there is in town. The crop was a light one all over the country. In this State the product was not large enough to feed the bees for the winter, and honey had to be bought for that purpose.

The California crop was a small one, and the product of the hives in Illinois and Indiana was light. New York failed to secure the usual supply, which is very large, the New York crop being barely large enough to supply the home demand.

That is not much of a "corner!" We might say the same of Chicago; nearly all the honey now for sale being held by about two "firms!" And yet all buyers can be accommodated.

The following sensational item we take from the Chicago *Times* of Jan. 15, 1888. It is headed, "Now it is a Honey Trust—The Latest Combination Proposed to Boost up Prices:

The convention of honey-producers in the State of New York will begin at Utica Tuesday next. Three days will be occupied in the deliberations. J. L. Scofield will preside. The producers of over 5,000,000 pounds of comb honey and 1,000,000 pounds of extracted honey as an annual crop will be present.

Among other subjects to be discussed will be the shape, size, and style of the packages for the coming year, the price to be charged to the wholesale dealers, and a plan for unity of action to prevent the cheapening competition which has marked the sale of honey during the past.

It is proposed to form a trust, to be composed of all the large producers in the State, nominally to regulate the size of combs, so as to unify the marketable packages, but actually to buy up all surplus honey when there is a glut of production, so as to keep up the price and shut out competitors who might be willing to sell at a sacrifice. It is expected that this plan will meet with great opposition from the small producers.

At this writing the New York Convention has held its last session, but we are not yet advised as to the "doings" there. We hope to be able to lay it before our readers next week.

The "Honey Trust" is probably only a canard, but of that we shall hear more definitely when the proceedings are published. To control, in a healthy and honorable way, the honey market, is very desirable and praise-worthy.

The *Echo*, a nice dollar weekly newspaper of Detroit, Mich., makes mention of us in the following language:

THE AMERICAN BEE JOURNAL, of Chicago, now entering upon its 24th year in a highly successful career, is the oldest paper in America devoted to the interests of its special field. It is well edited in all of its departments, is attractive in appearance, and is a reliable authority upon the topics of which it treats.

The "Wiley Lie" in England.

It is exceedingly unfortunate that in the absence of its editor, some one has endorsingly copied in an editorial in the *British Bee Journal*, the silly lies going the rounds of the newspapers, about "artificial honey" being made in New York, etc., a la Wiley! Did we not know that the editor, Mr. Cowan, was at his winter home in Switzerland, and that he therefore knew nothing of its publication until seeing it in the *Bee Journal*, we should feel much worse about it.

The article in question may be found on page 568 of the *British Bee Journal* for Dec. 28, 1887. It reads thus:

We have noticed the ever-increasing production of honey all over the world, but this is not the danger the apiculturist has to contend with. America and Canada may collect their tons of pure nectar, and yet there is room for more. By an increased sale of honey our British productions will come to the front; once let a man taste prime honey, and he will never go back to inferior. The danger we have to contend with is the unprincipled scientist, the man who uses his knowledge of bees for unlawful purposes; and further, the man who advances his nefarious scheme without the aid of bees at all. The history of the first of these individuals we have recently learnt from a clergyman who had been traveling in the far West, and visited many of the adulterating bee-farms. This apparent bee-keeper settles down to carry out his practices in a quiet place with a favorable climate; he has a large number of hives, but the pasturage of the district is quite immaterial to him, as his bees have to obtain their stores from large feeders placed all over the apary. Containing what? Our informant was unable to find out, as although everything in the establishment was shown to him without reserve, yet he was not permitted to taste the contents of the vats or feeders from whence the bees were obtaining their supplies. The latter of these scientific bee-keepers is best described in the following quotation from a magazine of this month: "Artificial honey now made in New York is so much like the genuine article that only experts can detect the difference. It is in racks, the same as the natural product, and now and then the wings and legs of a few dead bees are to be seen to further the deception. It can be sold at a profit of 5*d*. per pound.

As usual in such cases, a clergyman is brought into it, so as to give some appearance of truth to the story—for he "visited many of the adulterating bee-farms," says the article.

It is a base slander—a nefarious lie; neither the clergyman in question, nor "any other man" ever visited any such "adulterating bee-farms!" They do not exist!!

It is nothing more nor less than a scandalous falsehood—the production of a sensational reporter's brain, written for *spice*, but lacking even the flimsiest "thread" of truth!

Its only possible excuse is the infamous "scientific pleasantry" written "for the fun of the thing," by Prof. Wiley—who is so unprincipled as to let it "fly" on electric wires to "the uttermost parts of the Earth," without a word of regret, or denial!

When cornered by the AMERICAN BEE JOURNAL he admitted that he wrote it as a scientific pleasantry, never dreaming that

any one would imagine it to be a sober fact. Now the *British Bee Journal* republishes it under the heading of "Facts." It is astonishing, to say the least!

We have repeatedly offered large sums of money to persons (one of them a clergyman, too) who had repeated this story as a fact, to take us to the place where these "artificial combs" are made, or where the "adulterating bee-farms" may be found, but no one can take us to them! No such places can be found!

Mr. A. I. Root, editor of *Gleanings in Bee-Culture*, has for two years had a standing offer of \$1,500 to any one who will point out such places to him—yet there are none who can do it. They do not exist!

Now, when honey is scarce and prices high, it is just the time for putting this "artificial comb honey" on the market at good prices, for our British cotemporary says that it is "so much like the genuine article that only experts can detect the difference." But what are the facts? Not even a single pound of the "artificial honey" can be produced! Not even a single "adulterating bee-farm" can be shown!

Send your "clergyman" over here, Mr. Scribbler, to point out such farms. It will pay him to do so!

Disturbing Bees in Winter.—W. Z. Hutchinson writes as follows on the results of disturbing bees in winter, in the *Farmer's Review*. He argues quite correctly that sometimes it is necessary to disturb them sufficiently to find out if they have sufficient food; and that in such a case it is better to examine them than to let them starve:

Many bee-keepers advise us to lock the bee-cellar, and not open it again until spring, saying that the least disturbance is injurious to the bees. Others say that disturbance is no injury, that the cellar may be entered at any time with a light, the hive opened, and even combs taken out without any deleterious results following.

In all probability the cause of winter losses lies in something aside from disturbing. Improper food, or an undesirable temperature are more to be feared than disturbance; if these are right, disturbance, unless carried to an extreme, will do no harm; if wrong, disturbance may be, and probably is, an aggravation.

But, says one, why disturb them? Well, bees are sometimes short of stores, and bee-keepers might let them starve for fear of disturbing them.

Early in winter bees go into a quiet state bordering on hibernation, and this quiescent state should be as long and quiet as possible; towards spring breeding begins, and the bees are then more active, and disturbance would probably do less harm than in the earlier part of the winter.

It may be questioned if simply going into the cellar with a light and quietly lifting covers or quilts, and peeping under them at the quietly sleeping bees, can be called a disturbance, unless it be too long continued.

It is, of course, a better way to see that the bees have sufficient food in the fall, that they are placed in good warm quarters, and then let them alone, as nothing is gained by disturbing them, but when these things have been neglected, they should be attended to, even though the bees are disturbed thereby.

BIOGRAPHICAL.

FATHER L. L. LANGSTROTH, THE HUBER OF AMERICA.

But few of those who in the present day are using the movable-frame hive and practicing the modern methods and management of progressive bee-culture, realize how many sore "trials and troubles" beset the "pioneers" in developing the pursuit. That development was slow, and every "progressive step" was beset with many difficulties. The methods and management of to-day are an evolution, and to the Rev. L. L. Langstroth and his co-worker, the lamented Moses Quinby, we owe an overwhelming debt of gratitude for their patient and un-

he took great interest in natural history, and the happiest days of his youth were those spent in watching the habits of the various insects found in and near the city of his birth. His parents were of the "old school," and deeming such studies the height of youthful folly, gave him no encouragement therein, and it was not until the year 1838, that he began to learn something of the honey-bee. At that time he procured a colony or two of bees, and began studying them under great disadvantages, he at that time never having seen or heard of a work on bee-culture; and for the first year of his pursuit in this direction, the only published work of that kind that came to his notice was written by a man who doubted the existence of a queen-bee.

After graduating at Yale College, he pursued the study of theology, and was settled over his first church at Andover, Mass. His health became in a short time so much impaired, that he was obliged to give up his pastoral charge, and in 1839, he removed to Greenfield, Mass., where for a few years he was engaged in teaching.

Rev. L. L. Langstroth.

tiring exertions in revealing to us the mysteries of the home of the honey-bee.

Hundreds—aye, thousands—to-day are using the improved methods, who know but little, if anything of these notable men.

We give herewith an illustration showing the kind, and beneficent face of Father Langstroth, (the latest article from whose pen may be found on page 55 of this paper), and subjoin a brief biographical sketch written by Mr. J. E. Pond, for the *American Apiculturist* about four years ago.

It is with great pleasure that we have the productions of his pen, consequent upon the return of his mental powers, by even a brief respite from his painful and oft-returning "head trouble." Mr. Pond's article is as follows:

Lorenzo Lorain Langstroth was born in Philadelphia, Pa., Dec. 25, 1810. As a boy

Finding that out-door labor and exercise of some kind was absolutely necessary, he devoted such as he could spare from his duties as a teacher to his apiary, and carefully verified all the experiments of which he had read, and entered into many of his own, for the purpose of gaining such knowledge by actual observation, as might be useful to him or to bee-keepers in general.

The methods of management then in use were not at all satisfactory to him, and he was constantly endeavoring to devise some way or means, whereby complete control of the whole interior of the hive might be given him.

He thoroughly tested bars and slats, and even endeavored to make a practical use of "the leaf-hive of Huber." This leaf-hive, however, was too clumsy (as any one may learn by attempting to use one), and he became almost discouraged at the poor success he met with.

At last the idea came to him, that if bees will build comb on bars set on top of the hive, why will they not build it in a frame hung in the hive? He tried this plan with

fear and trembling. Failure had been his lot so many times, that he had hardly dared to hope for success with this his new fancy. As we all know, this experiment did succeed, and the result was that in 1852, he introduced the frame to the public, and so well was his work matured, that the same style of frame he then devised, is now used more largely than any other, in the exact form he first devised it, and by the ablest apiarists in the country.

It will be needless to enter into the many discouragements and great opposition, with which he met in his endeavor to bring his frame into general use. It has been introduced, and introduced fully and completely; and such are its merits, that the Langstroth frame is now used wherever bees are kept.

By the term Langstroth frame, I do not mean simply the original frame he devised, and which he still advises; but I do mean that all sectional movable hanging frames, by whatever name may be known, are Langstroth frames.

As an inventor, the name of L. L. Langstroth will live as long as bees are kept, and generations yet unborn will revere his memory. By means of his powers of invention, and through his instrumentality in putting that invention before the public, the apiarist of to-day, with a few days' practice only, is enabled to see and observe for himself, all those mysteries of which Virgil has so beautifully sung, and which the various writers of the past were only enabled to find out, as was Huber, by long years of patient labor, such were the difficulties that then surrounded them.

With the introduction of the frame a new era began, and through its means bee-culture has been raised from a business of insignificance, to one that is now barely second to any other.

Mr. Langstroth was not only successful as an inventor, but also as an author. His treatise on apiculture, "The Hive and the Honey-Bee," stands at the head of all written works on the subject, and has fairly earned the high distinction given it, of "the classic of apiculture."

Mr. Langstroth is now an old and feeble man. His health was impaired in early youth by too close attention to his studies, and now he is able to do but little for himself.

Modest and unassuming in his manners, and confiding as a child in the honesty of the world, he, to-day, instead of having reaped a fortune as the result of his valuable invention, is not worth a single dollar. But for all this, he stands before the world as one of Nature's noblemen, an honest man. He has fairly and fully earned the proud title that all bee-keepers, who know him, admit belongs to him—the prince of apiarists; the Huber of America.

At the apicultural meeting in Chicago, in 1883, the Rev. L. L. Langstroth was present, and gave an interesting epitome of the rise and progress of American apiculture, and said substantially as follows:

In experimenting with bee-hives he ascertained the exact distance that bees will not join with propolis or build intervening comb. When this fact was demonstrated, all there was to do was to surround the comb in the bar with wood, and leave this distance between it and the hive, and it would not be fastened with propolis, or comb built in it. Thus the movable-frame was born.

While he was experimenting with it, a friend came into his bee-yard, but he did not hear him or see him until he said, "Friend Lorenzo, thee has not made an invention, but it is a revolution." Time has proved this to be true.

Mr. Langstroth said, that if the movable-frame had not been born to him, it would have been to some one else, as the time of its advent had fully arrived.

QUERIES REPLIES.

TRANSFERRING BEES ON CROOKED COMBS.

Written for the American Bee Journal

Query 509.—On transferring, what would be the best way in the spring to manage a colony of bees, which had built their combs on a curve and diagonally in the movable frames? Would it be better to cut right through or take the frames out bodily, and replace the comb in frames as well as could be done?—New York.

I would transfer by Mr. Heddon's new system.—P. L. VIALON.

Drive the bees out, turn the hive upside down, cut loose the attachments, if any, from the sides of the hive, and dump out the whole business, *en masse*; then pick out the best combs for transferring, and melt up those curved too much.—C. C. MILLER.

Cut out all the crooked comb, extract the honey, and melt it for wax. Place frames filled with full sheets of foundation in the new hives. I would not bother with old crooked combs. Some of the best may be used, especially if it contains brood. It is generally more satisfactory to use full sheets of foundation in the frames.—C. H. DIBBERN.

Take out all the frames, separate carefully, and use all good comb; melt up all that is not suitable, and replace it with foundation.—H. D. CUTTING.

Let the bees swarm; 21 days thereafter drive out all the remaining bees and hive them. Next convert the crooked combs into wax. Such combs are not worth bothering with.—G. M. DOOLITTLE.

Cut out the combs, and shape them to the frames. Use the ordinary methods of transferring.—DADANT & SON.

Start on an outside frame, cut the combs loose from it the best you can, and remove it. You will now have room to cut the combs from the next frame. Use the straightest combs, and reject those that cannot be pressed into position. Secure them in position by wired sticks until the bees fasten them.—J. P. H. BROWN.

The best way is to keep an eye on the bees, while they are building, and not get into such a scrape. If the hive stands just right, perpendicular at the sides, with an inclination of 2 inches, they will do it. Press the combs back, and get them into as good shape as possible.—MRS. L. HARRISON.

If it had no brood, I would give it full sheets of foundation, and melt the combs into wax, and give them the honey from the combs, or feed syrup. I would save the comb with brood in

till batched, and then make that into wax. Take the frames out bodily.—A. B. MASON.

Cut the combs loose from the top-bars, and pry them off. Then cut the combs loose from the side-bars, and lift them out.—M. MAHIN.

Cut the combs out, leaving each one as perfect as possible, and replace them straight in the frames, secured by clamps, sticks or strings.—EUGENE SECOR.

Cut right through and take out one comb at a time from one side. Take the combs in a warm room, and straighten them on a board or between two boards—there will be no harm done to the capped brood in the operation, with care; then transfer, tying the combs in the frames with cord, using side-pieces of wood to support the combs where needed. I would manage them like any other transferred colony, *i. e.*, keep them warm, give plenty of food, and empty combs or full frames of foundation, if needed.—G. L. TINKER.

Practice what has been called "modern transferring," as practiced and advised by James Heddon, and described by him in back numbers of the BEE JOURNAL.—W. Z. HUTCHINSON.

When the weather is sufficiently warm, so that the combs will bend without cracking, remove the frames bodily, then cut the first comb loose from all the frames except the first, and from the first so far as it is not in the right position; then bend it into place and fasten, and do the same with the others in turn.—R. L. TAYLOR.

Sometimes when combs are not quite straight in the frames, but are straight as to themselves, they can be turned about and made straight in the frames. I do no transferring, any more, upon the old system.—JAMES HEDDON.

Take the combs out and straighten them. I do this by laying them in frames, and pressing them, when slightly warm, between two pieces of board. The frames protect the comb.—J. E. POND.

I have frequently transferred combs from frame hives in the condition you describe. My way is to cut loose the two outside frames and remove them. I then pry loose all the frames and lift them out together, bees and all. Commencing on one side, the frames are cut loose and slipped from over the combs. I then removed one comb at a time, and transferred to the frames in the usual way. The curved and crooked combs were first laid on a board and pressed straight, and then fitted into the frames.—G. W. DEMAREE.

Take out in such a manner as will secure the combs with the least break or disfigurement. Just how to do this

can only be decided by an eye-witness. Follow Mr. Heddon's plan; it is probably the best, in any event. Wait till swarming-time, and drum out the bees; giving them on foundation. Wait 21 days and repeat the operation, then extract the honey and melt up the combs.—A. J. COOK.

Cut through the combs; take out one at a time and straighten them, and then transfer in the ordinary way. The "better way" would be to give the bees new frames of comb foundation. Such crooked combs are worth nothing, except for melting into wax.—THE EDITOR.

HORIZONTAL BARS AND BEE-SPACES IN HIVES.

Written for the American Bee Journal

Query 510.—Do you consider the horizontal bars and bee-space in the shallow brood-chambers of the sectional hives an impediment to the queen's laying capacity during the height of her egg-laying period?—Illinois.

No.—M. MAHIN.

No.—MRS. L. HARRISON.

Yes.—A. B. MASON.

I do.—J. P. H. BROWN.

I do not.—A. J. COOK.

I do not know; I have never tried them.—J. E. POND.

Yes, "I do," and I do not want any in my hive.—H. D. CUTTING.

Yes. Try it. It will cost you but little.—DADANT & SON.

I do not, and I have several hundred colonies in such hives.—R. L. TAYLOR.

Probably not; still, reason would say that the bees would better be breeding eggs and larvæ, rather than bars and empty space.—G. M. DOOLITTLE.

No. But suppose it was, what then? We do not make hives simply for the convenience of the queen.—W. Z. HUTCHINSON.

They are a disadvantage in the early spring, but seem not to be in the way after the warm weather sets in. See my answer to Query 508.—G. W. DEMAREE.

No, sir, they are not in the least; and the future will demonstrate for you what the past has demonstrated for me.—JAMES HEDDON.

I do not think that the little time lost by the queen in passing from the bottom to the top frames will make much difference.—P. L. VIALON.

I have had no experience with the sectional brood-chamber hives. I should consider the bars and bee-space through the centre of the brood-nest an objection.—C. H. DIBBERN.

Not having tried these very extensively, I do not know; but I think that

when the proper season for egg-laying and brood-rearing comes, such things are no impediment. When a queen gets up in the section-case, and stays there too long, you will think she enjoys odd nooks.—EUGENE SECOR.

Hardly, as that occurs when the weather is quite warm, and bees can keep a large surface covered, making it easy for the queen to pass back and forth from one section to the other. There may be a little disadvantage from having the bees obliged to cover a space where the queen cannot lay.—C. C. MILLER.

They are, in early spring, when the colony is weak in numbers, but after the bees become strong enough to enter an upper case, I regard the horizontal bee-space between shallow brood-cases an advantage, as breeding is thereby greatly facilitated. Except for queen-breeders' use, a brood-frame should not be so shallow that pollen will be stored in sections placed over one brood-case; that would mean a frame not less than 7 inches deep.—G. L. TINKER.

Oh, no! The inconvenience to the queen, if any, is not worth a passing thought. At that time, the weather is warm. If it is detrimental at any time, it would be in the spring when the bees are weak in numbers; but those having shallow brood-chambers in use, in large numbers, say that such is not any impediment.—THE EDITOR.

CORRESPONDENCE.

DRONES.

At what Age are Drone-Bees Disposed to Mate?

Written for the American Bee Journal
BY REV. L. L. LANGSTROTH.

On page 614 of the BEE JOURNAL for 1885, I published some observations showing that under conditions apparently quite favorable, a drone crept out of its cell in about 24 days and 8½ hours after the queen had laid an egg there. After nearly two years of prostration from severe head trouble, grateful to Him who has restored my health, and with kind greetings to the bee-keeping fraternity, I continue the record of observations then made:

August 13, 1885—Drones fully two days old can only make short, flying leaps.

August 14—When three days old, if tossed up into the air, they fly well. One of this age kept out of the hive half an hour, and eagerly licked up some thin honey.

August 27—I gave some drones just hatched in a good colony, to a strong nucleus.

August 30—At 2 p.m., with the thermometer indicating 80°, four drones took wing. One coming just outside, discharged a whitish, cream-like mass, quite unlike the feces of the common bee, which was eagerly licked up by the workers! Another, caught before it took wing, discharged a clot of a somewhat yellow color. Evidently drones cannot retain their feces as long as workers. Some provision would therefore seem to be needed against a colony taking harm, when the cleansing flight of the drones is unreasonably delayed. As no drone was gone more than five minutes, none had left to mate.

September 1 and 2—The weather was unfavorable, and a few drones took wing, but not to mate.

September 3—The temperature was 76° at 2 p.m., and the weather fair, with a gentle breeze. Of the many drones that flew, some returned in less than five minutes, most in ten minutes, and a few in fifteen minutes. I think that not one sought to mate, for a drone, unsuccessful in finding a queen, will not come home until his honey-sac is nearly empty—which usually happens in about half an hour.

From all the observations made at this time, I conclude that drones cannot be relied upon for sexual duty, until they are at least eight days old, and that most of them are not serviceable quite so young. Unlike the common bee, the drone having no special office inside the hive, it is wisely ordered that it should seek to mate when about half the age of a worker.

September 15—The temperature was 60° to 76°, and the weather was cloudless. At 1 p.m. drones were in full flight. I put a Jones' perforated-zinc guard on that strong nucleus, to be able more easily to catch the returning drones. The most of them evidently flew to mate; the last two were gone 51 minutes. I caught them all; they filled two large queen-cages. After most of them had been confined over half an hour, I placed the open cages more than a foot from the hive-entrance. To my surprise, many of them unable to take wing, crawled to "the flight hole," a truly woe-begone set of beggars, impatient, nay importunate, to be fed; and the workers were all eagerness to supply their wants! One, too far gone to crawl or even to beg, on having his proboscis wetted with thin syrup, though at first barely able to take it, soon grew strong enough to fly. From numerous experiments made at this time, it seems that if drones are kept from feeding only half

an hour after returning from a wedding-trip, they become too weak to fly.

Catching, on the same day, some drones which were being worried by a strong colony, their honey-sacs were found to be well filled. It is easy to see how soon a drone must succumb, if the bees merely prevent it from eating. I believe that more perish in this way than by any actual violence done them by the workers.

I hope to be able to continue this subject in a future number.

Dayton, O., Jan. 10, 1888.

FIRE INSURANCE.

Insuring and Wintering Bees—Sowing Alsike Clover.

Written for the American Bee Journal
BY J. B. LINDLE.

In reply to Mr. C. A. Waldron, about insuring bees against loss by fire and lightning, I will say that I have \$500 insurance on bees in the cellar or in the yard, not to exceed 200 feet from the dwelling; the valuation not to exceed \$10.00 per colony. They were insured on April 17, 1883, for five years, in the Phenix, of Brooklyn, N. Y. I could have taken \$1,000 insurance. During this time my apiary has never exceeded 270 colonies, nor have I had less than 140 colonies.

Owing to demand, sale, and the season, to-day I have over 100 colonies less than on June, 1887, as many of them starved. I did not obtain one pound of surplus honey, and I fed over 1,200 pounds of honey in frames and half-filled sections extracted from the year 1886. I have never fed 50 cents worth of sugar, although I have handled and kept bees for 31 years, and for over 15 years I have made it my special business. At least 25 per cent. of my colonies are light now.

Bees Wintered in the Cellar.

I winter my bees in the cellar, the hives being about four inches from the floor, and tiered 4 or 5 high. There is no covering over the honey-board, or oil-cloth on top, and the entrance is left wide open. I never allow the temperature to be below 40°, and never above 48°, if I can possibly help it. I have wintered bees with the honey-board off, and experimented in different ways, but for over five years I have wintered my bees as above stated.

The hives are tiered up now, with access to the front of each hive or entrance, to examine the entrance in order to keep it open. So far this winter my bees have been more quiet than usual, and scarcely any dead bees are outside. They seem to enjoy it in the

cellar, with the mercury 23° below zero outside.

Sowing Alsike Clover for Bees.

I can endorse all of Mr. Baldrige's article on page 10, except that I would sow 4 pounds of Alsike seed on most land, and not on thin, dry, sandy land. It will catch in wild-grass sloughs. It thrives best with red-top clover or pasture. If for seed, sow 10 pounds per acre, and it will not lodge so badly. Be sure to get clean seed, and not mixed with sorrel, as some Eastern seed is.

Muscataine, Iowa, Jan. 16, 1888.

BEE-CELLARS.

Wintering and Insuring Bees in Cellars.

Written for the American Bee Journal
BY E. W. COUNCILMAN.

This article is written in appreciation and corroboration of Mr. A. C. Tyrrel's article on page 25, on "Bee-Cellars." Three years ago I built a bee-cellar, and finished late in the fall so that the mortar in the walls had not time enough to get dry. But the cold winter came on, and I put in it 25 colonies. Of course the combs became somewhat moldy, but I lost only 2 colonies.

Last winter, the cellar having had plenty of time to become thoroughly dry, I had no moldy combs, and I put out every colony on the summer stands that I had put into the cellar. This winter I have 80 colonies in the cellar, and from the best of my judgment I believe that I will carry them all through.

Now as to the secret of my success: Of course I wanted to discover all I could about the conditions, and as a consequence a thermometer has been in constant use during all temperatures of weather. The temperature in the cellar has ranged from 32° to about 45°. Always in going into the cellar, I would hear that low, contented hum, except perhaps towards spring, and during the warm, soft weather.

I have thought many times of making the cellar warmer, even by artificial heat, thinking that the bees would use less honey, perhaps breed faster, and come out stronger in the spring; but after comparing Mr. Tyrrel's experience with my own, I have concluded to adopt David Crockett's plan, when he hit the "bull's eye:" "Let well enough alone."

Insuring Bees in a Cellar.

In regard to insuring bees, mentioned by Mr. A. C. Waldron, on page 8, I would say that my bees are in-

sured in the Dutchess County Mutual Insurance Company. We have no trouble here in getting our bees insured, any more than any other valuables in the cellar.

Bee-Mortality in the Cellar.

I had a similar experience in regard to mortality among my bees, as Mr. Pinkerton describes on page 11; and besides, quite a number of my colonies had the diarrhea. I attributed the trouble to honey-dew (a substance with which I am not much acquainted). I found a black, sticky substance stored in the hives (in some hives large, and others small quantities), which beemen called "honey-dew." The bees which ate of this black and sticky substance, and especially those colonies that had stored a good deal of it, had the diarrhea, and large quantities of bees would be found dead in front of the hives. Up to the present time this winter, I have swept my cellar twice, and I have carried out perhaps not to exceed four quarts of dead bees. Last winter, from about half the number of colonies, up to the present time I am sure I had carried out twice or thrice that quantity. Indeed, I was frightened, for I thought that my bees were all going to die.

The mortality among bees throughout this State, and many other States, was terrible. Those who claimed to be competent to judge, estimated that one-half, or more, of the colonies died before the honey season was reached last spring.

My cellar is 14x18 feet, about 7 feet high, and has a cemented bottom. The walls are 2½ feet thick, and laid in cement. A 4-inch stove-pipe extends from near the bottom, near the centre, up through the kitchen floor, and is attached to the kitchen stove-pipe. This is all the ventilator the cellar has. The bee-cellar is separated from the vegetable cellar by a sliding door. I have been very successful in wintering my bees. The temperature ranges from 40° to 45°.

Newark Valley, N. Y., Jan. 13, 1888.

BEE-KEEPING.

What I Know and What I do Not Know about Bees.

Written for the American Bee Journal
BY J. M. HICKS.

I know that the year of 1887 was, as a honey year, in many localities a very poor one, and especially in this locality. We had no honey, but plenty of drouth. I know that but few bees have been so fortunate as to have gathered stores sufficient to last them through the winter; that I was not the only bee-keeper

who failed to get an ounce or a pound of honey as a surplus from my apiary the past season, but I let the bees keep all that they gathered, and fed them over 400 pounds of honey besides, in order that they should be well provided with honey for the winter.

I am frank to confess that the last year has been the poorest throughout Indiana, as a honey season, that I have witnessed in 50 years, and there will not be a hundred pounds of honey placed on the market, of the 1887 crop, for each thousand pounds of 1886 crop, or, in other words, not one-tenth as much honey was gathered the last year as was gathered in 1886, and I predict that whoever eats honey on the good, old buckwheat cakes for breakfast, will pay a handsome price for both honey and buckwheat flour.

I know that the science of bee-keeping is fast simmering down and into the hands of only those who will pay proper attention to the business, in order to make it a success. I also find that it is not those who can count the greatest number of colonies that make the most money at keeping bees, hence it is quite evident that a locality or certain neighborhood may become overstocked with bees, just the same as a given number of acres of grass can be overstocked with cattle, horses or sheep.

The Unknowable in Bee-keeping.

I do not know that bees can be successfully kept where there is no natural resources for their support, and no effort made by the bee-master to supply pasture for them to gather honey from; neither do I know that bees can be made profitable in any apiary unless they receive proper care and attention in order to make them so. I have also long since found out that pure Italian bees, and the black or German bees of this country, cannot be kept in the same apiary and have all the increase pure of either race. Neither do I know (as some profess) that a pure Italian queen that has mated with a black drone, can produce pure Italian drones afterwards, notwithstanding the opinions of some naturalists to the contrary; and furthermore, I have not yet learned that virgin queens can produce drones that can be relied upon in further propagation of their race; or in other words, I do not know that such drones can be of any use in the fertilization of other queens, either Italian or native. To sum it all up, I am still of the opinion that if a book was written containing all that we did not know, it would be a much larger volume than the one would be if all we know about bees were published in it. Attend to the bees, and they will pay!

Battle Ground, Ind.

PAST—FUTURE.

The Mysteries of Bee-Keeping all Done away With.

Written for the *Prairie Farmer*
BY MRS. L. HARRISON.

The day of the log-gum and square box as a receptacle for bees is now past, excepting when on rare occasions, a runaway swarm is caught, and there is nothing at hand to put them in but a nail-keg or salt-barrel. From such a beginning, many large apiaries had a start, for when the bees persisted in living and increasing, until even the discarded body of a pump had to be used to put them in, their owner roused up to the necessity of further accommodations, and the result was a "patent hive."

Some enterprising individuals took advantage of this state of things, and went through the country building bee-palaces, which had a short run, but a merry one. Their dupes thought them splendid, though there was an abundance of those terrible moths.

Following the bee-palace came a square hive, set up on high legs, and run to a point below, so those terrible enemies of the bees, the moths, would roll out at the bottom. This was good in some respects, and is occasionally seen at the present day at farm houses. All attempts at keeping bees in houses have been failures with one exception, which is pronounced a success, but is covered by a "patent."

There are two ways of managing bees; one is to let them alone, and the other is to control them, at least in a measure. In order to do the latter they must be in a receptacle from which they can be removed at the pleasure of their owner.

"Dehorning" Bees.

The secrets and mysteries of bee-keeping have all been let out of the bag, by the introduction of the movable-frame hive. And if some enterprising bee-keeper would only discover a way of removing the sting in like manner as horns are now removed from cattle, bee-keeping would make rapid advancement.

On my way to Chicago to attend the late bee-convention, I sat for a while in a seat with a lady who, in company with her husband, was bound for the Fat Stock Show. She said they were engaged largely in rearing Short-horns, and that last summer they purchased a vicious bull which she had feared would kill some of her children. The men had not had time to dehorn him until recently, but after it was done it was laughable to see how meek he was; the fight was all taken out of him. It did not appear to hurt him a mite, for

he went immediately to eating hay. Now, who will imitate the cattle-raisers and dehorn the bees of these weapons?

Apiarists are very uneasy, never content to tread in the beaten paths of their fathers; and when you think that you have the latest furniture, fully up to the times, something new is invented which leaves you far in the shade. The latest "fad" is invertible hives. Now, I cannot imagine what could possess any one to turn a hive upside down. I never tried it, but one of our horses did, and he did not want to repeat the experiment, neither did I, or the bees.

UNFILLED SECTIONS.

How to Utilize the Comb in Unfilled Sections.

Written for the *American Bee Journal*
BY W. H. STEWART.

It seems to trouble a great many bee-keepers to have so many unfinished sections at the close of the honey season. Now these unfinished sections I look upon as so many blessings, and I would like to have ten thousand of them on hand the coming spring. I do not want them to go back on the hives again for comb honey, but I will tell the readers how I dispose of them:

In the fall, after the honey season is over, I put them in wide frames, extract the honey, and then put the sections out of the way of the mice. I always use full sheets of worker foundation in the sections. In the spring, when the weather gets warm, or just before swarming time, I take a case-knife and run it around the inside of the section, cutting the comb out nice and square. These combs I fit nicely in the brood-frames, and fasten them with transferring strips or pieces of hard, twisted twine.

I always rear my own queens, and when one begins to lay, I give her a couple of frames of hatching brood, and fill up the hive with these filled frames, or hang them in extracting supers. In a short time I have worker-comb which is as nice and straight as any one would wish to see. These combs do not cost me as much as full sheets of worker foundation for the brood-chambers, yet they are just as nice and as good.

Let bee-keepers, like myself, who have more time than cash, try my plan and see if they are not well paid for their trouble; for I think that it does not pay a bee-keeper who buys all his foundation, to melt up a piece of comb four or more inches square.

QUEEN-REARING.

The Three-Cell Plan of Rearing Queens.

Written for the *American Bee Journal*
BY J. H. HIGGINS.

In regard to queen-rearing, I would say that a great many queens can be reared by the lamp-nursery method, and also by the nucleus plan; but are they as good queens as any? My experience says they are not. They are smaller, and do not live long; neither do they fill their hives with bees as well as do queens that have been cared for from the egg. The workers are not so large, and they do not work so well as do those reared from other queens; hence so many weak colonies and no honey. Can we not remedy this? I think that we can, and my practice proves to me how it can best be done. It is as follows:

I use a 9-frame hive, and when I want queens, I take from a strong colony the queen and all the brood-frames, and give them one frame of eggs just beginning to hatch, which I take from a choice colony. I then place one of their frames of honey on each side of the frame of eggs until the next day; this being done in the evening. The bees build queen-cells that night, some of them being good ones, and others are not. The following day I pinch off all but three of the best queen-cells, and give the colony some honey and six frames of brood just gnawing out. Bees will then be hatching all the time, which will keep the colony very strong, and the queens will be fully developed.

On the tenth day I divide the colony into three parts, with a queen-cell in each division, and give them the first six frames that I had taken from them.

Queens reared as above described, have proved to be good in every case; they are always large and prolific, and bees reared from them are large, are excellent workers, and they can carry more honey than can bees reared from inferior queens. The queens will lay more eggs, and last longer than any others that I can produce. They also winter well and build up very rapidly in the spring. I have them now nearly one-third larger than any bees I ever saw here.

I read of "over-dosing," in the *BEE JOURNAL*, but they do not do it for me with the "three-cell plan," as I call it. I believe in keeping all colonies strong at all times, and this is one of my plans of doing it. Try the plan and be convinced. But it will not do to rear "dollar queens" in this way; at least I could not do it.

ANATOMY.

**Rudimentary Glands in Bees,
and the Evolution Theory.**

Written for the American Bee Journal
BY PROF. A. J. COOK.

I am very glad to answer Mrs. Chaddock's very pertinent questions on page 44. The rudimentary gland of the queen surely argues not conclusively, of course, that the old-time queens were possessed of the same glands functionally perfect. Richer food, through long ages, developed enlarged ovaries, and a correspondingly greater fecundity. At the same time, less use caused a wasting away—atrophy—of the glands in question. The condition of the glands illustrates the law of retrograde development. In the same way snakes have lost their legs. Zoologists find rudimentary legs now, and believe such legs indicate legs once useful.

True, the absence of such glands in drones, and their reduced size in aged workers, argue neither for nor against evolution. Yet unless drones were to change their habits, we can readily see that "natural selection" could not lay hold of any variation in structure to produce such glands.

That rudimentary organs are in themselves conclusive proof that they originated from a useful condition of the same organs, is surely disproved by Mrs. Chaddock's happy illustrations. Yet from the study of fossil forms, and such animals as the blind fish in caves, together with the study of all related living species, have convinced biologists that in most cases rudimentary organs are the result of atrophy from lack of use.

REVIEW.

**The New Bee-Book Lately
Issued by Mr. Simmins.**

Written for the Canadian Bee Journal
BY SAMUEL CUSHMAN.

"A Modern Bee-Farm, and its Economic Management," is the title of the latest addition to bee-keepers' literature, and is written by Mr. Samuel Simmins, an extensive English honey-producer and queen-breeder. Many of us have his valuable pamphlet (before mentioned in these columns), and those who found that a treat will not be disappointed in this his latest production.

As the title implies, he tells us what he does and how he does it in the great Sussex apiaries, and it seems to me that bee-keepers must be few who can-

not find something new as well as interesting in the book.

The author tells us in the preface, that practical bee-keeping is his subject, and that with few exceptions the instructions given are based upon the writer's twenty years' experience in the apiary. That he has learned more by his failures than by his successes, as in the endeavor to overcome his difficulties he has brought out his most important methods of management. He believes the man who can give the subject close study and application, and finds himself adapted to the undertaking, may safely invest his money, and receive better returns than from many other occupations of the present day.

The book is not in any sense an encyclopædia of modern bee-knowledge; the author simply gives the methods found to be most economical and practical.

Under "Bee-Culture as a Profession," beginners are advised to first serve a couple of years in some well-established apiary, instead of keeping a few colonies and gradually increasing the number. Time and money will be saved, better plans formed, and success will be more certain. The amount of capital required is considered, and the various expenses estimated. Five hundred pounds, or about \$2,500 is considered necessary to properly commence the business with 100 colonies.

Much valuable advice is given on the sale of bees and queens, and under the manufacture of appliances beginners especially are advised to steer clear of the business of selling supplies. In the economy of the hive, the suppression of drone-production is a step toward the prevention of swarming.

The chapter on "The Varieties of Bees," is equal to anything I have seen on the subject. Blacks or natives are highly valued because they are well adapted to the production of comb honey; and when the bee-keeper has all the colonies he requires, no objection can be made to the sole use of this race when comb honey alone is sought for, although he mentions further on that pure blacks cease storing quite a month sooner, and are frequently troubled with wax-moths, while the foreign varieties never are.

It is claimed that blacks have great conservative energy; that the young commence work outside at a much earlier age, and a given number will produce and maintain a much larger amount of heat than the same number of any other race. That here is the sole reason why these bees are always ready to take to the supers, and are better comb-builders than others, though they may be occupying the same space with less than half the pop-

ulation. That here we have the best material for an improved strain of bees; and that by the admixture of foreign blood we may get greater laying-powers in the queen, a better disposition in bees, and eradicate the inclination to cease storing honey toward the close of the season, while it is yet to be gathered.

He advocates breeding from black queens crossed with Carniolan or yellow drones, Cyprians preferred to Italians. Black or Syrian drones should be vigorously excluded. He says that Italians store honey and draw out foundation later in the season than natives, as well as gather more honey; also they are more gentle, but their comb honey is not quite so good, and they are not as good comb-builders, are slow to enter supers, and quite useless for queen-rearing purposes. That Carniolans, of all pure races, are the best "all purpose bee," although not quite equal to the Cyprians as honey-gatherers; are the most gentle of all, and best for beginners. He thinks they were at one time a cross between the Cyprians and Germans, and the color reverted back to that of the majority. That Cyprians are destined to take the lead among the yellow races; though not suitable for the production of comb honey, they are very active honey-gatherers, of great beauty, and (with him) extremely docile. Their body is smaller than the native variety, and unlike the Italian workers, opens to a fine point.

In chapter 6, "How to Obtain Good Working Colonies," we find the following: "The secret of successful honey production consists in always maintaining the proper proportion of adult working bees in relation to the quantity of brood and young bees." That in our working colonies we should always have young queens, and retain none that have seen their second summer. That queens cannot be too prolific, but must do their best before the season opens, after which they will simply keep pace with the wear and tear upon the life of the workers. To provide that the best powers of the queen shall be used up before actual storage commences, we are to have young queens in very strong colonies the fall before.

There is much valuable advice given in the chapter on planting for bees, and we are assured that *systematic planting makes profits certain*.

I was much interested in feeding and feeders, buying, packing and moving bees, and especially in the production of wax, non-use of foundation, and management for heather honey.

It gave me great pleasure to see the following under queen-rearing: "It has been observed that a young queen

feeds upon pollen extensively until she has met the drone, from which time she is fed by the bees entirely upon digested food. Now just here I wish to show the folly of keeping young queens confined in the frame nurseries for a number of days after hatching, as is done extensively in several American queen-rearing apiaries. Without the nitrogenous food at this time when the constitution should be established, they are dragging out their existence upon sugar alone at the most important period of their growth."

Mr. Simmins believes, as does Mr. Alley, that better queens can be reared by proper artificial means than under the swarming-impulse.

In justice to the author I refrain from giving more of this book, but I can assure the readers that I have given but a small part of its good points. This work is now for sale in this country. It contains nearly 200 pages, and is well illustrated. I advise all progressive bee-keepers (especially those who make it a business) to thoroughly study this book.

Pawtucket, 3 R. I.

PALESTINE.

An Account of Bee-Keeping there by an Eye-Witness.

Written for the British Bee Journal
by J. BALDENSPERGER.

There is only one way to enter the "land flowing with milk and honey." According to mythology, Andromeda was exposed on the rocks lying out before the town of Jaffa to the seaside, forming a small harbor for little sailing vessels, and was delivered by Perseus from the sea-monster going to devour her. It is wild enough, the entrance to this town. I have been standing on the shore looking out for friends coming back from France and England, have seen them fighting their way through the angry sea, and exposed to the waves carrying the boats high up to the top and down again into a deep gulph of water hiding them from sight. Why do they not choose an easier way? The steamer can come no nearer, for the rocks which abound here. It is always a terrific sight to see travelers and pilgrims landing. Yet after having traveled so many days and nights, it is only a mile on the raging sea to touch the Holy Land. It is here the prophet Jonas found a ship going to Tarshish, embarked for that place, and was seized by a tempest. Joppa of the ancients, now Jaffa, is the port of Jerusalem. It is here that numbers of bees are kept, both in the original way of keeping

them, *i. e.*, in clay pipes, and in Langstroth hives, kept only by your humble servant.

Although Palestine is acknowledged by many authorities to be the real home of the honey-bees, and although we never read in the Bible of bee-keeping, yet, very often we read of the "land flowing with milk and honey" promised to Moses. Some writers on Palestine are mistaken when they mention wild bees as more abundant than the domesticated ones, because, in Psalm lxxxi. 16, the Lord promises honey out of the rock; this is only to illustrate the abundance in saying, "Even out of the rock shall I fill thee with honey." In nowise was it meant that the honey out of the rock was more abundant than the honey out of domesticated hives. Although it is possible runaway swarms were more secure from the interference of man before the invention of gunpowder, because they could not easily be had without breaking the rocks, yet certainly they did get some, or else it would not have been mentioned.

Very likely the Canaanites kept bees in the same way as the Arab population of Palestine, partly their descendants. All Eastern invasions were followed by a retrograde movement, agricultural, architectural, industrial, etc. We know that the Canaanites had chariots and highways, but nowadays an Arab is astonished to see a chariot, introduced only about 18 years ago from Europe; and, to use their own expression, it is a "thing moving along with nothing but two horses in front to drag it." They had oil-mills exactly the same as now. The invasions destroyed arts and sciences, whilst the weaker inhabitant of the country was always more or less abandoned, and continued in his primitive industry, thus carrying throughout more than thirty centuries household and agricultural implements without the least improvements, and in many cases carrying the very name throughout all the generations, notwithstanding the change of languages from the Canaanites, Hebrews, Greeks, Romans, Arabs, Latins to Turks and Arabs again.

Go to an Arab village, and you will find women grinding at the mill, either alone or as illustrated in Matt. xxiv. 71, "Two women shall be grinding at the mill." The mill is small, and can easily be transported. Two women sit down on each side of the mill (the upper mill-stone having a handle with just place enough for two hands), thus driving the mill, and singing a monotonous, solemn song of their departed loved ones and friends. It is to be concluded that the aborigines of this country kept bees in the same way as

the inhabitants now do, by comparing the above.

Honey was always abundant in Palestine—I mean real bees' honey, gathered from flowers of all kinds abounding in the land, the almond, pear (our largest crop), the orange-blossom, and the cactus; and in summer-time, when everything seems dry, the sesame (from the seeds of which the oil of sesame is produced, and used to a great extent in the country), and the labiate flowers, from which still the very highly flavored and high-renowned honey of Hymettus was gathered from thyme-blossoms.

Though some travelers tried to illustrate the fact of honey flowing from the trees, it is in no way common, for the want of trees or forests; and in the case of Jonathan, I Sam. xiv. 25-30, the honey was not dropping from the trees, but was flowing upon the ground, according to the new version; and, furthermore, Jonathan dipped his rod in a honey-comb, thus it was no honey-dew, and he said: "My father hath troubled the land; see, I pray you, how mine eyes have been enlightened because I tasted a little of this honey. How much more, if the people had eaten freely to-day of the *spoil of their enemies* which they found?" The Israelites came on the encampment of the Philistines, and suddenly fell on them. They overthrew everything, and the honey, kept in jars or he-goat skins then as nowadays, was overturned by the frightened cattle and soldiers, and was *flowing upon the ground*.

The honey-dew is only found in some trees, but in no locality that I know of, will it yield honey enough to give anything more than a taste to bees in search of water or pollen during the intermediate months of the honey-flow. In the Jordan Valley no bees are kept, because only the nomadic Arabs live here, and never trouble themselves in their wanderings with bees.

I dare say, except orange-trees and cactus-plants introduced here, the other honey-plants have always been here, and the country yielded honey in quantity sufficient to form an article of export (Ezek. xxvii. 17). Honey was translated from the Hebrew "dabash," the real old name for honey. The Arabic word for honey is "assal," whilst a treacle made of the juice of grapes and boiled is called "dibs" or "dibes" in Arabic; wherefore many writers suppose that the honey so often mentioned in the Bible was not bees' honey, but this dibes or grape-treacle; when we read in Judges. xiv. 8, 9, that there was a swarm of bees (daburin) and honey (dabash) in the carcass of the lion, and that Samson

took thereof in his hands and went on eating, it leaves no doubt as to the identification of "dabash" with honey, and can therefore be applied to most other instances of "dabash" as honey, excepting a few cases, as in Job xx. 1.

"Brooks of honey," were most probably meant for the grape-treacle, as can easily be understood if you bear in mind that grapes still are pressed out in pits cut into the rock, and flowing from one pit to another for purification, which was the method used thousands of years ago, and certainly never applied in the use of honey, because of robber bees and the thickness of honey too much would thus be wasted. The thinner treacle can easily be taken out of the rock again without much waste. And again, this "dabash"—bees' honey—was collected by the bees (daburin), and not the hornets, as suggested by some; hornets are now called "dababeer," and "dabur," the singular Arabic. The mixing up of the two names is comprehensible when we remember that the root of the word, "dabr," signifying "the buzzer" or "buzzing," was given to all Hymenoptera and Neuroptera, and was only distinguished later when civilization came in, and Arabs called the common fly "dibaan," the hornet "dabur," and the bee "nahle;" so with the sweets "dibs" or "dibes," the grape-treacle, and "assal" honey.

In almost every village of Palestine and Syria bees are kept, and, with a very few exceptions, they do not keep such numbers to depend upon them for their living, but simply a few hives placed one on the top of the other, having an arch built over them or some protection intended to keep away the hot sun-rays, which in summer-time would melt the combs but for the protection. The clay pipes are very cool as long as they are kept in the shade, but as soon as exposed to the sun they become fearfully hot. In winter time the accumulation of the hives keeps them warm in the first place, and again, nature helps itself, for any colony unable to winter is destroyed in the course of the autumn, by different enemies abounding here as in all other countries. The hornets, the wax-moth, the tellio-agamide, and gecko abounding here, and the bee-eater, being the most dangerous ones to be named.

In general, bee-keeping is carried on in very primitive and negligent ways in some respects, as weak colonies are never cared for—all such colonies are left over to themselves. The good colonies with plenty of food and bees only successfully pass the winter, thus establishing a good stock on one hand, whilst on the other, weak colonies could be united into a strong one.

The only work performed is in the swarming season, when swarms are watched for a few weeks in April and May, and hived into clay cylinders. The back covers are put on after hiving, and besmeared with wetted argillaceous earth. The interior is rubbed with citron leaves, and the small fly hole stopped with a few herbs for a day or two. They are then released, and not again looked to till the honey-crop.

In some localities honey is taken twice, gathered from the early flowers and in September. The more general honey harvest is the September crop. The covers are then hastily broken open, a few puffs of smoke from the pitcher-smoker (and it is a pitcher with a hole in the bottom, filled with manure; some burning coals are put into it, and by continual blowing the smoke is kept going) are blown on the bees, a comb or two of honey is cut out and put away, the cover is immediately replaced, and the bees are left to themselves for a whole year. In such apiaries the moth is the worst enemy, destroying numbers of bees yearly.

In the watered localities, or such as afford good food for the carnivorous hornets, the bees suffer greatly by them. They are the only enemies against which the inhabitants use their skill; they burn heaps of manure in front of the hives, keeping up a smoking for several weeks, from September to the beginning of November, which keeps the hornets out and the bees in.

The Palestine bees are good honey-gatherers, and the queens are very prolific and beautiful. It is not rare to have colonies yielding upwards of 100 pounds for a single crop, though it is not the average. This is for bees handled in Langstroth hives—our system. Excepting during the orange-blossoming in April, our bees can be handled without a veil, the strong perfume at that time filling the air rendering them fierce. Have any of your correspondents any experience as to the reason why bees are fierce—influence of weather, scent of flowers, etc.? With us the east winds render the bees angry, and the strong odor of orange-blossoms makes them fierce.

Jaffa, Palestine, Dec. 7, 1887.

BEE CONVENTIONS.

Wisconsin State Convention.

The bee-keepers of Wisconsin meet in their fourth annual convention, at the Capitol in Madison, Feb. 8, 1888.

In consequence of the State Agricultural Convention being held in the same week,

with its usually interesting essays, speeches, papers and discussions, the bee-convention will probably last but one day. Reduced rates can be secured on all railroads, thereby making the expense much less, and giving those who wish to do so, a chance to attend both conventions.

The following is the programme for the convention:

President's Address, C. A. Hatch, Ithaca
Notes from American Bee-Keepers' Convention, Frank Wilcox, Mauston.

Relation of Producer to the Commission Merchant, A. V. Bishop, Commission Merchant, Milwaukee.

The Heddon Hive and How to Use it, W. H. Putnam, River Falls.

How to Build a Bee-Cellar, D. D. Daniher, Madison.

How to Get the Best Extracted Honey, E. France, Platteville.

Comb or Extracted Honey; Which? F. Minnick, North Freedom.

C. A. Hatch, President, Ithaca, Wis.
Frank Wilcox, Secretary, Mauston, Wis.

Susquehanna Co. Convention.

The Susquehanna County Bee-Keepers' Association met at the Jay House, at New Milford, Pa., on Jan. 7, 1888. A discussion on the "Prevention of increase," began the proceedings of the day, and which was fully discussed. The subject, "Is it advisable to Italianize an apiary?" was taken up, and after a thorough discussion, it was decided that it was advisable. An interesting talk about hiving swarms was then given by E. B. Smith.

The number of colonies reported by 17 members, was 334, spring count, and increase, 191 colonies. Amount of surplus honey reported was, 11,175 pounds. H. M. SEELEY, Sec.

CONVENTION NOTICES.

The Eastern New York Bee-Keepers' Association will meet on Jan. 24, 25 and 26, 1888, in Agricultural Hall, at Albany, N. Y. Every one is welcome. We are sure to have a pleasant and profitable time. JOHN ASPINWALL, Sec.

The Des Moines County Bee-Keepers' Association will hold its next meeting on April 24, 1888, at Burlington, Iowa. JOHN NAU, Sec.

The Hardin County Bee-Keepers' Association will meet at the Court House in Eldora, Iowa, on the second Saturday in each month, at noon (12 o'clock), until further notice. J. W. BUCHANAN, Sec.

The next regular meeting of the Stark County Bee-Keepers' Society will be held in Grange Hall at Canton, O., on Feb. 4, 1888. A full attendance is desired, as business of importance will be considered. MARK THOMSON, Sec.

The Northeastern Ohio, Northern Pennsylvania and Western New York Bee-Keepers' Association will hold its ninth annual convention in the Commercial House Parlor in Meadville, Penn., on Wednesday and Thursday, January 25 and 26, 1888. Reduced hotel rates have been secured. C. H. COON, Sec.

The next regular meeting of the Susquehanna County Bee-Keepers' Association will be held at New Milford, Pa., on Saturday, May 5, 1888. H. M. SEELEY, Sec.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*
 Jan. 24-26.—Eastern New York, at Albany, N. Y.
 John Aspinwall, Sec., Barrytown, N. Y.
 Jan. 25, 26.—N. E. Ohio, Northern Pa. and W. New
 York, at Meadville, Pa.
 C. H. Coon, Sec., New Lyme, O.
 Feb. 4.—Stark County, at Canton, Ohio.
 Mark Thomson, Sec., Canton, O.
 Apr. 24.—Des Moines County, at Burlington, Iowa.
 John Nau, Sec., Middletown, Iowa.
 May 5.—Susquehanna County, at New Milford, Pa.
 H. M. Sealey, Sec., Harford, Pa.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

**SELECTIONS FROM
OUR LETTER BOX**

Bees Insured, etc.—D. P. Stevenson, Kenton, O., on Jan. 16, 1888, writes as follows concerning the insurance of bees against loss by fire :

On page 8, Mr. A. C. Waldron says that he tried to get his bees insured against loss by fire, and was refused. Well, I have my bees insured against loss in case of fire, and in a good company, too. My 40 or 50 colonies of bees are kept on the summer stands, between the dwelling-house and barn, on about one-fourth of an acre of ground, fenced in for a chicken park. I have dwelling-house, chicken-house, bees, barn, horses, cows, grain, etc., all insured in the same company. Bees did very poorly here the last season. It was too dry.

Wintering Well.—S. H. Mallory, Decatur, 9 Mich., on Jan. 10, 1888, says :

Bees are wintering well here so far. We have had quite mild weather most of the time ; 4° below zero being the coldest registered here. We are having a regular Michigan blizzard to-day.

Bees Packed in Leaves, etc.—Otto Kleinow, Detroit, Mich., on Jan. 16, 1888, says :

I began the winter with 86 colonies of Italian bees, about 75 colonies of them being in fine condition ; some of the others were weak and short of stores. All are on different sized frames, some in one and two story chaff hives, and some are in single-walled hives ; they are packed with leaves all around, and under the bottom, and all are alive now. Last season was very dry here, and bees hardly gathered enough for winter stores ; some of them I had to feed. I fed about \$25 worth, of the best granulated sugar. Some of my

colonies had from 25 to 40 pounds of honey in the hive. By Nov. 1, 1887, a few had only about 1 to 5 pounds of stores ; those, of course, were the late swarms.

Hive-Entrances in Winter, etc.

—W. S. McCrum, Etna Green, 8 Ind., on Jan. 16, 1888, says :

My 20 colonies of bees are being wintered on the summer stands, packed with 4 inches of clover chaff all around, and about one foot deep on top. The entrances are $\frac{1}{2}$ -inch by 4 inches wide. 1. Is that too large ; or is it not large enough ? 2. Would it not be better to close the entrances, or nearly so, with snow, when the temperature is at zero or below ?

[1. It is preferable to have the hive-entrances $\frac{3}{8}$ -inch high, and the whole width of the hive.

2. It would be as well to allow the snow to cover the entire hive, for protection against the cold.—ED.]

The Season of 1887.—Clarkson Pemberton, Lamoille, 9 Iowa, on Jan. 16, 1888, writes :

I had 26 colonies of bees, spring count, but as the honey crop was very short, I obtained only 200 pounds, and that was all from basswood. White clover was a failure in this part of Iowa. Bees did very poorly in swarming ; I had only 4 or 5 swarms the past summer. I think that all of my bees have honey enough for the winter. I like the BEE JOURNAL very much ; I could not do without it.

Cold Weather for Bees.—John W. Blodget, Flag Springs, Mo., on Jan. 16, 1888, writes :

The bees are going through the coldest spell that I ever saw in this country. On Jan. 13 the thermometer registered 14° below zero ; on Jan. 14, 12° below ; on Jan. 15, 26° below—the coldest that I have seen for 20 years, or over. I should think that bees in single-walled hives would freeze if ever bees freeze. I would like to see Mr. Doolittle throw bees on the snow with the mercury at 26° below zero, and then bring them to life again.

The snow is from 4 to 6 inches deep on a level, and the east and west lanes are drifted badly, being almost impassable. I think that the snow will protect the white clover from winter-killing. The only trouble is, that the ground being frozen, the water from the snow cannot get into the ground, and will all run off into the streams,

and thus leave the ground as dry as ever ; if so, we will have to depend upon spring rains to raise a crop of honey or vegetables. I welcome the weekly visits of the valuable BEE JOURNAL every Thursday.

Bees in Good Condition.—John K. Rich, Cato, N. Y., on Jan. 10, 1888, writes :

Last spring I had 17 colonies of bees, of which I sold one, and increased the remainder to 26 colonies. I sold one colony in the fall, and put 13 into the cellar ; the rest are on the summer stands, packed with planer shavings. I took nearly 800 pounds of honey, the most of which was comb honey, being a yield of about 32 pounds per colony, of basswood ; the balance was buckwheat and golden-rod. All of my bees are in good condition, and are wintering well.

Syrio-Albino Bees, etc.—E. F. Meeker, Duncan, Ills., on Jan. 12, 1888, says :

I commenced the past season with 120 colonies of bees, and I now have 138 colonies in the cellar. I did not take over 400 pounds of honey. The Syrian bees were far ahead of the other races the past season. I have them crossed with the Albinos, and I find that they are not bad to handle. I would like to hear from others, as to which of the races did the best the past season.

Golden-Rod and Aster Honey.

—Abner Pickett, Nassagaweya, Ont., on Jan. 9, 1888, writes :

I enjoy the weekly visits of the BEE JOURNAL very much. I am very fond of the bee-business. I commenced the past season with 91 colonies, increased them to 126 colonies, and have taken 4,200 pounds of extracted honey. The season became so dry that they could not get any honey until golden-rod and asters bloomed, then the bees filled up the hives very fast. I did not have to feed any, and I have them all in a wintering-house. They seem to be doing well. The temperature ranges from 40° to 44°.

Determined to Persevere, etc.

—Edw. Margileth, Mt. Carroll, Ills., on Jan. 16, 1888, says :

The BEE JOURNAL has been a constant source of interest as well as profit to me ever since I started in apiculture, which was in 1883, when I commenced with 2 colonies of hybrid bees. I am wintering 29 colonies in a cellar

at a temperature of from 45° to 38°, according to changes of the weather, and I am quite confident that the bees will winter all right. Notwithstanding the poor honey crop last year (I realized only about 300 pounds of comb honey from 27 colonies), I shall still persevere, hoping for better results.

Surplus Crate for Reversible Hive.—E. D. Keeney, Arcade, N. Y., on Jan. 8, 1888, asks:

1. Will Mr. Heddon please tell the readers of the BEE JOURNAL which kind of surplus crate he would use on his new hive, to get the most marketable comb honey, one year with another? The expense of the different kinds of crates is not to be considered. 2. Also, when bees are placed on the summer stands in the Heddon hive, in one section (packed to keep them warm), and they become populous and crowded, would he place the second section on top, or unpack and place the second section underneath? Which, in his estimation, would give the better result in breeding?

[1. I would use my reversible wide-frame and tin-separator surplus case, with the screw pressure, and reversible wide-frames, every time, in preference to any other style of case, where the matter of expense is not of great importance.

2. If your bees are "packed" at the time of year when a second brood-case will be needed, I do not care whether you put it above or below. If not packed, put it below, because it encourages the queen to renewed activity equal to spreading brood; and yet it does not spread the brood, but keeps it in the warmest part of the brood-chamber.—JAMES HEDDON.]

Cellar-Wintering of Bees.—G. W. Ogden, DeKalb, Mo., on Jan. 4, 1887, writes:

On April 20, 1887, I had 6 colonies of bees, and by buying some colonies and building up others, I had 34 colonies, from which I obtained 300 pounds of honey; but in the fall I had to feed 200 lbs. of sugar before putting them into the cellar, and then they were light in stores, but they are doing well.

Much is said about cellar wintering, but not enough. A cellar that is too cold is worse than none, and one too warm is the same. It should be dry and well ventilated; the temperature should range between 40° and 50°; it ought to be made as dark as possible,

and not visited more than once a week, to see that everything is all right. With a good light, any hive desired can be opened, with the temperature at 40°, and if necessary, proper care being used, syrup can be poured inside of the cover, and the cover then replaced. I have kept bees for 7 years, and what I knew about bees before last year I had gained by experience; but it was pretty expensive learning.

Honey Crop of Colorado.—J. M. Clark & Co., Denver, Colo., on Jan. 16, 1888, write:

The crop of honey in this State, last season, though not a full crop, was larger in proportion to the number of colonies kept, than in any other State.

Light Cellar for Bees.—H. S. Ball, Granby, Quebec, on Jan. 1888, says:

I live about 25 miles north of the State of Vermont, and for 15 years I have wintered from 25 to 60 colonies of bees without a single loss from other causes than starvation. I winter my bees in a common dwelling-house cellar, where more or less vegetables are kept. How is that for this cold climate? The bees usually remain in the cellar from Nov. 18 to April 15. But man is never fully satisfied, and so I think that bees would winter still better in a light cellar. We all know that a light cellar is healthier than a dark one, as a light room is. Will experienced beekeepers please state their opinions and experiences in regard to wintering bees in a light cellar? For 2 months this winter I kept my bees in the cellar before darkening the windows, and they seemed to enjoy the light.

Bees Wintering Well.—C. A. Haines, East St. Louis, Ill., on Jan. 11, 1888, says:

I had 5 swarms and 1,000 pounds of comb honey from 45 colonies, spring count, the past season. My honey was all from fall flowers. Bees are wintering well on the summer stands. I could not get along without the BEE JOURNAL.

Poor Season in Louisiana.—Dr. D. R. Fox, Jesuit's Bend, La., on Jan. 11, 1888, writes:

Bees did nothing here the past year, having barely supported themselves. I have extracted no honey since Feb. 1, 1887, and scarcely had a swarm, being an unprecedented state of affairs in this vicinity; and I have been keeping bees here with much profit for 15 years.

Honey and Beeswax Market.

CHICAGO.

HONEY.—We quote: White clover 1-lb. sections 18@20c.; 2-lbs., 16@18c.; dark 1-lb., 17@18c.; 2-lbs., 15@16c. Extracted, as above, 7@10c., depending upon the quality and style of package. Dark 2 or 3 cts. below above quotations. Receipts light and demand fair.
BEEWAX.—22@23c.
Dec. 20. S. T. FISH & CO., 189 S. Water St.

CHICAGO.

HONEY.—Prices range from 18@20c. for the best grades, with light demand; 2-lb. sections, 15@16c. Dark is not wanted. Extracted is steady at 7@10c., according to style of package.
BEEWAX.—20@23c.
R. A. BURNETT,
Dec. 7. 161 South Water St.

DETROIT.

HONEY.—Best white in 1-pound sections, 18@20c. Extracted, 9@10c. Demand brisk.
BEEWAX.—22@23c.
Jan. 20. M. H. HUNT, Bell Branch, Mich.

CLEVELAND.

HONEY.—Best white 1-lb. sections sell at 19@20 cts. Extracted 7@8c. Demand small and supply fair
BEEWAX.—22@25c.
Dec. 15. A. C. KENDEL, 115 Ontario St.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 16@19c.; the same in 2-lbs., 14@16c.; buckwheat 1-lb., 11@12c.; 2-lbs., 10@11c. Off grades 1@2c. per lb. less. White extracted, 8@9c. Market dull.
BEEWAX.—22@23c.
MCCAUL & HILDRETH BROS.,
Jan. 20. 28 & 30 W. Broadway, near Duane St.

KANSAS CITY.

HONEY.—We quote: Choice white 1-lb., 18@20c.; dark, 16@18c.; choice white 2-lbs., 18c.; dark, 15 to 16c. Extracted, white, in 60-lb. tin cans, 9c.; in barrels, 8c.; dark, in barrels, 5@6c. California 2-lb. white comb, 18c.; dark, 16c. Extracted, white, in 60-lb. cans, 8@9c.; amber, 8c.
BEEWAX.—No. 1, 20c.; No. 2, 16@18c.
Dec. 19. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—Choice comb, 18@20c.; latter price for choice white clover in good condition. Strained, in barrels, 5@6c. Extra fancy, and of bright color and in No. 1 packages, 4-cent advance on above. Extracted, in bbls., 6½@7c.; in cans, 7 to 9 cents. Short crop indicates further advance in prices.
BEEWAX.—20c. for prime.
Dec. 19. D. G. TUTT & CO., Commercial St.

CINCINNATI.

HONEY.—We quote extracted at 4@9c. per lb. Choice comb, 16@20c., in the jobbing way. The demand for extracted exceeds arrivals, and for comb the demand is tame.
BEEWAX.—Demand is good—20@22c. per lb. for good to choice yellow on arrival.
Dec. 12. C. F. MUTH & SON, Freeman & Central Av.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 17@19c.; fancy 2-lbs., 15@16c. Lower grades 16@20c. per lb. less. Buckwheat 1-lb., 11@12c.; 2-lbs., 10@11c. Extracted, white, 9@10c.; buckwheat, 6@7c. Demand has slackened some, and to make sales we must shade above prices. About Jan. 15 we expect a more active demand.
Dec. 31. F. G. STROHMAYER & CO., 122 Water St.

PHILADELPHIA.

HONEY.—Fancy white 1-lb., 18@19c.; fair 1-lb. 17c.; dark 1-lb. are slow sale at 14@15c.; fancy 2-lbs., white, 15@16c.; buckwheat fancy 1-lb., 13@14 cts.; common, 12c. Prices tend downward.
BEEWAX.—23@24c.
Dec. 11. ARTHUR TODD, 2122 N. Front St.

MILWAUKEE.

HONEY.—Choice white 1-lb., 20c.; fair, 19@20c.; 2-lbs., 16@18c.; 3-lbs., 16@18c. White extracted in kegs or half-barrels, 9½@9¾c.; in pails or cans, 9½ to 10c.; amber, in ½-barrels, 9¼@9½c.; dark in kegs and barrels, 7@7½c. Demand good, supply fair.
BEEWAX.—22@25c.
Dec. 15. A. V. BISHOP, 142 W. Water St.

SAN FRANCISCO.

HONEY.—We quote: White to extra, 15@18c.; amber, 10@13c. Extracted, white liquid, 7@7½c.; amber and candied, 5¼@6¼c. Market quiet.
BEEWAX.—20@24c.
Jan. 14. SCHACHT & LEMCKE, 122-124 Davis St.

BOSTON.

HONEY.—We quote: 1-lb. sections, 16@17c.; 2-lb. sections, 14@15c. Extracted, 8@9c. The market is not very brisk and sales are slow.
BEEWAX.—25 cts. per lb.
Jan. 12. BLAKE & RIPLEY, 57 Chatham Street.

KANSAS CITY.

HONEY.—We quote: Choice white 2-lb. sections, 17@18c.; dark 2-lbs., 15@16c.; choice white 1-lb., 18 to 20 cts.; dark 1-lb., 15@16c. White extracted, 7@8c.; dark 5@6c. Demand is light.
BEEWAX.—21 to 22c.
Jan. 10. HAMBLIN & BEARSS, 514 Walnut St.

DENVER.

HONEY.—Best white 1-lb. sections, 19@20c.; 2-lb. sections, 16@18c. Extracted, finest grade, 12½c.; dark, 8@9c.
BEEWAX.—20@23c.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. Feb. 1, 1888. No. 5.

EDITORIAL BUZZINGS.

Buzz, Buzz, Buzz!

From morning's first gray light,
Till fading of daylight,
It's stinging and toiling

The summer day through.
Oh! we may get weary,
And think work is dreary;
'Tis harder by far
To have nothing to do.

—St. Nicholas.

Mr. R. J. Kendall, whose many articles appeared in the *AMERICAN BEE JOURNAL* three years ago, is now in New Zealand.

Deep Snow is reported in all the New England States and Canada. Michigan, too, is reported to have snow 2 feet deep on the level, with the temperature at from zero to 16° below.

Best for Advertising.—Mr. Geo. E. Hilton, of Fremont, Mich., on Jan. 26, made this assertion, about advertising:

My pamphlets are going off like hot cakes. I am advertising in several periodicals, but the *AMERICAN BEE JOURNAL* has brought me more responses, so far, than all other sources combined! Long may it live.

Honey Vinegar.—A correspondent in the *Bee-Keepers' Magazine* tells what to do with dark fall honey, and make it of cash value, thus:

I had about 40 pounds of nice fall honey, so I asked a store-keeper what he was paying for such kind. He said 3 cents a pound, but I refused to sell, and took my honey home, put it in two 45-gallon barrels, and put boiling hot rain water with it. When it cooled off I put some vinegar "mother" in each barrel, and in the summer, I sold 90 gallons of the best vinegar that was in the county, at 16 cents per gallon. I paid my tax with it.

At the St. Louis Fair, held last fall, the premiums amounted to \$140, besides the diplomas awarded. These exhibitors obtained all the awards: William Kimble, DeWitt, Iowa, \$58; R. Grinsell, Baden, Mo., \$43; Dr. G. Lebrock & Sons, \$30; and Simon Moser, Bridgeton, Mo., \$1. It certainly paid the three first-named exhibitors to make a show of their bees and honey. They also obtained many premiums at other Fairs and Exhibitions in the West.

The Apiculturist is here in good time. The February number was on our desk on Dec. 27, and it is full of good matter on "bees," and for their "keepers."

The Year 1888 promises to be eventful. Five eclipses will occur—three of the sun and two of the moon; the first of which was a total eclipse of the moon on Jan. 28. It also gives five Wednesdays in February, being leap-year, consequently there will be five issues of the *AMERICAN BEE JOURNAL* in the shortest month of the year. It is only once in four years when there is more than just four weeks in the month, and the first and last days may not come on Wednesday for half a century.

Bees and Ants as Food.—An exchange says that the Cingalese (natives of Ceylon), eat the bees after robbing them of their honey. Caterpillars and spiders are dainties to the African bushmeo. Ants are eaten by various nations. In Brazil they are served with a resinous sauce, and in Africa they are stewed with grease or butter. The East Indies catch them in pits and carefully wash them in handfuls, like raisins. In Siam a curry of ant eggs is a costly luxury.

The Little Son of Dr. A. B. Mason is very ill, and the Doctor writes us that he has not had his "clothes off for six days and nights." We are much pleased to learn that he is a little better now, with prospects for recovery. The Doctor and his family have our sympathies.

"The Bee-Keepers' Advance and Poultryman's Journal" is the title assumed by Brother J. B. Mason, in the second volume. The January number is just at hand. It is enlarged to 20 pages, and looks well.

Convention Number—that is what the next issue of the *BEE JOURNAL* will be. We already have the reports of the proceedings of four conventions waiting, and we shall give nearly all our space to them next week.

Volume II of "Bees and Bee-Keeping," by Mr. Frank R. Cheshire, is published. As soon as we receive a copy we shall give a review of it.

Giving Credit for Selections.

On page 611 of the *BEE JOURNAL* for last year, we called attention to a chapter from our pamphlet, "Honey as Food and Medicine," being copied into several papers, credited to the *Farmer and Dairyman*, and signed Thos. Brasel, Portland, Oreg. In the last issue of that paper, Mr. Brasel makes an apology in these words:

I was surprised myself when I read the above notice; it was the first intimation I had of not giving Mr. Newman credit for his articles, and, of course, it was unintentional neglect on my part, and I think it was the first time I neglected to do so.

In past years I had furnished the *Farmer and Dairyman* several articles for publication, in which were occasional quotations from Mr. Newman's pamphlet, "Honey as Food and Medicine," and my only object in doing so was to inform the people all I could on the good qualities of honey as food and medicine.

We are always glad to have our articles copied by other papers when due credit is given, and we are glad to learn that the omission in this case was unintentional.

This is the Time for reading. The long winter evenings can be utilized by reading up bee-literature. We have all the newest bee-books, and can fill all orders on the day they are received.

Bees Flying.—In answer to the question, "At what temperature do bees fly?" the editor of *Gleanings in Bee-Culture* remarks thus in its issue for Jan. 15, 1888:

I know exactly, for I have just been out this 6th day of January, and watched the bees which were pouring out of the hives in different directions. As the sun did not shine at all, and there was no wind, I had an opportunity of getting a pretty fair test. A few started out when the thermometer stood at 50°, but there was not a general flight until it stood at about 55°. Had there been sunshine it would have made a vast difference; but as it was, they flew from entrances pointing to the north just as freely as if they were facing the south.

The Ohio Convention.—We expect to publish the report of its proceedings next week. In *Gleanings*, Brother Root remarks as follows concerning one well-known to our readers:

Dr. G. L. Tinker, of New Philadelphia, also contributed much of value to our meeting. The Doctor is not only a bee-keeper, but he is one of the finest workers, both in wood and metal, that we have in our State. He exhibited some beautiful samples of cases for sections, honey-boards, perforated zinc of his own manufacture, etc. Dr. Tinker is a firm advocate of sections open at the sides as well as top and bottom.

Poor Seasons and Hard Winters are an injury, but poor seasons come to nearly every business. In calculating, the profits of bee-keeping, we must make allowance, for poor seasons, and a loss in winter occasionally. After making this allowance the experience of those who put energy and push into their efforts, shows as good profits are usually obtained in any other rural pursuits.—*Exchange*.

GLEAMS OF NEWS.

Bogus Butter in England.—The following cable dispatch will show how Englishmen view the adulteration of food products:

LONDON, Jan. 23.—The law passed at the last session of Parliament, relating to the fraudulent sale of oleomargarine, went into effect to-day.

For the first offense the minimum fine is \$100, second conviction a fine of \$250, and third conviction \$500. The law provides that every package of oleomargarine shall be branded with the word upon the top, bottom and sides.

Retail dealers selling small quantities are required to deliver it to the purchaser in paper wrappers, on which the word "margarine" shall be printed in capital letters not less than a quarter of an inch square.

In case of doubt, where adulterated butter is exposed or sold, the act prescribes that the presumption of fraud shall be against the seller, unless he can prove that he bought the substance as butter, and holds a written warranty or invoice to that effect.

Similar restrictions should be enforced by law upon all adulteration of food products in America. We are glad to see that the United States Congress are wrestling with this subject now.

Foul Brood is very prevalent in Australia, as will be seen from the following from the *Australasian Bee Journal* for December, which has just come to hand:

In almost every district, from one end of the Australasian Colonies to the other, that scourge of the bee-keeping industry, foul brood, exists. Eight years ago it was only known to be in a very few widely-separated districts, and clean, healthy colonies were then the rule. The disease has spread to an alarming extent during the past few years, thousands of colonies have perished, and some districts have become so infected with it that it is only with the greatest vigilance and perseverance that bee-keeping, even on a small scale, can be carried on at all in them. Very few apiaries, indeed, can boast of being entirely free from the disease at the present time. It is now a matter of so serious a nature, in fact, that unless some thorough-going steps are taken very shortly to stamp out the pest, the bee-keeping industry in these colonies will soon become a matter of history. Hundreds of people have been compelled to give up keeping bees at considerable loss to themselves, owing to their inability to conquer the enemy, and many who looked to honey-production as a means of livelihood, or to augment their small means, have been sadly disappointed by their bees dying off.

Honey-Dew for Winter Stores.—In the *Michigan Farmer* we find the following item which explains itself:

As illustrating the vicissitudes of bee-keeping, Mr. S. Cornell, of Lindsay, Ont., had 212 colonies of bees which he put into winter quarters in the fall of 1886. Unhappily, the bees had stored honey-dew, and all that had laid in winter stores of this, largely succumbed "to the inevitable." In June of the following year, he had but 58 colonies remaining. Mr. Cornell now strongly advises extracting honey-dew, and feeding sugar syrup.

Alfalfa or Lucerne.—A correspondent wants us to answer the following questions about alfalfa or lucerne clover:

What is the best time of the year for sowing it? How much seed is required to the acre? What soil does it require? How many pounds are there in a bushel?

In reply we would say that lucerne or alfalfa (*Medicago sativa*) was introduced into the Pacific States from Chili, many years ago. It resists the driest weather, and it is said that when every blade of grass droops for want of moisture, it holds up fresh and green.

The hay is valuable for cattle, but as it is cut for this purpose early, that lessens its value for honey.

The seed should be scattered plentifully in the winter months, so that it may settle

Alfalfa or Lucerne.

into the soil with the spring rains and germinate. It will grow on any soil; there are 60 pounds to the bushel, and 25 pounds to the acre will be sufficient. It is said that this valuable grass was brought into Greece from Persia nearly five hundred years before the Christian era. It came to California from Chili, but it is now largely cultivated in England, France, and other parts of Europe, and gives satisfaction as a forage plant.

Alfalfa will be a prominent crop in all places where the winters are not too severe. The power to withstand great heat and dryness comes from the long, searching tap-roots, which are sent deeply down into the soil and find moisture which is inaccessible to other less energetic vegetation.

Pear Honey and pear cider in Switzerland are often found, and a Swiss correspondent from Parkville, Mo., has sent us the following concerning its manufacture:

I was born in Switzerland in 1837, and was partly raised there. I have no doubt whatever about honey in my native land being just as pure as we have it here. But "pear honey" is just as pure as such, and that it is frequently (though not extensively) made is a fact to which I can certify, for I have made it myself.

Pear cider is much more frequently made in Switzerland than apple cider. That, at least, was the case when I lived there. This cider is boiled down with fine sugar until it is of the consistency of honey, and put away in jars for special occasions. It has the full flavor of the fruit, and is a delicious "honey."

If there is any wrong in calling it "honey," it is a wrong without malice, and therefore not to be likened unto the "Wiley lie."

It is a misnomer to call it "honey," but no worse than to call apple butter, "butter," when it is in no wise butter. What we said about "Swiss honey," on page 819 of last year's *BEE JOURNAL*, only had reference to the real article or an adulteration of it.

The Scandalous Wiley Lie in New Zealand. The *Australasian Bee Journal* copied an article on glucose from *Harper's Monthly*, in which the author says that it is "much used by confectioners and brewers, as food for bees, in making artificial honey, but most of all for the production of table syrups. It then adds:

The passage which I have put in italics smacks very strongly of the famous "Wiley" scandal, and owes its origin no doubt to the same source, as the writer, in a note at the end of his paper, acknowledges his indebtedness for some of the materials, to "Prof. H. W. Wiley, of the Agricultural Department." The defense of the quality of glucose is not a very convincing one. To say that it is *probably not unhealthy* is certainly a mild way of putting it. It may not follow that it *must be poisonous* on account of the quantity of sulphuric acid used in its formation, but the process is not a very appetizing one, especially when we know that the glucose can be extracted in this way not only from corn and potatoes, but even from old linen or cotton rags, or any refuse containing starch of vegetable origin. Those who prefer such stuff to pure honey, even though the latter should cost many times as much, are scarcely to be congratulated on their taste.

Frightening Bees with Carbolic Acid Vapor is more effective if properly applied than smoke; in the case of straw-skeps it is the same. I have frequently advised bee-keepers not to pump the fumes into the hives; but many do not seem satisfied unless they can "go at" their smokers or fumigators as though they were puffers on a fire engine when the word is passed, "Down with her." You simply want to breathe, if I may use the expression, with the fumigator at about the rate that you breathe yourself, shifting it about to drive the bees back. The air passed out of the fumigator must be thoroughly impregnated with carbolic acid vapor, and must pass over the sponge at least twice to be thoroughly effective. I have driven hundreds of straw-skeps with the fumigator both in private and in the bee-tent, and have not used smoke in my apiary for two seasons.—*British Bee Journal*.

We Club the AMERICAN BEE JOURNAL and the "Bee-Keepers' Magazine" for one year for \$1.40; or with "Gleanings in Bee-Culture" for \$1.75; or with the "Apiculturist" for \$1.80; or the "Canadian Honey-Producer" for \$1.30; with the Bee-Keepers' Review, \$1.40; or all six for \$4.00.

New Subscribers can obtain the full numbers for 1887 and 1888, for \$1.75, while there are any sets of 1887 left.

IGNORANT PREJUDICE.

Several times during last year we made reference to the ignorant prejudice of the neighbors of Mr. Z. A. Clark, at Arkadelphia, Ark. His bees, on account of the drouth last summer, worked on the juice exuding from decaying peaches. Thereupon these same prejudiced individuals spread the "howl" that "Clark's bees are eating up the peaches." One ignoramus went so far as to declare that the bees ate up his "young ducks!"

Thereupon the City Council ordered the removal of the bees by June 6, and Mr. Clark was arrested for maintaining a nuisance by keeping his bees within the city limits, and ordered to remove them.

The Bee-Keepers' Union promised to help him defend his rights, and see the matter through, for it would be very detrimental to the pursuit to allow a decision against bee-keeping to be put upon record on the plea of its being a "nuisance."

Major J. L. Witherspoon, ex-Attorney General of Arkansas (who stands at the head of the Bar of the State), was employed to attend to the matter on behalf of the bees.

The case is now going to the Supreme Court on an appeal, and the Hon. S. W. Williams, of Little Rock, has been engaged to assist in defending Mr. Clark, who wrote us the following particulars last week:

I was arrested on Jan. 2, 1888, by order of the Mayor for maintaining a nuisance within the city limits, in keeping my bees there.

I think with the evidence we have, with Mr. Williams in the case, we will undoubtedly win. Now is the time for us to make this thing "hot," as it will affect the welfare of every bee-keeper that is so unfortunate as to live in an incorporated city or village.

I think that we should have two or three good lawyers in this case, as it will be a great blessing to bee-keepers in incorporated cities and towns for us to gain this suit. If we should lose it, we will all have to "get out" all over the United States. "In the multitude of counsel there is wisdom."

I shall have to sacrifice my time, business and bees in order to attend to this case of appeal. It will cost over \$300 to appeal it, and I am too poor to pay any more than I have already done in the expenses of the lower court, and for my attorney here. I must, therefore, appeal for help, through the Bee-Keepers' Union, to all the bee-keepers of America.

I am not able to carry on this suit and do justice to myself and family. I think justice to bee-keepers demands that this law be defeated, and not let us go before the world as a class of men that carry on a business that is "a nuisance." we will have to get affidavits from bee-keepers living all over the United States, stating whether bee-keeping is "a nuisance" or not. We have been condemned, but not by men that know anything about bee-keeping. If any one can give me advice, he will please write to me.
Z. A. CLARK.

We have repeatedly requested bee-keepers to join the Union, and thereby place it in a position to defend them in such cases as the above, and unless some hundreds at least do so at once, the Union will not be able to lift up a "successful standard" against the enemy. Reader, what say you about this? Will you become a member? The dues are now only one dollar!

QUERIES AND REPLIES.

MOVING BEES IN WINTER BY SLEIGH OR RAILROAD.

Written for the American Bee Journal

Query 511.—Will you kindly advise me as to the best time, and way, to move 12 colonies of bees that are packed in hives, with old combs in Langstroth size, closed-end frames? I want to move them on a sleigh three miles, over pretty rough roads, and then 17 miles by railroad, and then again 2 miles by sleigh. Do you think it advisable to move them in this way; or do you think it better to move them the whole way by sleigh? If I move them all the way by sleigh, after the first 3 miles the road is pretty good.—New York.

Move them all the way in a sleigh.—**MRS. L. HARRISON.**

I would wait until spring, if possible; if not, move them all the way by sleigh.—**W. Z. HUTCHINSON.**

I do not like to move bees so far in the winter; but if obliged to, I would use the sleigh all the way.—**A. B. MASON.**

I would wait until April or May, and move them in a spring-wagon either all the way, or partly by rail.—**M. MAHIN.**

If you cannot wait until spring, I believe I would as soon risk taking them all the way in the sleigh.—**C. C. MILLER.**

I should move them all the way by sleigh, by all means, if I moved them on snow. But why not wait until May, and then move them. I think that this would be better.—**G. M. DOOLITTLE.**

As I understand the question, I would pack them in straw, secure them to the sleigh, and make the whole journey with the sleigh.—**H. D. CUTTING.**

I should much prefer not to move them until April. If you must move them now, put a thick cushion of hay or straw on a sleigh, and move them all the way on it.—**R. L. TAYLOR.**

We would keep them on the sleigh, although it does not make a very great difference. But why do you not wait until the proper time—March—and move them on a wagon? It is far safer.—**DADANT & SON.**

I would arrange the time to suit my convenience, and the condition of the roads. I would prefer a sleigh. If the frames are well propolized, they need no extra preparation, only give plenty of ventilation by tacking wire-cloth over the entrance, and place them securely in the sleigh, with the frames running parallel with the road.—**J. P. H. BROWN.**

The best time to move them is when they can fly freely, immediately upon arrival; but it is not usually good sleighing at that time. We make no preference between all the way by sleigh, or cars and sleigh. Do not be

afraid to give them lots of ventilation, no matter how cold the weather is.—**JAMES HEDDON.**

I would not advise moving the bees on the cars in cold weather; but they can be moved by sleigh.—**G. L. TINKER.**

I would consider it very risky to move them so far before spring. I would get two spring wagons, load them with the frames crosswise of the bed, and make the one time handling do, by driving them through in one day. You should tack screen-wire over the entrances, to give sufficient ventilation, and they should have a flight the day following.—**J. M. HAMBAUGH.**

Move the whole distance by sleigh. Put the hives on straw in the bottom of the sleigh, then pack in the sleigh so the hives will not interfere with each other, or with the sleigh, in transit. Drive carefully, and where the roads are rough, with extra care.—**J. M. SHUCK.**

I should move them the whole distance with a sleigh, if the road is fairly good. They may go all right by rail, but the risk of changes is great, and can be avoided by moving at one job. The frames should be securely fastened in the hives, and ample ventilation given. It is not safe to move bees such a distance in the winter, in any case.—**J. E. POND.**

I should prefer to wait until spring; though I have known so many cases of bees being moved in mid-winter with entire success, that I should expect success even though I moved them now. I think that I should use the sleigh all the way. It would be cheaper, doubtless, and fully as well for the bees. Use plenty of straw, and disturb the bees as little as possible.—**A. J. COOK.**

I dislike very much to disturb bees in cold weather, and I should prefer to wait until spring. If it is necessary, however, to remove them now, choose a moderate day, and I should prefer to move them all the way by sleigh. As there are only 12 hives, and the distance is only a reasonable day's drive; one load would take them nicely, and you would be done with it. Fasten in the bees with wire-cloth, even in cold weather while removing them, and if carefully handled there is little danger.—**C. H. DIBBERN.**

I would move them the whole way while they were on the sleigh. I have moved bees in this way several times with perfect safety. Your close-end frames will stay in place without any wedging up. A friend of mine moved 100 colonies 40 miles in four loads, on a large spring-wagon. Not a comb was broken. Another time the same man hauled 50 colonies in Langstroth

hives, on a common farm wagon, on which he had a long hay-rack. We move them at any time in the fall, winter or spring. Perhaps towards spring would be the best in your climate, where bees do not have the opportunity to fly as often as they do here.—G. W. DEMAREE.

The combs are very brittle now, and it is dangerous to move bees at this season on account of the liability of breaking down the combs. The hives must be handled with care, and should only be handled at each end of the route—therefore a sleigh-ride all the way is better than part railroad. If they must be moved now, instead of in March, secure the frames, and load on the sleigh, so that the frames cross the road bed, and let them be very carefully driven, especially over the rough part of the road.—THE EDITOR.

WINTER FLIGHTS FOR BEES IN A CELLAR.

Written for the American Bee Journal

Query 512.—Should bees be taken from the cellar on a warm day during winter, so that they can have a flight? My cellar opens into the kitchen, and it is hard work to take them up and down the steps; but if it is necessary to take them out occasionally, I will do it. I fear that the cellar is too warm a part of the time, and there is no good chance to ventilate it. The temperature varies from 44° to 48°, but the bees seem quiet the most of the time.—Indiana.

No; let them remain where they are.—JAMES HEDDON.

Do not take them out.—DADANT & SON.

Not if they are as quiet as you say.—A. B. MASON.

Let the bees alone until spring, would be my advice.—G. M. DOOLITTLE.

Do not take them out. The temperature is all right.—W. Z. HUTCHINSON.

I would make every exertion to keep the cellar at an even temperature; and if the bees are quiet, I would not disturb them.—J. P. H. BROWN.

No, not at all. The temperature of your cellar is fairly good, and your bees are undoubtedly in as good condition as possible.—R. L. TAYLOR.

I have no experience with cellar-wintering, but I would not disturb them unless they are very restless, and show signs of disease.—M. MAHIN.

If they are quiet, let them alone; do not interrupt if all is well. If uneasy, let the circumstances suggest the change to be made.—J. M. SHUCK.

Not unless they are noisy and restless, showing diarrhetic symptoms, by discharging their feces around the entrance and over their combs. Give them ventilation if possible, and keep the temperature from 40° to 45°, Fahr.—J. M. HAMBAUGH.

The conditions must govern in all cases. If they are quiet and show no signs of disease, let them alone until you are ready to put them out in April. I think that the temperature is too high, at 48°.—H. D. CUTTING.

So long as the bees are quiet, I certainly should not disturb them. I do not give my bees any flight from the time they are taken in until they are taken out to stay in the spring.—C. C. MILLER.

I have never wintered bees in a cellar, but judging from my reading of experiments of this nature, I should prefer not to give them a flight. It may do no harm, and may so disturb them as to cause great loss.—J. E. POND.

They should not be taken out. The temperature is about right. If the bees get uneasy, later in the season, give them water. The temperature can be lowered if thought necessary, by placing some cakes of ice in the cellar. Another season put in sub-earth ventilation.—MRS. L. HARRISON.

Bees do not require to be removed from a good cellar for a flight during the winter, as long as they remain reasonably quiet. Indeed, I think it a disadvantage to do so, as it has a tendency to make them restless afterward. As long as the temperature can be kept below 50°, the bees are better off in a cellar than anywhere else. I have had bees confined for over five months, with no bad results.—C. H. DIBERN.

By no means. If you have a cellar where you can keep the temperature between 36° and 48° Fahr., and the bees have good food, they are all right. I do not carry my bees out until April. Should the bees become very uneasy, and by change of ventilation and temperature I could not quiet them, I should carry them out if a warm day came. I never expect, however, any such experience.—A. J. COOK.

As long as the bees remain quiet and healthy in the cellar, they may be left alone until April. Still the colonies will do better to take them out about March 1, and pack them on the summer stands. They will be less liable to spring dwindle, and will build up into strong colonies at least two weeks ahead of colonies put out of the cellar in April. It does no harm to remove the bees from the cellar at any time in the winter on suitable days, and return them after a flight, or pack them.—G. L. TINKER.

As long as they remain quiet, they will not suffer for a flight. I have kept a small colony in my office all winter, where there is a summer temperature kept up in the daytime, and the temperature goes down below the freezing point when the nights are cold. They are in excellent health

now (Jan. 20). I have another small colony that is kept in a vegetable and fruit cellar, at a temperature a little above the freezing point, during cold weather. The colony is moved into the office once in about ten days, where they are "warmed up" till they ventilate with a "loud roar" as in summer time. After their day's exercise, they are returned to the cellar. They are also in fine health. I am very much interested in these experiments.—G. W. DEMAREE.

As the bees are quiet in the cellar they are not diseased, and may with safety remain undisturbed until the spring comes. Keep the temperature as even as possible.—THE EDITOR.

BEE CONVENTIONS.

Wisconsin State Convention.

The bee-keepers of Wisconsin meet in their fourth annual convention, at the Capitol in Madison, Feb. 8, 1888.

In consequence of the State Agricultural Convention being held in the same week, with its usually interesting essays, speeches, papers and discussions, the bee-convention will probably last but one day. Reduced rates can be secured on all railroads, thereby making the expense much less, and giving those who wish to do so, a chance to attend both conventions.

The following is the programme for the convention:

President's Address, C. A. Hatch, Ithaca
Notes from American Bee-keepers' Convention, Frank Wilcox, Mauston.

Relation of Producer to the Commission Merchant, A. V. Bishop, Commission Merchant, Milwaukee.

The Heddon Hive and How to Use it, W. H. Putnam, River Falls.

How to Build a Bee-Cellar, D. D. Danlher, Madison.

How to Get the Best Extracted Honey, E. France, Platteville.

Comb or Extracted Honey; Which? F. Minnick, North Freedom.

C. A. Hatch, President, Ithaca, Wis.
Frank Wilcox, Secretary, Mauston, Wis.

CONVENTION NOTICES.

The Des Moines County Bee-keepers' Association will hold its next meeting on April 24, 1888, at Burlington, Iowa. JOHN NAU, Sec.

The Hardin County Bee-keepers' Association will meet at the Court House in Eldora, Iowa, on the second Saturday in each month, at noon (12 o'clock), until further notice. J. W. BUCHANAN, Sec.

The next regular meeting of the Stark County Bee-keepers' Society will be held in Grange Hall at Canton, O., on Feb. 4, 1888. A full attendance is desired, as business of importance will be considered. MARK THOMSON, Sec.

The next regular meeting of the Susquehanna County Bee-keepers' Association will be held at New Milford, Pa., on Saturday, May 5, 1888. H. M. SEELEY, Sec.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

CORRESPONDENCE.**HONEY-PLANTS.****Insuring Bees—Honey-Plants of Minnesota.***Written for the American Bee Journal*

BY J. M. DOUDNA.

On page 8, Mr. A. C. Waldron asks if any one has had experience in insuring bees against fire while in the cellar. I have had mine so insured for some years in the Minnesota Farmers' Mutual, of Minneapolis.

Linden and White Clover.

Linden is our only dependence for surplus honey. It has never failed, to my knowledge, and there are not bees enough kept in this county to gather a hundredth part of it.

White clover is now to be found in many places, but we have no old pasture fields, as in the East. Some years ago I bought a few pounds of white clover seed, and scattered it in such places as it would be likely to grow. I did this for several years, and got a few pounds of clover honey in 1886. It did not yield any surplus in 1887, owing to the drouth, but I think we will soon get a good return for the money invested. I was not as successful with sweet clover, as it does not get started along the roads at all.

Various Honey-Plants.

Motherwort promises to be the best honey-plant of all. It commenced to bloom on June 12, 1887, and the bees worked on it until frost. The bees did not leave it for linden. I found a few plants two years ago, and saved the seed, and now have a half peck to sow in the spring.

For pollen I have never seen anything equal to asparagins. Does it yield any honey? Golden-rod has never amounted to much as a honey-plant here. The bees scarcely notice the plenrisky-root, though there is plenty of it.

I tried the spider-plant, but I could not get it to grow, except from plants raised in a hot-bed. The Simpson honey-plant (figwort) soon runs out. The Chapman honey-plant is not hardy in this climate; the first severe freeze killed every leaf, and the root appeared to be dead before the middle of November.

Moths and Italian Bees.

What has become of the bee-moth? I have not seen one for two years. There was plenty of them before I had the Italian bees. I have several hundred surplus combs, and I have never fumigated them, but hang them on

nails driven in the rafters in the shop; but not a moth has appeared for the last two years.

I made a solar wax-extractor that is as near perfection as I could wish. I made it from the directions given by Mr. Demaree, on page 501 of the AMERICAN BEE JOURNAL for 1886.

Good Location for Bee-Keeping.

The bees appear to be wintering very well with the mercury at 44° in the cellar. The thermometer showed only a variation of 3° in the cellar during the late blizzard.

To any one seeking a location for an apiary, I know of no better place than this county. Land is cheap and good, with plenty of raspberry and linden, and as soon as clover is well started, it will fill the time between them. Good returns are sure to follow good management. Some of the best towns in this region have scarcely a colony of bees in them. But this is no climate for "fence-corner bee-keepers."

Alexandria, Minn., Jan. 20, 1888.

CALIFORNIA.**Keeping Bees on the High Mountains.***Written for the American Bee Journal*

BY G. W. COVER.

After the advent of the honey-bee to this State, the absconding swarms went to the Sierras. In a few years they were gathering nectar from the flowers on every hillside, from the valley of dates, figs and oranges, to the snow-manteled summits of the Sierra Nevada; away among the lakes, at the extreme limits of the timber belt, and in the gorges and canyons, is the hum of the busy bee heard. The writer has frequently found them at work where one could stand with one foot in a snow bank, and the other in a bed of flowers, in August.

I commenced bee-keeping at an elevation of about 4,000 feet above sea-level. The bees swarmed and did well. The mountains was still higher on either side, as I was in the canyon of the Yuba. The honey-flow is later as one ascends. I thought that I would move up a thousand feet higher, so the bees could work down in the spring, and they would have 1,000 or 2,000 feet above them later on. The trouble is, I cannot get any swarms at this elevation, something over 5,000 feet. I have been here about five years, and have not had swarms enough to keep up my stock. Bees swarm more below me, at 3,000 feet, and under that they swarm to excess, and all absconding swarms invariably go for the higher mountains.

The honey crop failed here for the first time in 14 years; there were no swarms and no honey the past year. Let us hear what has been the experience of other bee-keepers in regard to elevation, and what effect it has had upon swarming. I have tried box-hives, and the bees would not swarm from them.

Downieville, Calif., Jan. 2, 1888.

BEE-KEEPING.**Report of the Work and the Results in the Apiary.***Written for the American Bee Journal*

BY J. M. YOUNG.

In looking over the pages of the AMERICAN BEE JOURNAL, I am glad to note quite an improvement in the paper since last year. It is undoubtedly the best work published on apiculture. Every bee-keeper should read it.

Bees throughout this portion of the State did fairly up to the close of the basswood bloom, however only a fair surplus was stored from that source. Since that time only enough was obtained by the bees to make a fair living for them. I fear that a large number of colonies will be lost in this county, from starvation, long before spring. Apiaries that were well cared for during the last summer, will come out all right.

My report for the season of 1887 is far from being a good one, and is not encouraging, by any means. From 76 colonies, spring count, upwards of 1,700 pounds of honey, including both comb and extracted, was obtained; only about 20 colonies were worked for extracted honey, with two sets of combs. The remainder of the apiary was worked for comb honey throughout.

I put into winter quarters 96 strong colonies, with plenty of honey to last them until honey comes again; 75 colonies were packed in a summer-and-winter chaff hive, with the upper story filled with dry leaves and chaff. A portion of the hives are now entirely covered with snow; the remainder of the hives are about half-covered. Just as long as it stays cold I have no fears about their wintering all right. I am not going to disturb them until the weather begins to get warmer, and the snow begins to melt.

One or two days the last week the mercury was as low as 25° below zero; the average temperature for the week being at zero. With this temperature of the weather very long, I presume that bees wintered in single-walled hives will suffer badly.

Rock Bluffs, Nebr., Jan. 18, 1888.

CANADA.

Annual Meeting of the Ontario Bee-Keepers' Association.

Written for the American Bee Journal
BY R. F. HOLTERMANN.

The Ontario Bee-Keepers' Association met at Woodstock, Ont., on Jan. 10, 1888, at 2 p.m., the President, Mr. S. T. Pettit, being in the chair.

Mr. Malcolm read an essay entitled,

The Production of Extracted Honey.

Next to the movable frame no invention has done so much to increase the production of honey as the extractor. When it was found that combs could be lifted from the hive, emptied of their contents, replaced, and refilled, a stimulus was given to bee-keeping that the most enthusiastic never dreamed of. But much of this enthusiasm was based on theory. How simple it looked. Bees are easily wintered, honey is easily gathered, and if we can empty the combs just when we please, what is to hinder any one from making money by keeping bees. But hundreds, and I may say thousands, have found theory and practice two very different things when applied to bee-keeping.

Still bee-keeping has a future, and men and women will succeed in gathering the sweets of nature in large quantities to the benefit of themselves and the good of the public, and from anything we can see at present, honey in the extracted form will take the lead as regards the quantity, by large proportions. It is therefore important that the producer should understand the means of securing his crop in the highest degree of perfection.

As far as quantity is concerned, I am at a loss to know what to advise, so much depends upon the conditions, especially as regards the strength of the colonies, favorable weather, and the amount of nectar. Many of the most experienced apiarists fail in regard to the first, and the last two are beyond human control. But with all these conditions favorable, we do claim to know something. In fact, I have said in conversations and through the press, that if there was any one thing I knew, if there was any one thing I could cordially recommend, if there was one item of advice I could give with pleasure, it is, *do not extract honey till it is ripe*. And yet, strange as it may seem, there are men who know much more about bees than I do, who say this is not necessary, that honey can be ripened after it is extracted. I cannot account for this except on the principle that some men lack the ability to judge both flavor and texture.

It is an admitted fact that some men are color blind, but that is no proof that there is not a great variety of colors. So it is in judging of the quality of honey. Every one must know for himself. Believing this to be a matter of great importance, and wishing to impress it upon the convention, I would say that bees do not gather honey, they gather nectar, and from nectar produce honey. It is therefore a process of manufacture, and if it is removed from the bees before that process is finished, man cannot finish it.

If asked what the bees do that man cannot, I say, I do not know. But I do know, and many others know, that there is a flavor and texture about honey that has been thoroughly capped that cannot be produced except by the bees. Why is it that comb honey is so much preferred to extracted? Do people give nearly double the price simply because it is a fancy article? No doubt this accounts for part of the difference, but the principal reason is, the honey is really finer than honey extracted before it was ripe.

I believe it is unwise to extract from the brood-nest and mix the honey with what is intended for market; with very few exceptions can this be done without injuring the flavor and color. I believe in and practice taking all surplus from a top super. What the best size is for combs in the super, I do not know, having only had experience with combs the same size as those in the brood-chambers. I believe that this is the best practice, as it has several advantages that I need not here mention.

I also believe in using a queen-excluding honey-board, for by having the queens below, a great deal of trouble is saved while extracting. When the queen leaves the brood-chamber, it soon becomes a house in ruins.

A difficulty arises sometimes during a heavy honey-flow, when everything is full, but none of it ripe enough to extract. In that case it is better to put on a second super, on the tiering-up system; that is, putting the empty one under the full one. The objection to this is, that it is expensive. I have tried with some degree of success to remedy the difficulty by only putting in one-half of the super combs, when the super was put on. The bees commence to fill those, and just when they are commencing to build new comb in the empty half of the super, I fill it with the remaining combs. Those that were first put in will be filled and capped much sooner than if all had been put in at once, and frequently they may be taken out and extracted a few days before the others are ready. This is a kind of make-shift. The best plan is a second super. F. MALCOLM.

In reply to a question, Mr. Malcolm stated that he used a perforated metal honey-board. He could not say what the comparative yield of comb and extracted honey would be. J. B. Aches, M. S. Shell, J. B. Hall and others sustained Mr. Malcolm in the statements of his essay, especially as to the necessity of having the honey sealed before extracting. Mr. A. Pickett said he thought that it could be taken from a part of the body of the hive by means of perforated metal. The convention, by a large majority, appeared to be in favor of Mr. Malcolm's method.

The Mayor of the city, at this stage of the proceedings, gave an address of welcome.

J. E. Frith, of Princeton, whose bees have the foul brood, on account of careless and inexperienced neighbors, thought that the extractor was often dangerous in the hands of the inexperienced. W. F. Clarke, of Guelph, condemned the honey-extractor, but the members present however objected to this, and thought if the extractor is rightly used, it is a great acquisition.

A discussion at this time took place on the advisability of men commencing bee-keeping without experience, and a resolution was read as follows:

Resolved, That whilst it is the inalienable right of every body to enter bee-keeping, the same as any other honest business, it is the sense of this convention that it is unwise to do so without adequate knowledge and due qualification.

A vote was taken upon the resolution, after an amendment was made, allowing the purchase of a colony or two, and to gain experience as one went along from papers, books, and bee-keepers; 5 voted for the amendment, 8 for the resolution, and a large number did not vote all.

A long discussion followed upon "Cellar wintering of bees." The temperature of J. B. Hall's cellar at present is 54°; of C. McNally's, 55°; of Jacob Alpaugh's, 50°; and Martin Emigh's, 50°.

As to the question of under-ground ventilators or by air-pipes, the majority were in favor of discarding them, among them being Messrs. J. B. Hall, Emigh, and Alpaugh.

EVENING SESSION.

Mr. J. B. Hall read an essay upon

The Production of Comb Honey.

I am requested to give an essay on the best method of producing comb honey. Allow me to state that any method is but of little value unless in conjunction with the following conditions:

1. Bee-pasturage in abundance, of not more than two miles radius of the apiary.

2. That the pasturage should not be overstocked, but rather that it should not have enough bees on it to gather all the honey-flow.

3. That there be in charge of the bees, an apiarist adapted by nature, assisted by study and practice, to manage the same (but the nature part I consider the most important).

4. It is essential that a hive with movable combs, having a large top surface, be used.

5. That the bee-keeper be a specialist, or as the phrase is, "have all the eggs in one basket;" in that case they can be jealously watched and guarded, and used to the best advantage; not so if the eggs are mixed in many baskets with other things.

If the colonies have passed the winter and spring well, and are strong in bees and brood at the commencement of the surplus honey-flow, a good crop of comb honey can be secured by putting on the hive a shallow super of sections primed with comb or foundation. (I say sections, because if not in nice sections it cannot be sold to advantage.) Open the entrance of the hive to its full size, and when work is well commenced in the super, raise it up and put an empty super between it and the hive; continue thus until your judgment or experience tells you that they have enough space to contain the surplus honey that will be secured.

Other things being right, you will rejoice in a good crop of comb honey.

J. B. HALL.

A discussion followed as to the use of "dummies," and the method was condemned, unless the colony was of no more value, and could be destroyed after the honey season.

There was quite a diversity of opinion as to the use of full combs, full sheets of comb foundation, or starters in the brood-chamber, when working for comb honey. The weight of evidence appeared to be rather in favor of full sheets of foundation, unless one did not care if drone-comb was built. The old comb some found to soil the sections. The nicest sections could be secured by using starters only.

Time of putting on supers: If full combs are used, supers could be put on at once; if full sheets of foundation, almost at once; if starters, after the queen had commenced to lay.

Mr. S. T. Pettit then delivered

The President's Annual Address.

In reviewing the events that have transpired, and the work that has been accomplished during my term of office, I would notice the following:

1. That we have secured incorporation for the Ontario Bee-Keepers' Association.

2. That we have secured a Provincial Government grant of \$500 per year.

3. We succeeded in making an exhibit of honey on a grand scale at the Colonial and Indian exhibition at South Kensington, London, England.

4. We have gotten the management and the price-lists of the apiarian department of the leading exhibitions of the Province, more or less under the control of one association, and although we cannot redress grievances of the past, it will be the aim and object of the association to prevent the recurrence of grievances in the future.

5. The foundation of an Association Library has been laid, the first book, of which was a present from our good friend, T. W. Cowan, F. G. S., F. R. M. S., etc.

6. We would not fail to notice the gratifying fact that our apiarian literature has been augmented by the publication of the *Canadian Honey Producer*, by our enterprising friends, E. L. Gould & Co., of Brantford.

7. And last but not least, the membership of our association has been largely increased.

And now, in order to make our association all the more useful, I would say, that whatever way the "grant" may be used, strict justice must be done to all parts of the province, and that the weak must be supported as well as the strong.

The appointing of judges and the necessity of placing the price-lists upon a somewhat different basis should be dealt with.

I will repeat my suggestion of last year, that reduced railway rates should be secured for honey. To avoid unfair rates in England, honey is sometimes shipped under the name of syrup.

Owing to ill-health and sickness of a severe nature in my family during the last session of the Parliament, I was unable to apply to the Legislature for legislation to prevent the spread of, and to stamp out foul brood in the country. Would it not be well for the prevention of the further spread of foul brood, to appoint competent judges—to examine and report upon the health of the bees of all those who advertise bees for sale? All who own bees for sale should be very careful not to sell diseased bees, nor should bees be sold and shipped out of a diseased locality.

Another dangerous source of spreading foul brood consists in selling honey from foul-broody apiaries. Empty containers are thrown out, and neighboring bees lick up the disease and carry it home. Imported bees should be examined at the port of entry.

The question arises: Why should the sale of diseased bees, or any other

article calculated to spread the disease, be tolerated any more than the sale of cholera pigs, or cattle afflicted with pleuro-pneumonia? Great care should be observed by those who visit apiaries afflicted with foul brood, to most thoroughly disinfect themselves and all their tools before going into the vicinity of other bees. I am sure that the principle is gaining ground, that the wealthy should not sit down by the side of, and starve out and destroy, a poor brother who has placed all his means, and perhaps more too, in bees and the necessary buildings and other appliances for keeping bees.

The principle, as claimed by some, is not a "new force," but is the same commendable, kind and brotherly spirit that moved Abram, when he said unto Lot, "Let there be no strife, I pray thee, between thee and me, and between my herdmen and thy herdmen; for we be brethren."

To advocate the principle of the "survival of the fittest" in bee-keeping, especially since there are lots of inviting unoccupied fields, is simply to encourage the strong to worry and devour his weaker brother. There is no "Do as you would wish to be done by" in it at all.

Whereas an outlet for our surplus honey, is a question of vast moment to every bee-keeper in Canada, I deem it my duty at this time to say a word upon that important subject.

It will be remembered that a year ago I spoke encouragingly of largely increasing the production of honey in Canada, but when all the facts now bearing upon the case are put together, and weighed and balanced up, they force upon my mind the opinion (and I want that opinion to go upon record) that the British markets are virtually lost to us at paying prices, or even at prices at which a man can make a decent living. I know this is a dark picture to present to your minds, and I am exceedingly pained to be obliged to hang up in this cheerful room one so very opposite from what I could wish to present to the view of this intelligent meeting; but there is no alternative; duty to you all, and to myself as well, imperatively demands that I deal faithfully in this matter.

The collecting of statistics relative to our pursuit should be considered.

And now, in conclusion, I would suggest that the conditions are ripe for devising a scheme whereby all county bee-keepers' associations in Ontario may be affiliated with the parent body.

S. T. PETTIT.

C. McNally gave his method of wintering, and described his cellar. It is made of stone, 20x37, and 9 feet high. There are four sub-earth ventilators,

and a stove-pipe connecting from the bottom of the cellar with the stove-pipe above, and a "cooler" pipe from direct outside. The temperature for the last four years has been 48° to 55°, and he has never yet lost a colony. Some members have damp, and others dry cellars, and are equally successful.

R. F. Holtermann reported that he was about to build a cellar under a dwelling-house. First, stone wall, then a one brick wall inside, allowing an air-space between the two. The ceiling would be tongue and groove boarded, with felt paper, and between this and the floor above have a packing of sawdust; a spring flows through the cellar to equalize the temperature, purify the atmosphere, and probably help to keep the atmosphere dry, as the moisture in the warmer atmosphere would condense upon the cooler spring water. The finest cellar he had ever seen was that of J. Alpaugh, and he had his thus, all but the spring.

R. McKnight gave a description of his cellar or repository, the general temperature of which was 49°, often as low as 44°, but seldom 50°.

THE SECOND DAY.

The morning session of the second day opened with President Pettit in the chair. An essay was then read, written by Mr. James Heddon, of Dowagiac, Mich. Mr. Heddon very ably pointed out how much there was of speculation as to what would overstock a locality with bees. From reports, however, one could see that where a few colonies were kept, a large yield could be secured. His essay closed with the following paragraph:

"I am again determined to add my mite to answering the question, by continually increasing the number of my colonies, until a term of seasons, whose natural advantages and disadvantages, all considered, shall tell me something of this obscure problem."

An essay was read from Dr. C. C. Miller, of Marengo, Ills., which may be found on page 26 of the AMERICAN BEE JOURNAL, in regard to specialists in bee-keeping.

By the reception which the Doctor's essay received, many members were evidently in favor of specialists.

Mr. R. McKnight then read an essay on "Our local honey market, and how to cultivate it." [This essay will be published as soon as we have room for it.—ED.]

The board of directors reported that all the members of last year should have a copy of the revised work of Rev. L. L. Langstroth, on "The Hive and the Honey-Bee."

The Secretary reported \$166.90.

The association adopted a new Constitution and By-Laws, by means of

which county associations can affiliate with the provincial. County associations are to pay \$5 per annum, and must have five members (members of the Ontario). This sum is more than returned by the share of the grant which they secure for competition in prizes at the county show.

The following officers were elected: President, M. Emigh, Holbrook; Vice-President, J. B. Hall, of Woodstock; Directors: F. K. Darling, Almonte; A. Pickett, Nassagaweya; Wm. Cowie, Streetsville; Allen Pringle, Shelby; E. Schultz, Muskoba; F. A. Gemmill, Stratford; F. Malcolm, Innerkip; and R. McKnight, Owen Sound. Auditors: F. H. Macpherson, of Beeton, and R. F. Holtermann, of Brantford.

The convention then adjourned to hold the next meeting at Owen Sound, Ont.

Brantford, Ont.

NEBRASKA.

Results of Keeping Bees for Eight Years.

Written for the American Bee Journal
BY WILLIAM STOLLEY.

While, with many bee-keepers, the season of 1887 has been a season of short crops, I cannot complain, and the following is my report:

After selling 5 colonies in the spring, I began the season with but 23 colonies, which were partly in extra good, and partly in but fair condition.

The amount of honey that I took was 2,078 pounds, or an average of 90½ pounds per colony, spring count. I had but 2 colonies for the production of comb honey, which gave a little over 50 pounds each, in one-pound sections.

I increased my apiary to only 31 colonies, which are all well supplied with winter stores (each having about 23 pounds), and I have about 300 pounds of honey in the comb, put aside for late spring stimulation.

My best colony produced 140 pounds of surplus (extracted) honey, while the year previous (1886) I obtained 210 pounds from my best colony. This success I owe principally to the sowing of sweet clover, while fields of Alfalfa clover within two miles of my little apiary have helped the bees materially. (Remember that central Nebraska is naturally not well adapted to the keeping of bees.) Ever since Dec. 9, 1887, my bees have been covered up to stay, and enjoy their winter rest, in a beehouse on the summer stand.

So far we have had a very cold winter. On Nov. 27 the mercury was 32° below, and this morning it was 27° below zero.

For eight years I have kept bees. I commenced with but 2 colonies of hybrids. Guided by the teachings of the AMERICAN BEE JOURNAL and standard works on apiculture, I proceeded cautiously, and the result is, that I have as fine an apiary as there is to be found anywhere. During the eight years I have paid out for bee-house lumber, implements, comb foundation, queens, etc., \$642.16. My cash receipts for honey and bees sold are, \$1,636.78. The value of my apiary to-day is \$640.50 (but I would not sell it at that figure); hence, a balance of \$1,635.12 is left to pay me for my labor.

Of course I do not depend upon my bees for a living; but they are a source of pleasure and recreation to me. I like them!

Bees must be attended to accurately and promptly, whenever they require attention. Persons who are negligent about them, have no business to keep bees. They will only find themselves "left" sooner or later, if they attempt it.

During the last week it has been extremely cold, so that we could not get nor dispatch any mail matter. It was 35° below zero at 9 o'clock this morning. It is now abating, but is still 15° below zero.

Grand Island, © Nebr., Jan. 15, 1888.

THE PAST SEASON.

The Honey Yield, Swarming and Wintering.

Written for the American Bee Journal
BY JNO. A. THORNTON.

The bees came out the past spring in excellent condition, and never were better ready to gather a large crop of honey. But the honey did not come. Soft maple first yields honey and pollen here; elm, hickory, hard maple, etc., furnish an abundance of pollen until fruit bloom is over; but the fruit, especially apples, had no bloom last spring, consequently there was no honey from that source. Notwithstanding the above draw-back, the bees continued to increase in numbers until their hives were very full of bees. Most of the colonies were preparing to swarm by May 10, and one colony cast a swarm on May 8, but it did nothing until June 5, when it gathered enough to build comb.

Several more colonies swarmed about this time, but those colonies that cast swarms did not gather any surplus. More than half of my bees did not build comb and store enough honey to last them until the fall yield came. From those that did not swarm, I secured enough surplus to make an

average of 10 pounds each from 140 colonies, or 1,400 pounds, about half comb and half extracted honey, of very fine quality.

The fall yield was quite good—very nearly as good as the four seasons previous had been. The colonies all gathered a good supply for winter use, and an average surplus of 10 or 11 pounds, so that I had nearly 3,000 pounds for sale, with 150 good colonies for the winter.

I am wintering 25 colonies in the cellar, and the balance out-of-doors; 50 of the latter are in Root chaff hives, and some are in Simplicity hives, confined on 7 to 8 frames, with two $\frac{1}{2}$ -inch division-boards, one on each side, and an upper story half full of new wheat chaff. The balance are in Langstroth hives, prepared below the same as those in Simplicity hives, with a 5-inch chaff cushion in the cap.

Last Wednesday the bees out-doors had a good flight, and seem to be in excellent condition.

Lima, Ills., Jan. 8, 1888.

SELLING HONEY.

Bees Drawing Out Foundation—Ignorant Bee-Keepers.

Written for the American Bee Journal
BY JOHN TURNBULL.

I have just had a peep into my beecave, and find the bees very quiet, with very few dead ones on the floor. The temperature is 40° above zero in the cave, and 26° below outside. On Nov. 13, 1887, I put in 5 rather weak nuclei and 55 good colonies with 20 to 50 pounds each of buckwheat honey, and honey from the fall flowers.

I started in the spring of 1887 with 48 colonies, increased them to 60, and took 700 pounds of honey in 1-pound and 1 $\frac{1}{2}$ -pound sections. White clover yielded but little, and basswood the same. There was much golden-rod, but the bees did not work on it. Where the chinch-bug killed the winter wheat, wild buckwheat came up thick, and yielded well, and the bees preferred it to tame buckwheat.

For some reason or other, the bees did not like to draw out the foundation. I gave them some sections filled with comb, and they bulged them out of all proportions, some being 4 or 4 $\frac{1}{2}$ inches wide. I will have to use separators.

I have nearly all of my honey yet. I went to La Crosse, Wis., early in the fall to try to make some sales, and they asked me what I wanted for my honey. I told them 15 cents per pound. They laughed at me, and said that they could get all they wanted at 8 cents, and fully as white honey as I ever saw;

but it is worth 12 $\frac{1}{2}$ to 15 cents, and at retail 18 to 20 cents. I will try to get the names of those bee-men that sell their honey so cheap. They ought to read the good old AMERICAN BEE JOURNAL.

I tried to find the commission man in La Crosse that a "Rip Van Winkle bee-keeper" sold his honey to, as mentioned on page 789 of the AMERICAN BEE JOURNAL for 1887; but I could not find him. I know a La Crosse bee-keeper that bought several hundred pounds of honey for 8 to 10 cents per pound, and sold it at retail for 15 cents per pound.

La Crescent, Minn., Jan. 16, 1888.

CAVE FOR BEES.

The Season of 1887—Wintering Bees in a Cave.

Written for the American Bee Journal
BY A. REUSCH.

The past season has been the poorest one for honey in this locality that I have experienced since I have been in the bee-business. I began with 72 colonies in the spring, and a part of those were light, yet during April and May I got them into good working condition, but when June came the drouth commenced, and from that time they gathered hardly enough to live on.

My increase was 13 colonies. I had to feed the bees for winter, and I did not get honey enough for use in my own family, besides spending five months' labor, and an outlay of \$65 in cash. I believe in giving correct reports, whether good or bad.

A Cave for Bees in Winter.

I have always wintered my bees in the cellar, and very successfully. In 1886 I built a cave by digging 3 $\frac{1}{2}$ feet deep into the ground, and 25x8 feet, with posts of 6 $\frac{1}{2}$ feet set around it, 2 feet apart, and on top 1 foot apart, and then I nailed boards on all around. I banked up the sides and sodded them; on top I put earth about 18 inches thick, and covered the same with long slough-grass. In the west end is a ventilator made of lumber 7 inches square inside; at the east is an underground ventilator made of 4-inch tiling, and 60 feet long; and it has two doors, outside and inside.

The temperature ranges from 40° to 44°. The total cost was about \$50. I have 56 colonies in the cave, and 29 in the cellar, and they have wintered well so far, very few bees dying. I owe many thanks to the AMERICAN BEE JOURNAL for much valuable information.

Chariton, ♀ Iowa, Jan. 23, 1888.

WINTERING BEES.

How the Bees are Prepared for the Winter.

Written for the American Bee Journal
BY P. J. BATES.

I commenced the season of 1887 with 18 fair colonies of bees, from which I had 2 natural swarms, obtained 100 pounds of honey in one-pound sections, and a glass case of 24 pounds of comb honey, which I took to the Fair last fall, and which was pronounced the best filled and best appearing case of honey ever shown in this locality. Of course it took the premium.

On Dec. 5, I put 17 colonies into a new cellar under the sitting-room, without any ventilation excepting the door, where I go in every day to notice the temperature, which ranges from 38° to 46°. When at 46°, I can hear a low, quiet hum; when at 38°, the bees, to all appearance, are perfectly quiet. There has not been a pint of dead bees on the floor. The cellar is quite dry.

The bees were left in the same condition as they were on the summer stands, each colony being weighed when put in. The 3 colonies left on the summer stands were average colonies, in single-walled hives, without any protection except a cushion of forest leaves about 4 inches thick over them; and with an upward ventilation at the back part of the hive, $\frac{1}{2}$ inch by 4 inches, as an experiment, to try to get rid of the dampness that comes from the breath or cluster of bees. When I put them on the summer stands I will report again.

White Hall, Ills., Jan. 21, 1888.

SEASON OF 1887.

The Drouth Causes a Dearth of Nectar.

Written for the American Bee Journal
BY B. D. SCOTT.

I commenced the season of 1887 with 30 colonies of bees in fair condition, and increased them to 60 colonies. I bought 2 colonies last fall, so I have 62 in the cellar, and they are wintering finely, with the temperature at 42°, while it is 10° above zero outside. We have had no zero weather in this locality this winter.

My bees produced about 1,000 pounds of extracted honey, and 200 pounds of comb in one-pound sections, the past season. The season was very poor on account of the drouth. Alsike yielded well for a short time, but seemed to ripen all at once.

Basswood blossomed very profusely, and yielded honey for a few days; but when it should have been at its best, in an ordinary season, it was gone, being dried to a crisp on the trees without forming seed-balls. One bee-keeper said that he saw bees on the ground trying to get honey from the blossoms that had pollen.

Buckwheat has been a failure in this locality for several years, and why it is I am unable to explain, as the crop of grain is generally fair. We have had two poor honey seasons in this locality, but I am getting ready for the expected "gush" the coming season.

Ovid Centre, © N. Y., Jan. 21, 1888.

SPECIALISTS.

Some Comparisons in Regard to Bee-Specialists.

Written for the American Bee Journal
BY WM. H. BALCH.

A specialist in bee-culture or honey-production is a man (whether he owns 5 or 1,000 colonies of bees) who keeps bees for their real profit in dollars and cents; who studies their nature and habits, so that the best methods of management in spring, summer and winter may be applied; who uses proper appliances at the proper time, that the best results may be attained; who keeps posted on the market, watching the present production as well as the amount of last year's crop on hand; who puts his honey in the best marketable shape possible, and who devotes the necessary time to accomplish the foregoing.

I am very sorry that I am not a specialist (and all who keep bees), although my first earthly possession, aside from a hand-sled, was a colony of bees. I have sold honey by the ton, and hundreds of colonies of bees and queens. Bee-keeping has been but a side-issue with me, so, as Dr. C. C. Miller terms it, I am on the "middle ground."

Can the specialist produce honey as cheaply as the "happy-go-lucky beemen?" Oh, no! not in this region of country. But they are the very men that govern our home and city markets. Many may be surprised at that, but I can prove it by a demonstration, viz: The Doctor says that the bees cost the happy-go-lucky man nothing, and no labor bestowed. Well, that is about the truth; yet I have known some, and there are plenty of bee-keepers all around me, whose apiaries run up to 100 colonies, and each has 1,000 or 1,500 pounds of honey to sell.

Look at the specialist: He has a winter repository, shop, honey-house,

hives, sections, and other necessary fixtures, worth from \$500 to \$1,000. This, in a few years, will decay; but our farms do not, with 100 colonies, and with the necessary land to be occupied worth \$1,000 more. Here we have \$2,000 invested in perishable property, except the land, which will have to be replaced once in thirty years, or repaired to that extent. The interest on \$2,000 for one year, at 6 per cent., is \$120; to which add the replacing of perishable fixtures once in thirty years, which is \$66.66 a year, making a yearly expense of nearly \$187.

Then add to the above, hives, sections, crates, foundation, glass, etc., with winter losses, a hard year's work, and with the anxiety in a poor season; and then compute what your honey has cost the past two years! Some have put it up to a dollar per pound.

Oran, © N. Y.

COLORADO.

Report of the Colorado State Convention.

Written for the American Bee Journal

The fifth annual meeting of the Colorado State Bee-Keepers' Association was held at Denver, Colo., on Jan. 19, 1888.

The usual discussions on the best methods of preventing bees from robbing, best method of wintering bees, foul brood, bee-diarrhea, etc., were indulged in. The honey product of Colorado was reported proportionately larger than that of any other State the past season. The industry of bee-keeping is in a thriving condition, and is developing rapidly.

The following officers were elected: President, E. Milleson, of Denver; Vice-President, Mrs. Levi Booth, of Denver; Secretary, J. M. Clark, of Denver; Treasurer, Mrs. R. H. Rhodes, of Arvada; and the Executive Committee composed of Wm. Davis and Mrs. Levi Booth. J. M. CLARK, Sec.

TRANSFERRING.

When to Transfer Bees—Fastening Foundation, etc.

Written for the American Bee Journal
- BY F. B. REYNOLDS.

1. When is the time to transfer bees in the spring, from one hive to another?
2. When is the best time to put on sections?

My bees had a flight on Jan. 14, except 7 colonies in chaff hives, such as G. M. Doolittle describes. I have 35

colonies, some in Langstroth and some in Quinby hives. My bees did not gather much honey this season. I obtained about 500 finished sections, and about the same of unfinished sections. I am making 30 new chaff hives. I line the hives for winter with buckwheat hulls, of which I can get about a bushel in a hive.

Fastening Foundation in Sections.

The way I fasten foundation in the sections is, to put a dish over a small lamp, and put in it a piece of wax; take a glazier's knife and dip it into the wax, cut the starter the size wanted, take it in the left hand, and run the knife along on the section, then double it up, and you have it fast.

3. We have very much sweet clover here, our river banks being covered with it, and also the creeks; but my bees do not seem to work on it much. There is an immense quantity of it.

Rosburg, © N. Y., Jan. 16, 1888.

[1. Transfer bees in the spring, when there is the least honey in the frames, and in the middle of a fine, warm day.

2. Put on the sections when the honey-flow begins.

3. Many kinds of bee-pasturage do fail to produce nectar in some seasons, when the atmosphere is unfavorable to the secretion of nectar. Sweet clover is no exception to this.—Ed.]

BEE-CELLAR.

Space for Each Colony in the Cellar—Temperature.

Written for the American Bee Journal
BY C. P. HEWETT.

After having a well regulated beecellar with ventilators that can be opened and closed at will, then comes the most important point, viz: the space that each colony should occupy. I find that 16 cubic feet, no more nor no less, should be given to produce good results.

If more space is given, the harder it will be to keep the temperature up; less than that, the harder it will be to keep it down.

Proper Temperature in Bee-Cellars

I winter my bees at a temperature of 42°, and through this cold weather I have been able to hold the temperature at that point. We have now had 14 days that the temperature was below zero. I have not seen this mentioned by any writers. I consider it one of the most important points in wintering bees.

If the apiarist does not let the temperature go below 40°, or above 44°, he will not have any bee-diarrhea to report; if the hives are properly ventilated, unless the cellar is too damp.

Kingston, Wis., Jan. 23, 1888.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*

Feb. 4.—Stark County, at Canton, Ohio.
Mark Thomson, Sec., Canton, O.

Apr. 24.—Des Moines County, at Burlington, Iowa.
John Nau, Sec., Middletown, Iowa.

May 5.—Susquehanna County, at New Milford, Pa.
H. M. Seeley, Sec., Harford, Pa.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

SELECTIONS FROM OUR LETTER BOX

First Snow-Fall, etc.—Mr. John Boerstler, Vashon, Wash. Ter., on Jan. 12, 1888, says:

The first snow fell to-day. The temperature was 9° above zero for 3 or 4 days; it was very cold here for a few days.

Honey Quotations, etc.—J. S. Catterson, Harvard, Neb., on Jan. 11, 1888, writes:

I started last spring with 2 colonies, secured one swarm, one absconded, and I took 100 pounds of comb honey. In conversation with a grocer a short time since, he said that he would pay "Chicago prices" for honey now, and on asking how much that was, he said, "From 5 to 7 cents per pound." Having just received the BEE JOURNAL from the post-office, I showed him where our style of honey (we have no white clover or basswood in this locality) was quoted at 17 and 18 cents. He realized that he was beaten, and proceeded to set forth the unreliability of "market reports." He affirmed that his price-list so reported it to him; but he did not exhibit the list.

Severe Winter—Poor Season.—H. L. Rouse, Ionia, Iowa, on Jan. 13, 1888, writes:

We are having a very severe winter, an unusual amount of snow having fallen already. Last night and this forenoon the wind blew a perfect gale from the northwest, while the thermometer marked 21° below zero this morning, and it kept at 18° below zero all day. It is 22° below this evening.

It does not get above zero very far nowadays.

I am wintering 100 colonies in chaff hives, and nearly one-half are completely buried in the snow. I commenced the season of 1887 with 90 colonies, intending to work them for extracted honey, but, alas! when fall came I had some experience but no honey, or just barely enough for winter stores. Therefore a big cipher would represent my income from the bees the past summer. My apiary is not the only one in this locality that has failed to reward the apiarist for his labors.

The AMERICAN BEE JOURNAL seems better than ever in its New Year's dress.

Cleansing Combs—Plants for Honey.—A. H. Dunlap, Aral, Kans., asks the following questions:

1. What can I do with combs full of bees, dead from starvation? 2. Will the bees take them out if put into other hives? 3. Name 6 or 8 of the best honey-plants, in the order of their excellence, and give a brief description of how and when to sow, plant and cultivate them. Such information would be worth a great deal to us who have a scarcity of natural honey-plants.

[1. Let the bees clean them out.

2. Yes.

3. Any of the books on apiculture will give you the information.—Ed.]

Results of the Season.—Thos. E. Turner, Sussex, Wis., on Jan. 16, 1888, writes:

My 86 colonies of bees are doing finely in the cellar, so far this winter. The trying part of cellar-wintering I always find to be the last part of February and March. I have realized about 20 cents per pound for most of my 1,500 pounds of comb honey, and 10 cents per pound for 430 pounds of extracted honey—the crop of 1887. I hope for a full crop this year, instead of but 35 pounds per colony, for 1887; but I did better than many others around me, as some have hardly enough to winter their bees.

Honey for the Liver.—W. H. Smith, Mount Salem, Ont., on Jan. 21, 1888, gives the following directions for taking honey as a remedy for liver trouble:

Since my letter on page 27 was published, I have received several inquiries as to the method of taking honey for the liver, as mentioned in my letter.

In order to expedite matters, I concluded to reply through the AMERICAN BEE JOURNAL, and at the same time give all inquirers the benefit of my reply. Here it is, as practiced by my wife, who is now a living epistle of the virtues of honey as a liver medicine:

Take of Alsike clover or basswood honey, as much as can be taken without causing too much nausea, say every two hours through the day, until a cure is effected.

Bee-Escape for the Extracting-Room.—Albert H. Lind, Calumet Harbor, Wis., on Jan. 15, 1888, says:

I commenced the season of 1887 with 4 colonies, increased them to 10 colonies, and took 143 pounds of extracted honey. As a general thing, the honey crop of this part of Wisconsin was a very poor one. My bees were put into winter quarters on Nov. 20, 1887, and seem to be doing nicely. The bee-room gets its ventilation through a chimney. Will some one please write an article for the AMERICAN BEE JOURNAL on how to make a bee-escape for my extracting-room?

Bees did Well in 1887.—W. A. Evans, Gober, Tex., on Jan. 16, 1888, writes:

Bees did well here in the season of 1887. I started with 31 colonies, increased them to 66 colonies, and obtained 5,000 pounds of extracted honey.

Insuring Bees in the Cellar.—J. F. Miller, Rodman, N. Y., on Jan. 23, 1888, says:

As Mr. A. C. Waldron wishes to know about insuring bees against loss by fire, I would say that I have mine insured in the Niagara County Company, of New York City, from Nov. 1 to May 1, while they are in the cellar.

Good Yield in Texas.—Fred F. Rockwell, Leonard, Tex., on Jan. 18, 1888, writes:

Our season the past year has been good, my crop of honey being about 2,200 pounds from 18 colonies, spring count. The colony having my best Italian queen produced nearly 300 pounds of extracted honey. In 1886, during the drouth, I averaged 80 pounds per colony, and, strange to say, I did not get any surplus from the same source that I did in 1887. My surplus the past season was from horse-mint, cotton and fall flowers. In 1886 the yield was from rattan, and a new (to me) flower, analyzed by a botanist as one of the "golden-rods."

BEE JOURNAL

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post office and get your mail at another, be sure to give the address that we have on our list.

Simmins' Non-Swarming System will be clubbed with the BEE JOURNAL for one year, both postpaid, for \$1.25.

Beeswax.—We will pay 20 cents per pound, delivered here, for Yellow Beeswax. To avoid mistakes, the name of the shipper should always be on each package.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Money Orders for \$5.00 and under, cost 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Sweet, or Melilot, Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 lb., \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Yucca Brushes are employed for removing bees from the combs. They are a soft, vegetable fiber, and do not irritate the bees. We can supply them at five cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please to get your Neighbor who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now SO CHEAP that no one can afford to do without it.

Honey and Beeswax Market.

CHICAGO.

HONEY.—We quote: White comb, 16@18c.; dark, 13@15c.; Extracted, 7@10c. Market dull, but more active demand looked for when weather moderates.
BEEWAX.—22@23c. R. A. BURNETT, Jan. 25. S. T. FISH & CO., 189 S. Water St.

CHICAGO.

HONEY.—Choice comb, 18c., with some fancy held a little higher. Extracted, 7@9c. Demand light.
BEEWAX.—22@23c. R. A. BURNETT, Jan. 21. 181 South Water St.

DETROIT.

HONEY.—Best white in 1-pound sections, 18@20c. Extracted, 9@10c. Demand brisk.
BEEWAX.—22@23c. Jan. 20. M. H. HUNT, Bell Branch, Mich.

CLEVELAND.

HONEY.—Best white 1-lb. sections sell at 19@20 cts. Extracted 7@8c. Demand small and supply fair
BEEWAX.—22@25c. Dec. 15 A. C. KENDEL, 115 Ontario St.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 16@19c.; the same in 2-lbs., 14@16c.; buckwheat 1-lb., 11@12c.; 2-lbs., 10@11c. Off grades 1@2c. per lb. less. White extracted, 8@9c. Market dull.

BEEWAX.—22@23c. MCCAUL & HILDRETH BROS., Jan. 20. 28 & 30 W. Broadway, near Duane St.

KANSAS CITY.

HONEY.—We quote: Choice white 1-lb., 18@20c.; dark, 16@18c.; choice white 2-lbs., 18c.; dark, 15 to 16c. Extracted, white, in 60-lb. tin cans, 9c.; in barrels, 8c.; dark, in barrels, 5@6c. California 2-lb. white comb, 18c.; dark, 16c. Extracted, white, in 60-lb. cans, 8@9c.; amber, 8c.
BEEWAX.—No. 1, 20c.; No. 2, 16@18c. Dec. 19. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.

HONEY.—Choice comb, 18@20c.; latter price for choice white clover in good condition. Strained, in barrels, 5@6c. Extra fancy, and of bright color and in No. 1 packages, ½-cent advance on above. Extracted, in bbls., 6½@7c.; in cans, 7 to 9 cents. Short crop indicates further advance in prices.
BEEWAX.—20c. for prime. Dec. 19. D. G. TUTT & CO., Commercial St.

CINCINNATI.

BEEWAX.—Demand is good—20@22c. per lb. for **HONEY.**—We quote extracted at 4@8c. per lb. Choice comb, 16@20c., in the jobbing way. Demand fair and supply good.
Dec. 19. C. F. MUTH & SON, Freeman & Central Av.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 17@19c.; fancy 2-lbs., 15@16c. Lower grades 1@2c. per lb. less. Buckwheat 1-lb., 11@12c.; 2-lbs., 10@11c. Extracted, white, 9@10c.; buckwheat, 6@7c. Demand has slackened some, and to make sales we must shade above prices. About Jan. 15 we expect a more active demand.
BEEWAX.—23@24c. Dec. 31. F. G. STROHMEYER & CO., 122 Water St.

PHILADELPHIA.

HONEY.—Fancy white 1-lb., 18@19c.; fair 1-lb 17c.; dark 1-lb. are slow sale at 14@15c.; fancy 2-lbs., white, 15@16c.; buckwheat fancy 1-lb., 13@14 cts.; common, 12c. Prices tend downward.
BEEWAX.—23@24c. Dec. 11. ARTHUR TODD, 2122 N. Front St.

MILWAUKEE.

HONEY.—Choice white 1-lb., 20c.; fair, 19@20c.; 2-lbs., 1@19c.; 3-lbs., 16@18c. White extracted in kegs or half-barrels, 9½@9¾c.; in pails or cans, 9½ to 10c.; amber, in ½-barrels, 9½@9¾c.; dark in kegs and barrels, 7@7½c. Demand good, supply fair.
BEEWAX.—22@25c. Dec. 15. A. V. BISHOP, 142 W. Water St.

SAN FRANCISCO.

HONEY.—We quote: White to extra, 13@18c.; amber, 12@16c. Extracted, white liquid, 7 @8c.; amber and candied, 6½@7c. Market quiet.
BEEWAX.—20@24c. Jan. 14. SCHACHT & LEMCKE, 122-124 Davis St.

BOSTON.

HONEY.—We quote: 1-lb. sections, 16@17c.; 2-lb. sections, 14@15c. Extracted, 8@9c. The market is not very brisk and sales are slow.
BEEWAX.—25 cts. per lb. Jan. 12. BLAKE & RIPLEY, 57 Chatham Street.

KANSAS CITY.

HONEY.—We quote: Choice white 2-lb. sections, 17@18c.; dark 2-lbs, 14@15c.; choice white 1-lb., 18 to 20 cts.; dark 1-lb., 15@16c. White extracted, 7@8c.; dark, 5@6c. Demand is light.
BEEWAX.—21 to 22c. Jan. 10. HAMBLIN & BEARSS, 514 Walnut St.

DENVER.

HONEY.—Best white 1-lb. sections, 13@20c.; 2-lb. sections, 16@18c. Extracted, finest grade, 12½c.; dark, 8@9c.
BEEWAX.—20@23c. Jan. 16. J. M. CLARK & CO., 1409 Fifteenth St.

SAN FRANCISCO.

HONEY.—We quote: White comb, 17@19c.; amber, 12½@15c. Light amber to white extracted, 7½@8c.; amber, dark and candied, 6½@7½c. Market firm and stocks light.
BEEWAX.—22@23c. Dec. 12. O. B. SMITH & CO., 423 Front St.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the *American Bee Journal* must be sent with each order for another paper or book:

	Price of both.	Club

THOMAS G. NEWMAN.
EDITOR.

Vol. XXIV. Feb. 8, 1888. No. 6.

EDITORIAL BUZZINGS.

An **Illustrated Article**, giving some historical facts about bee-feeders, may be expected in next week's issue. It covers a period of over 30 years, and shows the many progressive steps in that direction.

While the Northwest has been freezing, with the thermometer ranging at 50° to 60° below zero for several weeks—now, the reports are that it is from 50° to 60° above in Missouri, Nebraska, and Kansas, and that bees are sporting in the balmy air. Oh! how changeable!

Conventions.—This week we give up most of our space to the proceedings of three conventions. There are many good points brought out in them, and these reports will repay a careful perusal. Some of the essays will appear later, as we can find room for them. In next week's issue we shall give a report of the New York State Convention.

If the **Ground Hog** came out of his hole on Candlemas-day (Feb. 2) in this locality he could not have seen his "shadow," and therefore as that "saw" goes, he came out to stay, and we are to have an early spring. We are therefore to be saved from six weeks more of cold weather, which it is claimed would have ensued had the ground hog seen his shadow and gone back into his hole for 40 days.

The Bees are Wintering Well so far, but it is early yet to prognosticate with safety. One correspondent expresses himself in this cautious manner:

So far our bees are "wintering splendidly," but we must not anticipate the story that may be told next April.

Bees Wintering in Box-Hives.—

The question is often asked why bees in box-hives fare better in winter than those in frame hives. As a rule they do not fare better; there are some cases reported similar to the following, which comes from Mr. S. P. Stone, of Holly, Mich.:

In 1859, in a town adjoining, a swarm of bees was put into a hive, the inside measure of which is 16 inches square and 22 inches high. The entrance is 4 inches long and 1/2 an inch high. One-third from the bottom is four 1/4 inch holes, side by side; one-half way up, is one 1/2-inch hole, and in the top is a 2 inch auger hole, to admit the bees to a box for surplus. A board is laid over the hole when the box is off. It stands out-of-doors, without protection of any kind, has never been moved, has yearly cast from 2 to 5 swarms, and is in good condition; yet they are native black bees! Mr. Editor, can you tell us why they have thus lived and prospered, while others have perished?

Can we tell what caused the epizootic? Can we determine why yellow fever spreads over a Continent? Can we give the reason for the extreme prevalence of typhoid fever at the present time? These often take possession of a locality, or even a single family, and those on another street or other localities, are not affected by it!

Can we tell "why these bees have lived and prospered while many others have perished?" No. We can "guess" at it—but no one can "tell" with certainty.

A correspondent wrote us as follows some time ago:

One of our neighbors in the fall had 84 colonies of bees in box-hives; but all were dead in the spring but one, and that one was strong, and commenced to swarm early. In the next fall he had 33 colonies in box-hives, and again lost all but the same one, and that cast a large swarm in the following May. In the latter box hive the combs are

built from each corner to the centre, as shown in the engraving. I know of several instances very similar to the above.

Now, may not this instance serve to illustrate the matter, and help to solve the mystery? Perhaps the box-hive mentioned by Mr. Stone has combs built in a similar manner—fully protected from the winter's cold—thereby saving the lives of the bees during our long and tedious winters!

At least we shall guess that it has, and offer this as our answer to the question.

We are Sorry to learn that Mr. J. Vandervort, of Laceyville, Pa., inventor of foundation mills, has suffered loss by fire.

Where Shall it be?—Many are anxious to know where the next International Convention is to be held. Mr. R. R. Ryan, ex-President of the Nebraska Bee-Keepers' Association, writes thus about it:

I would like to have the National Convention held, if possible, at Columbus, Ohio. Then we could take in the "Centennial," the National Re-union of the G. A. R., and the Bee Keepers' Convention. If nothing happens lots of the "old boys" will be on hand. Rates will be low, the attendance large, and a grand good time may be expected in all the departments.

So far the votes have been about equally divided between Columbus and Cincinnati. Let the rest of the "votes" be sent in at once, so that the matter may be decided as soon as possible.

Live as Long as Sheep and Hens.—

As another example of the ignorant "scribbling" of those who write for the daily press, we may cite the following from the New York Ledger:

The scientific culture of bee-breeding and honey-making is leading to interesting discoveries with regard to honey-bees. According to the reports of experts, queen-bees live as long as sheep and hens, and have marked distinctions of disposition and character, which they so vigorously transmit to their offspring that the introduction of a new queen into a hive will change the character of the entire swarm in a few months. The queen lays all the eggs from which the bees in a hive are hatched, and they take their ruling qualities from her. Hence some swarms are industrious, while others are lazy; some are good-natured, while others are ill-tempered, and so on. As soon as it is found that a queen's progeny are of an undesirable kind, she is killed by the bee breeder, and another queen put in her place.

Just fancy a queen-bee living as long as a hen or sheep. It is now even questioned whether a queen should not be superseded after the first year of her existence!

Mr. F. A. Lockhart, of Lake George, N. Y., who sent the "item" from the Ledger, comments upon it in these words:

I have seen sheep 12 years old, and hens 14 years old. I never had a queen-bee that lived to be of that age. I do not know where the New York Ledger got its report of experts from. Perhaps where they live, sheep and hens do not live to be very old. I think the experts had better learn a little more about queen-bees, sheep and hens before they compare their ages.

Warm Weather is reported by several in the Northwest, but the following from Mr. John Blodget, of Flag Springs, Mo., written on Jan. 31, 1888, seems to carry off the palm, at 90° in the sun. He says:

Mybees had a fine flight on Jan. 29, 30, and 31. It is very warm; the mercury standing at 90° in the sun, and 50° in the shade. My bees are all alive and healthy. I never saw so few dead bees on the bottom of the hives. I could hold all of the dead bees in my hand. They speckled the snow a very little indeed for so long a confinement. I like the chaff packing very much.

New Subscribers can obtain the full numbers for 1887 and 1888, for \$1.75, while there are any sets of 1887 left.

GLEAMS OF NEWS.

Poisoning the Bees.—Under this heading, on page 803, of our issue for Dec. 21, 1887, we referred to a malicious article in the Atlantic, Iowa, *Messenger*, advising grape-growers to poison the bees in their localities.

It also asserted that "the grape-raising industry has been almost entirely killed out in Ohio, by this nuisance." This we stated was a malicious falsehood, and asserted that the author of it was either ludicrously ignorant, or a willfully malicious slanderer!

Mr. W. M. Bombarger, of Harlan, Iowa, a member of the Iowa Horticultural Society, and a fruit-grower, has written to the Iowa *Homestead*, of Des Moines, a further refutation, stating that the article in the *Messenger* should "receive the condemnation of the intelligent grape and fruit grower of the State which it misrepresents." Mr. Bombarger further says:

That the grape raising industry in Ohio has been killed out by honey-bees or apiarists following their harmless pursuit, I assert is false, whether the assertion be made maliciously or ignorantly, and is proven so by the report of the commissioner of agriculture for 1886, page 116, where, commenting on "The shrinkage of yield in Ohio," he reports as follows: "The shrinkage of grapes in 1881, 1883 and 1885 was due principally to three facts which cannot be separated—rot, mildew, and the effect of the previous severe winter."

On page 117, is a table showing the shrinkage to be from 27,503,000 pounds in 1882 to 9,043,216 pounds in 1885.

As to any such devastation to grape crops made by honey-bees in Illinois, I have not in my annual excursions through horticultural reports, newspapers or bee-papers got the least hint, but have found that grape crops have suffered there of late years from the same cause as in Ohio. I would like very much to have the *Messenger* send me some of these papers and names of parties sustaining the loss.

The third paragraph of the above reads very much to me as if the writer does not know what he is talking about. If bees could pierce the grape skin they would not leave it any more than a child would nine sticks of candy to spoil in a package after taking one from it.

Close observation and repeated experiments show us that bees do not puncture grapes, but help themselves only to such fruit as is burst by weather or over-ripeness or punctured by hornets, wasps, or torn open by poultry and birds. I think if the writer watches closely another season he will find that birds do the work, and after they mangle the bunches the bees suck out the juices from the broken husks which he can make no possible use of.

Since he speaks of rot, it may be *Phoma Wicola* or black-rot, as described on page 115 and 116 of the report above mentioned. It places our portion of the State in the black-rot district.

I regard the honey-bee as one of my very best friends in grape and small fruit culture, and keep a small apiary in my smaller vineyard, which is so located that the path of the bees in the air to their best pasturage during the blossoming season is over my larger vineyard.

I find the bees so valuable in fertilizing fruit bloom that I not only encourage my

neighbors to keep them, but intend doubling my stock in the near future. Their value is greatest whenever we have cool, wet weather during the fruit-bloom, and the winds cannot carry the pollen in dust form from flower to flower.

As to this writer's statement that grapes are worth more than bees, I disagree. I have harvested \$36 worth of honey from 2 colonies, and over \$20 from one colony of bees in one season, and left plenty of honey for wintering. I have generally found an off honey year a good grape year, and *vice versa*; and thick grape growing and bee-keeping can be worked profitably together. I harvested nearly 1,000 pounds from my apiary vineyard this year. I found bees on a few bunches that jays and thrush had mangled. One need not be stung by these if after cutting off bunches, and while holding the stem between the thumb and finger he carefully, with grape shears in his other hand, clips off mangled grapes and lets the same fall with the bees thereon upon the ground.

I have had much trouble with jays and brown-thrush destroying my grapes. But since they are so successful in the destruction of injurious insects, I think it inhuman to shoot them. There are many things that do so. I have found that the report of a gun will keep them away; and further, that fire crackers, that are less expensive, if properly used will answer the purpose. It is no trouble to hire small boys, and cheap, too, to walk up and down grape rows, loaded with fruit, and fire them off. If you repeat this several times a day it is all that is necessary. By careful observation of the habits of the birds you can soon tell how often to fire them off. A small patch of grapes near a house can be protected from birds by one's family by the same means. If you have children it will be their delight. And it is well for workmen and pickers in vineyards to carry them, and when they see a bird among the vines to fling and explode a fire cracker beneath it.

A cannon fire cracker exploded in the midst of a flock of jays does pretty effectual work. I would advise our friend above to have his family keep the birds away from his grapes, and not try to poison the bees, that want to take a little pay for pollenizing our flowers, in sipping up the sweet juices of mangled bunches that he can make no possible use of, and which are in that condition because he has not kept birds away from his vines. W. M. BOMBARGER.

Here is the testimony of a fruit-grower in the matter of the value of bees to grapes, which we commend to the careful perusal of all the enemies of bee-culture.

The Honey Market is thus described by R. A. Burnett, of Chicago:

Prices are lower than during November and December, and sales much lighter. It may be that the extreme cold weather of January has checked the demand, but the offerings are becoming heavier; and many commission houses, that during the fall months had no honey, now have several consignments which they are trying to dispose of on easy terms, if they find buyers.

Sorghum.—Now that sorghum is once more attracting the attention of farmers throughout the country, and has this time apparently come to stay, it is well to know that the *Sorghum Hand Book*, a valuable treatise on the cultivation and manufacture of sorghum, may be had free of charge on application to the Blymyer Iron Works Co., Cincinnati, Ohio.

Honey Trusts.—The daily papers are determined to have a "honey trust" somewhere. One day it is said to be formed in New York; then it is Chicago, which is to have it; then Boston. Each city paper palms it off on "the other fellow." The Boston *Record* of Jan. 17, gives this humorous and very unfair sketch of the "trust":

The New York bee-keepers propose to form a "trust," nominally to regulate the size of the comb to be produced, but really to control the market.

When this honey trust is formed there ought to be some way found to get it to boycott glucose, and allow the bees to feed upon clover and other wild flowers. Dame Nature formed a honey "trust" a great many years ago, and the modern bee-keeper has been industriously at work to nullify its main provisions. The honey of the markets to-day bears less resemblance to the white clover honey made by the few colonies of bees it was the fashion for every farmer to keep a half century ago, than oleomargarine does to the butter our mothers produced with the old "dash" churn. It used to be—

How doth the little busy bee
Improve each shining hour,
And gather honey all the day
From every opening flower.

Now, however, under the directions of bee-trusts, that little type of industry is gorged with glucose, and forced to produce an article whose chief resemblance to the rich and delicious comb taken from the stray hives of old is its form.

What a happy day it will be for America when it can be said that the atmosphere of this free and enlightened country is too rarified for trusts. Trusts are the glucose of business.

It would be a happy day for America if the unprincipled "scribblers for the press" found the air too rarified to permit their existence! In lying, and writing "scientific pleasantries," they seem to revel, no matter what pursuit is injured, or who may be ruined!

There is no truth in the "Honey Trust" matter, and *we trust* that these scribblers will now turn their villainous attention to something else. If they must write such stuff, give some other pursuit a twirl! and *Give us a Rest!*

Krainer Bees.—S. W. Morrison, M. D., Oxford, Pa., sends us the following "History of Krainer Bees in the United States:—"

I find that Carniolans were first known here as "Krainer bees," and that in 1879, a consignment of twelve queens labeled "Cyprians," reached A. J. King in New York, for some person with a German name in Iowa. These were not Cyprians, but Carniolans, as the shipper afterward confessed; the Iowa party probably thinks to this day he had Cyprians. I would like to have his name and address. Does any one know of an earlier importation of Krainer or Carniolan bees?

A Modern Bee-Farm, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

QUERIES AND REPLIES.

PROTECTING HIVES FROM HEAT, AND COOL NIGHTS.

Written for the American Bee Journal

Query 513.—Will an outer shell, or cap, to protect the section-case from the sun and cool nights, pay for the extra expense and labor, with a section-case made of $\frac{3}{8}$ -inch lumber?—New York.

Yes.—J. P. H. BROWN.

No.—A. B. MASON.

Yes.—M. MAHIN.

No.—EUGENE SECOR.

Yes.—J. M. HAMBAUGH.

No. I have used such thin cases, and the bees worked well in them; but perhaps the nights here are not as cool as in New York.—G. L. TINKER.

I think not. I consider it a waste of material to make them.—J. M. SHUCK.

I have never been able to discover any advantage in such a shell.—R. L. TAYLOR.

No. A case made of $\frac{3}{8}$ -inch lumber, and painted, is all that is necessary. Use shade-boards in hot weather.—C. H. DIBBERN.

For the purpose mentioned, no. But you will need a cap before it is desirable to put the case on, and frequently after it is taken off.—Mrs. L. HARRISON.

I think it might; but I prefer a super made of $\frac{3}{8}$ -inch lumber.—C. C. MILLER.

I think it will; at least it pays me in this locality to use an outer case to protect the sections.—H. D. CUTTING.

Yes; for you can use it for years, and it will be of advantage when the sections are taken away for feeding or for packing absorbents.—DADANT & SON.

I think it will pay well. I should prefer thicker lumber in the section-cases, if no outer case was to be used.—J. E. POND.

It might be an advantage in cool nights, but it would be no protection against the sun.—W. Z. HUTCHINSON.

I decidedly think not. Such an arrangement is in the way of a handy tiering-up system, and really does no good if it was free from other objections.—G. W. DEMAREE.

I doubt if it is of any use at all. I want no such cap. Just the section-case covered with a plain board.—A. J. COOK.

I should say not. I do not know just the climate of all parts of New

York, but in this locality, latitude 42° (no mountains), we use and prefer from $\frac{1}{2}$ to $\frac{3}{8}$ of an inch, and an outer cap is a positive injury, as we know from repeated experiments. A shade-board is always worth ten times its cost of construction and manipulation.—JAMES HEDDON.

I think so, but many do not seem to think that way. As I use wide frames, I consider a cap a necessity.—G. M. DOOLITTLE.

A plain board for shade against the rays of the sun would be preferable. It is very doubtful if the "shell" would pay for the cost.—THE EDITOR.

DIMENSIONS OF HIVE AND NUMBER OF FRAMES.

Written for the American Bee Journal

Query 514.—1. What number of square inches of comb-surface should there be in a hive? 2. What distance should brood-frames be from centre to centre, the end pieces being $\frac{3}{8}$ of an inch, and the top-bars 1 inch? 3. What are the inside dimensions of the frame you use? 4. What number of frames in each hive do you use?—Maryland.

1. That depends upon many circumstances. 2. One and $\frac{3}{8}$ inches.—W. Z. HUTCHINSON.

1. Not less than 2,500. 2. They will work well if but $1\frac{1}{4}$ inches. 3. Eight and $\frac{1}{2}$ by $16\frac{1}{4}$ inches. 4. Eight, but prefer ten.—A. B. MASON.

2. One and $\frac{1}{2}$ inches. 3. The standard Langstroth frame. 4. Eight for comb honey.—Mrs. L. HARRISON.

2. From $1\frac{3}{8}$ to $1\frac{1}{2}$ from centre to centre. 3. Nine by $13\frac{1}{2}$ inches. 4. Nine frames.—H. D. CUTTING.

1. From 1,500 to 1,800. 2. As near 17-16 inches as you can get them. 3. Inside, $16\frac{3}{4} \times 8\frac{3}{8}$ inches. 4. Eight to 12, depending.—J. P. H. BROWN.

1. A hive too large one season may be too small the next. 2. A little less than $1\frac{1}{2}$ inches. 3. Nine and $\frac{1}{2}$ by $11\frac{1}{4}$ inches. 4. Eleven usually; but I have hives as small as 7, and as large as 15.—M. MAHIN.

1. That will depend much upon the construction of the hive, and the manner in which it is to be used. 2. One and $\frac{3}{8}$ inches. 3. The brood-frame I shall use hereafter has about the same capacity as the Gallup frame, but it is not so deep. 4. Eight frames.—G. L. TINKER.

1. It depends upon circumstances, and what you are working for. 2. One and $\frac{1}{2}$ inches, or slightly less. 3. I use several sizes, but prefer the Langstroth frame. 4. For comb honey and cellar wintering, I prefer 8 frames, and often contract the latter to 6, when having prime swarms.—EUGENE SECOR.

1. From 2,880 to 3,000, if you measure both sides. We use still larger hives, and prefer them. 2. We prefer $1\frac{1}{2}$ inches. 3. Ten and $\frac{1}{4}$ by 18 inches, old Quinby style. 4. Nine frames and two division-boards.—DADANT & SON.

I use the 8-frame Langstroth, and the 12-frame Gallup hives. The distance from the centre may vary a little—about $1\frac{1}{2}$ inches. I use break-joint honey-boards. I have a few of the new Heddon hives.—A. J. COOK.

I use myself, and consider the ordinary Langstroth hive $14\frac{1}{2}$ inches wide, inside, and holding 10 frames evenly spaced. The inside dimensions of my frames are $8\frac{1}{2} \times 17$, outside $17\frac{3}{8} \times 9\frac{1}{4}$. The top-bar is $19\frac{1}{2}$ inches long outside.—J. E. POND.

1. A hive should be capable of holding from 8 to 10 square feet of comb. 2. One and $\frac{3}{8}$ inches, or a little less, without reference to the size of the top-bars and end pieces. 3. I use frames $17\frac{1}{2} \times 4\frac{3}{8}$ inches, inside, and others $16\frac{3}{4} \times 8\frac{1}{2}$ inside. 4. Sixteen of the former and 8 of the latter.—R. L. TAYLOR.

1. Perhaps from 10 to 16 square feet, varying at different times of the year. 2. One and $\frac{1}{4}$ to $1\frac{3}{8}$; no matter about the width of the top or end-bar. 3. About $17\frac{1}{2} \times 8\frac{3}{8}$ inches, but I should rather have the Standard Langstroth hive. 4. From 4 to 8, according to the time.—C. C. MILLER.

After long experience and many experiments, I have adopted a hive containing about 1,700 cubic inches, and think that about right for producing comb honey. 2. Frames should be $1\frac{3}{8}$ inches apart from centre to centre. 3. The inside, or comb measure of frames in my new hive, is 6×20 inches, and I use 10 frames to a hive.—C. H. DIBBERN.

1. I use a brood-chamber containing 1,500 cubic inches, or near that. 2. I use them $1\frac{1}{2}$ inches apart. 3. Ten and $\frac{3}{4}$ by $10\frac{3}{4}$ inches square. 4. Nine, except with new swarms; with these I use only from 5 to 6.—G. M. DOOLITTLE.

1. I use 10-frame Simplicity hives at my home apiary. Single body 2,600 cubic inches. In my apiary abroad, I use the 10-frame Quinby, *a la* Dadant, hives. Single body 3,600 cubic inches. 2. Frames spaced $1\frac{1}{2}$ inches from centre to centre. Inside dimensions of the Simplicity frame, $16\frac{3}{4} \times 8$ inches. Of the Quinby frame, $17\frac{1}{2} \times 10\frac{1}{2}$ inches. All of my frames are cut $\frac{1}{4}$ of an inch thick. In the Quinby, the dimensions are made for eleven frames, a division-board to occupy the space of one.—J. M. HAMBAUGH.

1. The Standard Langstroth frame contains 140 square inches of comb. Ten frames would give 1,400 square inches of comb. By employing divi-

sion-boards you can use from 1 to 10 frames in the hive to suit the size of the colony. 2. One and $\frac{3}{8}$ from centre to centre of the top-bars. 3. Frames are gauged from the outside, to make them uniform in size. I use the Standard Langstroth frame, which is $17\frac{3}{8} \times 9\frac{1}{2}$ inches, outside measurement. 4. Just as many frames as the size and strength of the colony demands; usually ten in the heated part of the season.—G. W. DEMAREE.

My frames are of the Langstroth size, and present about 288 square inches of comb surface each. Eight frames to the hive gives me 2,264 square inches. Before storage begins I slip in another frame, making about 2,500 square inches of comb surface. This extra frame increases the strength of the colony and lessens the empty space in the brood-chamber at the same time.—J. M. SHUCK.

1. We have used extensively and prefer a solid brood-chamber of the following capacity and shape: Ten inches deep, $11\frac{1}{2}$ inches wide, and $18\frac{1}{2}$ inches long, inside measurement. In this we use 8 Standard Langstroth combs in suspended frames. This size and shape is not always the best for all purposes, and at all times; but as a compromise for all purposes and all times, we would not change it in the least. In my patented divisible brood-chamber give new functions and results appear, and another capacity is preferable. We keep the length and width of the frames the same, and the combs the same distance from centre to centre. The combs are little longer, however, because the frames are tight-fitting in the cases. As the brood-chamber is horizontally divisible, and the halves practically interchangeable, there are two sets of 8 frames, each frame containing a comb 5 inches deep, and this brood-chamber is of the capacity of the 10-frame Langstroth hive, and from it we realize the advantages of both large and small, and shallow and deep brood-chambers. Now, our friend can make figures which will make my answer complete.—JAMES HEDDON.

1. The "times and seasons" control the amount of comb surface in a well regulated hive. 2. The space between the brood-frames should be a little less than $1\frac{1}{2}$ inches from centre to centre. 3. I have used several sizes and kinds, but prefer the Standard Langstroth hive. 4. It contains 10 frames, but their use depends upon many conditions and circumstances.—THE EDITOR.

Look Over last year's numbers of the BEE JOURNAL, and if any are missing, send for them at once, as we have but few left now, and they are daily becoming less.

BEE CONVENTIONS.

OHIO APIARISTS.

Fifth Annual Convention of the Ohio Bee-Keepers.

Written for the American Bee Journal
BY FRANK A. EATON.

The convention was held at Columbus, O., on Jan. 10 and 11, 1888, and opened at 9 a.m., President E. R. Root in the chair.

After the routine business of reading the report of the last meeting, and the reports of the officers, the first topic was announced for discussion, viz:

Bee-Conventions, How to Make them a Success, and their Value to Bee-Keepers.

A. I. Root—It pays to hold and attend conventions. It has been hard work to get me out. I owe a debt of gratitude to Prof. Cook and others, for getting me started; it does me good, and I am thankful that I have been induced to attend conventions. I learned of a new 5-cent comb-honey package at Manistee, by going to the Michigan convention, and getting out among folks last month. He spoke of the joint meeting of the horticulturists and bee-keepers of Michigan; of a two hours' address by a Professor—but when it came to the bee-keepers' time, they were up and alive, speaking briefly and to the point, and they had lots of intelligent fun.

Dr. Mason—It does not pay me in dollars and cents, for we can get the best thoughts and the valuable suggestions of our best men who attend the conventions, in the published reports of the meetings, but it pays socially.

Dr. Besse—It pays me by learning of new appliances, getting new ideas, mental culture, etc. I have got my pay already, and the convention has only just started.

H. R. Boardman—It pays the specialist financially, and always pays all socially.

N. Hutches—It has paid me well. I have kept bees 49 years, but I used to keep them in the old "box" and "gum" hives, but from attending conventions I have learned of bee-periodicals, and all that I know about keeping bees in the right way. I have 40 colonies in good condition; three years ago I cleared \$300.

Dr. Tinker—I feel that it pays, and that these gatherings are of value and interest to the bee-keeping fraternity.

The general impression was, that it paid to attend conventions, and that those depending upon the published reports lost a great deal.

Dr. G. L. Tinker, of New Philadelphia, O., then read the following essay:

The Sectional Brood-Chamber, and Its Advantages.

If it had been announced that I was to discuss the advantages of sectional hives, we should be dealing with a practical subject, one with which every bee-keeper in the land should be familiar. But the subject in hand is one in sore need of discussion, since, for some cause, very little has appeared in our bee-periodicals to enlighten us concerning it.

My first season's experience with sectional brood-chambers seemed very favorable. It happened to be an extraordinary season with us, and any hive with good management would have made a fair record. The past season was not a good one, and the defects of the new hive were apparent in many things. As compared with the Simplicity hives, of which I had seven in use, they were a marked failure. The bees in the Simplicity hives of my neighbors also did better. They not only had more bees all through the season, but had more surplus, and stored enough for winter, while the bees in the sectional brood-chambers had to be fed for winter.

I am reluctantly compelled to make this confession, partly because of my own disappointment in these hives, and partly because of the kindly feeling I entertained for the inventor.

I will give in detail my experience with the sectional brood-chamber, and my reasons for abandoning it. In the first place, the horizontal half of a brood-chamber is too small for a swarm, too small for a colony in the fall, and too small for wintering. It is too small for a swarm, since, with a queen-excluding honey-board, the bees will store much pollen in the surplus sections, and soon dwindle down to the size of a good nucleus. It is too small in the fall, since the bees are limited in space for stores and brood, and become too weak in numbers to winter to the best advantage. It is too small for wintering, since it will not contain sufficient stores to winter the colony and make a respectable start in brood-rearing in the spring.

Thus it will be seen that one of the cases of such a hive, by itself, is of no value in the hands of the practical honey-producer. It is required that both parts of the brood-chamber be used together to make any thing like a success of it. But if they are so used, the following difficulties arise: In the spring, the colony breeds up slowly, and without much attention will not get ready for the harvest. When at last it does get ready, if the honey-flow is extra good, the bees proceed to fill up the horizontal space

with brace-combs, and fill in with honey. The bee-keeper now thinks of interchanging the sections and bringing the brood to the top, but finds a strong lever is required to pry the hives apart. He quickly finds he can neither interchange the parts nor close the hives without killing hundreds of bees. They pile upon the broken surfaces, and a smoker is required in order to cut away the honey.

If robbers are troublesome, it becomes a serious matter, and the bee-keeper soon gives up the interchanging business as a bad job. It seems that bees do not build brace-combs to the same extent between whole brood-chambers, tiered one upon the other, as between these shallow cases. After all, there is no advantage from interchanging the sectional parts, since the bees will carry the brood upward and breed just as rapidly where no interchanging is done, as where it is. As the season advances, the bees put all the honey, or nearly all, in the upper case, so that the whole brood-chamber is required for winter.

The "shake-out" function is a good deal easier to talk about than to carry out in practice. With black bees and a little smoking it may be done, as it does not take much shaking to get them out. With Italians, Syrians and Cyprians, it is a very difficult matter, and the bee-keeper is easily persuaded not to try it again.

Finally, sectional brood-chambers are objectionable because of the extra expense of so much rigging for the amount of honey they contain, and there are no advantages to compensate for the extra cost.

The sectional, or storifying hive, will be the hive of the future. By this I do not mean a hive with a sectional brood-chamber, for one of the parts of such a hive is only half as large as the standard brood-chamber, whose capacity, as fixed by Fathers Langstroth and Quinby, is 2,000 cubic inches of space, which will contain, in suspended brood-frames, about 1,350 square inches of comb. I have already shown that the half of such a brood-chamber is too small to be of any practical use by itself. Nothing less than a capacity for 800 square inches of brood-comb is deserving the name of brood-chamber, and such a one may be successfully used. I mean instead, a hive made up of two, three, or more brood-chambers tiered one upon the other, or, as our English brethren term it, "storified." As this latter term is more elegant and expressive, I shall use it.

"Storifying hives" have many advantages over other kinds of hives. I have no doubt that the popularity of the Simplicity hives is due more to

this one feature than any other. We have had them in use in this country for many years, but it is only within the last few years that we have fully appreciated this admirable function. It is highly significant that our English friends are placing so much stress upon this point. Of late they have given no premiums to any but storifying hives.

In this connection I have but one suggestion to make, and I have done. It is, that, if the Simplicity hives were cut down to take a 7-inch brood-chamber, it would be nearly perfect as a storifying hive. It would then be just right for a swarm with a queen-excluding honey-board; it would be just right for wintering, and it could be "storified" at any time in the working season, to make a large hive according to the necessities of the bee-keeper.

DR. G. L. TINKER.

H. R. Boardman—I have made and used sections and supers 5 inches deep before I ever heard of such things.

A. I. Root spoke of queens laying in a circle, and thought that deeper frames like the Langstroth, were more desirable than sectional ones, on that account.

H. R. Boardman—I have known a cross-bar in the centre of a comb, to stop the queen from laying on the opposite side. I cannot look favorably upon the sectional hive; perhaps from prejudice, but I think not.

The Secretary—I used a sectional hive last season, but I find enough disadvantages to deter me from changing the present mode for it.

E. R. Root—What about the thumb-screws? Is there not a difficulty in the manipulation of frames?

Dr. Tinker—I find no trouble to manipulate Heddon's frames, after getting the first one out; but, frequently, that is quite difficult.

Dr. Mason—I do not think that the sectional brood-chamber is a practical success. I like to have my frames so that I can lift them out and look at them. What are the advantages of reversing?

Dr. Tinker—The only advantage of reversing, is to get the frames filled with comb; if not filled, queen-cells will be built at the bottom, during swarming time; but if filled, they will be built along the centre.

E. R. Root—I think it quite an advantage to have full frames of comb.

A. S. Goodrich—I have had experience with full frames; used wired frames, and let the foundation come to the bottom-bar.

H. R. Boardman—Comb fastened at the sides, is sufficient for extracting.

A. S. Goodrich—If three sides fastened, make the combs quite secure,

will not four sides fastened make them more so?

Dr. Tinker—I like to have the combs fastened to the bottom-bar nearly the whole length, leaving holes enough for the bees to crawl through.

G. R. Morris—When the foundation is fastened to the bottom-bar, the bees cut it out.

H. R. Boardman—I do not want combs fastened to the bottom-bar, as the combs will be sure to sag or bulge just above the bar. Reversing the brood-chamber is entirely impracticable. In reversing in hot weather the comb would be soft and drop over.

Dr. Tinker—I can reverse brood-chambers in April, and have the frames filled without danger of falling over.

Henry Bates—I want the combs down to the bottom-bars, and no wires.

Dr. Mason—Do you run for comb honey?

Henry Bates—Yes.

Dr. Mason—You have no experience then in handling combs?

Adjourned to 1:30 p.m.

The afternoon session was called to order by President Root, and the topic for discussion was.

Bee-Keeping in Connection with other Pursuits.

Frank A. Eaton led the discussion as follows:

Bee-keeping as a pursuit is of such magnitude, and requires so much attention and thought, that to couple it successfully with other avocations, requires rare business qualities and good judgment. The question as stated leaves it open, as to whether bee-keeping shall have the dignity of business, or be simply an adjunct, or a recreation. I take it that the question this convention chooses to consider is the keeping of bees in such numbers as to raise it above a mere play thing.

To keep bees at all, means time and work, and as the number of colonies increase, so must the other business be neglected, and those professions and callings which afford and give the most time and leisure are the best suited to go hand in hand with bee-keeping.

Perhaps the greatest and best idea of how bee-keeping can be carried on in connection with another pursuit would be to cite my own case. I manage from 75 to 150 colonies of bees each season; they require my entire time and attention from March until October. I prepare my hives, sections, and in fact make all preparations for the busy season during March and April, as I ship bees and queens, beginning by May 1.

I also run my apiary for both comb and extracted honey (principally

comb), and in that my time is most busily occupied until the first of October. Then I aim to get my honey nearly all marketed by the first or middle of November.

The bees have now occupied my entire time from 8 to 8½ months of the year, leaving from 3½ to 4 months that bee-keeping alone cannot fill.

Having been in the music business prior to my keeping bees, it gave me considerable experience in this line, so that at the close of the bee and honey season, I lay in a stock of pianos and organs, on consignment, for the holiday trade. I realize several hundred dollars each season from those odd months, and thereby fill in the year. The supply business goes well with bee-keeping at all times of the year.

Small fruit and market gardening are well suited to bee-keeping, but as the care of each come about the same time, help will be required. However, the benefit bees do to the fruit-bloom, in the way of fertilization, more than pays for any extra help needed.

Another pursuit that is generally conceded to go hand in hand with bee-keeping, is farming, but I am of the opinion that this is not true. I do not believe that any man can be a successful bee-keeper and farmer at the same time, as the requirements of each are numerous, and require the most care and attention at the same time. If one is cared for, the other is sure to be neglected.

Dr. Mason—When I farmed I made a success of both.

A. I. Root—It is not best to put all your eggs in one basket. I recollect how a man once wrote to me for prices of 40 colonies of bees. I advised him to buy only 2 or 3; and, better still, only a nucleus, and stick to his other business. He accepted the advice, and finally made a success of bee-keeping.

C. E. Jones—I cannot quit farming nor keeping bees; they go well together. I get everything ready for the bees in the winter. There is more profit in my bees than in my farm, but I want both.

A. S. Goodrich—I made a success of farming, but failed with bees, except to get honey enough for home use.

N. Hutches—I made a success with the bees on a 200-acre farm. I would rather be a bee-keeper than a United States Senator.

A. I. Root—If a man is enthusiastic enough, many can make a success of both.

A. Benedict—I have made a success of bee-keeping and general farming for 45 years.

Dr. Mason—I have a neighbor that has 100 colonies of bees and a good farm, and makes a financial success of both.

S. R. Morris—I started in keeping bees and farming, but made a failure of it until I had help; now I make a success of both.

S. Hains—I farm and keep from 50 to 100 colonies of bees. I want both. The best my bees have ever done was to give me 150 pounds of extracted honey per colony.

The next topic was entitled, "Bee-keeping as an exclusive pursuit," and an essay by Dr. C. C. Miller was read.

H. R. Boardman—If a man puts his whole soul into bee-keeping, he will succeed, but he must not divide his soul up into two pursuits.

Dr. Mason—I differ with Mr. Boardman.

H. R. Boardman—By putting my whole energy into my business the past year, I succeeded in getting a fair crop; had I done anything else in connection with bees, I would have failed.

A. I. Root—I believe that if a man has his bees in first-class condition, and makes an effort by sowing, he can get a good crop in any season.

Bee-Pasturage.

C. E. Jones—It will pay to keep 100 acres of land to farm, and 100 colonies of bees, and sow for honey production. I have sown two acres of sweet clover on good land and made it pay.

H. R. Boardman—I have been in the habit of furnishing my neighbors Alsike clover seed at cost. They make a success with it, as a grass crop. In this way I have succeeded in getting over 200 acres in my neighborhood.

S. R. Morris—I furnish Alsike in the same way.

A. S. Goodrich—I have the hay to sell to my neighbors when they get out, and they sow the seed.

Dr. Mason—I think the Chapman honey-plant is superior to any other, and will pay much better than sweet clover. The honey tastes and looks very much like linden.

A. I. Root—The Chapman honey-plant yields day and night, and is a pure sweet; but I doubt if it pays to sow 2 or 3 acres of good land with any plant that is good for honey only. I think, however, it would be a good plan to have the commissioner of agriculture distribute the seed among bee-keepers.

C. E. Jones—Buckwheat pays, but must be sown at the right time and in the right way.

On being questioned by Dr. Mason, he said, sow in April on good, well-prepared soil, and roll well. It blossoms with white clover, and does not injure clover honey. It gets ripe, and should be sown again about June 20. I get two crops of honey and seed on the same ground in one season.

Dr. Mason—Two years ago there was buckwheat near my apiary. The

bees mixed the buckwheat with my white honey, and spoiled the whole crop.

C. Culp—My father had his neighbors sow considerable buckwheat one season, and got a good yield; but the honey was dark and strong, and did not sell well.

The Election of Officers,

for the ensuing year, resulted as follows: President, Ernest R. Root; Vice-President, H. R. Boardman; Secretary and Treasurer, Frank A. Eaton.

On motion a cordial invitation was extended to the North American Bee-Keepers' Society to change the location of its next meeting to Columbus, Ohio, during the Ohio State Centennial Exposition between Sep. 4 and Oct. 19, 1888.

It was voted that when this Convention adjourns it shall be, to meet at the same time and place, and also with the next meeting of the N. A. B. K. Society.

EVENING SESSION.

Dr. H. Besse opened the next topic on "Wood vs. Tin Separators; is it profitable to dispense with either?"

A. I. Root—By fastening foundation at both top and bottom, you can dispense with separators.

H. R. Boardman—I tried some of the Heddon cases without separators and failed; then I tried broad frames, with separators, and succeeded. The loss of time in looking after the sections, without separators, amounts to more than the loss of honey with them. I prefer wooden ones. I leave my honey on until the flow is over. I very much favor saving and using the partly-filled sections of the previous year.

Dr. Tinker—I find that the bees will fill and finish partly-filled sections from the previous year. Separators are a hinderance to sections without side openings, but I want separators with side-opening sections.

Mr. Loomis, an editor, was present, and being called upon, gave a brief talk, and asked as a novice, "Must I try all these things and find out?" Several in reply said, No; consult good bee-keepers, and read bee-periodicals.

Question-Box.

1. Which of the following methods of working bees are the most profitable; selling queens, bees, or producing comb or extracted honey? A. I. Root—Whichever the market demands, or all four, if you have a demand. It would be impossible to decide definitely.

2. How can swarming be best controlled, when working for comb honey alone? H. R. Boardman—By shaking bees into empty brood-frames with sections.

3. Which is the best mode of ripening extracted honey; artificially or with the bees? Dr. Mason—Leave it with the bees.

4. How old may queens be kept and remain profitable? A. I. Root—Sometimes four years, but not often. A. Benedict—The more space the queen uses the shorter time she will live.

5. Is it best to assist the bees in cleaning up their hives in the spring, or should they be left to do their own work? Frank A. Eaton—Help them, if they need help.

6. Give a remedy for spring dwindling. H. R. Boardman—Winter properly.

7. Should colonies wintered in cellars be put back on the same location they occupied in the previous season? A. Benedict—Set them where they were the previous season. Dr. Besse—Set them anywhere, at night. H. R. Boardman—You cannot tell how the weather may be the following day. If set out at night it might prove disastrously. Dr. Mason—Set them out anywhere. A. S. Goodrich—Set them out where they were. I lost 30 colonies by setting them out in a haphazard way. S. R. Morris—Put them where they were.

8. Which is best, to hive new swarms on full frames of foundation, drawn out comb, or starters only? Dr. Mason—On starters, with surplus above, and a queen-excluding honey-board.

9. Can worker bees be reared in drone comb? A. I. Root—Yes, in some instances.

10. Has the queen full control of the fertilization of the egg? Dr. Tinker—Yes.

11. Is the progeny of a drone-laying queen of any value as drones? A. I. Root—Yes. Dr. Tinker—No. A. Benedict—No.

12. What should be done with colonies that get damp when wintered in the cellar? A. I. Root—Let them alone. Dr. Mason—Give warmth and ventilation.

A. S. Goodrich asked, what ails my bees? Half of them are dead, and the balance will die as soon as they get strength enough (laughter). I fed them up for winter on granulated sugar syrup, with a little tartaric acid in it. A. I. Root—What sort of vessel did you mix it in? A. S. Goodrich—Galvanized iron. A. I. Root—They were killed by poison from the action of the acid on the zinc. Adjourned.

WEDNESDAY MORNING SESSION.

The first topic was, "Extracted honey; its production, and the best method of marketing it," by Dr. A. B. Mason.

The Doctor having urged in his essay the putting of nothing but the best extracted honey on the market, A. I.

Root asked him what he would do with the bad honey? He replied, make it into vinegar.

H. R. Boardman—I started in with producing extracted honey, but had to conform to my trade.

E. R. Root—Can candied honey be melted and remain as good as before? Dr. Root—Yes; but great care must be exercised. Messrs. Boardman and Morris thought not, but Frank Eaton and others agreed with Dr. Mason.

An essay by Chas. F. Muth was then read on, "The commission man and his relation to the honey-producer, as affecting the sale and price of honey."

A. I. Root—We cannot spare the middle-man, especially such a broad-hearted man as C. F. Muth.

C. E. Jones—The middle-men are all right; the trouble lies with the producer.

The association passed a vote of thanks to Dr. C. C. Miller and Chas. F. Muth for the valuable papers they furnished in their absence.

WEDNESDAY AFTERNOON SESSION.

H. R. Boardman then read an essay on "In-door vs. out-door wintering of bees, and the advantage of the former."

S. R. Morris asked Mr. Boardman if it is advisable to set bees out during the winter for a flight?

H. R. Boardman—Sometimes, but the bee-keeper must be the judge.

S. R. Morris—Will they dwindle in the spring worse when wintered in the cellar? Mr. Boardman—Not as badly.

FRANK A. EATON, Sec.

[As the essays are lengthy, they will be published hereafter as our space will permit.—Ed.]

NEBRASKA.

Report of the Proceedings of the Nebraska Convention.

Written for the American Bee Journal
BY J. N. HEATER.

The bee-keepers of Nebraska assembled in annual convention Jan. 11 1888, at Lincoln, Nebr. The convention was called to order at 3 p.m. by the President, R. R. Ryan, who presided throughout the session with H. N. Patterson as Secretary. Mr. Emmerston T. Abbott, of St. Joe, Mo., was made an honorary member.

Messrs. Heater and Tower were appointed a committee to examine the reports of the Treasurer and Secretary, after which the President made an address upon the aims and needs of the bee-keepers of the State.

The election of officers was postponed until evening.

Messrs. Muir, Johnson and Heater were appointed a committee to consult with the State Horticultural Society to see if arrangements could be made for holding a joint session of a half day with that society.

The work of the meeting was then given up to asking and answering questions. Under this head the following questions were fully discussed: Is there such a thing as a high-bred bee? What is the best manner of uniting weak colonies for wintering? Do the moths ever trouble the Italian bees? Is there any rule or sign by which you can tell when bees are robbing each other? What is foul brood? How long will two queens work together in the same hive? After these discussions, the convention then adjourned until 7 p.m.

EVENING SESSION.

"What are the essential points in locating an apiary?" was discussed by J. S. Hodges and J. L. Blanchard.

The speakers favored a southeast slope located near or in a timber, with water near at hand, and plenty of honey resources in the flight of the bees.

This question was then opened to all for discussion, and a number of the members gave their experience and their preference of location. There was a diversity of opinion, some favoring the fronting of the hives to the east, and others to the south. The general opinion was, that an orchard with trees planted about 8 feet apart, and kept well cut back, was the best location.

E. Tower made a few remarks upon the question: "How much comb foundation, if any, should be used?" He said there was no question as to the benefit of the use of comb foundation. The principal question, and the one upon which there was the most division, was that of what quantity should be used. Mr. Tower thought that all beginners should use full sheets.

Mr. Trester said it was used by bee-keepers because it was cheaper than allowing the bees to make it. He was in favor of using all that could be put in the hives, as was also Mr. Heater, who recommended the use of heavy foundation, thus supplying the whole demand, and relieving the bees of all work in secreting this wax.

The committee appointed to confer with the Horticultural Society in relation to holding a joint meeting with the bee-keepers, reported that the Horticultural Society had gladly accepted the invitation, and would be present at the afternoon session to-morrow, to hear the paper of Prof. Bessey, on "Honey Plants."

Adjourned until 9 a.m.

SECOND DAY.

The convention was called to order at 9 a. m., and after the usual business, a communication was read upon a "National Organization," from John Aspinwall, Barrytown, N. Y.

"How does bee-keeping pay compared with other occupations?" was the subject of general discussion among the members. It was the general opinion that bee-culture could be made profitable if the proper means were adopted.

J. N. Heater read a communication from E. M. Hayhurst, of Kansas City, upon "Results of spring work with bees." This closed the morning session.

AFTERNOON SESSION.

A joint meeting of the bee-keepers and the Horticultural Society was held in the afternoon. Prof. Charles E. Bessey, Ph. D., professor of botany at the university of Nebraska, read an essay upon "Some honey-plants of Nebraska," in which he said:

If we carefully examine the structure of a nectar-bearing flower, we find invariably that the nectar glands have a definite position in relation to the organs of fertilization. While there is an almost infinite variety in the details, yet it may be stated in a general way that the nectar is always so placed that insects in gathering it are compelled to come in contact with one or more of the organs of fertilization. The nectar is the bait by means of which insects are made to visit the flowers, in order that the pollen may be carried from plant to plant. This is its only use, as has been abundantly proved by wide observation of many careful students of this department of nature.

Now, inasmuch as all flowers have to be fertilized, it might be assumed that all flowers must have nectar. Such, however, is by no means the case. If we examine carefully the flowers of plants, we find that a great many have the pollen carried from plant to plant by the wind. Such are said to be wind fertilizers, and observation has shown that in all instances they are destitute of nectar, or nearly so. Again, there are some plants which have such a structure that the pollen of its stamens comes easily into contact with their stigma, and thus fertilization is effected without the intervention of any outside agents. Such are called self-fertilized flowers, and here again the nectar is absent. Finally we have the plants whose numbers can only be expressed by tens of thousands, in which the structure is such that fertilization can only be secured by the intervention of insects, or in some cases of nectar-loving birds, as the humming birds.

In these plants which depend upon insects for carrying the pollen from flower to flower, it is found that some parts of the floral mechanism is peculiarly adapted for the purpose. Generally there are such structures as compel the insect to enter the flower in a particular way, and thus it touches the pollen-sacs with some part of its body, and carries some of the pollen to the next flower it visits. This it does while trying to secure the honey, and the contrivances to secure this result in different plants are among the most remarkable and interesting in the whole vegetable kingdom.

Rev. E. T. Abbott, of St. Joe, followed Prof. Bessey with a few practical remarks upon bee-culture and honey plants.

Mrs. Heater read a very concise and carefully-prepared essay on "How to prepare honey for display and the market," for which the association very gracefully passed resolutions of thanks. The fact was then brought out that Nebraska honey commanded 2 cents more per pound than honey produced in Iowa and other eastern States.

The question whether honey should be judged from appearance or taste, was discussed at some length, and was compromised by the decision that both appearance and taste should be taken into consideration.

"Fall Breeding" was the subject of a very interesting paper by Mr. Heater. The success of bee-culture depends largely upon the fall breeding. Mr. Heater advised feeding in the fall, but not later than the latter part of September. The young bees should have their cleansing flight before going into winter quarters.

This subject was discussed in its different phases, and the meeting adjourned until evening.

EVENING SESSION.

Only a few members braved the storm and attended the meeting. These did not lack enthusiasm, however, and entered heartily into the discussions. The questions which were brought forward were: "Can the swarming impulse be controlled; if so, how?" and "Which is best, to divide for increase or natural swarming?"

The following officers were elected for the ensuing two years: President, M. L. Trester; Vice-President, R. V. Muir; Secretary, J. N. Heater; Treasurer, T. Johnson.

THIRD DAY.

The closing session was mainly occupied by the reading of a very interesting essay by Rev. E. T. Abbott, of St. Joseph, Mo., on the "Honey Bee; its anatomy, the products of its operations, and its relations to flowers and plants." [This essay will be pub-

lished as soon as we can find room for it.—Ed.]

The committee on examination of the sample of honey brought in by a citizen of Lincoln, reported as follows:

"Your committee, to whom the jar of California honey put up by J. H. McDermott, of Chicago, was referred, pronounced it in their opinion impure and unfit for family use; and think that the man should meet with public condemnation for putting such an article on the market as honey."

The meeting then passed resolutions of thanks to its retiring officers, and to Mrs. J. N. Heater, Prof. Bessey, and Rev. E. T. Abbott, and extended to the latter a special invitation to meet with the society at their next annual convention.

Adjourned to meet at Lincoln in the second week in January, 1889.

J. N. HEATER, Sec.

VERMONT.

Convention held at Burlington, on Jan. 18 and 19, 1888.

Written for the American Bee Journal

BY MARCIA A. DOUGLAS.

According to programme, the convention was opened on Wednesday afternoon; the President, P. E. Abbey, in the chair.

After reading the minutes of the last annual meeting, the Constitution, etc., the convention listened to a poem entitled "Vermont Bees," by F. H. Wheatley, of St. Johnsbury, Vt., which was followed by a discussion, the general opinion being that there are two races of what are called "black bees."

One member related a visit to a neighbor's apiary who complained that a part of his bees were not good honey gatherers, but were lively and cross, making it difficult to manage them, while others in the same yard were of a more peaceable disposition, and better workers. On examination it was found that the former were small black bees, while the latter were the brown German bees.

Mr. A. E. Manum was asked what he thought of the Holy Land and Cyprian bees. He said he was favorably impressed with the Holy Land variety, but not with the Cyprians, because they are too cross.

One member stated that in one season his Italians produced 30 pounds per colony more than the blacks; and the stings were more numerous from black bees.

Mr. Manum was asked if he had Italians that would work on red clover. He replied that he had, and gave some proofs in his experience; he thought that they would not work as well in

some seasons as others. He was asked if he did not think that the tubes of the clover blossom was shorter in some seasons and localities than in others. He said the soil, atmosphere and other causes made a difference.

V. N. Forbes had known German bees working on red clover one season, but not in others, on the same field.

Spreading Brood in the Spring, etc.

Is it advisable to insert empty combs in the centre of a brood-nest for the purpose of spreading brood in the spring? This topic was opened by F. M. Wright. His experience had proved that if done at all, it must be done with great care. It might be advisable when the weather becomes warm, but he would "go slow." He inserted at one time two combs into a strong colony of bees, and it gave them a setback that they did not get over that summer.

Mr. Manum stated that he lets the brood-nest alone; keeps the brood-chamber contracted, and the bees warm. Sometimes he put a comb of honey next to the brood-nest on the outside. He was asked if he practiced feeding meal or salt to bees in the apiary, and replied he had done so in former years, but did not now, and could not say that it did any good.

Preventing Increase.

The following question was led by A. E. Manum, "What is the best method to prevent an increase of colonies?" He had not found it possible to prevent swarming by cutting out queen-cells; he could get more comb honey by allowing the bees to swarm; he then puts two or three swarms together, allowing all the queens but one to return to the old hive with a portion of the swarm. He has prevented increase by living swarms on a few combs, using a queen-excluding honey-board, giving plenty of box-room, and then destroying the old bees in the fall, as they would be likely to die before spring anyway. Another way is to take the queen from the colony, and return her after 15 days, cutting the queen-cells out in the meantime.

H. L. Leonard did not think it possible to prevent swarming, but it could be checked; he would give plenty of box-room, and practice the "tying up" plan; he would compel bees to care for themselves as much as possible, and would plan to save time as much as any other item.

EVENING SESSION.

The following committees were appointed by the chair: On Nomination—H. L. Leonard, O. J. Lowery, and V. N. Forbes. On Awards—J. W. Smith, P. D. Percival, and M. F. Cram.

On Resolutions—F. H. Wheatley, and Miss Marcia A. Douglas.

Bee-Keeping as a Business.

"Bee-Keeping in Vermont—does it pay?" This topic was opened by R. H. Holmes, who discussed the question under the following heads, as given by N. G. Webster, who was to lead the discussion, but was not present. Its hindrances are a poor location; our long, cold winters; and lack of a thorough knowledge of the business. A person must have good judgment, and plenty of common sense.

Its expenses and profits were set forth in an essay by J. H. Larrabee. He thought the expense of an apiary of 100 colonies of bees, with all the necessary fixtures and utensils for carrying it on successfully, with the addition of a \$200 honey-house, would be worth \$1,000. The average yearly expense he placed at \$620, which included labor, interest, running expenses, etc. The average yearly income was placed at \$800, leaving a net income of \$180 to represent the risks of wintering, disease, the shipping of honey, etc.

The question was closed by H. L. Leonard under the head of "Bee-keeping as a business." He thought nothing was worthy the name of business that would not pay expenses and leave a margin for profit. Bee-keeping would do this. It has its "off years," when it will not pay, like all other kinds of production; but no more so than others. There are but few locations in Vermont where bee-keeping cannot be made to pay to a greater or less extent. There are less enemies to bees than in almost any other section of our country, and the average yield per colony is larger. Bee-keeping in Vermont has paid and will pay, but it is essential that one understands the business and management of the apiary.

Mr. J. Van Deusen, of Sprout Brook, N. Y., said that the formation of the hills and valleys of our State was favorable for honey production, as we would be favored with early and late bloom of the honey-producing plants.

This discussion was followed by an essay by Mrs. F. A. Wolcott, entitled,

The Pleasures and Difficulties of Bee-Keeping.

She thought there was pleasure in seeing the clean, white sections of honey taken from the bees, by some one else, also in preparing it for market, but there were some things not so pleasant; and she related an instance of attempting to hive a refractory swarm, and receiving 33 stings as a reward for her labor. She also spoke of the expenses of the business keeping in advance of the profits for

the first few years, which have to be met first.

Miss Marcia A. Douglas read an essay on the question:

Should Women Keep Bees and Join the Bee-keepers' Association?

She could speak from experience, that while there was much hard labor in connection with the business, she saw no reason why a woman could not keep bees, to a greater or less extent, as successfully as the sterner sex, provided that she was adapted to the calling, and in love with it. If men were benefited by associations and interchanging of ideas and methods of work, why not women?

THURSDAY MORNING SESSION.

The Secretary's report showed the present membership to be 139; an increase of 30 since the last report. The Treasurer's report showed that the expenses of the past year has been \$33.12, and the receipts, including the amount in the treasury, \$24.02, leaving a deficiency of \$9.10, which was made up by contributions from those present.

It was voted by the members of the association that Art. 5 of the Constitution be amended to read as follows: "Any person may become a member of this association by giving his or her name to the Secretary, and paying annually to the Treasurer a sum not exceeding one dollar, except ladies who shall be admitted free." It was voted that the members be required to pay 50 cents each, to defray expenses for the coming year.

The following were appointed a committee to revise the present Constitution, and bring it before the consideration of the next annual session, P. C. Abbey, H. L. Leonard, R. H. Holmes, and Miss Marcia A. Douglas.

The committee on nominations reported as follows: For President, R. H. Holmes; Vice-Presidents, F. M. Wright, D. S. Hall, and J. E. Crane; Secretary and Treasurer, Miss Marcia A. Douglas. They were then elected as officers for the ensuing year.

The committee on awards reported the exhibits made, and the committee on resolutions presented several resolutions, which were passed. Then the newly elected officers assumed their respective positions, and the next topic was opened by F. H. McFarland, of St. Albans, on

Is it Profitable to Use Full Sheets of Foundation in the Brood-Chamber?

He said it is a waste of wax to use full sheets, although more honey may be secured by their use. In full sheets, the foundation is sure to sag and cause elongated cells near the top, which the queen is slow to occupy. Mr. Lowery advocated the use of starters. Mr. Leonard would use full sheets, even if

they were not wired. Mr. Percival uses full sheets in the middle of the brood-nest with starters on the frames at the sides.

In reply to this question, Mr Manum said if old combs and starters are placed alternately in the brood-box the combs will be bulged. He discouraged the general use of foundation, but thought that the specialist could not afford to do without it.

Mr. Davis, on account of expense, last year tested the use of starters, and being satisfied with the results, tried it again.

As to the width of the starters, some thought an inch better than three or four, while others preferred the latter width.

The Question Drawer.

1. What shall we do with unfinished sections at the close of the honey season? Mr. Manum advised to extract them or feed to the bees between fruit bloom and honey-flow. If candied, uncap and place them over the brood-nest, to be cleaned by the bees.

2. Is it advisable for bee-keepers to join the Bee-Keepers' Union? Mr. Manum said, yes, by all means. It is on the same principle as insurance on buildings.

3. Is it profitable to use a bee-tent to place over the hive during manipulation to prevent robbing? Mr. Leonard said yes.

4. Is comb honey injured by freezing; if so, in what respects? Mr. Manum said that the flavor is unchanged, but the caps are sometimes injured, and the combs cracked.

5. Are bees ever smothered from having the hives covered with snow? Mr. Manum answered no; the more snow the better. When a thaw comes clear the entrance. Dead bees should be removed, as sometimes they clog the entrances, thereby smothering the bees.

The discussion of "Marketing Honey" was participated in enthusiastically. Most of the reports were laughable as well as lamentable. The convention adjourned to meet at the time and place designated by the executive committee.

MARCIA A. DOUGLAS, Sec.

CONVENTION NOTICES.

☞ The Des Moines County Bee-Keepers' Association will hold its next meeting on April 24, 1888, at Burlington, Iowa. JOHN NAU, Sec.

☞ The Hardin County Bee-Keepers' Association will meet at the Court House in Eldora, Iowa, on the second Saturday in each month, at noon (12 o'clock), until further notice. J. W. BUCHANAN, Sec.

☞ The next regular meeting of the Susquehanna County Bee-Keepers' Association will be held at New Milford, Pa., on Saturday, May 5, 1888. H. M. SEELEY, Sec.

CONVENTION DIRECTORY.

1888. Time and Place of Meeting.

Apr. 24.—Des Moines County, at Burlington, Iowa. John Nau, Sec., Middletown, Iowa.

May 5.—Susquehanna County, at New Milford, Pa. H. M. Seeley, Sec., Harford, Pa.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

SELECTIONS FROM OUR LETTER BOX

Bees are Quiet, etc.—Geo. G. Scott, Wadena, ♂ Iowa, on Jan. 18, 1888, writes:

My 34 colonies of bees are wintering well in the cellar. Thus far they have been as quiet as I ever knew them to be. The temperature is from 38° to 48°. My surplus honey last season was about one-third of a crop, and I was pleased to get that much. Last Sunday the mercury was 44° below zero at sunrise, and again at midnight.

Sections and Separators.—Chas. W. Bradish, Glendale, N. Y., on Jan. 23, 1888, asks the following questions:

As I intend to change my surplus arrangement from two-pound to one-pound sections, and as I have never used any of the latter, I would like to ask: 1. What kind of one-pound sections is the best, all things considered? 2. What advantage are 4 bee-spaces? 3. If separators are used, what width is the best? My bees are now all in good condition. All are alive, and the temperature is from 35° to 40° in the cellar.

[1. The one-piece sections have entirely run all others out.

2. The general opinion expressed by the largest honey-producers at conventions and elsewhere, is that they are of but little if any advantage.

3. Two inches.—Ed.]

Extracts from a Diary.—James F. Johnson, Salem, ♀ Mo., on Jan 28, 1888, writes:

The New Year came in warm and cloudy. January 4 was warm and pleasant. The bees had a jubilee, the thermometer being 64° in the shade. The bees carried in water. On Jan. 12 the weather turned cold and stormy. On Jan. 14 we had a blizzard, which left several inches of sleet on the ground. On Jan. 25 the bees had a chance to fly; the sleet and ice melting fast, and the bees looked clean and

bright. On Jan. 28 the weather was still warm and pleasant, and the bees are beginning to prepare for spring.

In reply to L. G. Reed, on page 11, I extract the following from my notes on "Plants for Honey:" "As a substitute for white clover and basswood, —mustard and sunflower. The black walnut tree is also valuable."

Quite Warm.—S. J. Miller, Topeka, ♂ Kans., on Jan. 28, 1888, writes:

My bees had a fine flight to-day, it being 70° above zero, and it was uncomfortable in the house unless the windows were raised. I think our winter is broken.

More than Pleased.—F. M. Taintor, Coleraine, ♂ Mass., on Jan. 30, 1888, has this to say about the BEE JOURNAL:

I am more than pleased with the new appearance of the BEE JOURNAL. I thought it was perfection before, but now it comes in even a newer and neater appearance, and is a great honor to its publishers. I feel proud in showing it to friends, and at one dollar a year I do not see why every person, keeping even one colony, can afford not to have it.

Good Results.—F. H. Benton, Renovo, ♂ Pa., on Jan. 28, 1888, says:

I commenced the season with 10 colonies of bees; increased them to 13, and I got 500 pounds of comb honey, and 100 unfinished one-pound sections. I winter my bees on the summer stands; they each had from 40 to 60 pounds of stores to winter on.

Bees Uncasy in the Cellar.—Robert Cissnan, Hageman, ♂ Ind., on Jan. 31, 1888, writes:

I have kept bees in this locality for ten years. The season of 1887 was the poorest that I have experienced. From 115 colonies in fair condition in the spring, I have taken about 100 pounds of comb honey, and increased them to 140 colonies. I had to feed them 300 pounds of sugar for winter stores. They went into winter quarters in light condition. I will have to feed them in the spring. I have wintered my bees in the cellar for the last three seasons, with success. They are not wintering very well now; they are uneasy and crawl out of the hive in great numbers; bloating up as large as their skins will hold. I do not know the cause; it may be that I put too much tartaric acid in the sugar syrup. One-half of the bees in this locality,

kept by small bee-keepers, will starve to death before next spring. I will try to take good care of my bees, hoping that next season may be more favorable. The AMERICAN BEE JOURNAL is a welcome visitor. I have read it with interest for the last eight years, and I could not get along without its information.

[Most likely you mixed your syrup in a vessel made of galvanized iron, and the bees were poisoned from the action of the acid on the zinc.—ED.]

Got Good Prices for Honey.—

H. H. Rosebrock, Owatonna, ♀ Minn., on Feb. 1, 1888, writes :

My bees wintered well in 1886 and 1887. I put in the cellar 90 colonies in the fall of 1886, and took out 90 in the spring of 1887. No "spring dwindling;" prospects were never better, but the dry summer made my honey crop 1,000 pounds of extracted, and 1,000 pounds of comb honey. I have 105 colonies in the cellar now. The bees in my new Heddon hives were the first to swarm last spring, and I like them well for comb honey. I sell my honey at home mostly. The editor of the BEE JOURNAL has my thanks for assisting to get better prices for honey.

Bees and Red Clover.—B. F.

Fritz, Fulton, ♀ Mich., on Jan. 27, 1888, writes :

In the BEE JOURNAL of Nov. 17, 1886, page 731, Joseph Beath, of Corning, Iowa, says, if any one's bees worked on the first crop of red clover he would like to know it. Mine did last June, in large numbers. They were working there when we commenced haying, and were there a week later when we finished. It must have been heavily laden with nectar, as I observed a bee on a pale blossom. The bright sun shone on it, and I could see the tongue in the tube, and it did not go over half way to the bottom. My bees did fairly well last year. I have 12 colonies, all wintering well but two colonies.

Father Langstroth.—Mr. James

Heddon, Dowagiac, ♀ Mich., on Jan. 26, 1888, wrote as follows :

It was with much pleasure that I viewed our genial and genius-faced friend on page 53 of the AMERICAN BEE JOURNAL. It was pleasant to read Mr. Pond's sketch of his life-work, but one moral point, one which is of vast importance to our great benefactor, seems to have been over-looked, viz : Why

should one who did so much for his brothers, now have so little to show for it? What is the trouble? Has he been profligate, spending his money as a whirlwind spends the leaves of a forest, or did ingratitude rob him? Some of us have paid him \$10 each as a small reward for the great benefits we have received, but is it not a truth, and one that should never be left out, when his history is written, that through the action of a few designing men, that this great benefactor and good man was robbed of the due reward of his labors?

[It has been repeatedly stated, that he was defrauded.—ED.]

Support the Union.—F. A. Snell, Milledgeville, ♀ Ills., on Jan. 29, 1888, writes :

If necessary for the good of the Bee-Keepers' Union, call on me for a donation of \$1 towards the Defense Fund. The apathy of the bee-keepers is astounding. I should think that every bee-keeper in America would see the great importance of energetically supporting the Bee-Keepers' Union. The Union is supporting right and justice, in every sense of the word. It would be a power in the land supported to the extent that it should be. It has done much by the support of the noble little band of brothers of which it is composed. The Union, I think, should have at least 1,000 members.

Allow me to congratulate the publishers upon the very neat and tasty appearance of the AMERICAN BEE JOURNAL for 1888.

Zephyrs from the West.—F. P.

Stiles, Haverhill, ♂ Mass., on Jan. 28, 1888, writes :

I wish the fellow that works the bellows out your way would kindly point them in the opposite direction. By strict economy, with the aid of the proverbial "east wind diet" of New England, we have managed to live quite comfortably until recently. With the displacement of east wind by your western zephyr, and the necessity of hiring a boy to hold our hair on, the outlook is a disastrous spring dwindling, unless we can unite with some plumber.

Not Discouraged.—F. J. Sawin.

Monmouth, ♀ Ills., on Jan. 30, 1888, writes :

I had 70 colonies of bees, spring count, but I did not get a pound of honey nor a swarm. This was caused by drouth. I packed my bees on the summer stands; they had honey

enough for winter stores, and I thought they would winter well. I examined them to-day, and I find that they have the diarrhea. I expect to lose all of them; but will stock up in the spring, if there are bees enough left in Warren county. I am not discouraged, for we must expect reverses in any business.

The good old AMERICAN BEE JOURNAL in January improved so that I hardly recognized it, when it came on its friendly visit. I could not keep bees without it, and do not see how any one else can.

Wishing that the Bees were in a Cellar or Cave.—M. Miller,

Le Claire, ♂ Iowa, on Jan. 27, 1888, writes :

It has been one month and two days since the bees in this country have had a flight. It has been quite cold most of the time. We had a thaw for two days last week, but there was no sunshine; consequently the bees did not have a flight. Lots of bees went into winter quarters short of stores; consequently there will likely be considerable loss, especially if this cold weather continues long. I wish I had mine in a good cave or cellar. They are packed on the summer stands.

Right Temperature for Bees.

—W. B. Stephens, Stephen's Mills, ♀ N. Y., on Jan. 24, 1888, says :

I commenced the season of 1887 with 157 colonies of bees, and increased them, by natural swarming, to 230 colonies. They stored 6,000 pounds of honey in one-pound sections, and 2,000 pounds of extracted honey. I have 146 colonies packed with chaff, and 84 colonies in the cellar, all being in good condition. The bees in the cellar are the most quiet with the temperature at 40°. I have had it above and below that point, but 40° seems to be about right.

Bees Wintering Satisfactorily.

—W. Mason, Fillmore, ♀ Ind., on Jan. 25, 1888, writes :

The bees are so far wintering well, notwithstanding a heavy crop of honeydew was stored, but it was of superior quality. Reports from all parts of the State at our convention was satisfactory. The attendance was not as large as common, but the meeting was interesting. We were honored with the Agricultural Room in the new State House. After the adjournment we were shown through the basement of the building, where we obtained much information.

Newaygo Co., Mich., Convention.

The Newaygo County Farmers' and Bee-Keepers' Association will hold their annual institute at the Congregational Church, Fremont, on Thursday and Friday, Feb. 9 and 10, 1888.

Programme Thursday, Feb. 9, morning session, 9 o'clock sharp—Music by the Fremont Glee Club. Prayer by Rev. J. Roberts. Music by the Glee Club. President J. B. Jewell's annual address. Address of Welcome, by Joseph Gerber, President of the F. B. M. A. Sheep Husbandry, Mrs. P. W. Hall. Corn is King, Thos. Stuart.

Afternoon Session, Thursday, 2 p.m.—The Roman Standard of Agriculture, M. W. Scott. Under Draining, Wilkes Stuart. The Most Profitable Breed of Horses for the Farm, S. V. Walker. The Farm Boys of Michigan, Mrs. M. W. Scott.

Morning Session, Friday, Feb. 10.—Music by the Glee Club. Prayer by Elder Gardner. Music by the Glee Club. The Relative Benefits of a Creamery to the Village and Country, J. R. Dudley. Practical Bee-Keeping, W. E. Gould. Secretary's Report.

Afternoon Session, Friday, 2 p.m.—Election of officers. The Best Orchard Fruits for Western Michigan, Irwin C. Fox. The Relative Benefits of Apiculture, Horticulture and Agriculture, Geo. E. Hilton. Selection of time and place for the next meeting. Adjournment.

Geo. E. HILTON, Sec.

One of our Correspondents asks this question :

What proportion of first swarms, placed in a single section of a Heddon hive, will re-swarm, if a queen-excluding honey-board and plenty of crates for surplus comb-honey is furnished to the colony?—E. D. K.

By request, Mr. Heddon answers the question thus :

With my experience during the past four summers, I reply—no greater proportion than with any other hive, whether controlled or not. The contracting system which reduced the brood-chambers of the Langstroth hives and others down to the size of one case of our divisible brood-chamber, was practiced years before the new hive and system was dreamed of, and no trouble from re-swarming was reported. Some seasons swarms of that year re-swarm to some considerable extent, but they do it alike from all kinds of hives. At least this has been my experience.

New Catalogues for 1888 are on our desk, from the following persons:

B. J. Miller & Co., Nappanee, Ind.—20 pages—Bee-Supplies.

James J. H. Gregory, Marblehead, Mass.—56 pages—Vegetable, Flower, and Grain Seeds.

John Nebel & Son, High Hill, Mo.—10 pages—Bees, Queens, and Bee-Keepers' Supplies.

E. Kretchmer, Coburg, Iowa—30 pages—Bee-Keepers' Supplies.

Northrup, Braslan & Goodwin, Minneapolis, Minn.—50 pages—Farm, Vegetable and Flower Seeds.

J. D. Goodrich, East Hardwick, Vt.—12 pages—Hives and Bee-Supplies.

E. M. Bullard, West Swanzey, N. H.—12 pages—Poultry and Flower Seeds.

Please to get your Neighbor who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now SO CHEAP that no one can afford to do without it.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

Simmins' Non-Swarming System will be clubbed with the BEE JOURNAL for one year, both postpaid, for \$1.25.

Beeswax.—We will pay 20 cents per pound, delivered here, for Yellow Beeswax. To avoid mistakes, the name of the shipper should always be on each package.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Money Orders for \$5.00 and under, cost 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them.

Clover Seeds.—We are selling Alsike Clover Seed at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. White Clover Seed: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. Sweet, or Melilot, Clover Seed: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tittle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

We Club the American Bee Journal for a year, with any of the following papers or books, at the prices quoted in the LAST column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	Club
The American Bee Journal	1 00	1 00
and Gleanings in Bee-Culture	2 00	1 75
Bee-Keepers' Magazine	1 50	1 40
Bee-Keepers' Guide	1 50	1 40
Bee-Keepers' Review	1 50	1 40
The Apiculturist	2 00	1 80
Canadian Bee Journal	2 00	1 80
Canadian Honey Producer	1 40	1 30
The 8 above-named papers	5 90	5 00

and Cook's Manual	2 25	2 00
Bees and Honey (Newman)	2 00	1 75
Binder for Am. Bee Journal	1 60	1 50
Dzierzon's Bee-Book (cloth)	3 00	2 00
Root's A B C of Bee-Culture	2 25	2 10
Farmer's Account Book	4 00	2 20
Simmins' Non-Swarming	1 50	1 25
Western World Guide	1 50	1 30
Heddon's book, "Success,"	1 50	1 40
A Year Among the Bees	1 75	1 50
Convention Hand-Book	1 50	1 30
Weekly Inter-Ocean	2 00	1 75

Cabbage and Celery	1 25	1 15
How to Propagate Fruit	1 50	1 25
History of National Society	1 50	1 25

Every Subscriber is our authorized agent; we have no others, and we greatly desire that each one would at least send in the name of one new subscriber with his own renewal for 1888. The next few weeks is the time to do this. We hope that every subscriber will do his or her best to double our list of subscribers.

This is the Time for reading. The long winter evenings can be utilized by reading up bee-literature. We have all the newest bee-books, and can fill all orders on the day they are received.

We Club the AMERICAN BEE JOURNAL and the "Bee-Keepers' Magazine" for one year for \$1.40; or with "Gleanings in Bee-Culture" for \$1.75; or with the "Apiculturist" for \$1.80; or the "Canadian Honey-Producer" for \$1.30; with the Bee-Keepers' Review, \$1.40; or all six for \$4.00.

One Dollar invested for the weekly visits of the AMERICAN BEE JOURNAL for 1888, will repay every apiarist in America.

Should Any One receive this paper any longer than it is desired, or is willing to pay for it, please send us a postal card, asking to have it stopped. Be sure to write your name and address plainly. Look at your wrapper-label.

A Favorable Word from any of our readers, who speak from experience, has more weight with friends than anything we might say. Every one of our readers can lend us a helping hand, in this way, without much trouble, and at the same time help to scatter apicultural knowledge and promote the welfare of our pursuit.

A Pocket Dictionary will be presented for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. Feb. 15, 1888. No. 7.

EDITORIAL BUZZINGS.

How dear to my heart is the fierce howling blizzard,
Which comes from the North like a wolf on the fold.
Predicted by Foster, or some other wizard,
The charger of snow, and the demon of cold ;
How sweet to be caught in its grasp like a feather,
And find yourself wrapped round a telegraph pole ;
O, how we adore it, this wild winter weather ;
The blizzard that comes when we're all out of coal ;
This wild, whirling blizzard, the razor-edged blizzard,
The loud, howling blizzard, fresh from the North
pole. —Lincoln Journal.

That is poetic—but the blizzards very soon
drive away all poetry, when they take full
possession of a locality.

Mr. Richard Grinsell, of Baden,
Mo., well-known to many who attend Fairs
in Iowa, Nebraska, Kansas and Missouri as
an exhibitor of bees and honey, is dead.
He was an intelligent and progressive
apiarist.

“Perhaps the Clearest and best
idea.”—That is how the first line of the last
paragraph but one on page 87 should have
read. It was an oversight of the printer.

The Penn. Farmers' Institute
is now in session at Oxford, Penn. To-
morrow morning S. W. Morrison, M. D.,
gives an address before it on “Bee-Culture.”
The Doctor will, no doubt, give them an
enthusiastic talk—for it may be truthfully
said that “every bee-keeper is an enthu-
siast.”

Home Markets for honey can be
made by judiciously distributing the
pamphlets, “Honey as Food and Medicine.”
Such will create a demand in any locality at
remunerative prices. See list on the second
page of this paper.

Birds and Fruit.—Mr. W. M. Bom-
berger, of Harlan, Iowa, whose article on
“Poisoning the Bees” was on page 84 of
last week's issue, writes as follows concern-
ing the birds who injure the fruit in this
locality :

We are in a prairie country. Our planted
groves, near which vineyards and small
grape patches of farmers and others are
situated, being the nesting place and natu-
ral *habitat* of birds, literally swarm with
the feathered tribe in summer, when the
open stretch of prairie country afford them
an excellent feeding ground. An open
prairie country under high cultivation is put
to a great disadvantage by injurious insects
that at times destroy whole crops. Timber
planting and a greater annual advent of
birds will help cure the evil. Since they
have a good living, a surfeit of insect food,
it seems to create in them a voracious ap-
petite for fruit, especially grapes, as a surfeit
of meat in man does an appetite for the
same.

The “birds” are the destroyers—not *the
bees!* The farmers should be correctly
informed concerning their friends and
enemies. Then the bees will be found to
be their greatest benefactors—fructifying
the bloom, and causing their trees to bear
fruit abundantly.

Cork for Winter Packing.—J. H.
Howe, Mansfield, Mass., on Feb. 5, 1888,
asks about “cork” for packing :

My bees had a good flight to-day, the
thermometer indicating 52° on the north
side of my house. I also examined one
colony, and found the bees in good condi-
tion. We have had three weeks of very
cold weather. It was 20° below zero on one
morning, but not much snow. Is ground
cork good for packing chaff hives for win-
tering bees?

Yes ; “cork” has been used for winter
packing for bees. Imported white grapes
are often packed in ground cork, and it can
be obtained from fruit-stores very cheaply.
Its advantages are that it never becomes
musty, and it is *odorless*. Cushions can be
made of cloth and filled with the cork, for
winter packing.

We are Sorry to announce that Mr.
W. Z. Hutchinson and his little daughter
have been laid up with bilious fever. A
letter from Mrs. Hutchinson last week in-
forms us that both are improving, but, as
the result of this indisposition, the *Review*
for February will be a little late.

Honey-Dew in February.—Mr.
George E. Hilton, of Fremont, Mich., on
Feb. 8, 1888, thus describes the honey-dew
he has seen on the ivy :

I have just discovered that our English
ivy is infested with aphides, and the leaves
are sticky with the spray they have thrown
off. In one place I found a large one and a
ball of the stuff attached to it, half as large
as a kernel of wheat, granulated, and as
light-colored as clover honey.

Scatter the Leaflets.—Look at the
list (with prices) on the second page of this
paper.

Pollen and Sugar Candy.—A.
Sherington, Dutton, Mich., on Feb. 2, 1888,
asks the following questions :

My bees are in good condition, and they
have had no flight since Nov. 20. The
weather is now very pleasant. 1. My bees
have no pollen. Can they breed without it?
2. Can I supply them with it? If so, in
what way? 3. How is the sugar candy
made for the bees for winter feeding?

1. Bees cannot rear brood without pollen
or a substitute for it.

2. Yes ; as early in the spring as they can
fly, you can place some rye meal at some
distance from the hives ; put on top of it
some honey on which the bees have com-
menced to feed. This will insure their im-
mediate attention to the meal.

3. For winter feeding, use 4 parts coffee A
sugar and 1 part water ; simmer till it be-
comes quite hard on being cooled, mould in-
to frames of 1 inch thickness, and lay it on
top of the frames, using sticks underneath
½-inch square ; or mould it in brood-frames,
tie hemp twine around to hold it in place,
and put it in the center of the brood-cham-
ber.

Rural Life is the title of a new bi-
monthly published at 20 cents a year by C.
Weekesser, of Marshallville, O. It has 16
pages, is nicely printed, and well edited. It
makes a creditable initial number. The
following is an editorial item on the “scien-
tific pleasantries” which may in time prove
very *unpleasant* to Prof. Wiley :

The intense drouth of the past summer,
which shortened the honey crop so ma-
terially, has exposed the falsehood of the
statements so extensively circulated, that
honey is being made of glucose, deposited
in machine-made combs, and sealed with
hot irons—a statement as absurd as that
which was lately circulated in regard to
eggs being manufactured.

If this could be done, the present season
would be the time for those dextrously
skilled inventors to reap a golden harvest
by marketing the manufactured product ;
but, notwithstanding the short supply of,
and the urgent demand at a high price for
honey, the bogus article is nowhere to be
found, for it has never been made.

J. P. Miller, of Chicago, has been ex-
hibiting bees in New Orleans, La., and
other cities, and has just returned. He is a
good talker, and describes the habits and
characteristics of bees while publicly ma-
nipulating them. He exhibited them at the
Museum in this city last fall, to large
audiences.

It is Extravagant Economy not
to have hives, sections, comb foundation,
etc., on hand when needed. To prevent
disappointment, order early what you will
need in that line. Then the hives can be
nailed and painted in odd times, and the
sections put together, so as to be ready at a
minute's notice. It is a sad disappointment
to need these things and then not have
them on hand. They should be ordered
very soon. We are promised an early
spring, and a good honey crop.

GLEAMS OF NEWS.

Factory for Canning Honey.—

One at least is in existence. It is conducted by Mr. A. Christie, of Smithland, Iowa. The *Exponent* of Dec. 15, 1887, describes it thus:

Mr. Christie owns five apiaries with from 500 to 600 colonies of bees. All the honey from these apiaries are brought to his Smithland canning house to be put up for the market. This is a more extensive job than one would think, and the process is more complicated.

The honey, when extracted from the comb, is barrelled up and taken to the store-house, where it is kept until the time for canning begins, which is generally about the first of December.

The building where the canning is done, is a substantial brick structure 23x30 feet, and two stories high, with an ell for an engine room. The arrangements are such that when the honey is brought in, it can be unloaded from the wagons on a level with the upper story, and the barrels rolled in. Then the barrels are placed on end, the heads taken out, and the honey is emptied into a tank holding about 100 gallons. This tank is made of boiler iron, and heated to a moderate degree by steam. From this tank the honey passes through a pipe which is regulated by a stop-cock, into a reservoir having a capacity of three barrels. From this reservoir it passes through another pipe into a steam chest. This pipe is made of block-tin, and is made in a spiral form, so that the honey may be kept in motion, for if it remained in one place too long it would be over-heated, and a little too much heating spoils it. In the chest it is heated to the required temperature, and drawn off into cans, the heat preventing granulation.

The capacity of this apparatus is two barrels per hour. In addition to this there is a steam chest in which cans are placed, and the steam being let on, the honey melts and runs into the same tank in which the barrelled honey was placed. This makes the whole capacity of the factory three barrels per hour. The honey is drawn off in cans, varying from one to sixty pounds each, but the largest demand is for the one-pound cans.

An engine of six-horse power drives the machinery and furnishes the steam for heating purposes. Mr. Christie travels during the greater part of the year selling to dealers in various parts of the country.

The Lecture of Prof. N. W. McLain, which we mentioned sometime ago, is to be delivered before the "Academy of Sciences" at Stevens' Art Hall, 24 Adams-st. Chicago, on Monday, Feb. 27, 1888, at 8 p.m. The subject will be the "Construction and function of bees;" which will be illustrated by large charts. Prof. Higley will preside. Seats will be free, and all will be welcome.

The "Chapman Honey-Plant"

has been placed by the Department of Agriculture upon the "free list." All persons desiring the seed can procure it FREE, by writing to Hon. Norman J. Coleman, Commissioner of Agriculture, Washington, D. C.; or if they desire a larger quantity than is furnished by the Department for experimental purposes, undoubtedly they can get it by requesting their representative in Congress to send it to them.

Pleasant Words come from our brother publishers, in noting the advent of the BEE JOURNAL for 1888. To all we say, "Thanks;" and we hope that the pleasant relations between the editors of the many bee-periodicals will long continue, and their exertions for the prosperity of the pursuit be fully rewarded. We give those so far received a place here:

The first numbers of our esteemed contemporary, the AMERICAN BEE JOURNAL for 1888, have come out in a new dress. It is printed almost wholly from new type, and the matter has been somewhat rearranged. Altogether, it is a decided improvement. As in times past, *Gleanings* extends the right hand of fellowship, and wishes the publisher every success. In this connection we note with pleasure the brotherly feeling existing among all our bee-periodicals at the present time, and likewise the absence of little petty jealousies which, we are sorry to say, used to crop out once in awhile.—*Gleanings*.

No. 1 of Vol. XXIV, of the AMERICAN BEE JOURNAL is on our desk, and we must confess that Editor Newman has made his paper look very nice in its new dress and new type. The head-lines of all articles are in large, clear, full-faced type. The contents and general make-up are perfection. Bro. Newman is a man of progress, and never takes a back step.—*American Apiculturist*.

The AMERICAN BEE JOURNAL comes to us in an entirely new dress of type, which makes a decided improvement in its appearance. In its articles, the AMERICAN BEE JOURNAL keeps abreast of the times, is a credit to its publishers, and worthy of patronage. We wish it every prosperity.—*Canadian Bee Journal*.

Like an old friend in new clothes comes the AMERICAN BEE JOURNAL for Jan. 4, 1888. Its appearance has been much altered and improved. We hope to see those biographical sketches continued through the year.—*The Bee-Hive*.

This is Leap Year. February has 29 days, and begins and ends on Wednesday. Washington's birth-day comes on Wednesday. Memorial Day falls on Wednesday. The Fourth of July is Wednesday. Lent begins to-day—Wednesday, and every Wednesday in the year the AMERICAN BEE JOURNAL will be published, no matter whether it is hot or cold, wet or dry, cloudy or bright sunshine! Wednesday is surely the "lucky day" of this year of three-eighths (888). If it possesses any "enchantment," it "augurs" well for the bees that pass in and out comfortably through a three-eighths inch (888) auger hole. Hurrah for three-eighths (888) and Wednesday!

Letter Postage.—It has been proposed in Congress to reduce letter postage to one cent. The Post-office Committee of the House has reported back adversely the proposition. We do not want cheaper postage, but more efficient service, especially in the country. Fourth-class postage might be reduced (on parcels of merchandise), but we can hardly hope for that, as it would affect the high-tariff of the express companies. If you have any influence with your Congressman, it will pay the reader to use it to secure a rate of one cent for 2 ounces as postage for fourth-class matter.

The Stark Co., O., Convention.

The Stark County Bee-Keepers' Society met in Grange Hall at Canton, O., on Feb. 4, 1888. The President, Jacob Oswalt, of Maximo, being absent, W. S. Kline, of Bolivar, was chairman *pro tem*. Owing to the very slippery condition of the roads and streets, there was a small attendance, but notwithstanding this fact a very pleasant and profitable time was had. A committee, consisting of Henry Beatty, of Massillon, J. H. Smith and L. J. Wise, of Canton, were appointed to wait on the Directors of the Stark County Agricultural Society, to ask for a revision of the bee and honey premium list. After the questions from the query-box were answered, the society adjourned to meet on Wednesday, April 11, 1888. MARK THOMSON, Sec.

Prospects.—It is yet very hard to prognosticate, but the indications point to a good honey-season. Mr. C. H. Dibbern, in the *Plowman* for February, says:

At this time the prospects for a good honey season are excellent. Snow has covered the ground all over the northern States since early in December. It is true that, owing to the drouth, clover is not abundant, but what there is will likely be good. Judging from present indications, all other plants will be good also, so that the bee-keeper may reasonably look for a good honey harvest in 1888.

So far, bees that were well supplied with honey, or sugar syrup, fed early enough, are in good condition, whether wintered in cellars or out-of-doors. Bees, however, are not yet "out of the woods," by a good deal. At the present time, January, the weather is quite severe, and many a colony, not properly provided or cared for, will "go to the wall" before the gentle spring comes again, with its sunshine and flowers.

New Catalogues for 1888 are on our desk, from the following persons:

Oliver Foster, Mount Vernon, Iowa—12 pages—Bees, Honey and Supplies.

J. M. Jenkins, Wetumpka, Ala.—36 pages—Bees, Honey and Supplies.

J. C. Vaughn, 88 State St., Chicago, Ills.—80 pages—Garden, Flower and Vegetable Seeds.

Mrs. Stennett, a lady bee-keeper of Blanchard, Ont., was thrown from a sleigh and killed, on Sunday, Jan. 22, 1888, by a runaway horse. Mr. S. was also thrown out of the cutter, but escaped without much injury. She was an estimable lady, and was beloved by all who knew her.

"The Bee-Keepers' Advance and Poultrymen's Journal" is now the title of Bro. Mason's paper, published at Mechanic Falls, Maine. It commenced its second year with the poultry addition.

The Canadian Honey Producer completes its first volume with the February number, which is filled with the report of the Ontario Convention.

Postage in Canada on fifth class (parcel post) was reduced on the 1st inst. to 1 cent per ounce. The registration fee is 5c.

QUERIES REPLIES.

DOES HONEY DETERIORATE IN GRANULATING?

Written for the American Bee Journal

Query 515.—1. Does honey deteriorate in the process of granulation? 2. If so, at what stage does it commence, and when does it cease to deteriorate, if ever? I am prompted to ask this question, by the judges at our State Fair deciding against my honey, on the plea that it had commenced to grain, and consequently, to deteriorate.—C.

1. No.—P. L. VIALLO.

1. No, it does not.—A. J. COOK.

1. I never supposed that it did.—JAMES HEDDON.

1. I think not, necessarily.—EUGENE SECOR.

1. I think not.—R. L. TAYLOR.

1. It does not, I think, deteriorate.—W. Z. HUTCHINSON.

1. This is the first instance that I have ever heard of honey deteriorating from granulation.—J. M. HAMBROUGH.

1. Comb honey does; extracted honey does not. 2. I cannot answer definitely.—MRS. L. HARRISON.

While it is possible that some of its aroma may be lost, there is no deterioration of quality.—J. P. H. BROWN.

1. I think not. 2. Tell those judges to test the matter more closely, and see if they do not alter their minds.—G. M. DOOLITTLE.

1. Good honey does not deteriorate in the process of granulating. 2. The judges at the State Fair did not understand their business.—M. MAHIN.

1. I think not. 2. Honey on exhibition, that has commenced to grain, is generally cut about two points by expert judges; not because it has commenced to deteriorate, but because it has not the attractive appearance of honey free from granulation.—H. D. CUTTING.

1. No. 2. Good judges, were they not? Melt some of that granulated honey *over water*, and let them taste it side by side with honey that has never granulated. They will not be able to tell the difference.—DADANT & SON.

As I am a comb honey producer, I have had but little experience on this line. I do not think, however, that granulation deteriorates good extracted honey. If I were buying, I should prefer to have it granulated.—C. H. DIBBERN.

1. No, not in *quality*, if it is thoroughly ripened and put into barrels, tin or glass, and sealed up air-tight. 2. Your judges must have been comb honey producers, and never saw well-ripened and well-cared-for extracted

honey. Send them over this way, and we will fix them up all right. This was one of the most interesting and best discussed subjects at the recent Ohio State Convention.—A. B. MASON.

I do not think that granulation deteriorates well-ripened honey. Some claim that it does. It is a mooted question; still I think that the deterioration so caused will only be found in honey not well cured.—J. E. POND.

Honey well-ripened loses nothing by granulation; at least I could never discover that it does. Honey loses, to a certain extent, the aroma of the flowers after extraction from the comb, but this deterioration is not due to granulation. Granulated comb honey is not considered so appetizing as that which has remained liquid, and will not command the best price if the granulation is detected.—J. M. SHUCK.

1. In my opinion it does not, and I think I have some experience. 2. If honey deteriorates at any time, it is the result of bad management or bad conditions. I have samples of honey dating back to 1877, and quite a number of the very best judges have pronounced the samples perfect in quality, and in preservation. Some of the best samples of honey that I have ever seen began to granulate quite early in the fall—in fact, in advance of other honey that was not so fine in quality.—G. W. DEMAREE.

1. No; the crystallization of sugar is not a chemical change of elements. If honey is granulated and slowly heated by means of a water bath, until it becomes liquid, there is no change or loss of principles; hence granulated honey is not deteriorated honey. But if a tin can of candied honey be placed directly on a stove to liquify it, there will be a loss of volatile principles, and the honey be damaged. This may account for the judges' opinion.—G. L. TINKER.

1. That depends. Some consider granulated honey inferior from the mere fact of its granulating. If in the comb it will bring a less price generally. If extracted, the granulation would not be objected to by some. It may be of good or bad quality, independently of the granulating. 2. If the fact of its granulating is considered deterioration, then the deterioration commences when the first granules can be detected, and ceases when it is perhaps half granulated.—C. C. MILLER.

Comb honey is not desirable if it is granulated, because it cannot be liquefied without destroying the comb, and is therefore of no more value than extracted honey. If the honey was a good article, and well-ripened before being extracted from the comb, it has

not deteriorated a particle. If it was watery or unripe, it may sour in the process of granulation, but in liquefying even this souring is cured by the heat necessary to liquefy it. The "judges" were not good judges of honey.—THE EDITOR.

HOW TO PREVENT MOLD IN A BEE-CELLAR.

Written for the American Bee Journal

Query 516.—What is the best way to prevent mold in a bee-cellar? This, to me, is the greatest drawback in bee-keeping.—Minn.

By ventilation.—C. C. MILLER.

Ventilate it.—MRS. L. HARRISON.

Keep the air dry and cool.—W. Z. HUTCHINSON.

Ventilate to let off the moisture, and keep it warmer.—A. B. MASON.

Sprinkle slacked lime on the floor, and give the sides a coat of whitewash.—J. P. H. BROWN.

Keep the cellar dry, and give the hives plenty of ventilation.—M. MAHIN.

By keeping the cellar dry; but dampness and mold will not hurt your bees at all, if the temperature and food are right.—JAMES HEDDON.

I think that good ventilation would answer the purpose to a great extent.—P. L. VIALLO.

I put a two-bushel bag of sawdust in my cellar every two weeks, and find that I have a sweet smelling cellar compared with what I had before using the sawdust.—G. M. DOOLITTLE.

What harm is the mold doing? Anything that would take up the moisture in the air would prevent it. Try stone lime or dry sawdust.—R. L. TAYLOR.

Is the cellar not too cold? Try keeping it warmer. If sufficiently warm, say never colder than 40°, and still moldy, I should ventilate it, or try to dry the cellar.—EUGENE SECOR.

If I only knew the conditions or the cause I could reply better. Give good ventilation. Whitewash the walls with a good lime wash, to which add 2 ounces of carbolic acid to the pail of whitewash.—H. D. CUTTING.

Ventilate it plentifully. We would remove the bottom-boards entirely. We always have more mold wherever we leave on the bottom-boards. We would also advise you to raise the hives off the ground.—DADANT & SON.

Too much dampness is probably the cause. It might be prevented by tile draining, and a thorough system of ventilation, with artificial heat from a stove for several days before the bees are put in for the winter.—J. M. HAMBROUGH.

Keep the cellar dry and well ventilated. Keep the hives well ventilated also. Be sure that the stores are well ripened before the bees are put up for the winter.—J. E. POND.

First, confine the bees to the number of combs that they can occupy, say six Langstroth frames of comb. Second, remove the bottom of the hive or give large lower ventilation.—G. L. TINKER.

The best way is to so ventilate your cellar that it will be dry. But why do you care for mold? If the bees are all right, I think that the mold will do no harm. Things in my bee-cellar mold. Yet my bees winter exceedingly well. I do not fear dampness as I used to.—A. J. COOK.

Keep the cellar dry. Mold does not always accompany bad results otherwise; yet I would prefer not to have it. Proper temperature, say 45° to 50°, Fahr., with good ventilation and drainage, will usually prevent any excess of mold in the hives.—J. M. SHUCK.

Make the cellar as dry as possible by cementing the floor. Plaster the walls and ceiling, ventilate the cellar thoroughly during the summer, and whitewash it a few weeks before putting the bees in. Leave the windows open until the bees are put in, and no mold will appear; at least that is my experience.—C. H. DIBBERN.

This trouble of "mold," which means a condition of dampness, is what makes cellar wintering nearly out of the question in a mild, changeable climate like that of Kentucky. Some experiments that I now have on hand, indicate strongly that bees will be wintered in the cellar on a new plan in the future. The cellar will be kept at a low temperature, just above the freezing point, and at intervals of ten days or longer, as experience may fix the time, the cellar will be heated up to a high temperature till the bees by ventilating throw off all excess of moisture, and prepare themselves for another winter nap. The "heating up" will destroy the mold.—G. W. DEMAREE.

Dampness is the cause of "mold," but as its presence in a cellar is of no detriment to bees, it is difficult to see how that can possibly be "the greatest drawback to bee-keeping," as stated in the question. To prevent "mold" in a cellar, give it ventilation; lime or sawdust could be used to advantage to absorb the moisture.—THE EDITOR.

A Modern Bee-Farm,* and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

CORRESPONDENCE.

BEE-FEEDERS.

Historical Reminiscences Concerning Bee-Feeders.

Written for the American Bee Journal

BY J. M. SHUCK.

What are known as trough feeders have been in use a long time. The earliest practical feeder that I have noticed is described by M. Quinby in "Mysteries of Bee-Keeping Explained"

QUINBY'S FEEDER.

—1855 edition. This was a tin-pan, 10x12 inches, and 2 inches in depth. This pan was fitted with wooden partitions to prevent the bees from drowning, and was then fixed in a hole cut in the bottom-board of the hive just large enough to receive the pan which rested on cleats nailed to the under side of the bottom-board.

Space was allowed in the end of the pan for a reservoir in which to pour the feed which ran under the partitions and was thus accessible to the bees.

CARY'S FEEDER.

This reservoir projected behind the hive, and when not used for filling was covered by a board of suitable width. The feeder was thus inaccessible to outside bees, and was probably very effectual as a feeder. I have copied the engraving of this feeder as it appears in the book alluded to, and have added only the vessel pouring the syrup, and present it here so that the reader may fully understand it.

Wm. Cary's feeder was described in the *American Agriculturist* for May, 1868. This was also a trough feeder,

to feed at the top of the hive, and was all made of wood, except the glass cover. I have also copied the engraving of this feeder. It will be seen that one side is cut away so as to better show the interior, where the bees may be seen climbing upon the partitions and sipping the feed.

There is in this feeder also a reservoir into which the feed is poured, and which the bees cannot enter, but they do enter through a hole in the bottom of the apartment at the other end, and pass over the inner wall which is $\frac{3}{8}$ of an inch below the glass cover, and thus get at the feed.

These two feeders were probably the best form of any in use down to 1870

or later. In 1874 I had some feeders cut with a wabbling saw at Heath's Planing Mill here in Des Moines, which so far as I know were the first ever made by that method. They held about half-a-pint, and were very much the same as those brought out by Mr. A. I. Root, in 1877, and illustrated in *September Gleanings* for that year, I think. I had at this time been for some months perfecting my entrance feeder, and simple as it may seem, it took a long time to get it into shape,

which finally was done, and it was patented in 1878.

I then had a little tilt with Mr. Root, who honestly thought I had appropriated his Simplicity feeder for my own purposes. The fact was that he invented the same thing I had already done, but at a later date. It is scarcely necessary to state that although we got a little *warm*, a comparison of data enabled us to get along without either bloodshed or a lawsuit.

In 1880 and thereafter I began to combine these feeder blocks in various

ways, so as to be able to feed larger quantities at once. These experiments finally resulted in the "top and bottom feeder," that is, it may be used on

ENTRANCE FEEDER.

the top of the hive or at the bottom, as the bee-keeper may choose. This feeder is composed of two feeding blocks, and has bee-passages at the sides of the blocks, and also at the ends, so that any drip or leakage will be sure to fall within the hive, and may be taken up by the bees.

This feeder is constructed on the plan of the movable-comb hive, every part of the inside may be reached by

TOP AND BOTTOM FEEDER.

the bees and cared for by them. When in use on the hive, the hive-cover just covers the feeder; and when in use under the hive, the hive covers the feeder, and the bees pass in at the entrance in the bottom-board under the feeder, and through it into the hive proper.

Des Moines, Iowa, Jan. 30, 1888.

IN COUNSEL.

Northwestern Illinois and Southwestern Wis. Convention.

Written for the American Bee Journal
BY D. A. FULLER.

The annual meeting of the Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association convened at Rockford, Ills., on Jan. 17, 1888, with Vice-President Swezey in the chair.

The minutes of the last meeting were read and approved.

The reports of members for 1887 showed 1,098 colonies of bees in the spring, and 1,028 in the fall, with only 970 pounds of surplus honey.

Mr. A. J. Swezey, of Rockford, Ills., read an essay entitled,

Lessons to be Learned in a Poor Year for Bee-Keeping.

Apparent failure does not always portend ultimate disaster. Many of the most important enterprises of the World have been nourished amid defeat and disaster. The first Atlantic telegraph cable was broken and lost in mid-ocean. The second was a dead wire in the bottom of the Atlantic. It took ten years more of patient investigation, and the utmost efforts of science and skill to make the Ocean telegraph a success.

A number of years ago people tried to make sugar from sorghum cane, but the attempt was a financial failure. Norman J. Coleman, United States Commissioner of Agriculture, has faithfully prosecuted and continued his investigations and experiments, and if recent reports are true, he will yet make sugar-making under his new process a grand success.

The bee-keepers of this country do not always find their efforts crowned with an abundant harvest. The uncertainties of the business sometimes comes with astonishing promptness and prominence. I know one man who invested about \$200 in the business, and before getting any considerable returns, his bee-inventory was reduced to 2 colonies of bees! But that man afterward became one of the most successful bee-keepers of northern Illinois.

The past year has brought no immediate financial profit to the bee-keepers of this Association. From this apparent failure, the wise bee-keepers may learn some profitable lessons.

1. That like the crops of the agriculturist, much of success depends upon the vicissitudes of the seasons, and that it is of importance to study how best to overcome or withstand its extremes of drouth or flood.

2. That bees will not gather a large crop of honey unless the blossoms grow that produce the honey. That if the season is such that the white clover is a failure, we should grow some honey-producing plants to supply the honey.

3. That the bees should at all times be well cared for, and kept in good condition so that if at any season of the year there is a supply of honey, they will be fully prepared to gather it.

4. That during a term of years there is no more honey produced than enough to supply the market for the same term of years. That if a good honey harvest fills up the market one year, it can be shipped to a less-favored locality, or a succeeding poor year will use it all up.

5. That only persevering, scientific bee-keepers will attain any great success in the business. Those who ex-

pect good crops of honey without care and labor on their part, will be so disgusted with their success in a poor year, as to abandon the business.

6. That the wise bee-keeper should economically save the proceeds of prosperous years, or he will have to do some other business during poor years to pay living expenses.

7. That bees should be particularly well cared for during a poor year. By the law of probabilities, the next year will most likely be a good one for honey. It will bring a good price in the market. The bee-keeper will want all of his bees in condition to gather all they can.

A. J. SWEZEY.

Quite a discussion ensued as to the advisability of carrying honey over from a good year to a poor one, like the present.

Chas. Kisar exhibited some white clover honey, carried over from 1886, which was very nice, and certainly looked as good as any new honey.

Mr. O. H. Swezey said that he carried a considerable portion of his 1886 honey crop over; that it froze and cracked some, but the price realized for it was far better than he could have had when taken from the hives in the fall of 1886.

The discussion brought out from this showed that good, well-ripened honey could be carried over from one year to another.

The question, "When is the best time to put bees in the cellar?" showed that most of the members put them in from Dec. 1 to Dec. 7.

Dr. Miller and Mr. Hollingsworth thought that bees should be put into the cellar earlier, as the disturbance at that time was not good for them.

President Highbarger arrived and took the chair, when the merits of the Chapman Honey-Plant was discussed. Some of the members had some growing, but not enough to say anything in regard to its merits. Japanese buckwheat no one had tried, but all recommended the planting of basswood, and some thought that trees 5 or 6 feet high would grow and do better than smaller ones.

The convention then adjourned until Wednesday at 9 a.m.

SECOND DAY.

On Wednesday morning the meeting was called to order by President Highbarger, when an essay from Mr. Herriek, entitled, "The experience of a beginner in bee-keeping," was read.

A communication from the editor of the *Bee-Keepers' Magazine*, asking the consideration of the Association as to the advisability of forming an International Bee-Keepers' Association. The

following resolution was carried unanimously:

Resolved, That the formation of an International Representative Bee-Keepers' Association is desirable.

The "Question-Box" was opened, and answers given by Dr. Miller to the satisfaction of all.

In the afternoon an essay was read from Mr. Gammon, on "Comb Foundation." He commenced with the comb, told how he made the wax, and how it was prepared for foundation, in a very concise way.

The election of officers resulted as follows: For President, L. Highbarger, of Leaf River; Vice-President, A. J. Swezey, of Guilford; Secretary, D. A. Fuller, of Cherry Valley; and Treasurer, O. J. Cummings, of Guilford.

The convention then adjourned until May 22, 1888, to meet at Rockton, Ills.

D. A. FULLER, *Sec.*

ALSIKE CLOVER.

How Much to Sow, Where to Plant, How Many Seed to the Pound, etc.

Written for the American Bee Journal
BY M. M. BALDRIDGE.

On page 56 of the BEE JOURNAL, I find the following in regard to Alsike clover: "I can endorse what Mr. Baldrige says, on page 10, about Alsike, except that I would sow 4 pounds instead of 2 pounds of seed to the acre; and I would not sow it at all on thin, dry, sandy land. It will catch in wild-grass sloughs; but thrives best with red-top clover or pasture. If wanted for seed, sow 10 pounds per acre, and it will not lodge so badly. Be sure to get clean seed, and not mixed with sorrel as some Eastern seed is."

It always pleases me to have my ideas analyzed and criticized, when free from offensive personalities as the foregoing seems to be. What we all want are facts, no matter from whence they come.

As a rule it may not pay to try to raise Alsike on thin, dry, sandy, or worn-out soil, but Alsike will do well on any soil that will produce a good crop of red clover when the two clovers are mixed. Now, do not forget that statement, and try to grow Alsike by itself, or on any dry soil that will not produce red clover. And when mixed with the usual quantity of red clover and timothy, I still advise not more than 2 pounds of Alsike seed to the acre.

Now does the reader catch my idea? The 2 pounds Alsike is to be added to the usual quantity of red clover and

timothy, so that, in case the Alsike fails to grow, from any cause, the land will be properly seeded anyway, and the only loss which ensues is simply the cost of the Alsike seed.

But let us see what we add when we use 2 pounds Alsike seed to the acre. The Alsike Leaflet says that a pound of Alsike has about 600,000 seeds, or three times as many as the common red. Now as I have never counted the seeds in a pound of Alsike, I do not know whether the statement is true or not, but I presume it is not far from the truth. Then 2 pounds of Alsike will have 1,200,000 seeds. Now how many seeds will this give to a square rod or a square foot of land? To the square rod 7,500, and to the square foot about 27 seeds! If only one out of every three seeds grow, and they are properly distributed over each square foot, there would be nine stools of Alsike, and they would cover the whole surface if allowed to do so. It is no uncommon thing to find Alsike stools 6 inches across when not crowded for room.

My experience is that 2 pounds of Alsike seed is ample, when mixed with timothy and red clover as stated, and it is also my experience, with not less than 70 acres of Alsike in one year, that 40 pounds of seed is ample when sowed alone. And to make the Alsike stand up, and to keep it away from the ground, I should much prefer to mix it with timothy, than to use 10 pounds of Alsike for that purpose, even when wanted expressly for seed.

But, as I want everybody to grow Alsike profitably and successfully, I still insist on the use of the common red clover, so as to secure the proper shade for the Alsike in dry seasons. If we could always be sure of wet seasons we could then safely dispense with red clover. As a rule it is no trouble to grow Alsike by itself in Canada, owing to its cool, moist climate, but we do not all happen to live in Canada!

The idea of being careful when buying Alsike to get good seed, and free from sorrel and other foreign seeds, is a good one. I have seen Alsike with apparently 25 per cent. of sorrel seed mixed with it. Alsike is now so very cheap that no one should hesitate to pay the price of a No. 1 fresh, clean seed. At \$9 per bushel for extra choice Alsike it is no more expensive than the common red at \$3 per bushel! And why? Because one bushel of Alsike will seed as many acres of land as three bushels of red clover. Besides, a ton of Alsike hay, after the seed is threshed therefrom, is worth more for cattle or sheep than a ton of the best cured and unthreshed common red.

Some 20 years ago, when I was growing Alsike extensively, and on

rented land at \$5 per acre, the price I then paid was \$60 per bushel, and thousands of pounds of the seed were sold, at retail, at \$1.50 to \$2.00 per pound! The present exceedingly low price for Alsike seed is simply evidence that it is now grown extensively, and with the greatest of success by thousands who have got hold of the secret as herein indicated.

St. Charles, Ills.

THE EXTRACTOR.

My Position in Regard to the Extractor.

Written for the American Bee Journal
BY WM. F. CLARKE.

The report of the recent Ontario Bee-Keepers' Convention on page 72, is a lop-sided affair. Some of the most interesting discussions are omitted, while special prominence is given to the sayings and doings of the reporter and his father-in-law. I do not propose supplying its omissions, but crave space for a few remarks concerning a single reference made to myself. The "report" says: "W. F. Clarke, of Guelph, condemned the honey-extractor, but the members present, however, objected to this." Objected to what? My condemning the extractor? Not at all. I was allowed entire freedom of speech, without objection on the part of any one.

There are few bee-keepers of judgment and experience who will not concur in most of the remarks I made on that occasion. I said, it was doubtful whether, on the whole, the extractor had been beneficial to apiculture. It had opened the door to adulteration of honey, and had been used most injudiciously by many, who tore up the brood-nest without mercy, took large quantities of unripe honey, and really put on the market an article of strained honey, so much brood, pollen, etc., being thrown out of the cells. The extractor had been the means of lowering the price of honey, and if not used until the honey was ripe, and the cells were capped, I questioned if extracted honey was more profitable than comb honey. While preferring not to use the extractor myself, I strongly urged those who did use it to leave the brood-nest intact, and do their extracting from the combs of an upper story, as recommended in Mr. Malcolm's excellent paper, out of which the discussion arose.

The one point of difference between myself and other bee-keepers present was in regard to the question whether, all things considered, it was advisable to use the extractor at all. My own

preference for comb honey is shared by me with some of our best and largest producers of honey, and this question is one that must come to the front.

I doubt much if the honey market will ever be in a satisfactory condition, so long as large quantities of the inferior extracted article are produced. These are the great disturbing element, and no one can read the quotations and note the difference of price between the cheaper grades of extracted honey, and first-class comb honey, without feeling that the production of extracted honey, so far as it is carried on, should be rigidly limited to that of the highest quality.

St. Thomas, Ont.

NEW YORK.

Bee-Keepers of the State in Convention.

Compiled from the Bee-Keepers' Magazine.

The 19th annual convention of the State Bee-Keepers' Association was held at Utica, on Jan. 17-19, 1888, with President W. E. Clark in the chair. The minutes of the last meeting, and the Secretary's report were read and approved.

The first discussion was on,

Various Honey-Plants for Bees.

Mr. A. I. Root said that he had considerable experience in cultivating plants for honey. He had raised catnip, but it required too many plants to make a satisfactory showing, and the same was true of mignonette. He said: "I once had 40 colonies of bees that worked on a field of buckwheat two miles away, and I regard that the best showing of artificial pasturage I ever saw. Buckwheat honey is dark, however, and the yield is irregular. We get good results from Alsike clover. The crop pays well for the hay and the seed, aside from the honey. We call the clover honey "gilt edge." The cultivation of rape is carried on in places for its seed, and we get good results from the plant in the way of honey. The raspberry is cultivated for its fruit as well as for honey.

John Aspinwall, in speaking of the tulip tree, said that in passing under a tree one day he pulled down a blossom, and it was filled with honey. All of the blossoms were covered with honey, and there were myriads of bees there. There had been no rain for several days.

Mr. Dickinson—The supply of honey depends largely on climatic conditions at all times. In my opinion, any one who plants anything for honey alone, will "get left." When clover yields

honey, it is of a fine quality. When you find bees working on white clover, you find them on the red. Buckwheat is simply buckwheat, and nothing more, and as far as the Japanese or other varieties are concerned, I cannot see that one is better than another. Raspberries produce a large amount of honey, and if I had to take my choice between this plant and the clover, I would take the former. My bees work on red, white or Alsike clover.

J. H. Taylor—There is a great difference in the locality as regards the quantity of honey produced. This year the bees failed to get honey from buckwheat near Ilion, but later at Jordanville, the same bees, when I took them there, worked on the plant freely. I find that they will gather honey from buckwheat on hills when they will not in the Mohawk valley.

Mr. Aspinwall—It seems to me that it has been proved this year that there is something else than climatic changes that affects the yield of honey. The conditions were apparently favorable for honey, but the yield was light.

President Clark—Fifteen years ago I got a good yield from buckwheat, but since that time I have not been able to get a good yield from that source. I presume that my bees get a little buckwheat honey, but they consume it.

Mr. Dickinson—I. L. Scofield has an apiary at Chenango Bridge, in a buckwheat country, and where he once had a large yield of honey, he now gets but little. Bees work very little after midday. If the night has been warm, and a fall of dew follows, the conditions are favorable for the bees.

Mr. Knickerbocker—The bees in our section did not work on the basswood trees in 1886, but last year they did.

Mr. Root—How many have succeeded in increasing the yield of honey by moving their bees from one place to another?

Mr. Taylor related an instance where bees had been moved two miles, and they had worked much better.

Mr. Root spoke of an instance where bees had worked on buckwheat in the afternoon.

Mr. Dickinson—Can any one report a yield from sumac?

Mr. Knickerbocker—Mr. Jackson, of Deposit, says that he gets a good yield of honey from sumac every year. We have a little in our place, and it yields very well.

Mr. Taylor—The bees work on the red sumac in our locality very nicely.

After some miscellaneous talk, the convention adjourned until 7 p.m.

EVENING SESSION.

The President called the convention to order at 7:15 p.m. After the en-

rolling of new members, the time was given to miscellaneous discussions.

In reply to this question, "Does it pay to use full sheets of foundation in the brood-chamber?" Mr. Foster said that he had always used full sheets, and his bees never go into winter quarters with over 15 or 20 pounds of honey.

Mr. Betsinger said that for extracted honey full sheets of foundation should be used.

Mr. Knickerbocker said that taking the average of the season right through, he would not do without the foundation if it cost a dollar a pound.

Mr. Aspinwall—In Cuba they use full sheets, but of course they work only for extracted honey.

The prevailing opinion seemed to be that full sheets of foundation should be used in the brood-chamber.

Feeding Sugar to Bees.

Mr. A. I. Root, in response to a query from the President, said he thought that a pound of sugar is equal to a pound of honey for supporting bees. Granulated sugar is better than honey for this purpose.

Secretary Knickerbocker—It seems to me a detriment to bee-keepers that sugar has ever been mentioned in connection with bee-keeping.

Mr. Aspinwall—The question of adulterating honey has been dropped entirely.

Mr. Root—I have made a standing offer of \$1,000 for a comb of artificially manufactured honey.

Mr. Aspinwall—I will give a thousand dollars for a square inch of it that cannot be distinguished from that made by the bees.

Mr. Foster—If it is a losing matter to feed sugar to bees to put into sections, why is it not a losing operation to feed it to them through the winter?

Mr. Root—Simply because it is better for the bees.

Mr. Aspinwall—I think that the sense of the Association is, that it is ill-advised to feed sugar to bees if there is any possible chance of the honey getting on the market.

Mr. Kilbourn—My bees want 500 pounds of something to winter on. I think I can secure the necessary quantity of sugar or syrup for \$20, whereas the honey would cost \$40. As a matter of business, I think that we have a right to use sugar for wintering the bees.

Mr. Betsinger—Syrup will cost 5 cents a pound. Does any one want to take what honey I have left next season, after I have sold what I want to, and allow me 5 cents a pound? I think not. Therefore, taking honey away and feeding sugar instead, is not advisable.

Mr. Foster—That is what it is coming to, unless something is done.

An extract from the *American Grocer* was read, in which it was stated that in New Jersey 42 samples of bottled honey was analyzed, and it was ascertained that out of 31 samples put up by packing houses, only six were pure. The samples purchased of farmers, however, were all pure.

Mr. Root—I fear there is a mistake about some of those samples examined. The State Chemist of Ohio says that it is a difficult matter to tell when honey is adulterated. Bees gather every variety of honey.

Mr. Aspinwall—With the polariscope you can detect the presence of 5 per cent. of glucose. A point in the article just read is, that the honey procured of dealers was nearly all found to be adulterated, while that purchased of bee-keepers was all pure. There is a law against adulterating honey, and can we not induce the State chemist to analyze honey sold on the market?

The question of "Artificial Fertilization" was on the programme, but N. W. McLain, who was to lead it, was unable to be present, owing to illness. A letter from him was read, expressing regrets at his inability to be there.

Mr. Aspinwall—When a bee has lost its hair on its thorax, it is diseased, and the malady is termed bacillus decapillis. There are isolated cases in many colonies, but the disease does not spread.

Mr. Root—In "the nameless bee-disease" the members of the colony become weak, have shiny backs, and many die. New queens have to be introduced.

Mr. Aspinwall—The introduction of new queens is a great secret of success in bee-keeping. A queen hatched this season should never be kept over the next.

At this point a recess was taken until 9 a.m.

LIGHT IN CELLARS.

Value of Light in the Bee-Cellar in the Winter.

Written for the *American Bee Journal*

BY T. F. BINGHAM.

Thinking that some of the readers, in the near future, may have a few colonies of bees to winter, and for which they do not wish to spend much money to make a cellar or cave, not even to render their ordinary cellar dark and unpleasant to use for the ordinary family purposes, I have decided to state a few points perhaps overlooked by bee-keepers, in regard to light in the cellar as a means to the paramount purpose of healthfully wintering bees.

In this article it is not the intent to exhaust the evidence, neither to establish the theory thus far among scientific bee-keepers not mentioned as a possible factor to successful wintering. I shall simply state that I have been in the habit of wintering part of my bees in cellars at various times and in various places, according to circumstances. However radical I may have been, only in one instance has the ordinary stereotyped rules been disregarded by me, so far as darkness was concerned. I have in all cases absolutely excluded light from my cellars except in one case, when I wintered successfully a few colonies in Allegan, Mich., in a very light cellar, where vegetables were kept for the daily use of a large family, composed mostly of children, who went when they pleased into the cellar for apples, etc.

The point that I wish to bring out conspicuously is, that light is essential to the welfare of all warm-blooded animals, to which rule bees are in no wise an exception; neither are plants. It will of course be at once assumed that in order that bees may be quiet, human ingenuity must exclude from them all light as the first and prime essential.

"Habit," the lamented Artemus Ward said, "is a bad habit." While in a certain sense his statement is correct, I shall not presume that the many gifted bee-keepers and writers who have, and now do advocate wintering bees in dark cellars and caves, do so simply out of respect to the time-honored custom, without giving all the accessories, which they so explicitly explain, due thought and consideration. No; but on the contrary, their articles seem exhaustive, and so far as a recapitulation of the accidents and purposes which have come under their consideration goes, the evidence and conditions given leave little room for reasonable difference of opinion.

The fact still stands out boldly, that perhaps the one most important factor entering into the proper statement of the wintering problem has been hitherto omitted, viz: Light. Light in the cellar; light in the hive, and light in the swaying trees.

Having so far outlined what I wish to be understood, allow me to give a pen-and-ink sketch of the few of my bees now in the cellar, to illustrate what has been written:

My cellar is 6½ feet high, and 30 feet square, and under my house where we live. This cellar has three ordinary three-pane double cellar-windows, one on the east side, one on the south, and one on the west side. These windows render the entire cellar comparatively light. The walls are of stone, plastered with hydraulic cement mortar. Around

the cellar on all sides a row of 2-inch drain-tile are laid a few inches below the level of the cellar, and leading out below the house, to drain the cellar (which is nicely accomplished).

The cellar bottom is covered about 2 inches deep with dry sand. This sand is used in preference to cement, as I regard it as being more healthful to the family and the bees. Every spring this coat of sand is removed, and a new coat returned in its place. Of course the cellar is sweet. It is also cool in summer, and warm in winter, as the entire bottom plays its part in radiating and absorbing the heat.

On the east side of the cellar, facing the east window, and about 10 feet from it, are three rows of hives, six hives in each row, piled one above the other, three high. Eighteen colonies of bees stand facing the east window squarely. Each hive has an entrance 23 inches long facing the window. The bees are at liberty to take in all the light there is, and the light is ample to read by.

They have all the daylight and brilliant light in the morning when the sun shines obliquely through the window into the cellar. The bees are at liberty to fly also, but few, however, take such liberty; when they do, they head to the hive as if in the open air, and after a short fly, they dart to the window, where, of course, they die.

It will be said that the cellar is cold or the bees would not keep so still. The temperature has averaged, up to date (Jan. 17), 45° or more; only once has it touched 40°, and then only for a few hours; while most of the time it has shown 50°.

It is not as a matter of convenience that these bees are placed as they are. They have been so placed, because I believed daylight essential to the welfare of the bees. Next May, when the clover blooms, I shall know how well my belief was founded. Should it prove well founded, a valuable experiment will have been made public; as it will then be reasonable to keep a few bees in an ordinary cellar. It is very pleasant to be able to see how the bees are doing, without the aid of a lamp.

To the bee-keeper having a fertile imagination, a long list of desirable features can be made possible in the "light" of the light cellar, as well as in the light of these experiments.

In this article no effort has been made to show that perhaps five months in a dungeon may be as detrimental to bees as to human beings; neither that the absence of light for so long a period may or may not be as detrimental to bees in a cellar as a much greater degree of cold in the sunlight. Neither has it been the part of this article to

prove that spring dwindling, diarrhea, etc., would not have taken place had the bees affected with it been wintered in a light cellar instead of a dark one.

One point remains not yet clearly stated, viz: that it is not light that causes bees in a cellar to be uneasy. If, then, that is not the cause, of what value is it to surround them in impenetrable darkness? We have all seen bees slowly withdraw from activity to repose, as one by one the plants ceased to yield honey and pollen; and when no incentive to industry longer existed, how unbroken became their repose. Is there any evidence that darkness played any important part in such quiet? Were the bees more at rest in the night than in the sunlight?

The fact that bees do winter just as well under apparently much less favorable conditions in the open air, is, to say the least, a point in favor of the vitalizing influence of fresh air and sunshine!

Abronia, Mich.

BROOD-COMBS.

Large or Small Combs, and Divisible Brood-Chambers.

Written for the American Bee Journal
BY JAMES HEDDON.

It is with pleasure that I read the article by J. W. Cullinan, on page 39, on the above subject, controverting the mistakes of Mr. Hambaugh, on page 804 of the BEE JOURNAL for 1887.

It is undoubtedly highly proper and important that we discuss the merits of dividing one brood-chamber into two horizontally divisible parts, interchanging these parts instead of inverting. This brings us to the question of Mr. Cullinan's article on page 39, at the close of which he asked me to give an account of my success with the divisible brood-chamber.

At the beginning, I wish the reader to understand the difference between double brood-chambers, or several brood-chambers piled on top of each other, and one brood-chamber proper, divided into two parts, and constructed in such a manner as to be perfectly adapted to interchanging the parts with each other for special purposes. There has been so much said already that it seems unnecessary to enumerate and discuss each function by itself. I cannot see how full-grown men with any experience in the business can imagine any objection to the "sticks and spaces" that occur between the sections of the divisible brood-chamber. You all know very well that bees never breed up faster, nor winter

better in any hive than in box-hives, so full of cross sticks that oftentimes the combs are all in pieces running in almost every direction. Four years' experience has demonstrated the truth of my reply to Query No. 508, on page 39.

I once paid \$18 for a box-hive which was $\frac{3}{4}$ full of comb, the capacity of the hive being ten times larger than the Langstroth; it contained about double the number of bees usually resulting from one queen; I doted on the large number of frames I should fill with comb when transferring this colony; upon opening it I found so many sticks running through it that I believe I got only 3 or 4 Langstroth frames of comb out of it; all the rest being in pieces no larger than your two hands. This colony had wintered safely, when many others had died by its side during the seven winters they had been in this hive. They had only swarmed two or three times during the seven years, but the swarms that issued were said to be of double size. When one section of the divisible brood-chamber is in use in the spring, before breeding has reached a status that more room is needed, its smaller size and shallow form both favor the conservation of heat in the brood-nest, and the bees breed faster than in any other hive I have ever used. That bees will breed up faster in the spring and keep warmer in the winter in shallow hives than in deep ones, is proven both by theory and demonstration. As cold is not the main cause of winter mortality, experience has shown but little difference as regards successful wintering. When the single brood-chamber, which is used in the spring, is well filled with brood, and more room is needed, the second one can be placed under it in the direction which the queen naturally breeds, downward, leaving the brood already on hand in the warmest part of the hive. This is the correct method of giving more breeding room. All can see it in theory, and I know it to be true from four years of direct experience.

It seems to me that any experienced bee-keeper should see at a glance, without any experiment whatever, (knowing from past experience that as the brood moves downward the upper portion of the brood-chamber is filled with honey), that the alternating of the two halves should cause the bees to carry this honey above, affording the queen the opportunity, and stimulating the disposition to fill that brood-chamber full of brood.

To close, I will say a word relative to our experience here, which, to me, tells very much. I have in use many of the best modifications of 8-frame Langstroth hives containing reversible

Langstroth frames completely filled with straight, all-worker combs which I will not throw away. Hardly a day passes in the summer time, when my foreman and students are not making remarks something like this: "Oh, if all of your hives were of the new pattern!" "Why don't you transfer them all into the new hive?" "We can handle twice as many of the new style of hives," etc., etc.

Mr. Cullinan is quite right when he says we should not "imitate nature in the construction of our hives." Our hives should be fitted to the operator more than to the bees; and in conclusion I will say that we should adopt such hives and other fixtures as experience proves to be best.

Concerning Dr. Tinker's essay read at the Ohio Convention, and the discussion following it (see pages 86 and 87), I am glad to notice what was said about the MERITS of sectional brood-chambers. I think, however, that only Dr. Tinker could speak from experience—none of the others having more than one of the hives in use, if any. In the light of the article by Dr. Tinker, on page 154 of the BEE JOURNAL for 1886 (published also in *Gleanings* on page 203), many will wonder if the Doctor is not now in error instead of then—the two positions being diametrically opposed to one another. *I know that he is wrong now*, as do many good apiarists who have had experience with the sectional brood-chamber hive.

Dowagiac, Mich.

INDIANA.

Report of the State Convention at Indianapolis.

Written for the Indiana Farmer
BY G. K. HUBBARD.

In the absence of President F. L. Dougherty, Dr. Collins, of Hamilton county, was made chairman of the convention.

The discussion of honey-plants revealed the fact that Alsike clover is the favorite, being both excellent as a honey-producer and a forage plant. One member said that it was a good feed for milch cows, and thus was able to make "the land flow with milk and honey."

On the question of bees puncturing grapes, the opinion was unanimous that it was out of the power of the insect to do so. Mr. Muth, of Cincinnati, said that when wasps and hornets have punctured the grapes the bees will extract the juices, but their mandibles are not fitted for cutting through the skin. He said that the grapes would not be disturbed by the wasps

and hornets, if the bees are near the vineyard. He also recommended salicylic acid and carbolic acid as remedies for foul brood, but the only sure cure is fire.

On the second day the subject, "Women keeping bees and becoming members of the association," was discussed.

On bees freezing, Mr. Mason said that bees cannot be frozen in a cluster if the hive is dry, but they can be chilled to death if the hive is cold and damp.

Regarding wintering bees, Mr. Bull said: "Three things are essential at all seasons of the year. They need honey, bee-bread, and water. If it is desirable to have bees winter well, do not fail to furnish water. It will prevent them gorging themselves. As to wintering out-doors or in the cellar, each had its advocates.

The association indorsed the resolution of the State Board of Agriculture on the State Library. The association also resolved to appoint a delegate, to co-operate with delegates from other societies in presenting this matter to the Legislature, with instructions to endeavor to secure an appropriation by the Legislature sufficient to cover the expense of publishing the association's report, and other expenses incidental to its annual meetings.

The following officers were elected for the ensuing year: President, Dr. E. H. Collins, of Mattsville; Vice-President, Wickloff Mason, of Fillmore; Secretary, Geo. C. Thompson, Southport; Treasurer, Mrs. Irvin Robbins, of Indianapolis.

The convention then adjourned.

BEE-ESCAPE.

Plans for Making Bee-Escapes for Extracting-Rooms.

On page 77, Albert H. Lind asks how to make a bee-escape for his extracting room. In reply to the question, Dr. C. C. Miller, of Marengo, Ill., describes his plan as follows:

Bees will fly to the light, so it is important that there shall be no light admitted to the room except where the bees can escape. The place for escape may be a hole in the wall a foot square, or it may be a whole window. In either case, cover the whole of the aperture with wire-cloth, and let the wire-cloth be large enough to continue a foot or so above the aperture. Now if the whole thing be nailed down tight, of course no bee can get out; so some plan must be devised to make the upper part stand out from the outside wall, for you understand that the

wire-cloth is nailed on the outside, not the inside of the building.

At each side of the window nail a piece of common lath on the building, so that the lower end shall come 2 or 2 inches below the upper boundary of the aperture, and let the lath extend upward as far as the wire-cloth goes. Now nail the wire-cloth on the lath. It may be necessary to have a piece of lath midway between the two side-pieces, so as to hold the wire-cloth more firmly to its place. This makes an open space of $\frac{3}{4}$ of an inch through which the bees can go up and fly off, but no bee will think of starting at the top to come in.

The sash must be taken out of the window, or if less light is needed the upper sash can be let down, and a cloth, no matter how thin, be hung over the sash inside. In this case the wire-cloth need not cover the lower part of the window, but pains must be taken to make the window bee-tight.

For greater economy, musquito-netting may be used for all but a foot or so of the upper part, and even that may be of musquito-netting, but it is so apt to get out of order.

Mr. S. Burton, of Eureka, Ills., gives his method as follows:

To make a bee-escape, I tack screen-wire on the outside of the window frame, and make a hole at the top corner of the window about 2 inches in diameter. Then make a tube of screen-wire about 5 inches long, to fit the hole in the screen; at the other end make about a half-inch hole. The bees will pass out at the hole, but none will enter. As they will go to the window to get in, there may be two or three such bee-escapes in the same window, if desired.

Rev. T. H. Dahl, of Stoughton, Wis., gives the following plan:

I will be glad to describe my own bee-escape, as it is an excellent one, and as far as I know it is the best yet in use. I would not part with it for fifty dollars, as it not only clears the honey-house of bees, but also of all other insects. It is not my invention, but it is used to a large extent among bee-keepers.

I use wire-cloth on the outside of all the windows in the room, and I fix it on so as to reach 6 or 8 inches above the window.

I put it on in this way: I nail a piece of lath as long as the screen on each side of the window, and fasten the wire-cloth on these pieces, and at the bottom of the window. There will then be an open space of $\frac{3}{4}$ of an inch between the wall above the window and the wire-cloth. Through this hole

all the bees will escape, and none return, as the bees or other insects always try to get upward, and not downward.

It is better to darken all other windows but one, when you will get the bees out, and of course it is not necessary to put wire-cloth on more than one window. By this "escape" I keep my honey-house entirely free from bees and flies during the whole summer.

Mr. Enoch Babb, of Herbst, Ind., writes as follows about his bee-escape:

I like my bee-escape very well, and it is made as follows: It is a common window in a double frame, that is, one frame inside of the other. Make the outside frame large enough to receive the inside frame containing the window, which should be put in like any ordinary window in a dwelling. To raise or lower it, put in a small bolt through both frames in the centre between the bottom and the top, oval the outside of the inside frame a little, and the window swings around and around.

Work near the window, and all the bees that are carried in will soon fly and alight on the window, when, in a twinkling, the window can be turned inside out. In real hot weather raise or lower one window-sash, and put in a wire-screen, or tack on musquito-bar to give ventilation.

BEE-STINGS.

The Rheumatism Cured by Bee-Stings, etc.

Written for the American Bee Journal

BY E. W. COUNCILMAN.

Mrs. L. Harrison, on page 57, favors some plan by which bees may be deprived of their sting. I emphatically protest! If such a thing is attempted, I shall certainly enter a complaint to Prof. Berge for cruelty to insects.

But laying all "pleasantry" aside, I want to say that everything has its uses, and nothing was made in vain. Three years ago, when I commenced bee-keeping, I was so afflicted with rheumatism that it was very difficult for me to stoop and pick anything from the ground. Indeed, I was a great sufferer from that terrible disease. After working among the bees for awhile, I noticed that my lameness began to disappear, and now I am comparatively free from rheumatism.

Last summer I learned for the first time that homœopathic physicians used the virus of the honey-bee for rheumatism. This set me to thinking. I am firmly of the opinion that the bee-stings (of which I have received a few), have been the cause of my relief, for I have taken no treatment for

that dread disease. So do not "dehorn" the bees!

In one part of my article, on page 56, I am made to say that the temperature of my cellar is from 32° to 45°, and in the closing paragraph it reads from 40° to 45°. Either I made a *lapsus calami*, or it was a typographical error. It should read "from 30° to 45°," to be exact.

In extreme cold weather it has been down to 28° at the bottom of the cellar, and in the spring, during soft weather, it was 45°. I meant to give the average (which I believe to be the secret of my success in wintering bees), which is from 30° to 45°.

Newark Valley, N. Y.

[It was printed exactly as written in the copy.—ED.]

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*

- Apr. 11.—Stark County, at Canton, O.
Mark Thomson, Sec., Canton, O.
Apr. 24.—Des Moines County, at Burlington, Iowa.
John Nau, Sec., Middletown, Iowa.
May 5.—Susquehanna County, at New Milford, Pa.
H. M. Seeley, Sec., Harford, Pa.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Colonies in Good Condition.—W. D. Renfro, Troy, Ills., on Feb. 7, 1888, says:

I have 27 colonies in good condition on the summer stands. Last month on two days they had good flights. I examined some of the hives, and they have plenty of bees and honey. As the last year was a poor one for honey, I got only about 300 pounds of comb honey, in one-pound sections. I am thankful that we have as much as we need for ourselves, and some to spare.

The Season of 1887.—M. L. Barney & Bro., Hartford, Wis., on Jan. 18, 1888, write:

We wintered 117 colonies last winter, and lost one colony by spring dwindling. We had a poor season last year. We sold \$175 worth of bees and queens, and 4,575 pounds of honey. We have now on hand 140 colonies, all of which are doing well. We expect to lose a few colonies this winter, owing to an accident which prevented our preparing them properly for winter.

Few Dead Bees—Honey Trusts.—J. M. A. Miller, Galva, Ills., on Feb. 1, 1888, writes:

In 1887 I had only 2 swarms from 50 colonies, and about 20 pounds of honey. I had a lot of honey on hand last May, and I only realized about 8 cents a pound for it; now I notice that honey is selling in the same store for 30 cents per pound. That is a great change, indeed. I have 48 colonies safely stored in the cellar—some are quite strong,

and others not so strong. I examined them yesterday, and all are as quiet as I ever saw them; yet they are quite lively, and for some cause, that I cannot explain, there is not a pint of bees on the cellar bottom. Why is this?

I was told the other day that a "honey trust" was being formed in Chicago, and that was the reason honey was so high and scarce. I think that the dry weather has had more to do with the scarcity and prices than any "trust." Hence, if we have a good season this year, the first honey that is put on the market will receive the highest price. Of course the price will soon fall, but not to where it was last spring.

[The formation of a honey trust in Chicago, is a *myth*!

As there are but few bees dead on the cellar bottom, the presumption is that late breeding gave them mostly young bees to go into winter quarters with, and consequently there are but few to die with old age.—ED.]

Value of Packing Bees.—Jno. A. Buchanan, Holliday's Cove, W. Va., on Jan. 25, 1888, says:

Mr. Seabright, on page 45, expresses himself as being in accord with the packing system. He began the last season with 63 colonies. They were strong, as they had been packed all winter and spring; he got 60 pounds of honey. His not-far-distant neighbor, Mr. Lewedag, from 26 colonies, wintered in single-walled hives, with but a cushion over the frames, secured 250 pounds of comb honey. Will Mr. S. "fix this up," so that it will help him out with his pet theory?

Bees Breeding Early, etc.—A. V. Kouba, Crete, Nebr., on Jan. 31, 1888, says:

We are having very cold weather this winter; on Jan. 15, the thermometer registered 32° below zero. My bees are being wintered on the summer stands, and so far they seem to be in fine condition, except one colony that is weak. We are having nice weather now, the mercury being up to 65°. The bees had a good flight to-day, and also a few days before. I examined the weak colony to-day, and contracted its brood-chamber to three frames. In the middle of one comb I found a circle of eggs. I opened the hive of a strong colony, and found three combs with eggs, in a circle from 3 to 4 inches in diameter. I prefer a good chaff hive, for wintering out-doors.

Wintering on Summer Stands.—J. Rosecrans, Anburn, N. Y., on Feb. 1, 1888, writes:

I commenced the season of 1887 with 7 colonies, increased them to 9 colonies, and took off 400 pounds of honey in one and two pound sections. The bees are on the summer stands without any packing or cushions, with only a piece of cotton-cloth. They were all right when last examined, and I trust that they will continue to be so. I wintered them last winter on the summer stands, in the same way, with the loss of only one colony, which starved.

Early Breeding of Bees, etc.—Wm. Stolley, Grand Island, Nebr., on Jan. 31, 1888, writes:

From Dec. 20, 1887 until Jan. 25, 1888, we had fearfully cold weather in central Nebraska; it was at zero or far below, and once even 35°, Fahr., below zero. On Jan. 26, it became warm enough for bees to fly,

being 50° in the shade. Ever since it has been quite warm, and to-day the mercury was 60° in the shade. I have improved this warm spell, and overhauled all of my bees. The hives were cleaned, all chaff packing dried, and in a few cases frames of honey were put in, where the winter stores were insufficient to last the bees well into spring.

I found all of my bees in excellent condition, but I was surprised to find that a number of colonies had in one, two, and even three frames, patches of capped brood. My aim always is, to keep my bees from early breeding, and I cannot understand why they should breed earlier in this exceptionally cold winter, than in previous much warmer winters, since the winter packing is the same as usual; unless it is that my bees are wintering exclusively on natural stores, with lots of pollen, when formerly I removed the pollen as much as possible, and fed the best coffee A sugar syrup instead.

I will try to give my bees frequent flights, if possible, and thus I hope to prevent diarrhea and loss. I learn that many bees have succumbed to the cold that we have had in this section of Nebraska.

Cold Weather—Canadian Locomotive.—Chas. Solveson, Nashotah, Wis., on Jan. 31, 1888, says:

Bees in the cellar are wintering finely, but those on the summer stands are having a hard time of it, and it is not to be wondered at, with the mercury for weeks at from zero to 40° below, with but two or three abatements of but a day's duration. To-day, however, we are having mild weather.

By-the-way, how slow that Canadian "locomotive" travels! I have been patiently waiting for the sounds of the "merry bells" that were to convey such astounding news of an invention that would "cause a great commotion among the dry bones, and not yet extinct fossils of bee-dom;" and yet so simple that the relator could hardly refrain from "laughing out right at the stupidity of the whole tribe, that not one of their number ever thought of it before." Did you ever! Well, well! I hope Bro. Clarke will not keep us in suspense much longer, as I fear it will be the "whole tribe" that will laugh next, unless something turns up pretty soon.

[This is respectfully referred to Bro. Clarke for reply.—ED.]

Cleansing Flights for Bees, etc.—Evan R. Styer, Morgantown, Pa., on Jan. 23, 1888, writes:

On Nov. 14, 1887, I packed 11 colonies in a bee-house, placing the hives within 2 inches of each other, and putting meadow-hay around the insides. The house opens to the south. I fed 150 pounds of sugar syrup to 10 colonies, one colony having stored enough for winter use. On Dec. 9, bees had a good flight, and on Jan. 14 they had another cleansing flight. There was snow on the ground, and but few bees were lost in the snow. All the colonies have lost considerable in bees during the winter. If this continues until March, some will be weak. Some of the colonies have only six frames each, while the rest have eight. What comb honey I produced was nice, and I received 30 cents per pound for it; and now I am selling extracted for 18 cents per pound.

I prefer the two-story Langstroth hive to any other. I expect better results the coming season, as I intend to sow a great deal of Alsike clover seed, and will prevail upon my neighbors to do so.

The BEE JOURNAL is a welcome visitor at our fireside, and the information which I receive is of great advantage to me. Indeed, I cannot see how I could get along without it.

BEE JOURNAL

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

Simmins' Non-Swarming System will be clubbed with the BEE JOURNAL for one year, both postpaid, for \$1.25.

Beeswax.—We will pay 20 cents per pound, delivered here, for Yellow Beeswax. To avoid mistakes, the name of the shipper should always be on each package.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Money Orders for \$5.00 and under, cost 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Sweet, or McIlrot, Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Honey and Beeswax Market.

CHICAGO.
HONEY.—We quote: White comb, 16@18c.; dark, 13@15c. Extracted, 7@10c. Market dull, but more active demand looked for when weather moderates.
BEESWAX.—21@22c.
Jan. 25. S. T. FISH & CO., 189 S. Water St.

CHICAGO.
HONEY.—Choice comb, 18c., with some fancy held a little higher. Extracted, 7@9c. Demand light.
BEESWAX.—22@23c. R. A. BURNETT,
Jan. 21. 161 South Water St.

DETROIT.
HONEY.—Best white in 1-pound sections, 18@20c. Extracted, 9@10c. Demand brisk.
BEESWAX.—22@23c.
Jan. 20. M. H. HUNT, Bell Branch, Mich.

CLEVELAND.
HONEY.—Best white 1-lb. section a sell at 19@20 cts. Extracted 7@8c. Demand small and supply fair
BEESWAX.—22@25c.
Dec. 15 A. C. KENDEL, 115 Ontario St.

NEW YORK.
HONEY.—We quote: Fancy white in 1-lb. sections, 16@19c.; the same in 2-lbs., 14@16c.; buckwheat 1-lb., 11@12c.; 2-lbs., 10@11c. Of grades 16@2c. per lb. less. White extracted, 8@9c. Market dull.
BEESWAX.—22@23c.
MCCAUL & HILDRETH BROS.,
Jan. 20. 28 & 30 W. Broadway, near Duane St.

KANSAS CITY.
HONEY.—We quote: White 1-lb., glassed, 16@17c.; unglazed, 17@18c.; and dark 1-lb., glassed, 15c.; unglazed, 16c.; white 2-lb., glassed, 16c.; unglazed 2-lbs., 17c. California white 2-lbs., 17c. California extracted in 6-lb. cans, 8c. Market quiet and receipts are larger.
BEESWAX.—No. 1, 20c.; No. 2, 18c.
Feb. 9. CLEMONS, CLOON & CO., cor 4th & Walnut.

ST. LOUIS.
HONEY.—Choice comb, 18@20c.; latter price for choice white clover in good condition. Strained, in barrels, 56¢c. Extra fancy, and of bright color and in No. 1 packages, ¼-cent advance on above. Extracted, in bbls., 6¼@7c.; in cans, 7 to 9 cents. Short crop indicates further advance in prices.
BEESWAX.—20c. for prime.
Dec. 19. D. G. TUTT & CO., Commercial St.

CINCINNATI.
BEESWAX.—Demand in good—20@22c. per lb. for HONEY.—We quote extracted at 4½¢c. per lb. Choice comb, 16@20c., in the jobbing way. Demand fair and supply good.
Good to choice yellow, an arrival.
Jan. 24. C. F. MUTH & SON, Freeman & Central Av.

NEW YORK.
HONEY.—We quote: Fancy white 1-lb. sections, 17@19c.; fancy 2-lbs., 15@16c. Lower grades 12@2c. per lb. less. Buckwheat 1-lb., 11@12c.; 2-lbs., 10@11c. Extracted, white, 9@10c.; buckwheat, 6@7c. Demand has slackened some, and to make sales we must shade above prices. About Jan. 15 we expect a more active demand.
Dec. 31. F. O. STROHMEYER & CO., 122 Water St.

PHILADELPHIA.
HONEY.—Fancy white 1-lbs., 13@19c.; fair 1-lbs. 17c.; dark 1-lbs. are slow sale at 14@15c.; fancy 2-lbs., white, 15@16c.; buckwheat fancy 1-lb., 13@14 cts.; common, 12c. Prices tend downward.
BEESWAX.—23@24c.
Dec. 11. ARTHUR TODD, 2122 N. Front St.

MILWAUKEE.
HONEY.—Choice white one-lb. sections, 18@19c.; 2-lbs., 15@16c.; 3-lbs., 14@15c. Dark and broken not quotable. Extracted, white in kegs and tin, 9@9½c.; ½-barrels and barrels, 8½@9c.; dark and mixed in same, 6@7c. Market slow; better demand expected.
BEESWAX.—22@25c.
Feb. 2. A. V. BISHOP, 142 W. Water St.

SAN FRANCISCO.
HONEY.—We quote: White to extra, 15@18c.; amber, 13@16c. Extracted, white liquid, 7@7½c.; amber and candied, 5¼@5½c. Market quiet.
BEESWAX.—20@24c.
Feb. 4. SCHACHT & LEMCKE, 122-124 Davis St.

BOSTON.
HONEY.—We quote: 1-lb. sections, 16@17c.; 2-lb. sections, 14@15c. Extracted, 8@9c. The market is not very brisk and sales are slow.
BEESWAX.—25 cts. per lb.
Jan. 12. BLAKE & RIPLEY, 57 Chatham Street.

KANSAS CITY.
HONEY.—We quote: Choice white 2-lb. sections, 17@18c.; dark 2-lbs., 14@15c.; choice white 1-lb., 18 to 20 cts.; dark 1-lb., 15@16c. White extracted, 7@8c.; dark, 5@6c. Demand is light.
BEESWAX.—21 to 22c.
Jan. 10. HAMLIN & BEARSS, 514 Walnut St.

DENVER.
HONEY.—Best white 1-lb. sections, 19@20c.; 2-lb. sections, 16@18c. Extracted, finest grade, 12¼c.; dark, 8@9c.
BEESWAX.—20@23c.
Jan. 16. J. M. CLARK & CO., 1409 Fifteenth St.

SAN FRANCISCO.
HONEY.—We quote: White comb, 17@19c.; amber, 12¼@15c. Light amber to white extracted, 7¼@8c.; amber, dark and candied, 6¼@7¼c. Market firm and stocks light.
BEESWAX.—22@25c.
Dec. 12. O. B. SMITH & CO., 423 Front St.

We Club the American Bee Journal for a year, with any of the following papers or books, at the prices quoted in the LAST column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

	Price of both.	Club
The American Bee Journal	1 00	1 00
and Gleanings in Bee-Culture	2 00	1 75

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

New Subscribers can obtain the full numbers for 1887 and 1888, for \$1.75, while there are any sets of 1887 left.

Look Over last year's numbers of the BEE JOURNAL, and if any are missing, send for them at once, as we have but few left now, and they are daily becoming less.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

This is the Time for reading. The long winter evenings can be utilized by reading up bee-literature. We have all the newest bee-books, and can fill all orders on the day they are received.

A Pocket Dictionary will be presented for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

We Club the AMERICAN BEE JOURNAL and the "Bee-Keepers' Magazine" for one year for \$1.40; or with "Gleanings in Bee-Culture" for \$1.75; or with the "Apiculturist" for \$1.80; or the "Canadian Honey-Producer" for \$1.30; with the Bee-Keepers' Review, \$1.40; or all six for \$4.00,

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. Feb. 22, 1888. No. 8.

EDITORIAL BUZZINGS.

"All is not gold that glitters."

Worth is not measured by show.

Noise is not always productive.

Works make the world's clock go.

The drone is the noisiest bee in the hive,
Yet he brings not a drop to keep him alive.
The plain busy workers are early afield,
And by constant labor their worth is revealed.
—EUGENE SECOR.

Mr. W. Z. Hutchinson is seriously ill; lung trouble being added to his fever. This will retard his recovery. This is particularly unfortunate at this juncture in the history of the *Review*. We hope to be able to give better news next week.

Died at the residence of her son, W. O. Titus, 86 Hicks St., Toledo, O., on Feb. 5, 1888, at 3:30 p.m., Mrs. Eliza Titus, aged 76 years. Mr. Titus is one of the BEE JOURNAL family, and an ardent lover of bees. Since losing his wife several years ago, he has devoted his attention and energies to his widowed mother, who has been in her second childhood for years, as though she was all he had on earth to love. We condole with our brother in his bereavement.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Scatter the Leaflets.—Look at the list (with prices) on the second page of this paper.

Alsike and Melilot.—Mr. Peter J. Bates, of Whitehall, Ills., writes for information as to these two honey-plants :

As there is scarcely any Alsike, and to my knowledge no sweet or mellilot clover grown in this locality, and as most of the farmers consider the two as one plant, to describe the difference, if there is any, in a short article in the AMERICAN BEE JOURNAL, would be very satisfactory to me and to others wishing to propagate it.

Alsike clover and *mellilotus alba* are very dissimilar, as will be seen by the engravings of both, given on this page.

Alsike is a hybrid of the red and white clovers. The stem and the branches are

ALSIKE CLOVER.

finer and less woody than the red. It does not turn black, but remains the color of well-cured timothy. It has, as the engraving shows, numerous branches, and a multitude of blossoms which are very rich in honey. The blossoms at first are white, but soon change to a beautiful pink, and emit considerable fragrance. The leaves are

MELILOT CLOVER.

oval, of a pale, green color, and may readily be distinguished at any stage of their growth from the white or red clover, by the total absence of a pale, white blossom on the upper surface of each leaf.

Melilot is a biennial, and blooms from the middle of June until November. It is hardy, and flourishes on any soil. Its flowers are very modest, but perfume the air generously in all the surrounding locality. Both plants are alike in one thing—they supply the bees with nectar plenteously, and the honey from the bloom of each is of the best quality.

The Bee-Keepers' Union needs a thousand more members. It now takes only one dollar a year as membership fees, and no more will be asked for unless the members vote it themselves. Why there are not ten thousand members is the great mystery. The following letter from Mr. J. Few Brown of Winchester, Va., sets a good example, and speaks in a business-like manner :

I have read Mr. Z. A. Clark's letter in regard to his arrest by order of the Mayor of Arkadelphia, Ark., and your note urging upon bee-keepers the importance of paying their dollar and joining the Union, thereby assisting in "lifting up a successful standard" against the ignorant and prejudiced enemy, and also securing for themselves the benefit of the Union, should necessarily arise.

Although I have paid my dues to the Union for the present year, I hereby authorize you to draw on me at sight for \$3 more, if you fall short of the amount needed in assisting Mr. Clark in defending his suit, and present certificates of membership to three of the most likely persons to have similar action brought against them. I do not imagine there is a single bee-keeper who would not be willing to give 3 or 10 pounds of honey each season to assist a brother bee-keeper out of trouble, and why not give a dollar, especially when they know not when they may be the beneficiary themselves.

The past season was the poorest, except one, for honey in this locality we have had for twenty years, and the hardest in my experience for selling what little was produced. I think bee-keepers might help the demand for their product if they would form themselves into a committee of the whole, and resolve whenever they take a meal from home, especially at a hotel or public house, to ask for honey, even if the meal costs a little extra.

Mr. Arthur Todd, of Philadelphia, Pa., died on the 11th inst., and was buried on Tuesday, Feb. 14, 1888, at 2 p.m. We hope to be able to give a biographical sketch in our next issue. We know nothing of the cause of death, and hence it is the greater surprise. His age was 46.

When last we met it was in Paris, France, eight years ago, and we then took a voyage together between heaven and earth, in a balloon. It was a very pleasant visit we then had. Since then he came to America, settled in Philadelphia, and was a prominent member of the Philadelphia Bee-Keepers' Association.

The Lecture of Prof. N. W. McLain, which we mentioned sometime ago, is to be delivered before the "Academy of Sciences" at Stevens' Art Hall, 24 Adams-st. Chicago, on Monday, Feb. 27, 1888, at 8 p.m. The subject will be the "Construction and function of bees;" which will be illustrated by large charts. Prof. Higley will preside. Seats will be free, and all will be welcome.

This is the Time for reading. The long winter evenings can be utilized by reading up bee-literature. We have all the newest bee-books, and can fill all orders on the day they are received.

BOOK REVIEWS.

BEEES AND BEE-KEEPING.

Mr. Cheshire's second volume, entitled "Bees and Bee-Keeping," is on our desk. It contains 650 pages, and is nearly twice as thick as the first volume, which was devoted to the "Scientific" portion. This book presents the "Practical" part of bee-keeping. Like the former, it is beautifully printed and bound, in the highest style of the art. These volumes can be obtained at this office: Vol. I, \$2.50; Vol. II, \$3.00.

After reviewing the Langstroth and Quinby hives, the Bingham hive is described and the author remarks concerning it:

If the bees are to be examined, the hive can be opened at any desired spot; increase or decrease, division or union; even tiering up, can be performed with celerity. For the latter purpose, however, the Bingham hive is most suitable.

Mr. Cheshire then introduces and illustrates the Heddon hive, and of the divided bee-spaces remarks:

This principle of allowing a half bee-space above and below, in each horizontal section of the hive, so that the needed $\frac{3}{8}$ -inch, and no more, is given in any possible combination, is a salient and new feature in the Heddon.

The queen-excluding honey-board with alternate perforated zinc and wood strips, as used on the Heddon hives, is approved by Mr. Cheshire. While criticising and disapproving of the "close-ended frames" of the Heddon hive, he says:

We must, to be fair, remember that the idea is to manipulate hives, not frames, and that almost every required operation can, it is held, be performed without the removal of the latter.

After comparing it with Mr. Hooker's (English) hive, the author remarks thus:

It would be both unphilosophical and unfair thus to dismiss the Heddon without noting that it has called our attention to some points of great moment, and that it has also interwoven with old plans, novel methods which will hereafter make their mark. It is narrowness, not patriotism, that would deny to one of another country his full meed of praise, and I conceive that the unprejudiced will not dispute that the half bee-space in each hive section, and in the bottom-board—the narrow, abutting edges, giving possibility of rapid handling—and the general invertibility of the whole, although associated, perhaps, with some crudities, yet mark another hill-top passed in the progressive march of practical apiculture.

The "Alley drone and queen trap" is illustrated and described, with others of English make. They call them "swarm arrestors." What we call "comb foundation," is herein named "wax midrib." The Root, Van Deusen and Pelham comb foundation is described, after giving a general history of the invention. Of bee-smokers, Mr. Cheshire, after mentioning many kinds, remarks thus:

All the different forms of these are practicably reduced to two—the Bingham and the Clark.... The Bingham is mostly used, and is my preference.

Mr. Henry Alley's method of queen-rearing is fully described and illustrated. Mr. Cheshire disagrees with Mr. Alley in some details of management.

Folding or one-piece sections are described, illustrated and approved, and many section-cases are represented.

The history of the honey-extractor is recounted, many kinds are delineated, and the salient points of each detailed. Of uncapping knives, Mr. Cheshire remarks:

Thin-bladed knives, turned up near the end, to permit of cutting into hollows, are frequently used, but the Bingham-Hetherington knife is justly the favorite. The stout blade is so beveled that it must be kept up from the comb, whereby the "cling" is greatly reduced. The edge should be keen, and the hollow front permits of sharpening on a bone. It is helpful to use the knife hot; the best plan being to have a pair—one standing in heated water while the other is in hand. The water should not boil, or the wax will be melted and adhere to the knife, delaying the operation.

But we cannot pursue it further in this brief review. It is a pity that the book should have been published in "parts," for, when put together, its subjects are considerably mixed up, and there is some repetition. The chapter on hives is bewildering, especially to a beginner. If the book had been written more concisely, and less of the minor details given, it could have been published in one volume, and would have been far more acceptable to American readers. Its price is not excessive for the amount of matter given, but at one-third the price with a corresponding quantity, it would have found its way into thousands of apiaries where now it will never be seen.

We are sorry to notice that the author used the adjective "apiarian" instead of the noun "apiarist." He repeatedly calls queen-rearing, queen-raising; and also mentions drone-raising and worker-raising. In speaking of laying worker-bees, he incorrectly calls them "fertile workers."

While he enumerates many American inventions, methods, and prominent apiarists, several of the latter are conspicuous by the absence of their names, which cannot be accounted for by an oversight. This, with some other defects we have noticed, prove the correctness of the poetic quotation on page 195 of his book:

"He that expects a perfect thing to see,
Expects what ne'er was, nor is, nor e'er shall be."

"The Western Bee-Keeper," especially adapted to apiculture in the Mississippi Valley—West, Northwest and Southwest," is the title of a new quarterly published by Joseph Nysewander, Des Moines, Iowa, at 25 cents a year. The first number came to hand on the 13th, just as our last issue was printed. It contains 16 pages, is nicely printed, and has 12 pages of reading matter, comprising many items of interest. This makes the second bee-paper already started in the first month of a year succeeding the most notable failure of a honey crop in a decade. The nerve of the publishers deserves success, and their papers are a credit to the pursuit.

GLEAMS OF NEWS.

Bees Gathering Honey in January.—H. G. Burnett writes to the Florida Farmer and Fruit Grower, as follows:

It does the heart of the bee-keeper good to hear the bees hum in these bright, sunshiny January days. How busy they are! From daylight till dark they are busy rifling the purple bloom of the pennyroyal of its hidden nectar. I pause frequently in my work in the nursery or garden, thinking I hear a "swarm," but it is the roar of the wings of the busy thousands going or returning heavy laden with their precious spoils. It reminds me of my experiences in old Iowa, during a good "clover season," only the clover bloom seldom lasted over a month, while the pennyroyal lasts four months here.

Bees are now building up—some even starting queen-cells for swarming—and all are fast filling the upper stories of the hives with the thick, heavy, minty-flavored pennyroyal honey.

I have seen bees at work late in the day on pennyroyal bloom that in the morning was white with frost. The pennyroyal is very persistent in honey secretion. I have watched the bees working on one clump of plants day after day for over three months, and have counted over a dozen bees at work there at one time, and if the day and hour were propitious, never less than half a dozen, yet the "supply" seemed equal to the "demand."

The General Opinion is that the bees are wintering finely so far. Mr. T. F. Bingham writes: "Here the bees are wintering very finely, I think, though they have yet had no chance to fly."

Mr. C. H. Dibbern, of Milan, Ills., on the 4th inst., wrote as follows:

We have not had a day warm enough for bees to fly, for more than two months. This morning it was 22° below zero. Bee-keepers who winter out-doors, will lose disastrously. Mr. Wright, near Davenport, Iowa, has already lost 100 colonies out of 140. Others in this vicinity have suffered nearly as much. Bees in winter repositories are all right.

Mr. C. H. Putnam, of Galesburg, Ills., on Feb. 8, wrote as follows about the bees:

Having just examined my bees, I can report that, thus far, they are in excellent condition, and are wintering finely. They are very quiet, and no signs of disease are visible as yet.

I have now 114 colonies, which were put into winter quarters on Dec. 12 and 21, 1887, which was the latest they ever remained out. They are in two double-walled beehouses, where successful wintering has been the rule for several years.

The temperature at which the bees remain in the most quiet state is 42° to 45° above zero. Last season was the poorest that I have known in the 15 years I have been in this locality. I had only one new swarm, and no surplus honey worth mentioning from 113 strong colonies in the spring of 1887. The most of them had sufficient honey to carry them through the winter, though lest some might come short I fed a quantity of old extracted honey remaining on hand. Last fall I weighed each colony separately, and allowed them from 30 to 35 pounds of honey each, after deducting the weight of hive, frames, combs, etc.

While it is rather discouraging to contemplate the dismal failure of the past year, it may yet prove a "blessing in disguise," and if we only have a good season this year, I shall not complain.

BIOGRAPHICAL.

Wintering Bees in the South by Mr. T. F. Bingham.

In continuation of the biographical article on page 21, we here present some items of interest in addition to those there found, giving his experience in wintering bees. We also present another and better engraving.

In my hastily-written sketch, on page 21, I think that perhaps I omitted some facts that would interest the readers of the AMERICAN BEE JOURNAL, if they are not of profit to them, viz: No mention is made of my change from New York to Michigan. I sold out my apiary in Gowanda, N. Y., in 1867—all the bees but one colony, which I went to Allegan, Mich., to which place I went to carry on the jewelry business. Immediately upon locating there I bought 20 colonies of bees, which, on the approach of winter, were put into the cellar under my house. In January and February, after I was through business at the store, as I had no time by daylight to do the transferring, the 20 colonies were transferred by lamp-light in my kitchen, to shallow framed hives, and returned to the cellar again.

The following spring and summer were favorable, and the bees did well. In the next season I bought 60 colonies more, and soon had them in flat hives also, and a season's product of fine honey was the result. The winter was provided for by enlarging the cellar under my house, so as to hold my stock, then about 150 colonies.

This was the winter following the National Convention held in Cleveland, the one over which the lamented M. Quinby presided. Fatal results followed that winter, and by the first of May I had but 22 colonies, and small at that. However, the next season was good, and 90 colonies with considerable extracted honey were ready for another winter's trial.

Disgusted with my last cellar experiment, I built a frame building large enough to hold 150 colonies, placed on shelves around the walls. This bee-depository was all above ground, but had a cement floor (plastered on the gravel). The walls and gable were filled with dry planing-mill shavings. The bees wintered finely. The following May my bees were all taken to Abronia, which, at that time, was all timber, about 10 per cent. of which was basswood.

A two-story bee-house was built there, and arranged for outside warming. The walls were thick, and filled with sawdust, and shelved, as was my bee-house in Allegan. The season was good, and I had a large crop of fine basswood honey, and a big fall crop of bonaset on which to winter my bees. They did not do well. May found me again with only 24 weak colonies out of 250, fall count.

I purchased all the bees I could find to recruit my apiary and save my combs.—Only a few, however, could be found, as nearly all the bees in the county had died.

That season my honey returns were small, but my combs were saved, and I had 180 colonies for my depository again, and all the hives were full of bonaset honey, as in the previous autumn. They were left later on the stands, and as death seemed to have hold of them again, the depository was warmed slightly, with a faint hope that it would be of value to the bees.

May again found me with 16 colonies. Bees were now bought in Kentucky and Tennessee to stock up my apiary again. My combs were again filled, and my decision was made to take my bees, with hives again full of bonaset honey, to Tennessee to winter. With hope, in November, the car was

started for Edgefield Junction, 10 miles from Nashville, as the place for the experiment.

The same diarrhea showed itself there, though the bees could and did fly as often as once in ten days. The spring dwindling was heavy, but not fatal. Nearly all the colonies came up to time, and were again taken to Abronia for a summer's work. In moving, however, all the unsealed brood was taken out, and breeding stopped. Cold weather followed, and at the end of a month, when clover was in its prime, I had only a few bees to gather honey.

Basswood, however, gave my then populous colonies a fine run, and I had honey to sell, besides 200 colonies ready for Tennessee again. I had determined again to winter there, and return a little later, and put in practice some points gained.

Accordingly, in September, nearly all the honey was extracted, and the bees put on board of a car. The weather became hot, but only one colony was injured in transit. The asters of Tennessee bloomed a few days after my arrival, and the bees got all the honey needed for their winter use.

On the aster honey they prospered finely. There was no spring dwindling, and no tired, worn-out bees, and spring breeding

houses would hold 3 colonies each, and an extra set of frames to each hive, (that is, one hive above the other), the two having but one bottom-board. Around the three hives, on all sides and beneath, 7 inches of after-math, or fine hay was packed; while on top of the two sets of frames (constituting one hive for winter), 14 inches of fine hay was packed.

This plan proved a success, and cheaper than Tennessee wintering and transportation combined. The first winter, however, demonstrated that the entrances were liable to become clogged with dead bees. To avoid this danger, a rim or frame the size and shape of the bottom of the hive, was made and put on the bottom-board for winter only. This rim raised the combs 2 inches from the bottom-board, and allowed all the dead bees and litter to remain beneath the combs, without detriment to the bees. This plan, and the absence of bonaset honey for winter, has enabled my bees to winter with safety and success.

T. F. BINGHAM.

ITEMS OF INTEREST.

A New Postal arrangement has been made between the United States and Canada, to go into full effect on March 1, 1888. Articles will be allowed to go into either country if admitted by the domestic law of either, except sealed packages (which are other than letters), and publications which violate the copyright laws of the country of destination, liquids, etc.

All articles exchanged under this arrangement are required to be *fully* prepaid with postage stamps, at the rate of postage applicable to similar articles in the domestic mails of the country of origin, and are required to be delivered free to addresses in the country of destination.

Articles other than letters, in their usual and ordinary form, on their arrival at the Exchange Post-Office of the country of destination, will be inspected by custom officers of that country, who will levy the proper customs duties upon any articles found to be dutiable under the laws of that country.

More Bumble-Bees for Australia.—The clover in Australia is in danger of dying out, because of the lack of sufficient bees to fertilize the blossoms. Several large quantities of bumble-bees have been sent there for that purpose, and now we note by the following from the Pittsburgh, Pa., *Commercial Gazette*, that another shipment is to be sent from Kentucky:

Joseph McDonell, of Lexington, Ky., has achieved prominence lately by his expressed desire to buy \$10,000 worth of Kentucky bumble-bees that understand the management of clover. They are to be sent to Australia to assist in growing clover there by carrying pollen from bloom to bloom. A gentleman who came from Australia last fall, and bought some stock from Mr. McDonell, made the arrangement with McDonell to supply him with the bumble-bees, and they will probably be gathered from the crop of next season. It has been known for years that it was necessary to have them in Australia. It will make business for the small boy of this country, and fun for the Australian school-boy in time to come.

MR. T. F. BINGHAM.

went on apace. Dr. Hamlin's apiary was then about a mile from my bees. Now was a good time to note the breeding qualities of my half-depth, no-bottom frame by the side of the standard Langstroth frame, under similar circumstances, and in large numbers (not one, single, isolated trial), as Barnum and Peyton, then the owners of the lamented Dr. Hamlin's apiary, had about 200 colonies. The result pleased me, and was a great wonder to the deep-frame men.

This time the hives were brought home packed with mature bees, just in time for clover bloom. They came safely, all but 3 colonies, which, while standing over Sunday on a side-track in southern Michigan, partly melted down, and failed entirely. The unsealed brood in all the hives had been taken out by the bees, and I had as before only old bees left to keep up the work of the hive and gather honey.

The results were no better than before. I got the clover yield, but failed to get the basswood. I had, however, some honey to sell, but my hope of wintering bees in the South and getting their honey in the North, advantageously, had been blighted. I should not again try the experiment.

I am now resolved to make small, one-roofed houses, each of all the six sides to be separate panels, and the corners to be held with short pieces of hoop-iron. These

QUERIES AND REPLIES.

WATER FOR THE BEES IN WINTER QUARTERS.

Written for the American Bee Journal

Query 517.—Is it essential to water bees while they are in winter quarters?—C. K., Minn.

No.—DADANT & SON.

No.—J. P. H. BROWN.

No.—JAMES HEDDON.

No; and do not do it.—R. L. TAYLOR.

Not if they are quiet.—M. MAHIN.

All of my experience says, NO.—G. M. DOOLITTLE.

Sometimes it is, and sometimes it is not.—A. B. MASON.

I have never found it so.—J. M. SHUCK.

It might be under certain circumstances, though I have never done so.—J. M. HAMBAUGH.

If in a cellar, yes; say twice a month, during February and March.—MRS. L. HARRISON.

I think generally not. I do not water mine.—C. C. MILLER.

I do not know. Many say that it is necessary toward spring, when they begin breeding.—W. Z. HUTCHINSON.

Under ordinary circumstances bees do not require water while in winter quarters.—C. H. DIBBERN.

Not at a low temperature; but if bees become uneasy at a high temperature, water will tend to keep them quiet.—H. D. CUTTING.

I have never considered it so. I give water, though, in early spring, after breeding has fairly started.—J. E. POND.

No; and as bees winter admirably with no pains or care of this kind, I do not think that it is advisable.—A. J. COOK.

I have no experience. We let our bees, here in the South, remain on the summer stands all the year round, and in winter it is very seldom that they are 3 or 4 days without a flight.—P. L. VIALLON.

I would not think it necessary or desirable, unless toward spring when they begin to breed and are uneasy. Then, if a little water will quiet them; it may be a good thing. I have never practiced it but one year. It is too much labor.—EUGENE SECOR.

I do not think that bees need water in their winter quarters, unless they are in a very dry place, and kept at a high temperature. I came very nearly drowning a colony in the cellar some

weeks ago, while experimenting with an enameled cloth over the frames.—G. W. DEMAREE.

I have tried it, but I did not think that it did any good. Last winter I had a few colonies that were uneasy in February, so I gave them water in fine shavings of the poplar. I saw them lap it up, but it did not quiet them. A flight did.—G. L. TINKER.

It is not essential, but some do provide water for those in cellars when they commence to breed in the spring.—THE EDITOR.

WHICH SIDE OF A HILL FOR WINTERING BEES?

Written for the American Bee Journal

Query 518.—In wintering bees out-doors, would it be better to have the apiary on the south side of a hill, facing south, where the hives get plenty of sunshine; or on the north side of a hill, facing north, and no sunshine, as some have contended?—Bee-Keeper.

I would take the south side.—W. Z. HUTCHINSON.

Give me the southern slope, every time.—G. M. DOOLITTLE.

Give them all the sunshine possible.—M. MAHIN.

The south side forever, in out-door wintering.—MRS. L. HARRISON.

I prefer the south side for this locality.—H. D. CUTTING.

The south or southeast hill-side is my preference.—J. M. HAMBAUGH.

On the south side, by all means, in my judgment.—J. E. POND.

In a northern climate, I should much prefer the south side.—R. L. TAYLOR.

I should say on the south exposure. But it may depend upon the climate somewhat.—EUGENE SECOR.

Facing south, by all means, if you do not want to lose your bees. There is nothing worse than a northern exposure.—DADANT & SON.

I prefer the apiary on the north side of the hill in a warm climate, and on the south side in a cold climate.—J. P. H. BROWN.

I would prefer a southeastern slope to my apiary grounds. But I have had my apiary on four sites in the past, differing widely from each other, and I have really seen but little difference as to the results.—G. W. DEMAREE.

I would give them all the sunshine possible, in out-door wintering. I have been experimenting on this line for a number of years, and I almost invariably find that those colonies winter best that are protected by a tight board-fence, or other protection from the north and west, and have the most sunshine. I am trying a plan now, by

raising the rear of the hives to an angle of 45°, facing south. Of course it is necessary to shade the entrance during bright, sunny days, while a light snow is on the ground.—C. H. DIBBERN.

I should not choose either location, but if obliged to use one or the other, I would choose the south side, and shade the hives.—A. B. MASON.

Here in the South our bees remain on the summer stands during winter, and I have always found those that have the full benefit of the sunshine in winter fare better than those that are too much in the shade.—P. L. VIALLON.

I should prefer the south side. While I may be wrong, I believe in a south slope for the bee-yard.—A. J. COOK.

I have had much experience in out-door wintering, and I prefer all the sunshine I can get, for the purpose.—J. M. SHUCK.

I prefer the south side of the hill; and if at any time the sun should tempt the bees out when they ought not to fly, place a small shade-board in front of the entrance.—JAMES HEDDON.

I would prefer an apiary on the south side of a hill. The more sunshine there is, the better. To-day (Jan. 24) I saw bees flying in the bright sunshine, with the mercury 26° in the shade. But few came out, and all got safely back.—G. L. TINKER.

I am not sure which might be better for the winter alone, but as the bees would probably stay in the same place during summer and winter, I should much prefer the south side.—C. C. MILLER.

In a northern latitude, place the bees on the south side of the hill. In the South some prefer the hives to face the north, but all desire them to have all the sunshine possible.—THE EDITOR.

CONVENTION NOTICES.

☞ The second annual meeting of the Southwestern Iowa Bee-Keepers' Association will be held at the Court House in Red Oak, Iowa, on March 6 and 7, 1888, when these subjects will be treated: Spring dwindling and how prevented—What time to transfer and Italianize—Spring management of bees—What are the most essential points in locating an apiary?—What size, width and form of section for comb honey?—Extracted honey, what should be its price compared with comb honey?—The sectional brood-chambers of bee-hives—Wide frames or section cases for comb honey—Use of comb foundation in Southwestern Iowa—Should the upper story of hives be double or single thickness for the production of comb honey? All bee-keepers are invited. Come prepared with questions for the Query-Box. Ladies are specially invited. E. W. FITZER, Sec.

☞ The Hardin County Bee-Keepers' Association will meet at the Court House in Eldora, Iowa, on the second Saturday in each month, at noon (12 o'clock), until further notice.

J. W. BUCHANAN, Sec.

☞ The next regular meeting of the Susquehanna County Bee-Keepers' Association will be held at New Milford, Pa., on Saturday, May 5, 1888.

H. M. SEELY, Sec.

CORRESPONDENCE.

SONG OF THE BEES.

D. AIKEN.

We watch for the light of the morning break,
And color of the grey eastern sky,
With its blended hues of saffron and lake,
Then say to each other, "Awake! Awake!"
For our winter's honey is all to make,
And our bread for a long supply.

Then off we vie to the hill and the dell,
To the field, the wild-wood and bower,
In columbine's horn we love to dwell,
To dip in the lily with snow-white bell,
To search the balm in its odoriferous cell,
The thyme and the rosemary flower.

We seek for the bloom of the eglantine,
The lime, painted thistle and brier,
And follow the course of the wandering vine,
Whether it trail on the earth supine,
Or 'round the aspiring tree-top twine,
And reach for a stage still higher.

As each for the good of the whole is bent,
And stores up its treasure for all,
We hope for an evening of heart's content,
For the winter of life without lament,
That summer is gone, with its hours misspent,
And the harvest is past recall.

DRONES.

At what Age are Drone-Bees
Disposed to Mate?

Written for the American Bee Journal

BY REV. L. L. LANGSTROTH.

Since writing my last article, on page 55, I have had the pleasure of seeing the first volume of Mr. Cheshire's admirable contributions to the physiology of the honey-bee. Without defining the time when the drone is disposed to mate, Cheshire demonstrates microscopically that the drone cannot be fit for this office until it is several days old at least, and my observations seem to show that sexual desire comes much later.

Mahan, as stated in my work on bees, seems to have first made the important observation that drones leaving the hive to mate, have a large supply of honey, which on their return is found to have been almost entirely consumed. I did not ascertain how many marital excursions the drones would average on a single day, but as they are often flying in favorable weather about three hours, it seems probable that a drone makes three such trips at least. To do this, the drone must consume twice as much honey as a swarming worker whose honey-sac carries from the hive almost a week's supply. The importance of preventing any over-production of drones is therefore obvious without further comment.

Let me here make some suggestions to those who think it best to exclude all drone-comb from most of their col-

onics. I say *suggestions*, because I fully realize that after being wholly precluded by ill-health, from the practical management of bees, for most of the last fifteen years, it would ill become me to speak in too confident a tone. In limiting the production of drones to just as few as we think will be needed for the timely fertilization of our queens, may we not go contrary to those wise precepts, "There is that scattereth and increaseth yet more; and there is that withholdeth more than is meet, but it tendeth only to want?" It is very easy to take it for granted that every bee in a healthy, populous colony, will do all that it possibly can for the prosperity of the hive, even in the entire absence of drones. So it is easy to assume that every bee in an "artificial" swarm will work just as well as it would in a natural one. But who that has had a large experience with both methods, can deny that for the production of comb honey at least, the natural swarm has that spur in the head, which artificial processes never seem to give it? Is it not reasonable to think, that for its highest prosperity, every colony of bees should be in a normal, that is to say in a natural condition?

What can be more certain than that strong colonies with very few or no drones, in the very height of the honey-harvest when such colonies crave them so much, are not in a proper condition to stimulate them to do all that they are able to do? Their owner may know that in his apiary there are drones enough for all needed purposes; but how is he to impart this information to the droneless colonies, when every healthy colony, by the fiat of the Creator, seeks such conditions as would be proper, if there was not another family of bees on the face of the earth? So far, therefore, from grudging to any colony a goodly number of drones, I would prefer to have one-third drone-comb in one of the central combs of the hive of each breeding colony.

I will conclude this article by giving some observations which show that to insure the mating of queens, many more drones seem to be needed than is commonly supposed. At the time I made my observations in 1885, a drouth had cut off the gathering of honey for so long a time, that I had no reason to suppose that any drones could be found for the mating of my queens, except such as I had bred and kept alive by daily stimulative feeding. Now for over two weeks, I had more than a dozen young queens which flew out nearly every day for mating, and some of them I know made several excursions on the same day. I had over 200 drones, and yet only a single queen

laid any eggs. When the weather became too cool to expect any favorable results, I dissected the other queens and found that none of them had mated. Now when my apiary was so largely devoted to queen-breeding, and I had thousands of flying drones, I had great success in the mating of queens at the same time of the year, and under circumstances no more favorable than when in 1885 I so signally failed.

Dayton, O., Feb. 10, 1888.

STATISTICS.

Securing the Statistics of Bee-Keeping.

Written for the American Bee Journal

BY J. M. YOUNG.

As the Statistician of the Department of Agriculture wishes statistics about bee-culture, so that a full and complete report can be made of this special industry, it is the duty of every bee-keeper throughout the country to assist in making out a report in regard to bees and honey. This matter has been referred to me to obtain as far as possible, this information from eastern Nebraska.

The matter of obtaining correct statistics is one of no small moment, and yet if every bee-keeper who reads this will lend a helping hand, and "put a shoulder to the wheel," a vast amount of information may be gained with but little labor. These reports, when all are in, or as many as we think we can get, will be forwarded to the Statistician of the Department of Agriculture, and very likely be published. Therefore every friend to the progress of bee-culture is earnestly requested to assist in making these reports as complete as possible. Let every bee-keeper in eastern Nebraska, who may read this article, send to me his name and full address; the number of colonies of bees that he had in the fall of 1887; how many in the spring of 1888; how wintered, in-doors or out-doors; and, if possible, how many pounds each, of comb and extracted honey obtained last year; the number of pounds of beeswax, and whether movable-comb or box-hives are used in the apiaries.

Send to me not *your own* statement simply, but that of your neighboring bee-keepers who you have reason to believe do not read bee-papers, and who are not likely to send in their own reports. If you do not choose to write a letter, the whole thing can be written on a postal card. Write very plainly, and address, J. M. Young, Rock Bluffs, Cass Co., Nebr.

SOME REPLIES,

To Questions which All were Invited to Answer,

Written for the American Bee Journal
BY C. P. HEWETT.

The questions were published on page 42, and are as follows :

1. How many keep a daily record of the temperature and degrees which they prefer in their depositories ?
2. How many believe in hibernation ?
3. How many can winter colonies on from 3 to 6 pounds of stores ?
4. How many have had bees steal eggs, and from them make queens ?
5. How many have had queens fertilized that did not leave the hive ?
6. How many have had queens become re-fertilized ?
7. How many have had queens die with the drones, on their bridal trip ?
8. How many have had bees hibernate, and remain so until taken out in the spring-time ?
9. How many can tell that they have a queenless colony in their apiaries, by seeing bees trying to steal eggs, before they notice the colony which is queenless ?
10. How many know that there is no vitalization in some queens' eggs, when they first commence laying in the spring, and the bees have no regard for her, more than any other bee, and swarm out ?

Harvey Feathers, of Royalton, Wis., sends the following answers :

1. I do. I prefer from 40° to 42° for very populous colonies, and from 48° to 50° for less populous ones.
2. I believe that the dormant state that the bees enter into when wintering well, might as well be called hibernation.
3. I cannot winter a colony on from 3 to 6 pounds of stores, through one of our winters of 5½ months.
4. I do not believe that bees steal eggs.
5. I do not believe that queens are ever fertilized in the hive.
6. I am doubtful if they ever are re-fertilized.
7. I have had queens that never returned from their bridal trip.
8. I have.
9. I cannot tell.
10. I do not. I do not believe that is the cause of bees swarming out in the spring-time. I have had a colony swarm out and cluster on a bush; while there, I cleaned the hive and combs real clean, and returned the bees. They staid and did well that season.

W. H. Stewart, of Kimball, Dak., answers some of the questions as follows :

1. I keep a record of the temperature in the bee-cellar, and I prefer that of 45°.
3. I have several times wintered full colonies of bees on from 3 to 4 pounds

of stores, and I can do it any time if I wish to do so, and have them come out in the spring as good in every respect as though they had consumed more.

7. I have had several queens to die with the drone on their bridal trips.

S. W. Conrad, of Hanford, Calif., replies to a few of the questions in the following manner :

3. I have wintered a colony on from 5 to 7 pounds of honey.

4. I have seen my bees steal eggs and rear queens therefrom.

5. I have had queens fertilized that did not leave the hive to meet the drone.

7. I have seen dying queens attached to the drones after the bridal trip.

HORTICULTURE.

Are the Bees our Friends?—The Vice-President's Address.

Read before the Iowa Horticultural Society
BY EUGENE SECOR.

In some localities, where grape-growing is the chief industry, and where, in certain seasons of the year, or in seasons peculiar in themselves, the honey-bees have given the growers more or less annoyance, some persons who have not studied the structure and habits of bees, and whose observations have not been as careful and thorough as the subject demands, have been ready to declare them a nuisance, and to banish them as an enemy to horticulture. Hence the question at the head of this essay is not only an interesting one, but important.

That they do, occasionally, annoy grape-growers, and perhaps others, is true. Those of us who keep dairy cows know that *they* sometimes break out of their proper enclosure, and give us trouble and annoyance in consequence; yet we should hardly be willing to forego the luxuries which they furnish us, nor forget their general usefulness, on so slight a fault. If good qualities over-balance the bad, bees cannot be an unmixed evil.

On the theory that everything was created to serve some good purpose in the economy of nature, what was the purpose in the creation of the honey-bee? Was it only that man's palate might be tickled with the delicious nectar which she finds hidden in the delicate chalice? I think not. The honey is of only minor importance. I believe that it was the Divine purpose to minister to our necessities and enjoyments, but in a different and more important way. "Male and female

created He them" was no less true of plants and flowers than of man.

In a good many of the species the sexual organs are not in the same flower. In others they are developed on distinct plants. In still others, although the flowers are hermaphrodite, the anthers and stigmas do not ripen at same time. Some means of carrying the pollen-dust from flower to flower, or from plant to plant, is necessary.

The wind is one of the fertilizing agencies, but the wind does not always blow during the brief opportune period when the pistils are ripe for receiving the life-giving dust; and if rains are frequent, thus keeping the pollen-germs too damp to be easily carried by the favoring breeze, many plants would fail to mature seed and fruit, but for the insects that perform this important service.

Charles Darwin, that eminent English naturalist, whose careful experiments have added so much to our knowledge of plant and insect life, states in his work on "Cross and Self Fertilization," that out of 125 species that he covered with netting, excluding insects when in bloom, more than half were either entirely sterile, or produced less than half the number of seeds of the unprotected plants. I will cite one only of the many so treated by him, namely, white clover. I quote:

"Several plants were protected from insects, and the seeds from ten flower-heads of these plants, and from ten heads on other plants growing outside the net (which I saw visited by bees) were counted; and the seeds from the latter plants were very nearly ten times as numerous as those from the protected plants. The experiment was repeated on the following year; and 20 protected heads now yielded only a single aborted seed, whilst 30 heads on the plants outside the net (which I saw visited by bees) yielded 2,290 seeds, as calculated by weighing all the seed and counting the number in a weight of 2 grains."

He says: "The most important of all the means by which pollen is carried from the anthers to the stigmas of the same flower, or from flower to flower, are insects belonging to the orders of Hymenoptera, Lepidoptera and Diptera.

The bees are the love-messengers which carry on the courtship and hasten the marriage of the blushing blossoms. They furnish the means of locomotion, and make it possible for distant and non-related flowers to meet in happy wedlock. Other insects do, indeed, play some part in this important work, but no other honey-and-pollen gathering insect increases with such rapidity in the spring, before the fruit-trees and small fruits blossom.

Bumble-bees are the chief fertilizers of red clover, because of the length of the corolla, but as only the queen lives over winter, and it takes her so long to rear her young, the first crop is ripe before her progeny are numerous enough to do much good; hence only the second crop is depended upon for seed.

We have another eminent English authority (Cheshire) for the statement that gooseberries are absolutely dependent upon insects for fertilization. He states that the failure of this crop so often attributed to late frosts, is often due to non-fertilization. The same author also says in reference to apple blossoms, that the stigmas mature before the anthers, and that every blossom needs five independent fertilizations to make a perfect apple. He says that many of the wind-falls are traceable to imperfect fertilization. Out of 200 apples picked up at random after a wind-storm, all but eight were traceable to this defect. The reason nature has stored nectar in such abundance in the orchard fruit-blossoms, is to entice the bees to travel over them and thereby secure seeds to propagate the species.

But a still more important service rendered by them is that of cross-fertilization. Nature appears to abhor the marriage of near relatives. Many plants, although provided with both male and female organs in the same flower, are yet guarded from the baleful effects of in-breeding, by the anthers maturing at a different time from the stigmas, as before stated. Others are self-fertilizing, but at the same time are much more fertile if the pollen from a distant and non-related plant be applied. In other words, the pollen from a distant and non-related plant of the same species is much more prepotent than that from the same flower or same plant.

Darwin's pains-taking experiments with self and cross fertilization carried on for more than 17 years, and followed up with numerous plants to the tenth and twelfth generations, led him to these conclusions: First, that cross-fertilization is generally beneficial; second, that self-fertilization is generally injurious.

Now the especial province of pollen and nectar gathering insects is to insure the cross-fertilization which is so beneficial. Nature does not usually stake all her chances on a single per-venture. It is both increase and improvement that are desired. If entirely dependent upon insects, then without them there would be no seeds and no increase. If entirely dependent upon the wind, then during a calm the blossoms would die of sterility. I think you will find it true, however, of

every plant or tree that secretes nectar in abundance, thus inviting the frequent visits of bees or other insects, that it is either sterile without insect aid, or else the crossing thereby insured is highly important.

Cross-fertilization is one of the most interesting as well as important studies in horticulture and floriculture. Without it, advance is impossible. Every apple would be like every other apple, and every flower as stereotyped as a printer's proof. Variety in color, in flavor, and in fragrance are largely, if not entirely, due to cross-breeding.

In an essay read before the Nurseryman's Convention last summer, our President Patten stated that about 75 per cent. (and he might have said 95) of all our improved fruits had come by chance. How much of this, think you, was due to the busy bee, in its quests after the pearly drop of nectar hidden for its finding? "Her honey is but a fraction of the results of her labors. Man has had tiny helpers that he knew not of. While he, for *seasons*, has selected and hybridized, they, for *ages*, have, with their little powers, toiled along, perpetuating every movement of the world of flowers toward the beautiful."

The Bees and the Fruit-Grower.

Now as to bees injuring fruits: I said at the outset, that they occasionally annoyed the fruit-grower. Perhaps it would have been more proper to say "fruit-pickers." If grapes or other soft fruits get bruised in picking, or if they burst from over-ripeness or damp weather; or if from any cause the skin is abraded so the bees can get at the soft, sweet pulp, they will tumble headlong over each other in their haste to get at the booty.

Those who have made a scientific study of their structure maintain that a bee's mandibles are not formed for biting or cutting like those of the hornet or wasp. They can only mold the wax that forms the comb, at a high temperature. If they could bite the skin of a grape to get its juice, why do they not bite open the corolla of the red clover blossom to get the abundant nectar which they can scent but cannot reach? Here, again, Darwin's observations are valuable. He says that he has many, many times examined the blossoms of the red clover, and often seen hive-bees sucking the nectar from the sides of the corollas, near the base, from little holes bored through them; but he does not arraign the bees for boring these holes. They only appropriate what other insects have made it possible for them to obtain. He says:

"As far as I have seen, it is always bumble-bees which first bite the holes,

and they are well fitted for the work, by possessing powerful mandibles."

Perhaps it may not be generally known, that there is, in Illinois, an apicultural experiment station, established and supported by the government for the purpose of determining just such disputed questions as this.

In the Agricultural Report for 1885, may be found a very full account of the means used to determine the possible injury which bees can do to sound fruit. A large screen-house was built, and several colonies placed therein, subjected to all the conditions which might be supposed to increase their pillaging instincts, viz: drouth, warmth and starvation. After being kept confined in this condition for a few days, 23 varieties of grapes, besides peaches, pears and other soft fruits, were hung in the house or placed on shelves; and while the bees visited them constantly, in search of food, not one was injured by them. Others were dipped in honey. Of course the latter was quickly appropriated, but not a skin was broken. Others were placed in the hives, and although polished like glass by constant travel, none were injured.

The limits of this essay will not allow me to pursue this part of the subject further. If any one wishes more testimony, he should read that candid report by a disinterested observer.

Forest City, Iowa.

BEE-KEEPING.

Experience with Bees in Poor Seasons.

Written for the American Bee Journal
BY GEO. W. MORRIS.

Bees have not had a flight for about ten days; they have had several since winter began. I have not lost a single colony this winter, although the thermometer has indicated zero temperature two or three times. I have only 11 colonies now.

My report for 1886 and 1887 is as follows, as near as I can remember:

In May, 1886, I sold all my bees (16 colonies) for \$100. Then I took charge of an apiary consisting of 100 colonies, for one-half of the honey and swarms produced, which amounted to 1,000 pounds of the former, and 34 swarms. This much for the work of May and June.

Right here I wish to give some facts in favor of strong colonies at the proper season. The strongest colony gathered in the last week of May, 90 pounds of extracted honey, all from locust bloom. The same colony in June gathered from white clover, 45

pounds, and cast 2 large swarms. This ended the honey season of 1886. If the other 99 colonies had gathered the same amount, the honey crop would have been 13,500 pounds, instead of 1,000 pounds.

If the flow of white clover honey had been as profuse as the locust flow, my crop would have been enormous. I never saw honey come in so fast from any other bloom, as it did from locust bloom in 1886, in proportion to the field-workers.

On account of the dry fall and hard winter, with a late spring and little attention, our increase of 34 colonies dwindled down to 22 by April 1, 1887. I moved my half home in a weak condition, but by close attention, I succeeded in getting them built up so that they gathered 250 pounds of clover honey last June, and in October 500 pounds from aster. The entire time required by me, including marketing, was only ten days.

To sum the bee-business up in its entirety, I am forced to conclude that it pays me as well, or better, than any other business that I can engage in, as regards the time and capital invested. Cornishville, Ky., Jan. 21, 1888.

WISCONSIN.

Report of the State Convention at Madison, on Feb. 8.

Written for the American Bee Journal
BY F. WILCOX.

At the recent Wisconsin State Bee-Keepers' Convention, four essays were read, followed by short discussions. President C. A. Hatch read an address, recommending among other things the use of small kegs for extracted honey, in preference to tin or glass packages.

Mr. Putnam asked, "Would not small packages, like tumblers, be better?"

Mr. Bishop said that small packages increase the cost of the honey by the extra cost of the packages. Customers do not wish to buy tin or glass by the pound. Five or ten gallon cans, or kegs, are preferred by his trade. Kegs are preferred to cans, because the honey can be more easily gotten out by retailers. He found that many customers wished to get good honey in the cheapest form possible.

A. E. Cooley—Honey in glass is looked upon as a luxury.

C. A. Hatch—Honey in glass bears a higher rate of freight than in kegs.

A. V. Bishop—There is a prejudice in cities against what appears to be adulterated. Honey in small glass jars or tumblers is more likely to be so regarded.

Mr. Bishop read an essay on "The relations of producers to the commission merchants." He recommends shipping honey by freight, and thinks that the demand for extracted honey is increasing. Large barrels or kegs may be used for dark honey, and small ones for light honey. Large or full-sized starters are sometimes found in comb honey while eating it, and give rise to a fear of adulteration. It is better to use them as small as possible.

W. H. Putnam stated that in a beecellar under his shop, with the temperature about 42°, the moisture condensed on the ceiling, though ventilated by two pipes, and wished to know how it could be prevented.

A. V. Bishop and F. Wilcox said, by making the floor above of the same temperature as the cellar.

Mr. Hoxie—Let one ventilator extend to the floor of the cellar, and the other just through the ceiling.

Secretary F. Wilcox then read his essay as follows, entitled,

Notes from the Chicago Convention.

On the morning of Nov. 16, 1887, I went to Chicago to attend the annual meeting of the North American Bee-Keepers' Society. Having an hour or two to wait for the opening of the convention, I visited the honey houses near by. I was pleased with the quantity and fine quality of honey seen. One thing I saw which I did not expect, namely, the shipping-crates were badly bedaubed with a composition which looked like coal dust and kerosene. Now what is the use of buying clear lumber, and keeping it perfectly clean and white, if when shipped it arrives at its destination in such a filthy condition?

A full report of the essays and discussions makes quite a little pamphlet, which can be had at the office of the AMERICAN BEE JOURNAL, for 25 cents; and it is well worth more than its cost, to any who will read it.

The question of re-organizing the North American Bee-Keepers' Society so as to make it a representative body is being considered. The best place to discuss it is in these State and district conventions. The plan proposed, as I understand it, is that the inter-national association shall be composed of those who pay annual dues to the association, and such others as may be sent to represent State and district associations; these bodies to become affiliated by the annual payment of a sum of money. The association thus organized would consist of one grand body, with subordinate bodies in the different States. It may well be supposed that if the bee-keepers of the country were thus thoroughly organized, they would possess a power for doing good,

or for the suppression of any evils that might bear unjustly on the pursuit.

At the present time, our associations are little else than mere annual gatherings of bee-keepers for the purpose of discussing the best methods of producing and marketing honey.

Desirable as it may be, there are some difficulties in the way of effecting such an organization. One is, the difficulty of organizing the local societies, and inducing them to send delegates. Another is, the payment of expenses of delegates from distant States. Whether such an organization is ever effected or not, it is well that bee-keepers should think of it, and be prepared to act as thought best at our next meeting.

Mr. Thos. G. Newman, of Chicago, was appointed a committee of one to try to secure a more reasonable rating of freight charges for extracted honey in barrels or kegs, as first-class freight is neither just nor reasonable.

Perhaps the most valuable work done at that convention was to propose two practical methods of collecting statistics of the honey crop, one or both of which may be carried into effect. One plan is to have Mr. A. I. Root employ three or four special reporters in each State, each one to report the crop for his portion of the State, which, in addition to the individual reports usually given, will give us some means of knowing whether the crop of the country is good, very good; poor, or very poor. Even though we should not know the exact number of pounds produced, we would know where there is an overplus, and where there is a shortage. Knowing this, we will better know what price to fix on our honey, and where to look for a market.

The second plan was for several members to write to the Commissioner of Agriculture, requesting him to collect and publish statistics of the honey crop in connection with the statistics of farm crops. In accordance with this plan I wrote and received the following reply:

SIR:—Your letter of Dec. 23, addressed to the Commissioner of Agriculture, has been referred to me for answer. We have now under consideration in this Bureau a plan for the gathering and publishing of information relative to bee-keeping, once or perhaps twice a year. In order to carry out this plan, it will be necessary to have a special corps of correspondents among those directly interested in the industry. It is desirable to have the names of one or two of the leading men in each county where apiculture is of any comparative importance. Can you assist me in obtaining such a list for your State? Very respectfully,

J. R. DODGE, Statistician.

From the above it seems that the Agricultural Bureau is willing to undertake the work of collecting statistics of the honey crop, which the bee-keepers of the country have so long

desired. All they ask is, that we shall co-operate with, and assist them, by furnishing the names of two or three intelligent bee-keepers in each county, who will interest themselves in trying to report accurately. I have prepared a list of two names from nearly every county in the State, but considerable correspondence and inquiry will be necessary before I can ascertain their willingness and fitness for the work. We have reason to be thankful to the Department for its friendly interest in behalf of bee-keeping.

In conclusion, I cannot better describe that convention than by reading a little poem, from page 755 of the AMERICAN BEE JOURNAL for 1887, written by Eugene Secor, of Iowa.

The convention then adjourned.

F. WILCOX, Sec.

PECULIAR SEASON.

Destroying the Basswood— Poultry and Bees.

Written for the American Bee Journal
BY H. M. CATES.

The past was one of the most peculiar seasons that I have known since I began keeping bees. The spring opened favorably, and every colony of my bees was strong in numbers until about the first or the middle of April, when there was about 15 days of the worst weather for bees that I have ever seen.

Every morning it would be fair and sunny, and the bees would roll out of the hives and go to the woods where soft maple and elm were in bloom. They would make a trip or two, loaded with pollen, when up would come a very cold north wind, and then great crowds of bees could be seen dropping in the grass between the woods and home, chilled to death. Such affairs soon reduced the colonies to nuclei.

White clover then opened, when the bees gathered enough to build up on a little, and by the time basswood bloomed, most of the colonies were strong enough to begin work in the sections. I finally obtained about 25 pounds of honey per colony, with no increase, except 2 colonies that I divided.

About the middle of last November I went with a horse and buggy, some 50 or 60 miles, to Williamsburg and Richmond; and as I drove along I kept a sharp lookout for bees, but I saw none except here and there a few in log or box hives, until I got to Williamsburg. There I saw the Reynolds brothers.

The next day I visited Mr. Reynold's apiary, and found him just packing his last hive for winter. He uses chaff

hives, and is very successful with his way of wintering.

Cutting the Basswood-Trees.

One thing that is going to injure the bee-business in eastern Indiana, is the "Excelsior" business. There are thousands of linden trees being cut here every spring for this business. One man sold over 2,000 fine linden trees last spring, that were in size from 6 inches to 2 feet in diameter. This was all cut within sight of my apiary, and it will leave us with no honey source except the clovers, white and Alsike; of the latter I have 3 acres that will bloom the coming season, and I shall sow 20 acres more of it in the spring.

Keeping Poultry with Bees.

Some bee-men advocate the keeping of poultry with bees. These same writers should have been in my apiary last May, and have seen a neighbor's large Pekin duck go flopping out from the bee-yard, with a dozen or more bees sticking around its eyes. At the same time the owner of the duck appeared, and was very angry at the bees. Had those, who advise keeping poultry with bees, seen the excitement in my bee-yard, they would think very differently on the subject.

Shideler, Ind.

COLUMBUS, O.

The Ohio Centennial Exposition Honey Exhibit.

Written for the American Bee Journal
BY DR. A. B. MASON.

The Ohio Centennial Exposition, to be held at Columbus, O., next September and October, offers about \$320 in premiums in the Apiarian Department, and will put up a building for the apiarian exhibit. I am sorry to say that the exhibit will be confined to residents of Ohio. I am Superintendent of the Department, and the Board of Directors wish me to furnish a plan for the building. I will send a premium list as soon as published, to all intending exhibitors, who apply to me for it.

I am sure that our honey exhibits at the Fairs have helped to work up a market for our honey, and if properly conducted, they do much towards showing up the importance of our industry.

When, a few weeks ago, I told some of the Directors that the annual production of honey in this country was said to be about 100,000,000 pounds, and worth \$15,000,000; and also about 100,000 pounds of beeswax, they "banged out" their eyes at me as though I was "lying," but I gave

them hot shot, and made them surrender.

I wish that our Ohio bee-keepers would "wake up" this season, and show the people at the Centennial the importance and beauty of our specialty, and make an exhibition of bees and honey worthy of our State.

It is intended to have the building so arranged that honey can be exhibited without the crates, and still be safe from bees, etc.

It was said that the honey exhibit at the Tri-State Fair at Toledo last fall, was the most attractive feature of the Fair; but the bee-keepers of Ohio ought to make the grandest exhibit at Columbus that was ever made in this country! Let us "pile up" the honey until the building is filled to its utmost capacity for a fine display.

Reduced freight and passenger rates will be made known in good time, and abundance of time will be had for arranging displays.

The last, or "Convention Number" of the AMERICAN BEE JOURNAL, is "worth its weight in gold." Every thing is boiled down, and the useless parts left out.

Auburndale, Ohio.

TEMPERATURE.

The Lowest Temperature at Which Bees Work.

Written for the American Bee Journal
BY S. D. HASKIN.

On page 67 is quoted from *Gleanings*, the temperature at which bees will fly. My observation demonstrates that they are safe if it is 45° in the shade or cloudy, and I have had one colony to work hard on buckwheat at that temperature. It was in this wise:

Keeping bees in a neighborhood in Pennsylvania where much buckwheat was raised, I detected the odor of buckwheat around one of my hives, and on examination found that they were storing that very article. Following their direction, I found that bloom plenty, and bees working on it pretty freely. The previous year the same field had buckwheat on it, and sowed with oats in the spring, the shelled or wasted grain came up with the oats.

But here is the peculiarity, and it shows why and how it is that sometimes we find so much difference in our honey, and in the same yard at this time:

I had about 50 colonies, and none of the rest of my bees paid any attention to buckwheat, but worked on willows, fruit and berry bloom until white clover came. There was a great deal of buckwheat raised that year, and

the 49 colonies and their increase did not store any buckwheat honey; but the fiftieth colony and its increase (one swarm) stored but very little except the buckwheat honey. But below is the test:

When it was getting quite late and cool in the fall, but no frost yet, one day I noticed my "buckwheat bees" were very busy, and the others were flying only for a little water. I followed the course of the working bees, and found that a neighbor had harvested some early buckwheat, and sowed the field with winter rye. The shelled buckwheat had sprung up, and was in bloom. It grew cooler towards night, and at 45° the bees worked pretty briskly, but at 44° they stopped entirely.

This test was quite satisfactory and interesting to me, though I had never written it for publication. It illustrates the peculiarity of bees' preference for the different honey sources and flowers. It was a good season for white clover and basswood honey.

On Feb. 1 the mercury rose to 44° in the shade, and some of my bees flew a little. It was the first since last November. The snow is 2 feet deep. It is a little cooler to-day, and is raining a little.

Waterville, Minn., Feb. 3, 1888.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*

Apr. 11.—Stark County, at Canton, O.
Mark Thomson, Sec., Canton, O.

Apr. 24.—Des Moines County, at Burlington, Iowa.
John Nau, Sec., Middletown, Iowa.

May 5.—Susquehanna County, at New Milford, Pa.
H. M. Seeley, Sec., Harford, Pa.

May 8.—Cortland Union, at Cortland, N. Y.
W. H. Beach, Sec., Cortland, N. Y.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

SELECTIONS FROM OUR LETTER BOX

Bees Wintering Well.—L. Hubbard, Waldron, Mich., on Feb. 7, 1888, says:

Bees appear to be wintering nicely. I have 100 colonies in the cellar, and nearly as many packed in chaff. There are no signs of diarrhea.

Glandular System of the Bees.—J. A. Proctor, M. D., Union City, Ind., writes as follows:

Prof. A. J. Cook, in discussing the glandular system of the bee, says that "one pair of glands furnishes the saliva; another the food for the larvæ. Drones do not have this gland, and it is only rudimentary in the queen, which shows that she once nursed the larvæ, as the queen bumble-bee now does in the spring." Will Prof. Cook please state what gland he alludes to by "this

gland?" What shows that "they once nursed the larvæ, as the queen bumble-bee now does?" I ask for this proof, that the bumble-bee has not changed, but still feeds its larvæ; and why the honey-bee has changed.

The Professor says, on page 58, that "richer food, through long ages, developed larger ovaries, and a correspondingly greater fecundity." How is it known that the queen gets any richer food than she did ages ago? Or that their ovaries are more developed now than they were ages ago? I see no change in the queen bumble-bee, and why in the honey-bee?

The Professor says, "In the same way snakes have lost their legs." (I suppose by being too lazy to use them.) "Zoologists find rudimentary legs now, and believe such legs indicate legs once useful." I ask for the proof, as it matters not what any one "thinks" about it.

The Bees are all Right.—Andrew Craig, Empire, Dak., on Feb. 6, 1888, says:

I have 3 colonies packed in straw on the summer stands. They are all right so far. It has been 34° below zero here this winter, but it ranges now from 20° to 40° above zero.

Standard Langstroth Frames.

—L. J. Stone, Littleton Common, Mass., asks the following questions:

1. How thick should the top-bars to the standard Langstroth frames be? 2. How much space should there be between the top of the brood-frames and the bottom of the section-cases? 3. Will bees build up as fast in standard Langstroth frames as in deeper frames? I mean in early spring.

- [1. Make them V-shaped, and $\frac{1}{8}$ of an inch deep.
2. Three-eighths of an inch.
3. Yes.—Ed.]

Good Locality for Bees.—T. M. Edwards, Kerrville, Tenn., on Feb. 8, 1888, writes:

My bees are wintering finely. I have 120 good colonies. We have a fine locality for bees and honey. I am trying to get my neighbors to use frame hives, but I succeed slowly. The AMERICAN BEE JOURNAL is a favorite in my family.

Swarms Alighting High, etc.

George Hodges, Belmont, N. Y., on Feb. 2, 1888, writes:

I now have 6 colonies of bees that are covered with snow. I have kept bees for 10 years in America. I notice that basswood or linden, as it is called in this country, is called "lime" in England, and sometimes it is called "white wood." The bees used to swarm up in the trees very high sometimes, so that I had to use a 30-foot ladder to get to them. In England I very seldom had a swarm to leave me; but here in one summer 3 swarms absconded for me.

Shipping Bees by Express.—S. J. Youngman, Cato, Mich., on Feb. 9, 1888, writes:

Being greatly interested in bee-culture, I am willing to give my views and experience to promote the same. I have always thought that bees might be sent to the North from parts of the South in early spring, and then be built up in time for the honey season; white and Alsike clover, with the basswood

bloom, being the principal sources of honey supply, and commencing in early June and lasting until the middle of July. I once was interested in a large shipment of bees from Louisiana, which consisted of 150 colonies, sent as freight, and being about 10 days on the road. The transaction was not a success, as the bees did not have stores enough to last them for so long a journey, and the transportation charges being very high. Some of them, however, were in good condition after the long journey. I have received bees also by the pound, in cages, from the South, which were generally in bad condition on arrival. I have arrived at the conclusion that the only safe way to transport bees long distances is by express, several small colonies being put in one package in a light, strong, shipping-crate, and not less than 25 to 50 colonies sent at a time, each nucleus to consist of say 1 to 2 pounds of bees, with a laying queen and one frame of sealed brood.

What Ailed the Bees?—Jas. F. Johnson, of Missouri, writes as follows:

On page 11, Mr. A. Pinkerton, speaks of great mortality among his bees. I have known bees to die from the same cause in this State, and in California. I knew of an apiary of 200 colonies situated on Santa Barbara island, 25 miles from land, in the Pacific Ocean. They came out of their hives and died, and the ground was covered with them. I kept bees on the main land three miles from the ocean, and some of my bees were afflicted in the same way; these bees were not confined, as the weather was quite warm. I wish some one would tell us if this is a disease, and if it is caused by food, or by the state of the atmosphere. By Mr. Pinkerton's article, we find that bees are affected, whether confined or not.

Fastening Foundation in Brood

Frames.—D. R. Rosebrough, Casey, Ills., writes as follows:

Lately there has been a great deal written about fastening starters of foundation in sections, and each bee-keeper has a method of his own which he thinks is the best. We all seem satisfied about the way to fasten starters in sections, but what troubles me considerably is, to fasten foundation in brood-frames. The foundation always sags for me when I put in full sheets, and give a swarm upon them; but if given to a colony made by division, it works all right. It seems to me that if a narrow piece of muslin or ribbon could be fastened to the brood-frames, and then the foundation fastened to that, it would be an improvement. I would like to have some one try this plan, or at least suggest something better than beeswax or rosin to fasten foundation.

Bees Wintered in the Cellar.

Wm. Cleary, Algona, Iowa, on Feb. 14, 1888, writes:

I have 33 colonies of bees. I commenced last season with 17 colonies, and I was unfortunate in spreading the brood. I obtained 350 pounds of honey, and fed about 100 pounds of sugar in the fall. My bees are very quiet in the cellar, the temperature ranging from 40° to 48°. I examined them a few days ago, and they are doing well. My cellar is very dry, and is under the sitting-room and bed-room, and divided from the rest of the cellar by a board partition. We have no frost in any part of it. It has no ventilation except what comes from the kitchen as we pass up and down after vegetables or coal.

A part of the hives are the Gallup style, with pieces of sacking or carpet on top of

the frames, with the tops and covers on, and a stick across the frames for a passage. The balance of my colonies are in S-frame Langstroth hives, 1½-story high, with a honey-board having a slat at the end with wire-screen over it, and with the caps on. That is all the ventilation they have, except what they get from the entrance.

I notice that the answers to nearly every question differ, which shows to me that we all have more to learn. How can I get straight, even-filled sections without separators?

[To use narrow sections will aid very much, but there is no sure method.—Ed.]

Old Foundation in Sections.—

Chas. Solveson, Nashotah, Wis., on Feb. 6, 1888, says:

I have between 3,000 or 4,000 sections that were filled with foundation in April, 1887, and as the last season was a failure, they were not used. Would it be advisable to submit them to a high temperature in order to soften the foundation, before giving them to the bees? Or, what should I do with them?

[Yes; that might do, or to steam them would be preferable. If you have any full sheets of foundation left, dip them in warm water before giving them to the bees. That will soften the wax, and freshen it.—Ed.]

Feeding with Unfinished Sections.—Henry Hohnadel, Fair Haven, Ills., on Feb. 6, 1888, writes:

Bee-keeping was very unprofitable last season; we had no surplus honey. I commenced with 46 colonies, and increased them to 56, by dividing them. I had no swarms. I commenced feeding in June with 500 unfinished sections of the previous season, to keep the bees from starving, as there was no honey to be had from either white clover or basswood. On Sept. 1 I bought about 500 pounds of sugar, and fed the bees syrup, on the Heddon plan. I then prepared them for winter quarters, and stored them away about Nov. 15; they appeared rather light when moved, and have not examined them since I put them into the bee-house, but I have always been very successful in wintering.

Very Cold Weather.—Ira Barber, De Kalb Junction, N. Y., on Feb. 10, 1888, says:

Another cold wave is hovering over northern New York. This morning the mercury was down to 30° below zero; but in my beecellar the temperature was 46° above zero. On examining the bees, they showed signs of being in too low a temperature for comfort and health, for every top-board that I took off was wet on the under side, and the cloths were in the same condition. We are having an unusually cold winter here, with not a heavy snow fall, but with roads badly drifted, and every prospect of cold weather for some time to come.

Albino Bees for Work, etc.—J. Moser, Festina, Iowa, on Feb. 9, 1888, writes:

This has been a very poor season for honey in this locality, but few bee-keepers having secured any honey at all. There was an extraordinary crop of basswood, and colonies which were in just the right condition gathered honey rapidly for a few days, when the honey-flow ceased almost entirely. Only the pure Albinos worked in the sections, where the Italians did not touch them

at all, and only secured a little in the brood-frames. The pure Albino bees were far ahead of the other races the past season.

My apiary consists of 90 colonies, 65 colonies being pure Albinos, and the others Italians and Syrians. The Albino bees are the handsomest that I have ever seen. They gave the best satisfaction the last four years, so that I feel like dropping all other varieties, and keeping them exclusively. My apiary is located near a public road, a row of hives are standing along side of the fence, and the bees have to pass over the road, but I never had any complaint that they attacked man or team.

In the season of 1886 my crop was 4,500 pounds of comb honey in one-pound sections, and 2,200 pounds of extracted honey from 45 colonies, spring count. In 1887 I took about 800 pounds of comb, and 1,200 pounds of extracted honey, from 80 colonies. I am wintering 70 colonies in the cellar, which are very quiet; and 20 colonies in chaff hives, that are buried in the snow.

Comb Foundation Fastener.—

Mr. Jacob Alpaugh, of Saint Thomas, remarks as follows about one that he has invented:

I notice on page 790, that Mr. Eden, in speaking about putting foundation in sections, says: "It is to be hoped that some of the many thousands of bee-keepers will discover a plan that will give general satisfaction." I have discovered the very method he calls for. I have used it for two seasons; and some of the largest comb honey producers are now using it. With it you need no melted mixture on hand, no warmed sections, nor a place having a temperature of 90° to work in, but just take the sections and comb foundation out of the box and go to work. It can be used in any out-door building, no matter what the temperature is.

I mail a sample of the machines' work to the editor, and ask him to state what he thinks of it. I can put on at the rate of ten per minute, which amounts to 6,000 per day. Is that not fast enough?

[The work is neatly and strongly done. Mr. T. W. Cowan, editor of the *British Bee Journal*, says he saw it in operation at the Toronto Fair, and he speaks very highly of it. Would it not be well to put them upon the market?—Ed.]

Hybrid Bees and the Italians United.—Daniel Whitmer, South Bend, Ind., on Feb. 7, 1888, says:

On Nov. 20, 1886, I placed 207 colonies of bees in the cellar in good condition, and left 33 colonies on the summer stands in the same condition. In the second week of April, 1887, I took 206 colonies out of the cellar alive, but about one-half dozen weak colonies. Of those on the summer stands I lost about 8 colonies, making about 14 colonies in all, including those lost by spring dwindling. I sold some, and united my hybrid colonies with pure Italians, in order to get rid of them, and at the same time making my colonies all very strong for the early flow from white clover. Of course some would object to this plan, but distributing bees and brood I find to be good.

I commenced the season of 1887 with 175 colonies of Italian bees, increased them to 250 colonies, and secured 5,000 pounds of surplus honey, 100 pounds of which was extracted. The past was a very poor season for honey in this locality, in consequence of the drouth. I had about one-half of a crop, and others were not so successful. On Nov. 23, 1887, I placed 200 colonies in the cellar in good condition, except 2, and the rest on summer stands. They are all doing well.

Oil-Stove in the Bee-Cellar.—F.

A. Lockhart, Lake George, N. Y., on Feb. 1, 1888, says:

I commenced the season of 1887 with 9 colonies of bees, increased them to 25 colonies, and took about 500 pounds of comb honey in one-pound sections. There was about one-third of a honey crop in this section of the country. Some bee-keepers near me secured no surplus at all. I bought 10 colonies in box-hives, which I intend to transfer to movable-frame hives in the spring. On Nov. 20, I put my bees in the cellar where the temperature ranges from 40° to 46°. They seem to be wintering very well. There are but a few dead bees on the cellar bottom. I keep an oil-stove burning in the cellar when it is very cold weather. A pipe connects the oil-stove with the kitchen stove above, which carries all gas and foul air from the cellar. It is very cold here; 48° below zero yesterday morning.

The AMERICAN BEE JOURNAL comes every week, bright and clean in its "new dress." I would not do without it for twice its cost.

A Home-Made Swarm-Catcher.

—A. H. Dualap, of Aral, Kans., writes:

Take a fiddle, new or old, and if it is worth nothing to excite the "light fantastic toe" it will do for the bees. Leave off the lower string, change the bridge so that the top will be hollow, or concave instead of round. Now construct a small, light frame with a wheel, and crank to turn the wheel, and fasten this frame on the top of the fiddle, so that the wheel will be above, and a little forward of the bridge. String up the fiddle, and pass a small silk cord (well rubbed with rosin) over the wheel and under the strings of the fiddle. Tune up the strings so that their combined tone will resemble the bees' tone. When they commence to cluster, take your stand close to some tree, bush, or anything upon which you would like to have the bees alight. Begin to turn the crank, turn slowly, turn on, keep turning, and never ask again, "Can bees hear?"

That "Canadian Locomotive."

—Rev. W. F. Clarke, of St. Thomas, Ont., gives a fresh clang to that locomotive bell:

For the information of "Bro." Solveson and others who appear to be getting anxious, permit me to say that "latest advices" about the approaching engine were published in the *Canadian Bee Journal* of Jan. 25, 1888. Replying to Dr. W. S. Adams' enquiries (page 896), the editor says:

We believe that we will be able to guide you "out of the woods," as you put it, Doctor, just as soon as our engravers get their work done. We have not been so hurried as we might have been. In a week or two, however, bee-keepers will all be "waking up" after the "hibernation" for the winter, and will be looking out for their requirements for next season. By that time we will have our engravings ready, and with them will be given a full and explicit description of our invention, which we trust will meet with a fair amount of approval. We want all the criticism going too, so if it don't "strike" you as "just the thing," we want you to speak.

Let me add, it is not I who am keeping the fraternity "in suspense." I was but the prophet who predicted the coming event; the fulfillment is in other hands. But, evidently,

"There's a good time coming, boys,
Wait a little longer."

[The ringing of the locomotive bell indicates the approach of the train immediately—unless it is a false alarm. The long delay in the above case, proves that the announcement was far too extravagant, and unless the invention materializes very soon, will prove it "a false alarm."—Ed.]

Clipping a Queen's Wing.—E. Jarvis, Fair Grove, Mich., on Feb. 3, 1888, asks the following questions :

1. Does a queen's wing grow out again after being clipped? 2. Does the clipped queen ever go out with a swarm? 3. If they get together, is it always on the ground, or down where she can crawl? 4. Does the swarm ever go out of sight of the hive? 5. Will the bees swarm before rearing a new queen?

- [1. No.
2. She attempts to, but the loss of her wing prevents her flying with the bees.
3. Yes.
4. Yes. When they find that the queen is not with them, they usually return; but sometimes they have another queen, or unite with another swarm.
5. They will attempt it and fail, unless they unite with another swarm, or follow another young queen on her bridal trip.—Ed.]

Bees Flying—Favorable Winter.—D. F. Park, Athens, Pa., on Feb. 14, 1888, says :

To-day the bees have had their first flight since Dec. 4, 1887. I have 85 colonies on the summer stands, and all were out but one, which had succumbed. I had introduced a "dollar queen" last season, and she proved worthless, not rearing bees enough to make a decent cluster. The winter has been favorable, the mercury having gone below zero but three times. Five, 10 and 16 degrees below zero has been the coldest, with very little snow.

CLUBBING LIST.

We Club the *American Bee Journal* for a year, with any of the following papers or books, at the prices quoted in the **LAST** column. The regular price of both is given in the first column. One year's subscription for the *American Bee Journal* must be sent with each order for another paper or book:

	Price of both.	Club

CONVENTION NOTICES.

The Cortland Union Bee-Keepers' Association will hold its spring meeting on May 8, 1888, at Cortland, N. Y., at 10 a. m. All bee-keepers are invited.
W. H. BEACH, Sec.

The Des Moines County Bee-Keepers' Association will hold its next meeting on April 24, 1888, at Burlington, Iowa.
JOHN NAU, Sec

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

New Subscribers can obtain the full numbers for 1887 and 1888, for \$1.75, while there are any sets of 1887 left.

Beeswax.—We will pay 20 cents per pound, delivered here, for Yellow Beeswax. To avoid mistakes, the name of the shipper should always be on each package.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one **FREE**, if you will send us 3 new yearly subscriptions for the *BEE JOURNAL*.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Money Orders for \$5.00 and under, cost 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Sweet, or Melilot, Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the *BEE JOURNAL* for one year for \$1.75; or we will present it *free*, by mail, to any one, for a club of three subscribers and \$3.00.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

It is **Extravagant Economy** not to have hives, sections, comb foundation, etc., on hand when needed. To prevent disappointment, order early what you will need in that line. Then the hives can be nailed and painted in odd times, and the sections put together, so as to be ready at a minute's notice. It is a sad disappointment to need these things and then not have them on hand. They should be ordered very soon. We are promised an early spring, and a good honey crop.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Look Over last year's numbers of the *BEE JOURNAL*, and if any are missing, send for them at once, as we have but few left now, and they are daily becoming less.

A Pocket Dictionary will be presented for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

We Supply Chapman Honey-Plant **SEED** at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

We Club the *AMERICAN BEE JOURNAL* and the "Bee-Keepers' Magazine" for one year for \$1.40; or with "Gleanings in Bee-Culture" for \$1.75; or with the "Apiculturist" for \$1.80; or the "Canadian Honey-Producer" for \$1.30; with the *Bee-Keepers' Review*, \$1.40; or all six for \$4.00.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2 00	3 00	3 50
1,000 Labels.....	3 00	4 00	5 00

★ Samples mailed free, upon application.

Please to get your Neighbor, who keeps bees, to also take the *AMERICAN BEE JOURNAL*. It is now so **CHEAP** that no one can afford to do without it.

A Modern Bee-Farm, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. Feb. 29, 1888. No. 9.

EDITORIAL BUZZINGS.

Bee-Men are in trouble! O, hear them call
On the "Union"—inviting one and all,
To join them, and nobly "the fight" endure.
For "pluck" shall win, and the outcome is sure!

Let us face the issue, hnt never shirk,
And our duty do in this grand good work.
The battle fight bravely—our rights to gain,
Help the weak brothers, their cause to maintain.

It is a Pleasure to announce that Mr. W. Z. Hutchinson is now recovering from his severe illness. Mrs. H. writes us that she expects soon to have him "up" again. Their daughter is also (we are glad to say) getting well—thanks to the faithful exertions and nursing of the "angel of the household," whom friend H. has often mentioned to us with the most endearing words. Oh! what is there in this world to compare with a faithful wife and fond mother? By her a "heaven" can be made on earth.

The Rev. C. F. G. Jenyns, rector of Knebworth, Herts, England, died suddenly on Jan. 26, and was buried on Feb. 1, 1888. Mr. Jenyns was a very energetic and enthusiastic apiarist, and a member of the British Bee-Keepers' Association. He was the author of a book about "Bees for the Young," which was noticed in these columns on pages 659 and 771. He will be missed in the much-depleted ranks of modern progressive apiarists.

Trees.—Geo. Pinney, of Evergreen, Door Co., Wis., is out with a catalogue of Evergreens and Timber Trees, and Seeds. He offers to send a copy to any person asking for it.

Scatter the Leaflets.—Look at the list (with prices) on the second page of this paper.

Securing the Statistics of Bee-Keeping.—That reliable statistics of the products of the apiary would be both interesting and valuable is quite beyond question; but the great problem which confronts the apicultural fraternity of to-day is, the best method to be employed in securing reports of the annual production of honey and beeswax in the United States.

The plan which we deem to be both feasible and easily introduced, is briefly outlined as follows:

Have "bees and their products" included in the blanks prepared for the use of the assessor in each township of each county in the United States. At the head of one column place the words, "number of colonies;" another with, "pounds of comb honey;" one with "pounds of extracted honey;" and still another with, "pounds of beeswax."

Then, when the assessor visits a farmer next May or June, and inquires as to the number of horses, cows and sheep owned, how easy it would be to ask at the same time these questions: How many colonies of bees have you? And if the number is stated, ask, How many pounds of comb honey produced in 1887? How many pounds of extracted honey? How many pounds of beeswax? To ask these questions and record their answers would be the work of but five minutes (and perhaps less) at each farm; and if all understood that such questions would be asked by the assessor, those who keep bees would have the answers prepared in advance, especially after the first year's experience with this method of obtaining statistics of bees, honey and wax.

There is no good reason why the statistics of the great industry of bee-keeping should not be as complete and reliable as that of the agricultural interests of this country; and that they may be so, is clearly proven by the correctness attained in the statistics of all other departments of rural pursuits.

We have already obtained the attention and approval of the United States Statistician, as shown on page 132, where he expresses great willingness, on the part of the Government, to aid in every way possible in securing to bee-keepers what they so much desire in the line of ascertaining as nearly as possible the exact number of colonies of bees kept in the United States, and the number of pounds of comb honey, extracted honey, and of beeswax annually produced.

In 1882 the Illinois Board of Agriculture inaugurated a plan similar to the one outlined above, and we published the table on page 51 of the BEE JOURNAL for Jan. 24, 1883. Some similar plans have been adopted in other States, but what we need is a uniform method for every county of the United States, such as can be had, if it is taken hold of by the United States Statistician. We very much doubt the feasibility of the plan to obtain reports from two correspondents in every county, as suggested on page 132. The only reliable method is through the assessors. Of this, we feel positive, and commend it to the Statistician.

Important Points in Breeding Bees are often lost sight of. Among these are the careful selection of mothers, and keeping a record of the queens in an apiary register. Every bee-keeper who would be considered an apiarist should keep a Register. We approve in the main the points presented in the following written for the *American Agriculturist* by Mr. A. H. Duff:

Queens for breeding should be selected with much care. This is overlooked by too many breeders, and the result is inferior stock which will not produce as well as that of better selections. Some breed mainly for color, others for the best workers regardless of color. Some think that an imported queen is the only one fit to breed from, while others are willing to use any queen that produces bees showing the three yellow bands characteristic of the Italian. This is a mistake. While a selected imported queen is doubtless the best to breed from, we have found by experience that not all imported queens are good breeders. We would not by any means discourage breeding from imported queens, but we are certain that by careful selection from home-bred stock as good results have been obtained as from any imported. There is no certainty in selecting a queen by her looks for breeding purposes. An inferior-looking queen may prove to be the best breeder. Neither can we tell to a certainty the superiority of a queen by testing her a single season. Colonies even with not the best of queens often have such advantage in condition as to come out ahead. We have often been greatly disappointed by queens apparently proving superior the first season, and afterwards turning out very poorly.

A yearly record should be kept of such queens as are in view for breeders, and, by close observations, in a few years a strain may be found having the desired qualities. It is not necessary to wholly disregard color in order to get working qualities. Those two points can be readily combined. The three golden bands encircling the body of the Italian bee should never be lost sight of.

The Elms in Bloom.—Mr. David Grossman, of Terrell, Texas, on Feb. 17, 1888, sent us some bloom of the elms on which his bees had been at work since Jan. 31, and had carried into their hives thousands of loads of pollen. It will be our turn to have bloom soon, here in the North. Everything seems to promise an early spring.

Clergymen and Bees.—An exchange, in speaking of the fostering care of the art of bee-keeping by clergymen, says:

The bee-keepers of this country are under great obligations to the clergy for the prosperity of their peculiar industry. To Rev. L. L. Langstroth belongs the credit of first inventing and introducing to American bee-keepers, and to the world, the movable-comb frame, which has well-nigh revolutionized apiarian pursuits, and done as much for the production of honey as the cotton-gin has for the great staple of the South.

By its use a colony of bees is almost wholly under the control of the bee-master. One interesting illustration of its many uses is found in the lessened production of drones, which are non-producers and yet great consumers. The skilled apiarist now cuts out from the movable frames all, or nearly all, of the drone comb, and substitutes workers' comb instead, and so rears a race of industrious workers in place of a hungry, worthless horde of drones.

GLEAMS OF NEWS.

Prefers Columbus.—Miss Dema Bennett, of Bedford, O., on Feb. 21, 1888, writes:

In regard to the place for holding the next meeting of the North American Bee-Keepers' Society I would like to express my preference for Columbus, O. I understand that the executive committee has the matter in charge. I think that under ordinary circumstances Cincinnati would be the better place, but this year there are quite a good many advantages in favor of Columbus, and I think that the attendance would be larger at the latter place.

Dr. Mason, the President, writes us on this subject as follows:

Auburndale, Toledo, O., Feb. 21, 1888.

The executive committee of the North American Bee-Keepers' Society is considering the matter of changing the place of its next meeting, but owing to Mr. Hutchinson's sickness, have not arrived at a conclusion, and will inform the bee-periodicals as soon as it does. There is no special need of haste, but the matter will be arranged as soon as possible; until then, it may as well, perhaps, be better to not vote on the matter.

Hints for March.—Mr. W. B. Treadwell writes the following to the *American Agriculturist*, as seasonable hints for beginners:

Examine every hive as far as practical, and should any be found in want of stores, these should be replaced at once, either by laying bars of cream candy over the tops of the frames, or by placing a feeder of hot liquid feed over the frames under the cushion, so that the bees can reach it without leaving the cluster. Do not feed in the morning, as this will be apt to induce robbing, and when fed during the day the bees become restless, are tempted to fly out, and thus become chilled and die.

When feeding for stimulation, we would advise the use of a good entrance feeder, which, when placed at the entrance the latter part of this month, should not be removed until apple blossom time. Pour about a gill of hot feed, made of two parts water and one part of honey or sugar, into the feeder every evening.

We cannot too strongly insist on the importance of regular daily feeding, when once begun. Confine each colony to only as many combs as the bees can conveniently cover, giving more combs as required. Be cautious, and not expand more rapidly than the increasing bees will warrant, as they may not be able to keep the brood warm.

Ventilation from above should now be stopped, by laying enameled cloth smooth side down over the frames. Stimulative feeding serves the same purpose, even if the brood-nest is full of sealed honey. This may, however, be uncapped. Guard against robbing by leaving no combs or sweets exposed, and contracting the entrances.

Should any colony be found queenless, either introduce a new queen or unite with some weak colony. In the North rye meal should be fed as a substitute for pollen.

Alsike Clover.—M. M. Baldrige, of St. Charles, Ills., wishes to make the following correction. The error was an oversight of the printer. He says:

Four pounds of Alsike clover seed is plenty for one acre when sowed alone. The types on page 105 make me say 40 pounds, which is just 36 pounds too much.

Statistics of the Honey Crop.—At the Chicago Convention Dr. Mason, Prof. Cook, and the Editor of the *AMERICAN BEE JOURNAL* were appointed a committee to correspond with the Department of Agriculture relative to securing reliable statistics concerning honey and beeswax production, the number of colonies of bees, etc., in the United States. Dr. Mason has received the following from the United States Statistician, which will be read with interest:

U. S. DEPARTMENT OF AGRICULTURE,
WASHINGTON, D. C., Feb. 21, 1888.

Dr. A. B. Mason, President of the North American Bee-Keepers' Society, Auburn-dale, Toledo, Ohio.

SIR: Your favor of the 15th inst., addressed to the Commissioner of Agriculture, and by him referred to me, is received.

After correspondence with Mr. Eugene Secor, of the Iowa Horticultural Society, Mr. Geo. E. Hilton, President of the Michigan Bee-Keepers' Association, Mr. Franklin Wilcox, Secretary of the Wisconsin Bee-Keepers' Society, and other prominent apiculturists, I have decided to make an effort to gather statistics relative to bee-keeping, to be published in our regular crop report at least once a year, provided those engaged in the industry take sufficient interest in the matter to furnish us with the necessary data. In the first place it will be necessary to have a special corps of correspondents made up entirely from those actually engaged in bee-keeping. To secure such a list of reliable men, we should have to depend upon the officers of various Bee-Keepers' Associations. Our regular correspondents who furnish us with monthly crop reports are made up in the main of ordinary farmers, and but few would be able to give reliable information relative to the present condition of apiculture; therefore, what we desire, and must have if a reliable report is to be made, is a list of intelligent bee-keepers one in every county where the industry is of any comparative importance. So far we have been able to secure such a list from the State of Iowa only, with the promise of a list from Wisconsin. Can you, from among the members of your society, furnish me such a corps, or give me the names of prominent men in each State who could do so?

I would also be under obligations if you and the fellow members of your committee would kindly give me the points, which, in your opinion, such an investigation should cover, and the queries which you would consider it advisable to put.

Trusting that you will give me all the assistance in your power in order that a full and correct report on the progress of this growing industry may be made, I am,

Very respectfully,

J. R. DODGE, *Statistician.*

This committee, as representatives of the "North American Bee-Keepers' Society," are now corresponding with one another for the purpose of formulating a plan to be followed by the different societies, in order to comply with the above request of the United States Statistician. They will endeavor to give him "the points," the "queries," etc., but many difficulties present themselves.

Now, we request any one who may have suggestions to offer, to send such to Dr. A. B. Mason, Auburn-dale, Toledo, O., at once, to aid the committee to finish the work in the most complete and perfect manner. Give the committee your BEST thoughts and most mature plan of operation—and do it NOW.

California Honey Crop in 1887.—Messrs. Schacht & Lemecke, of San Francisco, in their third annual market review of the honey and beeswax business of California, remark as follows:

San Diego county, which in former seasons has been the most productive county for honey, yielded very little, and only several carloads of the crop of 1887 have been shipped from the northern part of that county; the honey shipped from the city of San Diego having been kept for better prices.

In some parts of Los Angeles county, which formerly produced several hundred tons of honey, apiarists did not extract at all last year; while in others, not fifty miles distant, they extracted 400 cases of honey from 400 colonies of bees.

San Bernardino county had probably the best honey crop last season, for nearly every apiarist had some honey to sell. In the counties north of Los Angeles, comb honey has been produced. Part of it was very nice, in one-pound sections, and was sold at from 12 to 16 cents, according to quality; the rest of it was very poor, and should have been extracted.

It is very difficult to estimate the amount of honey produced in California, but we may say that during 1887 not over 500 tons of extracted honey and 100 tons of comb honey was produced, against 2,500 tons of both extracted and comb honey in 1886, 700 tons in 1885, and 4,500 tons in 1884.

Years may Come and Years May Go, but it will take a thousand of them to bring us to another year having as many 8's as we use to indicate the present time. Full many a lesson does this year inculc-8.

We may cogit-8 about our bees—dial-8 concerning their winter repose—and specul-8 with "Old Probs" on the unseasonable weather, which tends to invalid-8 what we calcul-8 to do.

We must not, however, hesit-8 to extric-8 them from untimely f-8, so that they may gradu-8 among "the flowers that bloom in the spring." To emancip-8 them from cruel f-8, will allow them to reciproc-8 with honied treasures in wondrous store, and let us anticip-8 our pleasures.

If we particip-8 in their labors we should never forget to supply their wants—else they may capitul-8, leaving us no bees to manipul-8, because we left them to f-8 until too l-8. That we deprec-8, at any r-8!

New Catalogues for 1888 are on our desk, from the following persons:

Thos. Jackson, Portland, Maine—10 pages—Forest City Nurseries.

F. N. Lang, St. Paul, Minn.—23 pages—Field, Flower and Vegetable Seeds.

F. E. Fassett & Bro., Ashtabula, O.—8 pages—Flower Plants.

D. C. Buck, Dundee, Mich.—4 pages—Queens and Bees.

A. I. Root, Medina, O.—40 pages—Bee-Keepers' Supplies.

A. Wortman, Seafield, Ind.—18 pages—Bee-Supplies and Poultry.

Jos. E. Shaver, Friedens, Va.—24 pages—Apiarian Supplies.

E. S. Armstrong, Jerseyville, Ills.—32 pages—Hives and Supplies.

INFORMATION.

Marks of Purity.—Hugh L. Lynn, Glenville, Ky., on Feb. 16, 1888, asks the following questions :

1. Is there any certain way of knowing Italians from hybrids? 2. Is not disposition a better proof of purity than marks? 3. When I first got an Italian queen she was a curiosity in our neighborhood, there being no other near it. Her daughter, reared that fall, mated with a black drone, there being no others near. Her workers were as large and as finely marked as any one could ask for. I think any man seeing them dead would have pronounced them Italians. But if he had handled them he would have called them hybrids.

1. Yes; 3 yellow bands in all the progeny of any Italian queen. If she has been impurely mated, then the yellow bands of the workers will vary in number.

2. No; "disposition" is often the result of gentle handling and management—but is not a *sure* indication of purity of blood.

3. While some of such hybrids may be well marked and fine looking, others would be inferior both in bands, manners, and appearance.

Swarms with Two Queens, etc.

—Mr. Locke Ferree, of Milroy, Ind., makes an inquiry concerning the swarms which issue having dual queens. He says :

The last season was hard on bees here. My bees had a flight two days ago, being the first for nearly four weeks. One of the colonies I think has the diarrhea. What shall I do for them? When two or more queens come out with a swarm, what will the bees do with the surplus queens?

If the bees have the diarrhea, a flight will help them very much. If more than one queen issues with a swarm, it is an indication that it is a second or third swarm. When an old queen has been lost, some ten or more days before, several queens will sometimes issue with the first swarm. Leave it to the bees to settle, as to which queen shall be approved.

Nebraska Convention.—Mr. J. N. Heater, of Columbus, Neb., on Feb. 19, 1888, writes :

We have lately had a few days of very warm weather, and the bees have had a number of flights. Mrs. Heater's 100 colonies are wintering well, and are in fine condition.

I sent the report of the Nebraska Convention as published by the *Nebraska State Journal*, and expected it to be credited to that paper. With my name signed as Secretary it looks to those who do not understand it, that I had complimented myself.

When we receive a report of a convention from the Secretary, no matter whether it is printed in whole or in part, we consider it as an official report, and credit it to the Secretary. We failed to notice the remarks referred to about the Secretary, or we should have made an exception in this case. The above will straighten it out.

National Bee-Keepers' Union.

Mr. R. L. Meade, of Nassagaweya, Ont., on Feb. 17, 1888, writes thus concerning the Union :

I am surprised at the bee-keepers of the continent, who have a National Union for the defense of their own business, and yet it seems to be so very poorly sustained by such an intelligent class of men as bee-keepers generally are. Bee-keepers, send in your dollar. Strengthen the "hands" of the Union, and place it in a position to assist those of our calling when there is any necessity. We want 10,000 names on the National Bee-Keepers' Union list for this year. Here is my dollar.

Yes; that is right. The only wonder is that there were not ten thousand members to the Union within a few months after its organization. There ought to have been a *general rush* to the defense of the pursuit. But too many are selfish, and think that so long as they are not molested, they will not join. But we notice that as soon as they are even threatened, they are rushing for some help, and want us to tell them what to do, etc. But the Advisory Board has decided that the Union ought to defend only those who have become members before they were in trouble. The present general apathy is very reprehensible.

Since writing the above, Mr. Z. A. Clark, of Arkadelphia, Ark., whose case the Union has now in hand, as before noted in these columns, has written to us stating that he has again been arrested for not moving his apiary outside of the city limits. He was fined, but appealed to the Circuit Court which meets next July. He was then informed that he would be arrested and fined every day in the interim, and if he does not pay the daily fine, he will be sent to prison!

The Manager of the Union has advised him just what to do, relying upon the fraternity to support in the defense of this and other cases now on hand. Will they do it?

It will take nearly two thousand dollars to successfully defend the cases now on hand, and the Union must have two thousand more members, or it will be obliged to let the cases go by default—and the pursuit will suffer an ignominious *defeat!* Reader, are you satisfied to accept the latter as the result of your apathy? If not, sit down at once and send a dollar to this office as a membership fee to the National Bee-Keepers' Union. You will get a receipt by return mail, and may then sleep soundly with the assurance that you have done your duty in this case! It is *now* or *never!* Inaction will insure defeat—activity is *life—energy—power!*

UNION IS STRENGTH!

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

How to do it.—M. M. Baldrige, of St. Charles, Ills., makes the following good points in confirmation of the views expressed in his address before the Chicago Convention last fall :

Honey, the commission men say, is slow of sale and lower than some time ago. The reason is obvious to me, and it should be to others. The main reason is, that the grocers are unwilling, as a class, to invest in cash 20 to 22 cents per pound at wholesale, for honey, and take their chances of selling the same at 25 cents, which they must do to secure any profit at all. The result is the honey remains in the commission houses.

Now what does this teach? Simply what my Chicago essay advocated, namely, the necessity of placing honey, in small lots, in grocers' hands, to be paid for when sold.

The fact is, there are at this time thousands of groceries, in this State, without a pound of honey in them for sale at any price. All the honey in the United States might have been sold by this date at 25 cents per pound for choice white comb, had it been kept where consumers could see and buy it.

The time will soon be here when the crop of 1888 will have to be placed on the market, and all should consider well the remarks of Mr. Baldrige, who has had more experience than almost any other man, in placing the honey on home-markets. We heartily commend the plan presented, and hope it will be practiced during the coming season.

Phenol for Foul Brood.

—Wm. Beall, Ligonier, Ind., asks the following :

In Cheshire's pamphlet on foul brood, on pages 16 and 17, he mentions "Calvert's No. 1 phenol." What is that? Our druggist knows nothing of it. How many drops are necessary to a quart of syrup for feeding bees, to cure foul brood?

It is difficult to obtain pure phenol except of the large wholesale dealers. Calvert's No. 1 can be obtained at this office. One drop to 500 drops of the syrup is the formula recommended by Mr. Cheshire, as will be seen by the following from his pamphlet :

"I found that 1-200 (that is one part of pure phenol to 200 parts of syrup) was refused by the bees altogether; that 1-400 might be given constantly to a sound colony without appearing to limit the queen in breeding, or *touch her health*; that 1-500 dispatched foul brood quickly, even while honey was coming in; and that 1-750 appeared enough when it was not. I have established these quantities as the correct ones." Moderate quantities are, therefore, not injurious.

A Compendium of useful know e

about bees. This is what the Germantown, Pa., *Telegraph* of the 1st inst., calls our bee-book. Here is its notice in full :

BEES AND HONEY. By Thos. G. Newman, editor of the AMERICAN BEE JOURNAL, Chicago, Ills. Price, \$1.—Gives in a concise manner the history of bees, tells how to establish and manage an apiary, describes hives and surplus receptacles, how to produce and care for honey, treats of bee-pasturage, improvement of bees, honey and bee shows, comb foundation and its use, honey extractor and its use, and closes an instructive and useful volume with general advice to beginners. It is a convenient compendium of useful knowledge on bees.

QUERIES AND REPLIES.

FEEDING SORGHUM MOLASSES IN THE SPRING.

Written for the American Bee Journal

Query 519.—Will it do to feed sorghum molasses in the spring, mixed with sugar? Or will it do without mixing?—H., Iowa.

Yes, either way.—R. L. TAYLOR.

I have had no experience with "sorghum" as a bee-food.—H. D. CUTTING.

Take the sugar and leave the molasses alone.—J. P. H. BROWN.

Anything that the bees will take, will do at that time of the year.—G. M. DOOLITTLE.

I would prefer to feed the best white sugar, and let the molasses alone.—P. L. VIALON.

If it is a good article it will do without mixing, if the weather is warm enough for the bees to fly.—A. B. MASON.

Sorghum is not fit to feed to bees at any time, mixed or unmixed.—M. MAHIN.

In the spring, when bees are flying freely, it will do to feed almost anything.—Mrs. L. HARRISON.

We would not use sorghum, although it matters less in the spring. But the best sugar, we think, is just as cheap, for it contains more food.—DADANT & SON.

I would not feed sorghum molasses under any circumstances. Trade your molasses for white sugar, and make a syrup.—J. M. HAMBAUGH.

If the bees need feed, and will take sorghum molasses, I should give it in the spring.—G. L. TINKER.

If used up in breeding, it would not be objectionable. It would answer, I think, without mixing.—W. Z. HUTCHINSON.

I think that it will do either way. I have never tried it, but I should be very willing to do so, if any one would furnish the molasses.—A. J. COOK.

I think that there will be no trouble in feeding it clear, when bees can fly; but I should not want any of it clear or mixed, in the hive for winter.—C. C. MILLER.

I have never fed sorghum molasses, but if the bees like it, I think it would do no harm when they are flying every day. Whether it would be economical feed or not is another question.—EUGENE SECOR.

It will do to feed anything in the spring, when the bees can fly freely, which they will eat. Probably the

sorghum molasses might do without the sugar. Surely the sugar would do without the molasses. Honey is better than either of them for feeding bees when they can fly and brood is desirable.—JAMES HEDDON.

It can be used in the spring either mixed or unmixed. It should only be fed in such quantities that it will *all* be used as food, and none stored for surplus or for winter stores.—J. E. POND.

If you can get the bees to take it, pure or mixed, it answers for breeding purposes as well as anything so far as I have seen; but some colonies are slow to take sorghum "in theirn." I have tempted them by flavoring it with honey.—G. W. DEMAREE.

I do not think that sorghum molasses will do, even if mixed with sugar. Such a compound would cost nearly as much as good sugar syrup, which is certainly much better for the purpose.—C. H. DIBBERN.

I never would feed bees anything inferior to honey. If there should be a charge of adulteration it will be convenient to be able to say that the alleged adulterant costs more than the article adulterated. Nothing "shuts up" the "smart Alecks" like this.—J. M. SHUCK.

It would be better to feed the bees with honey or sugar syrup. Why try to use sorghum molasses, and fuss with mixing sugar with it, when nothing would be saved, and absolutely nothing gained by its use? Sell the sorghum and buy sugar if you have no honey for spring feeding.—THE EDITOR.

MAKING HIVES, HAND-HOLES AND CAPS FOR HIVES.

Written for the American Bee Journal

Query 520.—I expect to make some hives with lumber planed on one side. 1. Will it be necessary to have the lumber on the inside of the hives planed? 2. What is the best way to make hand-holes in the hives? 3. What kind of a cap is best to turn rain and withstand wind?—M., Nebr.

1. No. 2. With a wabbling buzz-saw. 3. A board with cleats.—A. B. MASON.

1. No. 2. With a wabbling saw. 3. A sound, flat, cleated board.—W. Z. HUTCHINSON.

1. Hives with lumber planed on the inside can be more easily kept clean. 2. Use a wabbling saw. 3. Have the cap covered with tin.—J. P. H. BROWN.

1. It is not absolutely necessary, but it is better. 2. I do not need any. 3. A Langstroth cap, with matched cover, all things considered, is the best.—Mrs. L. HARRISON.

1. It is not necessary, but it is better. 2. We do not make any. 3. We

always use a roof over the cap.—DADANT & SON.

1. No; but I prefer to have it planed on both sides. 2. Hand-holes are best made with a gang of saws. 3. I prefer a plain board with cleated ends for a cover.—G. L. TINKER.

1. I would not make hives with lumber planed only on one side for my use. 2. With a wabbling saw. 3. A flat cap.—P. L. VIALON.

1. It is not necessary. 2. A wabbling buzz-saw does it excellently. 3. If a hive-cover is meant, a sound board well painted and cleated at the ends is good enough.—R. L. TAYLOR.

1. No, but it looks better. 2. If you can get a saw to cut them, that is best; if not, nail on a cleat. That serves about as well.—A. J. COOK.

1. It is not necessary, but I think it would be better. 2. A wabbling saw makes good work, but I think that a cutter-head makes a little smoother.—C. C. MILLER.

1. Have the inside planed, by all means. 2. Saw them with a wabbling saw. 3. Any that can be made water-tight. I have used all kinds, and have found no trouble.—J. E. POND.

Why not plane on each side and make a good, neat job of it? 2. A "dado head" is a good way; some use a wabble saw. 3. I do not know what is the best. What some think is the best, others would not use.—H. D. CUTTING.

1. I would use the rough side of the boards for the inside, then the hives can be painted, and it makes no difference to the bees. 2. I do not know. A strip can usually be nailed on, to answer the purpose. 3. Any kind that is water-tight, and will not blow off.—C. H. DIBBERN.

1. Lumber dressed on both sides always, and the lumber for hives should be "thickened" also, so that hives and parts of hives may be interchangeable. 2. Cut "hand-holes" with a wabbling saw. 3. A plain top-board made so that either side may be used next to the bees, is best. It soon becomes thoroughly propolized on both sides, and will not leak, and is not likely to blow off.—J. M. SHUCK.

1. No, it is not actually necessary, but enough better to pay for all trouble, in my opinion. 2. With a saw set wabbling, if you have a power saw. If not, holes bored for the fingers do very well. 3. I use one covered with tin, and I consider that it pays.—G. M. DOOLITTLE.

1. Yes, by all means. A rough surface will be a receptacle for large quantities of propolis. Little or none will be put on a perfectly smooth surface. 2. I see no need of hand-holes.

3. A cap made of $\frac{3}{4}$ -inch lumber, with comb roof. The cap should rest on cleats around the hive within $\frac{1}{2}$ -inch of the top of the brood-chamber.—M. MAHIN.

1. You will save the bees a great deal of unnecessary work by having the inside smooth. They will propolize a rough surface. 2. If you have no circular saw to make hand-holes, a cleat nailed around the hive on the outside near the top is just as good. 3. A board cleated to prevent warping is just as good as anything.—EUGENE SECOR.

1. It would be preferable to have the lumber dressed on both sides. 2. With a buzz-saw, set wabbling on the mandrel. 3. When we cannot get lumber wide enough to cover the entire top, and are obliged to make two-piece lids, we cut a saw kerf at the bottom of the inside joints $\frac{1}{2}$ -inch deep, and insert a tin, V-shaped. Of course all lids should have at least two coats of good paint.—J. M. HANBAUGH.

1. It is not necessary to have the lumber planed on the inside, although I prefer it so, but in your case, put the rough side in. 2. By setting a rip-saw wabbling, and then get some one who understands it, to tell you how to fix the rests, and let the pieces down on the saw, and take them up again without sawing your fingers off. 3. We have no trouble from rain or wind, and do not want any "cap" of any kind.—JAMES HEDDON.

1. If the lumber is ordinarily smooth from the saw, there is no need of dressing the inside of the board. I have used a number of hives made in that way, and they are as good as any. 2. In the absence of machinery to cut the "hand-holes" with a saw set wabbling, you can lay a $\frac{1}{2}$ -inch strip of wood about 3 inches below the top of the end-piece of the hive, and draw a line on each side of the strip, so as to be about $3\frac{1}{2}$ inches long; then with the point of a sharp pocket-knife, trace the lines, cutting as deep as you can conveniently; and then with a sharp, $\frac{1}{2}$ -inch chisel, make a cut slanting towards the centre at each end of the lines, pry out the "chip," and clean out nicely with the chisel. I can cut the hand-holes quite rapidly in this way. 3. I do not know what you mean by a "cap." I use a flat, cleated hive-cover, and a water-tight shade-board over it.—G. W. DEMAREE.

1. It is not absolutely necessary, but it would be very slovenly to have it rough. 2. A cutter-head does the work neatly, but a wabbling saw will do it well enough, if any hand-holes are thought to be necessary. 3. Opinions differ, but any cap will do that cannot easily be blown off, and which is water-tight.—THE EDITOR.

CORRESPONDENCE.

GOOD QUEENS.

Queens not Reared by Natural Swarming Inferior.

Written for the American Bee Journal
BY G. M. DOOLITTLE.

On page 790 of the BEE JOURNAL for 1887, appeared a very interesting article from the pen of that sharp, but good-natured writer, G. W. Demaree. I am really glad he wrote that article, for it gives me a chance to say some things which I have desired to say for some time. But I have no desire to do so, in aught but a kindly spirit, and for good, regarding the improvement of our queens; for the spirit of controversy should never enter into any discussion if we would benefit the world, and those with whom we disagree.

I accord to Mr. Demaree, that "right to his own views" which he gives to me most willingly, and would not have said a word further, were it not that he seems to think that my articles on the subject of queen-rearing are "mere assertions" which are based on "mistaken theory, except so far as I bring my own experience as proof of the soundness of my position." Did I desire so to do, I could bring to my rescue regarding the superiority of queens reared by natural swarming, such great lights as Grimm, Gallup, Heddon, etc.; but as Mr. Demaree only lays down his theories and experience beside mine, I consider it unnecessary to do so.

My experience with "artificial" queens dates back to 1870, when I became "crazy" on the subject of queen-rearing—crazy about that kind which "costs the apiarist nothing," or but a trifle at least, and so I reared lots of these cheap queens, only to find in 1872-73 that my apiary was almost ruined by the death of queens, dying of old age after a period of only eight months to a year and a half had elapsed after they had left their cells.

When the "dollar"-queen business was first started, I opposed it, as nearly all of our older bee-keepers know, opposing it on the ground that so many queens of the kind "which cost nothing," would be put upon the market. I have never fought such queens as Mr. Demaree rears, only so far as the claim is concerned that they are better than those reared by natural swarming. My main effort has been to impress upon the minds of all, that we as apiarists should try to rear queens of the highest type for honey-production, gentleness, good wintering qual-

ities, length of life, and strength of workers, enabling them to fly further, fly faster, and endure more hardships than their ancestors did. Has this not been a worthy object?

It is hardly fair for Mr. Demaree to take his best specimens of queens reared under the greatest care and skill at his command, and compare them with the poorest of natural-swarming queens. I am as well aware as any one, that even "queens reared by natural swarming" can be so abused as to have the queens of little value, in these days of controlling after-swarms by the many methods put forth. Candidly, did Mr. Demaree ever try my plan of rearing queens by natural swarming, where half of the swarm is returned to await the development of the young queens? And after such queens were laying, did he ever compare them with his that were reared under "scientific breeding?" If not, I wish he would do so and report. But to return:

Why I opposed the whole "dollar"-queen traffic, was because queens under this name, sent out for \$6 to \$9 a dozen, were reared by no "scientific breeding," but by all the poorest plans and tricks known to the trade.

To illustrate: A few years ago I wrote to a prominent queen-breeder, whose name stands very high, for a "dollar"-queen. He replied as follows: "I am shipping queens by nearly every mail, but as I am desirous of your good opinion, I would like to rear one for you when I rear my own, which I am now preparing to do. If you can wait, I shall be pleased to have you do so." If this queen-breeder was rearing and sending out queens, equal to queens reared by natural swarming, or as good as Mr. Demaree rears, why did he wish that I should wait? His pretensions in the bee-papers, that queens from the egg "were better than those from natural swarming," with such an acknowledgement from him, amount to nothing with me: and it was at this class of queen-rearers that my article was aimed, to which Mr. Demaree refers.

If all queens, reared and sent out, were as Mr. D. represents his to be, I should not have been called upon to have said a word. That they are not, is often proven by my correspondence.

One writes in the month of May: "What is the trouble with the queens that I have bought? Last week I found three dead in front of their hives. This leaves but two out of six introduced last fall. The season before, out of three introduced in August, I had only one left in the spring, and she failed in June."

Another says: "Out of nine queens purchased, seven did not live six

months, and only one of them lived a year." Still another says: "I am disgusted with buying cheap queens; five out of six purchased this season having died of old age." And so I might go on with many more of a similar nature, but the above is enough to convince all, that *all* queens sent out are not such as they would desire to stock an apiary with.

One thing, however, I am pleased to note, namely, that the number of poor queens sent out is growing proportionately less with each year, and I hope this state of things may continue, until all may feel the responsibility that is resting upon them, to do to others as they would be done by. Always bear in mind, fellow bee-keepers, that upon the queen largely depends the profit or loss in apiculture, and to her we must look quite largely, if we are to compete with the low prices of our product, predicted by some, in the near future.

Borodino, N. Y.

[Bro. Doolittle is right. We have repeatedly protested against the cheap-queen traffic. What we need is better queens, not lower prices. One good queen is worth a dozen poor and correspondingly cheap ones. This "heap-by-cheap" business is the bane of modern apiculture, and should be "frowned down" by all who desire its prosperity.—Ed.]

SHALLOW HIVES.

Shallow Brood-Frames and Side-Opening Sections.

Written for the American Bee Journal
BY M. M. BALDRIDGE.

Under date of Feb. 13, Dr. Tinker writes me as follows:

1. I am especially pleased to hear your opinion of 7-inch brood-frames. From it I infer that your verdict will not differ much from mine on the Heddon hive.

2. The great value of the open-side section rests mainly upon the proper ventilation which it affords.

My reply to the foregoing is as follows: 1. I have, as before stated, used many hives with brood-frames 7 inches deep, in the clear, and have used more or less of them since 1876; ten frames in each story, but eight frames would be better. Geo. Thompson, of Geneva, Ills., and Jas. M. Marvin, of this city, have used 6-inch brood-frames, 11 in each story, since 1877, and they still prefer them to deeper ones. They now use no other hive, and claim that bees winter as well in these shallow hives as in deeper

ones. They always winter their bees in the cellar.

I have read Dr. Tinker's essay on Heddon's new hive very carefully, but I cannot endorse all he says. I have not yet used this hive, but I do not apprehend any trouble in its use; nor do I expect to find the difficulties and objections as set forth in the Doctor's essay. I shall try to use some of the new hives the coming season, and then I shall know for myself. I still think, however, as favorable of Heddon's new hive as I did one year ago.

Open-Side Sections and Ventilation.

The open-side sections may be just what honey-producers want, and they may not be. I would rather use them awhile before I express an opinion. I can, however, force bees to store *all* their honey in any style of section; and, I think I know how to secure the surplus in sections free from bread—no matter how shallow the brood-frames may be. I also think that I know how to construct and to manipulate the sectional brood-chamber so there will be no comb, worthy of mention, between the two sets of brood-frames.

St. Charles, Ills.

NEW YORK.

The Second Day of the State Convention—Jan. 18.

Written for the American Bee Journal
BY G. H. KNICKERBOCKER.

The convention was called to order at 9 a.m., and the following were appointed a committee on exhibits: W. L. Coggsall, J. H. Taylor, and W. H. Beach.

The question, "How can we organize an international bee-keepers' association that will best promote the interests of bee-keeping?" was then taken up, and the following essay from Dr. C. C. Miller, of Marengo, Ills., was then read by the Secretary:

An Inter-National Bee-Society.

Before inquiring "how," it may be well to inquire whether it is desirable to do so at all. Only a few weeks ago an organization held its 18th annual meeting in Chicago, whose avowed object is "to promote the interests of bee-culture." As this is the thing inquired for, have we need of anything further? The North American Bee-keepers' Society has identified with it some of the best men of our ranks. So far as I know, great harmony prevails in it, quite free from bickerings and jealousies, its meetings are profitable and highly enjoyable, and the reports thereof eagerly read by thousands who

are not enrolled members. But the fact that among its warmest friends are found those who are raising the question as to some change in its character, shows that, as constituted at present, it is not all that can be desired.

Whether it be better to amend the present organization, or to organize anew, in either case it is desirable to discuss the matter thoroughly in convention, and also in the bee-papers, and try to find out just exactly what is wanted.

At the Chicago convention Mr. Newman suggested a plan of operation. Let others give their thoughts. If the matter is fully talked up, I do not see why we cannot be ready for action sometime during the present year, if indeed a feasible plan of action can be agreed upon at all.

I do not feel competent to map out a plan, and all I shall say is merely in the way of a starter. Perhaps it may help to say what there is in the North American Bee-keepers' Association, as now constituted, that ought not to be.

It ought not to be local. To a considerable extent it is comparing the last North American with the last Northwestern, both being held in Chicago. The North American had seven more members in attendance than the Northwestern, one more State represented, and one member from Canada. At the last meeting of the North American in New York, besides the members from New York, there were present as follows: Ontario, 7; Pennsylvania, 4; Georgia, 1; Ohio, 1; Massachusetts, 1; fourteen in all.

You can judge better than I, how much this differed from a State convention. Does it not look a little like a farce to call this a North American convention, in which more than six-sevenths of the States were in no manner represented? I remember hearing an old professor once say, "Yes, any fool can find fault, but the remedy is what we want." I have taken the fool's part, and leave others to find the remedy. I know that some New York bee-keepers are awake on this subject, and I shall look with interest for a report of your discussions, as indeed I always do. C. C. MILLER.

John Aspinwall—The cry for better organization comes from every quarter. We have no organization as it should be. The name "association" is a misnomer. We have conventions rather than associations. The formation of an international association must be accomplished by calling on the various associations, and these should be affiliated with the "national." It is ridiculous to think that an international association can be formed by

the North American Association, by simply saying, "We form ourselves into an International Association." It should begin with county organizations.

Mr. Aspinwall also described briefly the methods of the British Bee-Keepers' Association, which has a membership of 3,000; referred to the use of a "brand" by the dairymen, and advocated the adoption of a copyright label and a bottle with the mark of the association blown in it, to be used by all members of the association, thus giving a guarantee of the purity of extracted honey.

A. I. Root said that something ought to be done to obtain a more thorough organization, and that it should be a united and concerted body. He heartily favored the movement, and thought that more enthusiasm should be aroused among the bee-keepers, and that such an association should also look after the freights charged shippers, as in some places they charge more to carry honey than they do to carry molasses.

N. N. Betsinger was in favor of a "union," but believed that the association should be for the benefit of its members, and not for all the rest of the world.

W. L. Coggshall said that he was willing to make monthly reports, and give \$1 to sustain an organization for the dissemination of such reports to all members. Several others spoke briefly on the subject, after which the following resolution was offered by Mr. Aspinwall and adopted:

Resolved, That a committee of three be appointed to draft a scheme for the formation of an International Association, which shall be of benefit to its members; the report to be returned this evening.

The chairman named John Aspinwall, C. G. Dickinson and A. I. Root as the committee.

Miscellaneous Topics.

The giving away of secrets was discussed *pro* and *con*. Some were in favor of publishing everything, while others believed that for the best interests of those already engaged in the pursuit, all knowledge and secrets should not be scattered broadcast.

The origin and different treatments of foul brood was also fully discussed. Mr. Betsinger said that the simplest, easiest and surest method was by the use of salt. Some had laughed at and ridiculed the statements that he had made at Syracuse a few years ago, but he said that he now has Mr. N. W. McLain to back him up, and he considered him good authority.

The inaccuracy of the newspaper quotations in regard to honey was also

discussed. Thos. W. Mulford said that the market reports were hard to obtain, and must be taken from dealers near at hand; but if bee-keepers would send them correct reports, they would be glad to publish them.

A recess was then taken until 1:30 p.m.

AFTERNOON SESSION.

The convention was called to order at 1:30 p.m. by President Clark. The Secretary then read a letter from I. L. Scofield, the Treasurer, stating that he was sick. Mr. Betsinger suggested that the Secretary obtain the report of the Treasurer, by mail, and incorporate it in the minutes of the session.

The election of officers resulted as follows: President, W. E. Clark, of Oriskany; Vice-President, P. H. Elwood, of Starkville; Secretary, G. H. Kinckerbocker, of Pine Plains; and Treasurer, C. M. Goodspeed, of Thorn Hill.

President Clark then called Vice-President Elwood to the chair and delivered his annual address.

The Production of Comb Honey.

"The best management of the apiary to produce comb honey," was then discussed.

Mr. P. H. Elwood—The principal thing in producing comb honey is to get strong colonies early in the season, as almost everything hinges on this one feature. I cannot recall a single instance when our bees were in good condition, that we did not get a fair crop; but I remember that we failed several times because we could not get them strong in time for the harvest. I have used wide frames at the sides of the brood-nest, but we abandoned that because we got no more honey than by top-storing. We have practiced making colonies queenless for several years, and have had good results; no system that we have ever tried will produce as much comb honey as by this way. The principal drawback is in re-queening. We first adopted this method when we had chiefly black bees, and then did not have as much trouble in re-queening. We leave the colonies queenless 16 to 18 days.

Mr. Root—Will the colony not rear a queen if there was brood left in the hive?

Mr. Elwood—We prevent that by breaking out all the queen-cells on the ninth day.

N. N. Betsinger—I would advise a method very similar to Mr. Elwood's, except that I would not destroy the queen.

The Reversible Feature in Hives.

R. L. Crocker—I used the past season 46 reversible hives, and 41 Quinby hives. I followed the directions of

Mr. Heddon as nearly as I could, and was very successful. I worked the hives exclusively for comb honey, used only one shallow brood-chamber, and I did not reverse it. The past season was a very poor one. New swarms, that were put into the Heddon hives stored rather more honey in the boxes than those put in Quinby hives, and in the fall were as strong in bees as other new colonies, but had scarcely any honey in the brood-chamber, and some of them had nothing at all. The most of those in Quinby hives had enough to winter on. I have always had the best results the first season with the Heddon hives; after that the Quinby gives the best results. The bees in the Quinby hives also build up *very much* faster in the spring, than those in Heddon hives.

In answer to some further queries, Mr. Crocker said: "I am not as yet fully satisfied with the Heddon hive, and I do not think that it is the hive that I want."

Artificial Fertilization of Queens.

The subject of "Artificial Fertilization of Queens" was discussed as follows:

C. M. Goodspeed—Years ago this wonderful feat was said to have been accomplished. We have had 10 or 15 years of success alternating between the green-house, the tent, the barrel, the hive, the operator's thumb and finger, and last the royal-cell itself. Each of these has had its advocates, its experiments, its proclaimed success, and in its turn has sunk into the oblivion of practical nothingness. We will take a passing view of two only of the above methods of securing artificial fertilization. First, let us consider the manipulation as it is practiced on the royal-cell. After the embryo germ has attained some size, or about two days before the cell is capped, select two or three drone larvæ of about the same age, reduce them to complete jelly, and place in the royal-cell about two drops (or that bulk) of this mass. If more is used, the bees will eject the whole. I have also used the organs of mature drones for this same purpose. I can and have repeatedly produced queens by this process as large when first hatched as laying queens, and from all appearance one would judge them to be such. But in every instance during a whole summer's trial, I failed of getting the desired result; a short time after hatching they assumed the size and motion of a virgin queen. After the queen-cell is entirely completed, the same operation may be performed through the side of the cell, but the closing up must be carefully secured by melted wax, or the bees will destroy the whole. The above I call unsuccessful.

Mr. Goodspeed then read some extracts from a report of successful experiments made by N. W. McLain. Continuing he said:

I believe that the best method is this: Select the colony containing the drones you wish to use. Isolate it so far as convenient. Place the queen within hearing. Secure by guards both drones and queen from flight. Confine the drones until 4 o'clock, or an hour after the natural flight of drones. At the time and place of the experiment, give them a regular flight each day. At this time, when the selected drones are well in air, liberate the queen and wait for her return, which will be in a very short time. Nine times out of ten it will succeed in this way. The mating is perfectly natural, yet all the advantages of the "artificial" are secured with none of the disadvantages.

Combs in Unfinished Sections.

Mr. Foster asked if it was profitable to use the combs in unfinished sections the second year.

Mr. Elwood—Yes; extract the honey and use them as "bait" to get the bees to work sooner in the boxes.

Mr. Foster—I have done so, and taken pains with them, but the honey was of inferior quality, and the combs presented a watery appearance.

Mr. Betsinger said that the honey was not all removed from the combs; that this had granulated, and caused the watery appearance. It is always best, after the honey is extracted, to let the bees clean out the combs before putting them away.

Mr. Elwood—We expect the honey to be second quality, because it is gathered first, and remains longest on the hives; but I know of no way to get the bees to work in the sections as soon.

The President then appointed John Aspinwall and N. N. Betsinger members of the committee on Constitution and By-Laws, in place of S. M. Locke and I. L. Scofield. P. H. Elwood, C. M. Goodspeed, and J. H. Taylor were also appointed as a committee on resolutions, after which an adjournment was taken until 7:30 p.m.

EVENING SESSION.

The Secretary read a letter from Mr. L. C. Root, deeply regretting his inability to be present, and open the discussion on the question, "How can we increase the demand for honey and maintain present prices?" He, however, submitted an essay, which was then read, and the sentiments generally approved.

Mr. Aspinwall—I believe that Mr. Root has hit the nail squarely on the head, and covered the ground perfectly.

It was then suggested that, inasmuch as Mr. Root had removed from the State, the Association should make him an honorary life member, with all the rights and privileges of the Association. This was then done.

President Clark remarked, that the Association now had two Roots as honorary members, and if they only would strike deep enough, the Association would be firmly "rooted."

The committee on constitution and by-laws submitted its report, which was substantially the same as the old constitution, with the amendments which were made at Syracuse, in 1885. After a short discussion and a few slight changes, the report was adopted.

Mr. Root, of the committee on the question-box reported 16 questions and replies.

Marketing Comb Honey.

This subject was then discussed by N. N. Betsinger. Going back to the infancy of honey marketing, he noted the gradual increase in sales, and talked about prices for honey, past, present and future. He attributed the fluctuations, in a large part, to the packages in which it was sold. He thought that the improvements made, both in the packing and placing on the market, increased the sales, as the consumers were continually wanting something new. He believed that false reports in regard to the amount of the honey crop also had its influence on the market.

Mr. Dickinson said that there is now too much variety in shape and size of packages. I think that the wishes of the wholesale dealers in regard to the size of packages should be consulted. He also said that dealers preferred to have packages that were a little short, rather than over-weight; that is, a 25-pound package should weigh a trifle less, rather than to weigh 26 or 27 pounds. Retail grocers selling them out by the piece, lose on the heavier packages, and therefore they always reject them and selected the lighter crates. He also advised the grading of honey very carefully, without ventering the crates. Get the honey into the market as clean and nice as possible.

A few minor subjects were discussed, after which the report of the committee to draft a scheme for the formation of an international association was called for, which was then read, and after a short discussion, was "tabled" until a subsequent session.

A recess was then taken until 9 a.m.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

SECTION HONEY.

The Use of Thin Foundation for Comb Honey in Sections.

Written for the American Bee Journal

BY F. I. SAGE & SON.

During the past few years we have had much complaint, and many curious questions asked, regarding the so-called "fish-bone" found in honey in sections by consumers. We have before asserted that there are many thousands of intelligent people who believe that tons of comb honey is manufactured by man, without the least aid from the bees, and these people, when they purchase a section or two of honey in the centre of which they find a thick sheet of gutta percha (as they express it), are quite easily convinced that "Wiley" knew what he was talking about when he wrote his "scientific pleasantries."

That Wiley and thick foundation have greatly damaged the honey-trade, we have not the slightest doubt, and although many bee-keepers may take it all as a "huge joke," if they could but follow us through our honey-selling routes, they would be quickly convinced that we are correct in our estimate of the damage done to bee-keepers by these causes.

So well satisfied are we that the two causes named above have, and are damaging our honey-trade, that we the past season conducted some tests and experiments to decide as to which is the best style and manufacture of *thin* foundation for honey in sections; and without consuming space by going into the details of our tests, we will simply say that the *thin*, flat-bottomed foundation proved to be decidedly the best and most satisfactory of any. We hope that all bee-keepers of whom we buy honey will hereafter use thin, flat-bottomed comb foundation. We recommend this because it has proved to be most satisfactory to us, for we are not acquainted with the makers of it.

This section-foundation question is a serious one, and has more influence on the honey market than many bee-keepers are aware of. At first glance, we should most certainly decide that foundation made with natural shape of base would be most acceptable to the bees, but our practice proves the superiority of the flat-bottom foundation; and it has occurred to us that *possibly* the bees are *compelled* to still further thin and manipulate the flat-bottom cell in order to bring it to the desired shape.

We do not think it advisable for bee-keepers to make thin foundation for their own use, as not more than one in twenty would produce an article equal to that made by almost *any* of

the leading manufactures. Of one thing our bee-keeping friends may be certain, viz: That we shall hereafter be more particular when buying honey, to examine very closely the quality and thickness of foundation used in their sections. We hope they will consider their own and our interests identical in this matter, and govern themselves accordingly.

Wethersfield, Conn.

GRAPES AND BEES.

Poisoning the Bees, as Advised by the "Messenger."

Written for the American Bee Journal
BY G. B. OLNEY.

No doubt any one would have been surprised to have overheard the interview which I had on Feb. 11, with our Atlantic "Wiley," the editor of the death *Messenger*. After exchanging a few compliments, etc., I accosted him with the following: "I would be pleased to know the author of an item published in the *Messenger* a short time ago, proposing a plan of administering an active poison to the honey-bee, for the purpose of protecting the grape-culture of our vast and noble country, of this free and independent America."

"Well, yes," said Mr. Wiley, "I remember there was an article something of that nature in one of the back numbers, and, by the way, in some places the bees are creating sad havoc with many grape-fields, and I don't see why something isn't done to rid such parts of the country of the little pests. In some places there are State laws to protect certain districts wherein grape-fields exist to any great extent."

Where do such laws exist, Mr. Wiley? "Why, in California, for one." Any other place?

"Well, that is the principal place where grape-growing, as a general thing, is made a specialty, and the growers have to be protected."

By what authority do you say such laws exist in that State? "Why, Dick Harding told me, and he came right from there."

Dick Harding! said I. That little, low-lived, brainless, one-horse lawyer! Is it possible, Hank, that you have come to this, to lay yourself bare to the world from information received from a some-and-substance of a complete nothingness. If you are no better judge of calibre than that, I pity you.

I then gave him the BEE JOURNAL of Dec. 21, 1887. He looked at it, and then with a clinched fist, "banged" upon it, and roared aloud: "There's a lie right there; he says it is a local sheet!" It was no sheet at all; it was

a slip. I saw it before the fellow sent it, and I didn't know until lately that there was a BEE JOURNAL published.

Wiley, I beg to inform you that that BEE JOURNAL was first edited at Washington, D. C., by Samuel Wagner, in 1861; then in Chicago by Thos. G. Newman, and has a circulation throughout every civilized nation on the globe. I do wonder what you have been at the last twelve years of your editorial life! Not dead, are you? but sleeping! And now, sir, I think you have a much larger wad than you can conveniently swallow, and unless your throat is more elastic than I think it is, it may choke a little before you get it down. It is not likely you could do much harm amid the intelligent men and women that might perchance read your article; but there are some that might think they had struck a bonanza on "protection," and adopt your nefarious scheme of extermination, thus laying themselves liable to the law, damage the innocent, and do untold mischief.

I then left him in his dilemma, and called on a Mr. Bates, editor of the Cass County *Democrat* who is a gentleman, and an honor to his profession. He readily caught up the line of thought intended, and requested me to leave the number of the BEE JOURNAL with him. I did so, of course, and in the next issue of the *Democrat* he gave the *Messenger* and his nefarious article a severe censure.

Atlantie, Iowa.

STARTERS.

Fastening Foundation in the Sections.

Written for the American Bee Journal
BY ELIAS FOX.

I would say in reply to Mr. Eden's article, on page 27, that he is a very good mathematician, and so far as he has gone, he has figured correctly. I would like to have him compute the cost of fastening starters by using melting wax. I have tried both, and for me my method is cheaper, better, and more speedy.

I never have found any starters curled to one side, and I have had them stand all winter. If they are properly fastened by my method, they will not curl.

Mr. Eden also says that if I should use a starter that would reach across the section, I would find that it would prove very unsatisfactory. In reply to this I would say that I use the same implement for fastening foundation in brood-frames, and prefer it to any other method.

In reference to Mr. Haag's article on page 42, I suggest that I did not say that my method of fastening foundation was the only satisfactory method. It has *proven* so for me, and if Mr. Haag does not approve of it I would advise him not to use it. I have tried his method, and discarded it on account of the waste of time and wax. I said that not one starter in 500 would drop off, if properly put on! You cannot get bees enough on one to break it loose. I have no use for grooved sections.

My bees seem to be in as good condition as when I put them in the cellar, which was on Nov. 8, 1887.

Hillsborough, Wis., Feb. 2, 1888.

WINTERING BEES.

Bees Wintered in the Cellar—Rearing Queens.

Written for the American Bee Journal
BY WM. H. FORD.

In the fall of 1886, I put into the cellar 23 colonies of bees, and they wintered well. I took them out in the spring about March 28, with the loss of but one colony, its queen having died of old age. So I had 22 colonies to commence with last season. They built up fast, and were strong by the time apple trees bloomed. Swarms were expected early, but on the account of the dry weather there was scarcely any colonies that swarmed. I had only 5 or 6 swarms, but only one did anything, and the rest I doubled up.

I purchased one imported queen on Aug. 25, and a 3-frame nucleus. Can I rear queens from them in the spring? What method is the best for early spring?

I put 23 colonies into the cellar last fall, and I think they are wintering all right. They did not gather any honey the past season. Basswood bloomed about July 1, but on account of dry weather it did not yield any honey; so I had to feed my bees for winter stores. I put them into the cellar on Nov. 14, 1887.

I owe the AMERICAN BEE JOURNAL many thanks for what knowledge I have obtained from it. This report is written for my apiary located in Marshalltown, Iowa.

Yorkville, Ills., Feb. 6, 1888.

[Yes; you can rear queens from the imported bees in the spring. Remove the queen, and let the bees start queen-cells. If you want several queens, transfer the cells to nuclei, and when the queens are laying, you can introduce them to full colonies.—Ed.]

BRACE-COMBS.

The Objections to the Sectional Hives Discussed.

Written for the American Bee Journal
BY JAMES HEDDON.

I quote the following from a letter just received from one of New England's brightest bee-keepers, and withhold the name because I have not the writer's permission to publish it:

Referring to the essay read by Dr. G. L. Tinker, at the convention of Ohio bee-keepers, regarding the sectional brood-chamber, etc., will you please give, through the columns of the AMERICAN BEE JOURNAL, your answer to his statements; especially where he says, "If the honey-flow is extra good, the bees proceed to fill up the horizontal space between the two brood-cases, with brace-combs, and fill in with honey?" We have not yet arrived at this point. He seems to have given this style of hive a black eye, so to speak, and if you can give any satisfactory answer to this statement, we should be very glad to see it.

Well, neither have I yet arrived at the point in question. I can truthfully state that during a four-years' use of the hive, I have never met this brace-comb trouble, and the following quotations from Dr. Tinker's article on page 154, of 1886, makes his essay quite an enigma. I quote:

But first, what is the most practical and advantageous method of disposing of the brood near the sections at will? Beyond question it is the proper management of the shallow, sectional brood-chamber. Has it any disadvantages? We assert fearlessly that it has not, neither in wintering, the laying of the queen, nor in the manipulation of hives or combs.

In another place in that article we find this:

Again, as we shall not have occasion to handle the frames very much, but instead, the sectional cases, it will not be greatly to our advantage to have the frames as readily movable as are the Langstroth frames. On this account, a very simple case is all that is necessary to hold the frames.

This was written after my new hive was brought out, and in Mr. Root's foot-notes to the article, he says:

By the way, the Doctor's letter is a consideration of the principles suggested by friend Heddon, though he does not say so.

No, my name was not mentioned, but more than ignored, although nowhere in all prior bee-literature, could one word relative to these principles be found.

The honey season of 1886 was an extra good one in the Doctor's location, he tells us, and after passing through that good season, securing a large yield of surplus comb honey, especially over my divisible brood-chambers, as he wrote me, he sent me the following testimonial, dated Oct. 9, 1886:

I have been able the past season (which has been extra good in this locality) to make a full and, as I think, satisfactory trial of

your new principles, in the use of 38 hives. Your double brood-chamber of cases, made so as to be interchangeable and invertible, is a great success, in working for comb honey. The facility for contracting and expanding the brood-space is perfect, and the advantages to be secured are so great that the practical apiarist of to-day cannot afford to dispense with the use of a system so valuable.—DR. G. L. TINKER.

After carefully looking up the matter of the novelty of my invention, the Doctor placed in his circular for 1887, the following:

The new system of management of sectional bee-hives, recently introduced by Mr. James Heddon, has wrought a great change in the practice of many of our largest bee-keepers....The justice of Mr. Heddon's claims (of invention) have been generally admitted, and all should recognize his rights.

Now if the brace-combs did not prevent the Doctor from saying as above, "The facility for contracting and expanding the brood-space is perfect," during a bountiful honey season, by what hook or crook, or mistaken management, could he have experienced all these brace-combs during the past poor season? This is the first reported case of trouble of this kind, if I remember aright, and over 500 bee-keepers have the new hives in use.

But, as the correspondent says, the Doctor gives the whole thing "a black eye," and space forbids further refutations of his mistakes. They are not such bad ones, however, as were the "continuous passage-ways."

Here, we all believe we knew very much about the functions of the style of hive that the Doctor praises in his essay in question. Before we finally settled on the divisible brood-chamber, and realizing that it would be cheaper of construction, we made a single-case brood-chamber on the same plan of my present brood-cases, and while I much prefer it to the style of brood-chamber described by the Doctor, I found that I lost the advantages of the contraction system, rendered the shake out function only partially operative, as also the system of examining the condition of the interior of the brood-chamber, clipping out queen-cells, etc., without exposure to robbers, or removing a frame; and also that alternating system, so truly and positively eulogized by the Doctor in his former article. I found I could not afford to use a brood-chamber so small as the 8-frame Langstroth brood-chamber during the months of May and June, nor so large as that during other portions of the year.

But as to the philosophy of the Doctor's error regarding the impracticability of the bee-space between the sections of my new brood-chamber, and the practicability of piling one whole brood-chamber on top of another, I am sure all observing bee-keepers of any

considerable experience will at once recognize his mistake. Years of experience with both kinds of manipulation have demonstrated to me what I will now try to show the reasons for, basing my deductions on well-known facts.

Who does not know that bees build most brace-combs through that portion of the hive where storage is going on, rather than breeding? This is not all; just as surely as bees store most readily close to the brood, so of all places where most brace-combs will be built and stored with honey, none can compare with just above the brood circle.

As a rule, queens rarely breed clear up to the top-bars of the Langstroth frames, and the 10-inch Langstroth hive exceeds all other depths for the building of brace-combs between the top-bars of the frames and honey-board, or frames and surplus receptacles, where no board is used. As hives increase or decrease in depth, brace-comb building grows less, and more particularly is this the case as the depth is lessened.

When the brood-chamber is so shallow that the brood comes clear up to the top-bars, and that, too, nearly throughout their entire length, scarcely any brace-combs are found between them and the honey-board.

But one writes me that he did have lots of brace-combs built when he used but half of the new brood-chamber, or one brood-case. Certainly he did, because he contracted the brood-chamber, and then did not correspondingly enlarge the surplus department. Contraction is intended to, and results in, increased surplus comb-building, and in case we do not give ample room in the surplus department, the bees will turn this newly-created tendency to building brace-combs.

Now if one should pile one Langstroth brood-chamber upon another, and let the bees alone, the bee-space between them might not have as many brace-combs in them as would be found between the sections of the new brood-chamber, because almost double the room is furnished in the former case. But let us place two comb-honey cases on the new brood-chamber, making the total capacity the same, and then compare, and ten times as many brace-combs will be found between the two brood-chambers. In other words, a bee-space opened in the middle of the brood-nest, is not nearly so likely to be filled with brace-combs, as one opened just above it, or in the surplus department; and I suppose that all experienced bee-keepers know this.

I have never had one particle of trouble about alternating and separating the halves of my brood-chamber, and I never before heard of any one

who had, but all will have some if they neglect to give their bees the surplus room which the honey-flow demands. Every adverse report which I have heard, has resulted directly from improper construction or manipulation of the hives; usually the former. The hive and system are entirely new.

Reports Wanted.

Now, Mr. Editor, it seems that there is no longer any worthy dispute as to who is the inventor of the hive in question; and with regard to the value of it, would it not be desirable to test its use practically, and call for a brief report of the actual experience of those who have used them?

As I am now issuing a weekly paper, I know the value of "space," much better than formerly, and that the answers may be short (of few words) I would suggest the following questions, each to be answered with a word or two, and only by those who have used the hive in question:

1. How many hives have you used, and for how many seasons?
2. Who made the hives, and from what pattern?
3. What style of hive do you now prefer, all things considered?

Dowagiac, Mich.

[As the hive in question has been adversely mentioned in the report of the Ohio Convention, and as both it and the system of management are new, it will be in the interest of the pursuit to let those report briefly, as suggested, who have tested it. Let the replies to the above questions be brief and to the point, or else we cannot promise to give space to this matter. Send all the Reports to this office direct.—Ed.]

CONVENTION NOTICES.

The Cortland Union Bee-Keepers' Association will hold its spring meeting on May 8, 1888, at Cortland, N. Y., at 10 a.m. All bee-keepers are invited.
W. H. BEACH, Sec.

The Des Moines County Bee-Keepers' Association will hold its next meeting on April 24, 1888, at Burlington, Iowa.
JOHN NAU, Sec.

The Hardin County Bee-Keepers' Association will meet at the Court House in Eldora, Iowa, on the second Saturday in each month, at noon (12 o'clock), until further notice.
J. W. BUCHANAN, Sec.

The next regular meeting of the Susquehanna County Bee-Keepers' Association will be held at New Milford, Pa., on Saturday, May 5, 1888.
H. M. SEELEY, Sec.

This is the Time for reading. The long winter evenings can be utilized by reading up bee-literature. We have all the newest bee-books, and can fill all orders on the day they are received.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*

Apr. 11.—Stark County, at Canton, O.
Mark Thomson, Sec., Canton, O.

Apr. 24.—Des Moines County, at Burlington, Iowa.
John Nau, Sec., Middletown, Iowa.

May 5.—Susquehanna County, at New Milford, Pa.
H. M. Seeley, Sec., Harford, Pa.

May 8.—Cortland Union, at Cortland, N. Y.
W. H. Beach, Sec., Cortland, N. Y.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

SELECTIONS FROM OUR LETTER BOX

Light Honey Crop.—David Watter-son, Bristow, Iowa, on Feb. 5, 1888, writes:

I had 29 colonies of bees in 1886, and lost all but 3 colonies, and I have 9 colonies now. The winter had been very cold until last Thursday; it is pleasant now. The honey crop was light, but there was 25 or 30 acres of buckwheat near me, and I got 75 pounds of honey. The indications for white clover are good, if it does not get winter-killed. There are plenty of flowers on the prairies, and if we can save our bees, there would be plenty of honey. In 1887 the white clover was nearly all killed, and about 90 per cent. of the bees.

Bees Had a Fine Flight.—Jno. D. Wise, Camden, Ind., on Feb. 14, 1888, says:

I commenced the season of 1887 with 6 colonies, increased them to 10 colonies, and my crop of honey was about 60 pounds of comb honey, which I obtained from 3 of my strongest colonies. White clover yielded a little honey. Linden, although full of bloom, yielded no nectar. The bees stored enough from golden-rod and other fall flowers so that I think they will winter all right. They had a very fine flight yesterday, and seem to be in good condition. Six colonies are on the summer stands, with chaff cushions on the frames. I have 4 colonies in chaff hives.

Good Flights for the Bees.—J. M. Harvey, Brooks, Iowa, on Feb. 20, 1888, says:

I had 75 colonies of bees to commence the season of 1887, that increased to 107 colonies, and gathered 500 pounds of comb honey, and 500 pounds of extracted honey, from white clover and basswood. I stored 94 colonies in the cellar on Nov. 18, 1887, and they are in good condition, with the temperature from 44° to 48°. I have 13 colonies on the summer stands, and I have lost one; the others had a flight on Jan. 28 and Jan. 29, and also on Feb. 16 and Feb. 17.

Sawed Sections.—Chas. H. Van Vechten, of Victor, N. Y., asks:

How can I smooth the sections after leaving the saw. I get sections smoothed on one side; they are said to be sawed; then why are they smooth on one side, and not on the other? I run saws and cannot get one that will cut smooth enough for me.

[That is easily accounted for. The manufacturer gets stuff of double thickness, planed on both sides, and then saws it in two, leaving one side smooth; the other remaining as the saw leaves it.—Ed.]

The Bees in Northwestern Missouri.—J. G. Graham, Agency, Mo., on Feb. 18, 1888, writes:

We have over 100 bee-keepers, with about 1,000 colonies of bees, in this county, and many bee-keepers are using improved hives with all the modern appliances in their apiaries; but our bee-keepers are mostly farmers, and not writers, hence we do not hear from them very often.

Our honey crop was very short last year; Alsike clover and linden only, yielding any surplus, and we have but little Alsike. As Alsike blooms before linden, our honey was unmixed, and the quality was very fine.

Bees are wintering well (according to reports received so far), having had several flights since Jan. 1; my Syrians have already commenced brood-rearing, and everything promises well so far, for another season. Bee-keepers are enthusiastic in their talk about making our display at the Exposition next fall to outstrip our last; but time will tell better what we will do.

Trying Time to Come.—Edwin Hutchinson, East Avon, N. Y., on Feb. 21, 1888, says:

I had packed on the summer stands 84 colonies of bees in the fall of 1887. They flew from every hive yesterday, and seemed to be in good condition. But the trying time is to come—the month of March and the first half of April.

Drone-Laying Queens.—M. W. W. asks the following questions:

I have 2 queens, and about every thirty-sixth bee that hatches out, is a drone. I now have drones hatching out. What is the cause? Would it not be better to supersede the queens? They are mother and daughter.

[The queens are useless, and should be superseded as soon as practicable.—Ed.]

White Clover and Weak Colonies.—W. B. Thorne, Glenn, Kans., on Feb. 21, 1888, writes:

One would think from the many predictions, without investigation, that the coming honey crop would be large; but in those States where the severe drouth prevailed last summer, and where they depend upon white clover as the principal honey source, there will probably be disappointment. The older plants of white clover are almost entirely dead, and the dependence must rest upon the young growth, which, unless it be an extraordinary season, will not do to depend upon; and, no doubt, many will find their colonies in a weak condition, from the fact that the bees were old before going into winter quarters. All these facts before us, cause us to have more or less misgivings, and if I get an average of 35 pounds per colony, I will be content. A half-loaf is better than the past year's nothing.

Affiliated Bee-Associations, etc.—R. F. Holtermann, Brantford, Ont., on Feb. 11, 1888, says:

The Brantford Bee-Keepers' Association, at a meeting on Feb. 4, applied for affiliation with the Ontario Association. They are the first to take this step, and I had the honor to be the first to propose such a scheme (affiliation of county associations with the Ontario) in Canada. Reports show that bees are wintering well so far. Those wintering outside should soon have a flight. It was about 17° below zero yesterday.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

New Subscribers can obtain the full numbers for 1887 and 1888, for \$1.75, while there are any sets of 1887 left.

Beeswax.—We will pay 20 cents per pound, delivered here, for Yellow Beeswax. To avoid mistakes, the name of the shipper should always be on each package.

Preserve Your Papers for future reference. If you have no HINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Money Orders for \$5.00 and under, cost 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Sweet, or Melilot, Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 5 cents, postpaid.

It is Extravagant Economy not to have hives, sections, comb foundation, etc., on hand when needed. To prevent disappointment, order early what you will need in that line. Then the hives can be nailed and painted in odd times, and the sections put together, so as to be ready at a minute's notice. It is a sad disappointment to need these things and then not have them on hand. They should be ordered very soon. We are promised an early spring, and a good honey crop.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Look Over last year's numbers of the BEE JOURNAL, and if any are missing, send for them at once, as we have but few left now, and they are daily becoming less.

A Pocket Dictionary will be presented for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

We Club the AMERICAN BEE JOURNAL and the "Bee-Keepers' Magazine" for one year for \$1.40; or with "Gleanings in Bee-Culture" for \$1.75; or with the "Apiculturist" for \$1.80; or the "Canadian Honey-Producer" for \$1.80; with the Bee-Keepers' Review, \$1.40; or all six for \$4.00.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2 00	3 00	3 50
1,000 Labels.....	3 00	4 00	5 00

57 Samples mailed free, upon application.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

A Modern Bee-Farm, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Honey and Beeswax Market.

KANSAS CITY.

HONEY.—We quote: Choice white 2-lb. sections, 17@18c.; dark 1-lbs., 14@15c.; choice white 1-lb., 18 to 20 cts., dark 1-lb., 15@16c. White extracted, 7@8c.; dark, 5@6c. Demand is slow. White extracted is firm when in 60-lb. tin cans.
BEESWAX.—21 to 22c.
Feb. 29. HAMBLIN & BEARSS, 514 Walnut St.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 15@18c.; the same in 2-lbs., 13@15c.; buckwheat 1-lbs., 11@12c.; 2-lbs., 10@11c. Off grades 16@2c. per lb. less. White extracted, 8@9c.; dark, 5½@6c. Market dull.
BEESWAX.—22@23c.
MCCAUL & HILDRETH BROS.,
Feb. 21. 28 & 30 W. Broadway, near Duane St

CINCINNATI

HONEY.—We quote extracted at 4@9c. per lb. Choice comb, 16@20c., in the jobbing way. Demand fair and supply good.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Feb. 20. C. F. MUTH & SON, Freeman & Central Av.

BOSTON

HONEY.—We quote: 1-lb. sections, 16@17c.; 2-lb. sections, 14@15c. Extracted, 8@9c. The market is not very brisk and sales are slow.
BEESWAX.—25 cts. per lb.
Feb. 18. BLAKE & KIPLEY, 57 Chatham Street.

DENVER.

HONEY.—Best white 1-lb. sections, 19@20c.; 2-lb. sections, 16@18c. Extracted, 8@10c.
BEESWAX.—20@23c.
Feb. 18. J. M. CLARK & CO., 1409 Fifteenth St.

SAN FRANCISCO.

HONEY.—We quote: White to extra, 15@16c.; amber, 13@16c. Extracted, white liquid, 7@7½c.; amber and candied, 5½@6½c. Market quiet.
BEESWAX.—20@24c.
Feb. 18. SCHACHT & LEMCKE, 122-124 Davis St.

DETROIT.

HONEY.—Best white in 1-pound sections, 17@19c. Extracted, 9@10c. for light colored. Market weaker and supply only fair.
BEESWAX.—22@23c.
Feb. 17. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—Prices range from 16@18c. for best one lb. sections; 2-lbs. or about, 14@15c. Dark is slow of sale, with no steady price. Extracted moving slowly. Offerings of all kinds are large. Demand better.
BEESWAX.—22@23c. R. A. HURNETT,
Feb. 16. 161 South Water St.

KANSAS CITY.

HONEY.—We quote: White 1-lbs., glassed, 16@17c.; unglassed, 17@18c.; and dark 1-lbs., glassed, 15c. unglassed, 16c.; white 2-lbs., glassed, 16c.; unglassed 2-lbs., 17c. California white 2-lbs., 17c. California extracted in 60-lb. cans, 8c. Market quiet and receipts are larger.
BEESWAX.—No. 1, 20c.; No. 2, 18c.
Feb. 9. CLEMONS, CLOON & CO., cor 4th & Walnut.

MILWAUKEE.

HONEY.—Choice white one-lb. sections, 18@19c.; 2-lbs., 15@16c. 3-lbs., 14@15c. Dark and broken not quotable. Extracted, white in kegs and tin, 9@9½c.; ½-barrels and barrels, 8½@9c.; dark and mixed in same, 6@7c. Market slow; better demand expected.
BEESWAX.—22@23c.

EDITORIAL BUZZINGS.

HONEY-DEW.

There are many golden sweets
In the sunny soul's retreats
Which are not from the flowers of our planting nor
CRUE ;
But are oft heaven-willed,
And in mercy distilled,
Though the others our heart's had been panting to
share.—Eugene Secor.

Connersville, Ind., has passed an ordinance prohibiting the keeping of bees within its corporate limits, declaring the keeping of bees a nuisance! What are we coming to?

The Value of the Honey imported into Great Britain during the month of January was £465, about \$2,300. The value of the honey imported from the United States of America during the year 1886 into Great Britain, amounted to the grand sum of £27,107, or \$135,000.

Canadians are laboring with the railroads for a new classification of honey. That is what we need, also. There the postage on seeds is 4 cents per pound; in England it is 6 cents, but in the United States the outrageous tariff collected is 16 cents per pound!

Cod Liver Oil and Honey.—The former is very disagreeable to take alone, and honey cannot be mixed with the oil, unless there is an addition of some acid. An exchange gives the following formula to make cod-liver oil a pleasant medicine, for it is a great help in chest affections:

Take one-half pound each of cod-liver oil and extracted honey, add the juice of two lemons, and shake it until it is thoroughly mixed. It will be found a pleasant as well as a beneficial medicine.

Gathering Statistics.—The following, dated March 1, 1888, is received from Prof A. J. Cook, who desires its immediate insertion:

Soon after returning from the convention at Chicago, I wrote very fully to the Commissioner of Agriculture, and gave my letter to President Willits, who was to visit Washington, and asked him to press the matter personally, which he kindly consented to do. He wrote me from Washington that the head of the Department promised all possible aid, and asked that we should suggest how he could best serve us.

The Commissioner has also communicated with Dr. A. B. Mason, as published on page 132, and again asks for aid.

The committee, consisting of Dr. A. B. Mason, Mr. Thos. G. Newman, and myself, suggest that the bee-keepers all through the United States, write at once to Mr. Thos. G. Newman, and offer service as reporters of statistics.

The Commissioner wishes two for each county. While we can hardly hope for so much at first, the nearer we approximate to it, the more value we shall receive. Let every bee-keeper, then, proffer service at once. Then the committee can select by lot, or otherwise, from counties where more than two offer. Surely, bee-keepers will be prompt and generous. We ought to have a good corps of correspondents from each State, and one at least from each county in those States where bee-keeping is an important industry.

The Commissioner will send out blanks to fill out. The nature of these, as to how the bees wintered; what per cent. of a full crop of light honey in June and July was secured in your section? What per cent. of a full crop of autumn honey did you secure? What plants are valuable in your section? etc., will be considered later by the committee. Now for volunteer reporters!

BY ORDER OF COMMITTEE.
Will other bee-papers please copy?—A. J. Cook.

Mr. J. F. Dunn, of Ridgeway, Ont., on March 1, writes thus:

I believe that the plan you give on page 131, for collecting statistics of bee-keeping is the only one by which we can find out exactly all about the honey industry in this country. Just five hours before your JOURNAL came to hand, I mailed a communication to the Canadian Bee Journal (which I presume will be published in the next issue), detailing a plan substantially the same as the one you give. I send you this explanation that you may not think I wrote the article after seeing yours.

The bees had a flight on Feb. 24, after a confinement of 83 days. The winter has been favorable for the clover as well as the bees, and as a good season very often follows a poor one, we may expect a prosperous year.

We deemed that plan the best, but the time is now too late for it to be adopted this year—there being so much "red tape" to encounter at Washington. And again, each State has the arranging of its own method of assessing; and we may not get our plan adopted for some years. Meanwhile, the plan suggested by the committee may as well be faithfully tried, and if it is "found wanting," then the plan we suggested may by that time be "in working order;" for the methods are for different objects, and do not clash.

We are Glad to state that Mr. W. Z. Hutchinson is improving, and the Review for February will now soon appear.

Mrs. Cotton's annual circular for 1888 is sent us by Mr. C. W. McKown, of Knox Co., Ills., who remarks that she is "still hunting for green-horns, who are too penurious to take a reliable bee-periodical." On the envelope, Mrs. Cotton prints this attractive paragraph:

Every one who has a Farm or Garden can keep Bees on my plan with PROFIT. I have received one hundred dollars profit from the sale of Box-Honey from ONE Hive of Bees in one year.

So every one who buys her drawings, book and bees, expects a profit of \$100 on each hive of bees, for which she charges \$20, three times its value, or more. Such do the pursuit much harm by raising the expectation, and then landing the would-be apiarist in "blasted hopes."

The Chicago Academy of Sciences held a special meeting on Feb. 28, 1888, when Mr. N. W. McLain, Apicultural Agent of the Division of Entomology, Department of Agriculture of the United States, delivered an address on "The Anatomy and Physiological Development of the Honey-Bee," illustrated by charts and drawings. The lecture was very interesting, and the members of the Academy kept Mr. McLain busy answering questions for over an hour after the conclusion of the address, upon the habits and instincts of bees. A vote of thanks for the very interesting address concluded the exercises.

Cork-Dust for Winter Packing.

—In answer to inquiries received since the reply we gave to Mr. Howe, on page 99, we desire to say that ground cork, or "cork-dust," as it is called by fruit-men, cannot be obtained of any manufacturer or wholesale dealer—but the retail dealers, who obtain imported fruit in original packages, are usually glad to sell the "cork-dust" at 25 cents per bushel.

Bees are wintering finely, is the general remark from all parts of the country, from Maine to Colorado, and from Canada to the Gulf of Mexico. Mr. T. F. Bingham, of Abronja, Mich., on Feb. 26, wrote thus: "My bees had a fine flight last week. They are all right—both in and out-of-doors. The season seems to open early, so far." The present indications point to an early spring.

It is with Pleasure we notice that Mr. Eugene Secor has just had the honor of being elected one of the trustees of the Iowa State Agricultural College. These are elected for six years, one from each congressional district, by the Legislature. We congratulate Mr. Secor on this new mark of the appreciation of the public.

One-Cent Wax-Cakes.—The Cera Manufacturing Company, of Catonsville, Md., is making a specialty of one-cent cakes of wax. It takes 72 pieces to make a pound. There is a good margin for profit.

GLEAMS OF NEWS.

PERSECUTED AND IN JAIL.

Mr. Z. A. Clark, who has had daily trials and fines at Arkadelphia, is now in prison, for keeping bees in the corporate limits of that city. The following is a letter from one of his neighbors, with a donation of \$5 sent to the National Bee-Keepers' Union, to aid in his defense. The letter will be read with interest. It is dated Feb. 24, 1888:

I am not a member of the Bee-Keepers' Union, but please find enclosed \$5 for the fund for defraying the expenses of one who is now languishing in the city jail for violating a city ordinance of keeping bees in Arkadelphia, Ark. Mr. Z. A. Clark, whom I have known for about eight years, is an upright, civil, quiet, honest, hard-working man. No one stands higher here. He has been working hard to try and rise above poverty. He has a small home here, which is mortgaged. He has a wife, four little girls and a mother-in-law to care for.

I have been a resident here since 1858, and keep a few colonies of bees for pleasure and family use. I can afford to quit keeping bees, but Mr. Clark cannot without making a great sacrifice. The ordinance is an outrage, and is so considered here. Mr. Clark has several prominent attorneys, but is paying very dearly for the defense of his property and rights. I do not need any protection from the Bee-Keepers' Union, but some brother may fall by the wayside.

Send certificates of membership to the Union to five bee-keepers whom you may know to be worthy.

Mr. Clark has taken two appeals, and the third day when fined, refused to pay the fine and cost. He went to jail on the 23rd by the advice of his counsel.

S. A. RUDISILL.

We had just made out certificates for five bee-men who were not able to join the Union, but wanted to become members, when we received another letter in the same mail from England, signed "APIS," with another \$5 for the Union. This we treated in the same way, and made out five more certificates of membership, and sent to would-be members who could not afford to join the Union.

We also received the following from Mr. Clark, written in prison on Feb. 24, 1888:

I am in trouble, and in jail also. I have had three trials in three days, in succession. I appealed the two first trials, and came to jail yesterday. I am to be arraigned again to-day at 2 o'clock. My attorneys have claimed trial by jury each day, but it has been refused by the Mayor each day. I am somewhat unwell to-day.

I received a letter from the Hon. Sam W. Williams, our attorney in Little Rock, Ark., yesterday. He says that we are bound to win. I should be greatly relieved if I knew that he could be secured to come here and defend this case at the Circuit Court in July. It will cost \$250.00, but if I knew for certain that he would be here, I should be quite satisfied.

P. S.—3 p.m.—Just had another farce trial, and was denied right of trial by jury. Pleaded not guilty, and was fined by his Honor. I appealed it, and will have another to-morrow.

Z. A. CLARK.

The Manager of the Union had already sent Mr. Clark \$25 to assist in the local defense, and \$25 to Hon. Sam W. Williams, the most noted attorney in the State of Arkan-

sas, as a retaining fee. He will now take hold of the case, and by the aid of the Union will win it—at least we confidently hope so. His fees are \$250.00.

On the second day in prison Mr. Clark wrote us as follows:

ARKADELPHIA, Ark., Feb. 25, 1888.

FRIEND NEWMAN:—Yours of the 23rd with \$25 from the Union for local defense, is received. I also had the BEE JOURNAL poked through a crack to me on the eve of my first incarceration. The first thing I read was the letter of the Virginia friend, Mr. J. Few Brown, accompanying his enclosure to the Union defense fund. It cheered me, and made my heart rebound with joy.

I was arraigned again yesterday at 2 p.m., claimed right of trial by jury, was refused, pleaded not guilty, and a fine of \$8 was imposed upon me.

Z. A. CLARK.

Knowing that this senseless opposition to bee-keeping will spread like wild-fire if not successfully resisted, the Union has decided to make a lively fight in this case, and measure swords with the enemy, fully realizing that it would be very detrimental to the pursuit to allow a decision against bee-keeping to be put upon record on the plea of its being a "nuisance."

Mr. William Anderson, of Sherman, Mo., writes thus concerning this case and its importance to the bee-fraternity:

The day seems fast approaching when the bee-keepers will have to get a license. If we let the case go undefended, we shall hasten that day. Let us fight it, and if the Union has not funds enough, let it call for an extra dollar from each member. I was in favor of reducing the fees to join the Union, but I am now in favor of assessing its members to carry out its designs. We should fight this case, for every such suit we lose we are, as an organized body, that much weakened. Brother bee-keepers, let us defend a brother in trouble. The idea of bees eating up ducks and peaches! I believe that bee-men should try to bold up our banner, and support our order. Do not let us lose this suit. Now is the time for us all to prove our devotion to our pursuit.

The Little Rock, Ark., *Press*, of Feb. 24, thus discusses the topic under consideration:

The town council lately passed an ordinance making it unlawful to keep bees within the corporate limits of Arkadelphia. Mr. Clark, who is said to be a good citizen, an active prohibitionist, and an earnest member of the Presbyterian church, continued to encourage the producing of honey, and was arrested, brought before the Mayor and fined \$5. He refused to pay the fine, and the Marshal took him to the calaboose. Further legal proceedings are expected; but at the present time the bees are still doing business at the old stand. Mr. Clark is one of the most respected citizens of Arkadelphia, and will make a stubborn defense of his business.

Mr. Clark wrote thus from jail on Feb. 25, 1888:

We are having a trial every day, claiming trial by jury, etc. Yesterday we filed an affidavit signed by myself and two of our best and foremost citizens, setting forth that the Mayor was prejudiced and would not give us a fair and impartial trial, etc.; all of which has been overruled by the Mayor. We must gain this case, and not go upon record as upholding and keeping a nuisance within city limits, etc. My nearest neighbors—some of whom have lived by me for 7 and 8 years—will swear positively that my bees are not a nuisance, and that bee-keeping in Arkadelphia is not a nuisance.

A NEW INVENTION.

The Rev. T. H. Dahl, of Stoughton, Wis., writes thus concerning a new invention:

In the last number of *Tidsskrift for Biskjotsel*, the editor, Mr. Ivar S. Young, of Christiania, Norway, mentions a new invention by a German teacher, Mr. Koerbs. It is nothing less than the manufacturing of honey combs. What? Honey combs? Are we not rid of that "Wiley lie" yet. Does it even come from Europe? Oh! Let us take it easy! That new kind of wax-comb is not intended at all for table use. It can only be used for extracting purposes, but in that respect, it is claimed to be excellent. The bees deposit honey in its cells with the same willingness as in their natural comb; but they do not use it for pollen, and the queen never puts an egg in its cells. If this new kind of comb is what they claim it to be, a new era is at hand in the extracting business. We expect to hear something more about it, and when we do, the readers of the AMERICAN BEE JOURNAL will be kept posted.

We fear there is something about it not exactly reliable. Mr. Koerbs will not divulge the secret of its manufacture and use at present. He simply wants apiarists to "Look out for the engine when the bell rings," we suppose.

He intends to issue a pamphlet describing the process of manufacture, and the uses to which it may be put. To take orders for the pamphlet at 40 cents each, and when he has several thousands of such subscribers, then he will mail a copy to each, on the same day. In this we think Mr. Koerbs will be sadly disappointed. Americans will not nibble at that bait! As we understand it, the peculiarity of this invention lies in the fact as stated, that the comb mid-rib (not finished cells) will not be used by the queen for breeding, even if it is inserted in the brood-nest.

These combs are made of pure beeswax, by means of the Rietsche press, and are for use only for extracting purposes, which it is claimed is done in one-half the time now required to extract the honey from a comb.

Our friend, C. J. H. Gravenhorst, editor of the *Bienen Zeitung*, has seen the invention, and the combs "completed by the bees," and predicts a "revolution" in the matter of bee-comb, even if the invention accomplishes but one-half of what is claimed by Mr. Koerbs.

Bee-keepers will be apt to "look with suspicion upon the method employed to make the invention known," as remarked by the *British Bee Journal*, whose editor asks: "Why does not Mr. Koerbs sell his invention to some foundation manufacturer, and introduce it in that way? or, take out a patent and charge a small royalty?"

We shall watch this matter closely, and keep our readers posted concerning its advent and revelation—and ring the bell just in time for all to witness the arrival of the locomotive!

It is possible that this "invention" may turn out to be the construction of comb foundation having the base of larger cells than even drone-cells, which would be avoided by the queen, and used by the workers for store comb.

SUNDRY QUERIES.

Heat and Cold Endurable by Bees.—David Craig, Macleay, Oreg., asks the following questions:

1. How long can hatching brood, larvæ and eggs, be exposed to a low temperature without injuring or killing them? 2. How long can they be exposed to extreme heat without being injured or killed? State the extremes of temperature that they can endure.

Mr. N. W. McLain, by request, answers thus:

1. Eggs and uncapped larvæ cannot be exposed to a low temperature without injury. The length of exposure and the degree of temperature will determine the degree of injury. When it is too cold for the adult bees to fly with freedom, exposure of the brood is injurious, and often fatal.

2. If queen larvæ be exposed to extreme heat for two hours, they die. The range of temperature to which queen larvæ may be subjected, and still live, is from 60° to 98° Fahr. The normal temperature for queen-rearing is from 85° to 92° Fahr. *in the hive*. Worker larvæ can endure a temperature of 112° Fahr. *in the hive*, and a colony of normal strength do not allow the temperature to exceed that degree, even when the mercury is indicating 124° Fahr. outside of the hive.

Frequent Flights for Bees.—B. F. Barb, Joetta, Ills., on Feb. 22, 1888, writes:

Bees are wintering well so far, especially those that have plenty of stores. They have had a good flight every month this winter, and this month they have had more than one.

1. Why is it, that a part of my bees, when they come out on a warm day for a flight, will pull and fuss over each other as if they were fighting? I have seen them doing so in the summer time, but I thought that they were fixing up the young bees.

2. Do bees act the same in winter as in the summer, when they are queenless?

3. What time in the spring does the queen generally begin to lay eggs, in this locality, on the summer stands?

4. If a colony becomes queenless in the winter, should I give them some of the first eggs that are laid in the spring?

By request, Mr. N. W. McLain answers as follows:

1. Evidently the bees were trying to rob each other; the bottom-boards should be cleaned, and the entrances contracted.

2. The loss of the queen in winter has commonly a more demoralizing effect on the colony than in summer. The chance for repairing the loss is the measure of the apprehension and disquietude manifested.

3. That depends upon the season, the strength of the colony, and the race of bees. Under the conditions you mention, I should say very early in the spring. Caucasians begin breeding later than Italians, Syrians, etc., but they breed rapidly after beginning.

4. My practice would be to use the bees from queenless colonies in strengthening the weaker colonies in the apiary, in the early part of the season. Two strong colonies are more efficient for any purpose than three weak ones.

Scatter the Leaflets.—Look at the list (with prices) on the second page.

BIOGRAPHICAL.

THE LATE ARTHUR TODD.

The death of this prominent apiarist was noted on page 115, and a further biographical account promised. Mr. Todd traveled extensively in England, Germany, France, Switzerland and Italy, and also in Algeria in Africa, and was personally known to many of the prominent apiarists of those countries. He was intimate with Mr. De Layens, the noted French apiarist and author.

Mr. John Shallcross, of Philadelphia, has furnished the following biographical items of interest for publication, and also a photograph from which we have made the engraving which is presented herewith:

Arthur Todd, a prominent bee-keeper of Pennsylvania, died at his residence, 2122 N. Front Street, Philadelphia, Pa., on Saturday, Feb. 11, 1888, of typhoid-pneumonia.

MR. ARTHUR TODD.

Mr. Todd was born at Sandymount, near Dublin, Ireland, on Feb. 25, 1843. Prior to 1873 he was engaged in the dry-goods business, as general manager, in London, for the Dublin firm of Pine Bros. & Co., and at one time traveled through this country in their interests.

About 1870 he became interested in bee-culture, and subsequently made a tour through Europe, visiting the principal apiarists, and forming acquaintance with several prominent apiarists, with whom he kept up correspondence until the time of his death.

In 1877 he gave up his business in London, and went to Blidah, Algeria, to establish himself in the business of bee-keeping and the furnishing of apiarian supplies.

In 1878 he attended the Paris Exposition in the interests of the Algerian bee-keepers, and was awarded the large diploma. After the Exposition he removed to Rambouillet, in France, where he pursued his favorite avocation with considerable success. In the following year he took the "gold medal" at the Ville de Beuvais Exposition, and two "silver medals" at the Amiens Exhibition.

In 1880 he came to America for a permanent residence. He joined the Philadelphia Bee-Keepers' Association, and was its Vice-

President for the years 1884-85. His large experience and his intelligent discussion of all bee-questions, added much to the interest of the meetings. He was, at the time of his decease, a member of the New York State Bee-Keepers' Association, and was Vice-President, for Pennsylvania, of the Northeastern New York Bee-Keepers' Association.

From 1884 to 1887 Mr. Todd made large displays of bees, hives, honey and implements at the Pennsylvania State Agricultural Exhibition. His enterprise was rewarded with eleven silver and bronze medals, besides diplomas and cash prizes.

At the Burlington County Agricultural Fair, at Mount Holly, N. J., in 1886, he was awarded a medal for honey manufactures. During the same year he established a small public apiary at the Philadelphia Zoological Gardens in Fairmount Park.

Mr. Todd was a Fellow of the Royal Geographical Society, and an Associate of King's College, London. He was a careful student of modern apiculture, and well-informed upon everything pertaining to the history and management of bees. For the last four years he labored hard to open a profitable honey market in Philadelphia, but did not meet with the full success that his zeal and energy deserved. His loss to the Philadelphia Bee-Keepers' Association will be much felt.

How to Sell Honey.—M. M. Baldridge, of St. Charles, Ills., on Feb. 25, 1888, wrote as follows:

I do not find it necessary to sell extracted honey, when it is a choice article, to consumers, for less than 24 cents per pound, and could get a higher figure if I should try. It is but little trouble to convince the average consumer that liquid honey is really worth from 3 to 5 cents per pound more than the same would be, when added to the wax and wood. This fact can be easily comprehended by consumers, and no other will be volunteered by any one who understands the art of selling extracted honey properly.

Selling honey is a profession, and Bro. B. is a professional.

Why Advertise in the AMERICAN BEE JOURNAL? Here are some good reasons:

1. Because it has a large and influential circulation in every State and Territory, Canada, and other foreign countries.

2. Because it is well-printed, and an advertisement in it appears neat and attractive, and invites a reading.

3. Because it reaches just the class of persons desired—professional men, lawyers, doctors, and the best of the rural population.

4. The rates are low as possible, and the returns from advertisements are satisfactory.

New Catalogues for 1888 are on our desk, from the following persons:

Martin & Macy, North Manchester, Ind.—24 pages—Poultry and Bees.

Lewis Roesch, Fredonia, N. Y.—16 pages—Grapevines, Small Fruit Plants, etc.

E. C. Jordan, Jordan's Springs, Va.—24 pages—White Sulphur Springs.

Wm. Hoyt, Ripley, Maine—22 pages—Bee-Keepers' Advertiser No. 1—Apiarian Supplies.

QUERIES AND REPLIES.

PRACTICAL QUEEN-EXCLUDING HONEY-BOARDS.

Written for the American Bee Journal

Query 521.—Which is the best queen-excluding honey-board for practical use—one with wooden slats and strips of perforated zinc, alternate, or one made of full sheets of zinc the size of the hive? State why you prefer the one or the other.—Kentucky.

Full sheets of zinc. They give the bees more room to pass through.—M. MAHIN.

Wood and zinc combined, because of greater firmness.—EUGENE SECOR.

I prefer the full sheets of zinc, because it has more perforations, and is less in the way of the bees.—P. L. VIALLOIN.

I think that one with wooden slats is entirely better than either. The reasons are, cheapness combined with utility.—MRS. L. HARRISON.

I prefer the one with wooden slats and strips of perforated zinc. Full sheets are too liable to get out of shape.—J. P. H. BROWN.

I prefer the former, for the reason that it makes a much more substantial board, and is just as good in every other way.—G. M. DOOLITTLE.

The first mentioned is the best, because more rigid, and so more durable; and also because it is cheaper.—R. L. TAYLOR.

I have never used the wooden-slat honey-board. Zinc queen-excluders, the full size of the hive inside, answers all purpose.—J. M. HAMBAUGH.

For practical use, I prefer the wood and zinc. It is much easier to remove from the hive than are zinc queen-excluders, and keeps its shape better.—H. D. CUTTING.

I prefer that with wooden slats, because it keeps its shape and place better.—C. C. MILLER.

Some say one, and some the other; I have used both, and find but little difference if any in results. I think that the zinc sheets are preferable.—J. E. POND.

Wood and zinc, slatted. It has rigidity, thus keeping the bee-spaces exact, while the metal is thin and offers the least difficulty to the passage of bees; besides the openings are always exact.—W. Z. HUTCHINSON.

I prefer the full sheets of zinc with a wood rim. Practically, there would be but little difference in the results obtained from the use of the one or the other. The slat honey-board necessarily has an uneven face, and this

induces the bees to build "bits of comb" between the top-bars of the brood-frames and the board, and the slats hide this from the eyes of the apiarist, and the board must be ripped off when it is to be removed. The sheet of zinc is perforated all over its surface, through which you can see the "bits of comb," and the sheet will spring when you raise one side, and will admit a knife-blade to sever the "studs" of wax.—G. W. DEMAREE.

I prefer the first, as they answer so well as a double bee-space arrangement. The Heddon honey-board, with the zinc between the slats, I consider a wonderful acquisition to any apiary.—A. J. COOK.

The combined zinc strips and wood slats by all means. The reason is this: The honey-board made as above is substantial and strong, and will not warp, twist or get out of shape. Further, the break-joint principle can be easily and perfectly maintained with the combined honey-board.—JAMES HEDDON.

I find that wooden slats properly spaced please me best. If I were to use perforated metal, it would be in combination with wood. This method of making queen-excluders is doubtless well understood. I prefer wood to metal, because it does not scrape the laden bees as they pass.—J. M. SHUCK.

I must say that I do not know. I am experimenting with a half-dozen different devices, for excluding the queen from the section-cases. I am using a Heddon honey-board with slats only 3-16 of an inch apart, and it works very nicely. It is very difficult, however, to have the slats just right, and keep them so. To make the matter perfectly certain, I think that a full sheet of the perforated zinc is best.—C. H. DIBBERN.

The one with wooden slats and strips of perforated zinc is the best, but the strips of zinc should have two rows of perforations instead of one row. The strips should be only $\frac{3}{4}$ -inch wide, and be let into the slats a little less than $\frac{1}{2}$ of an inch. Then the two rows of perforations leave little zinc, and come so near the wood as to secure foot-hold to the bees in passing through the zinc, when, if the perforation are of a proper size, they are positively no hindrance to the workers. With full sheets of perforated zinc, it is only by a struggle that the bees can get through, and hence, they are a hindrance to the bees; and the same is true of the wood-and-zinc board if the perforations are too far from the wood. Again, the full sheets are more or less uneven, will sag, and be bound down to a great extent, while the wood-and-

zinc board is almost free from these objections.—G. L. TINKER.

The honey-board made of perforated zinc alternated between wooden slats is very preferable, because it can be more readily and conveniently handled; will keep in better shape and condition; and is stiffer and straighter. Full sheets of zinc will very often curl and bulge, the zinc being very sensitive to our ever-changing climate and temperature.—THE EDITOR.

THE RESULTS CLAIMED FOR REVERSIBLE FRAMES.

Written for the American Bee Journal

Query 522.—Do reversible frames produce the results claimed for them, by causing the bees (when the frames are reversed) to place the honey in the sections?—Rhode Island.

Not according to my experience.—P. L. VIALLOIN.

I cannot speak from experience, but I think they do.—MRS. L. HARRISON.

If the frames have brood in them down to the bottom, reversing, with uncapping, will.—A. B. MASON.

I do not know; I have never used them, and have no desire to try them.—M. MAHIN.

If the conditions are just right, it will in many cases.—H. D. CUTTING.

They certainly aid, if I can see straight.—A. J. COOK.

I presume that they generally do, but not always.—C. C. MILLER.

Yes, they cause the bees to remove the honey from below to above, as a rule.—DADANT & SON.

I think that the reversing of frames for this purpose has been largely abandoned at the present time.—G. M. DOOLITTLE.

Yes, at certain times, and under the right conditions, all of which have been explained before.—W. Z. HUTCHINSON.

I answer this question in the style of the quack doctor, when called to testify in a case of poisoning: "They 'mou't,' and then, they 'mou'n't.'"—J. P. H. BROWN.

Not in a practical way. I mean to say that the plan does not work uniformly, and if it did, there would be nothing gained by it in the long run.—G. W. DEMAREE.

If the honey is sealed, I think that the bees seldom disturb it. If thin and uncapped, the probability is they will remove it.—EUGENE SECOR.

I do not practice reversing, but the result claimed would undoubtedly follow if the reversing were done at the proper time.—R. L. TAYLOR.

The theory is, stores above, and brood beneath. Of course, should the frames be reversed, the honey will be carried above the brood; more especially, should the honey be close to the bottom-board and entrance.—J. M. HAMBAUGH.

I would not use reversible frames, simply, "too many bites to the cherry." Manipulation in bulk lessens the work of the apiary. Inversion does not prevent swarming, and does not always cause the honey to be "carried up-stairs," but by it a colony can be kept up to fighting and storing strength more perfectly than by any other one plan that I am acquainted with.—J. M. SHUCK.

There are times that bees will remove sealed honey from the brood-combs to the super without reversing the combs. My present opinion is, that the laying of the queen, and the state of the honey-flow, has more to do with it than the reversing of combs.—G. L. TINKER.

It is well known that I am an opponent of reversible frames, and for that reason my answer may be taken by some as an attempt to bolster up my opinion. I believe, however, that the results claimed for reversing frames, can be accomplished easier and better, and far more economically, in another way. Any answer to the above query is an opinion, only.—J. E. POND.

Yes, to a considerable extent, especially if the frames are deep. I had expected to test this matter during the past season, but owing to the failure of the honey crop, I could not do so. I think that reversing the frames or hives, a little before the honey season closes, is an advantage.—C. H. DIBERN.

I do not know all that may have been claimed for reversible frames. They do cause the bees to carry the honey into the surplus sections when reversed at the proper time. They are worth much more than their extra cost, because you can keep them at all times full of comb, leaving no lurking places for bees. I would no more go back to non-reversible frames, whether suspended or otherwise, than I would dispose of my spring-bed and adopt the old cord and anger-hole system.—JAMES HEDDON.

If the frames are reversed at the right time, the bees will doubtless carry the honey into the sections, but I doubt the expediency, in general, of the reversing system. While it may be advantageous at some times, and under some conditions, there are many serious objections to it—but it is unnecessary to enumerate them here.—THE EDITOR.

CORRESPONDENCE.

BEE-ANATOMY.

Evolution and the Glands in Bees.

Written for the American Bee Journal
BY PROF. A. J. COOK.

I gladly reply to Dr. J. A. Proctor's letter on page 124, even if I have received such a "shaking up" from Mr. Pringle, in the *Canadian Bee Journal*. The truth is, I do not relish being reviewed in another paper with disparaging remarks, in which case all readers have to take the critic's version, and cannot judge for themselves. Still I care not much. In all such cases I remember the stanza,

"Ever the right comes uppermost,
Ever is justice done."

Mr. Pringle misjudged me utterly. I did not back down because I was replying to a lady. As to evolution, as Prof. Le Conte well says, it is so probable in the light of recent research, that it is as irrational to talk of an evolutionist as a gravitationist.

That all rudimentary organs are remains of once useful ones, is not true. The rudimentary milk-glands in male mammals is an example. These structures are explained in other ways, not necessary to explain in a bee-paper. While I have the most profound respect for ladies, and would, I hope, be ever respectful and deferential towards them, I would never quibble or misstate knowingly, even in controversy with a woman. I assure Mr. Pringle that evolution needs no advocacy of error to hold it up; it can stand on truth's platform.

The glands I refer to as useful in providing food for larval bees and the queen, are large glands in the head of the bee. They are in the form of a compound leaf with very small leaflets. The fact that these glands, as mere rudiments, exist in the queen, would argue, not prove, that they were once useful organs in the queen. We positively know that the queen bumble-bee in early spring does feed the larvæ; indeed, at this time there are no worker-bees in the nest, and at this time these glands are large and active in the queen.

By the study of fossil animals, of embryology or the development of the young animal before birth, zoologists are convinced fully that higher animals have arisen from the lower; often the intermediate forms, as in the horse, snakes, and many other animals, have been found. Such proofs

are so abundant that the intelligent student is convinced. The fact that abortive organs, like the splint-bones of the horse, are found in all stages, argues loudly for evolution. Thus the abortive glands in the queen, in the light of cognate facts in other animals, suggests that the queen-bee was once able to feed the larvæ, when doubtless she was less prolific than now.

The honey-bee is the highest product of progressive development in the bee-family. Early in the rocks we find no fossil bees—indeed bees are the latest to appear; and from their complex structure we should expect this. As they have developed from a lower condition, they have advanced beyond others, and the queen has been set apart, and in the economy of their lives, has nought to do but lay eggs, and so, of course, she lays far more.

Some queen bumble-bees are now more prolific than others, and thus have less to do; thus they constantly tend to increase in prolificness.

The strongest argument as to snakes' legs comes from the study of fossils. Snakes, like animals, are found with legs. Snakes are very late to appear in the rocks. Though they are the lowest of reptiles, yet they were the last of all reptiles to appear, as geology clearly shows. The loss of their legs is a case of retrograde development.

This is too large a subject for a short article, and requires more space than is proper here. I would advise all who are interested in the subject, to procure Le Conte's work on evolution. This author is a Christian gentleman, no less than one of our distinguished scientists. Like the late Dr. Gray, he is a grand exemplification of Christ in the heart and life. At the same time, he is a master in science.

Agricultural College, Mich.

WINTERING BEES.

Cellar-Wintering and Insurance of Bees.

Written for the American Bee Journal
BY MRS. EMMA HULETT.

The past season was the poorest for honey that I ever have seen. I commenced the spring with 60 fair colonies, and increased them to 97 of the strongest colonies (both in bees and in honey) that we ever put into winter quarters. I never hived larger or stronger swarms than those of last season, and up to the present time my bees are wintering splendidly in the cellar or house, built above ground, 18x24 feet, and with sawdust filling of 22 inches. The bottom is dry and

dusty, and the hives and walls are as dry as when taken in, on Oct. 1, 1887. I have visited them only twice since then, and I found the temperature at 40°, the same as when they were put in.

The water was dripping from the upper ventilator into the tile sub-earth ventilator below, and on frosty and cold mornings the vapor may be seen escaping from the outside ventilator like smoke from a chimney. The winter was quite mild until Jan 1, and since then it has been quite severe, with considerable zero weather, and some sudden changes, which affects out-door wintering of bees. But of course from now on will be the "nip and tuck" with bees.

After 9 years of cellar or in-door wintering of bees, I concluded that such wintering is best; I believe that it will yet attain perfection, and that our pets will be wintered as easily as they are summered. By giving to the latest swarms, and also to the old colonies that did swarm, the extracting combs, they were nicely cared for, as to food of a nice article.

The demand for honey here is good, with none to supply it; but with hope for a good season to come this year.

Insuring Colonies of Bees.

In regard to insuring bees, I wish to say that I have insurance on the bee-house and honey-house attached, on all the implements, and \$5.00 per colony in the bee-house, or within 100 feet from the building, outside, if destroyed or damaged by fire from the burning of the building.

Our bees are situated between two main traveled roads; the hives all face to the centre of the bee-yard, and quite near to the road traveled the most, as it is the main line to the railroad and to town, but being fenced, and quite an ascent, it elevates them above all pedestrians, and we have never had any trouble or any complaints. As for our neighbors, we keep them, or their tempers, sweetened up with an occasional section of honey, which has never failed to conquer the most obstinate with us.

We combine blacksmithing with our bees, which works well, as Mr. H. and I have two boys to help.

South Dayton, N. Y., Feb. 20, 1888.

[Insurance of bees against loss by fire, especially when in a cellar, is very difficult to obtain in the West. There are but few fire insurance companies that will take the risk. When such can be obtained, we think it ought to be done, for it is much easier to pay for the insurance than it is to stand the loss, in case of fire.—Ed.]

NEW YORK.

The Third Day of the State Convention—Jan. 19.

Written for the American Bee Journal
BY G. H. KNICKERBOCKER.

The convention was called to order at 9:30 a.m. by President Clark. The Secretary then read an essay prepared by Mr. R. F. Holtermann, of Brantford, Ont., as follows, entitled,

Shading and Ventilating Hives, and Obtaining Extracted Honey.

In my experience, and the experience of the Germans in particular, shade and ventilation form no mean factor in securing a good honey crop. At the present time, where the price of a colony in the spring is no more than the price of the hive, its combs, and the number of pounds of stores required to winter the bees, to winter successfully and sell, is no gain; and to lose a colony is only a loss of the value of the stores consumed in winter. Therefore, every pound of honey we lose through increase, beyond what is absolutely necessary, is mismanagement. What we must aim at, is to manage our apiary in such a way that increase will be prevented by employing methods which will not diminish the honey yield.

There are methods recommended, and particularly so amongst beginners, which I hold are a positive waste of time and an injury to the colony. To break down queen-cells to prevent swarming is such a waste; to use perforated metal for this purpose is also a waste of time and material, and I incline to the opinion that to resort to any method to prevent swarming, after the bees have received the impulse, is also worthless; but I would not be positive about the latter, and leave the question with the convention.

What must we then aim at to prevent swarming, and how does it influence our honey yield? Prevent the very first step, namely, the impulse. How shall we do this? By shade and ventilation. I have at present, trees of such a height, and trained that the morning and late afternoon sun can strike the hive, and but little if any of the hot midday sun. I have ventilators in some of the bottom-boards, and the lids of the hives are raised at the back to permit a current of air passing over the quilt which lies upon the combs. I want a shade-board upon every hive, which shall be used with discretion.

The ground is covered with grass, carefully kept from growing sufficiently long to prevent ventilation at the entrance; earth and sand cause more radiation, especially the latter,

and are very trying on men and bees. I want no high board-fence, to exclude every current of air from the yard.

Then I find if a colony is left beyond a certain stage without supers to store honey, and receives, even though not yet indicated, the swarming impulse, giving of room will generally not check this impulse, but they will swarm before filling such a super, and this must be carefully avoided. Give room as required. This can be done more easily whilst working for extracted honey than comb honey. I use the 8-frame Langstroth, and with good colonies and during a good flow I use two full supers, allowing honey always to ripen or be capped. The first super is raised and the second put between it and the brood-chamber.

I use perforated metal; care should be taken to have a bee-space on both sides of the board. From colonies not so good, extract four combs out of the super, leaving the remainder until ready, when they are extracted, leaving the first four, and so on. In this way I have been very successful in preventing much increase and securing a larger yield per colony than my neighbors. Last summer my strongest colony gave me 270 pounds of honey, with no attempt. I have thus far handled 25,000 pounds, and know what a vast difference there is in honey properly and improperly taken.

R. F. HOLTERMANN.

Ventilation of Bee-Repositories.

The "Ventilation of bees in winter repositories" was then taken up. Mr. P. H. Elwood read an essay on this subject, which was very attentively listened to, and showed that the author was thoroughly posted in every particular, and was a very close observer.

N. N. Betsinger—I have an improved method of wintering bees, by burying them. The ventilator that lots in fresh air is the same height as the ventilator that carries off the impure air; in this way I can maintain a more uniform temperature, and by the use of slides in the ventilators, the temperature can be kept from changing scarcely a degree from the time of putting them in, in the fall, until taking them out in the spring. I believe that bees can be wintered perfectly in this way, consume but very little honey, and not have a handful of dead bees from each hive.

Mr. Elwood—I believe that most of us err in having too much ventilation in our bee-repositories. When I left home, the ventilators of exit were all closed, and the entrance ventilator left open. From the best authority, I can conclude that the air which would be required by one person, is sufficient for 250 colonies of bees.

A. I. Root said that apiarists disagreed somewhat in regard to the dampness of cellars in which bees are kept. He had heard of some instances where springs of water in the cellar were thought to be very beneficial, by keeping an even temperature, and also aiding in ventilation.

It was thought by some that running water would help carry off the moisture in the atmosphere, and therefore aid in the successful wintering of the bees. It was generally conceded that the different kinds of soil had much to do with changing the condition of the cellar.

The report of the committee on drafting a "scheme" looking to the organization of an international association was taken from the table. Mr. Aspinwall, chairman of the committee, explained the object of the resolution. It was discussed at length by the members, the majority of whom were in favor of the exchange branch, but some thought the international association too large an undertaking.

Mr. Elwood advocated the interchange of reports of amount of crops, etc., and asked if the bee-industry was not of sufficient importance to warrant a demand being made on the Agricultural Department for a report of the condition of the honey crop, say, for instance, in May or June, as to how the bees have wintered, and in the fall how large the crop was.

Mr. Dickinson thought there would be too many obstacles in such a demand. He believed that but few of the bee-keepers would care to give such information. He suggested that the Secretary ask the Secretary of the North American Society to notify all the associations in the United States to send delegates to the next convention.

After further discussion the report of the committee, which had been declared adopted, was again brought before the convention by the reconsidering of the vote, and this time was referred back to the committee for revision. Mr. Elwood was added to the committee.

Bees for Business.

"The coming bee for business" was then considered as follows:

N. N. Betsinger—We will not have to wait for "the coming bee for business;" it already exists; it is a full-blood Italian queen mated with a black or brown German drone. I want only the first "cross," and if the Italian queens are bred up to a high standard of purity and excellence, the workers will all be three-banded.

Mr. Goodspeed and Mr. Knickerbocker had noticed the same thing very often, but said that it was a hard matter to get Italian queens that would do this every time.

Mr. Goodspeed said that many of his customers preferred the dark or leather-colored Italian queens for honey-producing purposes; but that some others thought that pure Italians were good enough for them.

The subject of Italian queens and the markings of the workers and drones was also discussed.

The special committee on re-organization then submitted the following revised report:

Your committee would suggest that this Association shall resolve itself into a honey producers' exchange, for the purpose of gathering statistics of the wintering of bees, and the honey crop throughout the United States.

Resolved, That the duties of the Secretary of this association shall be the forwarding of suitable blanks to reporters, which they shall return on the first days of May, June, July, August and September, from every honey-producing State; no State to have more than six reporters, who shall fill out the blanks and send them by return mail to the Secretary. He shall have the reports printed and mailed to members and the reporters, by the 10th of each month.

Resolved, That the Secretary keep an account of his time involved in this work, and report the same at the next convention. He shall be empowered to draw upon the treasurer for funds necessary to carry out the work.

After a short discussion the report was adopted.

Mr. Aspinwall volunteered to defray any deficiency that might be occasioned in carrying out the plan of the committee. A recess was then taken until 1:30 p.m.

AFTERNOON SESSION.

President Clark again called the convention to order at 1:30 p.m.

Votes of thanks were adopted to the proprietor of Briggs' Hotel for reduced rates; to the daily papers for publishing such good reports; to the apiarists of other States for attendance, and to Mr. Aspinwall for an offer to meet any deficiency in the Honey-Producers' Exchange for the first year.

The committee on exhibits reported the different articles on exhibition, and G. H. Knickerbocker and J. Aspinwall were directed to have the "seal press" altered to meet the needs of the association.

The Treasurer's report is as follows: Received from Treasurer Scofield, \$14.05; membership fees for 1888, \$30.00; total \$44.05. Paid for printing, postage, stationery, and fee of Secretary, \$15.60. Balance on hand, \$28.55.

Adjourned to meet at Syracuse next year on the call of the executive committee. G. H. KNICKERBOCKER, Sec.

FOUL BROOD.

How to Eradicate the Scourge—Putting on Sections.

Written for the American Bee Journal

BY J. W. SMITH.

I think that the matter of foul brood will be one of the leading topics hereafter, for it seems to be getting scattered pretty well already. We have the genuine article here in the centre of this State. I am of the opinion that any information which can be given from actual experience (not theory) in the successful treatment and cure, aside from burning, will be thankfully received by many.

While I was at our bee-convention in Burlington the other day, I was talking of foul brood with one of the largest bee-men in this State, who has at present, I suppose, about 700 colonies. He told me that his bees had it about 18 years ago, and described how he cured it in one season. If I understood him rightly, it was as follows:

He moved the hive with the affected colony from its stand, and placed on the stand an empty box or old hive without combs or stores. He let the bees go into it and remain there for four days; then removed them and put a new hive in place of the box; he shook the bees into that, with empty combs or foundation, and let them stay. He took good care of the old hive, and all that belonged to it, and in that way he got rid of the foul brood. Does any one know of a better way?

Putting Sections on the Hives.

I would also like to know why it is not just as well to place all the sections that will be likely to be wanted on a hive, at once, to save the trouble of raising up and putting others under, and disturbing the bees.

Moscow, Vt.

STARTERS.

How to Fasten Foundation in the Sections.

Written for the American Bee Journal

BY H. C. GIFFORD.

I notice that in almost every number of the BEE JOURNAL something is said about fastening foundation in sections, and written by men, to all appearance, that ought to be well posted in this matter. It seems strange to me that so many differ in opinion, as there seems to me to be but one proper way to fasten the foundation, if to economize in material and labor is the object,

which, of course, it ought to be. My experience of last year is as follows :

I began by using a putty-knife, pressing the foundation in the groove, and then straightening it up. I dipped the knife in honey so that it would not stick, and, to do my best, some of them would pull off when the bees got on them, which makes bad work.

Then I saw an item in the BEE JOURNAL something like this : Take one part rosin and two parts beeswax ; melt them over a stove, just so they are melted, but not hot ; reduce the fire so as to keep it just warm, and dip the foundation in this mixture with the right hand, hold the section in the left hand, and press it into the groove of the section, when it is done, and you cannot pull it off ; the foundation will tear to pieces before it will let go. I tried it, and I found that it took only one row of cells to fasten it solid to the section, when by the other way it took two or three rows ; I could put them on five times as fast, and they were straight, solid, and so much neater to look at. There was no fear of their dropping off. If you do not use all the wax mixture, let it stand until you want to use it again, as it will not spoil or waste. It is a great saving in time and material, and any old wax will do. The less wax used on each piece of foundation, the better job you can do.

I would not think of using any other method than the above, after the experience I have had in this branch of our industry.

Last season was a perfect failure with me, yet I am not discouraged ; but I am afraid I would be if it was not for the weekly visits of the AMERICAN BEE JOURNAL, that clears everything up, and I feel refreshed after perusing its valuable contents.

Morris, Ills.

BEE-MEN'S TALK.

The Northeastern O., Northwestern Pa., and Western N. Y. Bee-Keepers' Convention.

Written for the Pennsylvania Farmer
BY C. H. COON.

This convention was opened at Meadville, Pa., on Jan. 25, 1888. After the reading of the President's address, the enrollment of members, and paying of dues, the election of officers was held and resulted as follows :

D. H. Lefever, of Hayfield, Pa., President ; J. A. Barrett, of Cherry Valley, O., 1st Vice-President ; C. H. Coon, of New Lyme, O., Secretary ; George Spitler, of Mosiertown, Pa., Treasurer.

The convention at 3 p.m. proceeded to the discussion of the subject, "How may we increase the product of our apiaries?" After a thorough discussion of this topic, which brought out many practical points, the question, "For the production of comb honey, by what management is the best possible result obtained, as to yield and quality?" was taken up. This discussion was followed by the question-box, after which the convention adjourned until evening.

EVENING SESSION.

The convention was called to order at 7 p.m., with President Lefever in the chair.

Can Extracted Honey of the Best Quality be Produced at Less Cost than Comb Honey of Like Quality?

Mr. Barrett affirmed that it could, and that if he got two-thirds as much for his extracted honey, it would pay him to extract it.

Mr. Phelps—If I produce good extracted honey, it will cost me quite as much as comb honey. It takes the bees just as long to produce the one as the other. My first consideration is to get all the honey produced possible. I make three grades of my extracted honey, and I think by so doing that I realize more money. It cannot be made to sell as well as comb honey. Then there is the cost of packages and trouble in getting them back again.

Mr. Barrett—I get more honey by extracting it. Let it ripen well before extracting, and it will come out of the comb without difficulty.

Mr. Mason—Honey of the best quality can be gotten only out of comb made with the honey. When we consider that the honey must be evaporated and ripened before extracting, I am forced to conclude that extracting-combs refilled cannot contain the best quality of honey.

Mr. Phelps—Ripening takes place after the cells are capped over, and Mr. Barrett well knows that the nicest honey can be produced only by allowing this process to be finished in the comb.

Mr. Mason—The cells must crack open before ripening. Bees ripen honey by heat.

President Lefever—After honey is once capped it can be ripened, if necessary, after it is taken from the hive, by putting it in a warm room. I will sell such honey as first quality, and it will give satisfaction, too.

Mr. Mason—Honey ripened outside of hives lacks in flavor. You can often observe sweat on the hive where the water is evaporating from the honey. Honey should be kept in a dry, warm room. If in a damp room it will absorb moisture.

President Lefever—The source from which the bees obtained the honey has much to do with its keeping qualities.

Mr. Phelps—I am aware that honey will absorb water at a certain heat. My experience is that the cause of sweating is to be found in the fluctuations of temperature. I think the proper temperature to insure against sweating is 80° to 90°. I store my honey in a room with a chimney running up through it. I find that the honey near this chimney never sweats ; but that farthest away, where the temperature varies at different times, sweats more or less. I have some that is four years old.

Question, "Is not your 1884 honey thicker than your new?"

Mr. Phelps—Yes, that farthest from the chimney is candied more or less, but that nearest is not.

Mr. Marley—My experience agrees exactly with that of Mr. Phelps.

For the Production of Comb Honey, by What System of Management is the Best Possible Result Obtained as to Yield and Quality?

Mr. McLane—Contract the brood-nests and feed up for winter ; but this is risky, though it was necessary last season.

Mr. Burnett—My experience is that in hives where the bees have free access to the whole hive, I could get more honey, and could get as good a price.

Mr. Phelps—They might begin where the widest space existed, but this does not prove the point.

President Lefever—I use separators. I cannot well get along without them. It is possible to get straight combs without them, but still I would use them for convenience.

Mr. Mason—My own system suits me best, but might not be adapted to other localities. I get no buckwheat honey, it all comes from clover or basswood. When the white clover begins to bloom I draw from the "boomers" to help the light ones. Then I put on the sections. Heat must be economized, because heat costs honey. I use full sheets of foundation. I think it is better than comb. I use a few combs as a bait, and keep empty sections near the brood-nest. I do not want too many frames in the brood-nests. I reduce to from 3 to 5 frames, then they have to go into the sections. Bees should not be deprived of the natural impulse to swarm, but they must be managed economically after this, if you would get any profit.

The convention adjourned to 9 a.m.

THURSDAY MORNING SESSION.

The convention was called to order at 9 a.m., with President Lefever in the chair. After some preliminary business, the programme was taken up.

Through what Channel Should the Products of the Aplary be Conveyed to the Consumer?

Mr. Belden sold the most of his product to a shipper, for cash. He thought it paid him better than to retail it.

T. F. Shepard, one year, took his honey to New York city, and sold it at 35 cents per pound, while at home, owing to the market being glutted, he could only have realized 10 and 12 cents for it.

Mr. Sutton had always been able to sell in the home market.

M. E. Mason—Some people look upon the middleman as a monster, when the fact is, without him it would be hard to get along. He had been in the business a long time, and has never yet seen a time when a large crop was general over the country. Now the middleman makes it his business to find where the crop is short. While the small producer could not afford to ship his honey, the middleman buys the surplus and ships it at less expense than could the small producer to where it is wanted, and by so doing helps to keep up the price in the home market.

Mr. Sutton—Many must sell at home. The large producer should look up a market for his honey.

Mr. Mason said that the past season a fair honey crop was produced in his vicinity, and honey was sold in Jefferson at 10 cents; he went and bought a lot of it. The price was put to 12 cents; he bought it. Then the price went to 16 cents; he bought what he wanted at the price. So by stepping in and buying he made money, as did the producer. Had he not bought, he thinks the price would have been low through the season.

C. H. Coon has been engaged in shipping poultry the past 20 years, and has always sold through commission houses, and has never lost a dollar until this fall. Always find out whether the house you ship to is "solid," and also before you ship an article, be it honey or anything else, find out whether there is a demand for it. Do not crowd the market. When honey is wanted, ship it; not before. He always grades his honey and keeps the best back, has made it a point to place some with the grocer where he trades.

Mr. McLane marketed about 2,000 pounds at 15 and 16 cents wholesale, when his neighbors sold at 10 and 12 cents. He took orders from sample, and sold 48 cases in a very short time, at the same terms at which they (the dealers) bought their other goods. His second shipment was one-half larger. Now he could not supply the demand.

Is It Best to Fill the Sections with Foundation, or only Use Starters?

Mr. N. T. Phelps always uses full sheets in sections, because it is better

fastened on the sides; combs stick to the wood better. He never uses starters unless he is short of foundation, when he invariably finds the combs not very well fastened in the sections.

Mr. Bartlett first used a V-shaped starter, but he believes that it is more profitable to use full sheets. When he used starters only, he was troubled with queens in the sections, which he attributed to the drone-combs being built there by the bees at the bottom of the starters. He had many sections spoiled then, but none now since using full sheets.

A vote was taken as to starters and full sheets, two-thirds being in favor of full sheets in sections.

Is Modern Bee-Keeping Sufficiently Remunerative to Warrant those who Aspire to the Luxuries of Life, to Engage in it as a Special Pursuit?

Mr. Phelps—It depends upon what are called luxuries.

I doubt about its being feasible, as we find people in the United States. If expenses were not too great, a person might make a living at the business.

Mr. Barrett—It depends upon the range which we have for the bees to gather honey in. If one could have the whole field within a radius of three miles, it might do, but as things are, if a neighbor would see me getting lots of money, "getting rich," as they say, the business would soon be overdone. As we find the circumstances, it will not pay to make a specialty of the bee-business, but as it is, the bees have paid better than any other branch of farming. I have induced neighbors to sow Alsike clover, which is a good yielder of honey, and makes most excellent hay. The trouble in bee-keeping is, to have forage enough for the bees.

What is the Best Method of Feeding Bees in the Spring?

Mr. Mason—Feed the "Good" candy over the cluster on top of the frames under the cushion; keep the bees warm.

Mr. Shepard—Feed syrup at the entrance.

Mr. Freeman—Feed syrup in a common quart fruit-can. Tie a thin cloth over the mouth of the can, and invert it over the cluster.

Mr. Reynolds—I like feeding on top of the frames best, because the bees do not become so excited as they do when fed at the entrance, consequently less bees are lost by flights off in the cold air.

The convention adjourned to meet in Franklin, in January, 1889. This last meeting, some of the oldest members say, was one of the best and most full of life ever held.

IOWA.

Report of the Nashua Convention of Bee-Keepers.

Written for the American Bee Journal

The Nashua Bee-Keepers' Association held its second annual meeting at Nashua, Iowa, on Feb. 18, 1888. The convention was called to order at 10 a.m., with Pres. Tracy in the chair.

The forenoon session was devoted to the discussion of topics of general interest. Alsike clover was highly recommended as a honey-plant, and one member who had practical experience with it, said that it was superior to other clovers for pasture and hay.

In the afternoon the following officers were elected: President, Thos. Tracy, of Nashua; Vice-President, Geo. H. Potter, of Ionia; and Secretary, H. L. Rouse, of Ionia.

The following questions and answers were then given:

Should bees be taken out of the cellar for a cleansing flight? No.

What amount of ventilation is best? Some preferred very little, and others preferred considerable.

Is shade desirable during the season? Yes; but natural shade is the best, and shade boards come next.

How large an entrance should the colony be given in early spring? One-fourth by 1 inch.

When is the best time to put bees in the cellar? The majority favored putting them in early in November; but better too early than too late.

Thirteen members reported that they were wintering 818 colonies, and that they obtained no honey in 1887.

President Tracy said: "Sometimes my bees become uneasy towards spring, and when I would take a painful of snow, and throw a spoonful in at the hive-entrance of each colony, they would become quiet." He winters his bees in the cellar. About two-thirds of the bees represented by the members are being wintered in the cellar, and the balance in chaff hives.

The convention adjourned to meet in Nashua, on May 19, 1888, at 10 a.m.

H. L. ROUSE, Sec.

CONVENTION NOTICES.

☞ The Cortland Union Bee-Keepers' Association will hold its spring meeting on May 8, 1888, at Cortland, N. Y., at 10 a.m. All bee-keepers are invited.
W. H. BEACH, Sec.

☞ The Des Moines County Bee-Keepers' Association will hold its next meeting on April 24, 1888, at Burlington, Iowa.
JOHN NAU, Sec.

☞ The Hardin County Bee-Keepers' Association will meet at the Court House in Eldora, Iowa, on the second Saturday in each month, at noon (12 o'clock), until further notice.
J. W. BUCHANAN, Sec.

☞ The next regular meeting of the Susquehanna County Bee-Keepers' Association will be held at New Milford, Pa., on Saturday, May 5, 1888.
H. M. SEELEY, Sec.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*
 Apr. 11.—Stark County, at Canton, O.
 Mark Thomson, Sec., Canton, O.
 Apr. 24.—Des Moines County, at Burlington, Iowa.
 John Nau, Sec., Middletown, Iowa.
 May 5.—Susquehanna County, at New Milford, Pa.
 H. M. Seeley, Sec., Harford, Pa.
 May 8.—Cortland Union, at Cortland, N. Y.
 W. H. Beach, Sec., Cortland, N. Y.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

Anticipating Favorable Results.—Eugene Secor, Forest City, Iowa, on Feb. 27, 1888, says:

I have not "disturbed" my bees since they were put into the cellar, some in October, and others early in November. They have been so quiet, with the cellar temperature at 35° to 50° (generally between 40° and 45°), that I have not thought it necessary to overhaul them. There are but few dead bees on the floor. I anticipate favorable results.

Cellar-Wintering—Buck-Bush.—G. S. Prime, Arapahoe, Nebr., on Feb. 18, 1888, says:

I am much interested in the question of light in winter for bees in the cellar. I am favorably impressed with the idea.

This is the best bee and honey country that I am acquainted with. I have kept bees in Indiana and Iowa, but this is the best for good, pure honey, the season through. We had a good yield here the last season, and the five years previous. Those who have eaten our honey want no other. It is largely from what is known here as "buck-bush," and it is much like the "snow-drop" that we had in our gardens and lawns in the East. It is very abundant in the low grounds on all streams where I have ever been, that have their source in the Rocky Mountains. I never see it on any other places. It blooms profusely for about three months.

I have wintered bees in the cellar for about twenty years, and I have had no loss except from mice or queenlessness. I try to keep the temperature down near the freezing-point. I think that nearly all the trouble in wintering bees in cellars, is in letting them get too warm.

Cleansing Flights—Bee-Keepers' Union.—H. M. Cates, Shideler, Ind., on Feb. 27, 1888, writes as follows:

Bees for the last three days have had a grand flight. This winter has been a fine one for bees, and in this locality there has been no snow of any consequence, and a very even temperature. It has been mostly dark days, so that bees wintered on the summer stands have had, on an average, one or two cleansing flights per month; this has kept them healthy. I have lost no bees worth mentioning, and to-day they seemed as strong as they were last September.

For want of a cellar to winter my bees in, I packed them, by making large boxes 12 feet long and 3 feet wide, which would hold 6 colonies to the box; I then packed clover chaff in between and back of the hives. I

have saved all except 3 nuclei that had nothing to live on when put in. So far the prospect for a honey crop here is good, as the white and Alsike clovers are not injured by the winter.

I have just read the editorial about the Bee-Keepers' Union, on page 115. You will find my membership fee enclosed with this letter, as I feel that I would not be doing my part, if I did not join the Union now. I think that all bee-keepers should encourage Mr. Z. A. Clark to press the battle to the very gates, for if we do not stand by each other in our rights, the day will soon come when bee-keepers will have to advertise that "I, or we, on a certain day, will apply to the County Commissioners for a license to keep bees." It appears that some people would like to have it just about that way.

Bees are all Right.—Col. R. Walton, Industry, Pa., on Feb. 27, 1888, writes:

Thus far my bees are all right, except very late swarms that issued about the latter part of September. I had about 6 or 7 swarms in that month; we had a nice flow of honey about that time, my colonies were strong in bees, and they began to swarm. I secured only about 200 pounds of honey from about 60 colonies of bees. I am experimenting some this winter with my bees. None of them are packed this winter, and all are on the winter stands, with a big box placed over them. The bees flew nicely last week, and they are all right except 2 small colonies.

Bee-Keepers are Happy.—Jacob Oswalt, Maximo, O., on Feb. 23, 1888, writes:

I am wintering my bees in the "Falcon" chaff live on the summer stands, and they now seem to be in fine condition. They had a grand flight to-day, and on examination I find that they have all pulled through the winter nicely, excepting two colonies. Bees in this section of the country, as far as heard from, are doing well, and bee-keepers are feeling good.

Bees Mostly in Good Condition.

—B. W. Peck, Richmond Centre, O., on Feb. 20, 1888, writes:

I have been out in the apiary examining my bees, and so far they are mostly in good condition; only 3 or 4 colonies having the diarrhea. I had 8 or 10 colonies that had only 12 to 15 pounds of honey; I examined them to see if they need any more, and I found they had enough to last until April, at least, having consumed but little honey. I do not believe that my loss will exceed 10 per cent. I have just purchased 3 more colonies from a neighbor, so I now have 47 colonies. I will report again in the spring.

Disposing of Surplus Honey.—

B. E. Foster, Utica, N. Y., writes:

What shalt we do with our surplus honey? This is often asked, not so much this year, as honey has been scarce in some States, but not in New York. Comb honey can be bought at 12 cents to-day, and extracted at 8 to 10 cents. Now how is it that honey is as cheap as it was last year in New York? Below is one of the reasons, I think:

Every year the bee-men feed so much sugar for winter stores for the bees. Now, if honey was used instead, how much would there be left? I would say none. But it seems as if the bee-men had got to feed sugar in order to keep their bees alive. This is not true, if we do as we ought, namely, feed nothing but honey, the loss of bees would be very small, if this is all that makes

the bees die. I would like to ask how much is made by extracting all the honey and feeding back sugar syrup, if their time is worth anything? I think that if we want to feed honey, we can always get it, if we have none. But the best way is to keep from 100 to 300 pounds of honey over for this purpose, and not sell the last drop.

I was pleased to read Mr. Lindle's article on page 55, where he says that he never fed 50 cents worth of sugar in 31 years, and for 15 years he had made bee-keeping his business. This shows that honey is as good as sugar. If you are afraid the honey is not all right, just bring it to a boil, and this will make it all right, if it came from colonies affected with foul brood. Let us feed no more sugar, but honey.

Colonies Strong and Carrying Pollen.—Albert Newman, Rolla, Mo., on Feb. 23, 1888, says:

My bees carried in pollen on Feb. 20, which is much earlier than usual. They are as strong now as they were last fall, notwithstanding we have had weather from 6° to 12° below zero. They are on the summer stands, protected on the east, north and west by a bank of straw. Those, however, who do not believe in book-learning, and read no bee-paper, will lose heavily, not knowing that all the bees had to be fed last fall in this part of the country. I fed about 170 pounds of granulated sugar to 17 colonies, and by the way they are breeding now, I will have to feed them some more before the honey-flow comes.

Light in Bee-Cellars, etc.—S. J. Youngman, Lakeview, Mich., on Feb. 23, 1888, writes:

I think that the article on page 106, by T. F. Bingham, giving his experience with wintering bees, is the most intensely interesting article published in the BEE JOURNAL since I have been one of its readers. Has it ever been given to the public before? I, for one, would like to know more of the details, especially of the transferring by lamp-light in *midwinter*. If those bees winter well, surely disturbance in winter is not disastrous to bees.

According to Mr. B's article on page 117, the Southern wintering question was surely given a good trial; but could not the unsealed brood have been saved by giving water to the bees, while *en route*? Or could not the transit have been hastened by sending the bees by express? Cannot Mr. Bingham be prevailed upon to give us another article on these subjects?

Carrying in Pollen—Honey-Plants.—W. M. Hess, Conway, Ark., on

Feb. 15, 1888, says:

My 10 colonies of bees are wintering well. Yesterday they carried in pollen for the first time this year. In 1887 they carried in the first pollen on Feb. 7, and the last on Oct. 16, and just got enough for a living. I had but one natural swarm, and it issued on July 13. Our bees generally swarm in May, but sometimes in April.

Our main honey-plants are sumac, ragweed, black-gum, cotton, hore-hound, willow, persimmon, and bonaset. There is not much buckwheat sown, and no clover. Clover thrives well here, but the trouble is to get it started on account of the grip-grass, but if once started, it will remain until it is killed out. Sumac is a good honey-producer, and of good flavor, but it gets sour before it is ripe. My bees nearly filled all the section-cases, and before they had it half capped over, it turned sour and run down through the brood-frames, so that the bees all left the inside and hung around

the outside of the hive or on the ground. The honey was as thin as water when they gathered it, and I had a great deal of trouble. I did not know what I should do with all this sour honey. Of course I took it off, and put it in the smoke-house. There was some bees in the section-case yet, and I left the hive open about 2 inches, so that all the bees could come out.

We have had no cold weather this winter, the coldest being 10° above zero. My bees have had flights for a week. I look for a good honey season this year. There are no Italian bees in this locality. I sent for an Italian queen last June, and I found the Italians far ahead of the black bees. I use the Langstroth hive, 16 inches long, 12 inches wide, and 11 inches deep, inside measure.

Results of 1887—Alsike Clover.

—D. L. Campbell, Royal Oak, Mich., on Feb. 24, 1888, writes :

Last year I think was the poorest that I have experienced in my 18 years of keeping bees. I started with 100 colonies last season, and they got a good start in the spring on elm, maple and willows. They commenced to swarm in May, and increased to 210 colonies. They stored about 2,000 pounds of surplus extracted honey, and 500 pounds of comb honey, with an abundance for winter, which is a better showing than most bee-keepers had for last year.

I sowed Alsike clover and furnish seed to my neighbors; I think that is one of the best honey-plants we have. It also makes the best of hay. I do not think that it will pay to raise any plant for honey alone, although I sowed some Chapman honey-plant seed last year, and I think that the same plant grows wild on new land in this locality.

I am wintering 125 colonies in the cellar, and they seem to be all right so far. I also have 73 colonies in chaff hives, and these had a nice, cleansing flight on Feb. 22 and Feb. 23, which they needed very badly, as they had not flown for over two months. I believe there will be serious loss among bees that are not protected, as I hear of quite a number already.

Swarming—Feeding Bees.—A. E. Maley, Auburn, Nebr., on Feb. 20, 1888, writes :

The weather is very changeable here. The bees have had a flight every few days. A swarm issued for me on Feb. 17, and after re-hiving them four times, I had to take a new hive with fresh combs, and drive them in with smoke. The weather since then has been damp and rainy. There has been about 14 inches of snow so far this winter, and it is all melted and soaked into the ground. We have a good prospect of an early spring, and a good season. I had some colonies that had to be fed in January, and I filled some empty combs with sugar syrup, and gave it to them, and they are now doing well. This is a much better way than to feed sugar candy.

Early and Absconding Swarms.

—Wm. Irwin, Columbus Grove, O., on Feb. 20, 1888, writes :

I commenced the season of 1887 with 7 colonies of bees; one was robbed, and the other 6 were in fair condition. I increased them to 22 colonies by natural swarming, and obtained 82 pounds of honey in one-pound sections. My bees are Italians and hybrids.

On page 472 of the AMERICAN BEE JOURNAL for 1887, Mr. Willis M. Barnum says that he had an extra large swarm one morning at exactly 7:30 o'clock; and then says,

"Who can beat that?" I can. I had a swarm on June 17, at 6:25 in the morning, and another at 7:10 a.m. They were prime swarms. I had a large second swarm that was bound to go to the woods. It issued on June 14, and returned to the parent hive. On June 15 it came out again, went about 40 rods, and then returned to the hive whence it came. On June 16 it started off again, and went $\frac{1}{2}$ mile. I "belled" them every time they went off, and they became disorganized and came back. On June 17 they came out again, and went high up on a tree, less than half a mile away.

I winter my bees on the summer stands, on from 4 to 6 frames, packed in wheat chaff and forest leaves. They had good flights on Feb. 12 and Feb. 13, and seem to be wintering well.

Bees did Well in 1887.—A. C.

Loomis, Grand Rapids, Mich., on Feb. 28, 1888, says :

My bees did well last year. I increased them from 4 colonies to 8 colonies, and obtained 350 pounds of comb honey.

Langstroth Hives—Light Cel-

lars.—H. S. Ball, Granby, Quebec, on Feb. 13, 1888, writes :

The best hive for this northern country, and I think for any other country, is the Langstroth hive. It is the best for wintering, and it exceeds any other that we have in this country for summer use. I have used them for ten years, and have never lost a single colony from any cause in wintering. I knew of one case where a man lost 190 colonies in what he called the Jones hive, and not one colony that was in a Langstroth hive. All were in the same cellar. I have used five or six different kinds of hives, and I say, give Langstroth the medal! Can bees be wintered in a light cellar?

[Yes; read the article on page 106, on this subject.—Ed.]

Bees Breeding Early.—H. G.

Frame, North Manchester, Ind., on Feb. 23, 1888, says :

My bees had their first flight last Saturday, the first since Sunday, Dec. 4, 1887, lacking just one day of eleven weeks' confinement, and nearly five weeks longer than last winter. My bees are wintering nicely so far, on the summer stands. My method of packing in the spring differs from nearly all the methods that I have ever read of. I examined several colonies to-day, and I found that some have capped brood, some have larvae, and some have nothing but eggs. Nearly every colony carried in more or less pollen to-day. I believe that we will have an early spring.

The Season in Texas.—B. F. Car-

roll, Blooming Grove, Tex., on Feb. 16, 1888, writes :

The season of 1887 in Texas will long be remembered; we had 5 inches of rain from Jan. 1 to Aug. 28. We had $16\frac{1}{2}$ inches at one time; from Aug. 28 to Nov. 8, 5 inches more; 8 inches in November, and about 10 inches up to this date. We have had 10 inches of snow, and the mercury 2° below zero here, and 18° below in northwest Texas. Bees began bringing in pollen on Feb. 8, ten days later than last year; and now the mercury is at 32° Fahr., with a prospect of a lower temperature before morning. The mint is up in the best stand since 1882, and the bee-men look for another grand honey crop. I have lost 40 per cent. of my bees,

and I am feeding the 25 colonies left, with a view of an increase to 75 colonies; as I have good combs in 40 two-story Simplicity hives. Six years ago there were within five miles of my place 1,000 colonies of bees; now there are about 200. I have plenty of room now.

The old AMERICAN BEE JOURNAL grows younger, puts on a brand new dress, and goes out to be admired by all who take a peep at its new face.

Honey and Beeswax Market.

KANSAS CITY.

HONEY.—We quote: Choice white 2-lb. sections, 17@18c.; dark 2-lb., 14@15c.; choice white 1-lb., 18 to 20 cts., dark 1-lb., 15@16c.; white extracted, 7@8c.; dark, 5@6c. Demand is slow. White extracted is firm when in 60-lb. tin cans.
BEESWAX.—21 to 22c.

Feb. 29. HAMLIN & BEARSS, 514 Walnut St.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 15@18c.; the same in 2-lb., 13@15c.; buckwheat 1-lb., 11@12c.; 2-lb., 10@11c. Off grades 1@2c. per lb. less. White extracted, 8@9c.; dark, 5@6c. Market dull.
BEESWAX.—22@23c.

MCCAUL & HILDRETH BROS.,
Feb. 21. 28 & 30 W. Broadway, near Duane St.

CINCINNATI.

HONEY.—We quote extracted at 4@9c. per lb. Choice comb, 16@20c., in the jobbing way. Demand fair and supply good.

BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Feb. 20. C. F. MUTH & SON, Freeman & Central Av.

BOSTON.

HONEY.—We quote: 1-lb. sections, 16@17c.; 2-lb. sections, 14@16c. Extracted, 8@9c. The market is not very brisk and sales are slow.
BEESWAX.—25 cts. per lb.

Feb. 24. BLAKE & RIPLEY, 57 Chatham Street.

DENVER.

HONEY.—Best white 1-lb. sections, 19@20c.; 2-lb. sections, 16@18c. Extracted, 8@10c.

BEESWAX.—20@23c.
Feb. 18. J. M. CLARK & CO., 1409 Fifteenth St.

SAN FRANCISCO.

HONEY.—We quote: White to extra, 15@18c.; amber, 13@16c. Extracted, white liquid, 7@7½c.; amber and candied, 5½@6½c. Market quiet.

BEESWAX.—20@24c.
Feb. 18. SCHACHT & LEMCKE, 122-124 Davis St.

DETROIT.

HONEY.—Best white in 1-lb. sections, 17@19c. Extracted, 9@10c. for light colored. Market weaker and supply only fair.

BEESWAX.—22@23c.
Feb. 17. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—Prices range from 16@18c. for best one-lb. sections; 2-lb. or about, 14@15c. Dark is slow of sale, with no steady price. Extracted moving slowly. Offerings of all kinds are large. Demand better.

BEESWAX.—22@23c. R. A. BURNETT,
Feb. 16. 181 South Water St.

KANSAS CITY.

HONEY.—We quote: White 1-lb., glassed, 16@17c.; unglazed, 17@18c.; and dark 1-lb., glassed, 15c.; unglazed, 16c.; white 2-lb., glassed, 16c.; unglazed 2-lb., 17c. California white 2-lb., 17c. California extracted in 60-lb. cans, 8c. Market quiet and receipts are larger.

BEESWAX.—No. 1, 20c.; No. 2, 18c.
Feb. 9. CLEMONS, CLOON & CO., cor 4th & Walnut.

MILWAUKEE.

HONEY.—Choice white one-lb. sections, 18@19c.; 2-lb., 15@16c.; 3-lb., 14@15c. Dark and broken not quotable. Extracted, white in kegs and tin, 9@9½c.; ½-barrels and barrels, 8½@9c.; dark and mixed in same, 6@7c. Market slow; better demand expected.
BEESWAX.—22@25c.

Feb. 2. A. V. BISHOP, 142 W. Water St.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows :

For 50 colonies (120 pages)..... \$1 00
" 100 colonies (220 pages)..... 1 25
" 200 colonies (420 pages)..... 1 50

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

New Subscribers can obtain the full numbers for 1887 and 1888, for \$1.75, while there are any sets of 1887 left.

Beeswax.—We will pay 20 cents per pound, delivered here, for Yellow Beeswax. To avoid mistakes, the name of the shipper should always be on each package.

Preserve Your Papers for future reference. If you have no **BINDER** we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Money Orders for \$5.00 and under, cost 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Sweet, or Melilot, Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

It is Extravagant Economy not to have hives, sections, comb foundation, etc., on hand when needed. To prevent disappointment, order early what you will need in that line. Then the hives can be nailed and painted in odd times, and the sections put together, so as to be ready at a minute's notice. It is a sad disappointment to need these things and then not have them on hand. They should be ordered very soon. We are promised an early spring, and a good honey crop.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Look Over last year's numbers of the BEE JOURNAL, and if any are missing, send for them at once, as we have but few left now, and they are daily becoming less.

A Pocket Dictionary will be presented for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

We Club the AMERICAN BEE JOURNAL and the "Bee-Keepers' Magazine" for one year for \$1.40; or with "Gleanings in Bee-Culture" for \$1.75; or with the "Apiculturist" for \$1.80; or the "Canadian Honey-Producer" for \$1.80; with the Bee-Keepers' Review, \$1.40; or all six for \$4.00.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2.00	3.00	3.50
1,000 Labels.....	3.00	4.00	5.00

☞ Samples mailed free, upon application.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

A Modern Bee-Farm, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Advertisements.

BEES, —ITALIANS—PURE—
Good in every respect. Cheap,
for the Quality. Address,
A. L. GOULD,
10Alt RIDGEVILLE, Iroquois Co., ILL.
Mention the American Bee Journal.

SMITH & SMITH

We have one of the largest
Bee-Hive Factories in the World.

Mention the American Bee Journal.

MINNESOTA AHEAD!

WE are selling 100 All-Wood Langstroth Brood-Frames for \$1.00; and Langstroth HIVES, with Supers, for 55 cts.
☞ Don't order your Supplies for 1888 until you see our Circular.

WM. H. BRIGHT,
10Atf MAZEPPA, MINNESOTA.

Mention the American Bee Journal.

FOR Quality and Price these SECTIONS have no equal. Send for Price-List, retail and wholesale; also of Wood Separators, Foundation, Cases, etc. Address as in the Cut above. 7A4t
Mention the American Bee Journal.

2-Story Langstroth Hive, 80c.

WE still have a few of those Two-Story Langstroth HIVES with 10 Brood-Frames, at 80 cents.

Who wants them? Speak QUICK, or it will be too late. Address,

SMITH & SMITH,
10Etf KENTON, Hardin Co., OHIO.

Mention the American Bee Journal.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV, March 14, 1888. No. 11.

EDITORIAL BUZZINGS.

Mamma and I were looking o'er
The last bee-papers for bee-lore.
Our three-year'd "pet" was busy too,
Removing wrappers from a few.

New costumed A. B. J. she spied;
Then, "Oh! new picture I see!" she cried,
Then paused—then, with admiring glee,
"A nice big 'pungkun!' Mamma, see."
—*Oliver Foster.*

Bees in Cellars should be allowed to remain there until settled warm weather. We often think of an apt remark made by Dr. Miller to us some years ago. It was this: "I never regretted letting my bees remain in the cellar too long, but I have often regretted taking them out too soon." Let all take the hint. Do not be in any hurry to take them out on the first fine day! Wait!

Fastening Foundation in Sections.—Mr. G. W. Cole has sent us some samples of the work done by his machine—the temperature being 40° and 46° in the room where it was done—the rapidity being 8 and 10 in a minute. He says the temperature should be from 60° to 90° to have the best results. The work is well done, and at the higher temperature (46°) it is perfect.

Candied Honey in Combs, etc.—H. V. S. Stout, Dover, Del., on March 3, 1888, writes:

I have a very few sections and combs in which the honey has candied. How can I get them cleaned up for use the coming season? Bees are wintering well. The weather has been mild, and queens are laying freely.

Give the candied honey in the sections and combs to the bees. They will clean them up.

Gathering the Statistics.—Some names have been received at this office of those who would be willing to act as correspondents for the gathering of statistics by the Government, but nothing like the number required, or even an apology for such number. Some approve the plan, and others do not. It is quite evident to us that no plan already mentioned will be acceptable to all, and, further, that there is much apathy in reference to the matter among bee-keepers. Perhaps they do not want it known what they are doing, and take a more selfish view of the affair. Here is a letter from E. France, of Platteville, Wis., who does not like the method we proposed, of gaining the information through the assessors:

It is stated on page 131, that the best and surest way to obtain statistics of the bee-industry, is to have questions in the assessors' blanks to be answered. That plan would not suit the average bee-keeper. Perhaps not one-fourth of the bees in the country are now taxed, and if the assessors took down the number of colonies of bees, honey, etc., he, of course, would have to set some value on the property, and levy taxes on the same. I do not know how to get the statistics; but I am satisfied that the assessor would not get one-half of the information, and what he did get, would not be worth very much.

That is right, let the matter be discussed freely, and all the points of interest brought before the readers of bee-literature. It is not so difficult to say what *will not do*, as it is to point out a successful method, which will give universal satisfaction. We are anxiously awaiting the advent of the person who will say, "Behold I show you a more excellent way," and who can prove the assertion satisfactorily.

Badly Stung.—Mr. G. B. Olney, of Atlantic, Iowa, on March 2, 1888, sends us the following item from the Cumberland, Iowa, *Current*:

We see by an article in the *Democrat* that the *Messenger* has succeeded in running against the red-hot end of the AMERICAN BEE JOURNAL. It does, or should feel the sting of the contact.

Mr. Olney remarks that there is a general interest arising in that community about bee-keeping, and that in consequence there will be many from Atlantic who will attend the Bee-Keepers' Convention at Red Oak this week. He adds:

The article from the AMERICAN BEE JOURNAL of Dec. 21, 1887, is going the rounds, and I am glad to meet so many with a pleasant smile (raised to about 90° in the shade). That "dose of poison" article is stinging the *Messenger* thoroughly on all sides. Having no shield to ward off the thrusts, it is compelled to quietly take all that comes, without the slightest resistance.

A Frame Lifter is sent to our Museum by Mr. B. E. Foster, Utica, N. Y. It consists of two bent wires as handles, operating two "nippers" at the ends of the wires, which hold the frame, and it will answer the purpose very well. It is placed in the Museum.

Change to Columbus, O.—We think that the expediency of changing the place for holding the North American Bee-Keepers' Convention is quite apparent. The Grand Army of the Republic will hold a Reunion at Columbus, O., during the Centennial celebration at that city, and these two attractions alone will call for cheap transportation—probably one-fifth of the usual fare. This item is usually the largest one for bee-keepers who attend conventions—especially the International. We understand that this matter is now before the executive committee, and the change from Toledo to Columbus should be made without the least hesitation or delay. All the "expressions" sent to this office but two, are in favor of the change to Columbus—and not one has been received which favored its being held in Toledo! Two State conventions have passed resolutions favoring the change to Columbus, and have elected delegates to attend that convention. Let the change be made and announced at once, so that all arrangements may be made for a rousing meeting.

Queens from the South.—L. B. Graves, of Nineveh, Ind., asks the following questions:

1. Would it be practicable to send South for an early queen, say April or early in May, to Italianize my 5 colonies of bees?
2. Would they be as hardy as queens reared in the northern States?
3. Are Albino a desirable strain of bees?
4. What is the general opinion of the Carniolans? Please answer through the BEE JOURNAL.

As there are many who have made similar inquiries to the above, we will reply for the benefit of all.

1. Yes; but it should not be shipped until the weather is settled and reasonably warm.
2. Yes; equally so.
3. Yes; if they have as good working qualities as their plumage.
4. They are hardy, and generally liked.

Be Wise and Be Happy.—This is the title of a circular sent to us by W. R. G., Greenville, Texas. It purports to be sent out from Chicago, and he wanted us to investigate the source. It is another of the many *frauds* operating through the United States mails. It wants the "dupes" to send a sum of money for a book entitled "Secrets of Bee-Keeping," which promises all kinds of impossible things, among the latter, it proposes to teach the buyers of the book how to get "from 200 to 600 pounds of honey from every colony."

We sent the money to the address named for a copy of the book. It was a boarding house; the person named had a small room there, but did his business only through the mail, said the keeper of the house, and she added, "He is not in through the day." The way to be *wise* is not to send money to such unknown persons. All the books of any value on the pursuit of bee-keeping can be obtained at this office without risk, at the publishers' prices.

GLEAMS OF NEWS.

Honey for Analyzation.—Mr. J. R. Bostwick, of New Milford, Conn., has sent us a copy of the *Gazette*, which states that he has supplied some honey to be analyzed from which a standard for the State will be made. He evidently has a double end in view, for with such a "State standard" derived from an analysis of his honey, he has a secure field for all the honey he can produce. The *Gazette* says:

On Jan. 27, H. L. Jeffrey packed at the residence of J. R. Bostwick a few samples of honey to be sent to the Connecticut Experiment Station to be analyzed, and the analysis to be used as a standard. Mr. Jeffrey, a few days before, had been requested by letter from the Station, to send some samples of liquid and comb honey known to be the *straight* article, for analysis.

When Mr. Jeffrey was sorting out and finishing up the crop of Mr. Bostwick's honey last October, he selected two one-quart jars full, with the intention of placing them in the hands of the State Board. One of the jars was taken to Hartford when the Agricultural Board met, the other went to the Experiment Station in the case of samples. In the same case was a sample of the same lot of honey equal in every way except that it had been exposed to the cold weather, and had become as hard as any sample of butter, but it was not frozen. This peculiar quality possessed by honey, to become hard at a temperature below 50°, and its peculiar appearance in that state, is as sure a test of purity as is any chemical analysis.

A 5 per cent. adulteration, or even an addition of water, is very plainly seen, as it leaves quite an amount of liquid among the granules of the sugars which the pure honey as it is gathered from the flowers is composed of. Honey that is not properly ripened is easily detected even by a person not an expert. Many look upon granulated or solidified honey with suspicion, and yet the fact is that the harder the honey the purer it is.

In the case sent to the Experiment Station were two samples of comb honey; one from the basswood bloom, usually sold by the misnomer of white clover, and the other was gathered from fall flowers and the juices of fruit. Both were rich and heavy in quality, though lacking in tempting appearance. Mr. Bostwick had about 13 gallons of this quality of extracted honey, and quite a crop of comb honey.

Eucalyptus Honey.—In the Oakland, Calif., *Enquirer* for the 9th ult., Mr. W. A. Pryal makes these remarks about eucalyptus honey:

All along the foothills near Oakland bees do well, and annually store a good supply of as luscious honey as one could well desire to eat. The honey gathered during the winter months may be said to be collected exclusively from the flowers of eucalyptus trees, and is of a dark color, and very thick. This honey is said to possess medicinal properties. The clearest and most delicious honey is stored during the latter part of May, and all through June.

Bees were first brought to this county in the fifties, long before they were introduced to the now famous honey regions of the State.

Scatter the Leaflets.—Look at the list (with prices) on the second page.

A Sugar-Producing Tree.—Mr. Lewis Proxmire, of Mt. Union, Pa., sends us the following from the *Grocers' Criterion*, for publication in the BEE JOURNAL:

A report comes from the East which is of great importance, if true. It is that there has been discovered in British India a blossom of such saccharine properties that it is destined to revolutionize the sugar business of the world. It is the flower of the mahwa, or moola, a tree of large size, which abounds in the southern portion of Hindostan. This blossom has a sweet taste, and yields one-half its weight in sugar. The Hindoos have for a long period been accustomed to extract a syrup from the mahwa's flowers but in the most primitive fashion, without attempting to develop a process. The tree, it is stated, demands neither care nor cultivation. It produces annually a thousand pounds (?) of blossoms, which it sheds during the night. The saccharine matter is also seeable for a spirituous liquor, and for an oil which may be used for both lighting and food. If this wonderful report is correct, it may be seen at a glance what a disastrous competition the mahwa is likely to make with existing sugar industries.

The best West India plantations produce 400 pounds per aspent (1¼ acres), and the French and German sugar beet farms do not equal this amount. But it is claimed that the blossoms of five mahwa trees will yield the same amount, a statement not consistent with the reported weight of the bloom, which, however, must be an error. From 200 to 250 trees can be grown upon an aspent from which it results that the crop of sugar will be from 40 to 50 times greater per acre of land than that of the sugar cane. The English-speaking Hindoo press is already urging the Government to take steps for making this new sugar industry a monopoly as far as possible.

We know nothing more of this tree than is stated in the article.

Dr. A. B. Mason has been appointed superintendent of the Apiarian Department of the Ohio Centennial Exposition, to be held at Columbus next fall. The Director General says that a suitable building will be provided for the Bee-Department, and that the superintendent shall have "full swing." The Doctor writes us as follows concerning the arrangements contemplated:

I have thought of having an octagonal building erected, with a fine large pyramid of comb and extracted honey in the centre, so made as to constantly, but slowly revolve with other pyramids, and different kinds of arrangements on the sides, all enclosed with bee-proof (and thief proof) wire cloth, and all the light to be admitted through the roof.

Suitable premiums will be awarded, and if the North American Bee-Keepers' Convention should meet at Columbus, there would be no trouble in getting the best judges in the country to award the premiums.

French Book.—From our friend and co-laborer Mr. Ed. Bertrand, Nyon, Switzerland, comes a new bee-book in the French language. It is a guide for the apiarist for each month of the year. It contains 150 pages, and is illustrated. Mr. Bertrand is one of the most progressive and practical apiarists of Europe, and his book is full of valuable suggestions concerning the proper management of bees. Its cost after paying transportation and postage is about 80 cents.

Bee-Cellars.—Mr. A. Bridges, of Ontario, gives this description of his preparation of his bee-cellar for the present winter:

I boarded the walls of my cellar with rough boards, leaving a small space between the stone walls and the boards, then I lined the board walls with building paper, and laid a board floor on the bottom of the cellar, leaving a 2-inch space between the bottom and the floor. This makes the cellar very dry and warm; no frost can possibly get in.

The Farmers' and Bee-Keepers' Association of Newaygo County, Mich., was held at Fremont, on Feb. 9 and 10, 1888, and new By-Laws adopted. The Glee Club rendered some excellent music, and a banquet was spread at the St. Charles Hotel, of which about 70 partook. Mr. Geo. E. Hilton was re-elected Secretary-Treasurer. Mr. W. E. Gould read an essay on "Practical Bee-Keeping," which was very interesting. "Relative benefits of apiculture, agriculture and horticulture," by Geo. E. Hilton, and a talk about "The Clover," by A. M. Alton, closed the exercises.

New Catalogues for 1888 are on our desk, from the following persons:

Frank A. Eaton, Bluffton, O.—12 pages—Eaton's Specialties.

Nixon Nozzle and Machine Co., Dayton, O.—20 pages—Spraying Machinery.

Wm. H. Bright, Mazepa, Minn.—24 pages—Bee-Keepers' Supplies.

Smith & Smith, Kenton, O.—24 pages—Implements in Bee-Culture.

G. M. Doolittle, Borodino, N. Y.—4 pages—Italian Bees and Queens.

H. P. Langdon, East Constable, N. Y.—4 pages—Bees and Queens.

Thomas B. Blow, Welwyn, Herts, England—64 pages—Bee-Keepers' Supplies.

W. E. Gould, Fremont, Mich.—12 pages—Bees, Queens, and Apiarian Supplies.

CONVENTION NOTICES.

The Wabash County Bee-Keepers' Association will meet at North Manchester, Ind., on April 10, 1888. F. S. COMSTOCK, Sec.

The Eastern Indiana Bee-Keepers' Association will hold its spring meeting on Saturday, April 21, 1888, at Richmond, Ind. M. G. REYNOLDS, Sec.

The Cortland Union Bee-Keepers' Association will hold its spring meeting on May 8, 1888, at Cortland, N. Y., at 10 a.m. All bee-keepers are invited. W. H. BEACH, Sec.

The Des Moines County Bee-Keepers' Association will hold its next meeting on April 24, 1888, at Burlington, Iowa. JOHN NAU, Sec.

The Hardin County Bee-Keepers' Association will meet at the Court House in Eldora, Iowa, on the second Saturday in each month, at noon (12 o'clock), until further notice. J. W. BUCHANAN, Sec.

The next regular meeting of the Susquehanna County Bee-Keepers' Association will be held at New Milford, Pa., on Saturday, May 5, 1888. H. M. SEELEY, Sec.

The tenth annual meeting of the Texas State Bee-Keepers' Association will be held at the yards of Vice-President W. R. Graham, in Greenville, Hunt Co., Texas, on May 2 and 3, 1888. A leading feature of the convention will be criticisms upon subjects that have been mentioned in the bee-papers. A good time is expected, so let all Texas and Arkansas bee-keepers attend. A cordial invitation is extended to all bee-keepers wheresoever dispersed. Remember, no hotel bills to pay at our conventions! B. F. CARROLL, Sec.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*

- Apr. 11.—Stark County, at Canton, O.
Mark Thomson, Sec., Canton, O.
- Apr. 21.—Eastern Indiana, at Richmond, Ind.
M. G. Reynolds, Sec., Williamsburg, Ind.
- Apr. 24.—Des Moines County, at Burlington, Iowa.
John Nau, Sec., Middletown, Iowa.
- May 2, 3.—Texas State, at Greenville, Tex.
B. F. Carroll, Sec., Blooming Grove, Tex.
- May 5.—Susquehanna County, at New Milford, Pa.
H. M. Sealey, Sec., Harford, Pa.
- May 7.—Welland County, at Welland, Ont.
J. F. Dunn, Sec., Ridgeway, Ont.
- May 8.—Cortland Union, at Cortland, N. Y.
W. H. Beach, Sec., Cortland, N. Y.
- May 19.—Nashua, at Nashua, Iowa.
I. L. Rouse, Sec. Ionia, Iowa.
- Aug. 14.—Colorado State, at Denver, Colo.
J. M. Clark, Sec., Denver, Colo.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

Bees in Fine Condition.—Calvin Boyd, Petrolea, Ont., on March 3, 1888, says:

I commenced the season of 1887 with 20 colonies, increased them to 37 colonies, and took 1,500 pounds of extracted honey, and 100 pounds of comb honey. I doubled up my colonies to 27 colonies last fall. I fed 400 pounds of sugar syrup, and packed them for winter on the summer stands. They had their first flight on Feb. 24, the first since the middle of November; they appear to be in fine condition. All the bees in this locality appear to be wintering well.

How to Fasten Foundation.—M. L. Cram, Mankato, Minn., writes thus:

My method of fastening foundation in sections, is as follows: By means of a blade fastened to a lever, I split the section before it is folded, from one of the ends to the first V-groove; then spreading the parts sufficiently, I insert the edge of the piece of foundation, of whatever size I wish to use, into the crack so made; then folding the section, the dovetailed parts hold the foundation between the parts of the split end as in a vice. Of course, with sections having bee-spaces only above and below, the right end must be split; that is, the end having the bee-spaces in it. By using a suitable gauge, the section is split exactly in the centre.

Packing Bees for Winter.—L. C. Seabright, Blaine, O., on Feb. 29, 1888, says:

Mr. Jno. A. Buchanan, on page 109, asks me to fix things up so as to help me out with my "pet theory," as he chooses to term the plan pursued by hundreds of practical apiarists in regard to chaff packing. I have tried other modes of wintering my bees, but none so successful as packing them on the summer stands. Admitting that I commenced last season with 63 colonies, only receiving 60 pounds of honey. Would Mr. B. say that had I wintered my bees in single-walled hives, with nothing but a cushion on top of the frames, as Mr. Lewedag had done, I would have secured a good crop of honey? Well, Mr. Lewedag has broken over the line, for he is wintering only 2 colonies *a la* Buchanan theory. I do not think that it is the fault of the hive, the

bees or my management, that I got no honey to speak of.

Last week we had beautiful, spring-like weather, and yesterday morning the mercury was down to 5° above zero. It is during such sudden changes in the latter part of the winter and commencement of spring, that I most appreciate chaff-packing.

Wintering Well—Introducing Queens.—Edmund R. Buller, Campbellford, Ont., on March 2, 1888, writes:

Bees are wintering well in this locality, and those in the cellar, from present appearances, are likely to come through all right, although we have had weather 30° below zero at times. One of my bee-houses, built in the side of a hill, and covered with cedar and earth, contains 50 colonies which seem to be doing remarkably well, with a steady temperature of 42°.

I wish some correspondent would give directions on how to successfully introduce virgin queens to strong colonies. I have tried it, and always have failed.

Moving Bees.—W. L. Ginter, McCallsburg, Iowa, on March 5, 1888, says:

I commenced last spring with 9 colonies, increased them to 18, by natural swarming, and obtained about 20 lbs. of comb honey from mustard, of which there is a plenty in this neighborhood. I am nine miles from any basswood, and there is but very little white clover here yet, but it is getting thicker every year. I winter my bees in the cellar, and I have to move about a mile this spring. Had I better let the bees have a flight before moving them? or shall I move them and then let them out?

[When taken from the cellar, put them where they are to stay, and let them mark their location, and enjoy a flight at the same time.—Ed.]

Marketing Honey.—Chas. H. Van Vechten, of Victor, N. Y., says:

The greatest market is for nice white clover honey, which is put up in the nice, 1½ pound sections. I canvassed a whole city over two different times, and I cannot sell 1,500 pounds in that city. But, hold on; one person said he could give 10 cents per pound; that he had written to several parties in New York, and he could not get such prices as are quoted in the bee-papers. I notice that in San Francisco they quote honey at 19 cents for the best in one-pound sections. There must a big mistake somewhere; for in a warm climate as that to keep bees, and being easy to winter, you find California honey in all the Eastern markets; and then see the quotations above New York, and other markets. There has not been a pound of honey sold here for less than 14 cents, and that was early in the season. Bee-keepers should never wait until this time of the year to sell honey. That is where the trouble is.

Feeling Encouraged—Honey-Boards.—Wm. Lossing, Hokah, Minn., on Feb. 14, 1888, writes:

I put 196 colonies in a winter cave in good condition, and they seem to be all right now. The last season was a poor one for honey in this part of Minnesota. There was no white clover, and very little basswood; but there was plenty of fall honey to fill up the hives for winter. My hives were never heavier than they were last fall. I am looking for a better time for bee-keepers, for the reason that poor crops connected with low

prices have discouraged a great many beginners, besides inducing some of the older ones to go out of the business. I have kept bees for 12 years, and never felt more encouraged. I had about 1,500 pounds of extracted honey, which I sold readily for cash at a good price.

Please answer the following: 1. Which kind of a queen-excluding honey-board is the best, all things considered? 2. Does perforated-zinc give perfect satisfaction to those who have used it for years?

[1. The "slatted" queen-excluding honey-board, made of alternate wood and zinc, is undoubtedly the best. As zinc contracts and expands with changing temperature, when used in full sheets over the brood-frames, it sometimes "bulges" or presents a contorted surface; the alternate wood and zinc allows room for expansion and contraction, and keeps it always straight and in place. For a general opinion, read answers to Query 521, on page 150.

2. Yes; as far as we have ever heard, it has "given perfect satisfaction, when the holes are of exact size. A worker, when loaded with honey, requires a hole five thirty-seconds of an inch, and this will exclude a queen or drone. Some of that first manufactured varied between five and six thirty-seconds, and did permit the passage of an under-sized queen.—Ed.]

Better Prospects for a Crop.—G.

W. Johnston, Holden, Mo., on Feb. 28, says:

Bees are wintering well here. Those in the cellar have used from 4 to 7 pounds of honey per colony; while those on the summer stands have consumed from 10 to 15 pounds. The prospect for a crop of honey is better than it was at this time last year.

Severe Winter in Canada.—Thos.

Stokes, Minesing, Ont., on March 3, 1888, writes:

We have had a pretty severe winter here, since a little before Christmas. The lowest it has registered was 27° below zero, on Jan. 21. It has been from 10° to 20° below a great many days. But for all the cold, my cellar has only lowered from 47° to 44°, and I think that is very good, not having any underground ventilation, or artificial heat either. Bees are wintering well. Snow has covered the ground all winter, about 18 inches on the level in the woods. The roads are very much drifted.

Selling Honey to Private Families.—David Wilcox, Oxford, N. H., on

Feb. 29, 1888, says:

I have 108 colonies of bees, and my last year's increase was 30 colonies. I had 2,400 pounds of honey, 500 pounds of which was taken from the brood-chamber and unfinished sections. There was little fall honey. I fed them about 400 pounds of sugar to carry them through the winter. I put 15 colonies into the cellar, and the rest in chaff hives. All are doing finely so far. I sold the last of my honey last week. Nearly all of my honey was sold to private families, from my wagon or sleigh. I believe more than ever in this way of disposing of our honey. I consider that we had about half a crop last year. There are but few who have used box-hives that obtain any surplus honey. I sell my extracted honey in quart jars, for the same price by the pound as the other. When the weather is warm, I carry it in bulk.

QUERIES AND REPLIES.

PROPER TEMPERATURE FOR BEES TO FLY.

Written for the American Bee Journal

Query 523.—1. At what temperature is it safe to give bees a flight? 2. Is it advisable to do so with snow on the ground? My bees were put in the cellar on Nov. 10, 1887.—Wis.

1. Fifty-five degrees to 60°. 2. Not unless quite warm.—A. B. MASON.

We would not give bees that are in the cellar any flight until spring. The temperature should be above 45°.—DADANT & SON.

1. At 60° in the shade. 2. No. Do not do it until it is about time for willows to blossom, except it may be as a doubtful remedy for a very serious disease.—R. L. TAYLOR.

Our bees here in the South are very seldom three days consecutively without a flight. I have noticed that they will not fly out when it is 40° to 42° above zero.—P. L. VIALON.

1. About 50° in the shade. 2. It would be desirable that no snow should be close to the hives in front. But why do they need a flight? Bees ought to stay in the cellar from Nov. 10 to April 10, with no bad results.—EUGENE SECOR.

1. I let the bees on the summer stands judge the temperature for themselves. I would not give bees wintered in a cellar a flight until taken out in the spring. 2. It is; the bees that are found on the snow, after a flight, are mainly old bees whose lives are spent.—MRS. L. HARRISON.

1. I do not generally put my bees out until the temperature is 55° or more; but if the sun is shining it might do at a lower temperature. 2. If snow is on the ground, I should like it pretty warm.—C. C. MILLER.

1. About 50° Fahr. 2. Yes, if the snow has a crust on it. If they are all right in the cellar, it is better to leave them until the snow disappears.—C. H. DIBBERN.

1. If bees in the cellar are meant, it is not best to give them a flight at all until spring, unless they are diseased and restless; and I am not sure that it is then. 2. It is safe to let bees on the summer stands fly whenever they want to, snow or no snow.—M. MAHIN.

1. Some of my colonies were put into the cellar last October, and I do not expect to take them out before April 8 or 10, unless I see pollen before that time. 2. My bees have had many a flight with snow on the ground, with no bad results.—H. D. CUTTING.

I would not remove the bees from the cellar while there was snow on the ground, unless they were very restless. Fifty degrees or 55° in the sun, 45° in the shade; and if very windy, not then. You must be governed by circumstances.—J. M. HAMBAUGH.

1. At 45° in the shade, if still, and the sun is shining. Otherwise it must be as warm as 55°. 2. Yes, bees can get off the snow as well as off the bare ground if the temperature is right. If your bees are quiet, let them alone till about April 10 to April 25.—G. M. DOOLITTLE.

1. Not lower than 60° Fahr. If the bees are quiet, let them alone. The very best evidence of successful wintering is that they are quiet. Go among them as much as is necessary to brush up and keep the room tidy, but do not fuss and tinker with them without cause.—J. M. SHUCK.

It all depends upon whether or not there is snow upon the ground, how brightly the sun shines, and how hard the wind blows. Leave a few (packed) colonies out as a guide. I have had mine fly safely at 50° in the shade, with snow, when the air was still and the sun was shining. It was 45° once.—JAMES HEDDON.

I should like 60° to 65° in the shade. I would not remove the bees until April 10, when they can commence work if they keep quiet, as they will if the food and the temperature of the cellar is all right. If uneasy in the hive, they may safely be given a flight on a real warm day, even if there is snow. Some cover the snow with straw.—A. J. COOK.

1. I leave my hives open all the time, and allow the bees to fly out whenever they choose. If any are not able to return, I consider them no loss, as they would, in my judgment, die if confined. 2. It makes no difference with myself, whether there is snow on the ground or not, for the above reason.—J. E. POND.

In this climate it is never safe for bees to take a flight when there is snow on the ground, and they seldom attempt to do so unless they have been confined unusually long, and are distressed for a flight. It depends upon the weather, in fact, more than on the temperature. On a still, sunny day, bees may fly safely at from 50° to 56°; while they fly with dangerous consequences at 60°, if the wind is blowing a stiff breeze.—G. W. DEMAREE.

The lowest temperature that bees may be taken from a cellar for a flight when there is snow on the ground, is 50° in the shade; but the air must be quiet and the sun shining clear. On putting them out, put straw or hay in front of the hives for the

bees to alight on. If it is a cloudy day, the temperature should be 60°. If there are high winds, with the sun shingling clear, the temperature should be at least 55° in the shade.—G. L. TINKER.

If the bees in the cellar are restless or diseased, it might be of advantage to give them a flight when the temperature is from 55° to 60° Fahr. If they are on the summer stands let the bees fly or not, as they desire, whether snow is on the ground or not. To take bees out of the cellar before April 10, in this latitude, is very unwise.—THE EDITOR.

PRACTICING CONTRACTION AND BUILDING COMBS.

Written for the American Bee Journal

Query 524.—1. In contracting the hive to five or six combs, more or less, for wintering, and the same to economize heat for breeding in early spring, do you work the combs to one side of the hive, and use one division-board? Or do you put the combs to the middle of the hive and use a division-board on each side? If you use two, what are your reasons for so doing? 2. When not using foundation, what way do you secure the building of the comb solid to the bottom-bars of hanging frames?—Ohio.

1. To one side. 2. I use foundation.—C. C. MILLER.

1. I use a dummy of the right thickness to fill the space desired. 2. By putting them in an upper story.—G. M. DOOLITTLE.

1. We never contract strong colonies to such small space. For winter we would use two division-boards rather than one, because we can put absorbents on both sides.—DADANT & SON.

1. I use a Langstroth hive 14½ inches wide, with 9 frames in the winter, and at least one inch of space over the top of the frames. 2. I use full frames of foundation, and consider it more profitable to do so than to use simple starters.—J. E. POND.

1. I put the combs to one side of the hive in nearly every case when I have to contract. 2. I use foundation.—H. D. CUTTING.

1. To one side, and one division-board. 2. Strong colonies will generally secure the comb to the bottom-bar. When they fail to do it, and it is necessary to have it done, I insert bits of comb to fill out.—J. P. H. BROWN.

1. I do not use division-boards. 2. The best way to get frames filled "solid" with comb, is to invert them, by turning the hive upside down. Very fair success may be attained by tiering the hives up, putting the frames to be completely filled over the brood-nest, but without a honey-board.—J. M. SHUCK.

1. When the hive is protected by chaff, etc., on the outside, I work the combs to one side of the hive, and use one division-board. If not so protected, I use two division-boards, and pack between the division-boards and sides of the hive. 2. By reversing.—A. B. MASON.

1. I use two division-boards, as it makes nearly a dead air space on each side of the hive, and protects the colony from the cold or sudden changes. 2. When I do not use foundation, I let the bees do as they please.—MRS. L. HARRISON.

1. In the middle, provided the colony was to be wintered out-doors, and not packed. If packed, or in the cellar, I would put them to one side. You see the reason, of course. 2. I know of but one practical way to get frames full of combs, foundation or no foundation, and that is by reversing. That secures them so, and keeps them so.—JAMES HEDDON.

1. I use two division-boards when there is room for them, and the reason is, that it "economizes heat." 2. I secure it when I use the combs for extracting purposes in the second story of the hive; that is, over the brood-nest, during a good honey-flow.—R. L. TAYLOR.

1. Yes; here in the South, when it is necessary to contract, we work the combs to one side, and use a wooden division-board. 2. I would not do without foundation. A few years ago, before the "foundation days," I either used a $\frac{1}{2}$ or $\frac{3}{4}$ inch strip of natural comb, or a triangular guide added after the frame was built out in comb.—P. L. VIALON.

1. I have, and I practice both ways. I think it about as well to use one division-board. If we pack well and warmly above, I think we need not mind side-packing very much, especially if bees winter well.—A. J. COOK.

1. I have in use a brood-chamber having about the same capacity as six Langstroth frames, and I will transfer the greater part of my bees to such brood-chambers in the spring. I shall not need to use division-boards in these hives. 2. I invert the brood-chamber.—G. L. TINKER.

1. It is better to use two division-boards. But if the frames are full of comb, contraction is of little value. 2. I let the bees do as they please. They do not want brood-combs attached to the bottom-bars. If the combs are put in an upper story, and filled with honey, they will generally be built solid.—M. MAHIN.

If the bees are to be wintered in a cellar, I would place the combs on one

side, using one division-board. For out-doors, I would use two. The dead air space or packing is, to some extent, a non-conductor of heat. 2. It can be done by inverting, or inserting pieces of comb.—C. H. DIBERN.

In winter, I work the combs to the centre of the hive, using a division-board at each side of the cluster, and filling the intervening space with dry maple leaves, chaff, or some equally as good an absorbent. After absorbents are removed in the spring, I usually confine them to the south side of the hive, to get the warmth from the sun, using but one division-board. 2. I use full sheets of foundation; hence I have no rule to obtain full combs otherwise.—J. M. HAMBROUGH.

1. I have never wintered bees on the summer stands. If I should, and should practice contraction, I would prefer the combs in the centre, and the division-boards on both sides. I would then pack some dry absorbent and non-conducting material between the division-board and the outside of the hive. 2. I know of no way to secure that result without inverting the hive or using it above another for extracting from. The latter will not always accomplish the object sought.—EUGENE SECOR.

1. My practice is to place the combs on the south side of the brood-chamber, and close with a division-board on the north side. This plan is decidedly best for this climate, as the bees get the benefit of the warmth of the sun, at intervals through the winter, and especially in the spring. 2. I do not care to have them built solid to the bottom-bars, except where they are used for taking honey from the combs. In that case some narrow strips of comb are pressed between the lower edge of the comb and bottom-bars, at their first use for extraction, and the bees will make them solid for all time.—G. W. DEMAREE.

1. To put the combs in the centre and have a division-board on each side, is preferable because of controlling the temperature by the use of cushions or absorbents on the sides, when bees are wintered on the summer stands. 2. As the bees evidently do not desire "the building of the comb solid to the bottom-bars of hanging frames," we see no reason in trying to "secure" such. We prefer the use of comb foundation.—THE EDITOR.

CORRESPONDENCE.

HIBERNATION.

What is Hibernation, as Applied to Bees?

Written for the American Bee Journal

BY J. F. LATHAM.

As an answer to the interrogatory on page 42, "What is hibernation?" I would say, analogically, the term signifies to pass the winter, Latin *hiemo*, to winter, and *hybernia*, winter quarters. In the roots *hi-bern(i)a(tion)* we have the material from which linguists have constructed the word, and assigned its modern position in etymology, which, when interpreted in the sense justified by the original, indefinitely conveys the idea of its subjects' passing the winter in winter quarters. In the accredited scientific acceptance of the term, hibernation is used to designate a condition; in the common acceptance it is used to designate an act.

The actual question is, which of the two definitions most correctly describes the general phases accompanying the passage of the hive-bee through its period of winter confinement in Northern latitudes? Bee-keepers in cold climates know from observation that their colonies pass the winter, in winter quarters of some kind; but they are not as positive in regard to their physiological condition during that period; nor is it possible that they can be, so far as optical evidence demonstrates the actual hibernal condition. Therefore, it would seem admissible to say, in the scientific appellation of the term, that the hive-bee does not hibernate.

It is a well-known fact that, in the temperate zones, the hive-bee is influenced, in a greater or less degree, by the periodical changes of the seasons; and, in experiencing those changes it must conform to natural circumstances, or "laws" governing the principles of life, animation, growth, disintegration and suspension, as well as the revivifying efflux of successive rounds of development in an androgynal aspect. But when the chemical process by which the flame of life is stimulated to activity, becomes inactive, the organic mechanism—the visible machine—which constitutes the living, moving, growing animal, or vegetable, ceases to exist as such; and dissolution follows, leading to the fact that, a total suspension of functional activity is preceded by a total absence of calorific combustion, the

only inextinguishable motor of animate existence.

It is very apparent that the hive-bee is only physically constituted to experience, to a certain degree, the coma to which the brute animals are subjected during the hibernal period, and can but lapse into short periods of repose; so that, when the fuel in its stomach becomes exhausted it must arouse, and eat to replenish the flames of life. The true hibernating animal does not partake of food during the hibernating period; although it does at times leave its hibernaculum during very mild and comparatively long-continued thaws, even in mid-winter.

After having passed the limits of a definite grade of development, in its progress from the vegetable to the animal, no animal can become frozen solid, or even become sufficiently benumbed by cold, as to wholly destroy its vital functions, and live. The hive-bee, in its evolutionary rounds, has advanced beyond the degree correlative of the vegetable, and is now very nearly, if not wholly a distinct species of the insect animal, so to speak, and its existence, organic structure, means of obtaining food, method of reproduction, and habits of domestic economy are irrefragable evidence that its condition is beyond the *radical* principles; but not beyond the *broad* principles that govern the periodical subsidence and revival of the strictly vegetable species.

When the season wanes, the forest trees and shrubbery put on their terminal buds; growth ceases; and the elements contributing to their development are held in suspension until the genial warmth of the spring sun stimulates a renewal of their cyclic round of activity. Is not this period of repose and period of activity, as illustrated in the economy of the vegetable, when unconnected with the animal, as admissible as when allied to, or performing its functions in union with the animal; when animate life is, in a certain degree, dependent upon the vegetable elements for the support of its impetus? Life, without the influence of motion on matter, is inadmissible.

When the term hibernation is used to describe the condition, or profound coma experienced by certain species of animals during the winter season, its scope can only include the vegetable elements, and must be confined, necessarily, to very nicely defined limits. Less than hibernation would be *nil*; more than hibernation would be dissolution. The intermediate condition, the equilibrium of the evolving forces, would be simply *repose*.

Again, it does not appear that the comatose condition evinced by the

hibernating species is habitual with the hive-bee, and does not accompany that insect from the regions of flowers and snow-storms, to the ever-blooming flora of tropical climes.

NATURE'S WAY.

Management of Bees on Natural Principles.

Written for the American Bee Journal
BY W. S. VANDRUFF.

In this article I suppose I will depart considerable from the present way of managing bees, and especially for surplus comb honey. I think that the present system of working for comb honey is far from being in accordance with natural principles, and this is why there is so much trouble in getting bees to work in the sections. It seems that with the present management it is almost impossible to get the bees to build nice, straight comb honey in sections, free from pollen and brood, without using queen-excluders, separators, honey-boards, etc.

To get the bees into the sections also seems to be a great problem, and it seems that the only way devised by our leading bee-keepers is to use some kind of "force work." We read of all kinds of contraction methods that can be devised to force the bees into the sections, and after they are in the sections, the next great trouble is to get them to build the combs straight, free from pollen and brood, without using force work again, thus forcing the queen to stay below by putting on a queen-excluder. I think that if the natural inclinations of the bees were fully understood, and by proper manipulation, all this trouble could be overcome.

We should study the secrets of the bee's nature more than we do, and theorize less, and not make hives and fixtures just as we think they ought to be, unless they are in accordance with natural principles. I will now mention wherein I think that the present system is not managed on natural principles:

1. Bees naturally build their combs about $1\frac{1}{2}$ inches apart, or a little less, from centre to centre.
2. Bees naturally cluster all together in one cluster to build comb. Now, to make the sections nearly 2 inches wide, and force the bees to build combs so far apart, is against their nature; and sections without side-openings are against their natural way of working. Also dividing up the cluster into a multitude of little clusters is entirely against the natural instincts of bees.

Just think of a surplus chamber with fifty or more apartments divided off only about 4 inches square, and a little less than 2 inches wide, as is the case in using wide sections with separators and without side-openings. No wonder that we read of so much trouble in getting the bees into the sections. The system is against the very nature of bees.

I have used several kinds of hives, and know of about all kinds in use, but I have yet to see or read of a hive that comes up to my idea of one that meets the natural inclination of the bees. I have never used queen-excluders or separators—I have always believed them a hindrance to the working of bees. I have always managed to get along without them. I have been studying the natural inclination of bees, and the more I work in accordance with their nature, the more I can accomplish. I am working on the natural-principle system, and I am succeeding beyond my expectations. I succeeded the past season in getting nice, straight comb honey in sections, free from pollen and brood, even in the brood-chamber, and without using queen-excluders or separators. I used no force work to keep the queen out of the sections, but manipulated according to the nature of the queens and bees.

There is a cause for the queen laying in the sections, a cause for the bees putting pollen in the sections, and a cause for the bees making bulged and crooked combs; and I am making it a special study to try to discover these causes, and a remedy for them. I expect in the near future to perfect a system of getting nice, straight comb honey, free from pollen or brood. Such a system I will call the "Natural principle system," as I will work entirely on natural principles. I expect to be able to get comb honey in either story of the hive, without using queen-excluders, separators, or anything of the kind. I believe that it is possible to get honey in sections side by side with the brood-combs, without the queen laying in the sections, and without using queen-excluders.

It is because the combs are not manipulated in exact accordance with the nature of the queen and bees, that we get brood and pollen in the sections. The more machinery and hindrances in the way of queen-excluders, separators, etc., that we have about the hives, the less honey we will get; because any system that is not in accordance with the nature of the bees results in a loss of honey, as it retards the work of the bees.

This article may bring forth many criticisms; I cannot expect much else, as I am attacking a system in general

use all over this continent, and a system most generally approved by the leading bee-keepers of the present day. But I do not think that they believe the system has reached perfection.

[This "attack" fairly takes one's breath—it is so sudden—so general—so positive. Well, we shall await the advent of the "Natural principle system," and its practical test. We know that perfection has not been reached—but the system may or may not be one of the steps leading to it.—ED.]

APPLE BLOOM.

Destroying the Codling Moth with London Purple.

Written for the American Bee Journal
BY JOSEPH BEATH.

I noticed sometime since in the *Western Rural*, an article from Prof. A. J. Cook, relative to poisoning the codling moth. Will he please give an article on that subject in the AMERICAN BEE JOURNAL, telling how to do it, so as not to injure the bees, where there are a large number of trees? and where to get a suitable force pump, stating the price, etc.

Corning, Iowa.

[The following is Prof. Cook's responsive article on the subject:—ED.]

No enemy of the apple has been so much and so justly dreaded as the codling moth, *Carpocapsa pomonella* Linn. This little miner of the apple—the so-called "apple-worm"—is so wide spread, and so generally destructive, that many thousands of dollars worth of apples have been destroyed by it annually. Of late, however, we have found a very cheap, safe, and effective remedy in the Arsenites, London purple, or Paris green. I prefer London purple, as it is cheaper, more easily mixed with water, and stays mixed longer.

To use it, we mix one pound of the poison to 100 gallons of water. We apply it in May, just as the blossoms have fallen from the apple or pear trees. If applied earlier it may poison the bees, and will do no good for a few days, till the apple is formed, and before that it may be all washed off by a heavy rain. If deferred longer than just after the blossoms have fallen, many of the larvæ—"worms"—will have entered the fruit, and so be out of harm's way.

The time to apply it is when the apples are the size of small peas. If no heavy rains come, one application answers so well that a second one

hardly pays. If a heavy rain comes within three weeks, a second application may well be made.

To treat an orchard, barrels of the liquid mixture should be taken in a wagon and drawn through the orchard and applied by use of a powerful force pump (as the poison is only held in suspension, of course it must be kept well mixed; we easily accomplish this by pumping into the liquid), so that the spray may be thrown on with such force that it will scatter to every fruit. With this weak mixture we can be so thorough as to be very certain to strike every apple, and yet not kill the foliage. If the spray is thrown on with great force, it scatters so that we are pretty sure to do very perfect execution. A good spray-nozzle is desirable. The Nixon—made at Dayton, Ohio—is the best that I know of.

NIXON FORCE PUMP.

The "Moody Field Force Pump" (N. Y.), attaches by a gearing to the wheels of the wagon, and so runs by the same power that draws the wagon. This costs about \$28, but pays well where larger orchards are to be treated. A. H. Nixon also works a cart which is so arranged as to run the pump. The former pump I have tried, as I have the nozzle, and I know they are admirable. The latter pump I have not tried.—A. J. Cook.

BROOD-CHAMBERS.

My Position Regarding Sectional Hives.

Written for the American Bee Journal
BY DR. G. L. TINKER.

There seems to be an effort to draw me out on this subject, but I have no interest in the matter, one way or the other, except the general good of bee-keepers; and to this extent, those who wish to draw on me, may do so freely.

The subject of the essay I wrote for the Ohio State Convention, as published on page 86, was suggested by friends who no doubt expected me to write favorably of sectional brood-chambers, and so promote the interests of Mr. Heddon; and that I should have done,

and have been glad to have done, if I could at the same time have written in the interests of bee-keepers. But that I could not do, and longer defend the sectional brood-chamber.

In the matter of bee-hives this experiment of Mr. Heddon is not the first, by any means, that has come to nothing; and he well alludes to one of the writers of a parallel nature. I am not at all ashamed of it, as in the case of Mr. Heddon's experiment and that of hundreds of others in this country, it failed in practice to "pan out" as beautifully as it did in theory. The only difference, if any, between us is, that my theory of "continuous passages" was not as finely spun as that on his divisible and interchangeable brood-chamber. Hence, I do not anticipate that my failure to realize will at all compare with his.

While failures have been the rule in introducing new bee-hives, they should not discourage us in the hope of obtaining something better than we now have; but they may well teach us that a trial of time will often bring out defects in our inventions that could not well have been foreseen.

As to my record in this matter, I confess to have thought well of the beautiful theories that Mr. Heddon gave us on bringing out his new hive, and only regret that they did not prove to be all that the gifted writer expected.

I have nothing further to add on the subject, to the carefully worded matter in my essay read before the Ohio convention.

New Philadelphia, O.

ALSIKE CLOVER.

Experience with Alsike Clover for Honey, for Pasture, and as a Fertilizer.

Written for the American Bee Journal
BY GEO. W. MORRIS.

I wish to add my little mite in favor of Alsike clover. Five years ago I obtained one bushel of seed, and sowed the same on about 20 acres of wheat and oats land, and got a fair stand of clover. The second year there was a fine bloom, and I had an extra crop of honey—1,300 pounds of extracted honey from 7 colonies, spring count, besides having 7 good swarms cast from them. I cut and threshed about 4 acres of the best of it, and received 6 bushels of nice, clean seed as a result.

I believe that it is equal to, if not better, as a fertilizer, than the common red clover, for three years ago I sowed, on shares, a field (wheat-field) belonging to another person, and the

result was a good stand of clover which was pastured the second season, and furnished a fine lot of grazing, too, considering that the land was thin and "tired."

The next spring (last year) this field was cultivated in corn, and although a comparatively dry season, it produced more corn and fodder than it had in one season for 15 years.

Another thing that I have noticed is, that horses inclined to rogue will always go to the field that has Alsike clover, thereby demonstrating their appreciation for this clover to other grasses. I have none sown at present, nor any land to sow on, but if some seedman will send to me a lot of Alsike clover Leaflets, free of cost, I will distribute them to farmers.

Cornishville, Ky.

HIVES.

Experience with Small Hives vs. Large Hives.

Written for the American Bee Journal

BY W. J. DAVIS.

I was much interested in the controversy between Messrs. Heddon, Dadant, and others, in Volume XXIII of the AMERICAN BEE JOURNAL, and then I proposed, at some further time, to give the results of my experience in the use of different sized hives.

I have no doubt that the season of the year at which the main honey harvest may be expected in different localities, has something to do in determining the proper size of hive for that place; and where the principal harvest occurs late (as in some portions of the West), a large brood-chamber may be preferable, hence Mr. Dadant may be correct in preferring such. But in northwest Pennsylvania our main harvest is from white clover, and commences about June 10, and lasts about four or five weeks. When the weather is favorable the yield of surplus honey is satisfactory. But good seasons are the exception. A majority of our Junes are either too dry or too wet for the best results.

After adopting the Langstroth hive in 1860, I made most of my hives to hold 8 Langstroth frames. The top-bar of the frame is 19 inches long. By way of experiment, I made about 60 hives to hold 12 frames in the brood-chamber, with an upper story for 80 pounds of surplus honey. These were mostly used for "out apiaries," of not more than 20 colonies each. A few of these large hives were used for several years in my home apiary, but never with satisfactory results; the larger the hive, the less surplus honey, and the most bees in the autumn.

About ten years ago I concluded to shorten my frames 5 inches, making them with a top-bar 14 inches instead of 19 inches. I made the change slowly, as facts demonstrated safety, until at present over 200 of my colonies occupy the shorter frames.

I am a specialist. I do not keep bees for fun, nor as a remedy for rheumatism. My bread and butter depends upon the success of the apiary. The hive that will give the most surplus honey without regard to increase of colonies, is the one for me. There are comparatively few bee-keepers who are located where the 100 or 200 pounds of surplus per colony is the average yield. Where one is so located where fields of white clover and forests of basswood abound, a hundred others will scarcely average 20 pounds per colony, and it is the sheerest nonsense to say that it is *all* in the *management*.

Pressing, then, that ninety-nine out of every one hundred bee-keepers of North America are not in a land flowing with milk and honey, it becomes a practical question how to secure the best returns for the capital and labor invested.

What I term a "small hive," as I use them, is one 12x13 inches, inside measure, and 10 inches from the bottom-board to the honey-board, and containing 752 square inches of comb, or 1,504 square inches of comb-surface. Allowing 28 bees to hatch from each square inch of comb surface, we have 42,112 bees hatching in every 21 days, or about 2,000 per day. This applies to the height of the breeding season, when there should be little or no honey in the brood-nest. During March and April I find that colonies build up more rapidly in the smaller hive, owing to the fact of greater warmth, or the better economizing of the heat of the cluster.

To get the brood-chamber crowded with bees, at the beginning of the honey harvest, and then apply the section-cases as fast as needed, raising the cases when about two-thirds full, and placing an empty case between the first case and the brood-nest, gives room sufficient. I find in every case that the bees in the smaller hives commence work in the sections several days sooner than in the larger hives. In poor seasons, like the summer of 1887, we are able to secure some surplus from colonies in small hives, while the large ones yield none.

Another reason why I prefer the smaller hives is, that on the approach of winter we have (to my mind) a proper sized colony of bees, and not a "boomer," with say one-half bushel of bees (and an exhausted queen) to consume the labors of the previous season, and be not one whit better on May 1,

than the medium sized colony of the previous autumn.

It must be remembered that 1,000 or 10,000 bees cannot be reared without that per cent. of exhaustion to the queen, and also of the stores of the hive, and it should also be remembered that at present prices, the bees themselves have no value in the fall of the year, as they will not sell for more in the spring than the cost of the hive, value of the combs, and stores consumed, allowing such stores to have been placed in a marketable shape the previous summer. I speak only of the production of comb honey (extracted has no market in this locality).

Another reason for my preference is, the ease with which the hives are placed in winter quarters, and removed again to the summer stands.

Youngsville, Pa.

WATER FOR BEES.

Is it Necessary in Winter? When to Put them in the Cellar.

Written for the American Bee Journal

BY J. M. LYMAN.

At the recent convention in Indianapolis, regarding wintering bees, Mr. Bull is reported as saying that it is essential that bees be supplied with water. I do not know why. In New York State I have wintered bees on the summer stands, in Ohio only in the cellar, and I have lost bees in both ways; here, however, only from starvation, possibly by having never provided water.

I have taken bees out of their winter quarters in the spring, and upon examination I have found them without one drop of honey in all their realm. By a little feeding they made prosperous colonies. There are essentials in order to obtain the best results in everything, but conditions sometimes make it so impracticable that those sweeping assertions generally fail.

When to Put Bees into the Cellar.

In another convention was asked the question, "When is the best time to put bees into the cellar?" Would not good, common-sense be the best source of information? I recommend putting bees early into their long night of winter. The chill of early November warns them that it is time to prepare for the inclement season that is about to precipitate "upon the face of all the earth."

Generally, from 10 to 15 days thereafter, comes a warm, bright, sunny day to gladden and refresh the gloomy, old days, and out-rush the bees for a flight, a change, a rest and sight-see-

ing, and seldom reclustering in the same compact, judicious positions previously occupied. Detached, straggling clumps of bees can be found separated from the main clusters, on different positions of the combs and sides of the hive, probably expecting the following day to assume their proper place and position; but, alas, the sudden and severe change, to which this climate is subject, proves fatal, for the day of sunshine is changed to a night of frost! From the chill they seldom recover, so the loss is more than the gain from their brief flight.

My bees are never taken from the cellar until they are placed in position for their summer campaign.

I have the utmost patience for what seems the silliest question, when honestly set before us for information (the one quoted above is one of the solid ones); but I have infinite contempt for the man who parades his opinions as deductions from logic and science.

Toledo, Ohio.

FOUNDATION.

Fastening it in Sections and Frames.

Written for the American Bee Journal
BY ED. S. EDEN.

It is somewhat interesting to me to read the different replies to my letter on "Fastening Foundation into Sections," as published on page 790 of the BEE JOURNAL for 1887. Each one claims that his method or machine is just what is wanted. But I fail to see as yet (even after reading Mr. Alpaugh's letter on page 125) that the point of satisfaction is reached.

One of the faults with the majority of machines is, that they cannot be adjusted to different sized sections. Some machines (and Mr. Alpaugh's is one of them) can only fasten foundation into 4-piece sections, and that before the sections are put together. Each machine must be made for a certain size of section.

I have found that a large majority of bee-keepers prefer to fasten the foundation after the sections are put together, as it is far better and handier in every respect. I believe that my plan comes nearer to the line of perfection, for I can fasten foundation of any size, from $\frac{1}{2}$ -inch to full sheets, into 1, 2 or 4 piece sections; either before or after they are put together, at the rate of 12 to 15 per minute, or from 7,000 to 8,000 per day.

My bees are wintering well; all are alive so far, and appear to be in good condition.

Eastwood, Ont., Feb. 24, 1888.

TEMPERATURE.

The Proper Temperature of a Bee-Cellar.

Written for the American Bee Journal
BY WILLIAM CROWLEY.

I have read Mr. Tyrrell's article on page 25, with very much interest, as it coincides with my experience as to the proper temperature of a bee-cellar. I would like to ask, if bees will break cluster and become restless on the summer stands at a temperature of 45° Fahr., why will not the same condition exist in the cellar at the same temperature?

I have wintered bees in my cellar for three winters, and the first two winters I intended to keep the temperature at about 45°, but, like Mr. Tyrrell, I failed to control the elements, and the temperature in the coldest weather went down to 28°, and remained from 30° to 35° the greater part of the winter; at that temperature my bees remained quiet, but when the temperature reached 40° and upwards, then they became restless, and a great many left their hives and perished on the ground.

Last summer I had a powerful colony of a choice strain of bees (a prime swarm) that stored 140 pounds of comb honey, being about double the average of my apiary. When I took off the supers and prepared this colony for winter, the brood-chamber was so full that all the bees could hardly get in. After putting them in the cellar, this colony was very restless, while all the others were quiet, until the temperature went down below 40°, then it gradually became quiet.

When I examined them a month after putting them in, I found that the death-rate in the strong colony was equal to a dozen of any of the other colonies. I offer this observation to strengthen Mr. Tyrrell's theory, that we should make the colonies as nearly equal in strength as possible, before putting them into winter quarters. When the colony became reduced in numbers, they could endure the same temperature as the others.

I must go a little further than Mr. Tyrrell; for I want my bee-cellar to range from 30° to 35°, or as near the freezing point (32°) as possible, to insure the best results. How many, from careful observation, dare leave the beaten track and "beard the lion in his den," on this question?

It seems to me that the climate in our different latitudes may have something to do with this question. Here in Minnesota the air is very dry in winter; it seldom thaws after winter begins, until it breaks up in the

spring. It is cold here at times; on the mornings of Jan. 15 and 20, the thermometer registered 40° below zero. We call it mild weather here when it is at zero, and 20° to 25° below zero is not bad.

Redwood Falls, Minn.

BEE-KEEPING.

The Italians vs. Common Bees—Honey-Plants, etc.

Written for the American Bee Journal
BY ROLAND SHERBURNE.

The past season may prove a blessing in disguise to some of us. The winter has been cold and steady, and no doubt nearly all the bees in this part of Iowa, that have been left un-eared for, will perish. As far as I can learn they are nearly all dead already in this neighborhood.

My largest apiary being in a good locality near timber, the bees gathered sufficient stores for the winter, after equalizing them. But the apiary near town, on the prairie, did not average 10 pounds per colony in the fall.

The past season fully demonstrated the great superiority of Italians over the common bees. What few nearly black colonies I had, did not gather more than enough to eat; and my best Italian-hybrids, that I had always considered equal to any as honey gatherers, did not do nearly as well as the pure Italians; while about a dozen hives that I had marked in the spring as extra colonies, fully proved themselves such. For one to have such hives with 50 or 75 pounds of honey in them, while rows of other hives equally strong in bees have but little honey, speaks volumes towards the profitability of bee-keeping.

I am wintering my bees in the cellar, and to all appearances they are in excellent condition. I expect to lose a few colonies for want of stores, if the cold weather continues long.

White clover, heart's-ease, and many other honey-producing plants are abundant in this part of Iowa, and as a consequence, a great many keep bees, and supply the local market with honey. It is brought to market in many ways, and, of course, sold cheap. If an excellent article is produced, it must find another market, for people rate the price by the cheapest sold.

I hope no one would for a moment be so selfish as to wish a loss, even in part, to an honest industry, that adds to our agricultural wealth, to the enhancement of a few; but the past season may prove to us the necessity of taking care of our bees, and of having a fair knowledge of them.

Lone Tree, Iowa, Feb. 25, 1888.

COLORADO.

Report of the State Convention Held at Denver.

The Colorado State Bee-Keepers' Association held an adjourned meeting on Feb. 23, 1888. There was an unusually large number present, and great interest was manifested. Colorado is rapidly coming to the front as a honey-producing State, and our beekeepers are alive to the needs of the hour.

The proceedings consisted in thorough discussion of topics pertaining to successful bee-culture.

The following is from the Colorado Farmer :

In discussing "The causes of candied honey," Mrs. Levi Booth considered it was owing to the kind of honey and the season ; when there was a good deal of dew and rain, honey does not candy. She had kept it in a dark room, and had 500 pounds candy solid in the comb. This year she had kept it in a light room, and it was in good condition, notwithstanding the fact that it had frozen.

Messrs. Davis, Rhodes and others thought that the candying of two or three years ago was caused by the dry season. The bees secured the honey from the yellow rosin-weed.

President Milleson had wintered bees on candied honey, not a spoonful of liquid honey being found in the hive ; but he kept a saturated sponge in the top. Bees must have the water. Before he used the sponge the bees tore the comb and scattered it to get out the moist parts of it.

V. De Vinney wanted to know if alfalfa honey would not candy faster than clover.

Mrs. Booth had no candied honey last year, yet her bees had nothing but alfalfa and bee-weed.

Louis Brock, of Littleton, had had the same experience.

"How often should the queens be changed?"

Robert James thought that if they would change every two years they would have stronger colonies. When asked by the President to give his experience with Cyprians, he said he would not keep them for they were too cross. He had counted 165 queen-cells in a single hive, fifty of them being capped over. They were so cross you could hardly smoke them down, yet they would fill a 20-pound box with surplus in a short time after swarming.

"Can you restore a colony of fertile workers? In what way?"

D. C. Thompson, of Brighton, examined his hives last year, and occasionally he would find no queen, but

fertile workers. He introduced queen-cells, queens in cages, etc., but to no avail.

"How long does it take to hatch bee-eggs?"

The President said: "By the best authorities, 16 days for queen-bees, 21 for workers, and 24 for drones to mature."

"Which is preferable, natural swarming or dividing?"

Mr. Rhodes considered there was not much difference. He divided as it was most convenient, where they kept an imported queen to get queens from. Natural swarms come when we do not want them.

The discussion showed that natural swarming would cause the most honey; dividing, the most bees.

"Is it advisable to keep bees unless familiar with theories of standard authors?"

Mr. Porter in answer would say, no. Out his way many had rushed into the business, and yet had to buy their honey. They should read and get one colony to practice upon. The first year he kept bees he thought he knew it all, but now he felt he knew nothing, although he studied much. The AMERICAN BEE JOURNAL was recommended.

Mrs. Booth, on the best method to prevent robbing, said: "Make the entrance to the hive about $\frac{1}{4}$ inch only, and this will enable the colony to keep out the robber bees."

Mr. Goodrich, of Illinois, said that they were satisfied with 15 days. They must be in readiness for their swarms. If they get ten days' good flow of honey they were pretty sure of 125 pounds of surplus honey. After 60 days from the time of the first flight, they can fill the hive. If you want bees, you must let them swarm naturally, but dividing the colonies might be successful. If the colony was weak, cut off the queen's head. Do not divide so as to depopulate the hive.

"How does California compare with Colorado in bee-culture?"

Robert James said that the white sage which grew in the canyons' was the chief honey supply. When there are a plenty of blossoms the honey crop is good. Since we have introduced alfalfa there is rarely a failure, but drouth often causes it there.

Mrs. Rhodes said that with alfalfa there was little honey four years ago. We were liable once in a while to failure.

Mr. Clark said all preferred Colorado honey. He could get 2 or 3 cents per pound more for it than for California, yet we must expect some failures, as all States had them.

"How can we best winter bees?"

Mr. Porter said that we need to pay little attention to that. We were so

busy that we left them out-doors, and they were all right. If he had a large cellar, and conveniences for getting them in, he would prefer the cellar. But if a little straw or earth be thrown on the north side, they can be kept out all winter.

The convention elected as delegates to the next North American Bee-Keepers' Convention, Mr. W. L. Porter, of Greeley, Mrs. Levi Booth, of Denver, and Mrs. R. H. Rhodes, of Arvada.

A motion passed unanimously, giving the preference to Columbus, Ohio, as the place of meeting of the next North American Bee-Keepers' Convention.

After discussing the time for holding the annual meeting, and the subject of rye meal for spring feeding, where there was a great diversity of opinion as to its value, the association adjourned to meet Aug. 14, at 10 a.m., in the Horticultural Association rooms.

J. M. CLARK, Sec.

QUEEN-CAGE.

A Cage for Introducing Queens, and How to Use It.

Written for the American Bee Journal
BY VET. TUCKER.

Quite a number of queen introducing-cages have been spoken of in the BEE JOURNAL, but the following suggested by a friend, I think is superior to any other that I have examined:

It is similar to the Peet cage, except that it is covered on both top and bottom with wire-cloth, and has a bee-space opening on one side, and a queen-excluding opening on the other. It is provided with food as usual, and the queen and her attendants are run in at the bee-space opening, when all is closed. The cage is then placed on top of the frames of a queenless colony, and a cover placed over, in which an opening has been made the size of the cage into which it is adjusted. Place a small cover over the cage. The queen is now similarly situated as in the Peet cage.

After the usual time given for the bees to become acquainted with the queen, remove the plug from the queen-excluding opening into the cage, and raise the cover even with the top of the cage, and fasten it by means of small pins inserted for the purpose. The workers now have free access to the queen, but the queen cannot leave the cage.

After leaving things in this condition for a short time, return and see if all is well, by lifting the small cover from the cage.

The object of the wire-cloth on top is, that these examinations, etc., can

be made without coming in contact with the bees.

If all is well, the bees will soon commence carrying the food from the cage to the frames below, and thus become acquainted with the queen. If, on examination, the bees are found belligerent, drop the cover to the bottom of the cage, and with a few puffs of smoke, remove all the bees but the attendants, and close the cage. After the usual time, the same can be repeated, and so continue until the bees are friendly to the queen.

When this has been accomplished, open the bee-space on the other side of the cage, and the queen can leave at her pleasure, and commence her labors without danger of attack. Thus the colony is not disturbed at liberating the queen—a factor of no small value, as disturbance sometimes causes the bees to attack their queen after she has been with them for months.

It is difficult to catch and cage a queen, if she is not accepted when liberated. With this cage the queen is always in hand. I have liberated queens which were immediately attacked and put to flight before going among the bees. This could never occur with the above-described cage. I think that it is nearly, if not quite, infallible.

Shelby, Ohio.

MOLDS.

How to Make and Use Foundation Molds.

Written for the American Bee Journal
BY JOHN FARIS.

Foundation molds are made as follows: Make two frames the size of the mold wanted, something like a slate-frame; hinge the two frames together, fit a board in one frame, lay a sheet of foundation on the board, and close the frames. Have the plaster of Paris already mixed, fill the top frame, working it well into every cell, and when the plaster sets, turn over the frames, and take out the board and fill the other frame in the same manner. Let them alone about ten minutes, and then pry open and take off the sheet of foundation, when the molds are ready for use.

Make a tin box for Langstroth molds, 44 inches long, 14 inches wide, and 6 inches deep, with a wooden rim around the top 3 inches wide. Now make another tin box an inch larger, and tack it to the rim; fill the empty space with water, and put it on a stove. Put the beeswax into the box, and heat the whole apparatus until the wax is thoroughly melted; then let the wax cool down, put in two cross-sticks

2 inches from the top of the box at one end of the box.

Before operating is begun, put the molds in luke-warm water, and let them get thoroughly wet; then put the molds on the cross-sticks in the box, and with a dipper or tin cup, pour the wax on one plaster. Close the molds immediately, and gently press them with both hands four or five seconds, and then plunge them into cold water a few seconds. Take them out, and pry them open, and peel off a perfect sheet of foundation, ready for the bees. Or, if you have 10 or 15 pounds of wax, you can dip one plate in the wax, put the plates on the cross-sticks, and close them as in the previous operation. This way makes foundation which will not sag or break down like the rolled.

Town House, Va.

CANADA.

Report of the Welland County Convention.

The Welland County Bee-Keepers' Association was organized at the Town Hall in Ridgeway, Ont., on Monday, Feb. 20, 1888. Owing to the heavy rains during the day, and the condition of the roads, many persons who had signified their intention of being present, were prevented. Eleven persons were enrolled as members. A courteous letter from Prof. Snider, regretting his inability to be present, and promising to be at the next meeting, was read. The following were elected as officers: H. J. Herber, President; C. H. Mathews, Vice-President; and J. F. Dunn, Secretary-Treasurer.

The different methods of wintering bees was pretty thoroughly discussed.

Mr. Herber winters his bees in a clamp, packed with sawdust in a barn, with the hive-entrances so arranged that the bees can fly on warm days.

Mr. Mathews winters his bees in a clamp, out-doors, the hives being packed in sawdust and forest leaves, with a cushion over the brood-nest, and the honey-boards off. His bees are in good condition.

H. Johnston winters his bees in double-walled sawdust hives, with a sawdust cushion 3 inches thick over the bees, and the super filled with coin-cobs. His bees winter well also.

A number asked, "Do bees seek a home before swarming?" The opinions seemed to be pretty evenly divided on this question.

One member said that a Mr. Troup, of Welland county, had observed a few bees cleaning out a cavity in a decayed tree, and the next day a colony from a neighboring yard occupied the cavity.

The Secretary thought that was no proof, and that bees do seek a home before swarming. A small swarm may have occupied the cavity first, and the one issuing the next day united with them.

Then followed a talk on living swarms and contracting the brood-nest. Mr. Herber favored contraction, but thought that the bees would be found in better condition for winter if contraction were not practiced. The bees would have to be fed, etc., and the novice had better let contraction alone.

Discussions on minor topics occupied the balance of the time, after which the convention adjourned to meet again in Welland, Ont., on Monday, May 7, 1888. J. F. DUNN, Sec.

Honey and Beeswax Market.

DENVER.

HONEY.—Best white 1-lb. sections, 17@19c.; 2-lb. sections, 15@17c. Extracted, 7@10c.
BEESWAX.—20@23c.
Mar. 1. J. M. CLARK & CO., 1409 Fifteenth St.

KANSAS CITY.

HONEY.—We quote: Choice white 2-lb. sections, 17@18c.; dark 2-lbs., 14@15c.; choice white 1-lbs., 18 to 20 cts., dark 1-lbs., 15@16c. White extracted, 7@8c.; dark, 5@6c. Demand is slow. White extracted is firm when in 60-lb. tin cans.
BEESWAX.—21 to 22c.
Feb. 29. HAMBLIN & BEARSS, 514 Walnut St.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 15@18c.; the same in 2-lbs., 13@15c.; buckwheat 1-lbs., 11@12c.; 2-lbs., 10@11c. Off grades 1@2c. per lb. less. White extracted, 8@9c.; dark, 5½@6c. Market dull.
BEESWAX.—22@23c.
MCCAUL & HILDRETH BROS.,
Feb. 21. 28 & 30 W. Broadway, near Duane St

CINCINNATI.

HONEY.—We quote extracted at 4@9c. per lb. Choice comb, 16@20c., in the jobbing way. Demand fair and supply good.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Feb. 20. C. F. MUTH & SON, Freeman & Central Av.

BOSTON.

HONEY.—We quote: 1-lb. sections, 16@17c.; 2-lb. sections, 14@15c. Extracted, 8@9c. The market is not very brisk and prices are slow.
BEESWAX.—25 cts. per lb.
Feb. 24. BLAKE & RIPLEY, 57 Chatham Street.

SAN FRANCISCO.

HONEY.—We quote: White to extra, 15@18c.; amber, 13@16c. Extracted, white liquid, 7@7½c.; amber and candied, 5½@6½c. Market quiet.
BEESWAX.—20@24c.
Feb. 18. SCHACHT & LEMCKE, 122-124 Davis St.

DETROIT.

HONEY.—Best white in 1-pound sections, 17@19c. Extracted, 9@10c. for light colored. Market weaker and supply only fair.
BEESWAX.—22@23c.
Feb. 17. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—Prices range from 16@18c. for best one-lb. sections; 2-lbs. or about, 14@15c. Dark is slow of sale, with no steady price. Extracted moving slowly. Offerings of all kinds are large. Demand better.
BEESWAX.—22@23c. R. A. BURNETT,
Feb. 16. 161 South Water St.

KANSAS CITY.

HONEY.—We quote: White 1-lbs., glassed, 16@17c.; unglassed, 17@18c.; and dark 1-lbs., glassed, 15c.; unglassed, 16c.; white 2-lbs., glassed, 15c.; unglassed 2-lbs., 17c. California white 2-lbs., 17c. California extracted in 60-lb. cans, 8c. Market quiet and receipts are larger.
BEESWAX.—No. 1, 20c., No. 2, 18c.
Feb. 9. CLEMONS, CLOON & CO., cor 4th & Walnut.

MILWAUKEE.

HONEY.—Choice white one-lb. sections, 18@19c.; 2-lbs., 15@16c., 3-lbs., 14@15c. Dark and broken not quotable. Extracted, white in kegs and tin, 9@9½c.; ½-barrels and barrels, 8½@9c.; dark and mixed in same, 6@7c. Market slow; better demand expected.
BEESWAX.—22@25c.
Feb. 2. A. V. BISHOP, 142 W. Water St.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write *American Bee Journal* on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Money Orders for \$5.00 and under, cost 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Sweet, or Melilot, Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

It is Extravagant Economy not to have hives, sections, comb foundation, etc., on hand when needed. To prevent disappointment, order early what you will need in that line. Then the hives can be nailed and painted in odd times, and the sections put together, so as to be ready at a minute's notice. It is a sad disappointment to need these things and then not have them on hand. They should be ordered very soon. We are promised an early spring, and a good honey crop.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Look Over last year's numbers of the BEE JOURNAL, and if any are missing, send for them at once, as we have but few left now, and they are daily becoming less.

A Pocket Dictionary will be presented for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

We Club the AMERICAN BEE JOURNAL and the "Bee-Keepers Magazine" for one year for \$1.40; or with "Gleanings in Bee-Culture" for \$1.75; or with the "Apiculturist" for \$1.80; or the "Canadian Honey-Producer" for \$1.30; with the Bee-Keepers' Review, \$1.40; or all six for \$4.00.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2.00	3.00	3.50
1,000 Labels.....	3.00	4.00	5.00

☞ Samples mailed free, upon application.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

A Modern Bee-Farm, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simms. For sale at this office. Price, \$1.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Advertisements.

Full Colonies of Bees for Sale

CHEAP, during the season of 1888,
C. M. HOLLINGSWORTH, Rockford, Ills.
11-15-19

1888. QUEENS. 1888.

I HAVE 50 Select Tested QUEENS of last year's rearing, that I will sell in April at \$3.00 each; in May, \$2.50; in June, \$2.00; and from July 1 to Nov. 1, \$1.50.

QUEENS, warranted purely mated, \$1.00; 6 for \$5.00. They are bred from the best of mothers and are superior to the common run of Queens sold at a lower price without any guaranty as to purity. I do not pretend to rear Queens under the Swarming Impulse. I believe with those who answer Queries in this JOURNAL—that it is a humbug. When it is necessary to stimulate to get good Cells, I do so, and that is all there is in it.

☞ Have your orders booked ahead, and send for the Queens when you want them. I will commence shipping Warranted Queens as early in May as possible. I guarantee safe arrival. Address, J. T. WILSON,
NICHOLASVILLE, Jessamine Co., KY.

The BUYERS' GUIDE is issued March and Sept., each year. It is an encyclopedia of useful information for all who purchase the luxuries or the necessities of life. We

can clothe you and furnish you with all the necessary and unnecessary appliances to ride, walk, dance, sleep, eat, fish, hunt, work, go to church, or stay at home, and in various sizes, styles and quantities. Just figure out what is required to do all these things COMFORTABLY, and you can make a fair estimate of the value of the BUYERS' GUIDE, which will be sent upon receipt of 10 cents to pay postage.
MONTGOMERY WARD & CO.
111-114 Michigan Avenue, Chicago, Ill.

THE BEE-KEEPERS'

REVIEW,

FOR FEBRUARY, is now out. (It has been delayed by the serious illness of its editor.) The special topic of this issue is "TEMPERATURE" as applied to bee-repositories. So much information on this topic has probably never before been gathered into so small a space. The treatment is exhaustive, and it would seem that nothing more need be said on the subject.

Among the contributors to this Number are such men as R. L. Taylor, James Heddon, H. R. Boardman, F. Boombower, T. F. Bingham, J. A. Buchanan and C. C. Miller.

Several pages are devoted to editorials upon a variety of live topics. There are also choice extracts from the writings of Prof. Cook, C. W. Dayton, C. C. Miller, and others.

A list of contents will not be published, as a copy will cheerfully be sent to all who ask for it. Price of the REVIEW, 50 cts. a year.

The Production of Comb Honey,

A neat little Book of 45 pages, price 25 cents. The REVIEW and this book for 65 cents. Stamps taken, either U. S. or Canadian.

Address, W. Z. HUTCHINSON,
111Atf FLINT, MICHIGAN.

WANTED,

Beeswax.—We will pay 20 cents per pound, delivered here, for Yellow Beeswax. To avoid mistakes, the name of the shipper should always be on each package.

THOS. G. NEWMAN & SON,
923 & 925 West Madison St., - CHICAGO, ILLS.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. March 21, 1888. No. 12.

EDITORIAL BUZZINGS.

We do Not hesitate to st8,
That 1888
Will doubtless be quite choice and gr8,
For bees to hurry up their g8;
And when they'e found some honey-fr8,
I'm sure we don't exagger8,
When boldly we assever8,
That not a worker will be 18
In sipping up the tempting b8.

The Greatest Blizzard of modern times raged last week all over the Eastern States, suspending business for four days, and working untold miseries to man and beast. Mails have been delayed by the abandonment of trains, and telegraph and telephone communications nearly all suspended. The blockade was raised last Friday, and the large cities were then restored to the world of commerce.

The Constitution and By-Laws of the Ontario Bee-Keepers' Association is on our desk. It contains 12 pages, if we may count the last page which is occupied with an advertisement of the *Canadian Bee Journal*, where it was printed. It displays *poor taste* to have the latter there, but as it is indifferently printed, perhaps the blunder of putting it there will be overlooked, as well as the advertisement itself.

Bees have Wintered Well.—That is the general verdict. The following are samples of the reports of all, and voice the universal hope for a good season.

P. C. Dowler, New Paris, O., on March 10, 1888, writes: "My bees have wintered finely on the summer stands. The prospects for the future are flattering."

R. F. Holtermann, of Brantford, Ont., March 10, 1888, wrote: "Our bees had a splendid flight yesterday, and reports so far go to show that bees are in very good condition generally. We can all stand a pretty good season, and we all hope for the best."

The *British Bee Journal* has copied our article relative to its editorial averring that an English clergyman has been to the United States, and had personally visited some "adulterating bee-farms" said to exist here. We branded the article of our cotemporary thus:

It is a base slander—a *nefarious lie*; neither the clergyman in question, nor "any other man" ever visited any such "adulterating bee-farms!" They do not exist!

It is nothing more nor less than a *scandalous falsehood*—the production of a sensational reporter's brain, written for *spice*, but lacking even the flimsiest "thread" of truth!

Its only possible excuse is the infamous "scientific pleasantry" written "for the fun of the thing," by Prof. Wiley—who is so unprincipled as to let it "fly" on electric wires to "the uttermost parts of the Earth," without a word of regret, or denial!

The *British Bee Journal* states that it has instituted "an inquiry into the truth of the information supplied" by the clergyman. That is just what it should do, and our confidence in the integrity of Mr. Cowan is such that we have no doubt of its being done. He was in Switzerland when the article was published, and we expect he was as much surprised and disgusted at its contents as we were.

Our friend, the Rev. L. L. Langstroth, wrote us on the 10th inst. the following scriptural quotation which is very applicable to the situation:

I see that your severe but just condemnation of the Wiley "pleasantry" very properly finds place in the *British Bee Journal*. Proverbs xxvi. 18, 19 reads thus: "As a madman who casteth firebrands, arrows, and death, so is the man that deceiveth his neighbor, and saith, Am I not in sport?" Does not that just describe the Wiley pleasantry?

Statistics.—We have received a large number of replies from bee-men consenting to become correspondents to supply statistics to the Agricultural Department on bees and honey. One remarks thus:

If there are two or more from one county, would it not be necessary for each to know who the others are, so that they may make arrangements to divide the territory, and make no duplicate reports?

We expect when the number is full, that it will be thought necessary to print the names and addresses, and arrange the territory assigned to each person. But we are not yet informed about the details.

Mr. Aaron Singer, of Wabash, Ind., has sent us one of the Statistical Blanks which have been used in that State since 1881. It is a very indefinite and antiquated affair. It has only these three inquiries:

Number of stands of bees.
Number of stands of bees killed by moth or other causes past twelve months.
Number of pounds of honey taken past twelve months.

The blank is headed: FOR STATISTICAL PURPOSES ONLY, and properly-put questions answered correctly would be all that could be desired. It is evident that the blank was made out by some one who knew nothing of bee-keeping.

Mrs. Ellen S. Tupper, who was well-known in apicultural circles some 20 years ago, is said to have died at El Paso, Texas, on March 12, 1888, where she was temporarily visiting her daughter. Since her arrest and trial for "forgery" in 1875-76, she resided in Dakota, where, we understand, her husband died.

Something like a dozen years ago, she obtained between \$30,000 and \$40,000 from banks in the West, upon "forged notes," endorsed in some instances by her friends, leaving the latter to settle with the banks after the notes had gone to "protest," and the purported signers had been proved to be mythical—among these, the editor of this paper may be enumerated for \$2,000, besides several hundreds of dollars for "expenses" and "other crookedness" on her part.

On her trial she pleaded "insanity," and to prove this, her lawyers exhibited several "bank notes" made payable to her, bearing the signature (or rather *mark*) of "Jesus Christ." On this plea she was acquitted, for the testimony against her was overwhelming! She was a "strong-minded woman"—but many have cause to regret that they ever saw her!! "Oh! Frailty! thy name is woman." But "peace to her dust!" Let it rest in peace.

Apiarist.—A correspondent asks the following questions:

Will you be kind enough to explain why "apiarian" cannot be used as a noun as well as "apiarist?" The suffixes "an" and "ist" both mean the same thing, and I confess I can see no reason why we should not say "apiarian." If not, why not?

Why is "queen-rearing" to be preferred to "queen-raising?" Please give us some more "light" on these words.

We reply, the standard authorities such as Webster, Worcester, Kirby and Zell, all agree that apiarist is the noun, and apiarian the adjective. The choice of the suffixes having already been made, it is unnecessary for us to explain *why*—we simply use the words as they are defined by lexicographers.

Queen-rearing is a more elegant expression than queen-raising—we therefore prefer to use it.

A White Clover Blossom is received from Mr. J. W. Winder, of Louisiana. While the Eastern States were taken possession of by a blizzard, and all the Northern States are experiencing "the chilling blasts" of winter, it is refreshing to know that somewhere the flowers are blooming, the birds are warbling their sweetest notes, and all Nature is smiling under sunny skies. Welcome, little blossom, as the harbinger of coming spring!

Mr. C. C. Dailey, of Chicago, has placed one of his tin feeders in our Museum. It has a projecting trough which may be put into the entrance of the hive, and under the frames which connects with the outside reservoir. We brought a similar one from Europe in 1879. This has more surface on which the bees can get the food.

GLEAMS OF NEWS.

The Weather in England.—The British *Bee Journal* for March 1, 1888, contains the following item on the comparative weather in Great Britain and North America:

While in the great northwest of North America we are told that those awful visitations called "blizzards" (*i. e.*, tornados of icy particles) have swept over large districts, destroying man and beast, that the whole country was freezing with the thermometer ranging from 50° to 60° below zero for several weeks, and then suddenly rose to 50° and 60° above zero, "causing the bees to sport in the balmy air," here, in old England, a week of unusually mild weather over the whole country was followed by a change to the opposite extreme, and for the last fortnight the earth has been frost-bound and covered in all parts by deep snow, the storms having begun in the north of Scotland, and spread southward, until the whole face of the land is covered with an icy garment of snow. From Scotland, Ireland, Wales, Somerset, Cornwall, Jersey, France, Spain, Switzerland, etc., the same accounts reach us, of snow and frost in abundance with cutting, searching north and east winds, such as the oldest inhabitants never remember to have occurred at this season of the year, when we were all looking for balmy airs and gentle zephyrs to usher in the spring. In our southern counties the hazel catkins were beginning to appear, the dead nettle and speedwells were in bloom, and on sheltered banks beneath the hedges the spring flowers were bursting into bloom, when horrid Winter, with icy hand, again seizes upon every scrap of vegetation and nips it in the bud. And still, as we write, snow on the hills, snow in the valleys, snow everywhere, and snow still falling! But we shall be told that vegetation was getting forward, that a check was required, that better now than later (yes, if we do not get it later as well) that—

"February should fill the dyke,
And if with the white
It's the better to like."

Well, let those like it who can, but we do not think our bees will be among the number. By the cutting, withering blasts, and driving, piercing snow, their numbers will certainly be thinned, and many a colony will fail to greet the sunshine—when it comes—with murmuring joyful hum and gaily quivering wing. For ourselves we shall in the future certainly pray, in dear old Virgil's words—"Di talem terris avertite pestem—O, ye gods, avert such a scourge from the earth."

Bees and Grapes.—The editor of *Popular Gardening*, when commenting upon the late meeting of the Michigan Horticultural Convention, and the discussion upon the value of bees to grape-growers, says that nearly all the testimony was in favor of the bees, and then adds:

Mr. J. A. Pearce had a new point in their favor. He said that birds punctured a large number of his early grapes, and the juice ran out, disfiguring the clusters, and he thought they would be entirely unsalable. But the bees came to his rescue and sucked up all the oozing juice, cleaning out the injured grapes, so that a slight brush would rub off the dry skins, thus the unpunctured grapes were clean, and he was able to put them on the market, securing fair remuneration for them. Many instances were given

were bees were indispensable in promoting the setting of fruits, especially in squashes, melons, etc., and the fertilizing of beans, clover and peas, which could not go on without the aid of bees.

Another Blow.—At the Maine Bee-Keepers' Convention, the President, in his annual address, gives another blow at the infamous lie of Prof. Wiley about manufactured comb-honey. He said:

We have just passed through one of the hardest seasons in our pursuit that has been known for many years. It is said there is never a cloud so dark but it has a silver lining. I think it is not hard to see at the present time that this poor season may be a blessing in disguise, and may work for the good of our business.

Our large markets had got over-stocked with honey, prices had been knocked down by shipping honey into the already over-stocked markets, until honey was selling at ruinous prices.

The Wiley lie was floating over the country, that there were numerous manufactories where bee-comb was manufactured and filled with glucose syrup, and sealed over with hot irons. The newspapers wafted this story along, and thousands believed the story, although it was so inconsistent.

This failure of honey from the flowers has cleared out the honey markets, so that commission men have called loudly for honey, at good prices. Where are these glucomanufactories all this time, that they allow the markets to become so bare of honey even at the doubled-up prices? This ought to open the eyes of the community on this subject, and strike a death-blow to that infamous lie.

Fastening Foundation in sections has been commented upon several times, and some machines described in these columns. On page 171, Mr. Eden made some statements about such machines in general, and on the one made by Mr. Alpaugh in particular. To this the latter objects; and, in justice to him, we must let him make the following correction:

As Mr. Eden in his article on page 171, refers more to me than any one else, I would like to correct some of his statements. He says, "one of the faults with the majority of machines is, that they cannot be adjusted to different sized sections, some machines (and Mr. Alpaugh's is one of them) can only fasten foundation into 4-piece sections, and that before they are put together." I would like to contradict that statement; one of my machines in use not far from where he lives (made a year ago), was made to suit sections of different sizes, and I have now arranged the machine so that it will fasten foundation in either 1 or 4 piece sections, and width from 1 to 2 inches, either before or after the section is put together, either for full sheets or starters.

In my last, I omitted to state: No matter what the temperature is, so long as it will permit the foundation to be handled.

JACOB ALPAUGH.

Our correspondents should be careful when making statements, to know that they are correct before they are allowed to appear in print.

The British Bee-Keepers' Adviser is the name of the new monthly published at two shillings per annum. Address J. Huckie, King's Langley, Herts, England.

Mr. R. A. Grimshaw, in the British *Bee Journal*, says that the "bee-disease" so-called which, sometimes affects bee-keepers (Mr. Heddon for instance) is "pollen-cold," or hay-fever. He prints, side by side, the symptoms of it given by the latter and Dr. Mackenzie in his work on "the catarrhal symptoms of hay-fever." Mr. Grimshaw then adds:

If we read what Pastor Schonfeld tells us on "What do bees use in winter when the pollen collected by them is exhausted?" we shall find plenty of evidence that there is plenty of pollen at hand in the hive in winter, in old combs, cell-walls, and margins, membranes left by the nymphs, and in the excreta of larvae at the bottom of the cells. He shows that even the stomach of the bee, let alone that of the larva, is unable to make all the pollen-grains yield up their contents, by reason of the hardness of the extirpating their digestive or assimilative juices. Now when bees go out of their hives silver and golden in hue, the body hairs covered with pollen, bent, as the insects are, in making the most of a honey glut, and leaving the pollen-cleaning until dark, the whole hive will be not unlike a flour-mill, the air charged with floating grains. If one, at this time, only take a peep under the edge of the quilt (even has a smell at the bees, as Mr. Heddon puts it) a current of hot air rushes out of the opening, carrying on it myriads of pollen-grains to the nostrils. By the showing of various bee-keepers, the disease instantly begins its course. What theory so reasonable as that he gets it from pollen grains fanned about by multitudes of agitated wings, especially when the apparent causes and symptoms are so identical with those of hay-fever known under other names, *e. g.*, pollen catarrh, summer catarrh, idiosyncratic catarrh, rose-cold, peach-cold, and pollen poisoning?

I do not doubt that the bee which flew close past Mr. Heddon's face, and gave him an attack, instead of discharging poison, wafted pollen-grains, which he inhaled. In short, with the infinitesimal percentage of people who are subject to pollen-poisoning, to keep off certain flora gives immunity, and equally keep away from the pollen collected by the bee, and there is no bee-disease. The two must be identical.

My remarks, however imperfect, would be still more so if I did not say something with regard to prevention, etc. Dr. Morel Mackenzie says, "If the poison be continually introduced into the system, the antidote, if one exists, can have but little chance of effecting a cure. Change of residence, from the country to the seaside or town, is recommended," (keep off the bees). And (strange to say, but welcome to bee-keepers), he recommends also a veil to be worn over the face. "I have found a 'double gossamer' veil, which can be had in several colors, answer the purpose in some cases. Protected in this way many people predisposed to hay-fever escape altogether." *Verb. sap.* Tobacco-smoke sometimes affords relief. One part salicylic acid to 1,000 of water, snuffed up the nostrils cuts short the disease. (Binz.)

Prevention being better than cure, let those who are susceptible wear a fine silk veil.

New Catalogues for 1888 are on our desk, from the following persons:

Edward R. Newcomb, Pleasant Valley, N. Y.—37 pages—Bee-Hives and Bee-Keepers' Supplies Generally. This is the handsomest catalogue of bee-keepers' supplies issued for the present year.

J. E. Pryor, Dexter, Iowa—8 pages—Bees, Honey and Supplies.

J. C. Sayles, Hartford, Wis.—9 pages—Apiarian Supplies.

MATTERS OF INTEREST.

The Bee-Keepers' Union.—The case of Z. A. Clark is now being attended to by two of the most noted lawyers of Arkansas: Hon. S. W. Williams, of Little Rock, and Major Witherspoon (ex-Attorney General) of Arkadelphia. Mr. Clark gives the following particulars of the present status of the case:

I was released on *habeas corpus* bond on March 2, for my appearance at 10 a.m. the next day. I had not been home with my family more than about three hours when I was arrested and taken before the Mayor and fined \$14 and costs, and remanded to jail again. Of course it would be nonsense to pay the fine, and go back and have the same thing to go over again the next day. Judge Williams advised me never to yield, as we rest on a constitutional right to defend our homes and property. I have suffered physically and mentally since this persecution began. We failed on the *habeas corpus* before the County Judge, and as my wife was worried and distressed about the matter, she had the whole apiary dumped outside the corporation line. This is a disastrous loss, as I have been hard at work about eight years to build up this apiary, and now it is taken from us without a trial by jury.

The Mayor fined me one day when no one had seen any bees about my place. He sent the Marshal to my house to ascertain if he could see any bees. One day it was cool, and no bees were flying. The Marshal did not see any bees, and swore that he did not, but the Mayor fined me "all the same."

We have appealed all the cases—eleven in number—the first day's fine was \$5, and an additional dollar for each day; the last day's fine being \$15. He even fined me after we had made affidavit asking for a change of venue, because that I "could not get a fair trial, and that he was prejudiced, etc."

I am confident that if bee-keepers could fully realize my condition, the Bee-Keepers' Union would have 10,000 members in 24 hours.

The following is a sample of many letters we have received. It is from J. T. Scofield, of Barnesville, Ohio:

I hope the Arkadelphia case will enlist the sympathy of bee-keepers who were not heretofore members of the Union. Our brother bee-keepers should be defended, and if necessary the case should be appealed to the court of last resort by the Union, and fully vindicated. I will pay assessments if needed.

Mr. James McNeill, of Hudson, N. Y., wrote thus on March 12, 1888:

I am much interested in Mr. Z. A. Clark's plucky defense of his rights in keeping bees. It is our duty to stand by him, and hold up his hands while he is suffering imprisonment, and put to great inconvenience and pecuniary loss in the defense of a principle which is dear to us all. Surely in a matter of this character the injury of one is the concern of all. I would willingly pay a dozen assessments rather than have Mr. Clark worsted in this matter.

No assessment would be necessary, if but a tenth of the bee-keepers of America should join the Union. The Manager does not favor an extra assessment, and will not consent to such, unless it becomes an absolute necessity. If its devotees will not defend the pursuit, who should do so? The

defense should have universal support. A few ought not to bear the burden for all.

Mr. A. C. Tyrrel wrote the following letter on this subject:

I enclose \$1 which please place to benefit fund to aid Mr. Clark in his suit with the city authorities of Arkadelphia, Ark., who, by an unjust ordinance, and enforcing the same, have deprived a worthy man of his liberty, and rights accorded to every citizen of the United States. Granting that Mr. Clark has been guilty of a crime in not obeying the decree of a City Council, and Mayor of that unsavory city—under the Constitution of the United States, he should enjoy the right of a speedy and public trial by an *impartial jury*, which it appears has been denied him. He should have applied for and have been released immediately on a writ of *habeas corpus*, and forthwith instituted criminal proceedings against the Mayor for depriving him of his liberty, and for refusing him a trial by a jury of his countrymen. He has a strong case if properly managed, and I believe he is entitled to damages for the unlawful act. In view of the fact that similar suits are liable to be commenced against bee-keepers without a moment's warning, let every bee-keeper in the United States who is able contribute \$1 to the Bee-Keepers' Union, to be expended in defending worthy bee-keepers who are unable to procure counsel. The amount is so small none would feel the loss, for it is not a loss when expended for a worthy purpose, and you will have the sweet satisfaction of knowing that a small portion of your money has been of lasting benefit to an unfortunate brother—a victim of prejudice and ignorant fanaticism.

Honey from Apple Blossoms.

Prof. Cook remarks in the *New York Tribune* that but few kinds of honey are superior to that from apple blossoms. The color is light amber, and though not quite equal in appearance to that from clover or basswood, it is not so dark as to be objectionable. The flavor is very characteristic, and reminds one of quince preserves. Upon sampling it no one has ever expressed anything but admiration of its quality. The fact that so early in the season as apples bloom, there are very few bees in the hives, as there are yet but few pleasant working days, accounts for the fact that we usually get very little honey from the fruit blossoms.

White Clover and Plum blossoms are received from Mr. E. Israel, of Mississippi. He says the bloom of the elms and maples have come and gone. White clover has been in bloom since the last of February, but he has not yet seen a bee on it.

Frank Leslie's Sunday Magazine

for April marks the fact of its being an Easter number by a fine hymn tune, "Christ is Risen," by C. Wenham Smith, and two Easter poems, viz: "Easter—Beside a Tomb," by Myrta Harper Lockett, and "Easter Flowers," by Maria A. Agur. "His Banner Over Me," comes to a happy conclusion, and a new story by George Macdonald, entitled, "The Elect Lady" is begun. As usual in this magazine, there are many short articles, and an abundance of illustrations, both large and small.

Gathering Statistics.—Mr. F. Wilcox, of Mauston, Wis., on March 9, 1888, sent us the following on the above subject:

In reply to your editorial on page 147, "Gathering Statistics," I will say: I have just mailed to J. R. Dodge, statistician, a list embracing one name from each county of Wisconsin where apiculture is of any comparative importance. Those persons known or recommended to me were marked to designate that fact. As to the willingness or fitness of the others, I advised him to satisfy himself by correspondence.

Your plan of asking for volunteer correspondents, is a good one, and will help you very much. In my opinion, no one should be depended upon until he first consents to serve, however well qualified he may be.

I do not understand just how the Department will use two correspondents from a county. If each reports the crop of the whole county, it will be a double report; if each attempts to report a portion of the county, I fail to see how they will know when they have it all reported and none counted twice.

If but one is employed to report the county, and he is paid something to cover the expense of correspondence, the name of every bee-keeper in his county can be obtained from the assessors or town clerks when he can furnish each bee-keeper with blanks, and ask for a report at certain specified dates. I doubt if a full and accurate report will ever be obtained without the use of money enough to pay the unavoidable expenses.

Permit me now to offer a word of friendly criticism of your plan of collecting statistics by assessors. The first impulse with some persons is to conceal some portion of their property from the assessor. The assessor also wishes to underrate the number of horses, cattle, hogs, sheep, colonies of bees, etc., that his town, city or village may have some advantage when it is equalized by the County Board. In short, the assessors would not report more than half or three-fourths the bees to the county clerk. In regard to the honey crop of the previous year, the assessor could get a fair estimate, but I can see but one way that the information can be used when we get it, that is, let one reporter from each county estimate what per cent. of last year's crop the present crop is, and then figure out the number of pounds from the assessor's returns.

Now I stop. I do not feel competent to give much advice on this subject.

The task is one of Herculean dimensions, and what the result may be it is too early now to even guess. We shall arrage the names into States, and perhaps counties, but that will represent considerable labor. The list will in all probability be printed.

A Correspondent desires us to state "which is best—to have the entrance face the end of the frames, or their sides?" To have it at the ends of the frames saves the travel of the bees, as they can enter at the end of any frame desired.

New Music.—We have received from Richard A. Saalfeld, 41 Union Square, New York, the following pieces of music: Rockaby Lullaby, by Chas. H. Williams; The Old Love Story, by Edwin Christie; White Sails in the Harbor, by J. P. Skelly; Pretty as a Butterfly, (Schottische) by Newcomb; Tripping Through the Clover, (Polka) by Ed. Holst. They retail for 40 cents each. Sent post-paid at half-price (\$1.00 for the lot), by the publisher, Richard A. Saalfeld, 41 Union Square, New York.

QUERIES AND REPLIES.

DISTURBING THE CLUSTER OF BEES.

Written for the American Bee Journal

Query 525.—In looking into a hive on a cool morning in early spring, by raising the hive from the bottom-board and peering up, or by raising the honey-board and looking down, where do the bees show the most activity, at the bottom or at the top of the cluster?—New York.

At the bottom, always.—G. M. DOOLITTLE.

At the top.—Mrs. L. HARRISON.

Other things being equal, at the bottom.—A. J. COOK.

I never take time for this particular investigation.—H. D. CUTTING.

I give it up; however, as heat rises, I would say, at the top.—J. M. HAMBAUGH.

At the bottom, usually. Why?—JAMES HEDDON.

At the top, I think. I never have tested the matter.—M. MAHIN.

I have never seen any difference.—C. H. DIBBERN.

On a really cool morning in early spring there would be no perceptible difference.—R. L. TAYLOR.

Probably at the top; but this is one of the important things which I never thought of.—EUGENE SECOR.

The bottoms to my hives are nailed on tight, except Heddon's and Armstrong's; and having used them but one season, I do not know; but in the cellar this winter the most activity is at the bottom.—A. B. MASON.

I do not know. Sudden admission of light is apt to disturb the bees at either the top or the bottom. As far as my observation goes, there is no difference.—J. M. SHUCK.

Invariably at the top—taking for granted that it is too cool for them to fly out; as the top is always the warmest.—P. L. VIALON.

If the querist has a practical object in view, in asking such a question, will he please state it? I give it up.—G. L. TINKER.

That depends. When undisturbed they would be more active at the top of the cluster. You cannot raise the honey-board nor lift from the bottom-board without some disturbance of the bees and signs of activity.—J. P. H. BROWN.

I have not often looked at the cluster from below. I should think that the "activity" would show more where the disturbance was the greatest, and you cannot look at the clus-

ter from below with as little cause of disturbance as you can look at them from above. Every thing else being equal, the cluster should show the greatest activity at the top of the cluster, as the greatest warmth of the hive is at the top of the combs, and here is where the first white tips of the lengthened cells appear in the early spring.—G. W. DEMAREE.

At a guess I should say below, if there is any difference; but I do not know. Make observations and you can determine, but I am not sure that the knowledge will be of any value.—C. C. MILLER.

I do not think that it will make any difference; that is to say, the most activity will be shown first where the bees are first opened to. But why open the hive at the bottom at all, if properly packed? or why disturb the bees at all, anyhow? I can see no good reason for so doing.—J. E. POND.

In the first place we would advise the author of the query not to open the hive on a "cool morning," unless absolutely necessary either to prove some scientific point or repair the effects of some dire calamity. In cool weather the warmest place is at the top of the frames, and there the bees will usually be clustered. The admission of light and air suddenly, will cause activity among the bees, whether it be at the top or bottom.—THE EDITOR.

DESTROYING DRONE-BROOD IN THE SPRING.

Written for the American Bee Journal

Query 526.—1. How will it do to kill all drone-brood as it may be capped over in the spring? 2. Will it prevent swarming to any extent? 3. Will it tend to make the bees cross? 4. Have you tried this method?—Ravenna.

1. I should not advise doing it. 2. It will not. 3. It will. 4. To some extent.—Mrs. L. HARRISON.

1. If you do not want drones, what do you rear them for? Kill them if you want to, and then rear more, and kill them, and so on, etc. 2. No. 3. No. 4. Yes, but I do not intend to do so any more.—A. B. MASON.

It will pay you better, and be more quickly done, to cut out the drone-comb and replace with worker-comb.—DADANT & SON.

1. It will do well. 2. To no great extent. 3. In most cases it does so. 4. I have, hundreds of times.—J. P. H. BROWN.

1 and 2. I do not think that it would pay for the trouble, or that it would prevent swarming. 3. I do not know. 4. No.—C. H. DIBBERN.

1. It is better not to have drone-brood. If killed, the queen will immediately lay eggs in the combs, and other drones will be produced. 2. No. 3. No. 4. No.—M. MAHIN.

1. It might do to cut out all drone-comb in the spring. 2. Many drones incite to swarming when there is much honey coming in. 3. Yes. 4. Yes.—G. L. TINKER.

1. Yes, it will do, but it is not profitable to rear brood to kill. Why not rear worker-brood instead of the drone-brood? 2. I think not. 3. No. 4. Yes, years ago.—R. L. TAYLOR.

1. It will do better than to let them hatch out. 2. No. 3. No. 4. I have uncapped considerable drone-brood.—C. C. MILLER.

I have to use this method nearly every spring on account of queen-rearing, to prevent having drones from hybrids or inferior queens, and I never noticed that it made any difference with the bees.—P. L. VIALON.

1. It would be better to keep the drone-comb out. 2. No. 3. No. 4. Yes, often, both by pruning out all drone-comb and cutting off the heads of the drones. The first method is the best, by far.—A. J. COOK.

1. I have not tried the plan for the purpose you speak. I do not think it will do to practice. 2. As to preventing the bees from swarming, I cannot say, but I do know that it will make them cross. Cut out the drone-comb and replace with worker-comb, before the bees occupy it.—J. M. HAMBAUGH.

1. It is far better to get rid of the drone-comb, so as to prevent the rearing and feeding of this brood. 2. No. 3. No, not unless you make them so by your careless handling. 4. I used to practice decapitating drone-brood, but I prefer not to rear such, of late years.—G. M. DOOLITTLE.

1. I would not advise it. 2. I do not believe that it would. 3. I cannot say. 4. No. It is too much trouble, even if it should be successful. It is too much like cutting queen-cells to prevent swarming—more work than the honey-producer can well afford.—EUGENE SECOR.

1. It is better to cut out the drone-comb before it contains eggs. It would be better still to use full sheets of foundation, and thus avoid drone-comb. 2. and 3. It will not prevent swarming, nor make the bees cross.—JAMES HEDDON.

1. It is not advisable to do so, unless there is likely to be a great number of them to play the part of worthless consumers. The best way is to remove the drone-comb from the brood-nest, and supply its place with worker-comb. 2. No, it has no effect

whatever, so far as I have been able to see. 3. I have noticed that bees were cross when I have decapitated their drone-brood. 4. Yes, often; but I now regulate the number of drones by regulating the combs in the brood-chamber.—G. W. DEMAREE.

1. It would depend upon circumstances. 2. I do not think that it will prevent swarming. 3. I do not remember that it made any difference with them. 4. I tried this plan years ago.—H. D. CUTTING.

1. It is first-rate if it is desired to prevent drone production for any reason. 2. I do not think that it will affect the matter of swarming at all. 4. I have often killed drone-brood in the comb, in days past; but of late years by the use of foundation. I can control the matter quite easily, and with far less trouble.—J. E. POND.

This can be done with a colony or two for experiment. The method, if it be a method, is not practical. Banish the drone-cells from the hive by the use of foundation, or patch up full frames of worker-comb; or, if you find that one of your colonies builds mostly worker-comb, use it for that purpose. Have all worker-combs by hook or crook, and do not rest until you get them.—J. M. SHUCK.

If you do not desire drones, cut out the drone-comb; if you kill the brood, the queen will lay eggs in the cells, and you will have more to "kill." That plan will not prevent swarming, and will not improve the temper of the bees.—THE EDITOR.

CONVENTION NOTICES.

☞ The Wabash County Bee-Keepers' Association will meet at North Manchester, Ind., on April 10, 1888. F. S. COMSTOCK, Sec.

☞ The Eastern Indiana Bee-Keepers' Association will hold its spring meeting on Saturday, April 21, 1888, at Richmond, Ind. M. G. REYNOLDS, Sec.

☞ The Cortland Union Bee-Keepers' Association will hold its spring meeting on May 8, 1888, at Cortland, N. Y., at 10 a.m. All bee-keepers are invited. W. H. BEACH, Sec.

☞ The Des Moines County Bee-Keepers' Association will hold its next meeting on April 24, 1888, at Burlington, Iowa. JOHN NAU, Sec.

☞ The Hardin County Bee-Keepers' Association will meet at the Court House in Eldora, Iowa, on the second Saturday in each month, at noon (12 o'clock), until further notice. J. W. BUCHANAN, Sec.

☞ The next regular meeting of the Susquehanna County Bee-Keepers' Association will be held at New Milford, Pa., on Saturday, May 5, 1888. H. M. SEELEY, Sec.

☞ The 19th semi-annual session of the Central Michigan Bee-Keepers' Association will be held in the Pioneer Room at the State Capitol, on Saturday, April 21, 1888. Prof. A. J. Cook will give an address. A cordial invitation is extended to all, as it will be a very interesting meeting. W. A. BARNES, Sec.

☞ The tenth annual meeting of the Texas State Bee-Keepers' Association will be held at the headquarters of Vice-President W. R. Graham, in Greenville, Hunt Co., Texas, on May 2 and 3, 1888. A leading feature of the convention will be criticisms upon subjects that have been mentioned in the newspapers. A good time is expected, so let all Texas and Arkansas bee-keepers attend. A cordial invitation is extended to all bee-keepers who ever dispersed. Remember, no hotel bills to pay at our conventions! B. F. CARROLL, Sec.

CORRESPONDENCE.

IN UNION IS STRENGTH.

Written for the American Bee Journal
BY D. C. BUCK.

Let us like a band of brothers,
Raise our standard high above,
And we'll fight for one another—
All for right and brother's love.

Let "advance," then, be our watchword,
And "In union there is strength;"
So let us thus be felt and heard,
All o'er our land's great breadth and length.

Then rally to our cause, friends,
Let's show what we can do,
In fighting for our rights, and then
Demonstrate that we are true.

Our Bro. Clark lies now in jail,
For keeping bees in town;
Let's help him out on bail,
Then beat the opposition down.

His loved ones now, with broken hearts,
Miss husband and father so dear,
Come, brothers, come! We'll take their parts,
And show that their cries we hear.
Dundee, Mich.

ALFALFA.

The Growing of Alfalfa in Colorado, etc.

Written for the American Bee Journal
BY WM. MUTH-RASMUSSEN.

In answer to Mary A. Goodale's article on page 792 of the BEE JOURNAL for 1887, I send the following from the Denver *Field and Farm*, in regard to alfalfa in Colorado:

How to Raise Alfalfa.

"Alfalfa is not an expensive or difficult crop to grow. The seed will cost here about 10 cents per pound, and 25 or 30 pounds is ample for an acre of land. It should be mixed and sowed with barley or rye, as usually the first year it is thin, and the barley will keep down the weeds, and at the same time make a splendid feed. Besides, it springs up quickly, and affords protection in the way of shade to the tender, young alfalfa plants. One man with a fairly good single team can plow, sow, and harrow in, about 2½ acres per day.

"There are various times for seeding alfalfa. Fall seeding is attracting some attention, although early spring planting is preferred by many. The month of February in Colorado, if the weather is open, and the ground has been prepared beforehand, is a good time to seed, for the late snows are very beneficial to the seed in the ground. It should be irrigated about three times between cuttings. One man will irrigate five acres per day if the ground is in good condition, and there is a fair head of water. It is

probably fair to estimate the expense of cutting, raking and putting in stack at \$2 per acre. Thus it will be seen that the total cost of the first crop of an acre of alfalfa, including the purchase of seed, plowing and planting, irrigating, cutting, stacking and baling, will not exceed \$8. Baling, however, is not commonly done, and that expense is usually dispensed with.

"The uses of alfalfa are fourfold. The cattle-men are the heaviest consumers of alfalfa. When it is fed, no grain is necessary to keep saddle stock in fine condition. A large amount is also fed to poor cows with calves, on a short range, which otherwise would not be able to raise their calves. And the time has come when the steers of this section, now shipped East and sold as feeders, will be fattened on alfalfa, shipped to the market and sold at 4 and 5 cents per pound instead of 2, as has been the custom for some time past.

"Another great use of alfalfa is in hog-raising, but as the great American porker has only a few friends in Colorado, the industry has not yet received much attention. It is said by those who know, that one acre of alfalfa will fatten forty head of hogs per year. We will figure the hogs at 200 pounds each, and say they are sold at Kansas City quotations at 3½ cents per pound—they are worth more money here—and it will be seen that one acre of alfalfa will grow \$280 worth of pork per year. Now figure the interest invested in the hogs, and the cost of earing for the same, and you have the net profit of your alfalfa.

"It would seem that with these facts at command, Colorado farmers ought surely to raise hogs sufficient to supply at least the Denver market, which has to depend largely upon the corn counties of Nebraska and Kansas for pork supplies."

There is no doubt that alfalfa is a valuable plant for honey, aside from its other uses. During eight years residence in this locality, where I depend altogether upon alfalfa for my honey crop, I have never found it a failure. In an ordinarily good season I can always depend upon getting two sets of (84) sections finished by each colony of bees, while some colonies will finish three sets (120 to 126 sections). The honey is very white, and of excellent body and flavor; but if wild flowers are abundant, as after a very wet winter, their honey will give the alfalfa honey an amber color.

The value of alfalfa as a honey-plant depends mainly upon how it is treated by farmers. In the southern counties, where barley is used for hay, alfalfa is used mainly as green fodder,

or sometimes as hay for milk-cows, and is cut as soon as the bloom appears—four to six times during the season. There it would consequently be of no value to the bees. Here the alfalfa is used as hay for horses, and is cut generally only twice, sometimes three times, and the first two cuttings never until it has formed seed, or is nearly out of bloom.

As it is always irrigated, and the roots strike deep down into the ground, it is independent of local rainfall. With plenty of snow on the mountains, furnishing the water for irrigation, we feel safe in predicting a good season.

The past year the first crop of alfalfa yielded well, but for some reason, probably connected with the causes of the general failure everywhere, the second crop yielded but sparingly. Still I got over 5,000 pounds of very fine comb honey in sections, which sold at a fair price; and I might have sold carloads (having had calls for such quantities) if I had had it.

P. S.—Alfalfa hay sells here for \$7 to \$8 per ton, unbaled, delivered to the buyer.

Independence, Calif.

REVERSIBLE HIVES.

Experience with the Sectional Hive—Severe Weather.

Written for the American Bee Journal

BY JOSHUA BULL.

The report of my success with one colony which I put into a Heddon sectional hive, is as follows:

Colony No. 7 swarmed on June 30, 1887, and was lived in a Heddon hive on a new stand, with full sheets of foundation in the brood-frames. After the above date, as poor as the honey season was last summer, this colony filled two sectional parts of the hive with brood and honey, and two more sectional parts solid with honey well capped over; also 56 sections $4\frac{1}{2} \times 4\frac{1}{2}$, and 7 to the foot, filled with honey and nicely capped over, besides another case of 28 sections which were about half filled when the honey harvest ended.

When I removed the supers from this colony at the close of the season, I was obliged to allow them three sectional parts of the brood-chamber for winter quarters, for the bees could not all get into two parts.

I do not give the foregoing as an average case; I had no other colony that did as well as this one—neither do I attempt to say how much or how little the hive had to do with the result. I simply state the facts in the case, and leave it for each one to draw his own conclusions.

In order to make the history of this colony a little more complete, I might say that the parent colony was wintered on the summer stand, upon deep frames of the Jones pattern; and that prior to the issuing of this swarm, they had filled and capped 54 sections $4\frac{1}{2} \times 4\frac{1}{2} \times 2$ inches, making 110 sections in all; and 4 sectional parts of a hive, besides some unfinished sections.

Cold Weather Since New Years.

Since New Year began, the winter has been very severe in this locality, frequent heavy storms alternating with extremely cold weather. On Jan. 21 my thermometer indicated 46° below zero, and on Feb. 9, 45° below; since the latter date it has not been quite so severe, although it is often below zero. Notwithstanding the intense cold, bees on the summer stands appear to be in fine condition, so far as can be ascertained without lifting the frames. Bees in my cellar are apparently as well and happy as they were last September. Although the mercury has been down to zero and below, every morning for the past five days, yet I heard a crow to-day, which is a precursor of spring.

Seymour, Wis., March 7, 1888.

KENTUCKY.

Bee-Hives and Frames as Used in Kentucky.

Written for the American Bee Journal

BY G. W. DEMAREE.

The article of J. M. Tyler, on page 821 of the BEE JOURNAL for 1887, will doubtless be a surprise to many Kentucky bee-keepers. From his remarks about the Langstroth hive, one not acquainted with the facts, would be led to believe that the Langstroth hive is a rare thing in Kentucky. I have attended nearly all the bee-conventions that have been held in Kentucky for the past ten years, and I have an extensive acquaintance with bee-men of the State, and it is *news* to me, to learn that the Langstroth hive has gone out of use in this State.

In 1884 the Kentucky State Bee-keepers' Society, through myself as its President, and Dr. N. P. Allen, of Mr. Tyler's own county, as its Secretary, sent out circulars to nearly all the bee-keepers in the State, and obtained about 100 replies. These replies among other things mentioned the kind of hives used by those making the replies.

These reports are now on file in my secretary, and they show that the Langstroth frame is well nigh exclusively used in Kentucky. More than four-fifths of all the movable-frame

hives in Kentucky are of the Langstroth style, as to size and make of frame; and four-fifths of the hives used are of the *ten*-frame size. I know but one bee-keeper in the State who uses 8-frame Langstroth hives extensively, and he lives in the northern part of the State.

I have often mentioned the fact to bee-keepers of Kentucky, that if all the States in the Union had adopted the Langstroth frame as have Kentucky bee-keepers, we would have a "standard frame" in the United States without any concert of action.

It is true that many of the advanced bee-men of the State have discarded the old portico and telescope features for a more convenient and handy outer case for the frames. But the frame itself has not been changed as to length and depth, and it is uniformity of brood-frames that makes the desirable interchangeable system of bee-hive manipulation possible.

In the olden time the bee-hive was regarded as simply a domicile—a home—for the bees, and to this day that idea clings with tenacious grip to many modern bee-men.

The big, clumsy chaff hives, legs and porticos, rabbeted or beveled tops to the sectional parts of the hive, roof-shaped hive-covers, etc., are all plain out-croppings of the old-fogy notion that the bee-hive is simply a *home* for the bees.

Were I going to build "homes" for my bees, I would build them of pressed brick, and put sky-lights in the slate roofs to warm up the "genteel" inmates of these palatial homes, in dreary winter, to enable them to take their meals more comfortably. But as my bees are my working stock, and I am the proprietor and chief manager of the enterprise, I resort to the most profitable methods of utilizing their working force, and in order to accomplish this, I put my bees on movable frames as implements in the production of honey, and these implements—movable frames—are adjusted in a handy, manageable outer-case which serves as a tenement, and store-house and work-shop for my little servants.

If anything more is necessary for the safety of my bees in the winter months, that must be a winter arrangement entirely disconnected from my hives. The honey harvest is the all-important season, and there must be no hindrance at that time.

There has been but little written on the subject of wintering bees in Kentucky, for the simple reason that plenty of stores is the main factor in bee-wintering in this State. Dr. N. P. Allen, in Mr. Tyler's own county, kept a large apiary for many years, and his plan for wintering was to confine the

bees to the brood department of the hive by means of a quilt, and in the empty super over the brood department he put about 4 to 6 inches of dry forest leaves, cut-straw or chaff. He never lost any bees if they had plenty of stores, when protected in this way.

I have wintered my bees in the same way as did Dr. Allen, for many years, except that I use from two to four extra quilts over the frames instead of the forest leaves, etc. I do this because quilts do not litter my bee-yard like leaves and chaff do, and give much less labor.

I never lose any bees if they have plenty of stores. All chaff hives and all *side* packing is not only of no service to our bees, but is a positive injury to their prosperity in the latter part of the winter and early spring, because such an arrangement deprives the bees of the reviving influence of the sun's rays at that season of the year.

It is a little strange, at least it will appear so to many practical bee-keepers in Kentucky, that metal queen-excluders, when used as horizontal division-boards, have been found to be a failure by Mr. Tyler. They are a perfect success when used by all the best-informed bee-keepers in this State, so far as I have heard from them. I use them extensively, and the perforations are never filled with propolis, if properly adjusted on the hive. Sometimes a few perforations are closed by the studs of wax built up from the tops of the frames, but this does no harm, as there is plenty of room for the bees to pass without these.

Many of the best things we have in practical bee-culture, are a failure under bad management. If Mr. Tyler will manage the metal queen-excluders in a proper way, I will warrant that he will throw aside the clumsy wood honey-boards, and never use them again. Let him put on the metal queen-excluders at the beginning of the honey harvest, and remove them as soon as the main breeding season is over (say about the middle of August), and he will have no cause to complain of propolis. But if he leaves them on until the bees begin to prepare for winter quarters, they will sometimes undertake to fill the perforations just as they will sometimes try to fill the spaces between the top-bars of the frames.

How the zinc-excluders adjusted between the brood and surplus department of the hive, where the direct heat of the sun never falls, could be the cause of the combs melting down in Mr. Tyler's hives, is another incomprehensible mystery. I presume that Mr. T. simply neglected to protect his

hives with good shade-boards during the unprecedented hot weather of last season. That was the trouble, not the metal excluders.

Mr. Tyler is cordially invited to join our State Bee-Keepers' Society, attend its annual meetings, and post up a little, or our good friend, Mr. Muth, will smile at him for hinting that he (Mr. Muth) is "behind the times" in bee-culture.

Christiansburg, Ky.

CAPPINGS, ETC.

Old Foggy Bee-Keepers, Swarming and Hybrid Bees.

Written for the American Bee Journal

BY H. J. ROGERS.

There are many bee-keepers in this neighborhood, and they are all of the "old-foggy" sort. I met one the other day, who, hearing of my success the past year, asked: "Can you raise a queen when you have no queen-egg?" This is a sample of other questions, all equally silly. Of course he would not invest \$1 in a bee-paper. He has kept bees for 50 years.

I predict a fearful mortality among bees in this section; not from lack of stores, but gross negligence in other details equally important. I can buy almost any number of colonies for \$2.50 to \$3.00, but I prefer to wait until the wintering problem is entirely solved.

I notice on page 824 of the BEE JOURNAL for 1887, that Mr. E. L. Holden speaks of having swarms issue in from 2 to 6 days after cutting out queen-cells, and putting back a swarm. I think that if he would wait two or three days before trying to find the cells, he would be more sure of getting them all; and he should remove two of the middle frames of brood and put frames of foundation in their place. This will be at once occupied by the queen, and brood-rearing will go on, while the desire to swarm is almost entirely overcome. Mr. H. should see that there is plenty of room in the supers at this time.

I shipped my honey last fall to a commission house in New York, and received 17½ cents per pound.

Is it a fact, that the honey stored by black or hybrid bees presents a much better appearance in the sections, than that stored by the Italians? My bees are hybrids, and when I can get 100 pounds to the colony in a good season, I do not believe it will pay to change. However, this may only be because I am a little old-fashioned myself.

In regard to bees roaring in winter, I would say that I never have heard

bees roar in cold weather unless something was wrong internally.

Value of a Bee-Paper.

No bee-keeper, in my opinion, can afford to be without the AMERICAN BEE JOURNAL. It has certainly been worth \$25 to me the last year! Some will smile at this, but I can furnish the figures to prove what I say. In the market reports alone, it more than pays back the "dollar," even though they may be somewhat unreliable—which I doubt.

Wintering and Transferring Bees.

Bees in this locality seem to be wintering well, although they are getting uneasy since the last "cold snap" stays so long (25 days). Yesterday it was cloudy, and the mercury was 30° in the shade, yet I noticed a few bees on the wing; of course none found their way back to the hives. I have bought 12 colonies in box-hives, which I shall transfer to Simplicity frames by the Heddon method. I want full sheets of foundation for the brood-frames; in no other way can I get perfect combs. I look for a good yield of honey this season.

Stannard's Cor., N. Y., Mar. 10, 1888.

[It is a fact that hybrid bees cap the honey in such a manner that a slight air-space is under the capping, and makes it appear a trifle whiter than other bees.—ED.]

BEE-CELLARS, ETC.

Cementing Cellars—Honey-Dew Called Manna.

Written for the American Bee Journal

BY JOHN B. LINDLE.

On page 41 I notice that Mr. C. H. Dibbern recommends cementing a cellar for bees? I have, and it is a failure with me. The bricks were laid in cement, the wall was 8 inches thick and grouted, with cement outside, arched, with 4-inch brick wall cemented outside, and the floor of brick, laid on cement. The inside walls were plastered with cement, but not back plastered. It is always wet and damp. I kept my bees in it, and lost over half of them. I now use it for storing pumpkins. It is an outside cellar.

Ten years ago I built a new cellar, with a house on top. The cellar is 32x16 feet, outside measure, has an 8-inch wall, with 4-inch studding from the ceiling some 4 feet down, is chamfered down at the lower end level with the wall, lathed and plastered all around with common caustic lime.

The windows are double and glassed. The chimney is midway along the foundation wall, with 4 bricks left out near the bottom for a ventilator. In this cellar I have wintered 270 colonies of bees, and lost but three during the winter of 1886-87. My cemented cellar is but 25 feet away. I can leave matches lay in the house-cellar for 4 or 5 days, and then light a candle with them. The walls are never damp.

Is Honey-Dew the Same as Manna?

Are those who reply to queries in the BEE JOURNAL, in accord with the following from the Agricultural Report for 1885, page 85?

"The nectar thus produced has a sweet and pleasant taste, and unquestionably forms at times no inconsiderable portion of our best honey; for bees are very eager in gathering it. The honey it yields is light-colored, has a pleasing taste, and is perfectly safe as a winter food for bees. The composition of honey-dew, as given by Bossingault and Zoller, is 48 to 55 per cent. cane-sugar, 28 to 24 per cent. of inverted sugar, and 22 to 19 per cent. dextrine. A little of the substance 'manite' has also been detected in it. This composition is exactly the same as that of the 'manna' collected by the monks at Mount Sinai."

Eureka! It is good to eat, good to feed, and has a scriptural name! Why not include all grades of extracted honey? What say you, brother bee-keepers? Call it *manna*.

Muscatine, Iowa.

THE "UNION."

The Apathy Among Bee-Men Regarding their "Union" for Defense.

Written for the American Bee Journal
BY B. F. LITTLE.

When the Bee-Keepers' Union was organized, thinking it a good thing, I became a member, and have paid perhaps for two years, but on account of the apathy of the bee-keeping fraternity, I dropped it. In California, where the most trouble was likely to arise, but a small number enlisted, so I thought the whole matter, so far as I was concerned, might go by default. But the way the matter looks now, no community has any guarantee of security.

Last year the Council of the little town of Clermont, Fayette Co., Iowa, deemed that no bees should be kept inside the corporate limits. Two bee-men had the choice of going out of the business, or move. One moved, and the other ceased keeping bees.

Last summer I was talking with Mr. ———, a short-hand court-reporter living in ——— county, Iowa, who, in reply to a question of mine, as to how he was succeeding in keeping bees, cursed the bees, and said that they were a nuisance; that he had got rid of them, and that his neighbors' bees had ruined his wife's flower garden by sucking all the sap out of the plants!

Last fall one of my neighbors claimed that my bees were taking all his grapes, saying the bees were thick on them. I have partially convinced him that it was the birds or over-ripe grapes that first did the damage. I am inside of the corporation, and no community is free from "cranks." If bee-men will let the golden opportunities slip, they will have themselves to blame.

Brush Creek, Iowa.

TEXAS.

My Experience in Keeping Bees in Texas.

Written for the American Bee Journal
BY A. C. ATEN.

The seasons of 1886 and 1887 were very poor here, most of those with box-hives and black bees securing no honey at all; but those with Italian bees and movable-frame hives generally got some surplus.

I began the season of 1887 with 85 colonies, increased them to 125, and obtained about 3,000 pounds of honey, all being extracted but 250 pounds.

My bees are in two apiaries, and have wintered well. They have been gathering pollen, and perhaps some honey, for over two weeks. There is no difficulty in wintering bees here, if we do not let them starve to death. The worst time we have in this part of Texas, is between the middle and last of March, directly after fruit-bloom. The bees use up all their honey in rearing brood, then comes a time when no honey can be found, and bees starve almost before we are aware of it. Let me say to Texans, beware of that time! You cannot be too watchful.

When they have exhausted their honey stores, they eat pollen, and it bloats them and causes the diarrhea, just as the bees have in the North, and that, too, when they can fly every day. I have seen this very often. But feed them honey or sugar syrup, and in a short time they will be all right.

The honey we got last year was of excellent quality. One of my apiaries is situated 13 miles, and the other 16 miles, north of the city of Austin; one being in a narrow strip of timber, and

the other a half mile from any timber. The land is as rich as any upland in Texas. The bees gather honey from numerous kinds of trees and plants, conspicuous among which are horse-mint, hore-bound, wild marigold, morning-glory, asters, cotton and richweed, besides many other plants of lesser note. Then we have peach, pear, wild and tame plum, haw, elm, India-gum, wild and tame China, the wild China being the best. For the last two years horse-mint has been a failure here, but I have never failed to get a surplus.

There are but few persons giving much attention to bees in this locality. One of my neighbors has nearly 40 colonies of black bees in box-hives, and did not get a pound of surplus last year. He has an excellent situation. There must be some reason for this.

Round Rock, Tex., Feb. 18, 1888.

BEEES IN A ROOF.

How to Transfer Bees from a Roof to a Frame Hive.

Written for the American Bee Journal
BY JAMES HEDDON.

I am requested to reply to the following from Mr. E. L. Plumb, Wind-sor, Conn. He asks:

Please inform me through the AMERICAN BEE JOURNAL, how and when to transfer bees from under the roof of a bay-window to the Heddon hive. The size of the roof is 6 by 8 feet. They have been there for three years, and are $\frac{1}{2}$ mile from my place. The owner of the house gives me the bees, honey and comb, if I will remove them.

If Mr. Plumb had my book, and would turn to page 32, under the head of "Modern Transferring," he would perhaps get an idea of how I would transfer the colony of bees that he describes above.

I do not know just how they are situated, but believing that they are so housed that I could drive out of their home, about two-thirds of the bees, I should get the "New Hive" all ready with frames filled with comb foundation, and then drive out the bees as above, and with their queen put them into the new hive, and carry them four miles away; then in 21 days open the old hive, or bay-window, and cut out the broodless combs, put the bees and their new queen into another fully equipped "New Hive," and carry them away as before. I would extract the honey from the old combs, and melt them up for wax.

There is no objection to transferring any of this empty comb into brood-frames, provided it is straight and all worker. I would not advise piecing when transferring combs; neither do I

practice transferring combs containing brood or honey.

After a few weeks—say from two to four—the colonies in the “New Hive” can be brought to your home, when they will stay in their permanent location. This moving 4 miles away would not be necessary if you could move that bay-window 4 rods away. The old colony need not necessarily be doubled; if increase is not wanted, simply carry the last “drive” out to the new colony, and add them to it. Smoke them well, and the bees will not quarrel, being all from one queen, and the queens can be allowed to fight it out, or you may destroy one, keeping your preference.

I would no more think of doing any old style of transferring than storing surplus comb honey in starch boxes.

Dowagiac, Mich.

HIVES—FRAMES.

Dimensions of Hives and Number of Frames.

Written for the American Bee Journal
by J. R. ROEBUCK.

This is the subject of Query 514, on page 85. It is a very important one to the bee-keepers, but more so to the bees. I think that my experience of 25 years with bees, and a number of contraptions called bee-hives (some of which cost me a good deal of money, and more vexatious and trouble than all of them are worth), enables me to answer some of “Maryland’s” query; hence I would like to add my views on this subject, with the answers given to the query.

As well might “Maryland” ask what size of harness a farmer uses on his horse. I cannot think of anything better to illustrate my idea than a comparison of a horse and its harness. That noble animal would be of little worth, so far as working it is concerned, without a harness suitable to its size and strength. So with a colony of bees, they are of little use unless they are in a hive suitable to their numbers.

It has long since been discovered that we either must have as many sizes of harness as there are horses to be worked, or that the harness must be made adjustable by means of buckles, etc.; the latter being adopted to be the most practicable. It seems to me that such ought to be the case in reference to bee-hives.

I will take the query in its order, viz: I. What number of square inches of comb surface should be in a hive? If I were to harness a horse, I would try to get the harness so buckled that

it would fit up nicely and comfortably all around the horse for which it was intended, whether he was large, small, fat or lean. In giving comb surface to a colony of bees, I would use the same judgment, and give only so much as would nicely accommodate the number of bees in the colony; I believe that any more or less is not only unnecessary, but actually injurious to the bees, the same as a harness is injurious to the horse if too large or too small.

I imagine that I here some one ask, *How much is needed?* I would measure the surface needed by the amount which the colony can comfortably fill when the temperature is so that bees fly freely, say at 60° to 70°. A short and yet a correct answer to this part of the query would be, a frame of comb to any number of inches that a colony can fill comfortably, and no more.

2. What distance should brood-frames be from centre to centre? For the brood-nest I would recommend them to be 1 7-16 inches, irrespective of the top or end bars of the frame; if for extracting, the distance, I think, should be more, say 2 inches, or even more.

3. What are the inside dimensions of the frame you use? I use a frame 8½x12 inches, which is equal to, as the bees usually fill them, about 200 inches of comb surface.

4. What numbers of frames in each hive do you use? I use from one to sixteen, according to the size of the horse—colony, I mean. In connection, let me say that my surplus cases rest on top of the frames, and are adjustable so that I can use 3 to 36 one-pound sections without tiering up; and by tiering up, as many hives more as the bees can fill.

Burton City, Ohio.

EMPTY COMBS.

Utilizing Empty Combs, Room for the Queen, etc.

Written for the American Bee Journal
by M. S. ROOP.

It is often asked, what to do with empty combs. Some say, render them into wax, hire some one to take them away, or hive young swarms on them. It seems strange that when it takes so many pounds of honey to make one pound of wax, that any one would advise destroying this valuable comb.

It would be a nice idea to hive a swarm of bees on empty frames, right in the beginning of the basswood honey flow, and keep fully one-half of them busy building comb below, until the honey-flow is over!

I know several bee-men who are too stingy to buy foundation, and while their bees are filling up the brood-chamber with worthless drone-comb (which they will do when there is a good flow of honey), my bees are storing honey in the sections; then they will say to me, “How in the world do you get so much more honey than I?”

Suppose the bees do crowd the queen; give them room above as fast as they may need it, and it will be seen that they will elevate the honey as fast as the queen needs the room below. Why will not the bees in a young colony move the honey above, just the same as the bees do in the hive they came from?

Carrying Honey above the Brood.

Some one has said that, as soon as the young queen begins to lay, the bees will move the honey above as fast as she needs the room below. This is strange. Black bees will often fill their hive with honey, and then stop work. The way to do with them is, to extract their honey late in the day, taking it out so clean that they will not have enough for “breakfast;” then it will be seen that they will go to work at once. A rule that will work to perfection in the Eastern States, will ruin bee-keepers in Iowa.

Bees are wintering very nicely in this vicinity.

Council Bluffs, Iowa.

INDIANA.

The Bee-Keepers of Tipton and Hamilton Counties Convene.

The Bee-Keepers’ Association of Hamilton and Tipton counties met at Westfield, Ind., on Feb. 4, 1888, and were called to order by the President, Dr. E. H. Collins.

The minutes of the previous meeting were read and adopted, after which the society listened to a very instructive address from the President, making suggestions for the benefit of the association; the first being that it appoint a reviewer, whose duty it shall be to correct any serious mistakes that might be made in our meeting, and read them at the close of each session;

Secondly, that the executive committee be directed to make out the programme during the first of the intervening months, and notify persons of whom work is expected at the ensuing meetings of the Association; and

Thirdly, that the executive committee appoint at least one person for each meeting to experiment on some subject to be agreed upon; so that we may have at least one idea well defined.

Orren Maker was appointed reviewer for the day.

Dr. Test then read an interesting essay on the "Agency of insects in producing color in flowers," of which the following is a brief synopsis: "Many insects, especially bees and butterflies, have an acute color-sense. The exhaustive process of flowering has a tendency to give autumnal tint to leaves near a flower cluster. Insects capable of appreciating and remembering colors, would then have a mark to guide them when hunting pollen for food. Cross-fertilization would then be aided, and more vigorous plants with more showy blossoms would be produced; the color-sense in insects would become as pleasurable as useful, and the gaudiest insects would be most attracted to their mates and leave the most numerous offspring, till in time the plants passed from the unvarying green of the coal age, to the floral magnificence of the present time."

J. D. Bray read an essay upon "Doing your work by others' methods."

Dr. Abbott read an essay written by his son, on "The artistic side of bee-keeping." He said a great many articles are judged mainly by their appearance, and honey is one of them. These are a few simple, primary rules for preparing honey for the market:

1. Extracted honey should be carefully strained through two thicknesses of some kind of thin cloth, before bottling.

2. Clear flint-glass jars should be used, for common green glass makes the clear golden yellow of the honey look a muddy, greenish yellow.

3. Plain, neat labels with the name of the producer, kind of honey, etc., should be used.

It would be well for honey producers to profit by the above suggestions.

A few of the members are raising Alsike clover, and find it good for both bees and stock.

The meeting then adjourned, subject to the call of the executive committee.

H. O. ESTES, Sec.

Photographs of Bee-Keepers.—

The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

A Modern Bee-Farm, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

CONVENTION DIRECTORY.

SELECTIONS FROM OUR LETTER BOX

Worst Part of the Winter.—G. M. Doolittle, Borodino, N. Y., on March 7, says:

According to that old "saw," regarding the bear seeing his shadow on Feb. 2, we were to have warm weather right along from that time on, but contrary to this we are having at this time, and for the past week, about the worst part of our winter, as far as cold and wind are concerned. Mercury at zero, or nearly there, is the order of the day in this locality, with no fight for our bees since last year. I almost envy those who report "bees flying," for I know that such with me, means safe wintering:

The Carniolan the Coming Bee.

—H. W. Carman, Hardinsburg, Ky., on March 6, 1888, writes:

My bees are in better condition now than ever before at this time of the year. I commenced the season of 1887 with 10 weak colonies, moving them 16 miles on a road-wagon, over a very rough road, about the middle of February, 1887. One colony was Carniolans, and the balance were Cyprians. I increased them to 21 colonies. I sold 10 colonies at \$7.50 per colony, and took 150 pounds of golden-rod honey in October. I have 11 colonies, 10 colonies Carniolans, and 1 colony of Cyprians wintered on the summer stands. I have not fed a pound of syrup or anything else. I hope to do a great deal better the coming season. I consider the Carniolan bee the "coming bee."

Use of Comb Foundation in the Sections.—Thos. O. Hines, Anamosa, Iowa, on Feb. 18, 1888, writes:

The inventor of comb foundation gave it the right name, for it is that and nothing more. Bees do not draw the wax out into cells. At the Nebraska convention some advocated putting in the hives all that could be put in, thus relieving the bees of secreting this wax. I cannot see that it saves what the bees would have to secrete to build this middle wall. I have often scraped the honey from the foundation, and have found it as perfect as when put in. I use heavy foundation the full size of the frame, and wired, for extracting, because they are stronger, and can be used oftener. In the

brood-nest I use starters 1½ inches wide, because I can get straighter combs; if used wider than 1½ inches, they get wavy.

I have a fine lot of unfinished sections, and I wish that I had as many more. I put these unfinished sections over the frames, and let the bees clean them out, when I carefully put them away, and use them next season. I can see no difference in quality from new ones.

I use starters in sections cut V-shaped, the full width. The "extra thin" foundation is the best. I cut the starters with a warm knife, and then use a plate just hot enough so as not to burn the wax. I put some pure wax on it, and when melted I take a section in my left hand, the grooved side up, and a piece of foundation in my right hand, which I wipe across and back over the plate of wax, and insert it in the groove. In this way I can put in 1,000 a day. I place my hives on the level so that the starters hang plumb, and in this way I get straight combs.

Rescue the Oppressed.—P. J. England, Fancy Prairie, Ills., on March 10, 1888, says:

I rejoice to know that I am one of the charter members of the Bee-Keepers' Union. It does seem to me that any bee-keeper with a soul as big as a "peanut shell," would come to the rescue when he knows that his brother is languishing in jail!

The Season of 1887.—W. H. Graves, Duncan, Ills., on March 8, 1888, says:

My report for 1887 is soon told. I wintered 96 colonies through the winter of 1886-87, and then doubled them down to 80 colonies. I never had bees in as fine condition as mine were on June 1. We all know what followed, and there is no use to repeat, suffice it to say that I took off less than 100 pounds of honey. I am very sorry that I put on a super. I cannot say how my bees are going to come through this winter. I have 45 colonies in the cellar, and 35 colonies on the summer stands.

Reversible Hives.—R. L. Crocker, Lockport, N. Y., on March 5, 1888, writes:

I notice that in the report of the New York State Bee-Keepers' Convention, on page 137, I am made to say that, "I am not as yet fully satisfied with the Heddon hive, and do not think it is the hive I want." Now that is not just the way I meant to be understood, but I should have said that I am not as yet fully satisfied that it is the hive I want, without further trial; for I am very much pleased with it for the first season, and have not had a chance to test it for the second season's work, only to a limited extent, and during a very poor season at that. So I am not fully satisfied that it is not the hive I want. I make this statement as only what is due Mr. Heddon and others who might wish to try the hive, and be deterred thereby after reading the report of the convention.

Hunting Bees, Ventilation, etc.—Frank Stephens, Hageman, Ind., on Mar. 10, 1888, writes:

In hunting bees in the woods for ten years, I found about 100 swarms. I found one good swarm that had 350 pounds of fine honey, in an ash tree.

During my experience in hunting bees I found several swarms in trees about 30 feet high; two trees had their tops broken off. The bees had been in trees for two years, that I know of, and the entrance was 8 inches in diameter. They wintered well,

and had lots of honey. They had upward ventilation. I have had bees in hollow logs several times, but I lost all of them.

I saw an article on page 811, referring to ventilation. I differ from that writer in regard to lower ventilation. Last spring my colonies did not have the diarrhea. I had the inside cellar door open every night into the pantry. When I would go down to the bees, they were perfectly quiet; I could not hear one bee hum. I think that upward ventilation proves to me to be the best.

Last year was a poor one in this locality. My 14 colonies were all strong in the spring, except 4 that were short of stores. I got about 300 pounds of comb honey in one-pound sections, and the increase was 11 swarms, secured by natural swarming, which gave me 25 colonies. These I put into the cellar on Oct. 5, 1887. They had a flight on Feb. 18. They are quiet in the cellar, but they had the diarrhea badly.

No Loss in Wintering.—G. W. Cole, Canton, Ills., on Feb. 29, 1888, says:

I have wintered 11 colonies of bees on the summer stands without loss. I used no protection, only covering them to the depth of 4 or 5 inches with plauer shavings on the painted muslin, which I use for summer cover on the frames. I do not think that it is necessary to remove the summer cover, and put on porous cloth for winter.

Honey-Comb or Wax Becoming Honey.—Mrs. I. J. Glass, Sharpsburg, Ills., on March 5, 1888, says:

Having several times heard it stated that *honey-comb*, when mixed with extracted honey, when grained or candied, would turn to honey (the comb or wax); and not finding it so in my own experience, I come to the BEE JOURNAL, hoping that I will state it plain enough so that I may find an answer. The question is this: Will honey-comb or wax become honey, when mixed with extracted honey, either when granulated, or before that process takes place?

[No. "Wax" and "comb" are not the same, and never become such.—Ed.]

The Canadian Convention Report.—Concerning Mr. Clarke's strictures on page 104, R. F. Holtermann, Brantford, Ont., remarks thus:

As Mr. W. F. Clarke has made some unwarranted comments on page 104, upon my report of the late meeting of the Ontario Bee-Keepers' Association, I wish to say that the spirit of his letter is manifest. Upon looking at the report which I made, the injustice of his attack is also manifest. I must admit, that when reporting conventions of bee-keepers, it would sometimes appear rather unfortunate that I stand in the relationship of "son-in-law" to one who is well and favorably known as a practical and successful bee-keeper, and one whose opinion is valued, and whose "sayings and doings" are reported amongst bee-keepers, not only in Canada, but the United States and Great Britain; and who also was President of the association, and occupied the chair. Under these circumstances, unless I follow the very rare practice of mentioning in my report that "President occupied the chair," without mentioning who he was, and unless I excluded the President's address, I am entirely innocent of reporting "the sayings and doings" of my very estimable father-in-law.

Then as to myself, I may have been a little presumptuous in giving a brief description of the bee-cellar that I was about to build, but even here I was honest enough to give Mr. Jacob Alpaugh credit for being the

father of the plan. I thought the plan so valuable that I adopted it, and will certainly be pardoned for thinking it a sufficiently valuable one to report; but I might have excluded my name, merely mentioning that "some one" said this.

Now as to the "most interesting discussions" which are omitted. In a condensed report which the AMERICAN BEE JOURNAL, with so much matter of value on hand, could only find room for, much must be excluded, and it must then be a matter of judgment as to what shall remain; and when matter of equal value has to be decided between, that which is newest to the readers of the paper you are reporting for should have the preference.

If Mr. Clarke means to say that I was absent when important matters were brought up, permit me to say that I always take full reports of meetings, and attend such sessions as I agree to; but Mr. Clarke can hardly mean this—this would be too dangerous ground for him to tread upon.

As to the position which I reported Mr. Clarke to have taken upon the honey extractor, I may here again have failed; I should either have excluded this as valueless, or perhaps Mr. Clarke will think I should have reported him at greater length; but I again state deliberately that some objected to Mr. Clarke's remarks, openly saying that we would have "strained" honey, if not extracted, and the feeling of our best bee-keepers was that the views expressed were not worth contradicting; he condemned the extractor—and no one else.

[Now that both sides have had an "airing of their views," let the matter rest. We have no room for such controversies.—Ed.]

Victory or Death.—R. B. Woodward, M. D., Somerset, O., on March 9, 1888, writes as follows:

I send you to-day my dollar for the National Bee-Keepers' Union. I did not realize the importance of the Union until I read the persecution of Z. A. Clark, of Arkadelphia, Ark., on page 148. I think that now is the time to fight for our rights against *ignorance and cussedness*, and that our contribution to the "defense fund" shall be liberal, and sufficient to employ capable attorneys. It is now *victory*, or *death* to the pursuit. I have no financial interest in the matter, as I only keep a few colonies for pleasure, and honey for family consumption.

[Yes; it is now or never. If the present suits against bee-keepers are allowed to go against them, then it is "all up." Every bee-keeper who happens to have jealous neighbors would then have to obey the order to *move on*, like the poor Indian, until he is driven out of the country.—Ed.]

Bees and Poultry.—W. C. Coffman, Pewamo, Mich., on March 5, 1888, writes:

I was somewhat surprised when reading the article by H. M. Cates, on page 123. My experience is different from his views about keeping poultry with bees. I let my Plymouth Rock and Wyandott chicks roam about the bee-yard and fields from early spring until fall, and in the past three years not more than one-half dozen chicks has been attacked by the bees, and those were some that would stand in front of the hives and peek in at the entrance, until a bee would persuade the intruder to move along, by stinging them usually about the head. The same chick does not stop to look for any bugs or worms about that hive, but moves on as fast as it can. I have never had a chick die from the effects of bee-stings, and I raise 200 each year. Those

who wish to keep poultry with bees, can do so without any trouble, as the bees will not kill the fowls, and they will receive as large profit for the money invested in poultry, as from any other rural pursuit. Bees in this locality are wintered in cellars, and are in fine condition.

Taxing Bees in Illinois, etc.—John Davis, Birds, Ills., on March 1, 1888, says:

It is rather early yet to report, but my bees have wintered splendidly this winter, with no loss so far. That is so much for chaff lives. I never have lost any bees in wintering. In this neighborhood bees have wintered well so far. Does the law require us to pay a tax on bees in this State?

[Yes; bees are taxable in the State of Illinois.—Ed.]

Honey and Beeswax Market.

CHICAGO.

HONEY.—We quote: Fancy white clover 1-lb., 16@17c.; 2-lbs., 15@16c. Dark is slow sale at almost any price. Extracted is scarce, and sells at 7@10c.

BEE SWAX.—23c.
Mar. 13. S. T. FISH & CO., 189 S. Water St.

CINCINNATI.

HONEY.—We quote extracted at 4½@9c. per lb., for which demand is good. Comb honey, 14@17c.—Supply large and demand slow.

BEE SWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Mar. 11. C. F. MUTH & SON, Freeman & Central Av.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 14@17c.; the same in 2-lbs., 12@14c.; buckwheat 1-lbs., 10@11c.; 2-lbs., 9@10c. White extracted 8@9c.; dark 5½@6c. Market dull; prices declining.

BEE SWAX.—22@23c.
Mar. 10. MCCAUL & HILDRETH BROS.,
28 & 30 W. Broadway, near Duane St.

MILWAUKEE.

HONEY.—Choice white one-lb. sections, 17@18c.; 2-lbs., 15@16c.; 3-lbs., 14c. Dark and broken not quotable. Extracted, white, in 1-lb. tins and ½-barrels, 8½ to 9c.; in tin and pails, 9½@10c.; dark, ½-barrels and kegs, 5@7c. Market slow.

BEE SWAX.—22@25c.
Mar. 10. A. V. BISHOP, 142 W. Water St.

DENVER.

HONEY.—Best white 1-lb. sections, 17@18c.; 2-lb. sections, 15@17c. Extracted, 7@10c.

BEE SWAX.—20@23c.
Mar. 1. J. M. CLARK & CO., 1409 Fifteenth St.

KANSAS CITY.

HONEY.—We quote: Choice white 2-lb. sections, 17@18c.; dark 2-lbs., 14@15c.; choice white 1-lbs., 18 to 20 cts., dark 1-lbs., 15@16c. White extracted, 7@8c.; dark, 5@6c. Demand is slow. White extracted is firm when in 60-lb. tin cans.

BEE SWAX.—21 to 22c.
Feb. 29. HAMBLIN & BEARSS, 514 Walnut St.

BOSTON.

HONEY.—We quote: 1-lb. sections, 16@17c.; 2-lb. sections, 14@16c. Extracted, 8@9c. The market is not very brisk and sales are slow.

BEE SWAX.—25 cts. per lb.
Feb. 24. BLAKE & RIPLEY, 57 Chatham Street.

SAN FRANCISCO.

HONEY.—We quote: White to extra, 15@18c.; amber, 13@16c. Extracted, white liquid, 7@7½c.; amber and candied, 5½@6½c. Market quiet.

BEE SWAX.—20@24c.
Feb. 18. SCHACHT & LEMCKE, 122-124 Davis St.

DETROIT.

HONEY.—Best white in 1-pound sections, 16@17c. Extracted, 9@10c. for light colored. Market weaker and supply only fair.

BEE SWAX.—22@25c.
Mar. 14. M. H. HUNT, Bell Branch, Mich.

CHICAGO.

HONEY.—Prices range from 16@18c. for best one-lb. sections; 2-lbs. or about 14@15c. Dark is slow of sale, with no steady price. Extracted moving slowly. Offerings of all kinds are large. Demand better.

BEE SWAX.—22@23c. R. A. BURNETT,
Feb. 16. 161 South Water St.

KANSAS CITY.

HONEY.—We quote: White 1-lbs., glassed, 16@17c.; unglazed, 17@18c.; and dark 1-lbs., glassed, 15c.; unglazed, 16c.; white 2-lbs., glassed, 16c.; unglazed 2-lbs., 17c. California white 2-lbs., 17c. California extracted in 60-lb. cans, 8c. Market quiet and receipts are larger.

BEE SWAX.—No. 1, 20c.; No. 2, 18c.
Feb. 9. CLEMONS CLOON & CO., cor 4th & Walnut.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Money Orders for \$5.00 and under, cost 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Sweet, or Melilot, Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Why Advertise in the AMERICAN BEE JOURNAL? Here are some good reasons:

1. Because it has a large and influential circulation in every State and Territory, Canada, and other foreign countries.
2. Because it is well-printed, and an advertisement in it appears neat and attractive, and invites a reading.
3. Because it reaches just the class of persons desired—professional men, lawyers, doctors, and the best of the rural population.
4. The rates are low as possible, and the returns from advertisements are satisfactory.

It is Extravagant Economy not to have hives, sections, comb foundation, etc., on hand when needed. To prevent disappointment, order early what you will need in that line. Then the hives can be nailed and painted in odd times, and the sections put together, so as to be ready at a minute's notice. It is a sad disappointment to need these things and then not have them on hand. They should be ordered very soon. We are promised an early spring, and a good honey crop.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Look Over last year's numbers of the BEE JOURNAL, and if any are missing, send for them at once, as we have but few left now, and they are daily becoming less.

A Pocket Dictionary will be presented for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

We Club the AMERICAN BEE JOURNAL and the "Bee-Keepers' Magazine" for one year for \$1.40; or with "Gleanings in Bee-Culture" for \$1.75; or with the "Apiculturist" for \$1.80; or the "Canadian Honey-Producer" for \$1.30; with the Bee-Keepers' Review, \$1.40; or all six for \$4.00.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2.00	3.00	3.50
1,000 Labels.....	3.00	4.00	5.00

☞ Samples mailed free, upon application.

Advertisements.

FOR SALE—Large Apiary with appurtenances. Reason, bad health. Address 12A1t DR. G. W. YOUNG, Lexington, Mo.

IMPORTED QUEENS.

FRIENDS: I have QUEENS in my Apiary as fine and as good as you can import to the free land of America. Yes, I mean just what I say! My Bees equal any that ever spread wing 'neath the sunny skies of Italy. You have but to try them and be convinced. From now through the season, Untested, \$1; Tested, \$2; Select Tested, \$2.50; Standard Breeders, \$3.00. BEES by the lb. \$1; Frame of Brood, 75 cts. R. H. CAMPBELL, (Lock Box 215), 12E12t MADISON, Morgan Co., GEORGIA.

ALSIKE CLOVER SEED

FOR SALE at \$6.00 per bushel. With 2 bushels of seed, sack is free; for less than 2 bushels, sack is 25 cents extra. On board the cars at Mauston. Address,

J. T. SMITH,
12A2t MAUSTON, Juneau Co., WIS.

THAT CANADIAN LOCOMOTIVE

IS Nowhere compared with **Eden's Patent Comb Foundation Fastener.** It will fasten foundation of any size or shape from ½-inch to full sheets, in 1, 2 or 4 piece Sections, either before or after they are put together, at the rate of 600 to 800 per hour. For neatness and strength it cannot be excelled. Not a particle of foundation wasted. No melted mixture used. Can be adjusted to different sized Sections, will work in any temperature, and will last a lifetime. When you order, send sample Section.

Price, Single Machine..... \$5.00
" Combined "..... 6.00

Address, **ED. S. EDEN,**
12A12t ST. CHARLES, MICH., U. S.,
and Woodstock, Ont., Can.

Electrotypes of Engravings.

WE can furnish Electrotypes of all the Engravings used in this JOURNAL or in our Catalogue, at 25 cents per square inch. If to be sent by mail, add 10 cts. for postage. No single Electrotype sold for less than 25 cts. Measure from outside points shown, on both length and width of the printed impression.

THOS. G. NEWMAN & SON,
923 & 925 W. Madison St., - CHICAGO, ILLS.

2-Story Langstroth Hive, 80c.

WE still have a few of those Two-Story Langstroth HIVES with 10 Brood-Frames, at 80 cents. Who wants them? Speak QUICK, or It will be too late. Address,

SMITH & SMITH,
10E1f KENTON, Hardin Co., OHIO.

Nothing Succeeds Like Success.

HOW I Produce Comb Honey. **TEN** years' Experience. First Thousand sold in four months. By mail, 5 cts. each; \$3.00 per 100. My illustrated Price-List of Supplies for the Apiary, Bees, Queens, etc., FREE.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. April 4, 1888. No. 14.

EDITORIAL BUZZINGS.

It Pays to wear a smiling face,
And laugh our troubles down,
For all our little trials wait
Our laughter or our frown.
Beneath the magic of a smile,
Our doubts will fade away,
As melts the frost in early spring
Beneath the sunny ray.

This is Our Special SPRING Number—the first in April—and contains six more pages of reading matter than usual; the rest of the extra pages being devoted to advertisements. The articles are very interesting and valuable, and we hope the advent of this large number of the AMERICAN BEE JOURNAL will formally usher in and give a general

Welcome to Spring.

Do Not strike at a bee, jar the hive, nor breathe on the bees.

Don't Believe It!—If you should see an advertisement agreeing for two stamps to tell you all about bee-keeping, and how to make \$25 per colony out of your bees, don't believe it.

It is Poor Economy to use old and dirty sections for comb honey. It will pay better to commit all such to the flames, and buy new and clean sections for new and delicious honey. New sections are so cheap now that there can be no excuse for using old ones.

Be Sure to order your hives, frames, sections, comb foundation in good time to have them at hand when they are required. It is poor policy to wait until such things are needed before ordering them.

False Charges.—The *Farmer and Stockman* published at Sioux City, Iowa, indulges in this little bit of ridicule:

What an array of tools the honey-bee would have to carry if the charges against it by its enemies were true. According to these enemies, the beecan "bite," "pierce," "tear," "cut," and "drill" their way into fruit and flowers, and "suck, draw, drain, eat and devour" the juices and pulp of said flowers and fruit. The next thing we may expect to happen, will be the grocers charging the bees with coming into their stores, boring holes in the syrup barrels and carrying off the contents.

This is to refute a silly item going the rounds of the press, which says:

Instinct of the honey-bee is admirably set forth in their practice of cutting into the base of flowers of which the corolla is too deep to be penetrated by the organs of feeding.

Their jaws are not formed for cutting into the base of flowers or anything else! What nonsense!

From Early Spring until the Honey-Flow, it pays well to feed every colony a little daily, even if they have an abundance of honey in the hive. It stimulates brood-rearing, and it is only by such judicious feeding that we can bring a colony up to the highest condition. It is from such that we reap the richest reward during the honey season. Such colonies are usually ready to swarm two weeks earlier than others, and powerful swarms result, instead of "hat-fulls." Whether bees are wintered in cellars or in chaff hives, they should remain in their winter quarters until settled warm weather comes in, which may be from the middle to the last of April, and sometimes even later.—*American Agriculturist for April.*

Hang the Adulterators.—The *Clearwater, Calif., Record* advises the hanging of the adulterators of the various kinds of food for humanity, and adds:

One of the city papers complains of the adulteration of foods and drinks, so extensively practiced in this country and age. This is a subject concerning which a great deal of righteous indignation has been poured out, through the press and otherwise, but as yet no practicable laws or plans have been adopted for stopping the almost universal practice of adulterating foods and drinks, by reason of which human health and life are being sacrificed at a fearful rate. The man who deliberately puts deleterious ingredients and health-destroying poisons into food which he knows will be sold to unsuspecting victims, is far worse than the average murderer.

And yet our National *Chemist*, who is paid for defending us against the nefarious schemes of adulterators, actually works in their interests, and defends them in their diabolical work.

Reports on the Heddon hive are still coming in. So far, 78 reports have been received, covering the use of over 2,000 hives. As to choice, 56 prefer the new Heddon hive, and 22 have not fully decided, or prefer some other kind.

It Still Lives.—In enumerating the many bee-papers of the present day, Mr. C. H. Dibbern, in the *Plowman*, remarks as follows:

One of the most remarkable things connected with bee-keeping is the great increase of papers and magazines devoted exclusively to the pursuit. About 25 years ago the AMERICAN BEE JOURNAL was started at Washington by the late Samuel Wagner. It was prophesied at the time that it would be short lived, that a journal devoted to one pursuit could not exist long. It still lives, however, and to-day is the largest and best bee-paper we have.

Bro. Dibbern has our thanks for his appreciative remark. Yes; the AMERICAN BEE JOURNAL still lives, and instead of being, as formerly, a monthly at \$2.00 a year, it now comes out weekly, and is published at \$1.00 a year—only 2 cents a number—and it may also be stated that it never was so strong and vigorous as it is to-day! That is what they all say, and just what we all know is the plain and unvarnished truth. May it long live to uphold the interests of the pursuit, and be the beacon-light of generations yet unborn!

Contraction, etc.—F. B. Reynolds, Rosburg, N. Y., asks as follows:

Bees are doing nicely, only 3 colonies being dead out of 85, and they were queenless. Please answer the following: 1. Is it necessary to contract the brood-chamber at this time of the year, to get good results? 2. What is the cause of my foundation cracking and breaking to pieces? I made a mold and got a perfect cast, but the foundation cracked and broke to pieces. I followed the directions as given on page 173.

1. Not absolutely and always—but it is preferable to do so.

2. Probably the trouble is in handling it in cold weather; but it may be caused by something else. We have never used "molds," and know nothing of the methods to be employed, more than we have already published.

Fertilizing the Clover.—A painstaking person made some experiments relative to the fertilization of the clover heads by bees, and this was the result:

Of white clover, ten heads unprotected gave nearly ten times as many seeds as ten heads covered with gauze; twenty heads covered produced only one poor seed, and twenty heads open gave 2,290 seeds.

Of red clover, 100 heads covered gave nothing, and 100 heads open produced 2,720 seeds.

Insects will abundantly cross-fertilize plants growing $\frac{1}{2}$ to $\frac{1}{3}$ mile apart.

Bee-Keeping in the South.—Mr. James M. Lisenbey, at the late session of the Florida Fruit Association, said:

Everything should be in order about the apiary. Let everything be perfectly clean about the hives, the grass and weeds cut from about the entrances. The bee-keeper should work with gentleness and care, avoiding jarring movements or anything that will agitate the bees. Care should always be taken that each hive contains a queen. If any are found to be queenless, they should be supplied with brood from some strong colony, or doubled up with a weak colony.

GLEAMS OF NEWS.

The Wiley Lie in England.—Our respected cotemporary in England, the *British Bee Journal*, contends that its statement is true, about the existence of the American "adulterating bee-farms," located in the "far West." It says on page 126:

On page 98 we reprinted the reproof of the editor as it appeared in the *AMERICAN BEE JOURNAL*, without comment on our part, and have made inquiries, and find that, so far as we can gather, all said in the article headed "Facts," is true. The clergyman who supplied the information, and whose name for obvious reasons we withhold, is a well-known dignitary of the church, whose word we cannot for a moment doubt. Whether he was a victim to a fraud we cannot say, but he further informs us: "The farm I was on was 15 miles from Kansas City. I do not remember the name, but there are plenty of them in the Western States." Perhaps, this will give American bee-keepers a clue to the detection of those unprincipled adulterators who are doing so much harm to bee-keeping.

It matters not whether the informant is a "dignitary of the Church" or not. The statement about the adulterating bee-farms in the United States, is a positive falsehood—such do not exist near Kansas City or at any other place in America. The "clergyman" was *deceived*, if he really thinks he was on such a farm! And if so, it is his *duty* to attempt to clear his skirts, by naming the place and the person who practiced such deception upon him! Out with it, Mr. Clergyman!

Again, our British cotemporary makes this assertion:

Our article was based on the above information, and we also gave an extract from a magazine, *The Monthly Magazine of Pharmacy, Chemistry, and Medicine* for December last, part of which—"So much like the genuine article that only experts can detect the difference"—the *AMERICAN BEE JOURNAL* considers the *British Bee Journal* to have said, but which was only a portion of the quotation from the *Monthly Magazine*.

There again the *British Bee Journal* is mistaken—we copied on page 52, its exact words, which were:

The latter of these scientific bee-keepers [the manager of the "adulterating bee-farm."—Ed. A. B. J.] is best described in the following quotation FROM A MAGAZINE of this month.

No; no, we made no such mistake! Immediately following the above, was the statement that "ARTIFICIAL HONEY" in "racks" was "now MADE in New York," so much like the genuine article that only experts can detect the difference." Merely another version of the infamous Wiley lie to cause another rack-et!

Finally, the editor of the *British Bee Journal* avows his disbelief in the story from that "Magazine of this month" in these words:

Naturally, subjects coming from a *Professor* would be considered facts, and we hope that our informant was deceived, although we must point out that there is a difference between "artificial combs" as described by Prof. Wiley, and which no bee-keeper for

one moment would believe it possible to produce, and the productions of combs by feeding, which is not at all impossible, as every bee-keeper will know.

Had our cotemporary thought far enough ahead last December to have come to this conclusion, that infamous citation would not have been *endorsingly* given! This is an after-thought of the *real* editor—the other was the blunder of a subordinate!

It seems to us that it would have been far better to have admitted the blunder, than to have attempted to defend it, and to have so signally failed!

We quite endorse the language last quoted, that "no bee-keeper for one moment would believe it possible to produce" the "artificial combs as described by Prof. Wiley!"

But how peculiar does that assertion appear when placed side by side with what that editor *endorsingly* copied into that original article entitled "Facts," viz:

The latter of these scientific bee-keepers is best described in the following quotation from a magazine of this month: "Artificial honey now made in New York is so much like the genuine article that only experts can detect the difference. It is in racks, the same as the natural product, and now and then the wings and legs of a few dead bees are to be seen to further the deception. It can be sold at a profit of 5d. per pound.

"Mistakes will happen in the best regulated" periodicals—but when the error is pointed out, it is better to acknowledge it than to try to defend it!

The Weather is varied enough to suit the most fastidious. We have all the varieties within 24 hours, with a change of 60° of temperature. Mr. Eugene Secor, of Forest City, Iowa, on March 26, 1888, writes thus concerning the weather in his locality:

The past week has discounted the stories of "the oldest inhabitant." One week ago we had a foretaste of Florida; immediately following, the rigors of Nova Zembla. One of the worst blizzards of the winter came close upon the heels of a balmy spring day, when geese were winging their way to the northern lakes, when robins were calling their mates to the familiar haunts in the orchard and lawn, and the bees (if in the open air) were sporting in the joyous sunshine. This is a country of mighty possibilities!

My bees are still in the cellar, and will stay there until the weather settles, "if it takes all summer."

Yes; by all means let the bees remain in winter quarters until settled warm weather has come.

New Catalogues for 1888 are on our desk, from the following persons:

The D. A. Jones Co., Ltd., Beeton, Ont.—20 pages—Bees and Supplies.

A. O. Crawford, South Weymouth, Mass.—20 pages—Honey Labels.

E. L. Gould & Co., Brantford, Ont.—22 pages—Bee-Keepers' Supplies.

G. K. Hubbard, La Grange, Ind.—12 pages—Hubbard Bee-Hive.

Abbott Brothers, Southall, England—72 pages—Hives and Bee Furniture.

E. W. Reid, Bridgeport, O.—24 pages—Small Fruit.

Woodman—Spare that Tree, is the first line of that old song so popular when we were a boy. It forcibly came to our mind when reading the following in the *Plowman* from the pen of Mr. C. H. Dibbern:

Last month I made some suggestions to the farmers to sow Alsike clover, buckwheat, and other crops of value for honey. Something can also be done to keep farmers and others from destroying trees, and other honey resources we already have. A number of years ago a neighbor and friend of mine was thinning out a wood lot of some 35 acres, near my apiary, by cutting out about three-fourths of the timber. This lot contained a good many basswood or linden trees that I had watched jealously. As they were not regarded as of much account for timber, I soon discovered that they were being cut down, and ash, oak and butternut left to grow. I had on several occasions given him a present of a few pounds of honey, and I now explained to him the value of the basswood trees for the bees. He at once agreed to let all the good shaped trees of this variety grow, and now I have some forty splendid linden trees within easy range as the result. The man is now dead, but whenever I see these magnificent trees, an impulse of kind remembrance comes over me. Perhaps others can do something on this line with their neighbors also. I have hundreds of linden trees within reach of my bees, but these are so near that they are of special advantage.

Much can be done to save the the honey-producing trees if attended to judiciously, and in the right spirit. The hint of Mr. Dibbern is a good one, and we hope will be acted upon by others.

Among Hints to Beginners, an exchange gives the following items of information:

Never crush a bee if you can help it.

Bees will not follow one into a building.

Newly-hived swarms should be placed in the shade.

It is easiest to manipulate bees when they are gathering honey.

Let all your movements be slow and regular, if you would not be stung. Do not be nervous or fidgety when working with bees.

The proboscis of the bee is moved like the trunk of an elephant, and is susceptible of expansion and contraction, and of being bent and twisted in all directions.

The Old Reliable "*American Bee Journal*" donned a new dress with the new year, and looks as neat and clean as a new dollar. It gives the latest news in bee-keeping, and we never knew a bee-paper that could take its place. Long may it prosper.—*Western Farmer and Stockman*.

CONVENTION NOTICES.

☞ The annual meeting of the Western Bee-Keepers' Association will be held at Independence, Mo., at the Court House, on April 25, 1888. It will be carried on as a sociable, friendly gathering. Let all bring their baskets and have a good time.
PETER OTTO, Sec.

☞ The next meeting of the Susquehanna County Bee-Keepers' Association will be held at New Milford, Pa., on May 5, 1888. The following subjects are to be considered: Bee-keeping for pleasure and profit—Spring work with bees—Is it advisable to use foundation? If so, to what extent?—How can we make our Association of the most practical value to its members. All are cordially invited to come.
H. M. SEELEY, Sec.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*
 Apr. 10.—Wabash County, at N. Manchester, Ind.
 F. S. Comstock, Sec., North Manchester, Ind.
 Apr. 11.—Stark County, at Canton, O.
 Mark Thomson, Sec., Canton, O.
 Apr. 14.—Union, at Menlo, Iowa.
 Mrs. J. E. Pryor, Pres., Dexter, Iowa.
 Apr. 21.—Central Michigan, at Lansing, Mich.
 W. A. Barnes, Sec., DeWitt, Mich.
 Apr. 21.—Eastern Indiana, at Richmond, Ind.
 M. G. Reynolds, Sec., Williamsburg, Ind.
 Apr. 24.—Des Moines County, at Burlington, Iowa.
 John Nau, Sec., Middletown, Iowa.
 May 2, 3.—Texas State, at Greenville, Tex.
 B. F. Carroll, Sec., Blooming Grove, Tex.
 May 5.—Susquehanna County, at New Milford, Pa.
 H. M. Seeley, Sec., Harford, Pa.
 May 7.—Welland County, at Welland, Ont.
 J. F. Dunn, Sec., Ridgeway, Ont.
 May 8.—Cortland Union, at Cortland, N. Y.
 W. H. Beach, Sec., Cortland, N. Y.
 May 19.—Nashua, at Nashua, Iowa.
 H. L. Rouse, Sec., Ionia, Iowa.
 May 22.—N. W. Ills. & S. W. Wis., at Rockton, Ills.
 D. A. Fuller, Sec., Cherry Valley, Ills.
 Aug. 14.—Colorado State, at Denver, Colo.
 J. M. Clark, Sec., Denver, Colo.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

Good Prospects for the Season.

—A. C. Aten, Round Rock, Tex., on March 22, 1888, says :

Bees are doing well so far. There has been no freeze or frost to amount to anything for the last six weeks, and we have had plenty of rain. The prospects are good for an excellent honey crop.

Abnormal Swarming.—A. D.

Lord, Amiret, Minn., asks the following questions :

1. Did you ever know of a swarm of bees to leave the hive after four days from natural swarming, and when they had made three frame-folls of comb, two partly full, and all laid full of eggs? 2. Did you ever know of 2 swarms of bees coming from one hive at the same time, and a queen with each?

Mr. Heddon answers these questions in this way :

1. Yes; but only once or twice among the thousands of swarms we have hived. Sometimes bees go contrary to all rules. We think we have had less of these exceptions than most bee-keepers, considering the number of colonies we have kept.

2. We all have both first and second swarms leave their hives with two or more queens, and with the after-swarms. Such is the rule, and should one of these swarms divide, and each have one or more queens, it would come under the head of your No. 2.

Rheumatism and Bee-Keeping.

—Wm. H. Graves, New Carlisle, Ind., on March 24, 1888, writes :

I feel that I would be lost without the weekly visits of the AMERICAN BEE JOURNAL, although I do not know that I will ever be able to do much with bees again. I have been confined to my bed with rheumatism, and under the doctor's care since the latter part of last July. I commenced the season of 1887 with 70 colonies, and increased them to 110, by natural swarming, and obtained

about 1,000 pounds of honey in one and two pound sections. My loss will be from 25 to 30 per cent., on account of not being able to take care of them last fall.

Hard Winter for Bees.—Frank Andrews, Smethport, Pa., on March 24, 1888, says :

I moved my bees about half a mile the first of last October, and it turned cold soon after. I lost some of the queens. I packed the bees on the summer stands, and I find that 15 colonies are dead, all but two dying queenless, and those had plenty of honey, but during the last cold spell they failed to reach it. My report for 1887 is as follows: I had 43 colonies, spring comit, and took 1,000 pounds of comb honey, and 800 pounds of extracted. This has been a very cold and hard winter for bees here. I think one-half of the bees are dead in this county.

Great Bee-Mortality Predicted.

—M. O. Tuttle, Osage, Iowa, on March 22, 1888, writes :

The mercury is 15° below zero this morning. (Take the bees out?) My bees were put into the cellar about Nov. 18, or Nov. 16 to 19, 1887. They are quiet, and in good condition. I have 170 colonies in one cellar, which is under the dwelling-house. The cellar is large, about 8 feet deep, dry, and ventilated by the chimney. A stove is used in the coldest weather. The temperature is about 45° now, but was 41° to 42° until near March 1. All but a few colonies have plenty of stores, and those had poor queens, hence all I care for them is their combs. We had no surplus to speak of last year. I predict great mortality among bees in this county, as those remote from timber had no supplies, and no matter what the locality, with those that were allowed to swarm during the one week of honey-flow we had—they are all gone, or will be going, if not fed. I notice some are prophesying a good season for 1888. I can wait for my boom this year, till about July.

Bees Wintered Well, etc.—Clarence W. Wilkins, Cortland, N. Y., on March 24, 1888, writes thus :

Bees have wintered well in this locality the past winter, and are "springing" quite fairly, although the weather is extremely cold. The mercury stood at zero last night, and will go below to-night. This is simply getting "our pay" for the severe thaw which we were subject to the forepart of the week. Last Wednesday, previous to this "freeze-up," the bees of this neighborhood had a jubilee. It was the first chance they have had for a good flight, and they improved it with a will. As yet I have lost but one colony out of the 25 with which I began the winter, and when it is considered that the bees have been shut in ever since last fall, this loss will seem slight—at least it does to me; and if I lose no more, I shall be well pleased with the result of my wintering.

The BEE JOURNAL was, in my estimation, previous to its renovation, far superior to any other apicultural periodical that ever came under my notice. Now, it has "fairly out-done itself."

Cutting the Basswood Trees,

etc.—L. Reed, Orono, Mich., on March 22, 1888, writes :

The snow is 2 feet deep yet. We have had a very severe winter; it has been blowing a gale for the last 24 hours, and the mercury has been down at zero all day. The prospects are for a late spring. There has been but one day here that bees could fly

since last November. I commenced in the spring of 1887 with 42 colonies, after selling 12 colonies. I sold 1,200 pounds of comb honey, increased my apiary, by natural swarming, to 83 colonies, and took 12 colonies on shares, making 95 in all. I put them into the cellar on Nov. 12, and I am a little uneasy about them, as there are more dead bees on the cellar bottom than usual. The prospects are not very flattering for next season. The basswood timber has been cut down at a fearful rate, this winter, there being thousands of cords of basswood bolts piled up at the railroad stations. It will soon be a thing of the past. We get about one-half of our honey-crop from basswood in this section, so we shall have to substitute something else for it, or go out of the business.

Varying Temperature.—C. F. G., Boonville, Mo., on March 22, 1888, writes :

The past year was a very poor one for the bee-keepers of this locality. There was no honey in the white clover, and very little in anything else. At the close of the season the bees gathered a little honey, the best Italian colonies averaging a fair winter supply. Those bee-keepers who failed to feed their poor colonies in the fall, and who then neglected them in the winter, invariably lost them. Several parties lost as high as 30 colonies and over, while almost all bee-keepers have lost more or less, and with not a few it was a "clean sweep." However, those colonies that were fed and properly cared for, wintered fairly well.

Last Sunday we had beautiful spring-like weather, the thermometer ranging as high as 84° in the sun, and the bees flew about quite lively, many carrying in pollen. This morning it was 14°, making a difference of 70° within four days. It is these sudden changes that kill so many bees, and especially those wintered in the cellar, and then prematurely placed on the summer stands. The arrival of the BEE JOURNAL is always hailed with delight by me.

CONVENTION NOTICES.

The Wabash County Bee-Keepers' Association will meet at North Manchester, Ind., on April 10, 1888.
 F. S. COMSTOCK, Sec.

The next meeting of the N. W. Ills. and S. W. Wis. Bee-Keepers' Association will be held in Rockton, Ills., May 22, 1888.
 D. A. FULLER, Sec.

The Eastern Indiana Bee-Keepers' Association will hold its spring meeting on Saturday, April 21, 1888, at Richmond, Ind. M. G. REYNOLDS, Sec.

The Des Moines County Bee-Keepers' Association will hold its next meeting on April 24, 1888, at Burlington, Iowa.
 JOHN NAU, Sec.

The Union Bee-Keepers' Association of Western Iowa will hold their annual meeting at Menlo, Iowa, on Saturday, April 14, 1888, at 10 a.m.
 H. D. LENOCKER, Sec.

The Cortland Union Bee-Keepers' Association will hold its spring meeting on May 8, 1888, at Cortland, N. Y., at 10 a.m. All bee-keepers are invited.
 W. H. BEACH, Sec.

The Hardin County Bee-Keepers' Association will meet at the Court House in Eldora, Iowa, on the second Saturday in each month, at noon (12 o'clock), until further notice.
 J. W. BUCHANAN, Sec.

The Marshall County Bee-Keepers' Association will meet at the Court House in Marshalltown, Iowa, on Saturday, April 21, 1888, at 10:30 a.m. The subject for discussion is, "Spring and summer management of bees." A general invitation is extended. A good meeting is expected. J. W. SANDERS, Sec.

The 18th semi-annual session of the Central Michigan Bee-Keepers' Association will be held in the Pioneer Room at the State Capitol, on Saturday, April 21, 1888. Prof. A. J. Cook will give an address. A cordial invitation is extended to all, as it will be a very interesting meeting.
 W. A. BARNES, Sec.

The tenth annual meeting of the Texas State Bee-Keepers' Association will be held at the beards of Vice-President W. R. Graham, in Greenville, Hunt Co., Texas, on May 2 and 3, 1888. A leading feature of the convention will be criticisms upon subjects that have been mentioned in the bee-papers. A good time is expected, so let all Texas and Arkansas bee-keepers attend. A cordial invitation is extended to all bee-keepers where-soever dispersed. Remember, no hotel bills to pay at our conventions!
 B. F. CARIOLL, Sec.

QUERIES AND REPLIES.

HONEY THAT WILL NOT GRANULATE.

Written for the American Bee Journal

Query 529.—1. Why is it that my honey will not granulate or candy? I would like to have it do so. I have some that is five years old, that is still liquid. It was well-ripened before I extracted it; I then put it into 6 and 10 gallon tin-cans, and let it stand with a very thin piece of domestic tied over it. Occasionally I took off the cloth and skimmed it. It was that way until winter, when I put the top on. I have tried it in glass jars, still it remains liquid. It will sometimes have some grains in it in the winter, but when summer comes, it all becomes liquid again. Our summers are of more uniform temperature here than in the North, the thermometer seldom indicating 100° above zero, or seldom falls to zero. 2. What can I do to make it granulate thoroughly?—Tennessee.

I know of no remedy. I wish that mine would act that way, but it does not.—G. M. DOOLITTLE.

I have no receipt to cause honey to granulate. Neither do I wish for one.—J. M. HAMBAUGH.

Honey from some bloom will not granulate, and I cannot tell you how to make it do so.—J. P. H. BROWN.

1. Honey from some plants granulates much more readily than that from others. 2. I do not know.—M. MAHIN.

We think that it was not ripe enough. We have never seen ripe honey that would not candy here, unless it was heated.—DADANT & SON.

I do not know. Ask a chemist. Aerate it thoroughly, and put it into an ice chest.—J. M. SHUCK.

I cannot say. If it is pure honey, and exposed to the air and cold, it should granulate.—MRS. L. HARRISON.

You do not say from what source the honey was gathered. Some kinds granulate sooner than others. I should not worry about that. I wish mine did not granulate. I believe that customers generally prefer it in liquid form.—EUGENE SECOR.

1. Some kinds of honey will not granulate. I saw some at the Ohio State Convention, that was four years old, and no signs of candying. 2. Try putting it in vessels, preferably barrels, that have had candied honey in them, and have not been washed.—A. B. MASON.

1. No doubt your honey is from some source which yields that kind that does not granulate, or does not granulate readily. 2. If it will granulate at all, bring it up North, and stir it, and let it get a few weeks of our zero weather.—JAMES HEDDON.

I have never seen our spring and summer honey granulate, but our fall

honey gathered from September to November always granulates at a temperature of 30°, and remains so until melted by heat. Probably if the honey was subjected to a very cold degree, it would granulate.—P. L. VIALON.

Honey in different localities seems to differ in this respect. My honey always granulates when cold weather comes, and sometimes sooner. I know of no way that it can be granulated artificially.—C. H. DIBBERN.

1. Extracted honey is not apt to candy if kept in a warm place, say 80°. 2. Place the honey where it will freeze.—G. L. TINKER.

1. The peculiar character of your honey is undoubtedly owing to the source from which it was gathered. All kinds of honey do not candy, although to do so is the rule. The riper honey is, the slower it is to candy.—R. L. TAYLOR.

Only tell us all how to get our honey like yours. If you mix with it some honey not well ripened, I think it may granulate. Possibly the flowers from which it was taken, are at the root of the matter.—C. C. MILLER.

1. I cannot give you just the reasons why; but I wish my honey would do as yours does, as I cannot sell granulated honey in my market. 2. Expose it to the light, and as cold as possible.—H. D. CUTTING.

1. This is one of those questions that no one can answer. I might guess a dozen things, and be wrong. Why not be contented with your honey as it is? Many of us would give much to know how to bring about this very state of things. The temperature probably has much to do with the matter.—J. E. POND.

I think it is in the nature of the honey, and I know of no way to secure granulation. I have honey from California and Louisiana—apparently nice honey—that has never shown any signs of crystallization even in our coldest winters.—A. J. COOK.

1. Honey seems to be a combination of *sucets*, and it depends upon the combination as to how soon, and under what conditions honey will granulate. The fact is, honey in a temperature as high as is natural to the immediate brood-nest, will never granulate. This proves that granulation is the result of low temperature, and some honeys are more susceptible to the cause, than some others. I have samples of honey running back to 1867, and two or three out of the number have never granulated, and the quality cannot be excelled. 2. Just let your honey alone. I wish that my honey would never granulate.—G. W. DEMAREE.

Your honey was either gathered from different kinds of flowers, or it was not ripe when extracted. To expose extracted honey to the air and cold will almost universally cause it to granulate. The exceptions are rare, and usually with some inferior qualities.—THE EDITOR.

COMBS FROM FOUL-BROODY APIARIES.

Written for the American Bee Journal

Query 530.—1. Foul brood exists in some apiaries in this locality. If I buy the comb of the extinct apiaries, and render it in a Cary wax-press in my bee-room, do I run much risk of introducing foul brood to my own apiary of 75 colonies of healthy bees? 2. If so, what precautions are necessary?—Apiarist.

I would not risk it.—M. MAHIN.

I should hardly think there would be any risk.—G. M. DOOLITTLE.

1. You do. You had better spend your time, money and energy in some other way.—MRS. L. HARRISON.

No, not with caution. The important thing is to be sure that the bees get no honey from the combs.—A. J. COOK.

I have had no experience whatever with foul brood. I would be extremely cautious.—J. M. HAMBAUGH.

We had rather not buy that comb, unless it was rendered into wax at the place where it is bought.—DADANT & SON.

I have never had, nor have I seen a case of foul brood, and I am not sorry of my ignorance, from what I have heard of the disease.—P. L. VIALON.

You do. If you *must* purchase, do all your handling of them after night, and burn up all refuse.—J. P. H. BROWN.

I know nothing about foul brood from experience, but I would not want to run even that much risk.—C. C. MILLER.

I do not know anything about foul brood. Our best books on apiculture treat of it.—J. M. SHUCK.

I would have nothing to do with frames that had been exposed to foul brood. If you value the bees you have, you cannot be too careful.—C. H. DIBBERN.

I have had no experience with foul brood, but I should not risk it. I would prefer to go to the apiary where the foul brood is, and extract the wax.—G. L. TINKER.

Yes, you do run a great risk. If you have anything to do with it, go to the place where the combs are, and melt them there, and do not bring anything, but the wax away.—H. D. CUTTING.

I am happy to say I know nothing of foul brood, only from reading, and you can get information from some pamphlet on the subject, worth a hundred times my theories.—EUGENE SECOR.

Not any, provided you do it so that not one of your bees ever gets a taste of any honey from these combs, or of the combs before they undergo the heating necessary to rendering the wax. My advice is, to render the wax somewhere else.—JAMES HEDDON.

1. To say the least, you run too much risk—more than any one who is not anxious to become better acquainted with the disease can afford to run. 2. Do not bring them any nearer your apiary than they are, until they are thoroughly boiled; and even that is not entirely safe, if the person who does the work is to be near your bees soon afterward.—R. L. TAYLOR.

I should think that it would be possible to box the combs so closely that no bees could get at them, and everything could be so carefully conducted that there would be no danger to your bees. But why not render the wax on the premises where the disease exists?—G. W. DEMAREE.

1. Foul brood is so insidious, and so easily carried from one hive to another, that it is dangerous to fool with it at all. Let it alone severely; that is, do not procure any comb or bees from any apiary where the least suspicion of the disease exists. An ounce of prevention is worth many pounds of cure.—J. E. POND.

1. I do not know what a Cary wax press is, and I would have nothing to do with the combs unless it was desirable to get them out of the way so that your own bees would not get to the combs. 2. *You cannot be too careful. Do not run any risks.* It has cost Mr. A. I. Root over \$1,000, and a few years ago it cost me from \$300 to \$500 in one season. Do not let your bees touch the combs. *Boil them, and everything about them that can be boiled, and wash your hands and everything that cannot be boiled, in Mr. Muth's preparation of salicylic acid.*—A. B. MASON.

Either have nothing to do with the combs, or else render them into wax at the apiary where they now are. You would run a great risk by taking these combs into your apiary, or placing them where your bees could get at the honey.—THE EDITOR.

A Modern Bee-Farm, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

CORRESPONDENCE.

THE DRONE.

Our Poor, Slandered Drone Asks for His Day in Court.

Written for the American Bee Journal
BY REV. L. L. LANGSTROTH.

"Virgil, who was a great poet, but not enough of a practical bee-keeper to know a laying from a virgin queen, was the first writer of much note, to have his fling at me. To him I was only an idle knave, born to consume the fruits of others' labors, and deserving no better fate than death, by ignominious expulsion from the industrious Commonwealth. Ever since he so grossly libeled me, to compare one to a drone, is the most orthodox form of denunciation for laziness, gluttony, and what has been called 'general cussedness.'"

Now I am proud to say to this Court, that I can disprove every charge brought against me, by simply proving, that to the best of my ability I

Sir Drone.

fulfil the express object for which I was born. Surely no creature can do any better than this, and excuse me for thinking that few men do as well.

Charged with Laziness.

If any of my enemies had authority to call the roll of my demerits, he would surely begin by accusing me of being too *lazy* to gather any honey. But an expert in points of this kind could remind him, that if he examines my proboscis, he will see that it is much too short for sipping nectar from the opening flowers.

Makes no Wax.

I am free to admit that I make no wax, but even Cheshire himself, whose microscopes have fairly turned me inside-out, will tell you that I have not a single wax-secreting gland, and am also without those plastic, trowel-like jaws which enable the worker-bees to mold the wax into such delicate combs.

Gathers no Pollen.

Now do not insinuate, that I might at least employ some of my leisure time in gathering pollen! Can you not see that my thighs have no basket-like grooves, in which it could be packed—and are quite destitute of the hairy bristles by which the workers hold the pollen in place?

Accused of being a Lazy Coward.

No doubt you have often denounced me as a big, hulking coward, that leaves to the women, the whole defense of the State. Are you not aware that I have no sting to fit me for acting on the offensive? Would that I had one proportioned to my bulk! if only that I might make proof of it, upon all who berate me for not accomplishing impossibilities!

I am not at all ashamed to admit that I spend the most of my time, not given to eating, either in sleeping, or in what you are pleased to call, listless moping about the hive. Has it never occurred to you, that if I should try to assume the restless activity of a worker-bee, I could be nothing better than a meddling busy-body, perpetually interfering with the necessary business routine? I guess the silly meddler who would put me up to such nonsense, ought more than once to have had a dish-cloth pinned to his rear, to teach him not to bother the women in their work!

Misunderstood.

I am sorry to number Shakespeare among those who have misconceived me, by calling me "the lazy, yawning drone"—but as one of my maligners has likened me to Falstaff, I may be allowed to quote in my own defense, what this great braggart, when accused of cowardice, says of himself to the Prince: "Was it for me to kill the heir apparent? Why, thou knowest I am as valiant as Hercules; but beware instinct; the lion will not touch the true prince. Instinct is a great matter; I was a coward on instinct. I shall think the better of myself and thee during my life. I for a valiant lion, and thou for a true prince." I lie not, like the false knight, when I say, that what you call my laziness, is a matter of pure instinct.

With all your boasted reason, you seem to have entirely overlooked the doctrine of the conservation of forces. You upbraid me with consuming so much of the precious honey, to the gathering of which I contribute nothing! Well! if I made a single un-called-for motion, would not that necessitate an extra consumption of food? What better can I do, then, than to keep as quiet as possible? There is nothing either inside or outside of the hive which calls for any

other line of conduct, until the young queens are on the wing; and as they do not sally forth until long after noon, why should I go abroad any earlier? I can assure you, that if bridal excursions were in order, as many hours in the day as the flowers secrete honey, no worker would ever be earlier to rise, or later to go to bed than myself.

Misrepresented.

I, an idle, lazy, listless loungeur, forsooth! Does any one wish to witness the most perfect embodiment of indefatigable activity? Let him then look at me, when at the proper time, with an eager, impetuous rush, and a manly, resonant voice, I sally from the hive! See with what amazing speed, I urge, what our old friend Samuel Wagner, called my "circumvolating" flights! For ought you know, I may cover greater distances in describing these vast circles, than the busiest worker, in the longest summer day. There is great need then, that I should be abundantly provisioned for such exhausting excursions, and it is only a law of nature, that on my return from them, all that I carried out with me, should be found to have been used up. If you taunt me either for the full or the empty stomach, I merely ask you if you have never heard of honeymoon trips among your own people, which began with extra-full purses, to end only with uncomfortably light ones?

Savage Delight over my Death.

To cap the climax of your abuse, what savage delight you take in seeing the workers drive me from my pleasant home! and how glibly you can moralize, over what you call a righteous judgment upon a life spent in gluttony, and inglorious ease! Just as if you did not know that the whole economy of the bee-hive is founded on the strictest principles of utilitarianism. Is not a worker-bee when disabled by any accident, remorselessly dragged out to die, because it can no longer contribute to the general good? Even so exalted a personage as the queen-mother herself, as soon as it is plain that her fertility is too much impaired, has a writ of *supersedeas* served upon her, in favor of one of her own daughters.

Knowing well the law under which I was born, I urge nothing against being put to death when Shakespeare's "pale executioners" deem the day of my prospective usefulness to be over. Truly, the sword of Damocles is suspended over my head, and from the hour of my birth, till that of my death, it may fall at any moment. Many biters are thus mingled with my sweets.

I have time to mention only one more. While I know that most of the young queens come safely back from

their wedding excursions, I cannot help sometimes foreboding the worst, when I see that no drone ever returns to tell us of his experience.

Appreciated by Bonner.

I will close my defense by reminding you how the good father of the great Scotch bee-keeper, Bonner, showed his appreciation of our persecuted race. It was his custom to watch every year for the first flying drone. Its cheerful hum so filled him with delight, as the happy harbinger of approaching swarms, with their generous harvest of luscious sweets, that he called an instant halt on the work of his busy household, and devoted the rest of the day to holiday feasting. The patron of the drones ought forever to bear the honored name of "Saint Bonner."

The Decision of the Court.

Sir Drone:—This court having heard your defense, declares it to be a true and manly one, all those to the contrary notwithstanding, who would further injure you by calling it nothing more than crafty special pleading. It only regrets its want of power to punish adequately your slanderers. But, alas, my worthy fellow! you must not expect too much from this acquittal. Remember how difficult it is for Truth to overtake a Lie that has got a start of only a single day. No doubt the time will come when those who have been stigmatized as the

"Lazy Fathers of the Industrious Hive,"

will be held in due honor by the world; therefore console yourself with this bright hope for the future of your race, while you protest against the lies that have had so many centuries the start of your true story, that you may well despair, in your short lifetime, of ever overtaking them.

Morals from the Drone's Plea.

It were easy to draw more than one good moral from the drone's plea, such as, "Do not give even a dog a bad name, unless you are quite sure he deserves it," but the moral which I think at the present time can hardly help suggesting itself to well-read beekeepers, may be very fairly styled the

Moral of the Prof. Wiley Scientific-Pleasantry Lie.

It is only too well known, to the sorrow of most of our large honey-producers, that some years ago Prof. H. W. Wiley, an entomologist in the service of the Government at Washington, published substantially this statement, viz: That honey-combs, after being manufactured, filled with glucose, and sealed over, all by human skill, so nicely as to escape detection, are largely sold as genuine bees' honey;

when the bees have had nothing to do with a single step in the whole cheating process. This absolute falsehood having got a good start as coming from a *scientific man* (?) has widely, at home and abroad, prejudiced the public against buying the purest honey, in the most beautiful combs.

Many times have I heard the above story spoken of as either undoubted truth, or have been asked if it were not the truth. It has been refuted again and again, and large sums of money have been offered by responsible parties, to any one who will produce even a small specimen of such a man-made product; and yet the story is constantly appearing in print in America, Europe—and not long ago even in Australia. It has found its way into a periodical of as high repute as the *British Bee Journal*, and it sometimes seems to have a greater vitality for mischief, than when it first started out on its hurtful career.

Prof. Wiley, when called to account for fabricating such a story, thought it a sufficient excuse to say that he meant it only as a "*scientific pleasantry*." Could any one wish him a harder task than over his own signature to try to stop the march of such an inexcusable utterance? Could there be a stronger condemnation of his conduct in this matter, than the words of Holy Writ? "As a madman who casteth firebrands, arrows and death, so is the man that deceiveth his neighbor, and saith, Am I not in sport?"—Prov. xxvi. 18, 19.

Dayton, O., March 8, 1888.

THE IDEAL.

Careful Breeding and Crossing Two Races of Bees.

Written for the *Western Tree Planter*
BY PROF. A. J. COOK.

We often read of a large, brown bee which was indigenous to this continent. I think that any such bee is only a variety of our common black bee, which was introduced into America long years ago, and so has become widely distributed, and it would not be strange if color variation had taken place to quite a degree. . . .

The good points of the black bees are: They cap their honey thicker, and so comb honey from them is very white; they are very ready to go into sections or a surplus chamber on top of the hive, at the dawn of the honey harvest. This point is specially prized by many of our best beekeepers. This fact leads many of our wisest apiarists to desire at least some black blood in their bees. . . .

I have had considerable experience with Syrian bees, and like them very

much. I am now carefully crossing Syrians and Carniolans in hopes to get the vigor and prolificness of the former, and the amiability of the latter. I believe that such a cross will give us the ideal bee. As bees, unlike cattle, are reared for a single purpose, there is no objection to crossing them. Indeed I believe one of the greatest lines of progress lies in this direction. If we can rear a race with the amiability of the Carniolan, the vigor and fertility of the Syrian, which shall also have the excellence of the black bee as a producer of comb honey, we shall surely make a great advance.

Agricultural College, Mich.

HIBERNATION.

Review of Mr. Latham's Article on Hibernation of Bees.

Written for the American Bee Journal
BY WM. F. CLARKE.

I suppose Mr. Latham will feel slighted if I do not pay my respects to his article on page 167, but really it is so hyper-scientific, that it well nigh bamboozles me. It reminds me of a young lawyer, who, in his maiden effort at the bar, indulged in such high-flown language, and used so many learned phrases, that the Judge, in summing up, was led to remark, that Mr. — had "soared out of the jurisdiction of his court." One word especially bothers me, viz: "androgynal." I am away from my library; "Webster-on-a-bridge" is not within reach, and I am obliged to "give it up."

Yes, Mr. Latham, we all know that hibernate in its common unscientific use, means merely to "pass the winter," and in that sense, we human beings, as well as the lower animals and insects, hibernate. So do plants and stones. But, as Mr. L. says, "in the accredited scientific use of the term, hibernation is used to designate a condition."

Why does he assert that we cannot arrive at any positive knowledge on this subject, "so far as optical evidence demonstrates the actual hibernation condition?" We can see that, under certain circumstances, bees form a tight cluster, and remain in an almost, if not quite motionless state. We know, too, that when thus quiescent, they consume the minimum of food, thereby showing that they eat seldom and sparingly. Many beekeepers have testified to observing the bees when so torpid that it required considerable disturbance to arouse them, and that when they wintered thus, their consumption of stores was very meagre.

Mr. Latham says, "The hive-bee is only physically constituted to experience to a certain degree" the condition of hibernation. If it experiences the condition in *any* degree, is it correct to say as he does, "that the hive-bee does not hibernate?" The same is true of the red-squirrel. It hibernates "to a certain degree." It is so constituted that it must arouse every now and then, "and eat to replenish the flames of life." Still, the red-squirrel is classed among true hibernators. Why, then, should not the hive-bee be similarly classified?

Mr. Latham says that no animated organized being "can become frozen solid, or even become sufficiently benumbed by cold as wholly to destroy its vital functions, and live." This is not so. The black ant can. Mr. Doolittle demonstrated this a long time ago, and in *Gleanings* of March 15, 1888, Prof. Cook states the same fact in regard to the black ant. "They seemed utterly dead. Pinching or rough treatment of any kind did not arouse them at all!" But on being subjected to warmth, they soon "become wide-awake and lively." The hive-bee is not so physically constituted as to be capable of this. It must have a certain degree of warmth to hibernate. Intense cold first arouses it to abnormal activity, and then causes it to succumb through exhaustion.

Mr. L. says: "Life without the influence of motion on matter, is inadmissible." Then there is and can be no hibernation in any case. Even the bear does not hibernate, according to this showing. The black-ant example is in point here again. So are the numerous well known cases of other insects and chrysalides that freeze solid, and yet thaw out and come to life again. Carp and other fish have been known to pass through the same experience. The fact is, we know but little, after all, about the life-principle. It is a great mystery. Life survives under certain circumstances, and then under apparently similar ones, becomes extinct. Truly we are all as Tennyson says:

"Like children groping for the light,
Like children crying in the night."

I must "fyle a demurrer" to the use of the terms "coma" and "comatose" in relation to this matter. They designate a state of disease. "Coma" is not healthy, normal sleep; hibernation is.

The statement, "it does not appear that the comatose condition evinced by the hibernating species, is habitual with the hive-bee, as it does not accompany that insect from the regions of flowers and snow-storms, to the ever-blooming flora of tropical climes," admits of question. There is a sum-

mer sleep, called by scientists, *astivison* (I think that is the term applied to it), and possibly the hive-bee takes a turn at that in tropical climes. Our brethren who keep bees in the "Sunny South," can perhaps inform us on this point. Bees must have a period of rest, surely, in the South, as well as in the North.

St. Thomas, Ont.

POLLEN—MOTHS.

At What Times do Mature Bees Eat Pollen?—Wax—Moths, etc.

Written for the American Bee Journal
BY G. M. DOOLITTLE.

I notice in a recent bee-paper that Prof. Cook claims that the diet of mature bees is largely composed of pollen. Well, I am no scientist, so I do not suppose it would look well for me to oppose the Professor, but as a "eat may look on a king," so I suppose it will not be objected to, if I ask him a question or two regarding his position.

What I wish to know is, at what times, or under what circumstances, do mature bees eat pollen? Surely, not at all times, or at their convenience, as I thoroughly proved in my experiments a few years ago, when I killed several colonies trying to make them eat it, as a means of support. They starved to death just as soon as the little honey was gone which I gave them, never touching the pollen, as far as I could see.

When I gave the experiments in the BEE JOURNAL, to prove that old bees do not eat pollen, as a rule, Mr. A. R. Kohnke took it up and said they (my experiments) proved nothing but my failure. He further said, "This does not prove that the bees do not eat pollen, for we know they do. Pollen is not, and cannot be the primary cause (of bee-diarrhea); certainly not. Primary causes are those which compel the bees to eat the pollen when they ought not to, viz., out of season. If Mr. D. had furnished besides pollen and a little or no honey, those other conditions necessary to produce the disease, I dare say he would have succeeded."

The above was written in 1883, and in all the years since, I have been trying to find out "those other conditions necessary," to make bees eat pollen, but so far, it has all proved a failure.

Now, Professor, here is a chance for you to get a great name, and do the world much good, by telling us how to know the conditions that are favorable to our success, along the line of a pollen diet for bees. Please tell us all you know about it, because if we can

keep our bees a part of the time on pollen, even if we cannot all of the time, it will be a great saving in honey, and rid our combs of so much pollen that we are often anxious to dispose of.

Keeping Wax-Moths from the Honey.

Picking up a bee-paper lately, to look over while I rested a few moments, I read in it this sentence: "As fast as the honey is sealed, it is removed from the hive, and all openings in the boxes pasted over with paper, so that the moth cannot get within to deposit its eggs." This was given as the true plan for keeping the larvæ of the wax-moth from comb honey. I was very much surprised that any writer of recent date should advocate such a doctrine as this, at this day and age of the world, for Quinby proved the fallacy of such a course, as long ago as 1865. In his "Mysteries of Bee-Keeping Explained," published in 1865, but written some time previous to that, he says:

"I have taken off glass jars, and watched them till the bees were all out, and was CERTAIN THE MOTH DID NOT COME NEAR THEM; then immediately sealed them up, absolutely preventing any access, and felt quite sure I should have no trouble with the worms. But I was sadly mistaken. In a few days I could see a little white dust, like flour, on the sides of the combs, and bottom of the jar. As the worms grew larger, this dust was coarser. By looking closer at the combs, a small, white, thread-like line could be perceived, enlarging as the worm progressed."

He then continues: "The reader would like to know how these worms come in the jars, when to all appearance it was a PHYSICAL IMPOSSIBILITY." To this he says he cannot give a positive answer, but thinks the bees carry them among the combs on their feet, where they are left to hatch.

That all should know that combs taken from the hive in the summer are liable to the attack of the larvæ of the wax-moth, and should be looked after, as often as once a week, is the object of my noticing this point here.

Hiving Back the Swarms.

A subscriber of the BEE JOURNAL says that he desires to control his bees so as to avoid increase, and asks what I think of the "hiving back" plan given by Prof. Cook, as compared with "let your bees swarm—just once."

I have not tried the "hiving back" plan thoroughly, except one season, when I used it on all the swarms that came, but the first one, as is recommended by its advocates. As that year we had rather a poor season for honey, it might not be fair to speak of it as a whole, so I will only say that, in a poor

season I would much prefer letting the bees swarm but once, to this or any other plan of preventing increase I have ever yet tried, and I have tried nearly all so far given to the public.

Instead of having that impetus for work which a swarm has when hived in an empty hive, they acted more like a "driven" swarm, working no faster for the first few days, than they did in the parent hive. This first few days' work of a new colony often decides the matter of a really good crop of honey, or only a fair crop, from such individual colony.

If I must really have no increase, then I know of no better plan than the above; but I think it will pay in the end to let the bees swarm, hiving them in empty hives, even if I have to double them up in the fall or early spring. I am positive that enough more honey will be obtained, to well pay for all the trouble; besides, it often happens that we meet with a loss in wintering, when we should be glad that we kept our increase over.

I am getting more positive every year, that the proper time to double up bees, if we wish to do so, is in the spring, rather than at any other time of the year; doing the work in May, or the forepart of June.

TRANSFERRING.

The Best Method of Transferring Bees.

Written for the American Bee Journal

BY GEO. F. ROBBINS.

The time is approaching when the above subject will become one of particular interest and inquiry to many. Already inquiries relating to it have appeared, and the answers being, as I regard them, misleading to beginners, I am prompted to tell what I think that I know about it.

A few weeks ago an inquirer was told to transfer during fruit-bloom. I cannot do it. The idea, of course, is that the combs will at that time be nearly empty of honey, while at the same time the bees will be so occupied that the operation will not start robbing. It may be so in some localities, but it is not so in mine, and I think it is so in very few. I once tried transferring in the height of apple-bloom, and in less than ten minutes I had almost the entire apiary upon me. Indeed, there has never been a season when I have not had to choose morning and evening to open hives at any time before clover began to yield well. Unless fruit-bloom keeps bees busier elsewhere than it does with me, the

one who attempts to transfer bees out-of-doors at that time will be sure to get into trouble, and may be very serious trouble.

The quickest, neatest, easiest, safest and best method of transferring is, to drum out the bees twice, and use the old combs for beeswax, *a la* Heddon. I would not use the combs in the new frames at all, unless they contain but little honey, and can be trimmed so as to fit into the frame. I do not at all like these combs made of chips, with a surface as rough as a cobble-stone pavement. The details of that method should be pretty much as follows:

About 21 days before white clover begins to yield copiously, is the time to drum out the first swarm. Here that time is usually from June 1 to June 5, so that the time to begin is about May 10 to 15. Place the new hive on the old stand. When making a new swarm this early in the season, empty combs must be used. One or two or them had better have a little honey. Full sheets of foundation might do in some localities, but I think not here, although I have not tried them.

Carry the old hive to a new stand, invert it, remove the bottom-board, place an inverted box of the same horizontal dimensions on top of it, and wrap a sheet around the whole, so as to keep light out and the bees in.

Now drum on the sides with sticks (not too heavily) at intervals for 15 or 20 minutes. As there is apt to be cool weather still in May, it will be better if a considerable cluster of bees is left in the old hive. But in 15 minutes the most of the bees, including the queen, will have passed into the drum-box. Turn the box mouth upward, and carry the bees and shake them upon the sheet in front of the new hive. Do not have the sheet so that the bees can crawl in clusters into crannies under and around the hive. Turn the old hive right end up, and watch it for a day or two. If there seems to be danger that they will be robbed, fasten up the entrance entirely for a few days, until enough bees can have time to hatch to protect their home. There will be no danger of their smothering.

In 21 days the bees will all be hatched except a few drones, and a queen about ready to lay. Now drum them out again, and put them in the new hive. They may now be put on empty frames if it is desirable. If the bee-keeper has correctly timed the first drumming, there will be but little honey in the combs to bother. Cut those combs out, and in the evening lean them in front of a few of the hives of the strongest colonies. Drum a little near the entrance until the bees

run out to see what is the matter. They will generally find the honey immediately, and clean the combs up by morning. The newly-made swarm will scarcely come out at all, as the bees will be engaged in secreting wax and building comb.

By the time the old combs are rendered into wax, I think all will conclude that the method described above is the quickest, neatest, easiest, safest, cheapest and best way to transfer bees. Mechanicsburg, Ills.

FREE LANCE.

Had I Not Better Start Another Bee Periodical?

Written for the American Bee Journal
BY EUGENE SECOR.

I think I had better start a new bee-paper. It has now been fully a month since one was born. If I do, it will not be a repetition of the old story in the fable, where the mountain labored and brought forth a mouse, either. It will be a genuine "Vesuvius" belching forth streams of bee-lore, till all the little craft are buried in oblivion.

The fact is, we need more "intellectual bee-bread." I am taking only ten bee-periodicals, and there is not room enough in them to hold what we do not know about bees and bee-keeping. Then, is not the time ripe for another? And why not furnish the necessary pabulum myself, according to the protective idea that we should buy nothing which we can produce at home?

I have already selected the name that the infant is to bear when the maternal throes are over. It shall be **THE FREE LANCE**. The title is suggestive. *Free*, because I shall get enough advertising—gratis—through this notice to put it well on its feet. *Free*, also, because I expect to out-do all my rivals, and furnish the paper to all subscribers for two goose eggs (OO). *Free Lance*, because I expect everybody to pitch into the editor to his heart's content. Its columns will be open to all manner of criticism on all manner of subjects. Everybody who wants to air his cerebellum shall have the inestimable privilege.

The editor's serene picture will occupy the centre of the top of the first page. Above it will cross two Don Quixote lances, and from either cardinal point of the compass will be the cut of a Cyprian bee pointing for his (the editor's) blossoming nose. His composure will indicate with what calm serenity he can withstand the darts of adverse criticism. He will take everything just as coolly as he

would if the four Cyprians, aforesaid, should all have reached his rubicund proboscis at once.

Its motto will be, "To be or not to be." In the future conduct of the paper that sentiment will be strictly adhered to. Its management will be original. Its advertising columns will be open to the world—and Canada—at \$2.50 per inch, brevier type, each insertion, when the advertiser planks down the "dollar of the daddies" in advance.

Every contributor to the reading columns must deposit with the editor, as a matter of good faith, at the rate of five dollars per column for the space he occupies. Then if he wants to tell all about his patent reversible double-action drone-trap, he can occupy just as many columns as he chooses. If he wishes to establish his priority claim as the first one to furnish the bees with timothy straws through which to suck honey from red clover, the editor will give him all the space he pays for. If any one is aching to disclose to the world (and Canada) his recent invention for bringing a swarm of bees out of the clouds (and juggling them as Franklin did the lightning), by turning a crank, he shall have the sympathy of the editor, and unlimited space in the "Free Lance" (for a consideration).

If the foregoing plan will not cause a shaking among the dry bones of bee-dom—a revolution in the history of apicultural progress—then this editor is no profit. I give fair warning to all bee-periodicals that are not backed by a National Bank, or a lucky concatenation of favorable surroundings, to clear the track or join my syndicate. "Look out for the locomotive when the bell rings."

Forest City, Iowa.

[The "Free Lance" may fight its way to popularity—but the "goose-eggs" will but poorly pay the expense of printing, paper, postage, etc. It will be a "free fight," and the editor will soon have his hands full and purse empty—for there are hundreds who are *spoiling* to take part in a "free fight." "To be or not to be; that's the question!" Like many others—it will "be" awhile, and then "not be" forever!—Ed.]

Photographs of Bee-Keepers.—

The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it *free*, by mail, to any one, for a club of three subscribers and \$3.00.

THE HONEY-BEE.

Its Anatomy, Products, and Its Relation to Plant Bloom.

Written for the American Bee Journal
BY REV. E. T. ABBOTT.

The story of bees reaches back beyond the pages of written history, and can only be fully known by studying it in the rocks of geological ages. As this would not be of any practical utility I will not attempt it, but will call your attention to some of the special features of its anatomy.

The bee has some peculiarities of structure worthy of our attention. But first let me remark that a bee belongs to the great class of animals known as insects, so called from the Latin "insectus" from "in," into, and "seco," I cut, because the bodies of many of them are divided into parts—that is, cut in. These parts in the bee are known as

Queen-Bee.

the head, thorax and abdomen. You will notice that we do not call a man who studies insects an insectologist, but we go to the Greek for a name and call him an "entomologist," and the science entomology from Greek "entoma," and "logos," a discourse. Now, this Greek word, "entoma," means the same as the Latin word "insectus"—"en," in, and "toma," to cut.

But to return—our bee belongs to the order of "hymenoptera," which means that it has membranous wings, from

Drone-Bee.

Greek "hymen," a membrane, and a word from the same language meaning wing. It belongs to the family "apidae," or bee family, and to the Genus known as "apis."

Please note that "apis" is Latin for bee, and that "apiary" is a place where bees and not "apes" are kept. Andrews, in his Latin Lexicon, under the word "apis," a bee, suggests that it is derived probably from Greek "hapto," to cling. "Apis," then, literally means a clinging animal, which seems a very appropriate name to one who knows the habits of bees. To follow the bee on down until we reach the individual, it belongs to the species "apis mellifica," so called because it gathers honey. Of this species there are several races, such as the German, or black, the Ital-

ian, Cyprian, Syrian, Carniolan, &c. These races are divided into varieties, and of each variety there are three kinds of individuals in each colony, or hive, known as queen, workers and drones. That is, in the summer, each hive in its normal condition contains the three kinds of bees mentioned. Briefly, the queen, or mother bee, which would be a better name—for she has nothing to do with ruling the hive in

Worker-Bee.

the ordinary sense of the word—lays the eggs; the workers gather the honey secrete the wax, and do all the work of the hive; the drones are the male bees and do no work whatever beyond that of impregnating the queen.

Its Anatomy.

We will now return to the anatomy of the bee and spend a few moments on the most interesting points of its organism. I invite your attention first to the head. The things of special interest about a bee's head are its mouth, jaws, tongue, antennæ, or feelers, and eyes, of things external; while the most important internal items are a few special glands with their secretions, and the brain ganglia. A bee's jaws do not move up and down, as do those of other animals, but sidewise. The jaws, while they are strong and well suited to the work they have to perform, are not toothed but smooth in the workers. The queen and drone have notched jaws. The jaws of the worker being

Head of Queen—Magnified.

smooth, it is entirely unable to commit the depredations upon fruit, such as grapes and peaches, which are frequently charged upon it. But more of this further on.

There is no more important member in the bee's body than its tongue, for it gathers with it all of the precious nectar that furnishes its own food, and at the same time helps to make glad the palate, if not the heart, of man in the days of buckwheat cakes or hot biscuit. The bee's tongue is so constructed that it can lap, like a cat, or suck up nectar like an elephant does water with his trunk. The tongue is not a tube, but is so made that the bee can form it into a tube if it desires to do so. Upon the length of a bee's tongue its value largely depends; for, as I have remarked

in one of my pamphlets, a bee, unlike people, cannot have too much tongue. This is one of the advantages that some of our new races of bees have over the natives or blacks. They have longer tongues.

The antennæ are very interesting and important organs also. I can see no reason, however, why they should be called antennæ. This is a Latin word and means "sail-yard." Why a bee's feelers should be called "sail-yards" I am at a loss to know. "Tentacles" would be a more appropriate name, it seems to me, as this comes from a Latin verb which means to feel or touch. But I have no authority for re-naming them, and will call them by their usual name. They are composed of twelve joints. The first is called the "scape" and the remainder the "flagellum," which two words are equivalent to a whip-stalk and lash.

The antennæ are covered with sensitive hairs that aid the bee very much in its examination of the cells and its fellow bees. In them, too, is located the bee's organ of smell; and Mr. Frank Cheshire, a noted scientific bee-

Head of Drone—Magnified.

keeper and writer, thinks he has discovered that without a doubt the bee's organs of hearing are located in the outer joints of the antennæ, so that with these two small organs the bee feels, smells and hears. I will not attempt a further description of these organs, for a writer and scientist of no less note than Swammerdam closed his description by saying: "I cannot refrain from confessing, to the glory of the immense, incomprehensible Architect, that I have but imperfectly described and represented this small organ; for to represent it to the life in its full perfection far exceeds the utmost efforts of human knowledge."

The bee is well supplied with visual organs, having on each side of its head a large compound eye which is composed of a great number of single eyes that are hexagonal in shape. Mr. Cheshire counted 6,300 of these facets, or small eyes, on one side of a worker bee; 4,920 in a queen, the mother of this worker; and in one of her sons, a drone, he found the immense number of 13,090.

In addition to these compound eyes, there are found on the upper part of the head three simple eyes, called "ocelli," from "ocellus," a diminutive of the Latin, "oculus," an eye.

We all know how accurately a bee can mark the location of its home, and how quickly it finds its way back to its own hive. Sir John Lubbock has demonstrated by a series of experiments, that bees can distinguish colors, and

that they show a decided preference for blue. He further states that bees have played a very important part in the development of the color of flowers. He is not alone in holding this view, as it is held by many noted scientists.

We call your attention, next, to the thorax, which furnishes points of attachment for about all the remaining external organs of our little but interesting insect. The thorax is composed

Head of Worker—Magnified.

of three rings, and the bee has three pairs of legs which are inserted on the under side of the thorax, a pair in each ring. There are many points of interest about these six legs, but I have space to note but a few of them. No one who has witnessed the marvelous skill and dexterity with which a bee handles its legs, can fail to be deeply interested in the legs of this wonderful little creature. They are very strong, and are composed of nine joints, which enables a bee to move them in many directions, and put them to many uses beside that of locomotion. A bee's foot is composed of two claws, which enable it to hold on to rough substances, or hang itself upon its fellows, as it does in swarming, and a soft, pliable substance called the "pulvillus," which

Leg of Worker—Pollen-Basket.

means a little cushion. A remarkable little cushion it is, too, for it enables the bee to walk up a glass, or any smooth substance, with about as much ease as it can a board. I remember reading, when I was a boy, in a district school, an article entitled "How a fly walks on a ceiling." I got the idea there that it had a kind of suction pump in its foot which enabled it to withdraw the air from under it, and the pressure of the air on the outside held the foot in place. Of late years I have learned that it does and has nothing of the kind, for it can walk in a vacuum as well as anywhere else; but it can not walk on a wet glass. Neither can a bee. The pulvillus of both bee and fly gives out a clammy secretion, which, for the moment, glues it fast. But, by a peculiar movement, the bee or fly is enabled to take it up and put it down in another place, and so can move up a smooth surface very rapidly by means of this viscid secretion. Since the bee cannot use its "pulvilli" with-

out loss of material, it is so arranged that it can, by an automatic movement, throw the "pulvillus" back and let its claws come in contact with the surface on which it is walking, or it can turn up the claws and let the "pulvillus" touch, at pleasure.

Its Pollen-Sacs.

You have all, no doubt, seen bees in the summer, when they were busy, come home to the hive with a peculiar looking substance sticking to the inside of their hind legs. This substance is the pollen of the male organs of flowers, and it furnishes part of the food of the nurse bees. The little cavity in which it is fastened is called the "pollen-basket," for it is a cavity that is formed by stiff hairs and the shape of the leg. The bee gathers this pollen with its tongue and the hairs of its legs and body, and then, by the use of the

only hinted at the wonderful organism of a bee's leg when I have done this. There is a peculiar notch, or opening, on each of the front legs with which a bee wipes its nose very much as you have seen an unclean boy wipe his with his coat sleeve. It is also used to clean off its tongue. It is very hard to describe without an illustration, but it is none the less useful to the bee.

A bee has four wings which also have their points of attachment in the thorax. They, too, are very strong, and, on the whole, are a fine piece of organism. When at rest, they are folded very closely to the body and occupy but little space. They carry a contrivance for increasing the bee's wing surface, and at the same time not have them extend beyond the body when folded. A flying animal must have a wing surface proportionate to the size of its body. A common blue-fly has two very large wings, and when at rest they extend out from the body so that, at the widest points, they are about one-half inch from tip to tip. This would not do for a bee, for it must be able to enter a cell five of which make an inch. Of course, a bee has two wings on each side, but this would not aid it any in flight, if they were not so constructed that the bee could use them as one. A simple bar on one wing and a row of hooks on the other enables the bee to do this.

The abdomen, the third and last part of a bee's body, has no external organs except eight wax-pockets, of which I will speak further on. These, however, are found only on the worker bee, not on the drone or queen.

Internal Formation.

The internal anatomy of a bee is equally as interesting as the external. They do not breathe by the use of lungs, as we do, but by openings, called "spiracles," of which the bee has fourteen; five on each side of the abdomen, and one behind the insertion of each wing. Its internal organs are located in the posterior part of the body, only one of which we have time to describe, or in which any special interest centers. This is the honey-sac, which is located in the anterior part of the abdomen, and is in connection with the mouth by means of the oesophagus, which extends through the thorax to the head. It has nothing to do with the true stomach of a bee, except it is in connection with it by an opening which is in the end opposite the entrance to the oesophagus. This opening is stopped by a plug so arranged that the bee can open and close it at pleasure. In the honey-sac the bee stores and carries home the nectar which it gathers from the flowers. It is furnished with muscles which enables the bee to empty it through its oesophagus and mouth. It can also remove the stopper, referred to above, and permit any food, which the honey-sac contains, to pass on into the true or chyle stomach, if it desires to do so. So, you see, a bee always carries its dinner-basket with it, and it generally carries some dinner in the basket except when going to the field in search of stores. When bees swarm they fill their honey-sacs and take this

much with them from their old home ready to set up business in the new.

A bee also has four pairs of secretory glands, to which we may call your attention further on. One pair is located in the jaws, two in the head, and one in the thorax.

We have sometimes heard it remarked of men who seem very dull, that their brains were in their heels. Now, while this is not exactly true of bees, yet it comes very near having brains, or brain substance in the form of ganglia, all over it. They are found on the median line of the body throughout its entire length, there being no less than five of these ganglia in the abdomen, and three in the thorax, with an abundance of nerves extending to all of the organs that have their points of attachment in it. This accounts for the wonderful tenacity of life manifested by these little creatures when maimed or decapitated. It has been remarked that drones have sometimes been known to

Bee's Tongue.

same tongue and legs, it forms the pollen into minute balls. It then takes them up with the front legs, passes them back to the middle legs, and with these packs them snugly away in the pollen-baskets of the hind legs until the pollen stands up and hangs over much like the way that hay does when loaded into a wagon bed. There is a little spine or spur, on one of the joints of the second, or middle, legs by which it removes this polleu, when it reaches the hive, very much as a man puts a crowbar under a stone to lift it up.

There is one other little organ on each of the front legs, to which I desire briefly to call your attention, and then I must leave this part of the subject and hasten on to other things of interest. I can assure you, however, I have

Bee's Respiratory Organs.

live longer, when in confinement, with the head cut off than they did without. I have often been surprised to see bees, whose heads had been mashed flat, walking along as though nothing had happened to them.

The term bee is used in two senses. First, to denote the full-grown bee, especially the worker; the second and broader signification includes the bee in every condition. I have been using it almost entirely in the first sense, but permit me now to call your attention to the bee in its

Stages of Development.

I will begin with the egg, which is white, about the size of a small pin-head, and shaped very much like the egg of a bird. It is deposited in the bottom of a cell by the queen, which cell has been previously prepared for its reception by the workers. When first laid it is covered by a glutinous substance which immediately hardens

and sticks it fast. In three days this egg hatches, and there appears in the bottom of the cell a young animal called a "larva," which word means "masked." It being so-called because the true character of the perfect insect is hidden. The larva is fed by the young bees an abundance of food which is probably secreted by one of the special glands of the head previously referred to, instead of a mixture of pollen and honey as has been supposed, and it grows very rapidly. In five days it straightens out in the cell and the bees seal it over. The larva soon spins its cocoon and enters the "pupa" state, so called from its lifeless and puppet-

Larva of the Bee.

like appearance. It remains in this condition about thirteen days. What it does during this time I would be glad to tell you, but I do not know. I only know that it passes through a gradual transformation until it becomes an imago, or perfect insect. In other words, a young bee full grown, about the twenty-first day after the egg is laid, cuts a circular hole through the capping, emerges from the cell, and begins to walk about on the comb. This is the history of the development of the worker.

But as I remarked before, there are three kinds of bees in each hive and they differ not only in their general appearance and the offices which they fulfill, but they have a somewhat different history as we trace their development from the egg to the perfect bee. The queen begins life in a cell three or four times as large as that of an ordinary worker. Her cell is perpendicular instead of horizontal. From the moment the egg hatches, which is on the third day, the young larva (not a "worm") receives an extra amount of food, which is also richer than that given to the larva of an ordinary bee. This extra food and care hastens and changes her development, and causes her to mature in a shorter time than would the larva hatched from the same egg in an ordinary cell and treated as are the larvae of worker bees. About sixteen days after the egg is laid, the young queen cuts a circular hole in the bottom of her cell, crawls out on the comb and begins to help herself to the honey about her. In four or five days she comes out of the hive, takes wing, flies away in the air, meets a drone, or male bee, is fecundated, returns to the hive, and, in two or three days, begins her life work of laying eggs.

Eggs that produce drones are laid in cells a little larger than those of the

workers, and it is about twenty-four days before his dronship makes his appearance. How it is that the queen is able to lay eggs that produce three kinds of bees so different in their development, appearance and office, is a matter of deep interest, but my space will not permit me to go into an explanation of it. I call your attention next to the

Products of Bees.

The products are wax, shaped into combs, honey and propolis. The early bee keepers and scientists, such as Reaumur and Swammerdam, held to the opinion that wax was made from the pollen, or "bee-bread," as it is sometimes called, which the bees were seen carrying in on their legs. About 1768 it was discovered by a Frenchman that this was not the case, but that it was the result of the secretion of the glands, found in the lower part of the abdomen, under the wax pockets to which I previously referred. It is secreted by the glands in a liquid state, passes through by osmosis on to the surface of the wax pockets, and there hardens in the form of little scales. During the busy season of comb building these can be seen protruding from between the segments of the abdomen, with the naked eye. The bee removes them from their resting-place by the use of a peculiar pair of nippers found between two of the joints of the hind legs. They are then passed forward to the mouth where they are mixed with the secretion of some of the special

Brood-Comb—with Queen-Cell.

glands previously referred to, worked up by means of the tongue and jaws, very much like a mason works mortar, until they become soft and pliable.

The bee is now ready to commence comb building, which it does by depositing little bits of wax on the frame where the comb is to be made. Another follows its example, and so the work goes on until "In the darkness and between the bees," to use the language of another, "grows downwards that wonderful combination of lightness and strength, grace and utility, which has so long provoked the wonder and awakened the speculation of the philosopher, the naturalist, and the mathematician."

A further description of this comb-building would be interesting had I the time. Suffice it to say that when

the comb is completed, it is composed of hexagonal, or six-sided, cells, and is constructed in a way that renders it very strong, and at the same time it occupies the smallest amount of space possible. Five worker cells occupy one inch of space, while four of the drone cells, which are larger, make an inch. This gives about twenty-five cells to the square inch on each side of the comb for the workers, so that, you see, a very small space will contain a very

Ovaries of the Laying-Worker.

large number of cells. The combs are now ready for the queen to lay eggs in them, or for the workers to use them for storing.

Relation to Flowers and Fruit.

There has been more or less prejudice against bees, by fruit-growers who are ignorant of a bee's organism and habits. You frequently hear people talk about bees eating up their peaches, grapes and other fruit, in a way that would lead one who did not know better, to think the bees had jaws, teeth and tusks like a tiger. Now, the truth of the matter is, a bee cannot eat up anything in that way. It has no teeth to do it with, and its jaw is so constructed that it cannot break even the skin of a sound grape. It can only suck or lick up the juice after the grape has burst from over-ripeness, or dry weather, or has been punctured by wasps or other insects. Bees are not only not a detriment to fruits and flowers, but I propose to explain now how they are a great benefit, and that we owe it to them that we have many of our fruits and flowers at all. Sir John Lubbock well says: "Most botanists are now agreed that insects, and espe-

Comb.

cially bees, have played a very important part in the development of flowers."

It has been demonstrated by such men as Darwin and others, that the flowers need the bees as much as the bees need the flowers, and that one is the complement of the other.

The honey and pollen which the bees take from the flowers, is the pay which the flowers give to the bees for services rendered, and the flowers are not injured by removing that which they gladly give. In fact, the bright color of the flower, and the nectar in its bosom are the allurements which it throws out to the busy bee to pay it a visit, and do the plant a service thereby. It has been truly said, "There is a protest made in nature, for some profound, perhaps inscrutable reason, against continuous in-breeding, which applies no

stage of development and in a receptive condition, it begins to grow and form what is known as the "pollen tube." This tube reaches down through the style, and in some inscrutable way finds and enters the ovule, reaching the embryo sack, and causing the germ there to form into a cell. Thus the new plant-life begins. You say, "what has all this to do with bees? and what have bees to do with this wonderful and intricate process? Simply this and nothing more: They aid the plant by bringing the pollen to the stigma.

They not only bring pollen, but they bring it from another plant, and thus avoid in-breeding which would be injurious to the future plant and fruit. It has been demonstrated that many plants are so constructed as to prevent the pollen of their own stamen from coming in contact with their own stigma. At the same time the flower is so arranged that a bee cannot visit it and secure its nectar, without bringing some of the pollen of another plant of the same kind to its own stigma. As it leaves, the bee takes with it pollen from this flower to fall upon the stigma of the flower next visited. Thus it is the plant aids the bee and the bee the plant, and so the chain of nature is complete. Bees never go from one kind of flower to another, but always to one of the same kind. They go from

Wax Segments of the Bee.

less to plants than to animals, to flowers than to bees."

To make my point clear, let me briefly call your attention to the structure of a flower, and the law of the perpetuation of plant and animal organism. A plant flowers, of course, that it may produce fruit and seed, but the flower will never mature into fruit unless certain laws are complied with, namely: The male element of the flower must be brought in contact with its complement, the female. A flower is composed of two sets of organs, the essential and non-essential.

The outside of an ideal flower is composed of two rows or whorls of modified leaves. The outer is called the calyx and the inner the corolla, and these make up the non-essential organs, or floral envelopes. The essential organs are of two kinds also, placed one above and within the other. They are called stamens, or fertilizing organs; and pistils, the organs to be fertilized. We will need to look a little more closely into their construction. On the top of the stamens of the flowers there is a little organ called an anther. This is filled with fine dust which is named pollen or "fertilizing dust." The pistil is composed of three parts, two of which are very important, and we must remember their names. They are called ovary and stigma. The middle and less important one is called the style. The stigma on the tip or some other portion of the style, is composed of loose tissue, and is not covered, like the rest of the plant, with skin, or epidermis. The ovary is a hollow case, or young pod containing rudimentary seeds called ovules. Now, these ovules contain the embryo of the future fruit and plant, but they will never mature unless they come in contact with some of the pollen dust of the anther found on top of the stamens of this or some other flower of the same kind.

The moment the pollen touches the stigma, if the stigma is at the proper

Egg-Tubes and Ovaries of Queen.

clover head to clover head, and never from clover head to any other kind of flower.

You, no doubt, have noticed how imperfect the apples are in some years. This is caused by cold weather during the fruit bloom which prevents the bees from visiting the blossoms sufficiently to secure their perfect fertilization. An apple is the result of the fertilization of five pistils; and if any of these fail to be fertilized, it is sure to be imperfect.

So you now see we need the bees in order to raise perfect fruit—in fact in many cases, any fruit at all. There was no red clover in Anstralia, and they could not raise seed there until they imported nests of bumble-bees to fertilize the clover. Italian bees would have answered the same purpose.

Honey and Propolis.

HONEY—the next product which we are to examine. It is the nectar of flowers gathered and stored in the comb where it is subject to a ripening and curing process by the bees. That it passes through some change and receives some secretions from the bee, after it is taken from the flowers, while in the honey-sac, and in the comb before it is sealed over, I have no doubt; but just what these changes are, and the exact nature of the secretion I am not able to tell. There are many theo-

Sectional View of Bee-Sting.

ries and speculations about this, but I have not the time nor disposition to examine them now. Let me say, however, while I am on this subject, that you cannot feed bees sugar syrup and have them make honey out of it. Neither has any one been able to make comb, and fill it by machinery with glucose, and sell it for honey. This has never been done, the popular yarns to the contrary notwithstanding. "Mark this," if you please.

Propolis, from "pro" before, and "polis," a city, is so called because the bees use it for stopping the holes in the hive, to protect their home or city. It is placed, as it were, before the city for a wall of protection. In other words, it is the bee's glue, or cement, with which it stops every crack and crevice in its hive. In fact, in time it gives the entire inside of the hive a coat of this propolis. It is a kind of resinous substance which the bees gather from various sources. They use it not only to stop the cracks of the hive, but to cover up any objectionable or offensive substance which may get into their hives. Drop a snail into the hive, and not being able to remove it, they will stick it fast to the bottom of the hive, and then cover it entirely with propolis.

They also put a thin coating of this propolis over the entire surface of all the sealed honey that is left in the hive over winter, or late in the fall. This

gives it a yellow, shiny look, and causes it to be rejected as second class by most people. But for my own part I think it is greatly improved by being left in the hive late in the fall, even though it is done at the expense of whiteness, which is only a matter of looks anyway.

Now we are at the end of our story for the present, yet I have only touched briefly the wonders of the bee and its work. We can but exclaim, in view of all that we have learned, in the language of Scripture, "Great and marvelous are thy works, Lord, God Almighty; in wisdom hast thou made them all."

St. Joseph, Mo.

EXCLUSIVE.

Should Bee-Keeping be made an Exclusive Pursuit?

Written for the Ohio State Convention
BY DR. C. C. MILLER.

Taking the question in a general sense, if a man should ask me, "Is it best for me to give up all other business and produce honey?" I should answer, "That depends. If your taste is mainly for money-making, the probability is, that, the way matters stand at present, you can gratify that taste more fully in some other pursuit. Still, it is possible that, in a favorable location, if you are fully posted in the business, and have no particular adaptation for money-making in any other line, bee-keeping may be the best thing for you to follow as an exclusive business."

But why EXCLUSIVE in any case? Simply this: The man who devotes his entire energies in one direction is more likely to be successful in that direction. Then, too, there are certain advantages in having a large number of colonies, such as making the cost of fixtures and other expenses less per colony, or, if you please, per pound of honey produced. In short, the reasons that, in general, during the past fifty years have tended to such a great subdivision of labor in all departments, apply with equal force to bee-keeping?

But suppose you have a liking for bee-keeping, and at the same time have ability in another line that is far more remunerative to you, say practicing law. By no means send the law adrift unless you have a strong dislike to it, but keep a few colonies as a recreation. The man who devotes his entire energies to the law as a vocation is likely to be a good lawyer, for one vocation is better than two; but, if, as an AVOCATION, he keeps a few bees, he may be the better lawyer for it.

Going still further down in the scale, or, rather, up, we come to the man who cares for money only for the enjoyment to be gotten out of it, and the good to be done with it. His business is, perhaps, that of a traveling salesman; and with a yearly salary of \$2,500 and all expenses paid, he may be considered hardly sane by his friends to adopt bee-keeping as his sole business, with no prospect of half the annual income.

But he replies something like this: "So long as I am a commercial traveler, no matter how much money I make, I am only getting ready to live. Life for me is where my wife and children are, and at my present business I can seldom be with them. Ten years from now I may expect to have laid by enough to withdraw from this distasteful life, and settle down at home to really LIVE. Now, why should I throw away this ten years of my life that I might have, if I settle down to bee-keeping and make a bare living for the rest of my earthly sojourn? No, thank you, I would rather commence to live NOW than to wait for the ten years that may never come."

Against entirely depending on the bees for a living, is the fact that seasons of partial or total failure may come; but this applies to all agricultural pursuits.

I have considered the matter only in its relation to the producer; and as the matter looks to me now, I should say that circumstances and tastes must decide for each one whether he should keep one colony or a thousand.

When it comes to the discussion of consumers' interests, whatever will furnish the best supply of good honey at lowest price is the thing to be desired. The tendency in all departments is toward subdivision of labor; and however nice it may be to talk about having all the stockings knit in the home, the shoes and coats made (as indeed they were not a century ago), still the shoe-factories and the stocking-factories have become almost a necessity. I do not see that honey obeys any different laws, hence it is probably best for the public that honey production become a regularly established business, followed by men who expect to devote their lives to it.

Marengo, Ill.

LIQUID HONEY.

Extracted Honey—its Production and Marketing.

Written for the Ohio State Convention
BY DR. A. B. MASON.

It has been said, that the tendency of the times is toward each one becoming a specialist; and as the struggle for success becomes greater, each one feels that every force must be husbanded and every effort made to accomplish the desired result: but, is it true that the greatest comparative success in bee-culture will be attained by the specialist?

Some know that I do not get as large a surplus of honey as many others; but that is no evidence that I do not know how to get all that my field furnishes. My locality is not favorable to large yields of honey, for, as I said at the Detroit Convention, there is a large city on one side and a wilderness on the other; at any rate, the soil is not favorable to the production of white clover; and linden, except a few trees, is not within the reach of my bees; but there are large areas of boneset, golden-rod, and asters, near by, and the

three combined have never furnished my bees with sufficient honey for winter stores.

If I am not mistaken, extracted honey has been in use over twenty years, and its desirableness for table and other uses, when compared with comb honey, has been fully established; and I believe an Ohio man, none other than our friend A. I. Root, was among the first, if not the first, to produce it in America.

Many people know the excellence and beauty of first-class comb honey, which needs no praise; but a first-class article of extracted honey is something with which most people are not familiar, they never having seen its crystal beauty, nor caught its delicate aroma, and never tasted its delicious flavor as gathered from forest and field. When served upon the table it makes a fine appearance, and, to many, "nothing is better for breakfast than hot cakes and honey." It can be poured upon them till they "fairly swim in luscious sweetness." If our table is ever set for a meal, and the pitcher of extracted honey is left off, some one of the family is sure to say, "Please pass the honey." We have no use for honey in the comb, except when we want to show off for company, and even they frequently prefer the fine, richly flavored extracted article.

The aim should be to produce honey for the masses, for those who cannot afford to pay for luxuries.

"A land flowing with milk and honey," both being very nutritious and strengthening, was promised to and was desired by the Jews as the "ne plus ultra" of good things. When properly ripened, white clover, linden, Alsike, alfalfa, and some other honeys, have a sparkling clearness, and the flavor is exquisite, and like other kinds, when candied are free from any liquid portions; and I have no doubt that such honey is generally really nicer than much of the well-capped white comb honey placed upon the market; and if all the extracted honey offered for sale were as thoroughly ripened as is comb honey, the latter would be almost driven from the market.

Is it not a fact, that extracted honey is depreciated in price mainly because its quality is inferior to comb honey, and is inferior because it is not properly ripened, or different kinds have been mixed, thus destroying their distinctive flavor? Each kind should be kept by itself, and so retain its distinctive aroma and flavor. Well do I remember how delicious the honey was that we used to get from bee-trees on the home farm in the East, in my boyhood days. We didn't know what kind it was, but now I know it was linden. To secure plenty of well-ripened honey it will be necessary to have strong colonies to gather and ripen it, and it should be extracted when it can be done to the best advantage of the apiarist and the bees. In the production of such honey it is often necessary to leave it in the hive with a populous colony for some time. When this is not convenient it should be as thoroughly ripened artificially. Many bee-keepers think that honey must be sealed to be ripe. This may be true in some seasons, and in

some localities, but I am sure that it may be sealed before it is ripe, and it may be ripe before it is sealed.

All are aware that there has been a great deal of discussion as to the proper time for extracting, some claiming that it saves honey and time to extract it before it is sealed, and that it is just as good when artificially ripened as when ripened by the bees; while others as earnestly contend that it should be well sealed before being extracted. It seems to me, although I have claimed the opposite to be true, that honey ripened in the hive, whether sealed or not, has a richer flavor, and possesses a finer aroma, than that ripened artificially.

To have plenty of bees, good queens are a necessity; and to give her room to "spread herself" and deposit eggs according to her ability, large hives are needed. For several years I took my surplus from the brood-nest of eight-frame Langstroth hives; but owing to their small size I had to extract often, and sometimes the honey was not properly ripened; and I am thoroughly convinced that an eight-frame Langstroth hive is not large enough for accomplishing the best results in securing extracted honey, although it may be the best for the production of comb honey.

As soon as the colonies are strong, whether in small or large hives, and the bees are building new comb at the top of the frames and in other parts of the hive, put on the surplus story, filled with empty wired combs, if you have them; if not, use full sheets of wired foundation, putting one or more combs of brood from the brood-nest, after having extracted the honey in the super, supplying the place of the comb of brood with foundation.

If it is intended to fully ripen the honey in the hive, and it requires sealing to be ripened, and the honey-flow continues, the super should be raised, and another prepared as before, put under it as soon as the combs are pretty well filled, and before the bees are in the least crowded for room, and the process repeated as often as necessary; and when the yield from the particular source has ceased, and the honey become thoroughly ripened, all surplus should be extracted, and everything put in readiness for the next flow. If it is intended to ripen it artificially, another super will not be needed, and the surplus honey can be extracted at the convenience of the apiarist, but always before the bees are crowded for room.

"Judicious tiering," some one has said, "will often have a strong tendency to prevent capping, while the ripening process goes on rapidly." I am satisfied—yes, I may say I'm sure—that in some localities and in some seasons it is neither feasible nor desirable to tier up and wait till the close of that particular honey-yield; not feasible, because of the large and rapid honey-flow that would require so large a number of extra combs and supers to hold the surplus; and not desirable, because the honey is very nearly, if not quite, fully ripe without being sealed over. This will possibly account for the difference in opinion in regard to ripening honey artificially, or ripening it in the hive.

In my locality it is frequently desirable and always feasible to tier up and wait till the close of the honey-flow before extracting, and I have of late, frequently asked myself if my eight-frame hives are not partially responsible for this condition of things.

The care of extracted honey is of more importance than it is generally considered to be; for if it is improperly cared for, much of its nice flavor and fine, delicate aroma is either injured or entirely lost. I believe the best results will be obtained by putting the honey in large vessels, preferably tin, for a few days, just long enough to allow all impurities to rise to the top, when it should be drawn off by means of a molasses-gate at the bottom, and into such receptacles as can be sealed up air-tight, and it will not in the least taint it, or injure the flavor. Honey so cared for can be kept as long as desired, and will be just as nice as when taken from the hive; and if such honey only were offered to the consumer, the market would not be overstocked.

I believe the time is not in the near future when there will be an overproduction of a strictly first-class article of extracted honey. Perhaps some of you are wanting to ask me, "What then is the cause of the low prices?" I believe there are two principal causes, and I hardly know which to place first—a poor article or an undeveloped home market; but I believe if I put "the last first" I shall not miss the mark very much. This brings me to the last part of the subject assigned me—"The best method of marketing."

I believe the most important thing of all in marketing extracted honey is, never to sell a poor article. The best time for selling seems to be in the fall and winter. The best way will be just the way your customers have been taught to buy it. Some markets demand tin pails, weighing, when filled with honey, from one to ten or more pounds. Other markets prefer glass pails, holding from one-third of a pint to a pint. Others prefer fruit-jars holding a pint or a quart, the smaller ones selling most readily. In other places the Muth honey-bottles meet with the most favor. Some localities require it candied, and others prefer it in a liquid state. My locality calls for it candied in stone crocks holding from one to four or five gallons.

The best place to sell is in the home market, and the editors of our bee-papers have been telling us so for a long time. Friend Newman, through the AMERICAN BEE JOURNAL, has been singing that tune so persistently and so long that it has become quite monotonous; but for all that, he is right, and he knows it, and seems to be acting under the inspiration of the adage, "Be sure you're right, then go ahead." Friend Root frequently awakes to its importance and repeats the story.

The Dadants have a town of only 1,500 inhabitants in their locality; and although they had 24,000 pounds in 1886, it was all sold in their home market, and at much better prices than would have been realized if sold by commission men in large cities, in competition with others.

A good way which has been adopted by some, is to call at houses and sweeten up the babies, leave a sample of the honey that they have for sale, with a circular, a card, or a leaflet, giving the uses of honey, and the price; and, within a few days, call with the honey for sale.

I should like to refer you to articles on pages 15 and 183 of GLEANINGS for 1886, on marketing extracted honey, and to many other articles on the same subject in the same paper. Do not take GLEANINGS, did you say? Well, you ought to, and then perhaps you would know better how to dispose of your surplus honey. Then turn to the "old reliable," the AMERICAN BEE JOURNAL, and read the articles by G. M. Doolittle (isn't that man wrongly named? but then, we've heard that things sometimes go by contraries), the Messrs. Dadants, and others, and post yourselves as to the how to do it. Did you say you don't take the AMERICAN BEE JOURNAL either? Well, what are you thinking about? Do you belong to the large family of bee-keepers, and are not using the means to inform yourself as to what is going on in the family? Perhaps you belong to the number who do not take any bee-paper because there is so much in them that is of but "little value." You do not talk that way about your grain and vegetables. You do not throw them away because there is chaff and dirt among them. "The good and the bad grow together."

Let me ask, "Where is all the honey produced by the thousands of bee-keepers, sold?" Is it not really in a developed home market? Some of you, perhaps, will say you sell to our friend Muth. Well, where does he sell it? Is it not in a developed home market, that it has taken him years of time, and cost him much labor to work up? Perhaps some of you will say that he ships large quantities to other markets. Suppose he does; do not those to whom he ships sell in a developed home market. Now, if you prefer to pay freight, and friend Muth, or the commission men, and those to whom they wholesale, instead of selling it yourselves, please do not complain about low prices.

Are any of you farmers, and did you ever sell any apples, butter, eggs, corn, or potatoes? How did you do it? Did you sit down in the shade, or by a warm fire, with a great, nasty quid of tobacco in your mouth, and literally befoul everything within reach with your filthy expectations, or with a well-filled old stump of a pipe fill the air with your (to you) beautiful, and, to others, offensive wreaths of smoke, disgusting, not "the girl you left behind you," but the one you once thought was the brightest, best, and sweetest being on earth? or did you load up the wagon and start out to find a market for what you had produced by earnest thought, and hard and persistent labor? Were you ever ashamed to ask the lawyer, doctor, minister, business man, or any one else, to buy what you had so honestly produced? If you were, and had a first-class article to sell, you belittled your vocation, and disgraced your manhood, and ought to fail.

Just try the same course with your honey, that you do with your other products, offering only a first-class article in first-class shape, and DO'NT TRY TO SHINGLE it. Let the specialists "go and do likewise;" and if they have more than they can dispose of in this way, then sell to the commission men, and they and you, I doubt not, will realize better prices.

Auburndale, O.

SPRING WORK.

Hints to Beginners about Seasonable Work.

Written for the Canadian Advocate
BY A SPECIALIST.

The season in which it is most difficult to manage bees is upon us, and the beginner is apt to make blunders which will decrease his honey crop, if not destroy his colony entirely.

If bees are wintered in a cellar they should remain there if possible until some of the early flowers are out, such as the willows, or even later; colonies may have diarrhea, which will be indicated by the spotted condition of the front of the hive, but unless this is very serious it is better to not take them out of the repository.

The idea that a colony may be taken out of winter quarters and allowed a cleansing flight upon a fine day, to be again placed in the old quarters at night, has been a very general one, but however much our best apiarists may differ upon very vital questions, upon this they are almost if not entirely one. A colony loses by such treatment. By keeping colonies in proper quarters through the changeable spring, when it may be bright, warm and tempting to the bees outside one moment, and raw and chilly enough another to cause the loss of all bees away from the hive, much is gained.

Bees upon their summer stands may be examined if they appear to be weak and short of stores; if you are satisfied they are not, leave them alone. See that the entrances are kept clear, and if there are many dead bees upon the entrance board, you may upon a fine day when bees are flying, assist them in their house-cleaning operations, by pulling dead bees out with a bent wire.

Avoid the exposure of any honey or any manipulation of hives that might tend to start bees into robbing. Of robbing, the inexperienced bee-keeper is perhaps more afraid than the experts are; all dread it after it has been commenced. By having the hive-entrances facing the prevailing spring winds, there is less liability to rob, the scent of honey, if any is at the back of the hive, being driven by the wind in that direction; if the opposite way, it is at the front and only an additional guide to the bees to enter at the front; if at the back they can get no entrance even if they find their way there. If a colony has not lost all fight, instead of contracting the entrance, leave it open, and this method is especially to be recommended if robbing has not yet commenced, and as a preventive.

SELLING HONEY.

Our Local Honey Market, and How to Cultivate It.

Written for the Ontario Convention
BY R. M'KNIGHT.

Until the production of honey in Canada becomes much greater than it is likely to be, the best market will be the home market. I have no sympathy with the class of bee-keepers who constantly lament over low prices and slow sales, who strain their eyes to catch a glimpse of the proverbially green fields that are far away, the verdancy of which pales as they are approached. The demand for honey and the prices paid for it are relatively as good here as elsewhere. I believe that this country needs and will take all the honey the bee-keepers can supply. The experience of the past warrants this conclusion.

What was the production of honey in this Province ten or twelve years ago, as compared with its production now? And what is its consumption to-day? Was there not a ton of honey put upon the market last year—poor though the season was—for every one hundred pounds offered twelve years ago? Then the man who had honey to sell carried it to the drug shop. Now the provision dealers are his best customers. Then honey was used as a medicine, or partaken of as a luxury—now it is frequently found on the breakfast table, and esteemed a wholesome, economical treat of diet. What is the conclusion to be drawn from these facts? Obviously that the demand is keeping pace with the supply; that honey is no longer associated with drugs or enjoyed only by the wealthy, but is steadily working its way into the homes of the poor, who are beginning to recognize the fact that its food value is worth what it costs them.

It is true that the price of honey is now much less than it was a decade ago, but it is also true that bee-keepers' requisites are better, and cost less than they did then; while the demand for what they produce is steadier and more extensive. To my thinking, honey is now selling for all it is worth as an article of food, and he who looks for higher prices, either here or elsewhere, is doomed to be disappointed.

The wholesale price of extracted honey in Canada markets has ranged from seven to ten cents per lb. for some years past, and I know of no market in which our bee-keepers can net better prices. I see nothing to prevent these prices being maintained if bee-keepers only show themselves equal to the requirements of the business they have embarked in. The general law that regulates the price of industrial and food products is, "a living profit on the labor and capital employed in their production," the supply and demand being well balanced.

It cannot be denied that the demand for honey in Canada has kept pace with the supply; neither can it be disputed that present prices give a fair profit on labor and capital employed in its production. The wisdom and duty of cul-

tivating the home market is therefore obvious. It is true that we have good reasons for anticipating a steady increase in production, as time rolls on, but we have just as good reasons to look forward to a corresponding increase in consumption, and a like increase in demand; but these will not follow without an effort on the part of both the individual bee-keeper and this Association to keep the market active and steady. It will be vain to look to the middle men to do this.

The output of the apiary is as yet a comparative stranger in the market, and it must be watched and protected by those most interested, and not left to the tender mercies of those who care only for the profits to be made out of passing it from one hand to another. With this end in view, the wants of our immediate neighborhoods must be fully met by keeping the local markets well supplied, and this should be attended to by those who have most in stock, and most at stake. Such are not the class of bee-keepers who demoralize and destroy the local honey market—their interests lie in the opposite direction and their interests will be conserved by not only abstaining from unsettling the market by cutting prices and unwisely putting their goods into every hole and corner, but by preventing their neighbors, who produce but little, from doing so.

It is, I venture to say, within the knowledge of every one of you, that the cutting of prices, nay the slaughter of honey, is carried on by small out-of-the-way bee-keepers who produce but little, have no regular customers, and whose income is not materially affected whether they sell what little they have at 10 cents or at 5 cents per lb. Such people, having no market already established, and not yet skilled in putting up their little honey in attractive forms, are compelled to sell it at or near home for whatever prices they are offered.

The usual practice of such people is to empty their honey into crocks or milk-pails, drive into the nearest town or village, and there make the rounds of the hotels and grocery shops, disposing of it for whatever prices they can obtain, frequently selling it two or three cents per lb. cheaper to one man than they succeeded in getting from his neighbor, but in most cases trading it off to the shop-keepers for goods. The purchaser getting it by way of barter, is generally willing to sell it to his customers for cash at what it nominally cost him. Thus both retail and wholesale prices are unsettled and the market demoralized.

What is the remedy for this—the greatest obstacle we have to contend against is building up a steady, profitable home trade? I think that the only solution to the difficulty is for the bee-keepers in every community to become honey-dealers as well as honey-producers.

Let them arrange with the dealers I have above described, to take all their honey at the close of the season at prices that is fair to both parties, and thus put themselves in a position to control their own market, and I am persuaded that most small bee-keepers

will be willing to meet their larger brethren in a scheme of this kind. The subsequent operations of the holder must be influenced by his situation. If he be an old stager he will have a greater or less business connection already established. If this be commensurate with what he has in stock, he can bide his time and let the buyer seek him, instead of him seeking the buyer. If it be necessary for him to push sales to effect a clearance of his stock, he may adopt the means successfully pursued by some people, and take to the peddling wagon. If this kind of traffic is distasteful to him he may select a few agents from among the shop-keepers.

It will be a mistake, however, on his part if he seeks to put his honey into every grocery and provision store in a town. If he should succeed in placing it in all, it will necessarily be in small quantities, and when shop-keepers take small quantities of an article they make little or no effort to push sales. If the article be honey, they will likely put a "gem jar" or two filled with it in the window, and stow the rest in some out-of-the-way place where it never meets the eyes of the customer. I would rather sell 1,000 pounds to one dealer than 3,000 to twenty dealers in the same town, at the same time, if I wanted to establish a market in that place. Better establish one good agency and stock it well than supply twenty store-keepers with a little just to add variety to their stock.

Let the holder select his man. He may be a grocer, a provision dealer or a baker. He must be a live business-man, occupying a prominent place on a leading business street, with a showy front to his shop. Make arrangements for the entire use of one of his windows and some space on his counter to be exclusively occupied with your honey for a given time. Then with your goods put up in attractive shop-bottles and suitable boxes, dress, or cause him to dress, his window in such a way that the display will arrest the attention of every passer-by, and I am free to say that man will sell more of your honey in a given time than 20 of his neighbors will do, keeping it as it is usually kept.

But do not stop here. Send a case of your best comb honey to the editor of the town paper and advertise the "show" in its columns. If such a display filled even one shop window in every town and village throughout the country, I am persuaded that we would hear less of honey being a drug in the market, for the jealousy of your agent's neighbors would soon be excited by his customers asking for that which he has not got, but which might be seen in such rich abundance in his competitor's window across the street.

In establishing such agencies, care should be taken to encourage their success by charging no more than a fair price to the agent, and by insisting upon him selling your goods at no more than a fair profit to himself.

The above are some of the many methods by which the local honey markets may be improved by the efforts of local bee-keepers. The aid of this Association can only be of an indirect kind. It can make its power felt, how-

ever, and by its local aid it can at the same time effect much general good by keeping the industry and the product of the industry prominently before the public. To this end a portion of the government grant should be set apart, and may be employed in a variety of ways.

A good plan, in my opinion, would be for the Association to offer one or more prizes for the best and most attractive display of honey at the local horticultural and agricultural shows, such aid to be given only to those districts that have organized local associations already affiliated to the parent society. How lamentably bare of such displays are local and county shows generally! Whereas if we were well represented at them, a vast amount of good would be done, in attracting attention and promoting sales.

Still another matter that the Association should take in hand is, the general diffusion of knowledge pertaining to our industry among the masses. Here, again, the general meetings of the horticultural and agricultural societies may be made to serve our interests by our sending to each of them a representative of our Association to remove the prejudices that are too common amongst their members against the so-called ravages of bees amongst fruit, etc.

In nearly every district within our corporate limits there may be found one or more bee-keepers who could worthily represent our Association at such meetings, and who would be gladly welcomed and heard by them, if our Secretary intimated to their officers the fact of his intended presence as our delegate. But to guard against disappointment, in such cases we ought annually to appoint one or more Association lecturers to fill appointments in case no local man was available. The expenses of such would of course have to be met out of the government grant, and in no better way can a portion of it be employed.

"The relation of bees to flowers" might be dwelt upon by the lecturer at horticultural meetings, and would indeed be a very good stock subject at all such meetings, or the work of bees in fertilizing and hybridization might either be incorporated or made a separate subject. Indeed, the subject-matter for lecturers is almost unlimited, and I know we have more than one man in our ranks capable of doing the work in a way that would be at once instructive to his audience, beneficial to the industry, and creditable to this Association.

Owen Sound, Ont.

As we Constantly Hear rumors of a great war in Europe which, beginning on the Russian frontier, may involve all the powers, it is interesting to know how France has prepared for the next struggle with Germany. "France's Bulwarks," in *Frank Leslie's Popular Monthly* for April, is a remarkable and careful article, showing the new lines of defensive works in that country, evidently from careful and cautious study. The whole number is bright and interesting.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Money Orders for \$5.00 and under, cost 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them.

We Club the AMERICAN BEE JOURNAL and the "Bee-Keepers' Magazine" for one year for \$1.40; or with "Gleanings in Bee-Culture" for \$1.75; or with the "Apiculturist" for \$1.80; or the "Canadian Honey-Producer" for \$1.80; with the Bee-Keepers' Review, \$1.40; or all six for \$4.00.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Honey and Beeswax Market.

CHICAGO.

HONEY.—Prices range from 16@18c. for best one-lb. sections, to 14@15c. for off color and condition; 2-lbs., 14@15c. Dark is slow of sale at almost any price. Extracted, 7@9c., with good supply. Light demand.

BEESWAX.—22@23c. R. A. BURNETT,
Mar. 22. 181 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 14@15c.; fancy 2-lbs., 12c. Lower grades 1@2c. per lb. less. Buckwheat 1-lb., 10@10½c.; 2-lbs., 9@9½c. Extracted, white, 7@7½c.; dark, 5½@5c.

Mar. 19. F. G. STROHMEYER & CO., 122 Water St.

CHICAGO.

HONEY.—We quote: Fancy white clover 1-lbs., 16@17c.; 2-lbs., 15@16c. Dark is slow sale at almost any price. Extracted is scarce, and sells at 7@10c.

BEESWAX.—23c. S. T. FISH & CO., 189 S. Water St.
Mar. 13.

CINCINNATI

HONEY.—We quote extracted at 4½@9c. per lb., for which demand is good. Comb honey, 14@17c.—Supply large and demand slow.

BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.

Mar. 26. C. F. MUTH & SON, Freeman & Central Av.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 14@17c.; the same in 2-lbs., 12@14c.; buckwheat 1-lb., 10@11c.; 2-lbs., 9@10c. White extracted 8@9c.; dark, 5½@6c. Market dull; prices declining.

BEESWAX.—22@23c.
MCCAUL & HILDRETH BROS.,
Mar. 10. 28 & 30 W. Broadway, near Duane St.

MILWAUKEE.

HONEY.—Choice white one-lb. sections, 17@18c.; 2-lbs., 15@16c.; 3-lbs., 14c. Dark and broken not quotable. Extracted, white in kegs and ½-barrels, 8½ to 9c.; in tin and pails, 9½@10c.; dark, ½-barrels and kegs, 5@7c. Market slow.

BEESWAX.—22@25c.
A. V. BISHOP, 142 W. Water St.
Mar. 10.

DENVER.

HONEY.—Best white 1-lb. sections, 17@19c.; 2-lb. sections, 15@17c. Extracted, 7@10c.

BEESWAX.—20@23c.
J. M. CLARK & CO., 1409 Fifteenth St.
Mar. 1.

KANSAS CITY.

HONEY.—We quote: Choice white 2-lb. sections, 17@18c.; dark 2-lbs., 14@15c.; choice white 1-lbs., 18 to 20 cts.; dark 1-lb., 15@16c. White extracted, 7@8c.; dark, 5@7c. Demand is slow. White extracted is firm when in 60-lb. tin cans.

BEESWAX.—21 to 22c.
HAMBLIN & BEARSS, 514 Walnut St.
Mar. 29.

BOSTON.

HONEY.—We quote: 1-lb. sections, 18@17c.; 2-lb. sections, 14@16c. Extracted, 8@9c. The market is not very brisk and sales are slow.

BEESWAX.—25 cts. per lb.
BLAKE & RIPLEY, 57 Chatham Street.
Mar. 24.

SAN FRANCISCO.

HONEY.—We quote: White to extra, 10@17c.; amber, 9@14c. Extracted, white liquid, 7@7½c.; amber and candied, 6@7c. Market quiet.

BEESWAX.—18@21c.
SCHACHT & LEMCKE, 122-124 Davis St.
Mar. 20.

DETROIT.

HONEY.—Best white in 1-pound sections, 16@17c. Extracted, 9@10c. for light colored. Market weaker and supply only fair.

BEESWAX.—22@23c.
M. H. HUNT, Ball Branch, Mich.
Mar. 14.

KANSAS CITY.

HONEY.—We quote: White 1-lbs., glassed, 16@17c.; unglazed, 17@18c.; and dark 1-lbs., glassed, 15c.; unglazed, 16c.; white 2-lbs., glassed, 15c.; unglazed 2-lbs., 17c. California white 2-lb., 17c. California extra in 60-lb. cans, 8c. Market quiet and receipts are larger.

BEESWAX.—No. 1, 20c.; No. 2, 18c.
CLEMONS, CLOON & CO., cor 4th & Walnut.
Mar. 19.

It is Extravagant Economy not to have hives, sections, comb foundation, etc., on hand when needed. To prevent disappointment, order early what you will need in that line. Then the hives can be nailed and painted in odd times, and the sections put together, so as to be ready at a minute's notice. It is a sad disappointment to need these things and then not have them on hand. They should be ordered **immediately.**

BEE-KEEPERS' SUPPLIES

FOR SALE BY

THOMAS G. NEWMAN & SON,

923 & 925 West Madison-St., CHICAGO, ILL.

In this and the following pages will be found a list of the Apiarian Supplies for which your orders are solicited. Remember that *low-priced Goods* are proportionately *inferior!* Excellence is cheapness!

If Goods are Damaged or not such as were ordered, do not return them, but write to us, and we will direct how to dispose of them.

Your Full Address, plainly written, is very essential in order to avoid mistakes and delays.

We Pay Postage on all articles quoted by mail. All others are to be sent by express or freight, at the purchaser's expense.

Goods will be Sent C. O. D. only when sufficient money is received with the order to pay charges both ways, in case they are not taken from the express office by the person ordering them.

How Goods are to be Sent, should be very distinctly stated. Anything to be shipped by freight should be ordered from 10 to 30 days before needed for use, according to the distance from Chicago. Express charges are high on long distances, and heavy goods should not be sent by Express, unless particularly needed for use at once.

Credit.—We sell on small margins, and cannot afford to take the risk of selling on Credit. If we did a credit business, we should be obliged to add from 10 to 20 per cent. to our present prices, to make up for those who never pay, and for clerk-hire to keep books, etc.—this we know our cash customers would not think to their advantage. In order not to do injustice to any one, we make this an **invariable rule—therefore do not ask for credit.** This system gives all the advantage to "cash customers," but the "credit system" works to their injury. We therefore always require **Cash with the Order.**

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Sweet, or Mellot, Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2.00	3.00	3.50
1,000 Labels.....	3.00	4.00	5.00

☞ Samples mailed free, upon application.

OPINIONS OF OUR PATRONS.

Before proceeding to enumerate any of the Goods we offer for your selection, we desire to call your attention to a few among the many unsolicited testimonials we have received concerning our Goods, and our promptness in filling orders. Please read the following:

Best.—The parcel came in due time. The veil and gloves are the best I ever saw.—G. H. PUGSLEY, Canada.

Well Pleased.—I am well pleased with the Excelsior Extractor. It beats the one I have been using, and is strong and durable.—H. W. HITZ, Illinois.

All Goods as Represented.—Thanks for the promptness my orders receive at your hands. All the goods are fully as represented.—R. E. GIBERSON, Illinois.

Prompt.—The hives came all right. Thanks for such prompt attention to my order. Hereafter I will know who to trade with.—JOHN D. MOORE, Illinois.

All in Good Order.—The hives and supplies I ordered of you came promptly, and in good order—in fact in better condition than I expected.—JOHN T. SNYDER, Illinois.

It is a Daisy.—The Bingham Smoker you sent me is the best I ever saw, though I have used four other kinds; but not one of them will begin to come up with this. It is a daisy.—D. S. WAY, Iowa.

The Best Extractor.—I like the Excelsior Extractor very much. W. M. Kellogg was here a few days after I got it, and he said it was the best extractor he ever saw.—J. M. AIKEN, Illinois.

Deserve a Gold Medal.—The foundation you sent me arrived here in just 36 hours after the order was placed in the mail here. I think you deserve a gold medal for your promptness in business at all times.—JOSHUA BULL, Wis.

Gratitude for such Promptness.—I must express my gratitude for the promptness with which you filled my orders for supplies during the season; also for the valuable information which the AMERICAN BEE JOURNAL brings every week.—A. SPERLING, Ills.

Convenient.—I have tried your honey kegs and find that that they are what we have long needed. They are made in a workmanlike manner; they do not leak, require no waxing, and are of very convenient size.—A. A. E. WILBER, New York.

Complete Machine.—The Excelsior Extractor is the most complete machine of the kind that I have seen. It seems impossible to make one more perfect. I have been waiting to get one to suit me, and now I can exclaim "Eureka."—E. SECOR, Iowa.

Entirely Satisfied.—The goods reached me in five days; thanks for your usual promptness. I wish to express my entire satisfaction in all my dealings with you. The articles have been shipped promptly, and upon arrival proved to be as represented.—GUST. MURHARD, Oregon.

Gave Entire Satisfaction.—The goods you sent me were all first-class, and gave entire satisfaction. I would not part with the Conqueror smoker or the honey-knife, if I could not get others like them. Thanks for filling my order so promptly; this I find, by experience, is your way of doing business.—GEORGE W. HARRIS, Indiana.

My Best Friend.—I could use no more do without the AMERICAN BEE JOURNAL than without my meals. I have always regarded it as my best friend and adviser in the management of my 50 colonies of bees. I know of nothing that could be compared to it, unless it be the excellent four frame extractor, and other articles purchased from you for the proper conducting of our apiary. Thomas G. Newman & Son is, with us, synonymous of all that is staunch and good. The book, "Bees and Honey," has been, and will always be, our guide. It is our ambition to establish an apiary second to none in the State.—D. A. DIMITRY, Louisiana.

SUPPLIES FOR BEE-KEEPERS—For Sale by Thomas G. Newman & Son, Chicago, Ills.

Comb Foundation for Brood-Frames.

All our foundation is made by Dadant & Son, who have justly earned the reputation of making the best foundation in the world. We keep four sizes on hand, viz: 4 1/4 x 17, 12 x 18, 8 x 16 1/2, and 10 x 11, and can fill orders in any quantity, promptly. Orders for special sizes filled within a week of the receipt of the order, without extra charge, and it will be shipped direct from the factory.

Table listing foundation prices by size and quantity, including options for mail, postpaid, and express shipping.

Prices Subject to Change, Without Notice.

BEESWAX.—We pay the current market price for Beeswax, as quoted in the AMERICAN BEE JOURNAL, cash on arrival. The name of the shipper should be put on every box, to prevent mistakes.

Thin Foundation for Surplus Honey.

We keep three styles of thin foundation for comb honey in sections. The figures in the first column giving the prices of the THIN—9 to 10 square feet to the pound. Those in the last column being the prices of the EXTRA THIN, and also of the Van Deusen (with flat bottom)—11 to 12 square feet to the pound:

Table comparing prices for Thin and Extra Thin foundation across different weight ranges.

Wired Comb Foundation.

This prevents sagging, making all combs strong and durable. It has flat-bottomed cells, exceedingly thin and even, the wire being incorporated into it. It is for use only in the brood-chamber. Size, 8x6 1/2 and 10x11 inches.

Table listing prices for wired comb foundation in different quantities.

Comb Foundation Mills.

Table listing prices for different sizes of foundation mills (Pelham, Vandervort, Root).

Carlin Foundation Cutter.

Small size, with tin wheel, . . . 10c
Large size, with steel wheel, . . . 75c
When wanted by mail, add 2c. to the former and 5c to the latter price.

Bee Veils.

The accompanying illustration gives a good view of these veils as they are worn,—making it a complete face protection. Price, by mail, 50 cents.

Bee Veil.

Carlin Cutter.

YUCCA BRUSH.

For brushing bees from the combs. Price, 5 cents each, or 50 cents per dozen. Postage, 1c. each, extra.

SECTIONS FOR COMB HONEY.

We carry in stock a large assortment of sections of the various kinds; all being made for single combs. A sample of either style sent postpaid for 5 cents.

FORNCROOK ONE-PIECE SECTIONS.

These are made of basswood, and are all in one-piece with the V-groove. The backs of the grooves should be steamed or dampened with a sponge, to save breaking at the joints. These sections can be put into shape, ready for use, much faster than any other style, and have become the most popular sections now in use.

We keep constantly in stock the two regular sizes, 4 1/4 x 1 1/4 and 5 1/4 x 6 1/4, a trifle less than 2 inches wide, with both narrow and wide tops; these will respectively hold about one and two pounds of honey each. We also have them seven to the foot, with narrow tops. The following are our latest reduced prices:

Table listing prices for Forncrook sections in quantities of 1,000.

DOVETAILED SECTIONS.

These are made in four pieces, 5 1/4 x 6 1/4, with wide or narrow tops; all a shade less than 2 inches in width. The prices are the same as the one-piece sections.

We fill all orders with the regular sizes, and 2 inches in width, unless otherwise specified.

PRIZE SECTIONS, (TO BE NAILED).

These Sections are made only of one size, 5 1/4 x 6 1/4, suitable for 5x6 glass, if desired, and are a trifle less than 2 inches wide. The top pieces are grooved for foundation. Being made by machinery, they are accurately and smoothly cut, and when packed in the Prize Crate, are very desirable and attractive. We keep two styles of these sections—wide and narrow tops—at the following prices:

Table listing prices for Prize Sections with narrow or wide tops in various quantities.

ODD SIZES, of any style, 5x6 inches (or less), will be made to order in quantities not less than 500, and will cost \$3 for 500, or \$5.00 per 1,000, and can be furnished in about a week from the receipt of the order. They will be shipped direct from the factory.

WIRE NAILS.

We carry a full line of wire nails, and can fill orders for any quantity promptly. For nailing Sections, Cases, Frames, Racks, Crates, etc., they are very essential.

The entire length of the nail being the same thickness, they do not loosen like ordinary iron nails, and are not as liable to bend or break. They can be easily driven through two pieces of tin.

From the assortment of lengths given in the table below, any kind of nailing may be done, even to making large boxes.

Table listing prices for wire nails based on length, size of wire, and number in one lb.

If wanted by mail, add 18 cents per lb. for postage. We can furnish larger nails—up to 5 inches in length—when desired.

BARNES' FOOT-POWER SAWS.

Fifteen Different Machines.

WILL SEND MACHINES ON TRIAL IF DESIRED

A complete illustrated catalogue and price list of these machines will be mailed free, upon application.

SUPPLIES FOR BEE-KEEPERS—For Sale by Thomas G. Newman & Son, Chicago, Ills.

STANDARD LANGSTROTH BEE HIVE.

(14x18 3/8 inches inside.)

The dimensions of this hive, and the ten different styles made, are exactly the same as the Improved Langstroth Hive.

SAMPLE HIVES—Nailed, not painted.

- No. 1.—Brood chamber with portico, 10 frames, 7 1/2 inch cap, but no surplus arrangement.....\$1 25
- No. 2.—Same as No. 1, with the Comb Honey Rack complete.. 2 00
- No. 3.—Same as No. 2, with an additional story containing 10 extra frames for extracting, interchangeable with those in the brood chamber—a complete 3 story hive:..... 2 50
- No. 4.—Brood chamber with portico, 10 frames, and a 7 inch story, with 7 cases containing 21 Prize Boxes, and tin separators, for surplus honey, with a 2 inch cap..... 2 25
- No. 5.—Same as No. 4, with an additional story containing 10 extra frames for extracting, a complete 3 story hive..... 2 50
- No. 6.—A complete 2 story hive containing 20 interchangeable frames, with a close-fitting—2 inch—cap 1 75
- No. 7.—Same as No. 6, with the second story containing seven cases holding eight one-pound sections each (56 in all), and two tin separators attached to each case, complete.. 2 85
- No. 8.—A 3 story hive containing 20 interchangeable frames and seven cases, as described in No. 7..... 3 25
- No. 9.—Brood-chamber with portico, 10 frames, and Heddon's surplus arrangement, containing 32 one-pound sections.. 2 00
- No. 10.—Same as No. 9, with the surplus arrangement containing 24 two-pound sections..... 2 00

All Langstroth hives have metal rabbets for the frames to rest on.

IMPROVED LANGSTROTH BEE HIVE,

With Manipulating Side.

This is a combination of the North Star Hive, patented by Sperry & Chandler, of Minnesota, and the Standard Langstroth Hive.

SAMPLE HIVE—Nailed, not painted.

- No. 1.—Brood chamber with portico, 10 frames, 7 1/2 inch cap, but no surplus arrangement\$1 75
- No. 2.—Same as No. 1, with Comb Honey Rack, complete 2 50
- No. 3.—Same as No. 2, with an additional story containing 10 extra frames, for extracting, which are the same size as those in the brood chamber—a complete 3 story hive 3 25
- No. 4.—Brood chamber with portico, 10 frames, and a 7 inch story, with 7 cases and tin separators containing 21 Prize Boxes, with a close-fitting—2 inch—cap 2 75
- No. 5.—Same as No. 4, with an additional second story containing 10 interchangeable frames—a complete 3 story hive.. 3 25
- No. 6.—A complete two story hive with a close-fitting—2 inch—cap, containing 20 interchangeable frames, for extracting 2 25
- No. 7.—Two stories, containing 10 brood frames and 56 one-pound sections with separators, complete..... 3 25
- No. 8.—Three stories, with 20 frames and 7 cases containing 56 one-pound sections, (the same as No. 7), complete..... 3 75
- No. 9.—Brood-chamber with portico, 10 frames, and Heddon's surplus arrangement containing 32 one-pound sections... 2 50
- No. 10.—Same as No. 9, with the surplus arrangement containing 24 two-pound sections..... 2 50

Parties ordering Material for Langstroth Hives should always order a sample nailed hive, as a pattern for nailing.

MATERIAL FOR LANGSTROTH HIVES—in the Flat, Ready to Nail.

The top and bottom boards, on all the Hives, are in one piece.

We make Hives Nos. 4 and 5 to contain 28 one-pound sections, at the same prices, when so ordered.

SECTION PRESS.

WE are now prepared to furnish Wakeman & Crocker's **PRESS** for putting together **One-Piece Sections**—at wholesale and retail. Price, \$2.50, by express. By the dozen—rate given upon application.

Wiring Tool,
FOR
Pressing Foundation
INTO
WIRED FRAMES.
SOMETHING
ENTIRELY NEW.

Price, by mail, 20c.
By express, 15c.

**PARKER'S
Foundation Fastener**

Price, 25 cents, by express, or 40 cents, post-paid. Suitable for 1 lb. sections.

The fastener should be screwed to a table. The illustration will show the position of the section and foundation, and the method of operating.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. March 28, 1888. No. 13.

EDITORIAL BUZZINGS.

Soon the Bees will gaily hover,
O'er the fields of blooming clover;
Searching for the sweets there yielding,
When caressed by love's gay rover.

Have you heard the jolly varlet?
Scarlet-breasted, piping clear,
Robin's sure that earth is waking,
Shaking sloth, and Spring is near!

The gentle showers soon will come,
From more genial Southern skies,
On the barren hillsides falling,
And bid the flowers to "Arise!"

Statistics.—In offering his service as a reporter of bee-keepers' statistics for Yates County, N. Y., Mr. A. F. Robson remarks as follows:

I am interested in this matter, as I own 200 colonies, and I think that this is the method. The plan of gathering the statistics by the assessors will not work in this (N. Y.) State, for personal property is exempt to the amount of one's debts, and so in most cases no questions are asked.

It is very difficult to mention any method which will be suitable to such a vast country as America.

We Regret to learn that Mr. A. Pinkerton, of Marshalltown, Iowa, was thrown from a load of wood some six weeks ago, and dislocated his shoulder, as well as injuring his neck. He is getting better now, but it was a great affliction for the family—his wife having been afflicted with dropsy for several years. His report concerning the wintering of his bees, is as follows, and is dated March 22, 1888:

My 122 colonies of bees are all very quiet in the cellar. The mercury stood at 41° this morning, in the cellar, and has stood at from 40° to 42° all the winter, except one cool morning when it got down to 37° for a short time. My bees have been very quiet, so I think they are doing well.

It Ought to Have a hundred thousand subscribers! This is what Dr. A. B. Mason says of the AMERICAN BEE JOURNAL. It could have them very easily if its many friends would exert their influence for it! We have done and are doing all we can to make it of permanent value to all the bee-keepers in America, and the more subscribers it has, the more it can do for the pursuit. Will our friends kindly induce their acquaintances who keep bees to send in their subscriptions? The Doctor says:

I do not want to praise it too much, but I must say that the AMERICAN BEE JOURNAL is "just a dandy!" It ought to have 100,000 subscribers. If any other bee-paper is worth \$1.00, what is the AMERICAN BEE JOURNAL worth?

It looks up at me, when I take the wrapper off, with a bright, clean face; eyes wide open and intelligent. I am just in love with it, and I do enjoy speaking well of my friends when they do a good thing.

As an inducement to our friends to enlarge the number of our readers, we will present a copy of the "Bee-Keepers' Convention Hand-Book," by mail, post-paid, to any present subscriber who will send to this office two new subscribers, with \$2.00. Remember you must *claim* the book when sending the subscriptions. It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By Laws for a Local Society—Programme for a Convention, with subjects for discussion—List of Premiums for Fairs, etc., etc. It is a valuable assistant to every bee-keeper.

To Clarify Beeswax.—Major A. Shallard, of Glenbrook, New South Wales, Australia, asks the following question: "What is the best way to clarify or clean cakes of dark wax and second quality wax?"

Melting the beeswax in a kettle of clean, hot water will do it. The dirt will separate from the wax and go to the bottom, leaving the wax to "cake" on the top of the cooling water. This will also improve the color of the wax.

Any clean, bright tin-pan will do to put it in, if it *flares* at the top. An iron vessel will generally spoil melted wax when put into it.

Ignorant Bee-Keepers.—E. Israel, of Oak Lawn, Miss., on March 20, 1888, writes us as follows on the average intelligence of the bee-keepers in his neighborhood:

There are 20 bee-keepers in this county, and only myself and one more keep bees for the money there is in them. Three others have frame hives, but they would be better off with box-hives; they do not keep them for pleasure either; they put them into the fence corners, on the ground, or on a box, and expect them to "work for nothing and board themselves," and then complain of getting no honey. Moths consume them, and weeds and briars hide them so that you could not get to them if you wanted to. You could hardly expect such bee-keepers to give the assessor any information, when it would look like taxing an agricultural product.

The Use of Big Words.—Mr. G. B. Sanborn, of Bristol, Vt., writes as follows concerning the use of big words:

I have just commenced in apiculture, and am deeply interested in it, but I find that the writers in this science, as in all others, use too many big words. The uneducated apiarist is unable to comprehend them. Therefore the prolixity of the stratagem might prove detrimental to the cause, as it would keep them assiduous so much of the time trying to excogitate and discriminate the promiscuous magniloquence. So do not be quite so profuse with your *big words*!

Let your conversational communication possess a clarified conciseness, a compacted comprehensibleness, coalescent consistency, and a concatenated cogency. In promulgating your esoteric cogitation, or articulating your superficial sentimentalities and amicable, philosophical or psychological observations, beware of platitudinous ponderosity. Eschew all conglomerations of flutulent garrulity, jejune babblement and asinine affections; and *do not use big words*!

Let your extemporaneous descantings and unpremeditated expatiations have intelligibility and veracious vivacity, without rhodomontade or thrasonical bombast—and *do not use big words*!

Sedulously avoid all polysyllabic profundity, pompous prolixity, psittacous vacuity, ventriloquial verbosity, and vanilloquent rapidity!

E. H. Cook, in the September number of the *Bee Hive*, on page 89, proposes that extracted honey be obliterated from the English language, substituting "abxeszioimdyfnyvqetjtgk honey" in its place.

Just see the prolixity of that word. I should like to know the ponderosity of that honey, viz: How many ounces would it take to make a pound?

This letter reminds us of a good story which is told of a public lecturer. It is this: One of his audience addressed him thus: "Mr. Lecturer!—Several times during the evening you have used the word periphrasis. Would you kindly inform me of its precise meaning?" "Certainly," said he, "it is simply a circumlocutory pleonastic circle of oratorical sonorosity circumscribing an atom of ideality lost in verbal profundity." We therefore can sympathize with Mr. Sanborn, and also say: *Do not use big words*!

State Statistics on Honey. are in the future to be had in Illinois. We wrote to the Secretary of the Illinois State Board of Agriculture to ask why there was no such statistical information given since 1883, and the following is his reply:

SPRINGFIELD, ILLS., March 17, 1888.

THOMAS G. NEWMAN, Esq.—*Dear Sir*:—Yours of late date is received. Each assessor in the State will in the future collect information annually in May, concerning the number of colonies of bees in each township in the State, as well as the number of pounds of honey produced therein.

The information sent you (1883) is the latest data on the subject, published by this office.

Yours truly,

CHARLES MILLS.

We have also received one of the new blanks, but we fear the information obtained in May of 1888, as to the number of colonies of bees in the year 1888, and the number of pounds of honey produced in 1887, will be quite useless for all practical purposes.

GLEAMS OF NEWS.

Prof. Wiley has again "put his foot in it," when giving the Senate committee on agriculture the result of his microscopic examinations of the various samples of lard submitted to him. He stated that lard made by Armour & Co., and branded "pure refined family lard," contained cotton-seed oil and stearine.

A sample of lard manufactured by Whitaker & Sons, branded "pure unadulterated, honest refined lard," contained no cotton-seed, while a sample manufactured by the same firm, branded "adulterated refined lard," contained cotton-seed oil. He had rendered the head, entrails, and intestines of the hog, and found them to make a pure lard that could not be distinguished from other lard. Leaf lard had a little less color.

Upon being questioned further on the quality of the lard obtained, the daily papers give these questions by the committee, and answers by Prof. Wiley:

Prof. Wiley said he did not think there was any way of distinguishing dead hog-grease from pure lard. The way the hog died had no effect upon the lard.

Senator Blair—These lards made from the intestines are as good as any?

Prof. Wiley—I had just as soon eat compound lard as pure lard.

Senator Blair—Do you eat dead hog lard?

Prof. Wiley—I presume I do. It is just as good as any other. I would as lief eat it.

The chairman—It is charged that manufacturers of lard take dead hogs and throw them in, entrails, hair, and heads, and white grease is rendered from them. Would that be noxious?

Prof. Wiley—I think not. There is nothing deleterious in decomposed animals.

This opinion of the *wily* professor is so disgusting to every honest man that the daily papers are administering to him a severe rebuke for such charlatany. The *Chicago Times* remarks as follows:

It is pleasant to be informed by Prof. Wiley, Chemist of the Department of Agriculture, that there is no way of distinguishing dead-hog grease from pure lard, and that the way the hog dies has no effect upon the lard. In that case, success to the adulterators. There cannot be too little hog's grease or too much cotton-seed oil and stearine in what is eaten as lard.

This is the same "skunk" who deliberately and wilfully endeavored to ruin the production and sale of "pure honey in the comb," by inventing his *lie* about the manufacture of combs out of paraffine, filling them with glucose, sealing them up with hot irons, and selling such as pure honey.

His work is all in the interest of *adulterators*—paving the way for their fraudulent products, and then covering them with the mantle of the United States National Chemist—saying that the abominable death-dealing, filthy and fraudulent production is just as good as the pure article!

Such nefarious schemes put to blush the honest and honorable—deceives our Governors and legislators, destroys honest commerce in healthy products, and fills the mouths of *clergymen* in other lands with

wonderful stories about adulterating bee-farms and the like, which exist only in the imagination of these would-be sight-seers!

This *wily* scamp and his followers are doing more damage to morals and honest dealing, than all other influences combined.

Seasonable Truths.—In her inevitable style, Mrs. L. Harrison crowds into one short paragraph in the *Prairie Farmer*, all these *hints* on important subjects for the present season:

Bee-keepers have been under a cloud the past year, but it is lifting, and clear sky appears. According to reports from all points North and West, bees have wintered well. The colonies out-doors have had frequent flights; those in the cellar are healthy, and the outlook is good. It is refreshing during these freezing nights and chilly days (March 13) to read of bees swarming and gathering honey in Florida and Louisiana. The blue-birds made a mistake this year, and returned to this locality too soon. Those who have bees in the cellar, should not be in a hurry to put them upon the summer stands, but let them remain until danger of freezing weather is past. Such a thing as a bee-keeper regretting that he did not remove his bees from the cellar earlier, has never been heard of, but the opposite has. If the bees are uneasy, give them a drink, and they will quiet down; sweep up the dead bees, and give the others fresh air, but let them remain.

Crop Reports.—Mr. Caleb L. Sweet gives us a "Prime" thought on obtaining reliable statistics. He says:

As you request correspondents to suggest plans for gathering statistics, let me state that Mr. Samuel T. K. Prime, of Livingston, Ills., is running one of the greatest bureaus of private "crop reports" in the world. I do not know how many correspondents he has in the United States and Canada, but my number is 1212. Correspondents get their circulars once a month, which is a summary of the correspondents' reports for their labor. Dealers, I suppose, pay him. He might take hold of this for the honey producers, and ask his reporters the questions desired. Under this plan the producers and dealers could have the reports by paying for them, while the consumers would not, to any great extent, be informed.

We have commenced a correspondence with Mr. Prime, to ascertain whether such an arrangement as that suggested by Mr. Sweet could be made at the terms upon which it could be consummated. As soon as we receive anything definite, we will inform our readers most fully. We are making progress, and hope to evolve something of great value to bee-keepers.

Mr. Geo. E. Hilton has had the second thousand of his pamphlet on the production of comb honey, printed at the office of *Gleanings*, and it is needless to say that the printing is a grand improvement on the former thousand, which was evidently done where they had no facilities for such work, and no experience in doing it. It is a great mistake to have books or pamphlets printed in such places. "Botch work" is all that can be expected in such cases, and all that is ever realized.

Entrance Controller.—Mr. A. C. Tyrrel, of Madison, Nebr., has sent us a contrivance for controlling the entrance of hives, by enlarging or ensmalling it. It consists of a bent piece of zinc with four holes, having another piece with three of such corresponding holes, which can be slid along, and thus make the entrance of any size desired. Mr. Tyrrel thus describes it:

I use the device on my hives to prevent robbing and swarming, and it is a drone-excluder. To open, push the slide one space to the right. This will allow the worker-bees free egress and ingress, and prevent queens from emerging. This latter is to be used in case it is necessary to be absent for a time from the apiary during the swarming season. To leave but one beespace, in case a colony is being robbed, push the slide one space to the right, if the spaces are already open; if closed, two spaces to the right.

When extracting or taking comb honey, if robbers are a source of annoyance, every hive can be closed quickly and effectively by simply pushing the slide so as to close all the open spaces. If the weather is hot, leave a half or quarter space open for ventilation.

The device is placed in front of the entrance to my hives. It has eleven spaces, but any length can be made to correspond with the hive used. A wire nail put through the upper right hand corner, allows it to swing to its place, perpendicularly with the edge of the hive, when not in use, and fastened with a small tack; which, when taken out, lets it drop to its place in front of the entrance, and it is ready for use.

It is desired to diminish the number of drones, or save the best for breeding purposes, after they leave the hive for a flight, drop the trap to the front of the entrance, and open the spaces. The workers can go in and out, but drones cannot get back.

I find this device much better than blocks I have used heretofore, for it is always at hand. It works like a charm.

Statistics at Conventions.—Mr. D. A. Fuller, of Cherry Valley, Ills., makes the following inquiry:

Why cannot the desired statistics be gathered at the bee-conventions better than any where else, by the use of cards?

As not one in fifty bee-keepers ever attend bee-conventions, taking reports from members who attend them, would be totally inadequate for statistics of the industry. To be of any value, statistics must include all the product of honey and beeswax, as well as the number of colonies of bees.

One of Our European subscribers, who is an Episcopal clergyman as well as an apiarist, desires to locate somewhere in North America, where he could in addition to pastoral duties devote his time to bee-keeping. If any one knows of such a combination, offering a permanence, he may address this office, and we will communicate with the clergyman.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the *Apiary Register* and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

Ekes and Nadirs.—Many of our readers will wonder what is the meaning of "ekes," as mentioned by Mr. Dadant on page 199. An "eke" is a small additional story (generally a half-story) placed under a hive to add to its capacity. A "nadir" is a whole additional story placed under the brood-chamber for the same purpose.

These contrivances are used in Europe, and the following from the *British Bee Journal* will give more descriptive information concerning them, and their uses :

NADRING.—Nadirs or nethers are vessels of wood or straw, or a compound of both, or a compound of both with glass, to be placed beneath a stock hive, either for the purpose of increasing the breeding space or providing storage room for honey. A nadir for a straw skep would be exactly similar to about 4 inches of the lowest part of the skep itself, supposing it to be cut off evenly; it is, however, made separately, and usually in the form of a straw ring of the same diameter as the skep, and when placed under the latter their junction is luted with a mixture of cowdung and clay, which form a hard cement, impervious to insects. The

sometimes called "raises;" and when hives are said to have been raised, it is implied that a nadir or an eke, or both, have been placed below the stock-hive.

These "ekes" and "nadirs" bear no relation to a brood-chamber that is divisible, and should not be confounded therewith.

Both large and small hives have their friends and admirers, but we cannot now give space to a prolonged discussion of these points. An article or two on each side will serve to show that this question, like many others, has two sides—and like our wives and babies, each of us think ours the best. This thought is both pleasant and pardonable in us all.

A Section containing a piece of thin comb foundation fastened to the top-bar came to our desk in a tin box, but it was all broken down. It is marked on the wrapper: From R. Barlow, Toledo, O.

Apiary of Mr. J. H. Robertson, Pewamo, Mich.

rim of an old barrow-wheel is often called into service as a nadir, and sometimes a simple wooden hoop is used.

With bar-frame hives shallow boxes are used of about half the depth of the stock hive, and fitted with frames to correspond. In ordinary box-hives similar shallow boxes are used without frames—the object being simply (as in the other cases) to increase the depth of the stock hive. In all hives where nadirs are used as above, the entrances should be kept in their original positions, *i. e.*, on the floor-boards, the nadir being intermediary between it and the stock hive. When nadirs are used as receptacles for honey, means are usually adopted to prevent the queen and drones from gaining access thereto, which is generally effected by interposing a slotted board or adapter, which will admit the workers only; and in that case the entrance to the hive must be on a level with the top of the nadir, so that the bees shall go down into it. There should, however, be a way out of the nadir at its lowest part, or the bees, finding it easier to get into than out of the slotted gateway, may become over-crowded and perish of suffocation.

Ekes are also used for enlarging a stock-hive, and sometimes for increasing the size of a super. Like the nadirs they are placed beneath, to increase the depth of the hive or super, but are much shallower than the so-called nadirs. Both nadirs and ekes are

Fungus and Foul Brood.—Mr. G. Wendelken, of Marietta, O., remarks thus about once having had foul brood in his apiary, and asks the following questions :

"How to cure foul brood" is a subject which interests me. All writers say that bacteria has some connection with foul brood. If these parasites really cause that disease, it is important to know their nature, how they are produced, and how to destroy them. I would like to have the following questions answered in the *BEE JOURNAL*:

1. Why is fungus sometimes called a plant and sometimes a living being?
2. Are the bacteria of foul brood plants or living beings?

Knowing that this was in the line of study of Mr. N. W. McLain, Manager of the United States Government Apicultural Station for Illinois, we sent the questions to him for consideration, and here is his reply :

1. Webster defines fungus as "a term applied by botanists to a large natural order of plants of a peculiar organization and manner of growth, comprehending mushrooms, toadstools, the microscopic plants which form mold, mildew, smut, etc.," and the term "being" he defines in the sense in which it is used in the query, as "an ani-

mal, any living creature; as, animals are such beings as are endowed with sensitive and spontaneous motion."

Accepting this definition of terms it would not be proper to speak of fungus, "an order of plants," as "a living being."

2. The disease known as the foul brood disease, is due to the presence of minute vegetable organisms, of the order of plants to which the term fungus is applied, growing and multiplying within the animal or living being.

Bacillus is the term applied to that genus of fungi which multiply in the larvae and adult organisms of bees.

These micro-organisms multiply by fission or division. Under congenial conditions they multiply with astonishing rapidity.

The germs of fungi may be speedily destroyed, and the growth of bacillus in larvae and bees, arrested by the use of suitable remedies.

We recommend the study of the pamphlet on "Foul Brood," by Mr. Cheshire, which can be had for a dime at this office.

Against Nature.—Many an argument is based on this remark, and the *Review* remarks thus concerning it :

"Not according to Nature." How often we hear this used as an argument against some method; those using it forgetting that it is not always to our advantage to allow Nature to have her own way. Almost the whole system of modern bee-culture is an innovation upon nature, and we ought no longer to ask, is it according to nature, but, all things considered, is it best?

The *Indiana Farmer* makes this additional comment upon the matter :

Here is a simple illustration carrying this point still further. We once introduced an Italian queen into a queenless colony, and within a day after being let out of the cage, and before she had laid any eggs, the bees swarmed and were put in a new hive, and the parent colony given a frame of brood from which they reared a queen. Now it would have been "according to nature" to have left the colony queenless both before and after it swarmed, and allowed them to dwindle away. Disregarding this old fogy whim, keeping them in movable-comb hives and handling them by an intelligent and progressive system, saved the bees. This is as far as we use the according-to-nature argument; of two methods, equally good, take that which most nearly conforms to the natural instincts of the bees.

New Catalogues for 1888 are on our desk, from the following persons:

W. E. Clark, Oriskany, N. Y.—24 pages—Bees, Queens, and Apiarian Supplies.

H. H. Brown, Light Street, Pa.—20 pages—Queens, Bees, and Supplies for Bee-Keepers.

M. E. Phelps & Co., Binghamton, N. Y.—8 quarto pages—Poultry.

S. W. Morrison, M. D., Oxford, Pa.—1 page—Carniolan Queens.

Berlin Fruit-Box Co., Berlin Heights, Erie Co., O.—32 pages—Berry Packages and Apiarian Supplies.

F. R. Pierson, Tarrytown, N. Y.—100 pages—Seeds and Plants.

C. W. Costellow, Waterboro, Maine—12 pages—Apiarian Supplies.

Thos. S. Wallace, Clayton, Ills.—4 pages—Italian Queens, Bees and Houey.

Scatter the Leaflets.—Look at the list (with prices) on the second page.

QUERIES AND REPLIES.

MANAGEMENT TO PREVENT INCREASE.

Written for the American Bee Journal

Query 527.—How would it do, when you desire no increase, to let the bees swarm naturally and then hive them on the old stand, placing the old colony close by, and at night or the next day open the hives of the old colonies and shake all of the bees off the combs in front of the new colony, letting them run in, thus giving the new colony a large force of workers? Then take the combs of brood and give them to weak colonies. You would then have some nice queen-cells to give to others in place of old queens, as it is said that queens reared by natural swarming are best. —Miss.

It will do.—DADANT & SON.

It will do very well.—A. B. MASON.

It would probably do very well.—C. C. MILLER.

It would do excellently, so long as your weak colonies held out.—R. L. TAYLOR.

In case you do not desire much increase, it will do very well.—J. P. H. BROWN.

It would be very fair practice if well executed; but you would have to dispose of your old queens first, before giving the colony a queen-cell.—MRS. L. HARRISON.

I hardly think that the plan would work well, as the weak colony would be likely to swarm in a week or two after the brood was given them. Otherwise it probably would work all right.—G. M. DOOLITTLE.

Yes, that is a very good plan as long as you have any weak colonies to build up. When all are strong and determined to swarm, what then?—C. H. DIBBERN.

This is almost too large a subject for so short a space. That might work very well if you always had weak colonies. But it seems to me that I should prefer increase from the colony strong enough to swarm, rather than try and doctor up a weak one.—EUGENE SECOR.

The plan I think will work, but should the honey-flow continue, they may swarm again as soon as queen-cells can be started. You can keep down the swarming impulse in a great measure by giving plenty of surplus room for the bees to store honey in.—J. M. HAMBAUGH.

Your plan will do, but why not shake the bees from the old hive at once, if the swarm is in a hive supplied only with empty frames of wired foundation, and add a surplus story or crate of sections? It is a risky business to give queen-cells in place of old queens.—P. L. VIALON.

I see no objection to this plan, but why not permit one swarm? It will doubtless produce more honey, if the colonies are all wintered well, and cared for in the spring.—A. J. COOK.

Try your plan with a few colonies, and see how you like it. Why not shake all off at the time of hiving, and have it done with, and not wait until night or the next day?—H. D. CUTTING.

Try it and see. It would be far easier for myself to return the swarm at once. Why not try instead some of the tested plans for non-increase, that have been given from time to time in the bee-papers during the past years? —J. E. POND.

A better way would be to return the bees and remove the old queen, and in five or six days destroy all queen-cells but one; or, better still, destroy all queen-cells, and give the bees a young laying queen. In the meantime, give plenty of room and plenty of ventilation.—M. MAHIN.

Your plan will work well enough, but it necessarily leaves the old queens on hand to intensify the swarming fever the rest of the season, and certainly the next season. I prefer my depletion system, which results in preserving the old colony with a vigorous young queen, and exhausts the swarm in storing surplus honey. Of course I mean when it is desirable to suppress increase.—G. W. DEMAREE.

Hiving all the bees of a colony into a new hive on the old stand after swarming, is good practice with a contracted brood-chamber in working for comb honey. But the uniting of the bees should be done as soon after swarming as possible. I had one colony to kill a large number of bees from this operation, put off till the next day.—G. L. TINKER.

This query answers itself, and sets forth an excellent method. The suggestion about the care of queen-cells, and superseding poor queens with those that promise well, is a good one. If the honey-producer does not rear and test his own queens, he goes into the harvest with no correct idea of the efficiency of his forces.—J. M. SHUCK.

It would be good, when you thus have use for the brood in the old colonies. If the weak colonies to which you give the combs of brood, are very weak, do not break up the parent colony until you fear the queen-cells will be hatching. I have practiced this many times, when I could use the brood to better advantage than to make increase. This is coming down to practical bee-keeping in harmony with the prevailing prices of honey. Go on, and soon you will want a hive different from the Langstroth.—JAMES HEDDON.

After disposing of the old queen, it might do to give the colony a queen-cell and carry out the plan proposed, but there are many better methods to pursue, but there is not space enough in this department to give the details.—THE EDITOR.

WIRED FRAMES WITH COMB FOUNDATION.

Written for the American Bee Journal

Query 528.—1. In using frames with starters and full sheets of foundation, would you advise using wired frames? 2. If so, how should they be wired?—S.

1. No.—G. L. TINKER.

1. For most people, I would. 2. Diagonally.—MRS. L. HARRISON.

I have used very few wired frames so far, but I shall try more the coming season.—G. M. DOOLITTLE.

1. By all means. 2. I use vertical wires, about 2 inches apart.—C. C. MILLER.

I have no use for wired frames, if good foundation is used, and it is well secured.—J. P. H. BROWN.

When we use wires at all, we use 2 or 3 horizontally. We do not believe in excessive wiring.—DADANT & SON.

1. Yes, every time. 2. I use about 3 or 4 wires equal distances, parallel with the frame.—J. M. HAMBAUGH.

I do not use the wired frames, as I have no difficulty in getting nice, straight combs without them.—C. H. DIBBERN.

1. Yes. 2. I put 8 wires (No. 36, tinned) up and down in a Langstroth frame; the end ones about an inch from the ends of the frame. I use a Given press, to put in the foundation.—A. B. MASON.

1. No. Certainly not when using starters. If you have the skill to have good, straight combs drawn from foundation without wires, you will like them better than any wired combs.—G. W. DEMAREE.

1. Always and invariably in both cases. 2. Put wires from the top to the bottom-bar about 3 inches apart, with diagonal wires on Langstroth frames, running from the ends of the top-bar to the centre of the bottom-bar.—J. E. POND.

1. If starters only are used, I see no necessity of wire. If full sheets are used, they are an advantage. 2. Perpendicularly, from 2½ to 3 inches apart.—EUGENE SECOR.

1. I do not think that I should, with starters; but I would with full sheets of foundation. 2. I wire the frames up and down, having the end wire within an inch of the frame end-bar.—A. J. COOK.

1. With starters, no; with full sheets, yes. 2. That depends upon the size and shape of the frame. A wire stretcher from the upper corners to the centre of the bottom-bar of the frame, will be sufficient with heavy foundation.—M. MAHIN.

I would advise wires always with full sheets, but not with guides. Narrow guides are better than wide ones; 3 or 4 cells wide is best.—JAMES HEDDON.

1. Yes, use 5 or 6 vertical wires to the Langstroth frame. 2. Sow them back and forth through the top and bottom bars, and draw them just tight enough to hold them straight.—J. M. SHUCK.

1. Invariably with full sheets of foundation. I would also use the wired frames with starters, but have them built between two straight combs. I have had many combs built on wire with only starters, but the building of too many drone-cells is an objection. 2. I use 6 wires running from top to bottom, and also diagonal wires and a tin bar in the centre.—PAUL L. VIAL-LON.

1. I would, if I had time to wire them, especially for extracted honey. 2. I have used frames wired horizontally, and also perpendicularly, and can see no difference. Last season I wired nearly all of my frames horizontally, with three wires.—H. D. CUTTING.

1. Yes. 2. With perpendicular wires about 2 inches apart, the outside ones being within $\frac{1}{2}$ an inch of the end-bars. Then if there is danger of the top-bar sagging, the wire should be continued from one of the upper corners down diagonally through the middle of the bottom-bar, and from that point up diagonally to the other upper corner; then a piece of folded tin should be sprung in at the middle of the top and bottom-bars, to keep them the right distance apart.—R. L. TAYLOR.

1. We certainly should not advise wiring frames when starters are used. When using full sheets of foundation there is some excuse for wires, but even then, in ordinary cases wiring is not so necessary as some imagine. 2. Wiring should be done from the top-bar to the bottom-bar, about 2 inches apart, with diagonal wire supports.—THE EDITOR.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

CORRESPONDENCE.

BROOD-COMBS.

Large Combs vs. Divisible Brood-Combs.

Written for the American Bee Journal
BY J. M. HAMBAUGH.

On page 37 of the AMERICAN BEE JOURNAL for 1886, from the pen of Rev. W. F. Clarke, will be found the following:

"The idea of manipulating hives instead of frames, though it may seem very simple to some, and superficial thinkers may hastily conclude that there is nothing in it, is *just going to revolutionize bee-keeping*, and 'don't you forget it,' Mr. Pooh-pooh, whoever you are."

The same writer on page 135, of the same volume, in speaking of the new Heddon hive, says: "That a new revolution is upon us, becomes daily more evident; no power can check it, and the sooner we fall into line, the less we have to unlearn."

A little further down the column he continues: "That the new hive will gradually supersede all others, and become the 'standard of excellence,' is one of the inevitables to which Mr. Demaree will have to bow with the best grace he can command." Still further on he says:

"This is what I want, and all I want. It is 'long-looked-for come at last.' I have dreamed of a hive like this, and the reality surpasses the dream. It will henceforth be a luxury to keep bees. The hard, slavish work is all taken out of the business, and what remains is mostly pastime. The danger now is that bees and bee-keeping will become too common. Everybody will want to rush into a business so inviting. But little honey will 'waste its sweetness on the desert air,' in the 'good time coming,' etc."

Was ever a hive so lauded at its birth, before its swaddling clothes were fairly donned? Its praises were echoed, long and loud, all over this broad land; and such undeveloped "boys" as the Dadants and myself could but hold their breath with wonder and astonishment to see how like a veritable cyclone it would sweep all other hives from the face of the earth.

Two or three years have passed since the birth of Mr. Heddon's cyclone hive, and noticing the reticence of those whom we expected to astonish the world with their wonderful achievements in the apicultural art, I framed my article on page 804 of the AMERICAN BEE JOURNAL for 1887, thinking

that I would develop something *pro or con*, with the result of Mr. Heddon's article on page 107 of the current volume. My article was intended to bring out the result in plain figures of disinterested parties, who have used all kinds of movable frame, and divisible brood-chamber hives, that a discriminating public might see which are the most profitable to the honey-producers; and now I ask that these important facts be given, and from disinterested parties.

The reader should turn to page 86, and read Dr. G. L. Tinker's essay on "The sectional brood-chamber, and its advantages." In a former article I have fully refuted Mr. Cullinan's theoretical etchings. I am by no means prejudiced, and stand open to conviction, but the means thereto must emanate from disinterested parties, who can show in black and white the profits of the divisible brood-chamber to exceed those of any other hive. Let us have light.

I have just received the following letter from Mr. Charles Dadant, which is too good to be concealed, and which will speak for itself:

FRIEND HAMBAUGH: What do you think of the article of our friend Heddon, about the large combs? We are *mere boys* since we are not able to see the advantages of his invention of the divisible brood-chamber, while such *full grown men* as Mr. Heddon and *his students* prefer it.

Some two or three years ago I wrote in the AMERICAN BEE JOURNAL that divisible brood-chambers were used about 250 years ago, by Butler, who, in his "Feminine Monarchy," shows hives composed of three ekes.

I know of at least twelve French writers who described eke hives, one of them, Radonau, in his Manual, published in 1821 (67 years ago), advised the use of well distanced triangular bars above each eke. In 1845 (43 years ago), Chas. Soria, in his "Notice sur la Ruche a Espacement," (space hive) advised to fix these bars above and below every eke, so as to leave a *bee-space* between them. Of course a great many hives were made on these indications. But soon after it was discovered that these bars, hindering the queen, decreased the crop; so L'Abbe Collin, in his *Guide*, published thirty years ago, advised not to place so many bars, and to use a wire to cut the combs before removing the ekes.

Mr. Hamet, for 32 years editor of the journal *L'Apiculteur* in his *Cours L'Apiculture*, advises to manage a four inch square hole in the middle of these bars, not to so much hinder the bees. Mr. Vignole also, in his book, "La Ruche," advises to use large

combs and roomy hives to increase the crop.

Such ideas are not exclusive to French bee-keepers. The brood-chambers of the standard German hive (*Normalmaas*) is divided in two stories. Mr. Regnier, of Saarlouis, after experimenting comparatively his German hive with the Quinby enlarged, known in Europe as the Quinby-Dadant hive, wrote in the *Revue Internationals L'Apiculture*, that his crop in German hives averaged 22 pounds, while his Dadant-Quinby's averaged 51 pounds (page 259).

In the same number, 318, 1887, page 255, the editor, Mr. Bertrand says: "Some of my neighbors, finding these large Dadant hives even too small, have enlarged them to 13 frames instead of 11, and I have seen some of them filled with bees and honey, together with two half-stories, the whole holding about 120 quarts, inside the frames, all from the same queen."

In the February, 1888, number of the Italian bee-paper, *L'Apicoltore*, page 61, a Mr. Giuseppe Bianchi, says that his Italian (German) hives averaged 67 pounds of honey, and his large *Americana* gave him 264 pounds.

If you desire it, I may give you the opinion as given in the bee-papers of Europe, of one hundred bee-keepers of France, Switzerland, Italy, Germany and Spain, who, after comparative experiments, have adopted the large and indivisible frames.

Had Mr. Heddon experimented seriously, before pronouncing his judgment, he would have added one more vote to the disinterested verdict, in favor of the enlarged Quinby hive, with suspended frames, *a la Langstroth*.

CHAS. DADANT.

[See comments on page 197.—ED.]

FOUL BROOD.

A Method for Eradicating it from the Apiary.

Written for the *American Bee Journal*
BY SAMUEL BARNHART.

I had 12 colonies last spring, 10 of them being badly affected with foul brood, and the other 2 were not affected at all. My best colonies instead of getting stronger in May, as they should have done, were getting weaker every day. I concluded that they might be affected with foul brood; so I went to see a bee-keeper who has over 50 colonies, and who knows what foul brood is, for his bees had it a year or two before; he pronounced it foul brood of the worst type.

My best colonies had not over two quarts of bees, so I made rough boxes and put the bees into them. Some

were put in the cooling room, and some were left on the stands for three days. I boiled the boxes for five or ten minutes, and scalded the bee-house and cleaned it effectually.

On the third day I put them in the same boxes with new frames and full sheets of foundation, using 6 frames instead of 8, and putting in two side-pieces instead of frames. I saved the combs that had any brood worth mentioning, filled a few boxes, and put a few bees with them to hatch out the brood; then I carried them to a neighbor. After they were all hatched out, I treated them the same way.

This was after the middle of May. I treated 3 colonies for a neighbor in the same way, but I did not save any of the brood, there being none to save.

I destroyed the combs, boxes and all. They were in common boxes. Two days after, I put them into new hives, partly filled with foundation. They have done very well, and have had no foul brood since.

I sometimes fear that my bees may have it next summer, as I know of one lot of bees that I am almost certain is affected; but the owner will do nothing with them.

I hived a swarm on nice, clean foundation combs (some only partly drawn out), which I saved. They were too nice to melt up. There had been no brood reared in them. I fumigated them three or four times effectually (almost melted them) with sulphur. I afterwards divided that colony, and they are both strong to-day.

There were 2 colonies not so bad as the rest, I left, thinking that they might get along, but they got worse. I then put the combs that contained any brood worth while, in a clean box, with a few bees, and left them, and they are there yet, and as good as any I have to-day. They were without a queen for fully five weeks; consequently they reared no brood. They lost their first queen; afterwards I gave them two frames with brood, and they now have one of the nicest and best Italian queens, and is one of the strongest colonies I have. Last fall there was no foul brood about them, and they had just as nice, solid sheets of sound brood as I ever saw.

I was born and reared among bees, and could always do just what I saw any other person do. My father used to have about 100 colonies, and any quantity of honey. In 1854 he had 60 colonies in the fall, but had only 10 colonies left in the spring. In 1857 he had 37 colonies. He died that winter, and the bees were nearly all sold at auction. I had then too much to do on the farm, and neglected the bees, but I have never been altogether without bees or honey.

A few years ago I made frame hives and transferred my bees to them, but I became too greedy for increase, and lost them through the winter. I have never used gloves or a bee-hat in either transferring, or in working with bees in any other way. I have a bee-house 18 feet long and 5 feet wide, placed on locust posts close to the ground. The front I have divided into five spaces, and in each space I keep 2 colonies. Those on the upper tier appear to do equally as well as the lower ones. There is a passage-way in the rear 2½ feet wide. It is lined, and has 4 inches of sawdust filled in.

In the winter I pack with straw between and on top of the hives, and also the passage. I have shutters to fit the spaces in front, making it completely dark. They have wintered well in it so far. I can easily keep them from flying, if the weather is unfavorable. I increased my apiary till I had 22 colonies, 14 of which are in the bee-house, and 8 in the cellar. I can see no difference in there wintering. My cellar temperature remains at about 40°. I had them all out on Feb. 11, and they had a good flight.

Greensburg, Pa.

BEE-HOUSE BURNED.

A Great Loss by Fire—Experience in Bee-Keeping.

Written for the *American Bee Journal*

BY C. H. BREEDER.

A terrible accident occurred here on March 8, 1888. At 4 o'clock in the morning we were alarmed by our neighbor's screams and rappings, and telling us that our bee-house was in flames. We at once tried to check the fire, but it had advanced to such an extent that it rendered all efforts in vain. The fire started in the smoke-room, in one corner of the building, constructed for the purpose of smoking meats. We estimate our loss at \$1,200, with no insurance. This certainly, placed among the ranks of misfortunes, is the greatest loss on record in the bee-line. If all people heed our warning, they will have their smoke-houses away from other buildings.

My Experience with Bees.

About eleven years ago I made my preliminary step in bee-keeping, by hunting and finding bees in the woods, and had 5 colonies the first season in box and log hives. I held no other hive in preference until about two years after, when I realized the vast importance of using frame hives. I saw an account of such a hive, and in making my selection, I preferred the 10-frame Langstroth hive, and at once

ordered ten finished hives; but when they arrived, some of my colonies had been swarming, and this made extra labor to transfer the swarms from the box-hives and nail-kegs into the new Langstroth hives. But it worked with great satisfaction.

This renewed my energies, and my increase became more as year by year passed. I always have kept my bees in strong condition, wintered in a partitioned department under my dwelling-house until the year 1883, when I concluded to build a bee-house and cellar.

My location is on the westerly banks of the Mississippi river, about 12 miles north of Burlington, in which honey has such an extreme demand. Nature has endowed my surroundings with such an abundant of honey-plants of every describable sort which grow in the Mississippi Valley and its adjacent rough bluff lands, and which give the bees every advantage.

The size of the cellar and house was 16x24 feet, made of frame, filled out between the outer and inner wall siding with sawdust, in order to keep extreme cold out of the cellar in winter. It was cool in summer, and a kindling fire would keep it comfortable in winter for making and repairing apiarian fixtures for the coming year.

It consisted of a carpenter-room, honey-room, and smoke-room. The carpenter-room was 12x16 feet, and in it there was a set of carpenter tools, a circular saw, work bench, 69 honey-racks filled with foundation, and comb, all ready for the coming harvest; 12 empty honey-crates of 24 pounds each, and 10 empty honey-crates of 48 pounds each.

The honey-room was filled with innumerable articles used in an apiary, \$35 worth of Dadant's comb foundation, a roll of perforated zinc, brood-combs to fill 20 hives, etc.

The garret contained 2,000 one-pound sections, and 1,000 two-pound sections, and 62 newly-nailed Langstroth hives. In the smoke-room had been placed our meats a few weeks ago, for smoking it in the near future. The bee-cellar had an 18 inch wall with a small, opaque window in each side, and end of it. The bottom was well cemented, with a chimney base in the centre, and a hole to carry off the damp air from the cellar. It was ventilated with a 5-inch tile inserted in the wall and extending 130 feet distant. The cellar contained 69 colonies of Italian bees, and on the morning of March 8, all was consumed by the flames.

In 1884 I had 101 colonies, but they became reduced to 69 colonies, by the grasshoppers the first year, and drouth the last two years. In 1887, although

there was too much drouth for actual comfort, we had about 200 pounds of surplus comb honey, which sold at 16 cents per pound; and 400 pounds of extracted honey at 8 to 9 cents.

All who keep a few colonies of bees should also read the AMERICAN BEE JOURNAL; for if its instructions are fully complied with, there is no excuse for not becoming prosperous and successful in bee-culture.

Sperry, Iowa, March 14, 1888.

BEE-KEEPING.

Keeping Bees in Missouri, and Fastening Foundation.

Written for the American Bee Journal

BY R. L. TUCKER.

I am 20 years old, and have been in the bee-business ever since I was old enough to do anything. At Arrow Rock, Mo., my father and I now have 86 colonies of bees, most of which belong to him; 56 colonies are pure Italians, 10 are Syrians, or Syrians mixed with Italians, and the rest are hybrids. Our bees came through the winter of 1886-87 almost entirely without loss. They were in splendid condition about April 1, but after that they seemed to build up very slowly.

The spring was very dry. At length the time for swarms and storing to begin arrived, which is about May 25 in this locality, but for some cause or other white clover had a very small bloom, and only yielded honey enough to keep up breeding. After this, I had to feed some of the colonies, especially the hybrids.

Boneset yielded some honey from Aug. 25 to Sept. 5, and on Oct. 1, the hybrids had an average of little over 5 pounds per colony, the Italian colonies about 20 pounds, and the Syrians about 35 pounds.

In preparing them for winter, I took one frame out of each hive, and spread the rest apart, giving the widest spaces to the centre frames. I use the Simplicity hive. I aim to give an average of 30 pounds per colony for winter stores. I fed 500 pounds of honey and 600 pounds of the best granulated sugar, making the sugar into syrup according to the "Heddon plan."

Our report for the season of 1886 is as follows: On May 15 we had 62 colonies in good condition, increased them to 88, by natural swarming, and took about 5,900 pounds of extracted honey, and 700 pounds of comb honey, all from clover, and the bees stored enough fall honey for winter. This time, also, the Syrians were ahead, the average stored by 6 colonies of Syrians being at least 25 to 30 pounds ahead

of the average stored by all the rest; they had the same opportunity, and the same attention as the others. I found them to be very cross and ill-natured to handle, but, on the whole, I think them worthy of attention, and that their good qualities more than counter-balance their bad ones.

Fastening Foundation in Sections.

I see that nobody has as yet given a plan for putting foundation in the sections as good as the one I use, so I will explain it:

I use one-pound sections, and full-sized pieces of foundation. Make a paddle 3½ inches wide, and get a stand or box about 30 inches high, and light a lamp and place it on the floor near the edge of the stand. Get a piece of board the width of the sheets of foundation, and place it on the stand, so as to have one end extend out over the lamp. Now all is ready to begin operations.

Place several pieces of foundation on the board with the edges exactly even (the edges of the foundation must extend over the edge of the board at least ¼ inch); turn up the light just right, dip the paddle in some water, and commence plastering the pieces of foundation in the sections. One will soon become very expert at it with a little practice, and it will not take nearly as long to get at it, as it does to tell it.

I have tried all the methods in use so far, and find that this excels them all, because it is quickly done, and if properly executed, the foundation never falls out.

I have been a constant reader of the AMERICAN BEE JOURNAL for years, and it has been a source of much delight to me. I have derived much useful information from it. I would like to hear, through its columns, a discussion of the bee-resources of the country, especially of the South and Southwest. Nevada, Mo.

BROOD-CHAMBERS.

A Review of Dr. Tinker's Position on Them.

Written for the American Bee Journal

BY JAMES HEDDON.

On page 169, Dr. Tinker has restated his position on the above topic. The Doctor is a very good writer, and the spirit of his sentences is kind, but his criticism of something he knows so little about, seems very unwise.

It is refreshing to know that the Doctor feels so kindly toward me that he would have been glad to promote my interests by saying something good of the sectional brood-chamber.

I believe I have never felt a financial interest in the invention in question, which rose paramount to my enthusiasm in the great improvement I have always believed it to be. This may be a bit of news to the Doctor, and to some others, but it is true, and how plain all will see it when, in the future, they learn the worth of the new hive. The reason why it does not look that way now is because all are looking ahead at something not yet fully conceived of; but if we read up the attacks upon Father Langstroth's great improvements, and the howl against the practicality of his hive, by those who, like the Doctor, had not yet caught a conception of its worth, and then take a look at both the hive and the inventor to-day, all seems clear enough.

At the time when Father Langstroth was being robbed, how many bee-keepers in this country do you think there were that did not think that he wrote his book, "The Hive and Honey-Bee," "for no other purpose than to sell hives and rights?" that every time he tried to explain the grand improvements which he knew that he had made (and no one could explain them so well as he)—improvements that he knew would benefit this world thousands of times more than himself alone, some one called it "Mr. Langstroth's interests," just as Dr. T. now mentions: "Mr. Heddon's interests." From whence did the Doctor get such groveling ideas of the person he was praising only one year ago? I do hope that he will give the names of the prompters of that essay. If not, will the prompters themselves do it?

The Doctor says this hive is not the first of my failures, any more than were his "continuous passage-ways" the first of his failures. But this hive is no failure, either with me or with others who have tried it, even so short a time as to only half understand its advantages.

Will the Doctor be so kind as to tell where I ever pronounced a thing *good*, and that too for years, and then pronounced it bad and threw it away for something that existed before it. But the Doctor threw away his continuous passage-way hive at once when my hive came to the public; and first claimed my invention, then acknowledged that it was mine, and procured a right to use it, and used it a little so "Tinkered" as to half destroy its functions; and now he recommends a hive made partly on my plan, but enough different so that (he claims) it does not infringe the letter of my invention, even if it does the spirit. Time will tell about that.

The Doctor speaks truly when he says that a long-time trial may bring

out defects that less time and theory did not discover. I am aware of this, so I have more than almost any one else, tested my theories on a large scale, and with many repetitions. Because I was aware of that fact, I tested the new hives two years—all the patent law would allow.

When we get answers to the call that I have made—answers from actual experience, I shall be glad to see how the experience of honey-producers agrees with that of the Doctor, who used a mongrel hive, and who is a very good workman, good writer, but poor inventor, I think.

Dowagiac, Mich.

[With the two articles on each side which have now appeared, the personal controversy between Dr. Tinker and Mr. James Heddon is closed. The BEE JOURNAL has too many other subjects waiting a chance for discussion, to give any more room to it.—ED.]

WINTERING BEES.

Season of 1887—Temperature of a Bee-Cellar.

Written for the American Bee Journal
BY JOSEPH BEATH.

My report for 1887 is as follows: On Dec. 5, 1886, I put 30 colonies of bees into the cellar, and on April 20 I took out 29 colonies alive; but they began robbing, and I lost 2 colonies, so I had 27 colonies to commence with on May 1. They were mostly in good condition, but as I made the prophecy in May, that there would be less bees in the spring of 1888 than there was then, I cut out queen-cells to prevent early swarming.

In June there was a fair honey-flow from white, Alsike and red clover. They were working on all at the same time, being about 2 bees on white clover, 4 bees on Alsike, and 1 bee on red clover; my bees being all *hybrids*, and two-thirds of them filled their supers, and increased to 40 colonies.

As I was very busy with my farm work, I only extracted about 50 pounds of honey, so that when the drouth came they had plenty of honey.

Now comes the queer part: Although they had worked on the first crop of red clover, not a bee was to be seen on the second crop, although the bumble-bees were working right along on it, and it was just the same with the sweet clover, smart-weed or heart's-ease. I did not see half a dozen bees at work on them, never a bumble-bee.

We had fair rains in August, so that we had good fall feed for cattle, but no

honey until the last half of September, when the strongest colonies filled up their hives again.

About the middle of September I took from the surplus departments of those that had it to spare, and gave to those that needed it, as I thought sufficient for winter, and I did not take off the balance until the middle of October, when I found those that I had fed, were again short, and some that had the upper story full before, were entirely empty below. So, after making them even again, I only took off 200 pounds more honey, making 250 pounds in all.

I then let them alone until Dec. 15, when in the morning I began to carry them into the cellar. But I carried only 6 colonies in, when they became too lively. The sun shone brightly, and they had a good fight. I carried the rest in at night and the next morning, except 6 colonies that had again become too light; for those I made candy, and put it on top of the frames, using about 40 pounds of sugar.

My cellar was at a temperature of about 40°, until the blizzard in January, when it fell to 32°, 30°, and on one day 28°. The bees had been very quiet, just giving forth a contented hum; but as the temperature fell, the hum was less and less, until at 28° I had to put my ear close to the hive in order to hear a sound; this being in direct opposition to the theory that, as the temperature falls below 40°, the bees fan their wings, thrash around, and raise a racket like a man thrashing his hands, in order to keep warm. Have others noticed anything similar to the above?

I thought best, however, to raise the temperature, and did so by placing a lamp in the cellar; the next day it was 32°, and the bees made more noise than they have any other time during the winter. But I think that was caused by the lamp's smoking. I remedied that, and kept it there for 2 or 3 days, until it was again 38°, and they had their natural hum. It has remained so to the present time (Feb. 13.) □

I wish to thank those who answered my query about "bees working on red clover." But to get any value out of it, we should know what kind of bees they have.

Corning, Iowa.

Photographs of Bee-Keepers.—

The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*
 Apr. 10.—Wabash County, at N. Manchester, Ind.
 F. S. Comstock, Sec., North Manchester, Ind.
 Apr. 11.—Stark County, at Canton, O.
 Mark Thomson, Sec., Canton, O.
 Apr. 14.—Union, at Menlo, Iowa.
 Mrs. J. E. Fryor, Pres., Dexter, Iowa.
 Apr. 21.—Central Michigan, at Lansing, Mich.
 W. A. Barnes, Sec., DeWitt, Mich.
 Apr. 21.—Eastern Indiana, at Richmond, Ind.
 M. G. Reynolds, Sec., Williamsburg, Ind.
 Apr. 24.—Des Moines County, at Burlington, Iowa.
 John Nau, Sec., Middletown, Iowa.
 May 2, 3.—Texas State, at Greenville, Tex.
 B. F. Carroll, Sec., Blooming Grove, Tex.
 May 5.—Susquehanna County, at New Milford, Pa.
 H. M. Seeley, Sec., Harford, Pa.
 May 7.—Welland County, at Welland, Ont.
 J. F. Dunn, Sec., Ridgeway, Ont.
 May 8.—Cortland Union, at Cortland, N. Y.
 W. H. Beach, Sec., Cortland, N. Y.
 May 19.—Nashua, at Nashua, Iowa.
 H. L. Rouse, Sec., Ionia, Iowa.
 May 22.—N. W. Ills. & S. W. Wis., at Rockton, Ills.
 D. A. Fuller, Sec., Cherry Valley, Ills.
 Aug. 14.—Colorado State, at Denver, Colo.
 J. M. Clark, Sec., Denver, Colo.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

of which they have not paid so well. It pays to give the need attention to the bees, and to have the honey in straight combs and clean sections.

A colony of golden Italian bees that was close to our kitchen door, swarmed three times one summer, and in about 90 days all the bees of the colony were black. They must have stolen an egg from which to rear a queen, or a queen went into the hive from another colony.

My 55 colonies are wintering very nicely, and are in good condition, having been packed well last fall. I think that if blanks were furnished assessors, it would be but little trouble to secure correct statistics of bees, honey and wax.

Bees Wintering Finely.—W. F. Roe, Canton, N. Y., on March 10, 1888, says:

Bees seem to be wintering finely in the cellar, but very poorly on the summer stands, where they are not well packed. My 132 colonies are mostly in the cellar, and are all right now.

First Flight since November.—H. M. Seeley, Harford, Pa., on March 12, 1888, says:

Bees appear to be wintering well. They had a fine flight on Feb. 23 and 24, and from my 7 colonies there was not more than one-half a tea-cupful of dead bees. It was the first flight since the last of November.

Putting Bees Out for a Flight.—B. T. Pierce, Grand Rapids, Mich., on March 14, 1888, says:

I commenced in the spring of 1887 with 26 colonies of bees, increased them to 50 colonies, and secured 800 pounds of honey in one-pound sections, although the drouth caused a poor honey crop. I commenced the winter with 51 colonies, and have lost two; 18 colonies are in the cellar, and the rest are packed on the summer stands. Ought those in the cellar to be put out for a flight, before it is warm enough to leave them out?

[No; not unless they are diseased.—ED.]

Early Spring Expected.—B. A. Manley, Milo, Iowa, on March 12, 1888, says:

Bees seem to be wintering fairly well here. I hear of some bees being in a starving condition, but where they were properly cared for in the fall, they bid fair to winter all right. I put 15 colonies into winter quarters, 2 of them being weak, but the balance were strong colonies. I have full faith in their being ready for work when spring opens. The prospect for an early spring is good.

Apicultural Statistics — Bees Starved.—J. M. Young, Rock Bluffs, Nebr., on March 15, 1888, writes:

Prof. A. J. Cook's letter on the statistic question was read with interest. The plan suggested by that committee is certainly a good one, but then, the method suggested on page 131, of obtaining them by the assessors, is the only sure plan, if it can be adopted.

For the last four years we have spent considerable time and money on this very question, and up to this date we only obtained something over 250 names in the State of Nebraska; some of these names are quite old, and perhaps they do not keep bees now at all. In a great many instances we have

sent out postal cards, and in return we seldom get full reports, and in many cases no answer at all. About all we get on them is the bee-keeper's address, and sometimes the number of colonies that is kept.

We came to the conclusion long ago, that if a correct statistics of bee-keeping would be had, no other method was more sure than that of obtaining through the assessors, the same as other farm products are obtained.

Bees throughout this county are wintering poorly, and also throughout other portions of the State. Starvation is the main cause. Perhaps nearly one-half of the bees will die from that cause.

Bees had a Genuine Flight.—Geo. E. Hilton, Fremont, Mich., on March 19, 1888, says:

Tally one more for chaff hives. This has been the first spring day, and the first day that the bees have had a genuine flight since last November. They pounced out of the hives as though they were swarming, and the air was literally black with them. It is certainly a sight to see 85 colonies virtually swarming at the same time. I have not had a single loss so far. The temperature is 60°.

Experience of Two Seasons.—Milo George, Bowling Green, O., on March 19, 1888, says:

So far as I know, bees in this part of Ohio have wintered well. I started in the spring of 1886 with 17 colonies, on Gallup frames, which I transferred to American frames, and increased them to 34 colonies. I obtained about 1,000 pounds of extracted honey, and 75 pounds of comb honey. I put 33 colonies into winter quarters, lost 4, and had 29 colonies in the spring of 1887. Last season was a very poor one, but I increased my apiary to 53 colonies, doubled it back to 39 colonies, and got about 20 pounds of comb honey, and 75 pounds of extracted honey. On Feb. 16 I examined my bees, and found some with 3 frames of brood. I have lost 5 colonies so far. My bees are in double-walled chaff hives.

An Old-Fashioned Bee-Hive.—W. F. Marks, Chapinville, N. Y., on Feb. 27, 1888, writes:

In buying bees a few years ago I came in possession of a hive that was something of a curiosity to me, and bee-keepers who have seen it, said that they had never seen anything like it. The party of whom I bought the bees, said that he started bee-keeping with the same colony of bees 40 years before; or, in other words, that it was the same colony of bees, without intermission, that he started with 40 years before. I had no reason to doubt him, and the hive was so rotten that I had to handle it with great care. It was in the shape of a cone, the brood-chamber being in the centre, and the surplus boxes three tiers, the upper ones projecting over the lower ones, and having the entrances in the bottom part that hung over the lower ones.

Packing Bees for Winter.—Allen Bartow, of Milan, O., writes:

What is there in packing bees for winter? Some say, "Invariably nothing." This is true where they are improperly packed in any one respect. Because bees have suffered and died when they have been poorly packed, is no reason that protection by proper packing is not beneficial.

What is the best protection suited to the climate in which bees are kept, according

Gray-Birch Sawdust for Pollen.—Frank Wilkins, Pelham, N. H., on March 13, 1888, writes:

I notice that a great many bee-keepers put out rye meal in the spring for their bees to use as pollen. If they will put out gray-birch sawdust once, they will never put out any more rye meal; for the bees will not work on rye meal, when the two are placed side by side. I wish every bee-keeper would try it, and enjoy seeing the bees carry the pollen from it. It must be gray-birch sawdust. I put 8 colonies of bees into my bee-house in December, and they are now in fine condition.

Bees in Good Condition.—John K. Rich, Cato, N. Y., on March 13, 1888, writes:

My 25 colonies of bees are in good condition, with plenty of stores to last them through the spring. I sold the last of my honey crop last week, at 16 cents per pound for the white, and 12½ cents for the dark honey. I have sold it all in my home market. I use a Barnes' foot-power saw, and make all my hives and frames.

Bee-Keeping as a Business, etc.—D. R. Rosebrough, Casey, Ills., on March 2, 1888, writes as follows:

It will never pay to mix up bee-keeping too much with other work; for then the bees are invariably neglected, if anything has to be slighted. It will not pay to try to make a living from bee-keeping in a poor locality, unless the bee-keeper owns a farm, and will grow honey-producing plants; nor will it be profitable to locate with bees where there are too many old-fogy bee-men. The first year that I kept bees, it paid me better than anything I ever did. I made a business of it, and cared for my bees properly; but since then I have had other duties, and have neglected the bees, in consequence

to the severity of the winter, as winters vary in the same places? We must study conditions of cold and heat, and see their effect on the bees, as regards their comfort and health. Bees in a state of nature are healthy. Are they ever afflicted with foul brood, or such other diseases? I say no. Man's manipulation has given these diseases to the faithful little workers.

I agree with Mr. Buchanan in most of his conclusions in the usual way of packing, but let us vary that packing just a little, and see what a difference it makes. Have the front or entrance side of a hive with a single wall, and it allows the hive to warm up, and the bees take flight whenever they would be benefited by a flight.

I agree with all that Mr. B. says of the ten-frame hive, and its condition. I would have the outside case as tight and dry as the hive inside, with the bare hive in front, and the hive 2 feet from the ground. This method keeps the bees from flying at every little warm spell that would take bees in single walled hives of $\frac{1}{8}$ of an inch, out to perish.

I believe, as does Mr. Buchanan, about ventilation. Any top ventilation is always attended with injury to the bees; while lower ventilation is natural, beneficial and healthful.

Fighting their Own Interests.—

J. A. Rickenbacher, Gahanna, O., on March 20, 1888, writes:

Bees have wintered pretty well around here. They had an occasional flight during the winter, which was to their advantage. I think the councilmen and Mayor of that place where Z. A. Clark lives, are fighting against their own welfare.

Diseased Colonies.—J. H. Blanchard, Boise City, Idaho, on March 9, says:

Bees in this locality are not doing very well. I have lost 2 colonies since March 1, from what I think must be diarrhea. My bees were put into winter quarters in a very strong condition, with plenty of bees, honey and pollen; and through all the cold weather, the mercury ranging 28° below zero, they were still strong. I cannot understand why they should die as soon as warm weather comes. When they took their first spring flight, they daubed their hives with a dirty excrement, which I washed off, and thought nothing of it; but they have done the same thing repeatedly ever since. Can any one explain this, and give me a remedy for it? It seems a little strange to me, that they should continue in this way in warm weather.

Fertilization of Queens.—John Andrews, Patten's Mills, N. Y., on March 12, 1888, writes:

I will answer questions 5 and 6 published on page 120 as follows: In rearing queens from an imported Carniolan queen, I had a young queen with a deformed wing, and could not fly; but I wished to save her, as I was short of queens. I put her with a small colony of bees about the middle of October, and kept drones with her until she was put into the bee-cellar about Nov. 20. Being anxious about her on account of the question of fertilization in confinement, I watched her very closely. She did not lay an egg before she was put into winter quarters; her wing had begun to spread out a little, but she had never flown an inch.

The next day after I took her from the cellar (about April 20), I examined her, and she had two good wings, and two frames of brood, larvae and eggs, with hatching bees. She met an Italian drone, and her bees through June and July were the most evenly

marked (two-banded) that I ever noticed. She did not bring her colony up so as to produce any surplus.

The colony being very gentle and handsome, I exhibited them to visitors every few days. In August I discovered that her bees were changing, and I could see no other cause for it, except that she had been out and met another drone; her bees turned nearly back to Carniolans, and what were once my beautiful bees, passed off like the morning dew, and were exhibited no more.

Did that queen meet the drone in the hive? Did she meet the drone the second time in July or August? My answer is, that she did these two things.

Another Carniolan queen, hatched about the same time and in the same lot, had as industrious a colony as I ever had; but she became fertile, and her bees hatched before being put into winter quarters.

Granulated Honey in Combs.—

Mary A. Goodale, Clear Creek, Ind., on March 15, 1888, asks:

How shall I proceed to empty brood-combs of granulated honey? I winter the bees on the summer stands, packed inside and outside. The stores are natural, gathered from aster and golden-rod. On examination I found that most of the unsealed honey is granulated; the bees are taking out some of it, but there is so much that I fear they will not remove all of it. Bees are in good condition, and are breeding.

[If the bees do not remove it all, and you do not need these frames of candied honey for spring feeding, you might melt them up, the wax would congeal at the top of the liquid honey, and both would thus become marketable.—Ed.]

Storing Surplus Honey.—F.

Schmitt, Yazoo City, Miss., on March 19, 1888, writes:

Last fall I had 240 colonies of bees, and I lost 40 of them during the winter. They commenced storing honey in the surplus department on March 17, from fruit-bloom, red-bud and maple.

Wintering Bees in Sectional

Hives.—Lighty & Zeigler, Mulberry, Pa., on March 16, 1888, write:

We find none of the faults with the Heddon hive that Dr. Tinker mentions in his essay on page 86. Our bees wintered just as well in the one section of that hive as in the extensive chaff hives. We winter our bees on the summer stands. In 1887 we obtained no comb honey from the colonies in chaff hives, while from the sectional hives we got a few hundred pounds. The season was very poor here. Our bees are equal now in building up.

Moving Bees from the Cellar,

etc.—A. Pinkerton, Marshalltown, Iowa, on March 13, 1888, writes:

The place where I have always kept my bees when on the summer stands is near the street, the first row of hives being within a few feet of it, and the last row 180 feet. I wish to move the front ones back when I put them out of the cellar. 1. Will it do to put those that have been in front, in the rear, or had I better move them all back, and keep the same in front that were there last fall? 2. Will Alsike clover do well on black, sandy soil, on a hillside, if sowed with oats?

Perhaps some would like to know how to keep bees from coming out of the hive

when carrying them in and out of the cellar. I take 3 or 4 linen towels, wet them in cold water, and place them in the entrance of the hives, so as to close the entrance; then after carrying the hive where I want it, I take the towel away, and not a bee will stick to the cloth. I learned this of Mrs. Dr. Lewis a few years ago, and I find it a great advantage if the bees are a little cross.

[1. Some pay no attention as to how the hives were placed in the previous season, when putting the bees out of the cellar in the spring, allowing them then to re-mark their locations. If it was thought more desirable to have the hives stand in the same relative position, we should advise moving them all back to the required distance.

2. Yes; but it would be better to mix "Alsike" with timothy or red clover, or with both.—Ed.]

Reversible Bottom-Boards.—

James M. Goodrich, South Frankfort, Mich., on March 10, 1888, writes:

On page 170 of the BEE JOURNAL for last year, I described my reversible bottom-board for the Simplicity hive thus: The board is 3 inches longer than the hive; there is a rim on three sides of it, $\frac{3}{8}$ of an inch wider than the bottom-boards are thick, and the same thickness as the body of the hive. The boards reach across the hive, and are the same length as the hive is wide on the inside, and are halved or matched, the rim being nailed to the board, so that it projects $\frac{3}{8}$ of an inch on each side of the board nailed to the hive, which rests on the rim, and this leaves a fly-hole $\frac{3}{8}$ of an inch in front, the width of the hive, and the entrance-blocks are held as firmly as in the portico hive, and the bottom-board is the same either side up.

I have now changed the bottom-board by having the rim wide enough to make the fly-hole $\frac{3}{8}$ of an inch on one side, and $\frac{1}{4}$ on the other. This is a great improvement, as one can change to the larger fly-hole by simply reversing, in hot weather or when hiving swarms, and can change back to $\frac{3}{8}$ by simply turning it back.

Proper Temperature of a Bee-

Cellar.—Geo. H. Potter, Ionia, Iowa, on Feb. 27, 1888, writes:

I have for a long time had a question that I wished answered, and it is this:

I usually have in a bee-cellar from 80 to 100 colonies of bees, in single-wall hives, with honey-boards down tight, and the only ventilation is the entrance, which is $\frac{3}{8}$ x 14 inches. They are tiered five high. What should the general temperature be for bees put in such a cellar? I use a frame 8 $\frac{1}{2}$ inches deep by 18 inches long, and have been quite successful in wintering; but I find that when the cellar is kept up to 45°, the bees get uneasy. I regulate the temperature by a large-sized oil-stove in the vegetable part of the cellar. I have come to the conclusion that perhaps those bee-keepers who recommend 45° to 50°, remove the honey-boards and spread over quilts, and raise up or remove the bottom-boards.

I have kept bees more or less for the past thirty years, and I just begin to find that I know but very little about the business. THE AMERICAN BEE JOURNAL is the first paper read upon the arrival of the mail, and, allowing me to judge, is the best newspaper published.

[That temperature at which the bees are the most quiet is best. In your case, we would try it at a lower degree, and regulate accordingly.—Ed.]

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Money Orders for \$5.00 and under, cost 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them.

Clover Seeds.—We are selling Alsike Clover Seed at the following prices: \$3.00 per bushel; \$2.25 per peck; 25 cents per lb. White Clover Seed: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. Sweet, or Melilot, Clover Seed: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Why Advertise in the AMERICAN BEE JOURNAL? Here are some good reasons:

1. Because it has a large and influential circulation in every State and Territory, Canada, and other foreign countries.

2. Because it is well-printed, and an advertisement in it appears neat and attractive, and invites a reading.

3. Because it reaches just the class of persons desired—professional men, lawyers, doctors, and the best of the rural population.

4. The rates are low as possible, and the returns from advertisements are satisfactory.

It is Extravagant Economy not to have hives, sections, comb foundation, etc., on hand when needed. To prevent disappointment, order early what you will need in that line. Then the hives can be nailed and painted in odd times, and the sections put together, so as to be ready at a minute's notice. It is a sad disappointment to need these things and then not have them on hand. They should be ordered very soon. We are promised an early spring, and a good honey crop.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

Look Over last year's numbers of the BEE JOURNAL, and if any are missing, send for them at once, as we have but few left now, and they are daily becoming less.

A Pocket Dictionary will be presented for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

We Club the AMERICAN BEE JOURNAL and the "Bee-Keepers' Magazine" for one year for \$1.40; or with "Gleanings in Bee-Culture" for \$1.75; or with the "Apiculturist" for \$1.80; or the "Canadian Honey-Producer" for \$1.30; with the Bee-Keepers' Review, \$1.40; or all six for \$4.00.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2.00	3.00	3.50
1,000 Labels.....	3.00	4.00	5.00

Samples mailed free, upon application.

CLUBBING LIST.

We Club the American Bee Journal for a year, with any of the following papers or books, at the prices quoted in the LAST column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

CONVENTION NOTICES.

The Wabash County Bee-Keepers' Association will meet at North Manchester, Ind., on April 10, 1888. F. S. COMSTOCK, Sec.

The next meeting of the N. W. Ills. and S. W. Wis. Bee-Keepers' Association will be held in Rockton, Illa., May 22, 1888. D. A. FULLER, Sec.

The Eastern Indiana Bee-Keepers' Association will hold its spring meeting on Saturday, April 21, 1888, at Richmond, Ind. M. G. REYNOLDS, Sec.

The Des Moines County Bee-Keepers' Association will hold its next meeting on April 24, 1888, at Burlington, Iowa. JOHN NAU, Sec.

The Union Bee-Keepers' Association of Western Iowa, will hold their annual meeting at Menlo, Iowa, on Saturday, April 14, 1888, at 10 a.m. H. D. LENOCKER, Sec.

The Cortland Union Bee-Keepers' Association will hold its spring meeting on May 8, 1888, at Cortland, N. Y., at 10 a.m. All bee-keepers are invited. W. H. BEACH, Sec.

The Hardin County Bee-Keepers' Association will meet at the Court House in Eldora, Iowa, on the second Saturday in each month, at noon (12 o'clock), until further notice. J. W. BUCHANAN, Sec.

The next regular meeting of the Susquehanna County Bee-Keepers' Association will be held at New Milford, Pa., on Saturday, May 5, 1888. H. M. SEELEY, Sec.

The Marshall County Bee-Keepers' Association will meet at the Court House in Marshalltown, Iowa, on Saturday, April 21, 1888, at 10:30 a.m. The subject for discussion is, "Spring and summer management of bees." A general invitation is extended. A good meeting is expected. J. W. SANDERS, Sec.

The 18th semi-annual session of the Central Michigan Bee-Keepers' Association will be held in the Pioneer Room at the State Capitol, on Saturday, April 21, 1888. Prof. A. J. Cook will give an address. A cordial invitation is extended to all, and it will be a very interesting meeting. W. A. BARNES, Sec.

The tenth annual meeting of the Texas State Bee-Keepers' Association will be held at the yards of Vice-President W. R. Graham, in Greenville, Hunt Co., Texas, on May 2 and 3, 1888. A leading feature of the convention will be criticisms upon subjects that have been mentioned in the bee-papers. A good time is expected, so let all Texas and Arkansas bee-keepers attend. A cordial invitation is extended to all bee-keepers whoresover dispersed. Remember, no hotel bills to pay at our convention! B. F. CARROLL, Sec.

New Subscribers can obtain the full numbers for 1887 and 1888, for \$1.75, while there are any sets of 1887 left.

Honey and Beeswax Market.

CHICAGO.

HONEY.—Prices range from 16@18c. for best one-lb. sections, to 14@15c. for on color and condition; 2-lbs., 14@15c. Dark is slow of sale at almost any price. Extracted, 7@9c., with good supply. Light demand.

BEESWAX.—22@23c.
Mar. 22.

R. A. BURNETT,
161 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 14@15c.; fancy 2-lbs., 12c. Lower grades 1@2c. per lb. less. Buckwheat 1-lb., 10@10½c.; 2-lbs., 9@9½c. Extracted, white, 7@7½c.; dark, 5½@6c.
Mar. 19. F. O. STROHMEYER & CO., 122 Water St.

CHICAGO.

HONEY.—We quote: Fancy white clover 1-lb., 16@17c.; 2-lbs., 15@16c. Dark is slow sale at almost any price. Extracted is scarce, and sells at 7@10c.
BEESWAX.—23c.
Mar. 13.

B. T. FISH & CO., 189 S. Water St.

CINCINNATI

HONEY.—We quote: Extracted at 4½@9c. per lb. for which demand is good. Comb honey, 14@17c.—Supply large and demand slow.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Mar. 11. C. F. MUTH & SON, Freeman & Central Av.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 14@17c.; 2-lbs., 15@16c. Dark and broken not quotable. Extracted, white in kegs and ½-barrels, 8½@9c.; in tin and pails, 9½@10c.; dark, ½-barrels and kegs, 5@7c. Market slow.
BEESWAX.—22@23c.
Mar. 10.

MCCAUL & HILDRETH BROS.,

HOOD'S SARSAPARILLA

Hood's Sarsaparilla is a carefully prepared extract of the best remedies of the vegetable kingdom known to medical science as Alternatives, Blood Purifiers, Diuretics, and Tonics, such as Sarsaparilla, Yellow Dock, Stillingia, Dandelion, Juniper Berries, Mandrake, Wild Cherry Bark and other selected roots, barks and herbs. A medicine, like anything else, can be fairly judged only by its results. We point with satisfaction to the glorious record Hood's Sarsaparilla has entered for itself upon the hearts of thousands of people in New England who have personally or indirectly been relieved of terrible suffering which all other remedies failed to reach. C. I. HOOD & CO., Apothecaries, Lowell, Mass. Price \$1.00, six for \$5.00 Sold by Druggists and Dealers in Medicines.

EDITORIAL BUZZINGS.

Plant Blessings, and blessings will bloom ;
Plant hate, and hate will grow ;
You can sow to-day—to-morrow shall bring
Blossoms that prove what sort of a thing
Is the seed—the seed that you sow.

We have received a copy of the Constitution and By-Laws of the Newaygo County Farmers and Bee-Keepers' Association, adopted Feb. 10, 1888.

We Regret to learn that Mr. G. H. Knickerbocker, Secretary of the New York State Society, has been afflicted of late with inflammation of the eyes, making it difficult to conduct his correspondence. He is now much better, and we hope will soon be fully recovered.

Mr. Thos. Wm. Cowan, editor of the *British Bee Journal*, was elected an honorary member of the Ontario Bee-Keepers' Society, at its last meeting. We regret to learn that friend Cowan has been very unwell during February and March, and has been confined to his winter home in Lausanne, Switzerland. We hope he will soon regain his usual health and strength.

Fractional Currency is again in demand for sending small sums through the mails. Postal notes are no more safe than currency, and can only be obtained at Money Order offices. Such are very inconvenient to obtain in the country, and silver coins are often lost in the mails. We are glad to note that the bill for the issuance of silver certificates of 10, 15, and 25 cent denominations passed the House on March 19, by 177 yeas to 67 nays. It will doubtless pass the Senate, and soon become a law.

Superseding the Queen.—Ira N. Lyman, St. Peter, Nebr., asks for information as follows :

What is the cause of the queen coming out of the hive on or about March 23? I have 3 colonies of bees. I bought a very weak colony early last spring, and one old colony and one swarm in July. The old colony had not swarmed. It stored about 100 pounds of surplus honey ; the other two stored only about 10 pounds more honey than enough to winter them. I put them into the cellar, and they are all strong this spring. It was from the hive of the new swarm that the queen came out in March. I put it back into the hive on top of the frames, and it soon came out again the second time, with a lot of guards. I put her back on top of the frames at the rear end of the hive, and she came out no more, so far as I know.

I put my bees out once in February, and then put them back into the cellar. I put them out again, and the time the queen came out was the third time I put them out. The cellar became damp, and the combs molded a little. The bees are grade Italians ; in home-made Langstroth hives. There is still snow on the ground, in places.

As the queen came out accompanied with guards, she was evidently being superseded by the bees, who judge her not equal to keeping up the strength of the colony. As she did not come out again when put back, she evidently was killed by the bees. You should examine the colony, and if you find it queenless, give the bees a frame of eggs when you have hatching drones, so that they may rear a queen and have her fertilized in due time. Meanwhile it would be well to give the bees some frames of brood from a strong colony, as soon as such can be spared. Or, better still, procure a queen and introduce her to the colony.

The New British Bee-Keepers' Guide Book, by Thomas Wm. Cowan, F.G.S., F.R.M.S., is on our desk. This is a new edition (the ninth, and seventeenth thousand). It is mostly re-written and greatly enlarged, now having 174 pages. This edition contains many new illustrations, and much new matter in our ever-advancing pursuit. This "Guide Book" is exceedingly interesting, and has been translated into more foreign languages than any other apicultural book. Its range of subjects covers the entire ground of practical bee-keeping, as is shown by the topics embraced in its 37 general heads. We can fill orders for it after May 1, at 50 cents, post-paid.

Honey-House.—Mr. G. A. Elliott, La Salle, Ills., on March 31, 1888, writes :

I have about 800 feet of 16-foot lumber which I intend to build a honey-house with ; is there any better plan than 12x12, 8-foot high? Last year was a very poor one here. I had 10 colonies in the spring of 1887, and only 12 in the fall, which were in Simplicity hives. They have wintered safely, so far. I am very much pleased with the *BEE JOURNAL*.

We should think 12x12 and 8 feet high would do very well for your honey-house—but it all depends upon your needs, as to the necessary capacity.

While we have been arranging a plan to have the United States Statistician gather statistics regularly and all over the country, Mr. A. I. Root, our friend and co-worker has been gathering from every State, intelligence which shows that there has been only about 15 per cent. of loss in bees during the past winter ; that there is a favorable prospect for a good honey crop ; that for three or four weeks honey has been gathered in the extreme South ; in the middle States the first honey is just now being gathered, and in the northern States none has yet been gathered.

That Bell has commenced to ring, over in Canada, and the first installment of the description of the new invention of Mr. D. A. Jones is at hand. It consists of a side-opening super and crate, and a system of management arranged to agree with such fixtures. Some adverse criticisms have been offered, and some predictions that it will revolutionize fixtures for obtaining comb honey. Let a good trial be made, and the result will be welcomed—which ever way it may point ; for we need all the good things, and can afford to throw all the bad away.

Plaster-of-Paris Molds.—Mr. P. Breman, of Lakeside, Ont., asks us to explain in the *BEE JOURNAL* how to mix plaster of Paris for making foundation molds.

It must be mixed to about the consistency of thin paste, and then used immediately—for it will "set" very quickly. Have every thing ready for its use before mixing it. Then let it stand for several hours to harden.

Care of Empty Combs.—A correspondent in Kentucky, writes as follows :

Please state in the *BEE JOURNAL* how to keep the moth out of frames of empty comb, and oblige a bee-keeper.

Strong colonies of Italian bees are the most effectual method of preventing the ravages of the moth. It is next to impossible to keep the moth out of hives, when such pests are prevalent.

In order to preserve empty combs, it is necessary to fumigate them repeatedly with sulphur, to kill the hatching worms. Close up the room containing the combs tightly, and burn the sulphur in it, after you have gone outside and shut the door.

Sawdust for Pollen.—Mr. Frank Wilkins, Pelham, N. H., has sent us some of the grey-birch sawdust which he mentions on page 203, to be used instead of rye-meal, upon which the bees will work in the spring for pollen. We will report later as to its bee-use, meanwhile thanking Mr. Wilkins for his trouble in sending it.

To Stimulate in Spring, some apiarists give the bees, as early as they will work on it, chopped oats, placed in trays.

GLEAMS OF NEWS.

Governmental Statistics.

The chairman of the committee on statistics, appointed by the Chicago Convention of bee-keepers, Prof. Cook, has sent this to the U.S. Statistician, to be sent out as a

CIRCULAR TO REPORTERS.

The general condition of the bee-industry is of great importance to bee-keepers. Will you please fill out this blank for your county, district or State, at once, according to your best judgment, and return immediately to

COMMISSIONER OF AGRICULTURE,
WASHINGTON, D. C.

Name.....
Post-Office.....
County.....
State.....
This report is for.....County,
or for.....State.

The Circular for April contains these questions:

1. What per cent. of the bees in your..... have survived the past winter?
2. By what method were the bees generally wintered?
3. What are the present prospects for next season's crop?

The Circular for July contains these questions:

1. What per cent. of an average crop of honey was secured in May, June and July?
2. From what sources was it gathered?

The Circular for September contains these questions:

1. What per cent. of an average fall-crop of honey is there this year?
2. From what sources?
3. What per cent. of an average crop is the product for this year?

Moving Bees a Long Distance.

—F. C. Erkel, Lexington, Minn., on April 3, 1888, asks the following questions:

I should like to know when is the best time to move bees. I have 38 colonies that I wish to move about 100 miles. Would it be best to move them soon after taken out of the cellar, or later on in the season? Also, which would be the better way to move them, by wagon the whole distance, or seven miles by wagon to the station, and then fifty miles by freight, when they would have to be transferred, and then fifty miles more by freight?

Move the bees as soon as possible after taking the bees out of the cellar, while the hives are not encumbered with much honey to break down, etc. We should prefer to move them the whole distance by wagons, seeing they must be taken seven miles in that way, for when they are once properly prepared and placed on wagons, much of the work is accomplished. The changing cars on two railroads, as well as changing from the wagon would be far more dangerous to the bees than to go all the distance by wagons. Secure the frames, and load on the wagons so that the frames cross the road-bed, and let them be carefully driven, especially over rough parts of the road.

The Reduction of Postage on seeds, plants, bulbs, etc., is now before Congress. In Canada the postage on such is 4 cents per pound; in England it is 6 cents; and in the United States it is 16 cents per pound! a manifest injustice. Let the law be amended at once.

That New Invention mentioned on page 148, concerning "comb" building, has been *revoked*. It is merely comb foundation "made on glass, wood, tin, card-board or other material, with the impression of the cells in wax on one side, the other being left smooth." The intention is to have the cells of double length, the mid-rib or foundation being at one side.

A great "splurge" was made at its announcement. There was a great ringing of the bell to announce the advent of the locomotive, but, alas, the coming of the engine creates no enthusiasm. It is almost a useless affair, if not absolutely so. Here in America, at least, we have no use for such an invention! We can secure longer cells by simply spreading the combs, but even that is undesirable, because of the slower ripening of the honey, and the consequent hindrance to the bees.

The method proposed to make the invention known made us look with suspicion upon it, as stated on page 148.

Some periodicals have been injudicious enough to announce it as a "new artificial comb"—which will to a few give some color to that scientific pleasantry which we have been fighting for years. Call things by their right names! This is the only safe thing to do.

Spring Feeding, Supers, etc.—

Mr. W. C. Peck, Larrabee, Wis., asks the following questions:

1. Which is preferable for the 8-frame Langstroth hive, a super made of 1-inch lumber to hold 24 sections, or one made of thin lumber and holding 27 sections?
2. Will brace combs be between the brood-frames and the sections, if the bee-space is reduced to $\frac{1}{4}$ inch, and the tops of the brood-frames scraped clean?
3. Is the sap of the sugar maple injurious to bees? or will it serve to stimulate them to breed in early spring?

1. Either would do, but we should prefer the thin lumber and 27 sections, other things being equal.

2. The space not being large enough for passage-ways, the bees will be likely to put brace-combs there.

3. Maple syrup will answer for stimulating the bees in the spring, when they can fly freely.

The Honey-Trade.—Mr. Geo. Henderson, of London, England, has sent us the following item:

The total value and amount of honey imported into Great Britain in the year 1886, was £25,610—or 21,533 cwt. The value and amount from the United States was £5,830—or 4,569 cwt. This is considerable less than that given in the AMERICAN BEE JOURNAL for March 7, but it is authoritative.

Loss in Winter.—Mr. E. D. Keeney, Arcade, N. Y., reports on April 4 that he put 301 colonies into cellars last November, and on April 4 took out 295 colonies in fine condition—being a loss of less than 2 per cent. That is an excellent showing.

Lend a Helping Hand.—Mrs. N. Stanley, Adria, Minn., on March 24, 1888, writes:

I send one dollar to aid the bee-keepers' "defense fund," and let me say to those bee-keepers who weekly read the BEE JOURNAL, that aside from the principle, "Do unto others as ye would that they should do unto you," is it not our duty to cheer and aid a sinking brother? Let us rally around our standard, and do battle for our rights and a just cause. Could I send an arrow of remorse into the heart of that Mayor of Arkadelphia, you may be sure it would be quickly sent. I am only a bee-keeper in a small way, and I do not expect ever to need the aid of the Union, nevertheless I cannot hear appeals for help, in vain.

Our bees the past season did better than some have reported. We obtained a surplus of 30 pounds of comb honey per colony, besides one large swarm and an abundance of stores for winter. The bees are wintering nicely in the cellar, being very quiet, with few dead bees.

I think so much of the AMERICAN BEE JOURNAL that I am binding it, and very attractive and useful volumes they make for convenient reference.

Mr. E. Liston, of Virgil City, Mo., has this to say about the Arkadelphia case:

Brothers, awake! Send in your dollar and join the Union. We that are being carried along on "flowery beds of ease," do not know how soon some one filled with malice and prejudice will put us in trouble. Even if we pass through without trouble, for the honor of our pursuit and our brotherhood, we should pay our little mites to help Brother Clark to obtain his rights as an American citizen. Your dollar is a mere pittance to what Mr. Clark is suffering. And to the Manager of the "Union" I would say, run it through all the courts—give Mr. Clark justice as an American citizen, and assess the fraternity for the necessary funds. Brother bee-keepers, think of this case, and be liberal.

Mr. C. Weeks, a queen-breeder of Tennessee, offers to present a colony of pure Italian bees to the Bee-Keepers' Union, to be awarded to the person who first sends \$4 to four membership fees to help support the Union. The bees are in a Simplicity hive. Who will be first to send the four members?

New Catalogues for 1888 are on our desk, from the following persons:

A. F. Bright, Mazepa, Minn.—16 pages—Bees and Poultry.

Geo. A. Wright, Glenwood, Pa.—1 page—Poultry and Bees.

Mrs. J. N. Heater, Columbus, Nebr.—16 pages—Bees and Apiarian Supplies.

Gould's Manufacturing Co., Seneca Falls, N. Y.—16 pages—Spraying Pump.

J. M. Hambaugh, Spring, Ills.—16 pages—Apiarian Supplies.

W. P. Davis, Goodman, N. C.—6 pages—Bees, Queens and Apiarian Supplies.

F. M. Atwood, Rileyville, Ills.—7 pages—Apiarian Supplies.

C. F. Muth & Son, Cincinnati, O.—34 pages—Honey and Bee-Keepers' Supplies.

Cork for Winter Packing.—Its advantages are that it never becomes *musty*, and it is *odorless*. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

APRIL SHOWERS.

The warm, sweet rain is falling
From April's changeful skies;
The green leaves on the Willows
Laugh out their glad surprise.
The Violet wakes from dreaming
Beneath the dead year's leaves,
Each blossom adds its brightness
To webs that spring time weaves.

The buds on Oak and Elm tree
Seen growing as we look;
Spring legends are repeated
By the babbling little brook.
The air is full of sweetness,
The skies are brighter blue,
The rain that falls in April
Makes all the old world new.

E. E. REXFORD, in *Vick's Magazine*.

Alfalfa as a Honey-Plant.

On page 8, Mr. William Willis tells his experience with alfalfa as a honey-plant, in California. On page 68, we gave more particulars concerning this excellent honey producer. A. H. M., a correspondent in Moroni, Utah, gives these particulars concerning its cultivation:

Lucerne will grow on any land that will produce wheat, corn or potatoes, and will thrive on many lands that none of these will grow on, especially very light sand or gravel, though it does well on clay. But it will not grow on any land that the water stands within one foot of the surface, and there is no use in sowing it in an alkali strong enough to keep wheat from growing. Though particular about wet land, it will stand any amount of wet in the summer, as long as there is plenty of drainage. It will also stand all of the water in the winter that may fall in the shape of rain, or snow that may melt.

It is a very quick grower, and will mature the first crop in about two months from the time that growth commences. The second crop will mature in about six weeks from cutting, and the third is about five weeks from cutting of the second. The second crop is the heaviest, but the first is a little the best feed, as it grows a little longer than the others. It will yield about on an average of six tons per acre, and I have known it to produce double that quantity. It is a perennial of the clover tribe, but will out-yield it two to one, makes just as good feed, and has a great advantage over the clover, for it never falls down, but stands up straight.

SOWING.—The best method is to sow broadcast about 15 pounds per acre, where the land is in good condition, but on very weedy land or clear gravel or sand that is very poor, put about 3 pounds more. You cannot get any crop from it the first year, but do not get discouraged if the plants are on an average of 10 inches apart, little, slim single stems about 4 or 6 inches high. Your prospect is good that you will get 4 tons per acre next year, and the next it will be as good as ever it will, and stand that way for ten years. It is best to sow with grain. Oats are the best; thus you will lose no time, but can have a crop from your land every year. In fact it does better to have it shaded when young. Sow at the same time that you do spring grain.

CULTIVATION.—Where there is plenty of rain, there is no cultivation needed, for it would be unwise to manure it, as it thrives fully as well on washed sand as it will on the best garden-spot, but in a few years it will make clear sand a rich land, owing to the decay of the root. The roots will sink themselves for a distance of 10 to 20 feet straight down. They are about 1½ inches in diameter, and fully one-half of that root

decays every year from the outside, and keeps growing larger from the centre every year.

It should be cut when in full bloom. A little old is better than too young; when the bloom is ready to fall off is not too late. Do not cut too much at once, for if you allow a rain to come on your hay after it is

cut, it will not be worth more than one-half for feed, and will be entirely worthless for market. Heavy dews are not good either. Rake into windrows, if cut with a mowing machine, and let dry until it begins to let the leaves fall when handled roughly, then pick it up and lay it in piles, just one fork-full in a pile, to cure. Do not roll it together, or it will not load easily, then you will have to pull it to pieces, thus losing one-half of the leaves. By following my directions you can put each on perfectly clean at one fork-full, and not waste time nor any of the leaves. But let me warn you against condemning it as a worthless lot of sticks, until you try your horses and cows and see them clean up the sticks before they do the leaves. There are not many animals that take to it when dry, without having it in their manger for a few days with other hay; but in a few days you will see the grass hay left, while the lucerne is cleaned up. A ton of lucerne will not go quite as far as a ton of timothy. Do not let hungry cattle get on it while green, especially when wet, for it will bloat them, which is apt to result in death. If you wish to pasture it, first feed your stock all that they can and will eat, and then turn them on the green lucerne, and no harm will come to them. It is the best thing to renew old, worn-out land that I ever saw, and there is not a weed or anything else in this country that can stand before it.

We would add that lucerne or alfalfa (*Medicago sativa*) was introduced into the Pacific States from Chili, many years ago. It resists the driest weather, and it is said that when every blade of grass droops for want of moisture, it holds up fresh and green.

On page 184 Mr. Wm. Muth-Rasmussen also gives his experience with alfalfa as a honey-plant. He obtained 5,000 pounds of comb honey from it, which he sold at a satisfactory price.

Alfalfa will be a prominent crop in all places where the winters are not too severe. The power to withstand great heat and dryness comes from the long, searching tap-roots, which are sent deeply down into the soil and find moisture which is inaccessible to other less energetic vegetation.

Canada.—At a meeting of the Board of Directors of the Ontario Bee-Keepers' Association, at Toronto, on March 28, 1888, the resignation of E. Schulz, of Kilworthy, was accepted, and Mr. McPherson elected to fill the vacancy.

The resolutions adopted were the following:

That all duly qualified local societies applying for affiliation on or before Aug. 1, 1888, receive an appropriation of \$35.

That each member of the association for 1888, receive an Italian queen, supposed to be purely mated and laying, for the purpose of introducing new blood into their colonies, and that she be received on or before July 1.

That the President, Secretary, and Mr. McKnight be a committee for the purpose of arranging for the supply of queens to the members, and that the same be of Canadian production.

That the Ontario Bee-Keepers' Association offer a special prize of \$25 for the most tasty and attractive display of honey at the Industrial Exhibition at Toronto; the display to be the production of the exhibitor, provided the Industrial Exhibit Association supplement it so as to make the prize fifty dollars.

QUERIES AND REPLIES.

NUMBER AND POSITION OF BROOD-FRAMES.

Written for the American Bee Journal

Query 531.—1. Are 12 frames $10\frac{1}{2} \times 10\frac{1}{2}$ inches, inside measure, sufficient for the brood-chamber? 2. For wintering on the summer stands, building up weak colonies in the spring, etc., would it not be preferable to have the frames the short way of the hive, say a hive the shape of the Langstroth?—Indiana.

1. No. 2. No.—MRS. L. HARRISON.

1. Yes. 2. Not for me.—H. D. CUTTING.

1. Yes. 2. No.—G. L. TINKER.

1. I think so. 2. No.—R. L. TAYLOR.

1. Yes, probably. 2. I do not know.—C. C. MILLER.

1. Yes. I prefer the regular Langstroth frame.—C. H. DIBBERN.

1. Yes, amply so. 2. It does not make any difference in this climate.—P. L. VIALON.

1. They are. 2. I do not think that it would matter much with your frames.—J. P. H. BROWN.

1. We prefer larger frames. 2. Not unless you can enlarge them afterwards.—DADANT & SON.

1. It would do very well. 2. Theory says yes; but I never have tried it.—A. B. MASON.

1. Yes. I use only 9 such frames, and consider them ample. 2. Such frames as the above must run the short way of the hive, for they can run no other way where 12 frames to the hive are used.—G. M. DOOLITTLE.

1. Yes. 2. No. The size and shape ($9\frac{1}{2}$ deep, and $17\frac{1}{2}$ or $17\frac{3}{8}$ long) of the Langstroth frame, is probably the best known.—J. M. SHUCK.

1. Yes, I would never use more than ten such frames for summer, and seven would be better for winter. I do not like that shape of frame at all. 2. I should prefer the frames of that depth to run the short way of the hive. The depth is objectionable.—JAMES HEDDON.

1. Yes. 2. I use 11 frames $11\frac{1}{2} \times 9\frac{1}{2}$ inches, inside measure, and of course the frames run the short way of the hive. The entrance is in the side of the hive, so that the frames run from front to rear.—M. MAHIN.

1. Yes, but I prefer 10 Langstroth frames, which is about equal in comb to 12 such frames as you mention. 2. I have some experience in the different ways of adjusting frames, and I think that you will gain nothing by placing the frames crosswise of the entrance.—G. W. DEMAREE.

1. Yes. 2. Having tried the short frame and the Langstroth, I have never been able to see any difference—wintering always in the cellar, however. Successful bee-keeping depends more upon the *man*, than on the hive or frame he uses.—EUGENE SECOR.

1. It might be, but the best results I have ever obtained were from hives with a brood-chamber capacity of 3,600 cubic inches. Location might make a difference. 2. It is generally conceded that the combs should hang straight with the entrance.—J. M. HAMBAUGH.

1. Yes, I think that they are about right, although I prefer the Langstroth frame, and 10 to a hive. 2. Not by any means, in my own experience. The Langstroth frame has stood the test of years, and never has been found wanting yet. Why not, then, let well enough alone?—J. E. POND.

1. I use just such a hive, $11\frac{1}{2} \times 11\frac{1}{2}$ inches, and I like it much. I think that $10\frac{1}{2}$ inches would be about the same—no essential difference. For several reasons I would say, yes. If all used such hives, I should prefer them to the Langstroth. As so many more use the Langstroth style, I think that is most desirable. This is a case where it pays to be with the majority.—A. J. COOK.

1. It is probable that 12 frames of that size would suffice for the breeding apartment, but I much prefer 10 Langstroth frames. 2. By no means; the entrance to the hive should be at the ends of the frames.—THE EDITOR.

MANAGEMENT TO PREVENT INCREASE.

Written for the American Bee Journal

Query 532.—Having as many bees as I care to handle, and working for comb honey, when the bees do swarm, ought I to take the queen away and return the bees, or cut out the queen-cells and return the old queen with the bees?—Ontario.

See answer to Query 527.—P. L. VIALON.

See Query 527, for an answer.—A. B. MASON.

Neither way would be good practice.—MRS. L. HARRISON.

You will find neither practice practical, as a rule.—JAMES HEDDON.

See Query 527, with answer.—J. M. HAMBAUGH.

It depends upon the age of the queen. If too old, kill her.—C. C. MILLER.

I think that the first plan will work, if after five days all the queen-cells but one are destroyed. The latter plan would not do at all—it would lead to inactivity, and to more swarming.—R. L. TAYLOR.

There are objections to both of your methods, but probably the least to the plan of cutting out all the queen-cells.—J. P. H. BROWN.

I would return the old queen with the bees; cut out all the queen-cells first.—H. D. CUTTING.

Your method would not always succeed. Using large hives will make less swarming.—DADANT & SON.

See answer to Query 527. The swarming fever should be subdued to get the best results.—G. L. TINKER.

I would prefer to hive the swarms and double up colonies in the fall; or, better still, double down one-half in the spring, so as to make all strong, and then increase to the original number by swarming when the season arrives.—G. M. DOOLITTLE.

Let them swarm, as Mr. Heddon does, and then reduce in the fall, will, I think, pay the best. Else remove the old queen and cut out all the cells but one; otherwise they will usually keep on attempting to swarm.—A. J. COOK.

Return the bees, taking away the old queen, and be *sure* to destroy all queen-cells but one. With plenty of room and ventilation, you will have no more trouble. But look out for too much honey in the brood-combs.—M. MAHIN.

This is a mooted question. I prefer to use the so-called artificial method of swarming, and thus control the matter of increase. I should prefer cutting out queen-cells and returning the queen, but ample room for surplus must be given, else a great risk is run of having the queen killed.—J. E. POND.

How to prevent increase when working for comb honey is one of the unsolved problems in bee-culture. I do not know of any one who can certainly control swarming. Many methods are used; sometimes one will give satisfaction for a season, and then the charm is broken. Most of the rules are subject to exceptions. I should not practice either of the methods mentioned in the query. I should not expect to control swarming by either of them.—EUGENE SECOR.

This will not work. If the old queen is killed and the bees returned, they will swarm when the first queen hatches out. If the queen-cells are all cut out, and the swarm is returned with the old queen, they will at once rear other queen-cells, and with a large apiary on your hands, you would soon be in a "peck of trouble."—C. H. DIBBERN.

Neither way you suggest will prevent swarming. If you should remove the queen and return the bees, the bees would swarm as soon as the

young queens hatched; and if you should cut out the queen-cells and return the queen with the bees, the bees would start queen-cells immediately. You can prevent increase by taking the queens away from the swarm, and return the swarm, and six or seven days after the swarm issued, destroy all the cells but one. Then again, on the tenth day go over the combs again, and destroy any cells that may have been started before all the larvæ was sealed, so as to leave but one young queen. This plan will work, but you will get tired of it.—G. W. DEMAREE.

Give the swarm on the old stand, and give it the supers from the old hive, so that the work of the colony may not cease. As the bees emerge from the parent colony, shake them in front of the swarm, or treat the parent colony in any way that your judgment may dictate. Do not be in haste to destroy queens and queen-cells. Care for them, test them, and preserve the most promising.—J. M. SUUCK.

Both of the methods you mention are objectionable. How to prevent increase invariably and successfully is one of the problems as yet unsolved.—THE EDITOR.

CONVENTION NOTICES.

☞ The next meeting of the N. W. Ills. and S. W. Wis. Bee-Keepers' Association will be held in Rockton, Ills., May 22, 1888. D. A. FULLER, Sec.

☞ The Eastern Indiana Bee-Keepers' Association will hold its spring meeting on Saturday, April 21, 1888, at Richmond, Ind. M. G. REYNOLDS, Sec.

☞ The Des Moines County Bee-Keepers' Association will hold its next meeting on April 24, 1888, at Burlington, Iowa. JOHN NAU, Sec.

☞ The Darke County Union Bee-Keepers' Association will hold its annual meeting on Friday, April 27, 1888, at Ansonia, O. J. A. KOE, Sec.

☞ The Union Bee-Keepers' Association of Western Iowa, will hold their annual meeting at Menlo, Iowa, on Saturday, April 14, 1888, at 10 a.m. H. D. LENOCKER, Sec.

☞ The Cortland Union Bee-Keepers' Association will hold its spring meeting on May 8, 1888, at Cortland, N. Y., at 10 a.m. All bee-keepers are invited. W. H. BEACH, Sec.

☞ The Marshall County Bee-Keepers' Association will meet at the Court House in Marshalltown, Iowa, on Saturday, April 21, 1888, at 10:30 a.m. The subject for discussion is, "Spring and summer management of bees." A general invitation is extended. A good meeting is expected. J. W. SANDERS, Sec.

☞ The 18th semi-annual session of the Central Michigan Bee-Keepers' Association will be held in the Pioneer Room at the State Capitol, on Saturday, April 21, 1888. Prof. A. J. Conk will give an address. A cordial invitation is extended to all, as it will be a very interesting meeting. W. A. BARNES, Sec.

☞ The annual meeting of the Western Bee-Keepers' Association will be held at Independence, Mo., at the Court House, on April 23, 1888. It will be carried on as a sociable, friendly gathering. Let all bring their baskets and have a good time. PETER OTTO, Sec.

☞ The next meeting of the Susquehanna County Bee-Keepers' Association will be held at New Milford, Pa., on May 5, 1888. The following subjects are to be considered: Bee-keeping for pleasure and profit—Spring work with bees—is it advisable to use foundation? If so, to what extent?—How can we make our Association of the most practical value to its members. All are cordially invited to come. H. M. SEELEY, Sec.

☞ The tenth annual meeting of the Texas State Bee-Keepers' Association will be held at the yards of Vice-President W. E. Graham, in Greenville, Hunt Co., Texas, on May 2 and 3, 1888. A leading feature of the convention will be criticisms upon subjects that have been mentioned in the newspapers. A good time is expected, so let all Texas and Arkansas bee-keepers attend. A cordial invitation is extended to all bee-keepers wheresoever dispersed. Remember, no hotel bills to pay at our conventions! B. F. CARROLL, Sec.

CORRESPONDENCE.

LARGE HIVES.

The Small Hives vs. the Large Hives.

Written for the American Bee Journal
BY CHAS. DADANT.

The article of Mr. W. J. Davis, on page 170, on large hives, reminds me of the objections raised, 25 years ago, by the bee-keepers with box-hives, who condemned the frames on account of the impossibility of taking them out after the building of combs. The combs were crooked, passing from a frame to another, and therefore such hives would never, never, be used by the majority of bee-keepers.

Of course such bad results were not to be imputed to bees, but to their owners, who had neglected to watch the building of comb, and to help the bees; while a few minutes per colony would have obtained the desired result.

Mr. Davis is guilty of about a similar neglect, for he writes: "During March and April I find that colonies build up more rapidly in the smaller hive, owing to the fact of greater warmth, or the better economizing of the heat of the cluster." Then he did not take the trouble of providing his large hives with division-boards, which would have enabled him to reduce the number of combs according to the size of the cluster of bees. We are not in a linden country; like Mr. Davis, our main crop is from clover. Here white clover begins to bloom about June 1. Yet we find less difficulty to get our bees ready in time, with our large hives and partition boards, than with small hives and no partitions.

A little thinking will explain the above. Suppose that, on March 1, we have a colony so reduced in numbers that it is unable to warm, sufficiently for breeding, more than 500 cubic inches. If we reduce the space inside of our large hive three combs, the upper surface of the room inhabited by the bees will be reduced to about 80 square inches; and the bees will be enabled to warm about 6 inches in depth, since the warmth always rises.

If, on the contrary, we have a 10-frame Langstroth hive, or even a 10-frame division of the Heddon hive, the surface of the whole will be about 250 square inches, and our bees will be unable to warm more than 2 inches of depth; 4 inches less than in our large hive. Then while the small cluster in our large hive will be able to keep the brood warm, the same number of bees

in the whole small hive will exhaust itself to prevent its brood from being chilled, and the laying will be altogether stopped.

Another curious objection of Mr. Davis is, that a queen can be exhausted by laying too much. During the spring, if bees find something to harvest, the queen is abundantly fed, and she lays more or less, not according to her liking—not according to the number of cells—but according to the quantity of food offered her by the bees. When the queen does not find cells to lay in, her eggs are dropped and lost. Besides, we can show by our experience, that although our queens can lay from 3,500 to 4,000 eggs per day, they are as long lived as any.

In our home apiary we keep from 80 to 100 colonies, all in very large hives. If our queens were exhausted by their excessive laying, they would not last, on an average, more than two years. Then the whole number would be replaced at the rate of about 3 or 4 queens every month. Three queens every month, from Nov. 1 to March 1, would give a loss of 12 queens, whose colonies would be queenless or broodless in March. We are far from losing half this number, on the average. Then our queens are not exhausted by their laying.

We can prove the same during the time of harvest; as we prevent swarming, the number of our swarms shows how many colonies replace their queens, since in such cases they swarm. As our 80 or 100 colonies do not give more than three swarms, on an average, during the honey crop, we know that our queens are as long-lived as those that inhabit small hives.

As to wintering bees in large hives, we know that according to the laws of nature, a large aggregation of animals, horses or sheep, and even bees, will be more comfortable in winter, than a small aggregation. If I needed to prove it, I would open to page 83, where Mr. S. P. Stone asks why a colony in a box-hive lived and prospered for 27 years. The answer is found in the size of the box; 16x16x22 inches, or 5,632 cubic inches.

On page 107, Mr. Heddon says that a colony in a hive as large as 10 Langstroth hives combined, had wintered safely for seven years, while many others had died by its side.

Both of the above colonies and hives were in Michigan, in the "bee-diarrhædom," as Mr. Heddon terms that State. Why did they winter better, if not on account of the size of the hives? I could multiply these examples, even without quoting our own regular success in wintering bees in large hives.

Hamilton, Ills.

HIVING SWARMS.

How to Secure the Swarms that Alight High.

Written for the American Bee Journal
BY C. W. HELLEMS.

I have kept bees about all my life time, on a small scale, just for my own use and amusement; and for the last few years I have tried to combine pleasure and profit on a large scale, but living in the city I have not ground enough to accommodate more than about 70 colonies, and then they are rather close together.

Until last year they had proved to be quite profitable, but then the crop was not more than one-fourth of that of former years. I have been in the habit of going up trees, some times as high as 40 feet, to take a swarm of bees; but two years ago last season I had a fall of 21 feet. The ladder slipped off of the limb that it was resting upon, and down I went, ladder, bees and all, to the ground. I was bruised, and pretty well shaken up, but no bones broken, but I secured the bees after a little while.

I then thought that I must use some other means of catching runaway swarms. I was getting too old a man to climb trees, being then in my 78th year, and my weight was 210 pounds.

I got a long, light pole, and fastened a small tackle block at the top of it, with a cord to run through the block. I made a small hiving-box that would hold 3 or 4 racks with combs in them, that the honey had been extracted from. When the bees had settled on a limb, I would put the pole up against that limb, and run the box up, either under or over the bees, giving them quite a jar, and in five or ten minutes they would all gather in the box on the combs. I let them down by the cord, and took them to the hive already prepared for them. This worked very well.

Last season I thought of and tried another plan. I planted a pole in about the centre of the bee-yard, about 50 feet high, with a tackle block at the top of it, and a cord to reach to the ground; when the bees began to come out to swarm, I run the hiving-box up as high as most of the bees were flying, kept the box moving slowly up and down a few feet, and often by the time the bees were half out of the hive, they would begin to gather in the hiving box. As soon as they were settled, I lowered them carefully, and took the box to the hive already prepared for them, and either shook off the bees in front of the hive, or lifted the frames and bees all out and put them in the hive, when the job was done.

I have often, in preventing bees from leaving the hive, taken a comb from the hive they came from, with brood in it, and put it into the hive of the new colony. I have never had them leave the hive since I adopted that plan.

This above-described pole-arrangement is new to me, and whether any one ever used it before, I do not know; but so far it has worked well. The hiving-box is made out of $\frac{3}{4}$ -inch stuff, very light, and just long enough to hang the frames in lengthwise, the same as in the hive, and wide enough to hold 4 or more frames. I found that combs lately extracted are the best.

If the apiary is large, I think that by having poles placed in different parts of the yard would save much trouble. When I leave the yard in swarming time, I always run the hiving-box up, and leave it there until I return. I then made another tight box that would hold the hiving-box, and I keep the hiving-box in it, with the combs always ready for use, but covered up so that bees in the yard cannot get at them on the ground, at the bottom of the pole, ready for use.

Bees did very poorly the past season in this locality, many of the colonies not gathering enough to winter on. I have 40 colonies on the summer stands, packed in chaff hives, and so far they are doing well.

St. Catharines, Ont.

GOOD QUEENS.

Are the "Queens Not Reared by Natural Swarming Inferior?"

Written for the American Bee Journal
BY O. O. POPPLETON.

On page 135, Mr. Doolittle has an article on the above subject, the most of which meets my hearty approval, but not all, and a further discussion of so important a branch of bee-keeping can do no harm.

All that part of Mr. Doolittle's article which condemns the cheap, unscientific methods of queen-rearing, meets my more than hearty approval, and the more that such influential writers on bee-culture as he is, will hammer away on that line, the better it will be for the interests of that pursuit; but readers are always quick to detect an over-statement of facts on which opinions and advice are founded, and any such over-statement always lessens the effects of such good advice.

The whole question simply is, whether queens reared by the best artificial methods known, are equal to those properly reared under the swarming impulse; and neither Mr.

Demaree's alleged mistake (I have none of the back numbers of the AMERICAN BEE JOURNAL here in Cuba with me, so I cannot examine the article referred to), nor Mr. Doolittle's mistake of comparing naturally-reared queens with poorly-reared artificial ones, touches the real point under discussion at all. Plausible and seemingly correct theories by scores, (I might almost say hundreds), have been given why such and such methods of rearing queens are the best, but the real truth of these theories must be tested by the many wide-awake, practical bee-keepers of our country who are rearing and handling queens by the hundreds, and only by their united experience for a series of years can the real facts be known.

Like many others who have made honey-producing their special business, I long ago learned that good queens were an absolutely essential element of success in that line, and to aid me in learning how to secure such queens, for several years previous to being compelled to leave Iowa on account of failing health, I kept an account of the method by which each queen in my apiary was reared. The four or five years that I kept this record before leaving, was too short and incomplete to be a definite guide, but it gave me some ideas.

It caused me to entirely abandon, even for experimental purposes, all careless methods of rearing queens, such as having them reared in nuclei, in weak colonies, or, in fact, in any colonies not in a thriving, vigorous and normal condition. The record was kept long enough to thoroughly satisfy me on this point. Although not fully satisfied of its correctness, I was coming to the conclusion that queens reared by any method, would average better if reared during the swarming season of the year; and may not this account largely for the preference given by Mr. Doolittle and others to naturally-reared queens?

The method of taking an old queen away from a strong colony, and allowing cells to be built on any or all of the combs was not satisfactory as regards quality of queens or ease of manipulation. Giving such a colony of bees a single comb of selected brood on which to build cells, was better in both respects, but not equal in the latter to the Alley plan. The Jones plan of getting natural queens gave as good ones as any, but I did not succeed in doing the manipulating as easily as I wished. I shall try to test that method further while down here.

Natural swarming gave good queens, but at an expense of extra labor not justified by the result. I had so little natural swarming in my apiary that I

had to work certain colonies for that particular object to obtain what cells I needed. The number of bees left in the old hives had no effect, so far as I could see, on the quality of the queens, at least so far as those were concerned that were in sealed cells when the swarm was cast. I tested returning none, returning a part, and returning all of the old swarm. The Alley method, with some changes of details, had so many advantages that I very closely watched the quality of the queens, and while my record, as already said, had been kept only four or five years, and covered some 150 queens only, that had been reared by that method, and therefore not full enough to be at all conclusive, yet they strongly pointed to the conclusion that such queens were fully equal in every respect to natural queens. One thing was certainly proven, namely, that to obtain good queens by any method required intelligent, careful working of the method—no slipshod work or attention would succeed.

While the larger part of Mr. Doolittle's article—all of that relating to poorly-reared queens—cannot be too often repeated by such writers as he is, yet it has no bearing whatever on the question under discussion, as stated in the caption of his article, and the good effects of the article must inevitably be lessened by its being interwoven with what many others, as well as myself, believe to be an overstated idea of the superiority of properly-reared natural queens, over carefully-reared artificial ones.

Mr. Doolittle makes so few mistakes that it is almost a pleasure when one does get a chance to have a good-natured discussion with him on some difference of opinion.

And now, Mr. Editor, I want you to take into consideration what I have said about an overstatement lessening the force of any argument, and apply it to the fight you have been making for several years past on the "untested queen traffic." Fight the "poor queen traffic" all you can, but always keep in mind the fact that ten dollars worth of the rightly-reared, young, untested queens are worth more to such honey-producers as I am, than is the same money's value of older tested queens.

The thing for all of us to fight is, the abuses of the traffic, and so far as my knowledge goes, those have been fully as great in the high-priced traffic as in the lower priced.

Havana, Cuba.

[Our remarks following the article of Mr. Doolittle, on page 136, were these :

Bro. Doolittle is right. We have repeatedly protested against the cheap-queen traffic. What we need is better queens, not

lower prices. One *good* queen is worth a dozen poor and correspondingly *cheap* ones. This "heap-by-cheap" business is the bane of modern apiculture, and should be "frowned down" by all who desire its prosperity.

It will be seen that we did not use the words "untested queen traffic." We want *quality*, not quantity; and our ideas in this respect are fully indorsed by both Messrs. Doolittle and Poppleton. For the past six years we have been fighting the "poor queen traffic," and shall continue to do so, because the interests of the pursuit demand it. In the first article we wrote on the subject in February, 1882, we used this argument against the purchasing of inferior queens for breeding purposes: "Who but a *lunatic* would think of buying a *cheap* Durham bull, full-blooded horse, or pig, for the purpose of breeding the best stock?" What we should be particular about is the quality, not the price. —ED.]

STATISTICS.

Suggestions as to Gathering Statistics of Bee-Keeping.

Written for the American Bee Journal
BY B. T. DAVENPORT.

In regard to gathering statistics, I would say that I agree with several others who have expressed an opinion in regard to it, that it cannot be done through the assessors, for the reasons already given; but it can be done through the bee-keepers themselves, those of them who are interested enough in the pursuit to go to a little trouble in getting the required information.

The "assessor's plan" would work all right where bees are not taxed, as in this town, and might perhaps work as well as any other method where they are taxed. I think that a list of those producing honey to sell (the smaller ones can be omitted) can be obtained through the several town assessors; but then, how can we best get the statistics after having their names, is another problem.

If the town assessors could be furnished with a certain number of addressed postal cards, with the proper headings all on, to be filled out at such a time and mailed, and let them hand each apiarist one, it seems to me like—well, I won't say it is the *best*, nor a good plan, but offer it as one way that has presented itself to me. I shall be willing to do what little I can to-

ward centralizing and making effective this huge undertaking.

I send \$1.00 for the defense fund, and though I am quite heavily in debt, I should be willing to pay several times this amount, rather than to see Mr. Clark beaten, and obliged to either make a great sacrifice by moving his property out of "Sodom," or give up as legitimate and upright a calling as a person can engage in.

It is warmer to-day, and rainy. The snow is 18 inches deep yet. Bees are wintering well, I think.

Auroraville, Wis., March 26, 1888.

MARKETING HONEY.

The Commission Merchant and the Honey-Trade.

Read at the Ohio State Convention
BY CHAS. F. MUTH.

It is the object of bee-keepers' meetings to stimulate a friendly relation among bee-keepers and the friends of bee-keeping; to gather knowledge in the art of bee-keeping by a friendly exchange of ideas, and to advise as to the manner of disposing of our product to the best advantage.

Although millions of pounds of honey are produced annually, and in every part of the world, and thousands of people are interested in the pursuit, and hundreds of bee-papers and agricultural periodicals are spreading knowledge and enlightenment on the subject in every land and in every language, yet the public are still poorly posted as to the many beneficent qualities of honey. Honey is comparatively little known yet, even to the great majority of our nearest neighbors.

A great deal of this unfortunate ignorance is due to our selfishness. Not only do our Canadian brethren represent their own linden honey as far superior to our American basswood, but our American brethren also will mislead the consumer when his own interest conflicts with that of a rival bee-keeper.

Our great anxiety to change the name of "machine-extracted" honey, for fear that consumers should translate a very proper name into an absurdity, such as "machine-made," or as "manufactured" honey, shows a weak spot indeed. Our own knowledge that the honey is pure, and was extracted from the comb by a machine, needs only our positive assertion to be accepted by a sensible community. We may succeed slowly, but we shall succeed best, with a straight and fearless story. Let us, therefore, always call our honey by the proper name, and never be afraid to show it, granulated or liquid. Expose the adultera-

tor, but do not look at your neighbor's honey with a suspicious smile.

The price of honey has been very low for a number of years—too low to satisfy producer or dealer—the same as all other products of the farm. Wheat at 70 cents per bushel is to our farmers no more satisfactory than 10 cents a pound for the best comb honey is to our bee-keepers, or 6 cents a pound for the best extracted clover, or 3 cents a pound for dark honey. But, what could be done under the circumstances? Could our farmers say, "We will keep our wheat until it brings a dollar a bushel?" Could bee-keepers form a "trust," or make a so-called "corner," or elect a commission to stipulate the price at which honey should be sold? It takes a younger man than I am to indulge in such impractical ideas.

If a number of our sanguine bee-keepers could have only a part of our experience, they would know that comb honey sells fast when cheap, but that it is almost impossible to dispose of a large lot if an advance of only a few cents per pound is added. They should not confound their own small home trade (even if their crop was 5,000 pounds or more) with the trade of dealers in large cities. They should know that the country is not saved, if only they have disposed of their crop at a good price.

There are two large dealers, one of them in New York, who, under the impulse of a "short crop," bought comb honey which they now offer at 2 cents per pound below cost. Such is not healthy business, and it will come back to the bee-keeper another season. Sanguine bee-keepers will be the cause if we have an over-production, a honey famine, and again an over-production all in the course of twelve months. This is within the range of possibilities in our country, where we occasionally slide from one extreme to another.

Comb honey will remain a luxury. It will sell fast when cheap enough, and though a good business can be done in it for the bee-keeper and dealer, its production will be only of secondary consideration as compared with that of extracted honey. Since manufacturers make use of extracted honey, it bids fair to become a staple article; nothing will hinder it from becoming such, unless the prices put on will place it beyond the reach of manufacturers. Its prices will be controlled more or less by the prices of sugar syrup, which cannot be otherwise. Let us make due note of it!

The wish to obtain the highest market prices is the most natural with producers, and nobody is more deserving of that privilege than they are.

Manufacturers know, from their time of labor, which is worth a certain amount per day, and their cash outlay, how to determine the price of their goods. Farmers, gardeners, bee-keepers, and others, however, labor for uncounted hours; and when their product is marketed, they have to accept the prices that they can get. They determine nothing.

When times are flush, and demand is good, good prices are realized, and the reverse is the case when times are dull. Is it a wonder that a sort of anarchistic feeling creeps over the producers? Our condition should be bettered. There is no doubt about it. But how shall we proceed?

Farmers sell their wheat to their neighboring mills, to dealers (middlemen), or they ship it to the city. Whoever pays the best price is the buyer. Gardeners, bringing their produce to the city, sell it in the market, as a general rule; but if they fail to dispose of it, they leave it with shippers (middlemen again) to dispose of it for them. These shippers have a custom among hotels and boarding-houses; other dealers ship to other places, and make a living in their own manner, benefiting themselves and others. Without these middlemen our gardeners would labor under great disadvantages. Our markets would be poor shows without the "huckster."

The same proportion holds good with bee-keepers. Honey-dealers are not only ornamental when occasion offers—for instance at fairs, exhibitions, etc.—but they are useful and indispensable to bee-keepers.

The dealer holds forth in a place handy to consumers and other dealers; makes himself acquainted with the wants of the public, and works up a demand, the like of which is just as impossible for the bee-keeper to do, as it is for the farmer to peddle out his own wheat among his neighbors. The dealer has facilities which the bee-keeper has not.

The truth of the proverb, "Everyone to his own trade," has been displayed to me lately so well that the matter deserves to be mentioned in this connection. A party had offered to us his services as salesman. Talking the matter over, he came to the conclusion that he would be a poor wholesaler, but that he would do better by buying the honey of us and selling it in his own manner, and on his own account. We had no objections.

He took a 50-pound can of honey on a passing street car, and went to the lower part of the city. Here he commenced to canvass, homeward, every house. His can became lighter as he

went on, and when he reached our neighborhood it was empty.

He took another 50-pound can, and canvassed another street in a similar manner, etc. In less than two weeks our friend and brother bee-keeper had sold 800 pounds of honey, and cleared \$67. He told me that he sold his own honey in the same manner when at home. How many producers in a hundred could do like he did? This time you see he was a middleman, useful to himself and others, and I had no reason to begrudge his large profits.

Middlemen are useful to all branches of industry, otherwise they would not be there. Large manufacturers would be lost without them. The prosperity of their business depends upon them, to a great extent; otherwise they would not pay them high salaries or large commissions.

It is a lack of experience, or a sign of narrow-heartedness in a number of bee-keepers, to consider the dealer a leech, instead of a benefactor—an opinion not shared, however, by the larger part of experienced bee-keepers.

In dull times, like the present, the bulk of the honey would remain unsold in the hands of bee-keepers, but for the unceasing industry of dealers, who take upon themselves responsibilities, invest their capital, and use their best endeavors for their own success and that of bee-keepers. Their interests are mutual, and their motto should be: "How can we best work and best agree?"

Cincinnati, Ohio.

SWARMING.

Do Bees Select a New Home Before Swarming?—Temperature and Ventilation.

Written for the American Bee Journal
BY J. E. HAND.

It seems that from Mr. G. W. Demaree's answer to Query 505, on page 23, that writer does not think that the bees select a new home before swarming, and no doubt there are many others of the same opinion. I used to think the same, until several instances came under my observation, that led me to conclude that bees do sometimes if not always, look for a home before swarming; though they are not always successful in their undertaking, I firmly believe that the majority of swarms know just where they are going before they leave the maternal roof.

I used to hunt bees during swarming time, and transfer them from the trees to the hives. On several different occasions, having found the tree which I supposed contained a large swarm, judging from the way the bees

were going in and out, upon immediately felling the tree, I was much surprised to find that there were only a handful of bees, which were engaged in cleaning out the hollow, preparatory to the swarm's taking possession. I soon found that it did not pay to cut bee-trees during swarming time, as not half of the trees cut at this time will be found to contain swarms.

Upon a certain occasion, one of my neighbors told me that a swarm of my bees had taken possession of the gable end of his house. Upon examination I found that the bees were going in and out through the siding, but from the inquisitive manner in which they were crawling into every hole they could find, I concluded that they were looking up a place to locate, and not wishing to lose a swarm of bees, I went home, when I found a large swarm clustered on a tree, and hived them, and they did not trouble the neighbor afterward.

One of my neighbors told me last winter that he secured 17 swarms in one season, by placing empty hives in trees. Now if bees do not look up a future home, there must have been a great many swarms of bees flying through the air, to have accidentally found so many of those empty hives.

Winter Temperature and Ventilation.

In Mr. Tyrrel's article, on page 25, he says that temperature and ventilation are the most important factors in the wintering problem, all else being of minor importance, as matters over which we have no control, such as honey-dew, improper food, etc. I think that Mr. Tyrrel is putting it pretty strong, when he says that honey-dew, improper food, etc., are of minor importance. My experience has proven that bees with stores of good, ripe honey, will winter under most unfavorable conditions; while with stores of poor honey, and honey-dew, they will not winter well under the most favorable conditions of temperature and ventilation.

Again, I cannot agree with Mr. Tyrrel, as to our having no control over the kind of food which our bees shall have for winter stores. The advanced strides of modern bee-culture, together with the improved manner of manipulating hives, places it entirely at the option of the apiarist, whether his bees will have honey-dew or something better for winter stores; and for my part, I expect to see it that my bees do not have honey-dew for winter stores in the future.

If Mr. T. had said that all those bees, during his experiments, had the same kind of stores, it might prove a great deal in favor of a lower temperature for cellars; but if his bees with stores of good honey wintered well at

28° to 30°, and again on stores of honey-dew did not do well at a temperature above 42°, it does not follow that 28° to 30° is the right temperature. I have always considered the matter of food a very important factor, and in conducting experiments it should always be considered.

The temperature in my cave never goes below 40°, nor above 43°, no matter what the weather is outside, and the cave did not cost ten dollars.

Osage, Iowa.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*
 Apr. 11.—Stark County, at Canton, O.
 Mark Thomson, Sec., Canton, O.
 Apr. 14.—Union, at Menlo, Iowa.
 Mrs. J. E. Pryor, Pres., Dexter, Iowa.
 Apr. 21.—Central Michigan, at Lansing, Mich.
 W. A. Barnes, Sec., DeWitt, Mich.
 Apr. 21.—Eastern Indiana, at Richmond, Ind.
 M. G. Reynolds, Sec., Williamsburg, Ind.
 Apr. 24.—Des Moines County, at Burlington, Iowa.
 John Nau, Sec., Middletown, Iowa.
 Apr. 27.—Darke County, at Ansonia, O.
 J. A. Roe, Sec., Union City, Ind.
 Apr. 21.—Marshall Co., at Marshalltown, Iowa.
 J. W. Sanders, Sec., LeGrand, Iowa.
 May 2, 3.—Texas State, at Greenville, Tex.
 B. F. Carroll, Sec., Blooming Grove, Tex.
 May 5.—Susquehanna County, at New Milford, Pa.
 H. M. Sealey, Sec., Harford, Pa.
 May 7.—Welland County, at Welland, Ont.
 J. F. Dunn, Sec., Ridgeway, Ont.
 May 8.—Keystone, at Scranton, Pa.
 Arthur A. Davis, Sec., Clark's Green, Pa.
 May 8.—Cortland Union, at Cortland, N. Y.
 W. H. Beach, Sec., Cortland, N. Y.
 May 19.—Nashua, at Nashua, Iowa.
 H. L. Kouse, Sec., Ionia, Iowa.
 May 22.—N. W. Ills. & S. W. Wis., at Rockton, Ills.
 D. A. Fuller, Sec., Cherry Valley, Ills.
 Aug. 14.—Colorado State, at Denver, Colo.
 J. M. Clark, Sec., Denver, Colo.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

Cemented Bee-Cellars.—C. H. Dibbern, Milan, Ills., on March 21, 1888, says:

In reply to Mr. John B. Lindle, on page 185, I will say that I have used exactly such a bee-cellar as described by me on page 41. During the last ten years I have stored, every winter, from 100 to 180 colonies of bees in it, and I have not lost to exceed 2 per cent. in wintering. The present winter will be no exception, as the bees appear to be in fine condition.

Finding the Queen, etc.—Frank Waring, Philipsburg, Pa., on March, 28, 1888, writes:

This is how I now find queens after all other methods failed: I procure an empty hive like the one with the bees in, move the old hive back a few feet, and put the empty one on the old stand, with a drone and queen trap at the entrance, so that all the bees have to pass through the zinc. I then take a frame out of the old hive, and if I do not see the queen, I shake enough of the bees in front of the new hive so that I am sure the queen is not on the frame;

then I put the frame into the new hive, cover it with a cloth, and proceed with another frame in the same way. If I get all the frames into the new hive without finding the queen, I find her trying to get in through the perforated zinc.

Last fall I had 14 colonies of bees, and now I have 13, one having frozen to death early in the winter. They were wintered on the summer stands, and are all in good condition. One strong colony had a hive-entrance 1½x12 inches, and is in splendid condition now. Yesterday I started the bees on rye meal, and to-day they worked on it with great vigor. Bees were flying in as great numbers as during a honey-flow in midsummer. I have one colony of pure black bees, and the rest are of all degrees up to nearly pure Italian.

Good Prospects—Hive Standards.—D. P. Barrows, Nordhoff, Calif., on March 21, 1888, says:

The season has opened very favorably, and the prospects are very fair for a good year for bees. There was very little honey last year, but our bees are doing very well, and the majority are well supplied with honey. My bees have not swarmed yet, but I am looking for them to do so soon, as there are a great many drones about the apiary, and in many hives. Will some one suggest a good standard for which to place hives on?

Experience in Bee-Keeping.—Walter B. Boutwell, Lowell, Mass., on Mar. 18, 1888, writes:

I began with 1 colony, increased it to 3 the first year, and the next year I increased them to 8 colonies; the next year I increased them to 13 colonies. I have lost all but 3 colonies. I had a swarm issue on Aug. 25, which was very late, but I thought I would try to save it. I hived it on comb foundation, and it gathered some honey before frost came; so I put it into the barn cellar, in a window, so that the sun would shine in very warmly. I fed it with one-pound sections of honey in the window, and it carried the honey into the hive; it wintered in that way, and in the summer it built up so as to make a very strong colony. I can sell a great deal of honey in Lowell for 30 cents a pound. There is not much honey in that town now.

Properly Caring for the Bees.—J. W. Sanders, Le Grand, Iowa, on March 22, 1888, writes:

I prepared my 64 colonies for winter last October, by strengthening the weak in stores from those that had enough and to spare, and putting in division-boards. I made a record of the condition of each colony, by giving the age and quality of the queen, number of frames, strength of the colony, and amount of stores. This I have in my apiary register, and also on a tablet which is tacked on the front of each hive, where I can see it at any time when in the bee-cellar.

On Nov. 19 and 21 I put all the bees into the cellar, where I intend to have them remain until about the time willow and maple are ready to bloom. The temperature of the cellar has been from 36° to 42° the most of the time since they were put in. A few times I had to use a little stove in order to keep the temperature above freezing, when it was 20° to 36° below zero out-doors, and perhaps a high wind. Such weather will some times affect cellars here, and I find it a good thing to have a thermometer in the cellar. March 18 was a very warm day, being 66° in the shade, but about 50° in the cellar, and the bees were more restless than at any

time during the winter. I opened the doors in the evening, so as to admit a good change of warm, fresh air.

The cellar is so arranged that I can open the outside doors, and not admit light to the bee-room. On March 21 I examined them, cleaned out the dead bees where necessary, and as far as I could see all seemed well except two or three colonies that were a little too much clogged up with dead bees.

The harvest of 1887, in this part of Iowa, was almost an entire failure, and from my own observations and inquiry, I think that there will be a large number of colonies that will perish during the winter, for want of stores where they were not properly cared for in the fall. The mercury this morning was 6° below zero. It is a good thing that the bees are in the cellar yet.

Bees Wintering Poorly.—Jno. G. Pursel, Round Plains, Ont., on March 29, 1888, says:

In this locality, so far as I can learn, bees are wintering badly, the losses being about one-half. They are badly affected with diarrhoea. I have 20 colonies in the cellar, which are all right. I wintered my bees at a temperature of 40°.

How the Bees have Wintered.—Roland Holmes, Ft. Wayne, Ind., on March 23, 1888, says:

Bees have wintered well in this locality. The drouth last year cut the honey crop short, my bees producing only 34 pounds of surplus per colony, and they were in good condition for the honey flow; but it did not "flow." I have 40 colonies at present.

Successful Cellar-Wintering.—E. P. Colburn, New Cassel, Wis., on March 23, 1888, writes:

My bees have wintered nicely. Five colonies were outside, in double-walled hives filled with dry sawdust. They had a cleansing flight on March 19, and I found that they were in fine condition. I have 40 colonies more in the cellar, which I have not taken out yet, but I know they are all right. My cellar has a furnace in one part of it, which makes it a nice place to winter bees. I never have any moldy combs to bother with in the spring. I never have lost but 3 colonies while wintering them in the cellar. I am very fond of bees, and owe what I have learned about them to the AMERICAN BEE JOURNAL. I am a miller by trade, have about 15 acres of land, with the bees near the mill, so that I can attend to them at odd times, with some of my wife's aid in case of necessity.

Bee-Stings—House-Apiary, etc.—Alva F. Wilson, Prairie City, Iowa, on March 25, 1888, writes:

I put 60 colonies into a bee-cave last fall, and I am ashamed to say I let 12 or 14 colonies starve; the rest are in fine condition. In mild weather I open the door in the south end of the cave, and also the ventilator in the north end at night, thus letting the bees have fresh air. I am a farmer, and I would as soon think of doing without my cows as to be without the bees. Bees sting occasionally, cows kick, but I will take the bees and honey for profit, in preference to the cows and butter, compared with the amount of labor and expense. Last year was a poor year for honey, as well as for other crops.

I think that I have found the best antidote for a bee-sting. It is lemon juice and salt. I cut off a piece of lemon, put a little

salt on it, and apply it. It will stop the pain instantly, and keep it from swelling.

I would like to hear from some one that has had experience with house apiaries. I am thinking of building one as an experiment, on a cheap scale, 10 feet wide, 50 or 60 feet long, one story high, to accommodate two rows of hives on each side; the walls to be double, and warm enough to let the bees stay in it the whole year around. It will have bee-escapes, as described on page 108. There is lots of bad weather on the farm, that I could work at the bees in the house, when I could not do anything else. They could fly when they wished. It is so much work to carry bees in and out of a cave, and they are always liable to mold.

Strong Colonies in Chaff Hives.—Nathan Mercer, Neosho, Wis., on March 18, 1888, says:

I have 83 colonies of bees left from 99 colonies, all in chaff hives. About one-half of them now cover 10 frames of comb, and are increasing fast. Twelve colonies starved to death. I supposed they had plenty of stores to last them until spring; but being such strong colonies, they consumed more than I expected. I suppose I will have to feed some.

Bees Wintering Well, etc.—J. L. Comstock, Sac City, Iowa, on March 28, 1888, writes:

My bees are wintering well so far. I have 31 colonies in the cellar. They had good honey to go into winter quarters with, being mostly basswood. In the spring of 1887 I took 52 colonies out of the cellar, and I sold 27, which left 25 colonies. I had only 7 natural swarms. My bees gathered 500 pounds of comb honey in one and two pound sections. I united 2 colonies in the fall, which made 31 good colonies, and all are alive. The indications are that we will soon have them on the summer stands. It is very warm to-day.

Rearing Queens, etc.—G. Crouse, Ithaca, Mich., on March 20, 1888, says:

I notice that Mr. Doolittle claims that queens reared by natural swarming are better than those reared as breeders generally rear them. Will some one please state in the BEE JOURNAL how they are reared in the latter case?

My bees have wintered well. I have 22 colonies in chaff hives, on the summer stands, with but one weak colony among them. So far I have not lost any, and young bees are hatching in nearly all of the colonies. I began last season with 11 colonies, sold 2 swarms, increased my apiary to the present number, and obtained 550 pounds of honey in sections. The bees were wintered on stores of their own gathering.

Cheap Queens.—W. H. Shaner, Leechburg, Pa., on April 2, 1888, says:

Last August I bought 4 cheap, untested Italian queens. One was ailing when I got her, and the colony kept its drones. The queen did not lay until October, when I noticed the bees carrying several young queens out. I examined the colony, and found a young queen (which has proved to be a drone-layer) and a little brood. On Feb. 12, I found another cheap queen in front of a hive, dead; and on March 26 still another. I am disgusted with cheap queens. I want no more of them.

Bees have wintered well in the cellar and on the summer stands. They carried in the first natural pollen on March 27.

Experience with Black Bees.—E. T. Smith, Bowling Green, Mo., on March 29, 1888, writes:

Last fall I had 47 colonies of mostly black bees, which were reduced, by doubling and letting the moth destroy them, to 23 colonies. I now have 7 fine colonies of Italians and pure hybrids. I want no more black bees. They are like poor land, which produces a good crop when the season is perfect. We have had some fine spring days, but mostly cold, damp weather. My bees brought in pollen from soft maple on March 18. I am not discouraged, but still fond of my bees, which I keep for pleasure, and, as my reports shows, not for profit.

Bees all Right in the Cellar.—A. J. Adkison, Winterset, Iowa, on March 29, 1888, says:

I put my bees into the cellar during the cold weather that we had the last of November, 1887, and they appear to be doing well. There are very few dead bees on the cellar floor, and they are very quiet. I have a partition across the east end of the cellar where the bees are, and I never go in there except to look at the bees. There is no window in that part. When the weather was 30° below zero outside, it was 36° above zero inside. I think that more than half of the bees that were left on the summer stands will die. Some bee-men have lost more than half of their bees already.

Bee-Keeping in W. Virginia.—G. C. Hughes, Pipestem, W. Va., on March 26, 1888, writes:

The industry of bee-keeping is yet in its infancy in this part of the State; yet I see no reason why it may not be made a profitable business. We are situated on the backbone of the Alleghany Mountains, where the cooves and valleys are covered with basswood, poplar, locust, etc., and the ridges are covered with sourwood. White clover grows spontaneously, and red clover grows well. My brother was the first to place bees in frame hives in this county, about ten years ago; soon afterwards he died, when the industry waned, until about two years ago Rev. Mr. Houchins and myself bought some bees in hollow-log gums, which we transferred into chaff hives. So far as I have been able to find out, bees have wintered well, and the prospects are good.

Cold Weather for the Bees.—W. Mason, Fillmore, Ind., on March 22, 1888, writes:

We are again in the midst of a blizzard, and with such a chill that a great amount of brood may be lost, as some have been feeding already to start brood-rearing, through some of the warm days just past, which I claim is bad policy. My bees have wintered well, having but two flights in four months, the first on Feb. 23, and the last on March 18 and 19. I always return my bees to their winter quarters on the appearance of a cold spell, in spite of other work. Bees have wintered well in this part of the State, and where properly packed, but of those left to take care of themselves, a large per cent. are lost. I find this to be the result of not taking a good bee-paper, and not attending bee-meetings and profiting by them. But such are not bee-keepers, but bee-failures. A great many bees are being lost by drowning in the sap-pails in the sugar orchards. My plan to stop this is, to take an ax and go to the nearest sugar trees and hack them as high as one can reach. The bees will go to that instead of the buckets.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Money Orders for \$5.00 and under, cost 5 cents. As these are absolutely safe, it will pay to get them instead of the Postal Notes which are payable to any one who presents them.

We Club the AMERICAN BEE JOURNAL and the "Bee-Keepers' Magazine" for one year for \$1.40; or with "Gleanings in Bee-Culture" for \$1.75; or with the "Apiculturist" for \$1.80; or the "Canadian Honey-Producer" for \$1.30; with the Bee-Keepers' Review, \$1.40; or all six for \$4.00.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

The Answers.—The following are the replies to the "Questions" propounded on page 141, concerning the new Heddon hive, tabulated in order to save space.

Names of persons who are using the New Heddon hives.	Number in use of these hives.	No. of Seasons.	By whom were the hives made?	From what pattern.	The Hive which I now prefer—every thing considered.

REFERENCES.—† Indefinite figures.
* Undecided, on account of poor season.
‡ Preference for comb honey.
‡ Making a quantity more for use.

In all, there are 79 answers from persons having 2,183 of these hives in use; of which 58 prefer the "New Hive," on account of the unpropitiousness of the past season, 16 have not decided upon its merits; while preferring it for the production of comb honey, 6 cannot decide upon its adaptability for the production of extracted honey; and 5 prefer some other hive.

It must be understood that this is not here given in the interest of any person, but for the information of bee-keepers in general.

It is Extravagant Economy not to have hives, sections, comb foundation, etc., on hand when needed. To prevent disappointment, order early what you will need in that line. Then the hives can be nailed and painted in odd times, and the sections put together, so as to be ready at a minute's notice. It is a sad disappointment to need these things and then not have them on hand. They should be ordered immediately.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Scatter the Leaflets.—Look at the list (with prices) on the second page.

A Pocket Dictionary will be presented for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

Your Full Address, plainly written, is very essential in order to avoid mistakes and delays.

Clover Seeds.—We are selling Alsike Clover Seed at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. White Clover Seed: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. Sweet, or Melilot, Clover Seed: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2.00	3.00	3.50
1,000 Labels.....	3.00	4.00	5.00

† Samples mailed free, upon application.

Honey and Beeswax Market.

CHICAGO.

HONEY.—Prices range from 16@18c. for best one-lb. sections, to 14@15c. for off color and condition; 2-lbs., 14@15c. Dark is slow sale at almost any price. Extracted, 7@9c., with good supply. Light demand.

BEE SWAX.—22@23c. R. A. BURNETT, 161 South Water St. Mar. 22.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 14@15c.; fancy 2-lbs., 12c. Lower grades 1@2c. per lb. less. Buckwheat 1-lbs., 10@10½c.; 2-lbs., 9@9½c. Extracted, white, 7@7½c.; dark, 5½@6c.

Mar. 19. F. O. STROHMAYER & CO., 122 Water St.

CHICAGO.

HONEY.—We quote: Fancy white clover 1-lb., 16@17c.; 2-lbs., 15@16c. Dark is slow sale at almost any price. Extracted is scarce, and sells at 7@10c.

BEE SWAX.—23c. S. T. FISH & CO., 189 S. Water St. Mar. 13.

CINCINNATI

HONEY.—We quote extracted at 4½@9c. per lb., for which demand is good. Comb honey, 14@17c.—Supply large and demand slow.

BEE SWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival. Mar. 26. C. F. MUTH & SON, Freeman & Central Av.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 14@17c.; the same in 2-lbs., 12@14c.; buckwheat 1-lbs., 10@11c.; 2-lbs., 9@10c. White extracted 8@9c.; dark, 5½@6c. Market dull; prices declining.

BEE SWAX.—22@23c. MCCAUL & HILDRETH BROS., 28 & 30 W. Broadway, near Duane St. Mar. 10.

MILWAUKEE.

Mention the American Bee Journal.

The Bee-Keepers' Review

FOR MARCH is devoted to "Planting for Honey." If undecided upon this subject, by all means read this Number. The April Number (which will be out about March 20) will take up the topic of "Securing Workers for the Harvest," or perhaps it would be more proper to say, "Spring Management."

R. L. Taylor, James Heddon, Dr. A. B. Mason, Dr. C. C. Miller, E. E. Hasty, F. P. Stiles, H. R. Boardman, J. H. Robertson, J. H. Martin and Oliver Foster are among the contributors to these two issues. Besides this, there are several pages in each Number devoted to extracts and to short, pointed editorials upon live and practical subjects. An exhaustive review of Mr. Cheshire's great work, "Bees and Bee-Keeping," is begun in the present issue.

Price of the REVIEW, 50 cts. per year. Samples free.

The Production of Comb Honey,

A neat little Book of 45 pages, price 25 cents. The REVIEW and this book for 65 cents. Stamps taken, either U. S. or Canadian.

Address, W. Z. HUTCHINSON, 11A1t 613 Wood St., FLINT, MICHIGAN.

Mention the American Bee Journal.

Bright Italian Queens.

I HAVE 50 Select Tested QUEENS of last year's rearing, that I will sell in April at \$3.00 each; in May, \$2.50; in June, \$2.00; and from July 1 to Nov. 1, \$1.50.

QUEENS, warranted purely mated, \$1.00; 6 for \$5.00. They are bred from the best of mothers and are superior to the common run of Queens sold at a lower price without any guaranty as to purity. I do not pretend to rear Queens under the Swarming Impulse. I believe with those who answer Queries in this JOURNAL—that it is a humbug. When it is necessary to stimulate to get good Cells, I do so, and that is all there is in it.

Have your orders booked ahead, and send for the Queens when you want them. I will commence shipping Warranted Queens as early in May as possible. I guarantee safe arrival. Address, J. T. WILSON, 11D4t NICHOLASVILLE, Jessamine Co., KY.

Mention the American Bee Journal.

SUPPLY DEALERS

AND OTHERS should write to me for SPECIAL PRICES on BEE-SUPPLIES for this fall and winter.

A heavy Discount allowed. Address, A. F. STAUFFER, 44D1t STERLING, ILLINOIS.

BEEES AND QUEENS READY TO SHIP.

FRIENDS, if you are in need of Bees and Queens, I can accommodate you at the following low prices: One Colony of Italian Bees, on 8 Simplicity frames, in light shipping-boxes, \$6.50; 5 Colonies, \$30. One Untested Queen, \$1.25; 3 for \$3.30; 6 for \$6. One lb. Italian Bees, \$1.25; 3 lbs., \$3; 6 lbs., \$5.40; 10 lbs., \$8.50. Prices to dealers sent on a Postal Card. Address, W. S. CAUTION, 13D4t PLEASANT HILL, S. C.

MINNESOTA AHEAD!

WE are selling 100 All-Wood Langstroth Brood-Frames for \$1.00; and Langstroth HIVES, with Supers, for 55 cts. Don't order your Supplies for 1888 until you see our Circular.

WM. H. BRIGHT, 10A1t MAZEPPA, MINNESOTA.

Full Colonies of Bees for Sale

CHEAP, during the season of 1888. C. M. HOLLINGSWORTH, Rockford, Illa. 11-15-19

Mention the American Bee Journal.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. April 18, 1888. No. 16.

EDITORIAL BUZZINGS.

All the Bells of heaven may ring,
All the birds of heaven may sing,
All the wells on earth may spring,
All the winds of earth may bring
All sweet sounds together.
Sweeter far than all things heard,
Hand of harper, tone of bird,
Sound of woods at sundown stirred—
Bees are swarming—welcome word,
Sounding in warm weather.

Hoge's Honey Company, in London, failed, and in February offered a "first and final dividend" of one-sixty-fifth of a penny to the pound sterling to its creditors, or about \$2.60 dividend for \$1,000. This is a wonderful offer for the London Yankee honey-dealer.

It is no Secret, although it is said to be "confidential," that an effort is being made to create a life-annuity of \$300 for the Rev. L. L. Langstroth. This very small amount is proposed to be raised by annual subscriptions or donations—or, more properly speaking, by "free-will offerings," borne by ready hands, with the hearty benedictions of the donors, and the warmest wishes for peace and happiness, to rest upon the head of this "grand old man," and Father of modern apiculture. As this matter is "confidential" among his friends, any one can obtain full particulars by sending a Postal Card giving your name and address to Dr. C. C. Miller, Marengo, McHenry Co., Ills.

A Modern Bee-Farm, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

Adulteration — Impurity, etc.—On page 265, Dr. Leers makes some very fine distinctions, while criticising a matter brought out at the New York Convention (see page 106). These distinctions will not bear the light of the definitions of these words by Webster.

For instance: To adulterate is thus defined: "To corrupt by some foreign mixture, or by intermixing what is less valuable; to pollute." An impurity is "an admixture of base ingredients." The words mean just about the same thing.

On our desk is one of the slips which one of Thurber's agents had the assurance to scatter at the New York Convention, stating that out of 42 samples of bottled honey analyzed, only 6 were pure, and Thurber's was one of the six. The whole thing looks like a base impostion, to use the words of the member of that convention who sent us the slip.

It is but a short time ago that the United States Chemist sent to honey-dealers in various cities for samples to analyze. Mr. Muth, of Cincinnati, sent him some, and nearly all were reported as "probably adulterated." Mr. Muth's were marked "probably pure." The whole thing was worthy of Prof. Wiley, the author of that infamous "scientific pleasantry!" He had the brazen effrontery to send to Mr. Muth for more samples to analyze. This was indignantly refused—in these words: "We know what we deal in, and handle only straight goods—and want nothing more to do with your *probably pure*." Good, for Bro. Muth. The name of that wily chemist will go down to posterity loaded with infamy!

If the chemist is honest and capable, would he not know the result of an analysis? Then is it not an evidence of fraud to say that a sample so analyzed is "probably pure?"

Statistics of Maine.—Mr. Isaac Hutchins, Secretary of the Maine Bee-Keepers' Association, has gathered statistics about bees in four counties in that State, and here are the aggregate figures:

Whole number of colonies reported: 3,353 in the fall of 1886; 2,068 in the spring of 1887; 3,737 in the fall of 1887; winter loss nearly 39 per cent., and the gain in number of colonies from the fall of 1886 to the fall of 1887, 11 per cent.; average amount of honey per colony, 12½ pounds.

Mr. W. Z. Hutchinson wisely remarks, that to produce comb honey in abundance, bees must be strong in numbers at the beginning of the honey harvest, and to secure this desirable condition, feeding must be carried on uninterruptedly for at least two months previous to the opening of the honey harvest. Aside from food in abundance, warmth is the great requisite for breeding. A colony of bees generates sufficient heat, but very much of it is lost by radiation. Warm, beautiful spring weather is sometimes followed by severe freeze which chills some of the brood.

The Summer Sleep of animals and insects was mentioned by the Rev. W. F. Clarke, on page 221, but his word *Æstivism* was incorrectly spelled, and Mr. C. desires it corrected. Our proof-reader was not familiar with the word, and consulted Webster's Unabridged Dictionary, and not finding the word there, made it as near to the writing as he could. Mr. C's writing is usually excellent, but in this case it was a little "blind," as printer's call it. When using a word not in the Dictionary, all should be very particular to write it so plainly that the spelling cannot be in doubt. Many of our best-informed writers are very careless in this particular. Of foreign words, botanical names, etc., each letter should be separated and written plainly.

The Union, Albinos, etc.—Chas. D. Barber, Stockton, N. Y., on April 9, 1888, writes:

It is warm here to-day. On April 4 I took my bees out of the cellar. I had put them in the cellar on Nov. 11, 1887, being in 145 days. They came out in good condition, and had plenty of stores. I think that we will have a good season this year. I lost but one colony. We have had a very cold winter. I think that we all ought to stand by Mr. Z. A. Clark. I am ready to pay an assessment, or five times the amount, to defend the members of the National Bee-Keepers' Union. Are there any bees that look like the Italians, but that are white instead of yellow? If so, what kind of workers are they?

Yes; Albino bees have white bands instead of yellow, and we have had such who would work fully equal to the best Italians.

In reference to the case of Mr. Z. A. Clark, we expect to be able to give some good news in our next issue. We can now say this much—that Mayor and those Aldermen have been ousted by indignant citizens, and if we mistake not, Mr. Clark's defense by the Union has been the prime cause of their expulsion from office.

Place of Meeting.—If the next meeting of the North American Bee-Keepers' Society is held at Columbus, it seems that we are to have a good place to hold the sessions. Dr. Mason, the President, says:

In a letter just received, I am informed that the hall of the House of Representatives has been granted for the use of the Bee-Keepers' Convention, at Columbus, O., from Sept. 18 to 21, inclusive.

We understand that circulars are to be sent to all the members to vote on the change from Toledo to Columbus, O. Let answers be returned as soon as possible, so that it may be decided definitely.

New Catalogues for 1888 are on our desk, from the following persons:

M. J. Dickason, Hiawatha, Kansas—16 pages—Bee-Hives and Supplies.

J. W. K. Shaw & Co., Loreauville, La.—4 pages—Bees and Queens.

Walter Harmer, Manistee, Mich.—1 page—Two-Ounce Honey-Sections.

GLEAMS OF NEWS.

Bee-Keeping in Belgium.—The following article from the British *Bee Journal*, gives a good idea of the interest taken in bee-keeping by the authorities in Belgium, and will be read with interest by Americans :

If we are to judge from the tenor of a communication which has reached the *Revue Internationale d' Apiculture*, from M. Karel de Kesel, of Amougies-les-Renaix, Belgium, is at last not only becoming alive to the importance of apiculture as a means of improving the condition of farmers and others engaged in agricultural pursuits, but is about to take such practical steps as will place it at no distant date in a line with other European countries. We cannot do better, therefore, than place before our readers a translation of M. Karel de Kesel's communication, as published in the *Revue Internationale d' Apiculture*, and which is to the following effect :

"I am in a position to inform you that our Minister of Agriculture has just approved a report upon *Practical means for spreading the knowledge of keeping bees in our country*, and decided to at once give effect to the following two recommendations, viz :

"First.—To hold an International Bee-Exhibition in Brussels in the course of the present year, of which I will send you later on the prospectus.

"Second.—To order fifty lectures to be given in the most suitable Belgian districts for successful bee-keeping.

"In order to spread as much as possible the knowledge of bee-keeping, it has been decided that for this year no more than one lecture is to be given in each district. This first lecture will deal merely upon the rudiments of bee-keeping and manipulating, so as to initiate into correct principles those who have already acquired a natural instinct in the management of bees.

"The lecturer will be furnished with horse and trap. In these he will carry about with him, among other things, a stock of bees to be used for practical demonstrations at his lectures. An adequate amount of publicity will be given, to the effect that a *bee expert is about to arrive with an ambulant apiary*, that he will bring with him bee hives on the movable bar-frame principle, that the combs will be removed from and replaced into the hive at pleasure, and that the bees will be seen working through glass. Mention will also be made that the lecturer will bring with him bees of several breeds, as well as bee-hives, from which as many as 75 kilos of honey can be obtained in favorable seasons ; and that, in fact, he will show them sundry bee-furniture of the latest invention, etc. It will also be made known that editors will be supplied gratis with a summary of the lectures, together with a lithographic design of an improved beehive, together with explanations and a list of the most approved books on bee-keeping. The explanations and documents which you have sent me, showing how a bee-association could be best organized in Belgium, will be of great assistance to me. Again M. Vernieuwe, attached to our Ministry of Agriculture, himself an amateur bee-keeper, has received the particulars which you and Mr. Cowan have sent him.

"We shall soon send out to all the bee-keepers known in Belgium an invitation to a general meeting, in order to agree upon the main point of a proposed association."

New Subscribers can obtain the full numbers for 1887 and 1888, for \$1.75, while here are any sets of 1887 left.

Fraternal Relations with our co-workers should always be maintained, if there is a possibility of its being done. We have often urged this, and at the International Convention held in Cincinnati, O., in 1880, we made some remarks upon an essay by Mr. A. J. King, relative to this, which were recorded in the printed minutes in these words :

President Newman remarked that it was exceedingly encouraging to witness the spirit in which Mr. King had written, and of his kind allusions to the Rev. L. L. Langstroth, whom some unwise enthusiasts are now trying to misrepresent and abuse. Mr. Newman said that he had not the pleasure of even a personal acquaintance with Mr. Langstroth, but revered him only for his noble work and devotion to the science and art of bee-culture. Mr. King's allusions to the necessity of adopting the newest and most perfect methods, as well as to keep abreast with the times in every department of apiculture, he regarded as the very keynote of success.

The speaker very heartily endorsed the position taken by Mr. King, that "the living issues" of to-day demanded of us something else besides bickering and strife, begotten of envy and malice. In the great work before us, he was happy in the thought that generally we were alive to our duty, and united.

Himself, the editor of the BEE JOURNAL in Chicago, he had been gallantly supported on his right and left on the platform at this meeting by the editors of *Gleanings in Bee-Culture* and the *Bee-Keepers' Instructor*, the two Ohio bee-papers. He had noticed in the auditorium the editor of the *Bee-Keepers' Guide*, of Indiana, who was taking a lively interest in the discussions, and the paper just read was from the editor of the *Bee-Keepers' Magazine*, of New York, and he noticed on the programme an essay from the editor of the *Bee-Keepers' Exchange*.

These six editors are now all arranged in solid phalanx, ready for the fray, and will give the common enemy a fierce and determined battle. This is not only flattering to the Society, but inspires all to look for a successful and triumphant issue. He congratulated the Society upon the self-evident union, peace and harmony now prevailing, and earnestly desired that it might be permanent. He felt happy that his term of office as President concluded under such auspicious circumstances.

It is a pleasure to note that these sentiments are fully endorsed by Bro. Root in the last issue in *Gleanings*, in these words :

Very often, in meeting bee-friends, and a good many times visitors at our establishment, when the subject of our bee-papers comes up, some, with a little embarrassment, acknowledge that they have been taking the AMERICAN BEE JOURNAL instead of *Gleanings*; and sometimes they seem to think that may be I shall feel displeased when I am told this. Why, bless you, friends, if I should let any such feeling get possession of me, I should be unworthy of my position. It affords me just as much pleasure to take a brother by the hand who has taken the AMERICAN BEE JOURNAL for years past—yes, and contributed to its columns—as if it were the other way. In fact, I am more likely to get original ideas, thoughts, and suggestions from him.

The AMERICAN BEE JOURNAL is an honor to our industry. It comes weekly, which is more than *Gleanings* ever expects to do, and it costs only a dollar a year. Bro. Newman has been standing faithfully at his post for many long years. Not a single number has failed, or even been behind-hand. Many of the best friends of *Glean-*

ings are among the contributors of the AMERICAN BEE JOURNAL. Now, if we cannot be brothers, all the same, even though we do take different periodicals, we are not up to the spirit and progress of the times.

True; quarrelsome and jealous persons are not up to the spirit of the times. *Gleanings* was started by its present editor in the same year that the AMERICAN BEE JOURNAL came into the hands of its present editor. Both periodicals have run along side by side, and while aiming to do the same work, are to-day in full harmony and fellowship—rejoicing in each other's prosperity. Long may these feelings continue.

While we cannot endorse all that we notice in other bee-papers, if we criticize anything we desire to do so respectfully; and if others criticize us in the same manner, there should be no contention between us, other "than that noble contention, or rather emulation, of who can best work and best agree." While harmony is desirable, jealousy is despicable.

Worth a Year's Subscription.

Many have written their congratulations upon receiving No. 14. It was a genuine surprise to receive that Special Spring Number of the AMERICAN BEE JOURNAL for April 4, 1888—and that day was a beautiful one in this latitude! The BEE JOURNAL did (as we expressed the hope that it might) "usher in and give a general welcome to Spring!" Here is what Mrs. M. B. Chaddock said about it :

Why, the AMERICAN BEE JOURNAL is having a boom; isn't it? First, it comes out in a new dress, so that I have to look at the heading a time or two to be sure that it is the old AMERICAN BEE JOURNAL; then last week there came such a wealth of reading matter—such a great wealth of engravings! Why, that one number is worth the whole dollar that you ask for the year. Are you going to keep on doing this way? I have said before, and I say it again, that editors are the most surprising people in the world!

Mr. A. C. Tyrel, Madison, Nebr., has sent us a photograph of his residence and apiary, and remarks as follows :

I send you a winter view of my residence and apiary in the far West; once considered the "Great American Desert." The honey-house is in the rear of the dwelling house. The bee-hives are not shown, from the fact that they are yet in the bee-cellar. When I bought the grounds in 1876, before the advent of railroads and the influx of actual settlers, I little realized that such wonderful strides would be made in my day and generation. Our county now points with pride to her public improvements, viz: Insane asylum, street railways, Normal College, Court House, three story brick blocks, two great lines of railways traversing the county east and west, and north and south, etc., and another surveyed.

The residence and grounds exhibit fine taste, and shows that the "Great American Desert" is being transformed into a rich garden, with trees and flowers, interspersed with grand residences of active, pushing men. The beautiful photograph is placed into the BEE JOURNAL album with much pleasure.

Honey as Food.—We copy the following item from the British *Bee Journal* on "honeyed food:"

The aim of your new venture would, mayhap, be furthered by the gathering together of receipts for eatables in which forms a part.

In the hope that you will find room for such, and that others of your readers will add to the stock, I send the following by way of beginning:

In Miss Gordon-Cummings's *Wanderings in China*, wherein she describes a Chinese dinner, occur "ham stewed in honey," and "pears sliced in honey," "crab-apples and chestnuts preserved in honey and dried." We are not told what kind of pears are used, but our stewing pears seem suitable.

It does not appear whether the ham is cured, or stands for leg; but perhaps the latter, for we have it, in his own *Confession* that St. Patrick found fresh pork seasoned with honey so luring that he ate more of it than was good for him. Being on board ship, where they were short of provisions, at last they fell in with a herd of swine, of whom, killing many, they ate their fill, seasoning the meat with an opportune find of wild honey. As might be expected, St. Patrick had night-mare. This was not due to the honey, but to the surfeit of pork to a starved stomach.

Your readers are advised (1) to try such of the Chinese dishes as they have a chance, and (2) to take warning by St. Patrick.—G. O. WRAY, L.L.D., *Bedford*.

In America our best hams are cured with honey, and pears and apples are often preserved in honey. In fact, honey has the quality of preserving, for a long time in a fresh state, anything that may be laid in it or mixed with it, and to prevent its corrupting in a far superior manner to sugar; thus many species of fruit may be preserved by being laid in honey, and by this means will obtain a pleasant taste, and give to the stomach a healthy tone. One who has once tried it, will not use sugar for preserving fruit.

Honey may replace sugar as an ingredient in the cooking of almost any article of food—and at the same time greatly add to its relish.

Digestion (all-potent in its effects on the mind as well as the body) depends largely on the food. Poor honey, received into a poor stomach, is the cause of many unhappy homes—while good, healthy food, received into a healthy stomach becomes "an Angel of Peace" to many a household.

Robbing.—An exchange wisely makes the following seasonable suggestions:

Stimulative feeding in early spring often produces robbing. This should be carefully guarded against, as disastrous results are often produced at this season by robbing. Colonies are weak in bees, and are not liable to protect their combs with such certainty as when strong in numbers at other seasons of the year. Hence we should be on our guard at the critical time. It should be ascertained if every colony has a fertile queen. This is the best preventive. Colonies having defective queens are always the foundation of trouble, and such never fail to come to naught if neglected. If good queens are not at hand to fill the deficiency, they should be united with other colonies containing good fertile queens.

BIOGRAPHICAL.

S. J. YOUNGMAN.

The following is a biographical sketch of this successful apiarist of Michigan, written at our request, by Mr. Youngman himself:

My father was born in Tioga county, Pa.; and my mother in Boston, Mass. My father afterward removed from the United States to the Dominion of Canada, but becoming complicated in the so-called rebellion or patriot war of 1837-38, he was obliged to leave. Applying to the Mayor of the city of London, for a "pass" to the United States, he was told by him in a very emphatic and bombastic manner, "Yes, I will give you a pass to London jail, and from there to h—." A hint being sufficient for the wise, he, like the Arabs, "folded his tent and silently stole away," coming to Michigan; and the subject of this sketch was born at Oxford, in Oakland county, on Feb. 1, 1848.

S. J. YOUNGMAN.

entitling him to the distinguished title of "Wolverine."

My father again removed to Montcalm county, settling in the town of Cato, in 1856. It was then a new country, and he moved through 20 miles of unbroken forest, apparently only the home of the Indian and the wild beast. The making of sugar from the maple tree, and hunting of the deer, was a source of revenue, and a pastime. It was also soon found that the woods were full of wild bees—the more strange, as there were no domesticated ones within at least 20 miles, and there but a few.

The hunting of bees soon was practiced, and the cutting of some huge pine trees for the honey was a much-looked-for event. The honey was quickly sold at a price that would make a modern apiarist smile; and although the honey was mostly from basswood, the way it was handled would make the purchaser of the present day decline, with thanks. It was when enjoying this exciting sport and revelling in the delicious sweet, stolen from the wild bees, that I conceived the idea of domesticating some of these, which were regarded, at that time, as being unmanageable insects. So some medium-sized trees containing bees were selected, and let down gently with a block and line. But this did not suffice. A deep interest was aroused. The interior of these log hives could not be exposed, so some movable-frame hives were procured, and some of the bees transferred. This was the beginning of an extensive apiary, con-

taining at one time 140 colonies in Langstroth hives, and with all the modern improvements, such as extractor, comb foundation, etc.

In 1884, I conceived the idea of having bees wintered in the South, and the same sent to the North in time for the basswood bloom. Bees having wintered disastrously at the North, a contract was made with Mr. E. T. Flanagan, of Illinois, to try the project. Accordingly a carload of bees were sent from Kenner, La., in a commo freight car, *via* Chicago, arriving at Lakeview, Mich., on the evening of June 19, 1884, having been about ten days *en route*. Many colonies had perished for want of stores.

As no agreement had been made with the railroad companies between Chicago and the place of destination, they evidently thought that so valuable a consignment should pay a round transportation price, and so the modest charge of \$489 was fixed upon by the companies of the two roads that the bees passed over. I refused to accede to their exorbitant demand, and also to take the bees. The railroad agent having such an "elephant" upon his hands, was obliged to call upon me for assistance to remove the bees from the car, and also to take care of them, which I was of course glad to do, as they were in need of having the dead bees removed from the hives, etc. The charges were finally reduced to \$140, which was quickly paid, and the bees removed to my farm some three miles from the depot.

I will not receive any more bees by freight, but will sometime give, in the *BEE JOURNAL*, my views as to how bees should be sent by express.

Although largely engaged in farming (having a farm of 480 acres), I still have time to attend to the bees. I had about 30 acres of Alsike clover the past season, and the result shows a larger yield of honey than any apiary near, that did not have access to the same. S. J. YOUNGMAN.

No Better Evidence of the spread of modern bee-culture over the world has lately reached us than a little journal published in Mahon, Balearic Islands, east of Spain, entitled *Revista Apicola* (Apicultural Review). It is edited by Francisco F. Andreu, and is thoroughly abreast with the latest improvements. Mr. Andreu has just been traveling through France and England, and has adopted the system most prevalent in the latter country. The large yields per colony made in England seem to astonish Mr. Andreu; but we seem to think his astonishment will increase when he learns the large yields made by Edwin France, for instance, in hundreds of colonies. He speaks of apiculture in France as being in a very backward state. He says that in the garden of Acclimitization, in Paris, the old box-hives are shown as representative of apiculture in France to-day. The journal has 8 pages, and is published at a nominal price which does not seem to be stated.—*Gleanings*.

Favors the Syrians.—John H. Guenther, Theresa, Wis., writes:

I commenced with 37 colonies last spring, and some of these were rather weak, because I put too much confidence in outside packing. I work for extracted honey, and depend upon Alsike and basswood chiefly for surplus. I have nearly all Syrian bees, and for our short season I think they are the best.

QUERIES AND REPLIES.

SPACE FOR BEES TO CLUSTER IN WINTER.

Written for the American Bee Journal

Query 533.—Would it make any perceptible difference in wintering bees in a cellar of the proper temperature and ventilation, to remove a few of the frames in the hives to give wider space for the bees to cluster? It seems to me that in a cellar properly ventilated and tempered, there is not enough in it to pay for the trouble.—E. W.

No.—A. B. MASON.

No.—DADANT & SON.

No.—G. L. TINKER.

No.—M. MAHIN.

I think not.—J. M. HAMBAUGH.

No, you are quite correct.—R. L. TAYLOR.

I have no experience in cellar-wintering of bees.—P. L. VIALLO.

The "perceptible difference" would be very small.—J. P. H. BROWN.

That is just what I think, having tried it.—EUGENE SECOR.

I do not spread the frames for winter, and I doubt its paying so to do.—G. M. DOOLITTLE.

I do not think that it would. It would be better to use "Hill's device" over the frames.—MRS. L. HARRISON.

I do not think that it will pay for the trouble and disturbance.—H. D. CUTTING.

No, not for wintering. Yet I prefer to do so, as it gives a smaller chamber in the spring. I always contract the brood-chamber before putting the bees into the cellar in the fall.—A. J. COOK.

I do not think that there is any need of so doing. Give an inch of space at least over the tops of the frames, and you will be as nearly right as is possible.—J. E. POND.

I do not think that it would be of any advantage whatever. It would not pay for the trouble.—C. H. DIBBERN.

Some good authorities attach much importance to it, but I have never thought it worth the trouble to make any change.—C. C. MILLER.

I have tried this plan repeatedly, and I find no marked results. Differently spacing frames between summer and winter, is not practical, and will never be generally practiced.—JAMES HEDDON.

Ordinarily, I would not do it. But if you use nine frames in an 8-frame hive, the combs are too thin to hold as much honey over the cluster as there ought to be. In this case it is well to remove one frame and space the re-

maining ones so they can "fatten up" a little. When frames are spaced $1\frac{1}{2}$ inches from center to center, the season through, this manipulation is not necessary.—J. M. SHUCK.

I think that you are right when you say that "there is not enough in it to pay for the trouble." I do not believe that there is anything to be gained by spreading the combs at any time or under any condition. That the cluster should be divided by the thin septums of the combs to insure ventilation and healthful conditions, is plainly indicated by the form of the brood-nest, as we see it in a state of nature.—G. W. DEMAREE.

If there were any advantage it would be so slight that it would not pay for the trouble.—THE EDITOR.

DUMMIES FOR CONTRACTING THE BROOD-NEST.

Written for the American Bee Journal

Query 534.—If I would use wide frames with a thin board on either side filled with chaff or some other substance, would it not be a good "dummy," or is it not the best? If not, what is the objection to it for contraction?—Iowa.

Yes, it is equal to any.—R. L. TAYLOR.

I think that it would be good.—MRS. L. HARRISON.

It is too expensive for a simple dummy.—A. B. MASON.

Yes, that makes a good dummy, for my experience says so.—G. M. DOOLITTLE.

Certainly, very good.—J. M. HAMBAUGH.

I think that it is good.—C. C. MILLER. It would be a first-class dummy.—M. MAHIN.

Wide frames when filled as you suggest, make a good "dummy."—J. P. H. BROWN.

Instead of thin boards on both sides, I would use cotton duck on the side towards the bees.—P. L. VIALLO.

I should think that they are all right for either purpose.—EUGENE SECOR.

It is good, but a board is cheaper, stronger, and more easily made, and about, if not quite, as good.—A. J. COOK.

We want the board to fill up at the ends. Your frame would not do so, and would leave an escape for the heat.—DADANT & SON.

Yes, it will make a good dummy if you would perforate with holes about 3-16 of an inch on the side next to the bees.—H. D. CUTTING.

I do not know, as I have had no experience with such an arrangement.—C. H. DIBBERN.

I have used wide frames as described, and they work well in a large brood-chamber.—G. L. TINKER.

Yes, the wide frames boarded as you describe, make first-rate "dummies," and I think that that is all they are fit for. My objection is, that they cost too much; besides, I prefer plain division-boards to any sort of "dummies."—G. W. DEMAREE.

It is a good "dummy," and just what I use with the Langstroth hive; but since I have used the new hive for contraction, I am discouraged from practicing contraction with the Langstroth hives.—JAMES HEDDON.

I do not understand the question, unless a chaff division-board is meant. If that is the case, I will say that I find no better protection than a frame of comb itself. I discarded all extra means of protection in the way of division-boards or dummies, some years ago, and I now lose no more bees than formerly.—J. E. POND.

Yes, this makes a good dummy or filler. I have made many in this way. The bottoms and ends should be cushioned so as to fit the inside of the hive. I do not use such things any more; they are too "dummy."—J. M. SHUCK.

Yes; as a "filler" it would be all right, if the ends and bottom were cushioned to make it fit tightly, and thereby retain the heat.—THE EDITOR.

CONVENTION NOTICES.

☞ The Eastern Indiana Bee-Keepers' Association will hold its spring meeting on Saturday, April 21, 1888, at Richmond, Ind. M. G. REYNOLDS, Sec.

☞ The Des Moines County Bee-Keepers' Association will hold its next meeting on April 24, 1888, at Burlington, Iowa. JOHN NAU, Sec.

☞ The Darke County Union Bee-Keepers' Association will hold its annual meeting on Friday, April 27, 1888, at Ansonia, O. J. A. ROE, Sec.

☞ The Cortland Union Bee-Keepers' Association will hold its spring meeting on May 8, 1888, at Cortland, N. Y., at 10 a. m. All bee-keepers are invited. W. H. BEACH, Sec.

☞ The Marshall County Bee-Keepers' Association will meet at the Court House in Marshalltown, Iowa, on Saturday, April 21, 1888, at 10:30 a. m. The subject for discussion is, "Spring and summer management of bees." A general invitation is extended. A good meeting is expected. J. W. SANDERS, Sec.

☞ The 18th semi-annual session of the Central Michigan Bee-Keepers' Association will be held in the Pioneer Room at the State Capitol, on Saturday, April 21, 1888. Prof. A. J. Cook will give an address. A cordial invitation is extended to all, as it will be a very interesting meeting. W. A. BARNES, Sec.

☞ The annual meeting of the Western Bee-Keepers' Association will be held at Independence, Mo., at the Court House, on April 25, 1888. It will be carried on as a sociable, friendly gathering. Let all bring their baskets and have a good time. PETER OTTO, Sec.

☞ The next meeting of the Susquehanna County Bee-Keepers' Association will be held at New Milford, Pa., on May 5, 1888. The following subjects are to be considered: Bee-keeping for pleasure and profit—Spring work with bees—Is it advisable to use foundation? If so, to what extent?—How can we make our Association of the most practical value to its members. All are cordially invited to come. H. M. SEELEY, Sec.

☞ The tenth annual meeting of the Texas State Bee-Keepers' Association will be held at the beards of Vice-President W. R. Graham, in Greenview, Hunt Co., Texas, on May 2 and 3, 1888. A leading feature of the convention will be criticisms upon subjects that have been mentioned in the bee-papers. A good time is expected, so let all Texas and Arkansas bee-keepers attend. A cordial invitation is extended to all bee-keepers whosoever dispersed. Remember, no hotel bills to pay at our conventions! B. F. CARROLL, Sec.

CORRESPONDENCE.

MONTH OF APRIL.

Written for the American Bee Journal
BY EUGENE SECOR.

The gentle showers
And springing flowers
Proclaim the winter ended ;
The perfumed breeze
From Southern seas
With song of birds is blended.

With active glee,
The joyful bee
Plays hide-and-seek with pleasure ;
From tulip-bell,
In search of *mel*,
She comes with dusty treasure.
'Tis time to wed
The maples red,
And bees transport their kisses ;
The willow sees,
Those blushing trees,
And tempts the little misses.

Box-elders smile,
And oft beguile
The insect world to tarry ;
Anemones
Too, treat the bees
To more than they can carry.

Thus April brings
The fruit of Spring's
Bright hopes and youthful ardor ;
The birds make love,
From wren to dove,
And, nesting, work the harder
At His behest
Who gave them rest.
So Winter's kindly given
To make us prize
These sunny skies,
And dream once more of heaven.
Forest City, Iowa.

VENTILATORS.

Automatic Ventilators for Use
in a Bee-Cave.

Written for the American Bee Journal
BY C. THEILMANN.

This is surely something new in bee-literature, at least I have never heard of it, or have I seen it in print. It is not theory, but facts, and my personal observations.

Some time ago Mr. Doolittle said that his bees do not need any ventilation, while in his cave in winter, and requested other bee-keepers to describe their experiments on the problem. As I winter my bees in a cave similar to one that Mr. D. has described in *Gleanings*, I will give my experiments for the past three winters.

I cannot refrain from expressing my surprise, that there is so great a difference in the results of the two caves, and I could hardly believe what Mr. D. tells us (if his observing abilities did not rank among the best of our scientific writers), namely, he had *no ventilation in his bee-cave all winter*; though there are many queer things in bee-keeping we do not yet understand.

Mr. D's cave is 26x6½ feet, 7 feet high to the plates, and contains 1,092 cubic feet; mine is 19x10 feet, 7 feet high, and contains 1,330 cubic feet; but if he would reckon the space above the plates, to the top of the roof, the difference in room would be still greater between the two caves.

My cave-entrance has three doors, and his has four; I have one underground ventilator (100 feet long, 4 feet under ground, made of 6-inch tiling), and one at each gable end, 4 inches inside, and 8 feet high, of boards nailed together. As I understand it, Mr. D's cave has ventilators, but he has them shut up during the winter; this latter, with my greater capacity of cave, and that I keep from 100 to 135 colonies, and Mr. D. only about 50 colonies in the cave, is the only difference of consequence between our caves; yet his bees keep quiet and winter well, while mine would suffocate—die, in less than one week's time, from *gasses*, if I would close the ventilators tight.

My experiments are as follows: Two years ago on Nov. 17, I put 100 colonies into the cave, and shut up the lower ventilator after the bees were all quiet; the temperature kept steadily at 42° above zero, until the week of Christmas, when a storm came on, with 20° below. I then shut up the two upper ventilators; the wind blew stronger and colder for four days, and it reached a temperature of 35° below in the evening of the fourth day. I went (or rather tried to go) into the cave, but every time I opened the inner door, my lighted candle went out. The third time I got in far enough with the light to see the register of the thermometer, which indicated 42° above zero by the time my light was nearly out; but thinking of *gasses*, I held it up high, but it did no good, so I lowered it, when I was at once in the dark. How is this explained, that *gasses* are heavy or light, low or high, on the bottom or on the top?

The time I was in the cave while the light burned, was not more than about half a minute. My head commenced to "swim," and I could hardly find the door, but I got out safely. Some of the bees were quite noisy. I at once opened all the ventilators (think of it, 35° below zero outside! How is this for a sudden change?) and in one hour's time the *gasses* had escaped and the bees were quiet. I then closed the lower, and partly shut the upper ventilators, but watched them closely afterwards.

Last winter we had just about another such a storm, when I tried the same thing, but went into the cave on the third day after closing the ventilators, and found the same conditions as the year before, but in a weaker de-

gree, as the time the ventilators were closed was shorter; this time I did not open the lower, but opened the upper ventilators, and have left them open ever since, and for the past nine days it has been 35° below zero (on two mornings, Jan. 15 and 16, it was 50° below zero); in the cave it keeps steadily at 45° above zero.

Almost all experienced bee-keepers, and other scientific men, would theorize that with two 4-inch holes in a bee-repository, with a temperature of 50° below zero outside, it would surely freeze considerably inside; but it must be remembered that the tubes are only 8 feet high, from the inside top of the gable end, and will create a great draft in the cave, especially when the outer air is much colder than the inner. But here comes in my natural automatic arrangement, which is as follows:

In moderate weather the upper ventilators furnish pure air enough to keep the cave at about 42° above zero; when the weather gets colder, white frost accumulates in and on top of the tubes, which makes the holes smaller; at zero weather the holes close to about 2 inches, and get smaller as the cold increases. At 10° below zero, a volcano-like cone forms on top of the tubes, through which a steady volume of steam rises four or five feet high, which is quite a curiosity to behold at sunrise.

At present (Jan. 18) there is a pyramid of ice one foot high on top of the tubes, closed solid; but next to the base of it the frost and ice is porous, through which ventilation goes on, and when the weather becomes warmer the frost melts gradually, which regulates it better than I possibly can. I have not done the least thing in regard to regulating the ventilators, since a year ago the forepart of this month, or since the second attack of the *gasses* in the cave, and my bees seem to enjoy it. By this, I feel that nature would do a great deal more for us, if we would only give it a chance, and direct our minds to aid it more closely.

The lower cave-ventilator is used only in the fall and spring, when it is too warm in the cave; 45° above zero is as high as my bees will stand it, without getting noisy.

One thing that I do not understand is, that the *gasses* did not raise the temperature in the cave. Will Prof. Cook, or any others, give us some light on this?

I forgot to mention that with all the *gasses* and sudden changes of temperature, the bees have wintered with little loss; but I am convinced that they all would die on account of the *gasses*, if all the ventilators were closed up for one week.

Theilmanton, Minn.

POLLEN.

The Use of Pollen as Food for Bees.

Written for the American Bee Journal
BY PROF. A. J. COOK.

If Mr. Doolittle will faithfully promise never to be guilty of any such "eat and king" absurdity again, I will most cheerfully comply with his request, on page 221.

First, we must have albuminous food or we will soon die. But suppose Mr. Doolittle attempts to live on pure cheese, almost wholly albuminous, and see how his experiment turns out. Dr. Kane was nauseated at the sight of fat at home; but near the North Pole he could take a pint of clear oil with a relish. Bees, like us, must have a variety of food. Again, the relative quantity of each kind will vary with circumstances.

Suppose that Mr. Doolittle should kill one of his chickens, and should open its crop and find corn. How long would it take to convince him that the chicken never ate corn. It is just so if we examine the digestive tube of a bee. We almost always find pollen—just such pollen as we may secure from the pine or other plants and trees. I will show some pollen from a plant and some from the intestine or stomach of a bee at the next North American Bee-Keepers' Convention.

Now, Mr. Doolittle, come and visit me, and I will engage to convince you. Still I would not engage to feed bees extensively on bee-bread, no more than I would feed friend Doolittle on exclusive cheese, should he honor and delight us with a visit.

Bees in summer, or whenever they are breeding and working hard, need much pollen. In winter they need very little, indeed I think they need almost or quite none. I know that Schonfield thinks that they must have pollen, and supposes that they feed upon cast skins and larval excreta from cells. I think that the great German experiment is mistaken. I shall know ere another year passes by.

Now that bees live wholly without pollen in winter, is not strange. In hot summer, when we exercise but little, we can live and enjoy life on a diet of exclusive fruit; while hearty food like meat is distasteful. Put us at hard work, and the meat is relished. Add cold winter to the work, and we like the meat fat. So the bee, during the winter quiet, when it is only just active enough to keep the temperature of the hive in the proper condition, eats only honey, and I think that it is the better for it. Hence while bees

must have pollen, they must also have honey; either alone would, as an exclusive diet, prove fatal to the bees. Without any honey, they die quickly; without pollen they die as certainly, but not as soon. If inactive and not breeding, the want of pollen is so slight that they take very little, and at times none for weeks or months.

Then, to answer Mr. Doolittle's question, and "get a great name," I will say: You can always get bees to eat pollen by securing the two conditions of activity and breeding. But at the same time they must have an abundance of either honey, or a substitute like syrup. But bees can never be kept on pollen alone.

Agricultural College, Mich.

BEE-NOTES.

Spring Care of Bees—Growing Alsike Clover.

Written for the American Bee Journal
BY J. M. HICKS.

The bee-master at this season of the year should know the exact condition of all his colonies, and especially know that each has plenty of honey and bee-bread to last them until the early spring flowers supply a new crop. Should the bees be destitute of bee-bread, it can be supplied by placing in tin pans or shallow boxes newly-ground rye meal, a short distance from the hive, from which the bees will soon carry to their hives a supply for present use.

I have often made a pool of mud, by throwing on sand with salt and sweetened water, for the purpose of giving the bees a watering place, as it is a well known fact that bees must have plenty of water in the spring, in order to feed and rear their young; hence they use water, bee-bread, and honey as food in rearing early swarms.

It would be well for all who contemplate keeping bees for their own use, or in making a business of it for profit, to purchase a few colonies now, and also get first-class movable-frame hives; and about two weeks before swarming time, the bees, combs and brood should be transferred into the new hives, which should be of such style that you can easily handle and manage your bees profitably. At the same time you can make a proper increase of colonies, not too many, but a judicious increase, say an increase of 3 from 2 good, strong colonies, and then work the bees for honey the first year, while you are gaining knowledge in their proper management. This of course depends very much upon the style of frame hive selected.

Alsike Clover for Honey.

The next duty the bee-keeper owes to himself and to the bees, in order to succeed, is to prepare at least a few acres of good pasture for the bees to work on. Alsike clover is the best, which produces many hundreds of pounds of the finest and best honey to the acre, in quantity, not to be excelled by any other honey known to the civilized world. The plant is of a very hardy variety, and not easy to *heave*, as is the red clover, by freezing. It is a perennial, and one of the best of hay-producing clovers. The first crop each year is the seed crop.

It is not too much to say that the hay of the Alsike clover is far ahead of all other varieties for cows giving milk, making the richest and best of butter. It is also grand food for fattening in the winter, and makes the best of pasture for all farm stock in the summer.

Four pounds is a sufficient quantity of seed to sow on one acre of ground; and it should be sown on oats, wheat or rye ground, as soon as it becomes dry enough to crack in the spring. I have had about 20 years' experience in the management of Alsike clover crops, and I have found that it will flourish well on almost all the soils in this country, the damp, wet lands seeming to be well adapted to its nature and growth. All the common bees, as well as the Italians, work on the Alsike bloom, and do well on it.

Battle Ground, Ind.

NATURE'S WAY.

Management of Bees on Natural Principles.

Written for the American Bee Journal
BY J. E. POND.

In his article on page 168, Mr. W. S. Vandruff says: "I suppose I will depart considerably from the present way of managing bees, etc.," and then states, in substance, that heretofore bee-keepers have been all wrong in their methods, and that he alone has discouraged the true means of success, viz., "Nature's way." He further says: "This article may bring forth criticisms; I cannot expect much else, as I am attacking a system in general use, etc."

Now I do not wish to criticise any one unjustly, but when a wholesale attack of this kind is made, and that, too, backed up by nothing but vague assertions, and without offering any remedy, or intimating any points connected with his wonderful discovery, I feel that I for one am entitled (before admitting Mr. Vandruff to have done

what he claims), to ask a few pertinent questions, viz: Who is Mr. Vandruff? How long, and to what extent, has he kept bees? What experiments has he made, and what way and manner has he verified his new (?) discoveries?

I am aware that there is much yet to be learned in regard to the science of bee-culture; that we perhaps are yet far from knowing all the hidden mysteries of nature as applied to the *Apis*—still I do believe that something has been learned in the past, and that it is a little “cheeky,” to say the least, on the part of an obscure man, to make assertions of a nature such as are contained in the article, in regard to those, who, right or wrong, have given us the benefit of their experience; and particularly so, when the author does not even give us a hint as to his own experiments.

Judging from the general tenor of Mr. Vandruff's article, I think that he has read a few works on bee-keeping, but none of recent date; “that he has used several kinds of hives,” but that he “knows all of about all kinds of hives in use,” without using them, is on *par* with his condemning the use of queen-excluders without having used them at all. He states a number of truisms in the article, but none that are not commonly known to the veriest novice in the business.

I am looking with impatience for a full description of “Nature's way;” and if upon trial it shall be found to be *the way*, no one will more readily accept it than myself.

North Attleboro, Mass.

PROTECTION

Is Wanted Against the Adulteration of Honey.

Written for the American Bee Journal
BY DR. WM. LEERS.

Mr. A. I. Root referred (according to the report of the New York Convention, on page 106) to a statement of the State Chemist of Ohio, that it was difficult “to tell when honey is adulterated.” This deserves an explanation.

I think Mr. Root, as well as the State Chemist, are mistaken about the significance of the term “adulterated” in connection with honey, and trade in general, confounding “adulterated” with *impurity*! Nearly all drugs as made in the factories, and all natural products sold in the stores, contain impurities; but if such impurities are not mixed for a fraudulent purpose, no notice is taken of it.

For an example: The immense quantities of acids employed in the

arts are all more or less *impure*, but no one would call them *adulterated*! Commercial sulphate of iron (green vitriol), as sold in the stores, may contain 10 per cent. of impurities (ordinarily more), is styled *impure*. It is made so by the manufacturing process, and purifying it so as to render it “chemically pure,” would be too costly, and would not improve it for the ordinary use in arts. On the contrary, if baking soda contains 5 per cent. of clay, it is properly called *adulterated*—the clay is mixed to fraudulently deceive the one who may be using it.

This applied to the honey-trade, would not make it an “adulterated” article, if bees should gather glucose, molasses, or any other sweet, occasionally found (as they sometimes do in times of starvation, or in the spring, if empty barrels are within their reach); or if strained honey is not as pure as extracted; this would simply be an impurity! If such, or any other contamination should happen, in a small degree, it may be somewhat difficult for a non-chemist to detect it, but to an experienced chemist it would not be difficult!

But such cases do not disturb bee-keepers. Their complaints are made against the manufacturing of trash (glucose with or without a small amount of cheap honey, and other drugs, under the name of “honey”) at prices with which the producers of genuine honey cannot compete! This is where the State Chemist is wrong, or Mr. Root mistaken.

The main question for the manufacturers is: Does it pay? Now the addition of a small amount of glucose, say 5, or even 10 per cent. in reality would not pay, and consequently, honey with so insignificant an adulteration, will not come into the market. It must be mixed in such proportion that the detection even for a less experienced man is easy. Honey contaminated with glucose, or other impurities, in so small proportion as to make the detection difficult, would not be called adulterated, “but impure,” or of a poor quality!

That, as Mr. Root says, bees “gather every variety of honey,” is correct; but that they gather a variety, which, by the chemist, may be declared “adulterated,” will seldom if ever happen. But suppose they did, the producer would be in a similar position to a farmer who had (without his fault) in his rye or wheat so much mother-corn, or in his clover seed so much dodder-seed, that he could not find a buyer; or of a merchant, who is condemned by public authority for selling merchandise, which (without his fault) had become unwholesome.

I will say to Mr. Aspinwall, that glucose in honey of a far smaller percentage than 5 per cent. can, by a non-chemist, be detected, not only with the polariscope, but also by easier methods. And commercial glucose also can easily be detected at all times. In other countries (England, Germany, Switzerland, etc.) it is not difficult, why should it be impossible in this? A law against adulteration of honey does not exist in Illinois, as far as noxious substances are concerned.

Time for Action.

In the past year, when honey was so cheap, was the proper moment for bee-keepers to have taken steps to protect their business. The universal adulteration of all human commodities had alarmed the public, the low price of honey stopped its adulteration, because it did not pay, and so strong efforts of the adulterators was not probable. The passing a law similar to that of New Jersey by the Legislature (or even by Congress) would not have found insurmountable obstacles—the demands of the public going in such direction, and no great interests opposing. For the law against the adulteration of milk and of butter, the chances were far less favorable.

Mr. Dadant, to whom I proposed to begin an action, said that the time was not favorable; State's rights were an obstacle, and adulteration had nearly entirely ceased. But State's rights will not soon be abrogated, and as soon as the price of honey has improved a little, adulteration will doubtless flourish again.

The prohibition of adulterated honey is a vital question for bee-keepers, and connected businesses. Important investments are made in bee-keeping, factories of apian supplies, periodicals, etc. What will be their fate if one bee-keeper after another abandons this unpaying business? Then, comb foundation mills may be converted into wash-wringers, and bee-hives into hen-coops, while people may eat unwholesome trash, and pure honey dries up in the fields!

Other industries work for protection, and have succeeded. Why are bee-keepers so easy? We do not want heavy duties, patents, appropriations for premiums or other support—we want protection against frauds upon the public! We need no “trusts” or “corners.” Manufacturers may sell their trash as cheap or as dear as they can—all that we demand is that it be sold to the public for what it is! The protection of the public against fraud, will also be our protection.

Sigel, Ills.

[Editorial remarks on this subject may be found on page 259.—Ed.]

HONEY-PLANTS.

The Season of 1887—Some Bee-Questions.

Written for the American Bee Journal
BY FRED. SIEVERT.

I commenced last spring with 5 colonies, increased them to 10, by natural swarming, and obtained no honey. Owing to the great drouth in this locality, the most of the bee-keepers had to feed their bees.

The principal honey-plants in this part of Indiana are linden and white clover, and the latter produced no nectar. There was but little fall honey secured from golden-rod and boneset. The linden trees in this vicinity have been considerably cut out, and it will prove quite serious to bee-keeping. The bee-keepers are encouraging the farmers to sow Alsike clover, which will be beneficial to the farmers as well as to bee-keepers.

I fed my 10 colonies 130 pounds of sugar syrup, according to the Heddon method, and put them into the cellar on Nov. 19, 1887, and I think they were put into winter quarters in fine condition. They have been confined for 126 days, and are in good condition now. The temperature in the cellar ranged from 40° to 48° Fahr., and the bees seemed to be the most quiet at 40°. I am favorably impressed with Mr. Tyrell's article on page 25, referring to proper temperature of a bee-cellar, hence I think that from 30° to 40° is the proper temperature for a bee-cellar or cave.

The indications for white clover are good, if it has not been winter-killed. There are plenty of flowers in the timber localities, and everything promises well for another season.

The BEE JOURNAL is a welcome visitor at our fireside, and the information which I have received from it is of great advantage to me; indeed I cannot see how I could do without it.

I want to sow some Alsike clover.

1. Where will it produce the largest crop, on high, clay, or sandy land, or on low, loamy soil?

2. What temperature is preferable to look at bees in the spring?

3. Is it essential to feed sugar syrup in the spring for stimulating brood-rearing?

4. Is it preferable to contract the brood-chamber to get the bees into the sections?

5. Will it prevent the old colony from swarming twice, by hiving the young swarm on the old colony's stand?

Chesterton, Ind., March 24, 1888.

[I. A moist soil is better than dry, sandy land for Alsike.

2. The temperature of the centre of the cluster averages 70° Fahr., and if the temperature outside is less than that, the hives should not be opened unless in an emergency.

3. It is not essential, unless they are short of stores, but it is sometimes desirable to feed them sugar syrup to stimulate brood-rearing.

4. Yes, if the colonies are weak.

5. Not invariably.—ED.]

STATISTICS.

Agricultural Statistics from the Crop Reporters.

Written for the American Bee Journal
BY C. L. SWEET.

As it is requested that those bee-keepers who are willing to report as to the condition of the bees and yield of honey in each county, I will agree to be one of them for Cook county, Ills.

I am one of the crop reporters for Cook county, and have been such for the past nine years. For the past two or three years, the blanks furnished to the correspondents have contained the question to be answered on the first day of May, as to the "condition of honey-bees;" and of course it was answered by all the crop reporters in Illinois, according to their best information. I had wintered about 100 colonies last year, and they were in good, average condition; so I marked that question 100. Now I suppose the blanks for this year will contain the same question.

Suppose the committee on bee-keeping statistics ask Mr. Charles L. Mills, of Springfield, Ills., to have printed in the blanks such questions as to the yield of honey, as they may desire to be answered on the first day of August and October. The number of colonies of bees and pounds of honey produced last year will, I suppose, be taken as usual by the assessors. The committee will then have made a commencement as far as Illinois is concerned.

The statistics taken by the township or county assessors in the several States, is also used by the Department of Agriculture at Washington, as a foundation upon which to estimate the amount produced; the number of acres being given for the year before, and the reporters answering from month to month, as the season advances, for the current year. For bees, the number of colonies, and pounds of honey and wax, forms the foundation.

The United States only takes the census including agricultural statistics, once in ten years, while the different

States take the agricultural part in some way every year. It may be that all the committee will have to do is, to furnish, as far as they can, the names of the reporters, and suggest the questions which they want answered, to the Washington Department, and they will take care of it afterwards. That is what they are there for.

The secretaries of the State Boards can be notified from there, what is wanted. They know who the secretaries are. Of course, if the statistics are taken by Government machinery, and at Government expense, it will be for publication. The "light" obtained will go on the house-top. I am on that side of this question. It will be for the consumer as well as the producer.

Glenwood, Ills.

WINTERING BEES.

Bees Flying in the Sunshine in Winter.

Written for the American Bee Journal
BY E. L. HOLDEN.

On page 788, of the BEE JOURNAL for 1887, Mr. J. A. Buchanan has an article on packing bees for winter, in which he says: "Bees in thin board hives come through in better condition than those in hives that are packed," and gives his reason for it, which is, that the sun shining upon the thin hive warms up the bees and causes them to come out and take a cleansing flight.

I have experience in wintering bees for more than half a century, and I early learned that the sun often warms up the bees, so that they will come out for a flight, when the air is much too cold for them; and the consequence was, that hundreds of them fell to the ground, and never returned to the hives. In such cases, the bees in the hives become very much reduced in numbers, and if many such days occur the chances are that the colony will perish.

Last fall there was a gentleman from Rhode Island at my place, who wanted to look over my bees, and inquired how I wintered them without losing any. He said that he lost his entire apiary of bees last winter, by their coming out on sunny days, and being chilled by the cold air. His bees were in thin hives, and not packed. I showed him my double-walled hives, and told him that I filled the spaces with sawdust.

Who has not seen snow on the roofs of buildings melted by the sun, when the general temperature was much below freezing? I have seen it melt on a roof facing the south, when the ther-

nometer indicated 20° below freezing. So fatal is the sun when shining directly on the hives, that I early learned to use wide boards, set up to shade the hives from the sun; and when there is snow on the ground I often scatter straw around, so the bees may fall on that, and not be chilled by the snow; then some of them will get back into the hives.

I do not know the lowest temperature at which a bee can fly with safety. It must be considerably over 40°, for a bee will perish at a temperature of 40°. Bees will sometimes rise from a hard crust of snow, but when it is new and soft, I have seldom seen one rise from it. Such has been my experience in this latitude; how it is in West Virginia, I do not know.

North Clarendon, Vt.

HONEY-BOARDS.

How they Should be Made and Used.

Written for the American Bee Journal
BY JAMES HEDDON.

In Dr. Tinker's reply to Query 521, he advises placing between the slats of a honey-board, queen-excluding metal containing two rows of queen-excluding passages. Let us investigate this theory by the light of what is well known to those who can correctly be called practical honey-producers.

In the first place the Doctor does not say whether he is using a Heddon honey-board (that is, one containing either, or both, the bee-space and break-joint principle)—I would rather use no honey-board, than one with either of these features left out. If the bee-space is not used, the tiering method is impracticable. If the break-joint feature is omitted, brace-combs will bother greatly between the top surface of the honey-board and the bottoms of the wide-frames, or sections, next to it, as the case may be.

Suppose the slats of the Doctor's honey-board are placed upon the break-joint principle. If they are that distance apart which just lets in one row of perforations (which, say is $\frac{1}{4}$ to $\frac{3}{8}$ of an inch), there will be no trouble with brace-combs between so narrow a strip of zinc and surplus cases above.

But one now asks, "Why, trouble with combs there?" I will answer from experience. All know that to have the least brace-combs in a bee-space, it should not be deeper than $\frac{3}{8}$ of an inch, scant, or 5-16 of an inch. As the zinc is $\frac{1}{4}$ of an inch further away than the general slat-surface of the honey-board, if this further-away surface is wider than $\frac{3}{8}$ of an inch, in go the brace-combs—the very things

that we use the honey-board to prevent. To be sure, the zinc might be tacked to the upper surface of the slats, but in that case the quantity of brace-combs below (that is, between the lower surface of the honey-board and the top-bars of the brood-frames) will be vastly multiplied—would be much more than are now found between the top-bars and surplus-cases, where no honey-board is used. While it is true that brace-combs below the honey-board are not to be compared with those above, as for the trouble they make, still though it be a fact that the honey-board does not, and was never devised to lessen the brace-comb building below it, yet it is a step backward to have them increased there.

Again, to have the slats far enough apart to admit of a strip of zinc so wide as to contain two rows of perforations, is to make the honey-board weaker; and last, but most of all, eight rows lengthwise of the Langstroth hive is ample to give a passage-way to more than twice as many workers as any Langstroth hive ever contained. The last I know to be a fact, from repeated tests made in different years in both of my apiaries. I made these on a large scale, and I am proud to go on record as controverting the fallacy of want of passage-room. If it was desirable, enough testimonials to fill a whole bee-paper could be obtained from those who can corroborate this statement, from actual experience.

The pride and pleasure which I take in placing before my fellow bee-keepers improvements in hives, is all the time marred by the proposed alterations by those who do not comprehend the things which they are imitating and proposing to improve. Certainly it makes one feel badly to see wholly original, worthless inventions setting forth claims of superiority; but when we find our own inventions altered and made impracticable on account of the alterations, then our pride as well as interest in the success of our brothers, is aroused.

I shall consider it a great favor if, in the future, those who claim to test any of my inventions, will not presume beforehand that they know more about it than I do; but be sure that they use them exactly as I make them; when, after proper experimenting on a comprehensive scale, their reports will be gladly received by all.

Surely the reports published on page 253, of those who have my New Hive in practical use, give sufficient reply to the criticisms by Messrs. Hambaugh and Dadant, on page 199. Those reports also settle the question of its merits, and hereafter it will only be necessary to discuss the best way to use it.

J. M. Clark, Sec., Denver, Colo.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

SELECTIONS FROM OUR LETTER BOX

Storing Honey and Pollen.—B. M. Faris, Fort Mill, S. C., on March 28, 1888, says:

Bees are all in good condition. I wintered 18 colonies on the summer stands in Georgia hives, with no loss. Bees stored honey and pollen in February from alder, maple and elm. Peaches and plums are in full bloom now.

[Some of the flowers were enclosed. It is refreshing to know that our fruit trees will soon commence to bloom.—Ed.]

Colonies Strong in Bees.—John F. Dipman, Fremont, O., on April 10, 1888, says:

I have been examining my bees for the last few days, and I find that they have wintered well out-of-doors. I lost only one colony out of 73. They are all strong in bees except 4 colonies.

Not a Colony Lost in Two Years.
—Ferd. Zastrow, Millhome, Wis., on April 9, 1888, writes thus:

The past winter has been the most severe for many years. I have lived here for 23 years, but I have not seen one like it. The thermometer indicated from 1° to 26° below zero on 25 different days, and on a good many days at zero and a few degrees above. Bees had no regular flight from Nov. 23, 1887, to April 3, 1888; but the long confinement and the pinching cold-snaps did not injure bees properly packed in chaff on the summer stands, while I have heard a good many complaints about colonies kept in the cellar. What I call properly packed in chaff, I will describe in a future letter. I have not lost a colony in the last two years, while every year before, as long as I have kept bees, was recorded as disastrous.

Good Results in Wintering.—Samuel Cnshman, Pawtucket, R. I., on April 6, 1888, writes :

My bees have come through in good condition, although I fed them for winter as late as Oct. 1. Out of 23 colonies in the home apiary, 3 have died, 2 of starvation. These were also made-up colonies from driven bees. In the Attleboro Apiary, 2 colonies out of 14 have died, and in the other apiaries none have died. This I call pretty good. All are strong. I shall test the "Simmins' plan" more thoroughly the coming season.

Colonies Generally Strong.—R. R. Murphy, Garden Plain, Ills., on April 9, 1888, writes :

I took my bees out of the bee-house last week, and found three dead colonies, one being starved; one was to all appearances queenless last fall, and the other was one that I transferred from a box-hive in November to extra combs from other hives. I have found two other colonies queenless out of 62 put in last fall. The colonies are generally strong in bees, and were breeding rapidly when taken out. There are heavy losses of bees where they were left outdoors without protection in this locality.

Bringing in Pollen.—S. A. Shnck, Liverpool, Ills., on April 17, 1888, writes :

Bees have wintered reasonably well in this locality. I placed 119 colonies in my bee-cellar, 5 colonies for a neighbor, and 113 of my own. They were all alive when put out some two weeks ago. The weather turned cold and stormy soon after the bees were put out. One colony starved during the bad weather, four were queenless and too weak to survive, and one nucleus swarmed out. A few others are quite weak. The mercury rose to 80° in the shade to-day. The bees were at work with a will, bringing in pollen from soft maple.

Hard Winter for Bees.—John Bauerfeind, Menasha, Wis., on April 5, 1888, writes :

The past winter was a very hard one for bees in this locality. My colonies were light last fall, and a long and severe winter was more than they could stand when short of stores. I began the winter with 67 colonies, but I have already lost 20 colonies, the most of them having starved. There is still 2 feet of snow on the ground, but to-day it looks spring-like, the snow is disappearing fast, and I may yet save one-half of my bees.

The Fertility of Queens.—John Andrews, Patten's Mills, N. Y., on April 2, 1888, writes :

As I have been somewhat disappointed in years past in the fertility of queens that I obtained from (what was considered) reliable breeders, most of which were obtained in September, I have come to the conclusion that late-reared queens are of not much value to me. The most of these queens were obtained simply for experiment, holding them over for the next year's observation. Now and then one has been up to the average of the bees in the yard in activity, but four out of five have been below the average. For years I have bred my own queens, and in this I have noticed that the late-bred queens did not produce active colonies, as a rule; and now the question is, should a bee-keeper breed queens after the honey-flow had ceased, from which the natural honey-supply comes? I know that

the breeders will say, "We feed to stimulate colonies that rear our queens." But can that produce as good results as come from a good honey-flow from the flowers, in the season of a natural swarming impulse? This question (to me) would be of some importance, if I wished to buy queens at the present time; and it will be somewhat gratifying to me, and perhaps beneficial to many, to have this question discussed through the AMERICAN BEE JOURNAL. My experience may not be the same as that of others.

Expecting a Good Season.—C. B. Thompson, Knoxville, Iowa, on April 2, 1888, writes :

My colonies that have wintered are very strong. I put 46 colonies into a cave, and took out 37 colonies in good condition. I am looking for a good honey year. Bees have wintered poorly; those bee-keepers that wintered their bees on the summer stands, and those that wintered them in cellars, have lost about the same per cent. as I did.

Freaks of Queens.—C. Weeks, of Clifton, Tenn., writes :

Some answers to Query 506, state that 2 queens never leave the parent hive with the first swarm. I once had a prime swarm issue with the old wing-clipped queen and 2 young queens. In the spring of 1886 I found 2 laying queens that had wintered in one hive. There was no mistake about it, as it was too early for drone-brood to be even capped in any hive. About one month later, when I next opened the hive, there was but one queen to be found.

[Yours are unusual cases—those answers contemplated the general practice in a normal condition.—Ed.]

Chaff Hives for Wintering.—Geo. H. Kirkpatrick, New Paris, Ohio, on March 28, 1888, writes :

I am wintering my bees on the summer stands, all in single-walled hives, crated, and packed in chaff. About 50 per cent. of my colonies are in chaff hives. I have used the single-story chaff hive for five years successfully. My bees had a fine flight on March 17 and 18. I examined and found all the colonies breeding. Bees in this part of the country, as far as heard from, are doing well, and bee-keepers are feeling better.

Honey for Bees in Winter.—Fayette Lee, Cokato, Minn., on April 8, 1888, writes :

The colony that I was wintering on nothing but honey was defunct on March 10. They had the worst kind of diarrhea, and were full of a dirty-colored water. They did not have 5 cells of pollen in the hive last fall. They had 15 pounds of the best kind of fall honey, and it was not capped over. They had no upward ventilation. They ate about 7 pounds of honey before dying, and I am now sure that dampness is the cause of bee-diarrhea.

Another thing that I have found out is, when the ground does not freeze, the cellar is damp, and so are the bees. This is the reason that they do not winter the same. The temperature of my cellar has been 45° all winter, and only for a little while last fall it was 50°. I wish every one would see if they do not find the lower row of hives very damp, and the bees sick, with the entrance to the hive all daubed from the diarrhea. I expect to lose 15 or 20 colonies out

of 96. The snow is one foot deep yet. I have taken 10 colonies from the cellar, and they are flying nicely. I expect to take the rest out this week.

Planting for Honey.—Wm. A. Ridenour, Elida, O., on April 2, 1888, says :

I commenced the season of 1887 with 7 colonies, and my crop was 225 pounds of comb honey in one-pound sections, from white clover and linden, although the drouth caused a poor honey crop. I bought 5 colonies in the fall, which made 12 colonies; I packed them on the summer stands, and they have wintered all right. On March 31 and April 1, they carried in pollen for the first time this year. I have 7 acres of Alsike clover that will bloom this summer. In 1885 I planted 60 linden trees from 1 to 2 inches in diameter, and they bloomed the second year after being planted.

Drone-Comb and Swarming.—James Irwin, Columbus Grove, O., on April 2, 1888, writes :

I must say that my bees have wintered extremely well this winter. I wintered them on the summer stands. They have been taking in pollen now for two or three days. The outlook for a good honey season is very promising. I noticed from some of my colonies that there were a good many young bees flying. Will the absence of drone-comb in a hive prevent swarming?

[The absence of drone-comb in a hive will not always prevent swarming—to give the bees extra room is generally more effectual.—Ed.]

Old-Fogy Bee-Keepers.—Mr. R. A. Rummel, Butler, Ind., on April 2, 1888, says:

Bees have wintered well, so far as I have heard. I asked one of my neighbors who keeps bees, to take the BEE JOURNAL. He said that he could not learn anything from it; that he knew more about bees now, than any of those who write for it. He generally has about 7 colonies in the spring, increases them to about 35 or 40 till fall, and all that are strong enough to draw their last breath, die before spring. He never obtains much honey from them.

[That is just the way of one-tenth of the world. Surely "When ignorance is bliss, 'tis folly to be wise."—Ed.]

Putting Bees out too Early.—A. B. Atwater, Marlon, Iowa, on April 7, 1888, writes :

I have not yet taken my bees out of the cellar, as I consider it too early. I took them out last year before the snow was off the ground, and I lost 50 colonies out of 80. I do not think that I will do so again. The weather is nice and warm. I did take one colony out about a week ago, and I will have to feed it to keep it from starving. My bees stored scarcely any honey last year.

Still in Winter Quarters.—Wm. Dyer, Hastings, Minn., on April 10, 1888, says :

My bees are still in winter quarters. There is too much snow on the ground yet, to put them out. They have been in the cellar about 140 days, and are still as quiet as they were the first week after being put in.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

CLUBBING LIST.

We Club the American Bee Journal for a year, with any of the following papers or books, at the prices quoted in the LAST column. The regular price of both is given in the first column. One year's subscription for the American Bee Journal must be sent with each order for another paper or book:

Your Full Address, plainly written, is very essential in order to avoid mistakes and delays.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; 1/2 pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Clover Seeds.—We are selling Alsike Clover Seed at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. White Clover Seed: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. Sweet, or Melilot, Clover Seed: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Cork for Winter Packing.—Its advantages are that it never becomes musty, and it is odorless. Cushions can be made of cloth and filled with the cork, for winter packing. We can supply all orders now at 10 cents per pound. Or a seamless sack of it, containing 15 pounds, for \$1.00.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages)	1 00
" 100 colonies (220 pages)	1 25
" 200 colonies (420 pages)	1 50

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels	\$1.50	\$2.00	\$2.25
500 Labels	2.00	3.00	3.50
1,000 Labels	3.00	4.00	5.00

Samples mailed free, upon application.

The Novelist—A Novel Enterprise.—Novel in name, form, purpose and method is *The Novelist*, Alden's new weekly magazine of American fiction.

It is certainly handy in form, beautiful in dress, excellent in all mechanical qualities, and low in price; well suited in all respects to meet the wants of the intelligent millions who are capable of appreciating "the best."

Terms, \$1.00 a year, at which rate it will give over 2,500 pages, equal to from eight to twelve ordinary American dollar novels.

The stories will follow successively, one at a time, a novel of ordinary length, thus being completed in from four to eight weeks. If one story does not please, you will not have long to wait for the next. For a ten-cent subscription (if you don't wish to enter for all at \$1.00), you will receive the first chapters of every story published during the year, which you can then order separately, if you wish. A specimen copy of *The Novelist* will be sent free on request. Address, John B. Alden, Publisher, 393 Pearl St., New York; P. O. Box 1227.

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Scatter the Leaflets.—Look at the list (with prices) on the second page.

A Pocket Dictionary will be presented for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

CONVENTION NOTICES.

The next meeting of the N. W. Ills. and S. W. Wis. Bee-Keepers' Association will be held in Rockton, Ills., May 22, 1888. D. A. FULLER, Sec.

The spring meeting of the Wisconsin Lake Shore Center Bee-Keepers' Association will be held on May 31, 1888, in Mueller's Hall, at Kiel, Wis. FERD. ZASTROW, Sec.

The Keystone Bee-Keepers' Association will hold its sixth annual meeting in the Court House at Scranton, Pa., on Tuesday, May 8, 1888, at 10 a.m. All bee-keepers are invited. A. A. DAVIS, Sec.

The Hardin County Bee-Keepers' Association will meet at the Court House in Eldora, Iowa, on the second Saturday in each month, at noon (12 o'clock), until further notice. J. W. BUCHANAN, Sec.

The semi-annual meeting of the Progressive Bee-Keepers' Association will be held in the Sons of Temperance Hall at Bainbridge Centre, O., on Thursday, May 3, 1888. Parties wishing conveyance from Geauga-Lake Station, on the Erie railroad 3 miles distant, will please notify Mr. L. H. Brown, Bissels, Geauga Co., O., so that arrangements can be made for the same. All interested are invited. MISS DEMA BENNETT, Sec.

Honey and Beeswax Market.

DETROIT.

EDITOR.

Vol. XXIV. April 25, 1888. No. 17.

EDITORIAL BUZZINGS.

Let Fate do her Worst; there are relics of joy.

Bright dreams of the past, she cannot destroy;
They come in the night-time of sorrow and care,
And bring back the features that joy used to wear.
Like the vase, in which roses have once been
distilled,
You may break—you may shatter the vase, if you
will,
But the scent of the roses will hang round it still.

Do Not take the bees out of cellars until the advent of settled warm weather.

The Appeal on the one-piece section is now before the United States Supreme Court. It was argued on the 13th inst., and a decision may be now made any day, by the Court.

Paint your Hives just for the sake of appearance, to which it adds so much. It is best to paint them of light colors, so as not to reflect the sun's rays, and make it "too hot" on the inside.

The Review for April is out, and contains much that is interesting to the craft. In the advertisement on page 281, it was promised to be issued on March 20—it should have said April 20. It was an oversight of the printer.

Has any One yet received any of the Chapman Honey-Plant seed from the Commissioner of Agriculture? A. Fiddes, of Centralia, Ills., complains that he sent for some six weeks ago, and has heard nothing of it yet. Perhaps it is like a good many other things at Washington, very slow work to get matters straightened out. There "red tape" is the rule!

Mr. Z. A. Clark, of Arkadelphia, Ark., whose appeal from the persecutions of the Mayor comes up before the Supreme Court in July, is gradually gaining the "upper hand." The Mayor and councilmen were badly defeated in the late election, and Mr. Clark is now sustained by the majority.

The case is docketed for the Supreme Court, and will come off probably at "the time appointed," and witnesses are becoming more numerous in favor of Mr. Clark and his bees. He has a few colonies now in the city, and is unmolested in keeping them there. He contemplates making public exhibitions of bees at the schools, and manipulating them before the classes, and all this with the sanction of the new authorities. This shows that the "persecution" was done maliciously, and without cause. Mr. Clark thus speaks of some new witnesses he intends to use:

A gentleman drove a two-horse team by my apiary last summer, and drove through as large a single "swarm" of Italians as you probably ever saw, and was not molested in the least. (Will he not make a good witness for us?) I saw this with my own eyes.

Two young ladies who have lived by me since my residence here, and often in my apiary, say they were never stung by a bee in their lives! (How will they do for witnesses?) We have others equally as good.

Killing the Moth-Larvae.—Mr. M. W. Hinkley, of Bowdoinham, Me., in the *Eastern Farmer*, says he has tried sulphur and failed, and thus describes his favorite method:

I have discovered that bee-combs infested with moth-larvae can be perfectly and safely cleansed by immersing them for a few moments (until the cells are well filled), in a quite strong solution of potash, then quickly and carefully rinsing and drying. Care is necessary in the handling, as the potash has a tendency to soften the comb.

Spiders rarely cause any trouble with bees. Strong colonies are fully able to repel them, should they enter the hive. All webs about the entrance should be brushed away, or bees will be caught and devoured. Some mistake the work of the moth-worms for spider webs.—*Exchange*.

Why Should Bees make the honey dark by traveling over it? This is what a correspondent asks. Prof. Cook says that bees emit a sort of glutinous fluid from their feet, when walking over a plain surface, to help them adhere to it. This is what stains the white cappings, and makes them look dark and soiled.

Breeding.—In an item on page 259, Mr. Hutchinson was said to advise *feeding* for two months previous to the honey harvest. For the last word in the fifth line read *breeding* instead of "feeding," and the item will then correctly convey the views of Mr. Hutchinson.

Swarming Box.—The *American Agriculturist* for May contains the following on the use of a swarming box:

During the swarming season every bee-keeper should provide himself with a "swarming box." This saves an immense amount of labor, besides obviating the damage often committed on valuable fruit trees and vines by cutting and mutilating them in order to detach swarms therefrom. This box may be made 10x14 inches, inside measurement. It should be perforated with many holes, $\frac{3}{8}$ or 1 inch in diameter; a pole 8 or 10 feet long should be fastened through the centre of the box, so that it may balance. After a swarm has pretty well settled on a branch of a tree, the box may be pushed up into the cluster of bees, when they will ordinarily take to it and occupy it. If they should not do so readily, the box, being open at one end, may be held under the swarm, when, by giving the limb a jar, a portion of the bees become dislodged into the box. The remainder will readily alight on the same, and all may be carried to the stand.

Storing Honey.—Mr. E. Israel, Oak Lawn, Miss., on April 11, 1888, says:

I send you some linden buds and leaves. My bees are storing honey in the sections, and working on white clover, which is in full bloom.

We have an abiding faith that the coming season will be a good one, and reports such as the above confirm our faith—promising prosperity for the bees, after many years of failure.

Strong Colonies to gather the harvest are very necessary. Mr. Dibbern, in the *Plowman*, remarks thus on this subject:

In regard to getting the best yield of choice honey, try to have all your colonies very strong when the honey-flow comes. This is best accomplished by feeding a thin syrup of honey each evening, commencing about six weeks before the expected yield. Give room in the sections as soon as needed to delay swarming as long as possible.

It Pays to be ahead of time in the matter of procuring hives, sections, foundation, etc.; when needed for use is too late to send for them—they should all be at hand then, waiting until wanted.

Feeding Bees in the morning is apt to induce them to commence robbing; feeding during the day is also dangerous during cold spells—for they sometimes become restless, fly out, chill and die.

Attention is Fixed on Germany. One veteran ruler, the Emperor William, has just passed away, and the grave is even now ready to receive his successor. The crown will rest on three heads in a single year. There are elements of deep interest in a reign like that of the Emperor William, whose life covered most of our stirring century. The story can be read in a finely illustrated article in *Frank Leslie's Popular Monthly* for May, which also gives an endless amount of interesting and attractive reading.

GLEAMS OF NEWS.

Honey by the Barrel, drawn from trees like maple syrup.—Mr. E. K. Dean, of Amenia Union, N. Y., on April 11, 1888, wrote us as follows :

From time to time I read in the BEE JOURNAL the product of the pen of some who are foolish enough to think that whatever they may say about the "wonderful and mysterious honey-bee" everybody is bound to believe ; and strange to say, a great many still continue to regard these industrious insects with the old-time wonder, and are perfectly ignorant of those "mysteries of the hive" (now so well understood by nearly or all subscribers of the BEE JOURNAL)—are ready to accept these fallacies with wonder and open-eyed amazement. I enclose a clipping from a Georgia paper, sent me by a friend, who evidently is astonished at its revelations. I also send his comments on the article, and think you will agree with me in thinking it strange that any one can for one moment credit the veracity of such preposterous statements. Here is his letter :

"This clipping from the Griffin, (Ga.) News, is unique in the annals of bee-culture. Of course honey is a natural product. If this account is verifiable, how do you account for it? Would it not be a good thing if a few of these trees could be grafted up here?
S. S. LEWIS."

This is the clipping :

After dinner at Mr. Mitchell's we were sitting on his front piazza, smoking, and I discovered some bees going in and out of a knot in one of the large oak trees in front of his dwelling. This tree is known to be over a hundred years old. I learned that several years ago a swarm of bees assembled in that tree as their new home, and they have worked and lived there ever since. After they had been there for three years, the colony became very large and strong, and no attempt had ever been made to rob them of their honey. At last Mr. Mitchell came to the conclusion that the tree must be full of honey, from seeing large numbers of flies and bees around the root of the tree ; so he set to work to devise some means to get the honey without cutting the tree down. After applying all the tests known to bee-men, he satisfied himself that the tree was full, and then decided to tap it like a fellow is tapped for dropsy. So he got a faucet and an augur and bored a hole in the tree near the root, and then screwed in the faucet, and to his surprise and great delight a solid stream of pure and elegant honey as clear as crystal gushed forth, and the supply seemed almost inexhaustible. It continued to pour out until he had filled six barrels ; and he has drawn each year since that time from three to four barrels of pure strained honey from that old oak tree, and up to this there seems to be no signs of a failure of the supply, as the bees are still a very strong and healthy colony.

The same year that Mr. Mitchell tapped the old oak tree there was a new, thick growth sprung up all around the old oak, of an unusual appearance, having a smooth bark and thick, waxy leaves. One day he pulled off one of the leaves and put it in his mouth, and found it to be very sweet, and upon examining the place from which he had plucked the leaf, he discovered that the plant was bleeding or emitting from the wound a clear, thick-looking juice, which, upon tasting and examination, proved to be honey. He then commenced to nurse the new volunteer growth with the tenderest care and attention, looking after them daily ; and as the summer advanced the plants continued to grow, and in the fall he selected and transplanted 300 of them in very rich

soil, 30 feet apart, and they grew very rapidly, making a beautiful display with their straight, smooth trunks, and their thick and glossy wax-like leaves. And the grove was seen and admired by all for miles and miles around. Mr. Mitchell's idea was that as large money was made from the sugar maple, by boiling the juice, he ought to make more from a tree that would run pure honey, and he was right. When the trees were four years old in the fall of the year, they were large enough to insert faucets. So he had 300 faucets made to order, and screwed them into the young trees, and the following spring the result was remarkable. Each tree yielded an average of 10 gallons of the richest golden honey ; the following year each tree yielded an average of 20 gallons, and now the average is about a barrel to each tree during the year, and the grove continues to grow and flourish, and shows no signs of failing to supply a bountiful yield in the years to come. The quality of the honey is so fine, and the flavor is so delicate, that it always commands the highest prices, and the demand is greater than the supply.

This is only another proof that the "flashy" reporters for the daily press of the country draw heavily upon their imagination in order to cause a sensation, and get up "spicy" articles for a credulous public.

All of the above sensational article is elaborated from the simple fact of some one finding a bee-tree in the woods, and taking from it some broken honey, unfit for the market, and mostly unfit for table use. The idea of drawing honey through a faucet from combs in a bee-tree!! The idea, even, is supremely ridiculous !

Bees and Grapes.—A correspondent from Middle Falls, N. Y., has sent us the following taken from the New York Sun of April 4, 1888. It is a question, and reply by the agricultural editor :

Can you suggest any means, besides bags, to protect grapes from the attacks of bees? The theory that bees do not attack sound grapes is a mistake. Half my crop was destroyed by bees last year.
WILLIAM N. NELSON, Millwood, Va.

ANSWER.—We do not know of any better way of protecting grapes from the attacks of honey-bees than by enclosing the bunches in paper bags. However, you might try spraying the vines with some liquid that would be offensive to the bees. Try a very weak solution of carbolic acid when you find the bees attacking the fruit. You are certainly right in your statements in regard to bees destroying sound grapes, and while entomologists know that bees will not only attack and destroy sound grapes, but also peaches, quinces, pears, apricots, and many other kinds of fruit, apiarists deny it, and endeavor to show that the bee cannot cut through the skin of such fruits, and that it is only after wasps and hornets have punctured the fruit that the bees attack it and suck out the juices. Langstroth, Quinby, Root, and other noted apiarists scout the idea of honey-bees cutting through the skin of grapes, while entomologists and thousands of practical fruit-growers know it to be a fact.

There is one side, however, of this question which is far too often overlooked, and that is the variability of the appetite or taste of the bees. One season the bees will attack various kinds of fruits, and daily gorge themselves with their juices as long as any can be found, and the very next season they may not touch fruit of any kind. Whether this variability is due to some peculiarity of the weather or season, we do not profess to know, but that the bees do take such freaks we have learned from ex-

perience. Next season you may not need any paper bags to protect your grapes from the attacks of bees.

Such "wiseacres" as the above editor, persist in asserting that bees attack sound fruit, when repeated assurances from entomologists and professors who have studied the anatomy of bees, and are thoroughly conversant with the subject, most positively deny that they are physically capable of doing so.

Out in California—such ignoramuses raised a howl about bees injuring grapes, and as a result, they sued a bee-keeper for damages, said to be done by his bees. This suit was carried to the Supreme Court, and the bees came out ahead. It was proven at the trial that the bees could not bite into the skin of a grape. A San Diego bee-keeper settled the question in this way, says the San Francisco Chronicle :

He took a perfect bunch of grapes, every berry of which was sound and in good order, and suspended it in the middle of a hive of bees for an indefinite time. It remained there several weeks, or perhaps months, and at the expiration of the period was removed in as perfect a condition as when first put in the hive. Thousands of bees had been crawling all over the fruit during that time, only too eager to attack the toothsome juice thereof, but had been unable to satisfy themselves.

Fruit men found that they had been fighting their best friends, and now have given up the persecutions of the innocent bees.

We might quote from scientists, professors, and others to prove that bees are incapable of damaging sound grapes—but of what use is it, when such scribblers as the *Sun* employs, make their bold assertions to the contrary. Verily, "Where ignorance is bliss, 'tis folly to be wise."

City and Country Life.—A correspondent in the British *Bee Journal* has this to say about the difference between life in a city and that in the country :

After our experience of the dense London fog up to noon on the 17th ult., the day after our annual meeting, when gas and electric lights failed to dispel the gloom, and choked almost to suffocation, pitying the gasping Londoners, while contrasting their state of existence with that of our own happy country fraternity, we exclaimed in fullness of heart,—

"We possess the flowers and trees,
Modern hives and golden bees ;
Fruit and nectar, both divine, ..
We shall reap at harvest time .."

And, finding on reaching our quiet country home, with its hive-scattered lawns and shrubberies, that the day had been one of brilliant sunshine, we were more than ever impressed with the truth of the old saying, "God made the country, man made the town."

New Catalogues for 1888 are on our desk, from the following persons :

Charles H. Smith, Pittsfield, Mass.—48 pages—*Apiarian Supplies*.

S. H. Stockman, East Auburn, Maine—24 pages—*Bees, Queens, and Apiarian Supplies*.

M. W. Shepherd, Rochester, O.—4 pages—*Bees and Queens*.

INTERROGATORIES.

[These questions were intended for the Query Department, but to save time and space, one reply is deemed sufficient, and is given by the Editor or some other member of that Department to whom he refers it.]

The Sections for a Beginner.—

L. wants to know the following :

What size of sections would you advise a beginner to use ?

The most popular sections are those holding a single pound of honey.

Carniolan and Black Bees.—J.

B. A., of Stittville, N. Y., asks the following question :

Are Carniolan bees as good for all purposes as the common black bees ?

Yes ; and some think that they are even superior to the Italians.

Foul-Broody Hives & Frames.—

C. A. S., of Connecticut, propounds this question :

Can I have the hives and frames, where bees have had foul brood, cleaned so as to render them safe to use again ? If so, how ?

Perhaps so ; but great care should be taken. Boil them in hot water. We should probably burn them all up. That would be safe.

Robber Bees.—H. L. R., asks this question :

If a hive containing capped honey, but no bees, be placed on a stand during the spring, will it be molested by robber bees ?

If the entrance is left open, it would be almost sure to be robbed. Such feeding is demoralizing.

Different Kinds of Foundation.—

J., of New York, desires the following answered :

1. Is foundation made with a Pelham mill just as good as that made with any other mill, everything else being the same ?
2. Is it as acceptable to the bees ?

Upon a test it has proven quite as good, and was as readily accepted by the bees.

Making Comb Foundation.—C.

W. desires information on the following questions :

1. What causes sheets of wax to crack on the dipping-boards, when the boards have been previously well soaked in water ?
2. What will prevent it ?
3. What is the best lubricator to prevent the sheets of wax from sticking to the rolls ?

1. Either the wax is too hot, or the air too cold.

2. Avoid the above conditions, and have the boards sharp at the edges, so that the wax will first crack there.

3. Lye is the best lubricant.

Drawing Out Foundation.—T.

O. asks the following question :

Do bees draw the foundation out into cells ?

Yes ; and they often *thin* the base, to do so.

Arranging Sections in a Case.—

J. L. C., of Indiana, asks the following :

1. As there is only a half bee-space, or half an opening in each section, how shall I manage about putting in the first and last rows so that there will be room for the bees to get in and out of the sections next to the sides of the section-case ?

2. Shall I put the sections up close to the sides of the case, or leave them away about 3-16 or $\frac{1}{4}$ of an inch ?

3. If so, how is it done so that they will be secure in their places ?

Use sections having $\frac{3}{8}$ inch openings instead of $\frac{1}{2}$ inch ; then the half of that space at the sides will admit the bees. In the absence of sections with $\frac{3}{8}$ inch openings, if your "case" is wide enough, place at the sides wood separators 1-16 inch in width.

Free Trade and Honey.—A

correspondent from New York asks the following :

What is your opinion in regard to the effect of free trade (in this country) upon the price of honey ?

It might work adversely at the start on low grades, but not so on the best quality. In our business we can compete with any country.

Separators and Moth-Worms.—

J. F. Gile, Basswood, Wis., on April 16, 1888, asks these questions :

1. Can I use sections without separators in the supers of the improved Langstroth-Simplicity hive ? 2. Are separators necessary in the brood-chamber, if frames are provided with half or full sheets of foundation ? 3. What shall I do with my comb honey in case it becomes infested with moth-worms ?

1. Yes ; if your super is arranged with reference to it.

2. Separators are not intended to be used with brood-frames. Wide frames holding 8 one-pound sections are sometimes placed at the sides of the brood-chamber ; in such, separators are necessary.

3. Fumigate it, by putting it in a closed room, and burning sulphur in it. This will kill the moth-worms.

"When we Consider that pure honey is the very essence of flowers and plants, in which, we are told, there is a remedy for every disease, surely we cannot doubt the happy combination of honey as medicine. The Scripture tells us in many passages of the wonderful efficacy of honey as food and medicine. As the treatment of disease becomes more and more rational, so will the value of honey as a medicine become more and more apparent." So says the *Rural Canadian*.

Statistics.—Mr. L. J. Stone, Littleton Common, Mass., on March 23, 1888, writes as follows :

As a volunteer to gather statistics on bees and honey, I offer my services for Middlesex county. There are not many bees kept here, but I have a team and can and will do the work carefully and thoroughly if desired.

It seems to me that the only way that we can get correct statistics is to have some one interested to personally see the different bee-keepers, and fill out the blanks, and not leave or send blanks for them to fill out, for I think that in seven times (if not more) out of ten, they will not fill them out correctly if at all. If we could have two or three in each county to take statistics, we could go and see them with our teams well enough, in this part of the country. Of course if there was but one in a county, so we had to go around on the cars, we ought to have our expenses paid, but that would only be a little. I take the AMERICAN BEE JOURNAL, and I was never better satisfied with a dollar investment in my life.

At first we thought the best way to get the statistics would be through the assessors or Statistical Bureau of each State ; but in all probability those gathered by persons interested in the pursuit, are of the most immediate value. We like the plan inaugurated by Mr. Root, in *Gleanings*, for that purpose ; of which we gave a summary on page 243. Those obtained through the United States Statistician will go upon record, and be handed down to posterity in the history of the material resources of the country. We fear that they will not be gathered and published soon enough to be available to the producer in regulating the market prices, etc.

A correspondent from Ohio has sent us the regular statistical blank used in that State, and adds :

The assessors in this State are under oath and bond to ascertain the number of colonies of bees, and the number of pounds of honey produced, and I can tell in a few minutes the result in this State. I know what I am talking about, for I am assessor, and have been for the last three years. Of course the result is only approximate. In 1885 there were 79,589 colonies, and 818,060 pounds of honey ; in 1886 there were 111,803 colonies, and 2,113,479 pounds of honey. With the proper effort we might get much information through the proper officers in the different States.

Frank Leslie's Sunday Magazine

for May is a valuable and interesting number of this favorite family monthly. Both solid and light reading, grave and gay, prose and verse, are found in its pages, and the many beautiful illustrations add to the interest and value of the text. Dr. Tatmage's sermon is a striking one on "Thirst in a Cavern," and there are many other good things in verse and prose, and a fine and vigorous hymn tune on the last page by C. Wenham Smith, to the hymn, "Crown Him with Many Crowns."

A Modern Bee-Farm, and its Economic Management ; showing how bees may be cultivated as a means of livelihood ; as a health-giving pursuit ; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

QUERIES REPLIES.

WHAT TO DO WITH ESCORT BEES.

Written for the American Bee Journal

Query 535.—What should I do with escort bees, when receiving a queen by mail?—Ohio.

Kill them.—C. C. MILLER.

Liberate them.—MRS. L. HARRISON.

You cannot use them to any account.—A. J. COOK.

I simply let them fly.—J. M. HAMBROUGH.

Let the poor things die. You cannot save them.—DADANT & SON.

Send them adrift to shift for themselves.—J. P. H. BROWN.

Let them shift for themselves. I have never succeeded in saving them.—M. MAHIN.

Liberate the bees in front of a queenless nucleus.—G. L. TINKER.

Let the bees go. It is always safer to introduce queens without escorts.—P. L. VIALLON.

If the shipping-cage is also one for introducing, like the "Peet" cage, leave them with the queen; at any rate, leave a few with her. My boy says, "Put the rest in a bird-cage."—A. B. MASON.

Open the cage and let them all go, and introduce the queen alone in the cage.—H. D. CUTTING.

Introduce them with the queen, or let them free, as so few bees are not worth the bothering with.—C. H. DIBBERN.

Anything except letting them fight with the bees of the colony to which you wish to introduce the queen.—R. L. TAYLOR.

Let them fly out of the cage and go where they will, before attempting to introduce the queen.—J. E. POND.

Open the cage on the inside of a window, and let the bees out; then cage the queen alone, or introduce her without her attendant bees.—EUGENE SECOR.

Always kill and bury every one of them. Should there be foul brood where the queen came from, you might, in this way, avoid getting it into your apiary.—JAMES HEDDON.

I used to just turn them loose to look out for themselves; but now I introduce them with the queen. I have experimented in this matter until I am perfectly satisfied that the workers can be introduced sooner than the queen can. I now rarely ever introduce a queen from my own apiary,

without taking a few bees with her.—G. W. DEMAREE.

If you have a queenless colony they may be given to it; otherwise they may as well be killed, for that is what any colony having a queen will do with them. It is not best to try to introduce them with the queen, for such a course often results in the loss of the queen.—G. M. DOOLITTLE.

If they are "Apis dorsata," send them to the AMERICAN BEE JOURNAL, in alcohol. If they are not, set them free, and let them take their chances. I have placed them caged with the queen in a colony of bees, and 72 hours afterward fixed the cage so that the bees of the colony could liberate them, and afterwards saw no sign of their untimely death. They are usually executed as intruders.—J. M. SHUCK.

It is safer to kill them—then there will be no danger of their communicating disease to your apiary.—THE EDITOR.

PACKING BEES ON SUMMER STANDS.

Written for the American Bee Journal

Query 536.—1. When bees are packed on the summer stands, is it necessary to put packing under the hive? 2. If so, how is it arranged? Please give details.—Michigan.

1. No.—R. L. TAYLOR.

1. No.—MRS. L. HARRISON.

We simply pack leaves, grass or straw under it, without further ado.—DADANT & SON.

1. No, but it is *best* to do so. 2. Make a double bottom and fill between.—A. B. MASON.

I think that packing under the hive is of but very little importance.—M. MAHIN.

I prefer to let the air pass under my hives to keep them dry.—G. W. DEMAREE.

It would certainly be better. Place the hives either on cut hay or chaff.—A. J. COOK.

The chaff-hive bee-men may have the space.—EUGENE SECOR.

After trying such packing I have concluded that it is not of enough benefit to pay for the trouble.—G. M. DOOLITTLE.

I have never put packing under the hives. I think that it is unnecessary.—J. M. HAMBROUGH.

It is not absolutely necessary, but it is best to pack under with straw or hay, if the hives can be kept dry.—J. P. H. BROWN.

Here in the South we let the bees remain on the summer stands without

any preparation whatever, all the year round.—P. L. VIALLON.

It is not absolutely necessary, but I think that it is a help to pack under the bottom-board with leaves.—H. D. CUTTING.

I do not think that packing under the hives is of any use unless it is to make a nice place for mice. What I understand by "under the hive," is under the bottom-board.—C. H. DIBBERN.

1. Yes. 2. If the hives rest near the ground, sawdust can be banked up against them, or leaves may be tucked beneath. I usually place my winter hives on a rim filled with sawdust.—G. L. TINKER.

1. I have never done so. I give 2 or 3 inches of space under the frames. I do not know that such packing will do any harm, but my bees winter well without it.—J. E. POND.

1. No, not if you have plenty of snow, and you do in our State. 2. The details of the arrangement varies according to the various methods of packing.—JAMES HEDDON.

I do not think that it is necessary, and I have tried it hundreds of times. As successful as I ever was in out-door wintering, was with a 6-inch hole in the bottom-board covered with wire-cloth immediately under the cluster. The wire-cloth was all there was between the bees and the weather. I had 4 inches of chaff at the sides and ends, and 6 inches of chaff on top. I risked my whole apiary of 40 colonies and lost none.—J. M. SHUCK.

It is neither necessary nor desirable. Snow would be better under the hives.—THE EDITOR.

INDUCING BEES TO BUILD COMBS IN CASES.

Written for the American Bee Journal

Query 537.—Could the bees be induced to build comb in surplus cases by placing them under or in front of the brood-chamber, where the bees would have to pass through in going to and from the hive; I mean for a short time, and then reversed.—Minnesota.

No.—DADANT & SON.

I can see no advantage in your doing so.—J. P. H. BROWN.

Yes, if they have no vacant room elsewhere.—C. C. MILLER.

Yes, sometimes, but not profitably.—R. L. TAYLOR.

Yes; but why not put them on top at once.—A. B. MASON.

It is utterly impractical for any and all purposes.—JAMES HEDDON.

Yes, they could be so induced, but I see no object in so doing.—G. M. DOOLITTLE.

Yes, but better results can be had by adjusting the cases over the brood-chamber.—G. W. DEMAREE.

I would consider it poor practice. Put your surplus cases where you expect them to remain.—MRS. L. HARRISON.

I have never tested this matter, but should go slow in adopting the plan.—J. E. POND.

This is quite a problem; fertile brains might put it in practical form. Who will try it? It might be so.—J. M. HAMBROUGH.

I do not know, but I should fear to try it on a large scale. If they did, would not the queen occupy them, and the combs be filled with pollen?—EUGENE SECOR.

From several trials I say no. Unless sections are placed right by the side or among the brood, they would better be above.—A. J. COOK.

I do not think that it would be of any help to you. Put them on top, where they belong.—H. D. CUTTING.

Yes, it may be done; but there will be a good chance for pollen in the sections. A better plan is, to invert the hive and put the sections over the brood-nest.—J. M. SHUCK.

I have had no experience in placing section-cases under the brood-chamber, or compelling the bees to pass through it in going from the hive. The natural place for bees to store surplus is over the brood-nest, as you can readily see by looking at a brood-comb.—C. H. DIBBERN.

I have tried that once with no success, therefore I cannot speak of it with much knowledge, but I do not believe that it will induce the building of comb. Contract the brood-nest, and move the frames closer together, and if honey is gathered, the bees will build comb on top as well as anywhere else.—P. L. VIALON.

If the colony is strong, and there is honey to be gathered in sufficient quantity, the bees will occupy sections over the brood-frames, if one section filled with empty comb, or, what is better, partly filled with unsealed honey, be placed in the centre of each row of sections; otherwise they had better not build comb.—M. MAHIN.

When honey is coming in, bees will build comb either under or in front of the brood-chamber; but as they prefer to carry the surplus above the brood, I believe, as a rule, that is the best place to put the surplus cases.—G. L. TINKER.

Bees will build comb there if they can find no better places, but the system is undesirable and impracticable.—THE EDITOR.

CORRESPONDENCE.

SPRING.

Written for the Youth's Companion
BY WILLIAM H. HAYNE.

When birds are singing
On brush and tree,
And opening roses
Allure the bee,—
When grass is growing
In glade and glen,
And young leaves gladden
The lonely ten,—

When earth yields glimpses
Of hoarded grain,
And the sunshine glimmers
Through threads of rain,—
When dew is falling
On stalk and bud,
And tervid fancies
Invade the blood,—

When brooks are flowing
In music free,
And warm winds travel
Across the sea,
When earth beguiles us
With smile or tear,
We know with gladness
That Spring is here!

LARGE HIVES.

Large Combs and Strong Colonies Conducive to Strength.

Written for the American Bee Journal
BY J. M. HAMBROUGH.

On page 789, Mr. Buchanan, in speaking of 15 colonies of bees which he purchased from a neighbor in large box-hives, with many openings about them, says:

"Such powerful colonies I had never seen in April. I could but view them with astonishment. Musingly I asked myself this question: Of what use is our modern system of contraction, and careful expensive packing, if bees will winter in such splendid condition as they have in these old excuses for hives? What do we know?"

Mr. Buchanan has evidently noted the superiority of large, roomy hives and combs in the case spoken of, and now I will just state that not only have dozens of instances come under my own observations, where bees were occupying large, roomy hives with combs built according to their own liking, but with them in movable-frame hives of two patterns, namely, the Simplicity and Quinby, *a la* Dadant. The difference has been so marked, that there can be no possibility of a doubt in my mind, as to the superiority of large, roomy combs and hives, for out-door wintering, and consequent large yields of honey per colony.

Another point unquestionably is, that they are nearer a non-swarming

hive, than those of smaller patterns, and equally as capable of increase should it be desired.

In regard to my statement on page 804 of the AMERICAN BEE JOURNAL for 1887, that where bees are found in all kinds of hives and left to build their own combs, that the same principle that governs one, governs all, in the main, (namely, large, deep, roomy combs, with stores above, brood beneath, and combs spaced from 1½ to 2 inches from centre to centre), Mr. Cullinan remarks on page 39, as follows:

"Did he not find those combs of all shapes and sizes, made and shaped more with a view of filling the repository in which they were built, than to honor any whim or requirement of the queen-mother?"

Most certainly not, unless driven to it for the want of space. A cramped "repository" will necessitate crooked combs, but as a rule, where they are provided with large, roomy brood-chambers, combs will be built as before stated.

Mr. C. says: "The Quinby frame, which is the frame that Mr. Hambrough alludes to, is too large and unwieldy for extracting, as well as slower of manipulations at all times." As Mr. Cullinan has never tried that which he condemns, we will let the public weigh the assertion for what it is worth.

I distinctly remember my first visit to Mr. Dadant's, and with all the arguments coupled with their long experience, failed to convince me that the "Quinby frame was too large and unwieldy, etc." Yet I never expressed myself so in print, but brought a frame of both brood-chamber and surplus department home with me, by which to make some hives, and satisfy my own mind. This was in the spring of 1883.

That spring I put 5 colonies on frames of this pattern, with only partial sheets of foundation. There was quite a marked difference in the strength of the colonies in the fall, during spanish-needle bloom, they filling their supers and brood-chambers from top to bottom; and with the same treatment, they came through the following winter much stronger in numbers, built up very rapidly in the spring, and having but a single tier of supers for each hive, they swarmed all around, and one of them sent out the second swarm. This began to make me open my eyes, and from that time on I began to pave the way to the use of the Quinby hive for extracting purposes, and the three subsequent years have more than confirmed my former convictions. Mr. C. should know that we are after the results first, and not so much the pleasure of handling. I quote the following from "Quinby's New Bee-Keeping," page 56:

"In 1874 I commenced with 100 colonies, and did not take any surplus honey until basswood blossomed—July 20. During the next 40 days I secured 10,000 pounds of surplus, and increased the colonies to 119, giving me an average of 100 pounds of surplus, from my old colonies."

In the spring of 1886 I had 33 colonies in Dadant hives; I extracted from their surplus departments on June 8. In just one week, or seven days, I ran over the same surplus departments and got from the 33 colonies 798 pounds of honey. On July 3 I got 1,238 pounds, a total of 2,036 pounds in 25 days, being an average of 81 11-25 pounds per colony. The gross product of the season of these 33 colonies was 3,992 pounds, or 121 pounds per colony, and this was obtained without a fall harvest, as it was almost an entire failure.

I had 49 colonies in all in this yard, and they increased to 56. The balance, or 16 colonies, were in 10-frame Simplicity hives, and they did not average as much by 15 pounds to the colony as those in the larger hives, notwithstanding the smallness of the number.

As regards my assertion, that we must imitate nature by making our hives after the style of *log gums*, etc., I will say that my article is written so plainly that a school-boy cannot fail to understand its meaning.

Now Mr. C. shows (by theory) how the horizontal bars and bee-spaces, instead of a detriment, become a benefit to the queen's functions as an egg-layer. He argues from the assumption that the queen is obliged to pass back and forth from each side of the comb, and concentrate her brood in the form of a ball or globe, with the instinct of concentration of heat for the protection of the brood. Very well; but let me ask if he ever observed frames of brood in March, of a colony in a normal condition. If so, will he not see 3 or 4 frames of brood probably 6 inches in diameter?

What would be the condition of this same amount of brood, were it placed in a single section of combs, *a la* Heddon? Would it not be spread more in the form of a pancake, than a globe? and would it be in a condition to get the concentration of heat from the cluster as it would in large combs?

Again, suppose two of the sectional bodies together, have an equal amount of brood in each, would it not be spread over more surface, on the two sets of combs, than on the one? Which would require the most bees in the cluster, to nurse and protect the same amount of brood, not taking into account the air-space that has to be filled in the centre of the cluster? A good queen can always keep her hive

stocked with eggs in the early part of the season, to the capacity of the colony to nurse and protect the same from cold, and the more unbroken and compact the cluster and brood, the more rapid will be the development of the same in early spring; and as the colony increases, so does the animal heat in the same ratio, and by the time we are in need of the queen's full power of egg-laying, which is from the middle of April to the middle of May in this latitude, the hive is so well stocked with bees, and cold snaps less frequent and severe, that the queen plys her vocation to the utmost capacity of her surroundings, with less regard for concentration of brood, and the consequence is, the better inside surroundings, to facilitate egg-laying, the stronger and more powerful will be our colonies; and, on the other hand, the more compartments into which the brood-chamber is divided, with the transverse bars, bee-spaces, etc., in the same ratio will we realize a loss, as the queen's time is taken up in passing from point to point.

In the face of these facts, wherein are the sectional brood-chambers an advantage in brood-rearing? I will challenge any bee-keeper to disprove the statement by actual test. We want facts—no fiction; and though some would try to make it appear that the prolificness of the queen is a minor consideration, I will state, that the hive best suited to the production of bees, is best suited to the production of honey, either comb or extracted, if the surplus receptacles are properly constructed and manipulated.

Mr. Hutchinson, in the *Review*, criticises my article on "Large vs. Small Combs," with an admission that, "In many instances, larger colonies are secured by using larger hives;" but continues, "What is gained? We simply have our bees and combs in fewer hives, and get larger yields per colony, but no larger per comb or per bee. Successful bee-keeping does not depend upon large yields per colony, but upon securing the greatest amount of honey, with the least expenditure of capital and labor."

Very good; and as the smoke has barely cleared away since the "wordy war" on small vs. large hives, in the *BEE JOURNAL* of 1885 and 1886, by Messrs. Heddon, Hutchinson, the Dadants and others, any thing that I might say would probably shed no more light upon the subject, than has already been given; yet I was tempted to investigate a little for myself, and here is the result:

Mr. H. says, "We simply have our bees and combs in fewer hives, and get larger yields per colony, but no larger per comb or per bee." Since

learning the above, I sent to a supply dealer for estimates on 8 and 10 frame hives, without inside furnishings, and I here quote his reply:

"Eight-frame hives would be worth just as much (as 10-frame hives), as we do not keep them stock. We would have to make them to order, and the extra trouble of making them would be worth all that we would save on the lumber." Now taking the regular catalogue-prices on 100 10-frame hives, with discount, would be \$61.75; this includes single bodies, platforms and covers. Now these 100 hives will hold 1,000 combs, and should we wish to put the same amount of combs into 8-frame hives, we would have to purchase 125 hives, which would cost us \$77.18; in other words, it would be nearly 6½ cents per comb for privileges in our 10-frame hives, and nearly 7¼ cents per comb for privileges in the 8-frame hives. Or, it costs us 1½ cents more per comb to work our bees in 8-frame hives than it does to do so in 10-frame hives.

Now if we can harvest more honey per colony, as Mr. Hutchinson admits, in 10-frame hives, and it is more expensive to work the same amount of combs in 8-frame hives, where is the economy in "securing the greatest amount of honey with the least expenditure of capital and labor," with the 8-frame hives?

As regards the idea of "making our hives so small that an ordinary prolific queen could lay two eggs in each cell, and 'loaf' half the time at that," it is too ridiculous for comment; and as my former arguments cover this subject, we will await the verdict of a discriminating public.

BEEES IN SPRING.

Results in Wintering—Immense Country.

Written for the *American Bee Journal*

BY T. F. KINSEL.

I put my bees out of the cellar on April 3, and found brood in all the colonies except 1, which was queenless; 3 colonies died, 1 was queenless, 1 starved, and 1 had an abundance of buckwheat honey of fine quality, and yet it died. I would be glad to say what ailed it, but I do not know the cause; nor could I discover any material difference between it, and some of the living colonies. There was some mold throughout the entire lot, but not more in the dead colony with plenty of stores, than in others that were alive, and had brood. I have finally come to the conclusion that where human patients, in the prime life take sick

and die, under treatment of skillful physicians, we may expect some loss in bees.

There are some impossibilities in bee-keeping, as well as in other callings; for instance, there was no general yield of surplus last year, and the cause seems to make bee-keepers disagree. If I felt as confident of the "why" of the death of the above-mentioned colony, with plenty of stores, as of the honey dearth last year, I would not hesitate to make an assertion, though in doing so I could offer no known remedy.

Last fall, in placing the colonies in the cellar, 8 were found too light to winter safely. In February the cluster was separated and a frame of honey hung in, so that they could feed. These colonies were among the best when put out on April 3. I did the same last year, and experienced no bad results. Some had the diarrhea in the cellar, and smeared the hive front, and when put out all spotted everything that they could alight upon.

Since putting the bees out, I have examined every frame in each colony, spacing close, according to Mr. J. E. Pond's plan. I am convinced that warmth and close spacing are essential in quickly building up colonies in the spring.

I winter my bees with 8 frames in a 10-frame hive, occupying *all* the hive, and leaving more space *between* the combs in winter. I use the Langstroth frame in Simplicity hives. It may be more expensive to hang combs of honey in the hives for winter stores than syrup, yet the convenience is an item not to be overlooked, and so far it has been safe here.

Our country is immense, climate variable, and no man should lose his judgment and follow advice regardless of latitude. Think of it, "men of the North," who are now sowing oats and barley, our good Editor already has received a white clover blossom from "the Sunny South!"

Shiloh, O., April 9, 1888.

HISTORICAL.

Something on Sectional Hives used 30 Years Ago.

Written for the American Bee Journal
BY M. M. BALDRIDGE.

Under date of Feb. 25, 1888, Chas. Dadant sends me an extract copied from one of my letters dated Feb. 13, 1888, which I reproduce as follows:

"Who ever used a breeding-hive made of two half brood-chambers, and arranged so as to divide the brood-nest instantly into two equal parts horizontally, to be used separately or inter-

changeably, and for the purposes as set forth by friend Heddon? There is something here in manipulation, which the Heddon hive, combined with his instructions, enables us to do, that seems both *new* and *novel*."

Mr. D. then adds this to show me, I presume, that the *features* and *functions* of the Heddon hive are simply *old ideas*, to-wit: "Please look at the AMERICAN BEE JOURNAL for April 14, 1886, page 231; and, at the following

engravings, which were published 30 years ago."

To which I reply as follows:

The cuts you inclose, and which are given above, represent a sectional hive of three horizontal divisions, but I have no means of knowing from what they show, nor from what you say in the AMERICAN BEE JOURNAL to which you refer, the *purposes* for which the said hives are made. The brood-chamber of the new hive of Mr. Heddon is also made of two or more horizontal sections, but the best approved form of his hive is made of only two half brood-chambers filled with close-fitting and yet movable frames, and arranged and manipulated thus and so, throughout, for *special* and very important reasons.

I certainly infer that one of the sectional hives to which you direct my attention, is simply provided with *bars*; and, in the absence of any proof to the contrary, I assume the right to infer

that these hives were never used as Heddon uses his, nor were they intended for the same purposes. Hives made of two or more horizontal segments are by no means new to me, as I have seen a few of such hives in actual use, perhaps 25 or 30 years ago, but they were of no special practical value, and I presume none of them can now be found in use! But, notwithstanding that fact, I have never seen a breeding-hive made of simply two half brood-chambers, and for the special and very important reasons as set forth by Mr. Heddon; nor have I yet seen any evidence that any one else has ever seen or used such a hive prior to Heddon's description, and his instructions for using the same. The great trouble is, Heddon and other advocates of his hive, are not intelligently understood by the general reader, and perhaps never will be! But the same was and still is true in regard to what constitutes a Langstroth hive. There are in fact, to-day even, but few who intelligently understand the special features and functions which were the sole property of Mr. Langstroth, as covered by the re-issue of his patent.

My motto is, and always has been, "Honor to whom honor is due." I always try, however, to hold myself open to conviction, and when I am convinced that I have been in error, I will cheerfully admit it. All I want is simply the *truth*, no matter how, nor from whence it comes.

SPRING WORK.

Some of the Things Necessary to be Done in Spring.

Written for the Western Plowman
BY C. H. DIBBERN.

It is wonderful how much can be written and learned about the bees. Week after week and month after month, and one year after another, papers, journals, and magazines are printed, and great books are written, all devoted to this one subject, and yet it is not exhausted. Indeed, the more we see, hear and learn in this department of study, the more we are surprised at how little we really know. One would think in reading the bee-periodicals, there would be much repetition, and that they would become very dry reading, but it is not so. The AMERICAN BEE JOURNAL, and other bee-papers, are our most welcome visitors. We are always sure to find something new, if not rich and spicy in them, and they are seldom laid down till the last article is read. Then there is something to think about for days after, and nights, too. Some one

perhaps has suggested an idea, unintentionally, it may be, that not only sets us to thinking, but to experimenting in various directions.

The Bees' Sting.

To many, the bee is an "animal" only to be avoided, to throw stones at their hives, like a lot of boys would at a hornet's nest. Of course such people do not like bees, and the bees soon learn to make the matter mutual. Their only interest is in the honey, if they could only get it away from them. There's the rub, they are afraid of those horrid stings. Now why did an all-wise Creator provide the sting, for is it not said that He made nothing in vain? Is it not easy to understand that without this weapon of defense—and they perhaps never use it only in defense—the poor bees would have had a hard time of it all these years?

Ancient History of Bees.

Bees existed, perhaps, before man was created. Herman mentions them, and they are referred to often in the Bible. Indeed their product, honey, was the only sweet known for hundreds of years. They have co-existed with man from the earliest times, sometimes cared for, but more generally neglected or hunted like the wild beast. In our own times, who does not remember the brimstone pit, where, after a season of patient toil, the poor bees were needlessly slaughtered for a mess of honey, bee-bread, brood and old comb? But a better day has come for the bees as well as the bee-keeper. From the writings of such men as Huber, Quinby, and Langstroth, and the light shed broadcast over the land by our bee-papers, we have learned the better way. We no longer "rob" the bees, but by our care, knowledge, and kind treatment, manage them in such a way that they produce much more honey for us than formerly, and the bee-keeper not only leaves them an abundance for winter, but in times of scarcity provides them with the needed stores.

When we think of the great progress that has been made in the last quarter of a century, of all the books that have been written, the conventions that are held, and the papers that are published, we often wonder if the time will ever come when man will know all that can be learned about so simple a creature as the honey-bee. Will it be in a hundred years, or will it be when he has counted and named the last star that can be observed through the great Lick telescope?

Preparing Feed for Bees.

In studying over the losses that have been reported, we begin to fear that it was not the cold that killed them, but that they were thoughtlessly poisoned.

The honey crop last year was so poor that many colonies had not enough for winter, and feeding had to be resorted to. A good many had never fed anything to the bees before. The bee-papers came promptly to our aid with well written articles by some of the most successful apiarists, describing fully the kind of sugar to buy, in what proportion to mix it with water and cream-of-tartar, etc. They forgot one very important thing, however, that was to caution us not to boil it in copper or galvanized iron vessels, and let it stand in them. I came very near making this same mistake. I had boiled a batch of syrup, using cream-of-tartar, in a copper wash-boiler, and the next day noticed that the acid was acting on the copper. I then emptied it out, and made more to mix with it. I fed it all, and so far do not see any bad results from it. It shows, however, how careful we should be in preparing food for bees, as well as for ourselves.

Active Work—Winter Experiments.

Well, the active work of the apiary is once more upon us. The bees should be removed to their summer stands as soon this month as the weather becomes fine. If the weather continues stormy, do not be tempted to put them out, if in repositories, no matter if it is April. If put out at such a time, many will be lost by becoming chilled in their attempts to fly, and spring dwindling will surely result. If bees have been out all winter, they will remain in their hives, as they have had plenty of pleasant days to fly.

All colonies should be examined as early as practicable, and their condition and wants ascertained and supplied. If any are dead, the combs should be taken care of, and stored for use at swarming time, where the bees cannot get at them. If the combs contain any considerable honey they may be given to such as are short.

The colonies should be equalized, as to bees and honey, as far as possible, so as to give all a fair start. They should have all the sunshine possible, and do not be in a hurry about putting on honey sections. When there is honey coming in, and bees are beginning to get crowded is time enough. Of course much depends on latitude. In the South, they will be gathering honey freely this month, while at the North little can be expected.

It is much better to devote all our energies to induce the bees to breed up to strong colonies this month and next, to have them in extra good condition for the clover and linden harvest, than to vainly spend time giving them room they cannot occupy.

From experiments made this winter, our ideas of in-door wintering have undergone a slight change. Hereto-

fore it has been our aim to make the cellar as warm as possible. This winter more ventilation was given, and at no time since the bees were put in last November, has the temperature been above 45°. The consequence is that the bees have remained clustered and very quiet all the time, and very few bees have died on the floor. They have consumed only a small quantity of stores, and their present condition is the best for many years. April, however, is a critical month for such as are not well provided for, and a good deal of feeding will have to be done.

BEE-LEGISLATION.

Selling the Right to the Nectar on Land.

Written for the American Bee Journal
BY W. J. WILLER.

Prof. A. J. Cook said at the Chicago convention, that when land is sold, the right to the nectar is not sold with it. Taking that for law, then it must be common property, and the people, as such owners, have a right to demand that it shall be gathered as economically as possible.

Let us look at the way in which it is gathered now. Supposing one-half is gathered by one-horse bee-keepers; they will get some bees to start with, and let them do as they like, the result is that each colony will cast from 3 to 5 swarms, thus using all the nectar to rear young bees, only to die from neglect. In this way the owners receive but very little honey in exchange for their nectar. The other half of the producers being experts, but little honey is wasted.

Why is it not as much the people's right to sell their nectar, as it is to sell their land? My plan would be to have it sold off in townships, on the same terms as school land is now sold, the bees to be kept two miles from the town lines, and the small producers to have the privilege of keeping bees until the owner of such territory has a stipulated number of colonies of bees.

The above plan would undoubtedly raise a disturbance at first, the same as actual settlers do with "squatters." Can any one tell how many bee-farms there would then be in the United States? One of the advantages of this plan would be, the ease with which the statistics could be gathered.

But "to err, is human," so the professor may be wrong; or, what is more probable, I may be wrong in my deductions.

Sandusky, Mich.

ARKANSAS.

Bee-Keeping in Southwestern
Arkansas—Bees Dying, etc.

Written for the American Bee Journal
BY R. M. RAWLINS.

Last year the honey crop was cut short by the drouth, the bees storing only about $\frac{1}{3}$ of a crop. Linden did not yield any honey, but the honey-flow up to May 15, was better than usual; after that the bees gathered but little surplus, in fact we did not take any after the rattan bloom in May. They had more honey than they really needed, unless it is in a late spring, such as we have sometimes.

Here bees are usually wintered on the summer stands, with the top stories on the hives. Bees do not freeze to death much, the greatest loss being from starvation, which occurs in March and April, after the hives are full of combs of brood and bees; when it is cold and rainy, if they have not plenty of honey, they have to be watched very closely and fed. With the movable-frame hive this can be attended to much better than with the box-hive, hence the loss is not so great now as formerly.

The principal honey plants are rattan, holly, and linden (or "linn," as it is called here). The fall flowers are principally asters, but cotton yields some honey. Clover is not sown very much, but the farmers are increasing the acreage in this honey-plant. We are dependent upon the forests for the most of our honey, and they are being cut down and the land cultivated, so we will have to encourage the planting of clover more than ever.

The box-hive bee-keepers say that the bees do not produce as much honey now as they used to do. They surely do not for such bee-keepers; but the Italian bees, kept in movable-frame hives, average per colony about 40 pounds, on the hills; bees near the river-bottoms produce one-half more.

The Union and its Non-Supporters.

I think, as the editor has said, that among so many bee-keepers it is a shame that no more belong to the "Union." It is too bad for an honest industry to be trampled upon as has been done in Mr. Z. A. Clark's case, at Arkadelphia. Mr. Clark had invested a considerable sum of money in bees and fixtures, and had increased them to the number of colonies that he expected to keep (150 or 175 colonies), expecting to get a living from the bees.

Bees Dwindling and Dying.

Last spring, 5 colonies in 12-frame Simplicity hives, with top-stories on, strong in bees, and with plenty of

honey, commenced dwindling. The bees that work seem to die the worst. Their abdomens are somewhat swollen, they crawl out and try to fly, and when the affected ones do work, it is very easy to detect that they are sick. Some hop from the alighting-board, and lie flapping their wings until they die. Some are dragged out by the well bees, and some rest on the alighting-board, flapping their wings, and constantly kicking and rubbing their feet. About the same number of colonies are in a similar predicament this spring, but not all of the ones that were affected last year.

The best colony in the yard is one of the sick ones. I say "sick," but I do not know what is the trouble with them. It cannot be the diarrhoea, and if they are poisoned, why are not more of them affected?

During the honey-flow last year, they gradually stopped dying, but the colonies became very weak before it ceased. Is there anything that bothers bees at night? It seems to me that they were troubled in that way. Can any one, judging from what I have described, tell what ails the bees, and how to cure them?

Okolona, Ark.

COLUMBUS, O.

The Bee and Honey Show at the
Centennial.

Written for the American Bee Journal
BY DR. A. B. MASON.

The following is the premium list for bees, honey, apiarian supplies, etc., for the Ohio Centennial Exposition to be held at Columbus, O., from Sept. 4 to Oct. 19, 1883.

No entry-fee will be required, and no charge made for space in this class, and all intending exhibitors in this class will be furnished with entry-blanks, rules, regulations, etc., free on application to me. Others desiring premium lists, etc., should apply to L. N. Bonham, Secretary, Columbus, O.

Exhibitors can begin arranging their exhibits on Aug. 21. Exhibitors' admission tickets, good during the Exposition, \$5.00. Competition and exhibition in this class, is confined to Ohio.

A building is to be erected for this Department, and it is very desirable to know at once how many will want space, and how much they will want for honey, and how much for other exhibits, so as to have the building of suitable dimensions; and I hope such as intend to make an exhibit will let me know immediately, what space they will need. Sometime since I made

such a request in *Gleanings*, and only two responded. At that rate no building will be needed, for a corner in some other building would do, and Ohio bee-keepers would have occasion to be ashamed of their lack of interest in this display of the State's material progress in this direction during a hundred years.

It is expected that the annual meeting of the North American Bee-keepers' Society will be held in Columbus during the Exposition, and Ohio bee-keepers ought, and I trust will, have pride enough in the good name of their State, and in this industry, to make the grandest display ever made on this continent.

As shown below, there is a first, second, and third premium offered on most of the exhibits, or articles, and the total amount offered is over \$400, being the largest amount ever offered by any State.

Such exhibitors as do not desire to remain at the Exposition, can leave their exhibits in my care, and they will be looked after and cared for to the best of my ability, and without charge; and such as do not care to arrange their exhibits themselves (except for display of comb and extracted honey) can send their exhibits to me at Columbus, O., after Aug. 21, with all charges paid, and I will see that they are properly placed and cared for, without charge, and they can visit the Exposition at such time as will best suit their convenience, and find their exhibits all in place.

I am in hopes that we shall be able to have an apiary established on the grounds, and have public manipulation of the colonies by bee-keepers who may visit the Exposition. As the Exposition is intended to show the material advancement of Ohio in a hundred years, it will be "just the thing" to have on exhibition the most antiquated appliances, as well as the most modern, and to show also how bees used to be kept and honey obtained, and I hope those having old things of interest in bee-keeping whether they live in Ohio or not, will correspond with me with a view to having such things on exhibition.

The old "log gum," box-hive, and the straw hive, all with bees at work in them, will be among the attractions, "if it takes all summer" to get them. The cow-bells, tin horns, and tin pans that used "to make the bees alight," will recall to some "the days of childhood," and make them young again.

Here is the Premium List in the Apiarian Department:

Bees, Honey, and Apiarian Supplies.

A. B. Mason, AUBURNDALE, O., Superintendent.

All entries close Aug. 6. Anything competing for a single premium cannot be included in a display. Colonies must be

exhibited in such a shape as to be readily seen at least on two sides. Such provision will be made for the display of comb honey (and other articles that might be injured by bees), that it can be exhibited without crates. Everything *must* be in place by the morning of Sept. 4, 1888.

Best display of comb honey (largest and most attractive).....	\$25 00

FOUNDATION.

Historical Description of the New Comb Foundation.

Written for the American Bee Journal
BY C. J. H. GRAVENHORST.

A bee-keeper of Thuringia, the homeland of Baron von Berlepsh, in Germany—a Mr. Koerbs in Bath Berka—has been successful in producing a new kind of comb foundation.

For a few years he had subjected his invention to a test, and found that it works very well.

A careful observation of the bees, suggested by a remark in the third and fourth edition of my book, "The Practical Bee-Keeper," prompted him to make experiments. His new foundation has the following advantages:

1. It is made of pure wax, by means of a hand-press, and it is not used by the queen for breeding, even if the foundation-combs are put in the brood-nest.

2. It is very durable, and the most delicate combs of such foundation will stand the employment of a full force in extracting the honey.

3. The honey is extracted very quickly, the operation scarcely requiring half the time that others take.

4. In bad seasons, these combs remain empty, not being used for breeding, and there being, unfortunately, no honey to collect.

5. The bees store no pollen there.

The separation of the honey compartment in the hive, from the brood-nest, becomes superfluous. As Mr. Koerbs told me this, I wrote to him, that he promised a good deal. Though I knew him as a successful bee-keeper, and fortunate inventor of a frame machine, I nevertheless was not over-sanguine in regard to his latest invention. But as Mr. Koerbs offered to give me particulars of his invention, I gave him my word of honor not to divulge his secret. Full particulars were given me, and in addition I received one of Mr. Koerbs' combs of foundation, completed by the bees, from which the honey had been extracted several times.

The matter did appear to me to be very simple, and I thought that if this new invention should accomplish only half of what Mr. Koerbs expects it to do, we shall undoubtedly see a great revolution in the manufacture of comb foundation, as well as in bee-keeping.

Mr. Koerbs has sold the patent of his invention to Mr. Otto Schulz, a German manufacturer of foundation on a great scale, who now has, by his patent, the right to manufacture this new foundation in Germany and Austria, and no one in these countries has the permission to use the new combs, except after buying the comb foundation from Mr. Schulz.

I do not like patents in bee-keeping matters, and should have been very glad if another plan were carried out, to the benefit of both the inventor of the combs, and the bee-keepers of Germany and Austria.

In order to enable bee-keepers to manufacture their requirements of such combs for themselves, Mr. Koerbs has started a subscription to a pamphlet in which his experiments, and also

the manufacture of the foundation, and the method of using it are described. Any one who would agree to take this pamphlet at 25 cents, would, in due time, receive a copy, postpaid, in case Mr. Koerbs secured at least a few thousand subscribers. The pamphlet would be mailed to all subscribers on the same day. But only 350 subscribers had agreed to buy the pamphlet. Many of the German bee-keepers condemned this way, and pleaded for a patent. Mr. Koerbs applied for a patent, and then sold it to Otto Schulz.

And now comes the secret: The new comb foundation is one-sided, with prolonged honey-cells. One side of a frame is closed with a tin sheet, covered with wax and worked into foundation. The bees work out the cells to double the length, and fill them only with honey. Perhaps many bee-keepers have seen one-sided combs in hives full of honey, and many perhaps have had combs with prolonged cells on both sides of each comb, and have seen only honey in them. I do not doubt that a comb of such qualities as Mr. Koerbs claimed for his, would be of great benefit for every bee-keeper, if he only understands how to use it in the right way; and this way will be found out, I think, next season.

Wilsnack, Germany, March 12, 1888.

CONVENTION NOTICES.

☞ The Darke County Union Bee-Keepers' Association will hold its annual meeting on Friday, April 27, 1888, at Ansonia, O. J. A. ROE, Sec.

☞ The next meeting of the N. W. 11th and S. W. 11th Bee-Keepers' Association will be held in Rockton, Ills., May 22, 1888. D. A. FULLER, Sec.

☞ The spring meeting of the Wisconsin Lake Shore Center Bee-Keepers' Association will be held on May 31, 1888, in Mueller's Hall, at Kiel, Wis. FERD. ZASTROW, Sec.

☞ The Cortland Union Bee-Keepers' Association will hold its spring meeting on May 8, 1888, at Cortland, N. Y., at 10 a. m. All bee-keepers are invited. W. H. BEACH, Sec.

☞ The Keystone Bee-Keepers' Association will hold its sixth annual meeting in the Court House at Scranton, Pa., on Tuesday, May 8, 1888, at 10 a. m. All bee-keepers are invited. A. A. DAVIS, Sec.

☞ The annual meeting of the Western Bee-Keepers' Association will be held at Independence, Mo., at the Court House, on April 25, 1888. It will be carried on as a sociable, friendly gathering. Let all bring their baskets and have a good time. PETER OTTO, Sec.

☞ The semi-annual meeting of the Progressive Bee-Keepers' Association will be held in the Sons of Temperance Hall at Bainbridge Centre, O., on Thursday, May 3, 1888. Parties wishing conveyance from Geauga-Lake Station, on the Erie railroad 3 miles distant, will please notify Mr. L. H. Brown, Bissels, Geauga Co., O., so that arrangements can be made for the same. All interested are invited. MISS DEMA BENNETT, Sec.

☞ The next meeting of the Susquehanna County Bee-Keepers' Association will be held at New Milford, Pa., on May 5, 1888. The following subjects are to be considered: Bee-keeping for pleasure and profit—Spring work with bees—is it advisable to use foundation? If so, to what extent?—How can we make our Association of the most practical value to its members. All are cordially invited to come. H. M. SEELEY, Sec.

☞ The tenth annual meeting of the Texas State Bee-Keepers' Association will be held at the headquarters of Vice-President W. R. Graham, in Greenville, Hunt Co., Texas, on May 2 and 3, 1888. A leading feature of the convention will be criticisms upon subjects that have been mentioned in the newspapers. A good time is expected, so let all Texas and Arkansas bee-keepers attend. A cordial invitation is extended to all bee-keepers whatsoever dispersed. Remember, no hotel bills to pay at our conventions! B. F. CARROLL, Sec.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*
 Apr. 27.—Darke County, at Angonia, O.
 J. A. Koo, Sec., Union City, Ind.
 May 2, 3.—Texas State, at Greenville, Tex.
 G. F. Carroll, Sec., Blooming Grove, Tex.
 May 3.—Progressive, at Bainbridge Center, Ohio.
 Miss Dema Bennett, Sec., Bedford, O.
 May 5.—Susquehanna County, at New Milford, Pa.
 H. M. Sealey, Sec., Harford, Pa.
 May 7.—Welland County, at Welland, Ont.
 J. F. Dunn, Sec., Ridgeway, Ont.
 May 8.—Keystone, at Scranton, Pa.
 Arthur A. Davis, Sec., Clark's Green, Pa.
 May 8.—Cortland Union, at Cortland, N. Y.
 W. H. Beach, Sec., Cortland, N. Y.
 May 19.—Nashua, at Nashua, Iowa.
 H. L. Rouse, Sec. Ionla, Iowa.
 May 22.—N. W. Ills. & S. W. Wis., at Rockton, Ills.
 D. A. Fuller, Sec., Cherry Valley, Ills.
 May 31.—Wis. Lake Shore Center, at Kiel, Wis.
 Ferd. Zastrow, Sec., Millhome, Wis.
 Aug. 14.—Colorado State, at Denver, Colo.
 J. M. Clark, Sec., Denver, Colo.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

**SELECTIONS FROM
OUR LETTER BOX**

Working on the Forest Bloom.

—T. M. Edwards, Kerrville, Tenn., on April 16, 1888, writes:

My bees are now booming on the great variety of forest trees that are now in bloom. The poplars will be in full bloom in a few days. My bees wintered well; out of 120 colonies only one starved to death, and 4 were queenless. There are no bees diseased in this country, and the prospects are fine. I had one swarm on April 14.

High Water in Iowa.—John B.

Lindle, Muscatine, Iowa, on April 16, 1888, writes:

I have had my share of trouble with high water. Over 100 head of cattle and horses, and over 60 sheep, and a lot of hogs are all on about 60 acres of dry land, the balance of my farm (consisting of 400 acres in all) being flooded with water. This changes all of my farming calculations. There is water in the cellar now. Cedar river is higher than any time since 1860. I have feed enough for my stock, but my poor bees suffer the most, as they are flying to the timber which is one-half mile distant, with one sheet of water for miles around on three sides of my place. The trees are budding, and also the willows. As the bees come in on the "home stretch" with pollen, they tire and chill with the cold wind, and drop by the hundreds to rise no more, then swept off by the current. It seems that one extreme follows another.

Experimenting with Bees.—John

Boerstler, Vashon, Wash. Ter., on April 6, 1888, writes:

Yesterday morning, about 10 o'clock, I noticed that the bees in hive No. 3, were not flying. I rapped on the hive, but I could not hear a sound; so I opened the hive, and there I found all the bees dead. I picked up the queen and layed her on the ground, and then I brushed all of the bees on the ground, but not a bee moved. I studied for five minutes what to do, and finally put all the bees and queen into a pail, and placed them near the stove in the house. What do you think they did? They began to move,

when I breathed on them, and after an hour's work they were all revived. I made syrup, and fed it to them in the combs, and a great many of them are flying again. I believe that I will yet save them from as close a call as I ever have known bees to have in my 20 years of bee-keeping. The bees are all right again to-day, and I think that they will do well by feeding them as I am doing.

Condition of the White Clover.

—Rev. M. Mahin, Bluffton, Ind., on April 4, 1888, says:

My bees have wintered well. I lost 3 colonies out of 34. In this part of the country I think that the white clover is badly damaged. At New Castle, where my bees are, it does not seem to be much injured.

Wintering Bees in Idaho.—F. H. McDonald, Star, Idaho, on April 10, 1888, writes:

The winters being usually mild here, bees, as a rule, are wintered on the summer stands, without any protection. The last winter being colder than usual, a few colonies froze to death, and others were made weak by the cold. On their first flight they daubed the hives considerably, but they soon became all right. The first pollen was gathered on Feb. 17. Colonies have built up fast, and are now strong.

Bees Not in Good Condition.—

Christian Weckesser, Marshallville, O., on April 16, 1888, says:

Bees are not in very good condition, generally, in this vicinity, and a very large per cent. have died. Cool winds are prevailing, and many bees will yet die, if not very well cared for. I notice that those colonies that were fed late in the fall, and "tinkered" with, are the worse for it, apparently. Those wintered in the cellar are rather the best, but most of them, though strong, had little brood when placed on the summer stands.

Good Outlook for the Bees.—B.

A. Manley, Milo, Iowa, on April 11, 1888, says:

March is gone, and April brings a good outlook for bees. My bees wintered in excellent condition. I packed them in corn-corb chaff from an elevator, which I will describe at some future time. Sometime ago it was thought that bees were wintering well in this section, but April reveals the fact that only the bees that were well cared for in the fall were able to get through. I hear of some losing all, and some having a small remnant left. But the thoughtful ones have no reason to complain. My bees are using this fine weather with all their might. I saw them carry in natural pollen on April 2. This is a good country for white clover, and it is starting up nicely.

Experience in Bee-Keeping.—

Jesse Willis & Son, St. Charles, Mich., on April 10, 1888, write:

Our experience with bees dates back 20 or 25 years, the first colony being taken from a bee-tree; since that time we have never been without bees. We have tried almost all kinds of hives—patented, moth-proof, and non-swarmer—as claimed by the makers, and many other kinds, and we have come to the conclusion that the closed-end Quinby is preferable for our own use; but we find them somewhat unhandy when

shipping bees. We now have 250 colonies of hybrids. We winter them in chaff hives with fair success, and work exclusively for comb honey, which we find the most profitable. The most of our honey is shipped north, to Bay City, Saginaw, and other places, as our home market requires but little. We generally aim to get our crates and sections ready, and also the foundation fastened in the sections, before the honey-flow comes. Our greatest trouble has been in fastening foundation in sections, and we have been helped out of that with one of the latest foundation fasteners. Our best honey-flow is from white clover and basswood. The fall honey comes from wild rice and buton-balls.

Colonies Need Building Up.—

Rev. John Hunt, Plain City, O., on April 11, 1888, writes:

Last fall I had 20 colonies of bees. Last season was a very poor one for honey. The white clover yielded nothing. I had no swarms, and no surplus honey—not even a supply for the bees themselves. Three colonies died during the winter, and the remainder are weak in numbers, though apparently in good condition, but will need building up greatly, to take advantage of the honey season, if it should be a good one. I have fed them on sugar syrup.

Bees Booming in Tennessee.—

John H. Christie, Dyersburg, Tenn., on April 9, 1888, says:

Bees are fairly booming. I do not think that I ever have seen them in as good condition at this time of the year as they are now. Some of my bees have begun work in the sections. I had a swarm on April 6. Peach and plum trees are through blooming, and pear, apple and cherry are now in full blast. Strawberry beds look white. I lost but one colony out of about 100 in wintering, and that starved to death for the want of honey.

Clamp for Wintering Bees.—

Justus Chapman, Woodville, Mich., on April 14, 1888, writes:

I started in the spring of 1887 with 2 colonies, having lost the balance of my bees during the previous winter. I increased them to 6 colonies, and took off 50 one-pound sections of white clover honey. The hives were heavy the last of October, when they were put into a clamp, *a la* Hutchinson, without cushions or division-boards, or other extras. They were taken out on April 9, and were all right excepting a slight diarrhea.

Heavy Loss in Bees—Alfalfa

Seed.—E. Jarvis, Fairgrove, Mich., on April 14, 1888, says:

There is, I think, a heavy loss of bees in this region, and many colonies have no honey left. We could not well double up colonies last fall, as there were many bees in each hive. I have 4 colonies left from 20. Some were in a shed, and some out in the wind. Two of those wintered outside are alive. My bees three years ago were hybrids, Cyprians and blacks. One queen mated with a yellow drone in 1887. Where can I get alfalfa or lucerne seed by the pound?

[It is worth 40 cents per pound by mail. It can be obtained at this office.—ED.]

Scatter the Leaflets.—Look at the

list (with prices) on the second page.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

The Convention. — The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Honey and Beeswax Market.

DETOIT.
HONEY.—Best white in 1-pound sections, 15@16c. Extracted, 9@10c. Little demand and few sales.
BEESWAX.—23@24c.
Apr. 12. M. H. HUNT, Bell Branch, Mich.

NEW YORK.
HONEY.—We quote: Fancy white in 1-lb. sections, 13@15c.; the same in 2-lbs., 10@11c.; buckwheat 1-lbs., 10c.; 2-lbs., 9c. Market dull.
BEESWAX.—24c.
MCCAUL & HILDRETH BROS.,
Apr. 7. 28 & 30 W. Broadway, near Duane St.

CHICAGO.
HONEY.—Prices range from 16@18c. for best one-lb. sections, to 14@15c. for off color and condition; 2-lbs., 14@15c. Dark is slow of sale at almost any price. Extracted, 7@9c., with good supply. Light demand.
BEESWAX.—22@23c. R. A. BURNETT,
Mar. 22. 161 South Water St.

NEW YORK.
HONEY.—We quote: Fancy white 1-lb. sections, 14@15c.; fancy 2-lbs., 12c. Lower grades 1@2c. per lb. less. Buckwheat 1-lbs., 10@10½c.; 2-lbs., 9@9½c. Extracted, white, 7@7½c.; dark, 5@6c.
Mar. 19. F. G. STROHMAYER & CO., 122 Water St.

CHICAGO.
HONEY.—We quote: Fancy white clover 1-lbs., 16@17c.; 2-lbs., 15@16c. Dark is slow sale at almost any price. Extracted is scarce, and sells at 7@10c.
BEESWAX.—23c.
Mar. 13. S. T. FISH & CO., 189 S. Water St.

CINCINNATI
HONEY.—We quote extracted at 4½@9c. per lb., for which demand is good. Comb honey, 14@17c.—Supply large and demand slow.
BEESWAX.—Demand is good—20@22c. per lb. for color to choice yellow on arrival.
Mar. 26. C. F. MUTH & SON, Freeman & Central A.V.

MILWAUKEE.
HONEY.—Choice white one-lb. sections, 17@18c.; 2-lbs., 15@16c.; 3-lbs., 14c. Dark and broken not quotable. Extracted, white in kegs and ½-barrels, 8½ to 9c.; in tin and pails, 9½@10c.; dark, ½-barrels and kegs, 5@7c. Market slow.
BEESWAX.—22@25c.
Mar. 10. A. V. BISHOP, 142 W. Water St.

DENVER
HONEY.—Best white 1-lb. sections, 17@18c.; 2-lb. sections, 15@17c. Extracted, 8@10c.
BEESWAX.—20@23c.
Mar. 1. J. M. CLARK & CO., 1409 Fifteenth St.

KANSAS CITY.
HONEY.—We quote: Choice white 2-lb. sections, 17@18c.; dark 2-lbs., 14@15c.; choice white 1-lbs., 18 to 20 cts., dark 1-lbs., 15@16c. White extracted, 7@8c.; dark 5@6c. Demand is slow. White extracted is firm when in 60-lb. tin cans.
BEESWAX.—21 to 22c.
Mar. 29. HAMBLEN & BEARSS, 514 Walnut St.

BOSTON.
HONEY.—We quote: 1-lb. sections, 16@17c.; 2-lb. sections, 14@16c. Extracted, 8@9c. This market is not very brisk and sales are slow.
BEESWAX.—25 cts. per lb.
Mar. 24. BLAKE & RIPLEY, 57 Chatham Street.

SAN FRANCISCO.
HONEY.—We quote: White to extra, 10@17c.; amber, 9@14c. Extracted, white liquid, 7@7½c.; amber and candled, 6@7c. Market quiet.
BEESWAX.—18@21c.
Mar. 20. SCHACHT & LEMCKE, 122-124 Davis St.

KANSAS CITY.
HONEY.—We quote: White 1-lbs., glassed, 16@17c.; unglassed, 17@18c.; and dark 1-lbs., glassed, 15c.; unglassed, 16c.; white 2-lbs., glassed, 16c.; unglassed 2-lbs., 17c. California white 2-lbs., 17c. California extracted in 60-lb. cans, 8c. Market quiet and receipts are larger.
BEESWAX.—No. 1, 20c.; No. 2, 18c.
Mar. 19. CLEMONS, CLOON & CO., cor 4th & Walnut.

Clover Seeds.—We are selling Alsike Clover Seed at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. White Clover Seed \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. Succet, or Melilot, Clover Seed: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Jones' Frame Pliers.

FOR taking frames out of hives, or moving them in any way desired. It is made of Japanned iron, and can be utilized in many ways. It has a long claw for loosening frames, and a hook which may be used for carrying other frames besides the one held by the Pliers. Price, 40 cents., by mail. By express, 30 cents.

EDITORIAL BUZZINGS.

Listen to the honey-bee
As it dances merrily
To the little fairies' drum—
Humming, humming, humming, hum,
Never idle, never still,
Humming, humming, hum.

In Answer to our question, "Has any one yet received any of the Chapman Honey-Plant seed?" Mr. Ed. T. Smith, of Pike Co., Mo., says: "I got a nice package weeks ago. I wrote to our Congressman." Several others have received some of it.

Letters are often lost which contain money—stolen in transit. We have lost several lately, and this item from the Chicago Times explains it:

Letter Carrier C. F. Burgwardt, of the West Madison Street Station, was bound over to the grand jury in \$1,200 bonds for rifling letters.

When a Money Order, which is absolutely safe, can be obtained for 5 cents, there is no excuse for carelessly putting money into ordinary letters. If a Money Order is stolen it can be duplicated. If a Money Order cannot be conveniently obtained, register every letter which contains money. As every clerk, carrier and route agent must account and receipt for every registered letter passing through their hands in transit, it is about impossible for a dishonest person to tamper with one, without discovery.

The Best Advertising Medium.

—The Bee-Keepers' Review for April states that while its advertisement has appeared in all the principal bee-papers, that of all those who have answered it, three-fourths say that they saw it in the AMERICAN BEE JOURNAL! Straws show which way the wind blows. As a means of placing anything of value before bee-keepers, the AMERICAN BEE JOURNAL stands at the head. The BEST is the cheapest.

The Appeal to the Supreme Court on the one-piece section patent was decided on Monday, April 23, 1888, by confirming the decision of the lower court. As we understand it, this nullifies the patent. It is strange that the Government should so often issue patents and then not sustain them. We have been appealed to for advice quite often about getting patents on some implement or contrivance, and have invariably recommended parties not to go to that expense and trouble, for we did not think that it would pay them to do so.

In this case, the costs have amounted to thousand of dollars, and to obtain the decision on the appeal it has taken nearly four years!

This reminds us of a story as given in *Texas Siftings*. It is thus:

A client meets his lawyer on the street and asks him how his case is coming on.

"Thanks to my skill," replied the lawyer, "I have obtained a judgment in your favor in the United States Supreme Court."

"After four years."

"But, my dear fellow, better late than never."

"How much do I get?" asked the client anxiously.

"The court decrees that you shall receive \$2,000. The costs and my fee will only amount to \$3,500, so all you will have to pay me is \$1,500."

"Merciful Heavens! and I must lose all my money besides!"

"Of course you lose all your money, but console yourself. You have gained your case. You can't expect to gain everything."

Such suits are *fat things* for the lawyers, and they are the only ones generally benefited. To *gain a suit* is a very empty thing, when that is all there is to it, after all the expense and worry. Our advice is again repeated—do not think of patenting any bee-implement; it will not pay!

The "section patent" contest is of no particular interest now to either party, for the price of sections have been so much reduced that there is but little profit in their manufacture.

Out the Chemist.—E. E. Ewing, Rising Sun, Md., writes thus concerning the scandalous schemes of Prof. Wiley, the National Chemist. Some time ago the Manager of the National Bee-Keepers' Union, wrote to President Cleveland concerning the intrigues of the wily professor, and asked him to cause an investigation. He is a National disgrace. Here is Mr. Ewing's remarks:

I think bee-keepers owe it to themselves, to the Government of the United States, and to the public, to get up a petition setting forth the scandalous lies of Wiley, that chemical fraud, together with his answers in regard to the lard of hogs that have died of disease, etc., praying the authorities at Washington to have him dismissed from Government employ, and send the petitions all over the country for signatures. Such a scamp is a disgrace to the Nation! What will be thought of American lard by Europeans who read such answers coming from a chemist in the employ of the Government. His honey lies and his lard chemistry look as though the author was in the employ of the adulterators as well as that of the Government.

Educate the Opposition.—Mr. G. A. Adams, of Perrysburg, O., on March 2, 1888, wrote his views of defending the pursuit as follows:

In sending my remittance for the Bee-Keepers' Union, I do not wish to be considered as approving of the *method* of defense by law. A better method, in my opinion, would be to *enlighten* the public instead of fighting it.

Would it not have been better for Mr. Clark, of Arkadelphia, to have yielded to the wishes of his fellow citizens, and removed his bees at once; and then quietly diffused a very little bee-knowledge among his neighbors? A little patience, and a little expenditure of money for Mr. McLain's report, and the many other testimonies which have been published, if judiciously placed, would do more to restore peace between Mr. Clark and his neighbors than a triumph at law.

In a town near me, a bee-keeper and a grape-grower came very near having a conflict last year. The grape-grower finding the bees troublesome when he came to gather his grapes, mashed some pears, and sprinkled a little sugar on them, and the bees left the grapes for the sugared pears, and he had no more trouble.

He told his neighbor of his success in getting rid of the bees, and the owner of the bees said he did not want his neighbor to feed his bees for nothing, and so gave the grape-grower a few sections of honey. Both men were pleased, and are good friends today. I venture to say that no lawing will ever take place between them. The sugar experiment convinced the grape-man that he had a better way of ridding himself of a nuisance than going to law, feeling lawyers, and cultivating the fighting qualities of himself and his neighbor.

Let me suggest the publication of a pamphlet by the editor of the AMERICAN BEE JOURNAL, which will give the facts about bees biting grapes, etc., and then let them be scattered wherever needed.

Yes; that is a good plan in ordinary cases. We should always be peaceable, and when our rights are not being trampled upon, submit to the views of our neighbors, but in Mr. Clark's case, only a very few opposed his keeping an apiary there, and they only spitefully and maliciously. Mr. Clark was opposed to the saloon element, and that element took this way of persecuting him. This is as we understand it. If we are to submit to such—then we may expect a "reign of terror" indeed. But backed up by the National Bee-Keepers' Union, Mr. Clark will be sure to score a *victory* next July before the Supreme Court.

At the Nebraska Convention the Rev. E. T. Abbott delivered an interesting address on "The Honey-Bee," only a synopsis of which came to us. We wrote to him for a fuller report of it, and the result was its publication on page 223. By an oversight it was not there credited to the Nebraska Convention. This explanation answers an inquiry concerning it, and at the same time gives the proper credit.

New Catalogues for 1888 are on our desk, from the following persons:

A. M. Gander, Adrian, Mich.—20 pages—
Apianian Supplies.

W. G. Russell, Millbrook, Ont.—16 pages—
Bee-Keepers' Supplies.

GLEAMS OF NEWS.

Comb Honey in 5c. Packages.—

Mr. W. Harmer, of Manistee, Mich., has for three years been engaged in putting up comb honey in 2-ounce packages, and has sold several thousands of them. Mr. A. I. Root, editor of *Gleanings*, visited his apiary last December, and thus describes in that paper his method of making these small sections:

He takes a $\frac{3}{8}$ board, just long enough to slip inside of a Langstroth frame. Then with a jack-plane, set coarse, he scoops off the shavings. The shavings, of course, roll up; but he tumbles them into a pair of wafer; and when they get well soaked, they are straightened out, piled up and dried. This gives thin strips of veneer, and cheaper than you can imagine. He then fixes a board as in the second engraving. The Langstroth frame is slipped over this board.

I want to say, first, that these little blocks are made by gluing a $\frac{3}{8}$ board on top of a $\frac{3}{8}$ board, as you see. Now, with a circular saw, cut grooves clear through the thin board until the saw strikes the thick one. These grooves are of such a width that three of the afore-mentioned strips of veneer will drop into each groove, the strips running lengthwise of the frame. When this is done, three short pieces of veneer are dropped into the grooves crosswise. But to make these bits of wood stay in place when the frame is pulled up, a little glue is put into each corner, with a camel's-hair brush. You want to be careful, so the glue will not run in too far, and stick to the form. Before you put in the glue, however, drop some little squares of foundation into each little section. The glue should just catch each cor-

ner of the foundation. When the whole thing is dry, lift it off and hang it in the hive. When the little sections are full and sealed over, take frame and all to the grocer; slip off the outside, and show him that he can separate the squares into long strips. With a sharp knife he can now cut them up into little cakes as wanted. If a customer wants two, four, six, or eight, let him have them all in a slice, to save handling so many loose pieces.

The engravings were kindly furnished by Mr. Root from *Gleanings*, and this description by Mr. Harmer is also from the same source.

Getting small sections filled, never troubled me; for I knew that bees would fill spaces with comb honey that are a little more than a quarter of an inch, so that, with a good honey-flow, I was not afraid but that they would fill a 2-inch space. I would say just here, that I have had sections well filled, only $\frac{3}{8}$ of an inch square, so that, in this particular, I was all right; and I have proved to my satisfaction, and, I think, to the satisfaction of the few beekeepers who have called on me, that I have developed a practical system for making small sections out of shavings from a common hand-plane, and will suit any size of sections for less than 1 pound of honey, with the proper mold or form for adjusting them.

The reasons why I wanted them are, first, because I have seen comb honey cut in pieces, making it leak in every instance, often being a nuisance, dabbling everything, causing considerable trouble, and making it difficult to give a customer, perhaps a boy or small child, a few cents' worth of comb honey; for every one has not 20 cents to spare to buy a whole section; and if they had, they do not always want so much. I think there are very few grocerymen who would cut a comb to suit such customers; and there are thousands of children around us that do not know the taste of comb honey on this account. I also thought that well-to-do people would buy them for the pur-

pose of putting one on each plate instead of serving or cutting into a large comb. These reasons have all been verified, for I have found such customers delighted in every instance. I have not had the opportunity of trying them at fairs, but I should think they would be just the thing, and would as readily bring 5 cents for a 2-ounce section as 4 ounces would on a piece of paper. That is what I sell them for, which is at the rate of 40 cents per pound, so that, in making these sections in the winter, you have profitable employment.

I can put hundreds together, and comb foundation in them in a day, ready for the honey-flow in summer. The size I have been making you will find by dividing a Langstroth brood-frame by 10 one way and 4 the other. The shavings for this size are $\frac{3}{8}$ of an inch wide, and 1-36 of an inch thick. I find this size, when filled, to weigh 2 ounces. I have just weighed 15 separately, which are on the work-bench, ready for market, and were not selected for uniformity of weight, and each one just balanced the scales at 2 ounces.

If these little cakes of comb honey can be put on sale in groceries, on the cars, at fairs, etc., they will prove a great boon not alone to honey-producers, but to humanity in general, by placing a pure sweet in small quantities within the reach of all.

Chaucer to Longfellow is the title of a new book just published by Johnson & Erskine, 107 Madison St., Chicago. This book contains 656 royal octavo pages, being a selection of lectures on English literature by the late Prof. John Fraser, a man of rare and scholarly attainments.

Among the great names of the period that come under review in the lectures are Chaucer, Surrey, Wyatt, Sidney, Raleigh, Spenser, Bacon, Shakespeare, Webster, Beaumont, Fletcher, Shelley, Ben Jonson, Milton, Burns, Hood, George Eliot, Mrs. Browning, Madame De Stael, the Bronte Sisters, Margaret Fuller, Mrs. Stowe and the Modern Novel, Tennyson, Longfellow, and Scotch poetry. Among all these great names there is no single one that the student of literature wants to miss, and nowhere will be found more concise and clear views of the true literary worth of each.

Prof. Fraser was an acknowledged master in literature. He combined scholarly abilities and culture, with a pure and popular

style. He instructs and conveys information in the most pleasing and interesting way. His lectures afford a rare opportunity at a trifling cost, of acquiring a knowledge of great men and their writings, which will become more and more in good society a mark of refinement, and a test of general accomplishment. Those who aspire to write gracefully and accurately, will find this book invaluable. Price, \$3.00. It can be obtained of the publishers.

INTERROGATORIES.

Colonies Close Together.—E. G. Haven, Belleville, Kans., on April 19, says:

I have 41 colonies of bees, and all appear to be doing well. Eighteen colonies were wintered in the cellar, and 23 colonies not on the summer stands, but were placed on a bench, close together, for the convenience of packing straw around them. They are all doing finely at present. 1. Will there be any harm in leaving them so close together during the summer? Or should they be placed further apart? 2. If so, what would be the best way of getting them separated, without their going back and being lost? 3. Is there any way to prevent the bees from gathering around the watering-tank where cattle drink?

1. Place them further apart.
2. Move them a little at a time. Jarring and smoking aid in causing the bees to mark their location anew.
3. It will be very difficult to prevent the bees from watering where they now do, unless the place is dried up, compelling them to seek another.

Tight Hive Bottoms and Covers.—F. Roulo, Portville, N. Y., on April 23, 1888, says:

Last fall I put 99 colonies in the cellar, and 59 out-of-doors packed in chaff. Both lots seem to have wintered equally well. Bees in this vicinity have wintered comparatively well; but they are affected considerably with the diarrhea, which I think is caused by so much cider being made here last fall. I put my bees out on April 17, and after reducing 6 by doubling up, I have 152 colonies left. I would like to have this question answered: Are not bees too warm with a tight bottom and cover on the 8-frame Heddon-Langstroth hive, at a temperature of 45°. Mine seemed to need more ventilation.

No; thousands of colonies are every winter carried through in perfect health arranged just as you mention. It is not more ventilation which your bees need. Very likely they are becoming overloaded with fecal matter, which is not caused by too much or too little ventilation.

Honey Candy.—C. H. Drummond, of Winslow, Maine, says:

I should like to ask, through the AMERICAN BEE JOURNAL, if any one will tell how to make honey candy, or is it patented?

The methods are not patented, but so far we have not been able to get a formula for publication. When we do, such will appear in the BEE JOURNAL.

QUERIES AND REPLIES.

Are the Zinc Queen-Excluders a Disadvantage?

Written for the American Bee Journal

Query 538.—Have you demonstrated in practice, that the zinc queen-excluder is a hindrance to the free passage of the bees from the brood-chamber to the supers? In other words, have you found any difference in the quantity of honey stored where such were used?—Mo.

No.—MRS. L. HARRISON.

No, to both questions.—A. B. MASON.

I never used a queen-excluder.—M. MAHIN.

I do not think that it is any hindrance.—A. J. COOK.

I have seen no difference in the amount of honey stored, by its use.—EUGENE SECOR.

I have not had experience enough to give a decided answer.—C. H. DIBBERN.

It has seemed to me that there was a difference, though I have not experimented largely in this direction.—J. M. HAMBAUGH.

I do not think that the zinc makes any difference in the amount of honey stored. If it does, I have not been able to discover it.—G. M. DOOLITTLE.

Summing up the advantages and disadvantages in its use, I find the latter over-balance the former; and I believe that I can get more honey when it is not used.—J. P. H. BROWN.

I have used the zinc queen-excluder so little that I cannot answer. The slat honey-board serves me for a queen-excluder.—C. C. MILLER.

I have demonstrated by the use of several hundred of them, and for three years, that they are not a hindrance.—JAMES HEDDON.

No. During the last season I had several colonies with queen-excluding honey-boards that stored more surplus than any colonies that did not have them; still I hardly think that the queen-excluder is to be credited with the difference.—R. L. TAYLOR.

I have tested zinc queen-excluders sufficiently to satisfy myself that they are a great advantage. I do not find that less stores are secured when they are used.—J. E. POND.

I have found no difference in the quantity of honey when using the perforated horizontal honey-boards. I have no doubt, however, that many persons fail to get the full benefit of the zinc excluders, for the want of the knowledge of the proper way to make and use them. There is practically no difference between the wood-and-zinc

horizontal honey-board, and those made out of plain sheets of zinc, if the latter are rightly made, and all the departments of the hive are rightly made and adjusted. The difference is one of cost only. The perforated excluder is a success.—G. W. DEMAREE.

The zinc queen-excluders are no hindrance to the bees.—THE EDITOR.

What and How to Feed Bees in the Spring.

Written for the American Bee Journal

Query 539.—1. When feeding bees in the spring, what kind of sugar is best for syrup? Should the syrup be thick or thin? 2. When an inside feeder is used, should it not be removed from the hive every morning, and left on only at night? Would it not raise a disturbance among the bees to leave it on during the day? 3. Should the feeder be removed from the hive for re-filling, or should the syrup be poured into the feeder without removing the latter?—New York.

1. Standard "C" sugar made into a thin syrup. 2. No. 3. Let it remain. The less you disturb a colony, the better.—MRS. L. HARRISON.

1. Coffee A or granulated sugar made into rather thin syrup. 2. No. 3. It depends upon circumstances, and the style of feeder used.—DADANT & SON.

1. Granulated. 2. I would not remove it. 3. I would not use a feeder that had to be removed every time you filled it.—J. P. H. BROWN.

1. Granulated or coffee sugar. I should use about 2 pounds of water to 1 pound of sugar. 2. No; not if your hive is bee-proof. 3. Fill the feeder without removing it.—R. L. TAYLOR.

1. Almost any kind will do, but I use either granulated or coffee A, and make it a little thinner than for winter feed. 2. No, to both questions. 3. I would not use a feeder that had to be removed to fill it.—A. B. MASON.

1. Granulated is best. I would make the syrup much thinner than for winter use. 2. No. It is best to leave it where you will want it again. 3. No. It will be empty. Pour the syrup into it while on the hive, and save all this extra work.—C. H. DIBBERN.

1. Granulated sugar, and tolerably thick, if much is needed. 2. Leave it on. 3. Pour it in the feeder on the hive. Beginners need to proceed with some caution about the whole business of feeding.—C. C. MILLER.

1. Honey is better than any sugar when bees can fly freely. Granulated sugar is the most apt to be pure. 2. No; it will be well to leave it on all the time. 3. A properly made feeder should not need to be removed to be filled, and no contact with the bees is necessary.—JAMES HEDDON.

1. The purest is the best, but a good article of C sugar is good enough. 2. No. It will make no disturbance. When bees become a little accustomed to being fed, it produces no excitement in the hive. 3. That depends upon whether the feeder can be filled without being removed.—M. MAHIN.

1. I have had limited experience. I should not be particular if the bees appeared to like it. I would have the syrup about the consistency of honey. 2. It would not be practical to remove the feeder, if you were feeding many colonies. 3. It ought to be refilled without disturbing the colony.—EUGENE SECOR.

1. Granulated sugar syrup; though any kind will answer for spring feeding. 2. No; not necessarily. Not at all if it is the right kind of a feeder. 3. That would be according to the kind of feeder that you are using. One of the Shuck pattern is my favorite, which does not necessitate removal.—J. M. HAMBAUGH.

1. It makes little difference, but I prefer granulated sugar at any time. I have it rather thin, and I like to have it a little warm. 2. I never move it at all, until done feeding for the season. 3. I would not like a feeder that had to be removed. I prefer to leave it in place, and to have it so made that we can feed without disturbing the bees at all.—A. J. COOK.

I use diluted honey, or sugar syrup of the best granulated sugar. I prefer it tolerably thin. I feed at night, only in quantity sufficient for the day's needs, and leave the feeder on. It causes no trouble with myself. 3. I pour the syrup directly into the feeder without removing it. I can see no reason for taking the extra trouble caused by removing to fill it.—J. E. POND.

1. At all times of the year I use granulated sugar for feeding bees, when I use any, which is not very often. However, for spring feeding, C sugar will answer all purposes, and is preferred by some. Thin syrup is best. 2. Leave it in all the time, but feed only what will be used during the night. 3. Pour in the feed without removing the feeder, as syrup will not harm the bees if they do not drown in it.—G. M. DOOLITTLE.

1. I prefer the best unrefined New Orleans sugar, flavored with honey; and coffee A as next choice. The former excites breeding best of all, when the weather is warm. Granulated sugar is a good winter food for old bees, but is nearly worthless for stimulative purposes, as nearly every element in the sugar is destroyed by poisonous acids. 2. Have the covers tight, and leave the feeders on the

hive till done feeding. A close-fitting hive with a contracted entrance precludes all robbing. 3. Just pour in the syrup while the feeder is in position on the hive.—G. W. DEMAREE.

1. For spring feeding the syrup should be thin. Make it of A sugar. 2. Leave the feeder in place, but give the bees only what is necessary. 3. Refill the feeder while on the hive, and save the trouble of removing it.—THE EDITOR.

CORRESPONDENCE.

MANIPULATION.

Easy and Profitable in Well-Adapted Hives.

Written for the American Bee Journal
BY REV. L. L. LANGSTROTH.

Although I was present at the Detroit Convention of bee-keepers in December, 1885, where Mr. Heddon first called attention to the system of management with his "new hive," I heard him too imperfectly to get any adequate conception of his invention. My head trouble returning soon after, and lasting nearly two years, I lost all interest in bee-matters, and it was only in February last (my attention being recalled to this hive), that I was impressed with the idea that it might be a great step in advance, in practical bee-keeping. From the very start I saw that many *abused* the power of manipulation given by the Langstroth hive, because they failed to see that progress lay in reducing the necessary manipulations to a minimum. In the latest work of our honored Dzierzon, his wonderful acquaintance with the habits of bees, seems, to Americans at least, to be greatly wasted upon a hive and system of management which would make our honey cost more than it would sell for.

To manipulate with whole cases of frames instead of by single frames, seemed to me a very wide extension of the principle so much insisted on in my first work on bees, published in 1853, that a hive ought not to require one single unnecessary motion either for the bee or its owner.

Influenced by such considerations, I determined to see the actual workings of the Heddon hive in his apiary at Dowagiac, Mich. As the weather on my arrival there was too cold to handle bees, I carefully studied the hive. From what I know of the habits of bees, and construction of hives, just as a short examination of a Munn hive shows me that it is worthless either for amateur or practical uses—so the longer I studied the Heddon hive, the stronger was my belief that it would accomplish what he claimed for it.

As soon as I could see bees handled in these hives, and could handle them myself, all my favorable prepossessions were fully confirmed, and knowing how little I could count upon the continuance of health, I felt that in justice to the public, as well as to Mr. Heddon, I ought to put this opinion on record, by writing to some of my bee-keeping friends.

I think that no one who knows how I was deprived of the legitimate fruits of my own invention, will be surprised that I should feel it to be a *positive duty* to use what influence I may have among bee-keepers, to secure for Mr. Heddon both the

honor and the profit to which he seems, not only to me, but to so many of our best apiarists at home and abroad, to be justly entitled.

Suum Cuique—"TO EACH HIS OWN."

From my earliest recollections my dear father enjoined this as a sacred duty upon his children—and I believe that all who know what I have done and written in connection with bees, will bear me witness that I have not departed from the spirit of his teachings. It was this strong sense of duty to give honor to whom honor is due, which made me desire, even before I had any correspondence with Mr. H. about his hive, to go to Dowagiac and judge of it for myself. I will now describe some of the most important things that I there witnessed:

1. Before I saw the easy working of his frames (*even in hives which had been occupied for several years by bees*), with close-fitting uprights (I prefer this French term to our word, ends), I could not conceive how they could possibly be handled as rapidly or safely as the Langstroth frames. The propolis trouble alone seemed to forbid this. Judge of my surprise then to find, that by leaving no space for bees to get between the uprights and the cases holding the frames, and by keeping the touching surfaces of the uprights so closely pressed together by the thumb-screws, as to leave no joint open wide enough for bee-glue, he had actually reduced the propolizing propensity of bees to a minimum!

My knowledge of the trouble and delay in manipulating all the previous styles of close-fitting uprights, led me to think that it would be quite difficult to handle the Heddon frames. To find that I was mistaken on this point, was a greater surprise than the way in which the propolis difficulty was met. In handling Langstroth frames of the standard depth (and still more with deeper frames), bees are often hurt between the uprights and case—a thing impossible with the Heddon arrangement, while at the same time the uprights of his case—as they go down into the hive, when a frame is put back—only *push* the bees away instead of pinching them between their closing surfaces. When the Langstroth frames are put back, even by experts, it often happens that they must re-adjust the spacing, to get room for the last frame, whereas, the Heddon frames always go to their proper places. As a matter of fact then, the Heddon frames can be safely handled with more rapidity than any in previous use; thus securing all the advantages of close-fitting uprights without their old inconveniences.

2. I was actually charmed to see how quickly the queen can be found in this hive. There is really no place where she can hide behind either the uprights of the frames, or on any of the frame pieces, or on the combs, which by a single inversion of their containing case, have all been made to completely fill the frames. Alarmed, now, by the introduction of both light and smoke into such a shallow case, she usually glides at once to the bottom-board to hide herself between it and the bottoms of the frames. If she does not show up when the case is lifted off, she can, as I have seen, be readily shaken out from such shallow and uniformly straight combs, so as to be easily secured.

To catch a queen with so little trouble, and with no danger of robbing, seems almost too good a thing to be believed, until it is actually witnessed, and the mere thought that such a feat is possible, must recall to many of my readers their weary queen-hunts, in the old styles of hives, under the broiling sun, and with the hateful annoyance of robber bees.

3. Another important feature in this hive is the remarkable rapidity with which the exact condition of affairs, in the brood-chamber, can be ascertained. In less time than is needed to remove and replace a single frame in other hives, a Heddon brood-section can be lifted off, and from its being

shallow enough to allow a good view of the combs from both above and below, even without shaking out the bees—the quantity of brood and honey, and everything else essential to be known, having been learned by a few glances of an expert's eye—the section may be replaced before any robbing can be done.

4. The shape, size and lightness of the parts composing this hive, greatly facilitate all necessary manipulations in the apiary, and must therefore make it peculiarly acceptable to all who for any reason wish to economize their physical strength. A weak person who cannot handle many hives needs it, and the strong man also needs it, that he may make all his strength tell, in the management of the largest possible number of colonies.

5. The simple way of holding the frames so firmly in place by thumb-screws, admirably fits this hive for safe transport. I use the word *transport* in its widest sense, so as to include every movement of any of the parts of the hive, from the simple lifting off of a section, to the carrying of a hive with bees for any purpose, to any distance, however short or long. I have seen a frame filled with comb, tossed about the room, and thrown out of a second story window—also a whole section of such frames slid, and even kicked about a room, and all without any injury to the combs.

6. I am strongly impressed with the great advantages, which seem to me must certainly be gained by one of the leading features of Mr. Heddon's invention and system of management, viz: the *divisible brood-chamber*—but as this is a point on which the season (April 17) gives me no opportunity to speak from actual observation, I relegate it to the many able bee-keepers who can speak from their own experience, remarking only that when capacious brood-chambers and surplus apartments are desired for any purpose, they can all be readily obtained in the best form, by the Heddon hive and system.

7. Perhaps there was no feature in the Heddon hive which surprised me quite as much as the facility it affords for the use of the extractor. Indeed, when I first gave it my attention, I was so ignorant of its scope, as to suppose that it was a conceded point that it could only be used profitably for the production of comb honey! This is one of the points where I cannot speak from my own actual observation; but those in Dowagiac, who have had the largest experience, affirm confidently, that, in a given time, they can actually extract more honey by the Heddon system than they could with their Langstroth hives, and give these reasons for their belief:

Nearly all the bees can be easily shaken out of the combs of the extracting sections, and these quickly carried to a safe place, where the few bees not shaken out, will soon leave them. The eight frames of a section may then be turned out in a standing position upon a table, by a single motion, their regular shallow combs uncapped with unusual rapidity, and all their contents extracted at the same time; and nearly all of this work can be done *under cover*. Need anything more be said on this subject, to those who have followed the tedious routine of shaking and brushing off the bees from each separate comb in the sun, and exposed to robber bees?

8. It need hardly be said to any good bee-keeper, who has carefully weighed the above points in favor of the Heddon hive and system of management, how greatly it reduces in an apiary the liability of robbing. Those who have the Heddon hives will have no use for any bee-bent, when they can so easily find the queen, or can shake out the bees from any section when necessary, to examine it at leisure under cover.

In reading this enumeration of benefits to be had from Mr. Heddon's invention, it might seem that if I have not exaggerated them, any one of a number of them must be

worth, to a person who handles many colonies, at least the price of an individual right to use his patent.

I can only say that I have sought to avoid all over-statements, and have, in addition to what I could see with my own eyes, questioned at much length some who have largely handled the Heddon hives, and have been from the beginning familiar with every step in the progress of his invention. I would therefore not be afraid to risk my reputation for sound judgment as to the great value of the forward step which he has taken, even if I did not know that my opinion accords so well with the experience of many who have had the opportunity to put the hive and system to the test of practical use.

It is proper that I should say before closing this article, that I have carefully examined the claims of the Heddon patent, and the reasons which have been thought by some to invalidate them. Neither my acquaintance with the literature of bee-keeping, nor my familiarity with our patent laws, nor any facts which have been alleged against the Heddon patent, lead me for a moment to question its validity.

History seems often to repeat itself. In my own day, how often it was declared to be enough to invalidate the claims of the first person who had invented a hive, which commended itself at once to those most largely engaged in the production of honey—how often, I say, it was thought enough, to show that some one before me, had used a frame in a bee-hive. It mattered nothing that I never claimed to have been the first to invent a movable-frame—that my frame and way of using it were fully described, and that the few frames which antedated mine were of no practical account—still the attempt was for many years persisted in (I sometimes shudder now at the bare recollection of those weary years), to persuade the bee-keeping public that my patent was invalid.

On all sides patents sprung up, using, BUT NOT CLAIMING the most valuable features of my invention, and one bee-paper, having then the largest circulation, went so far as to accuse me of perjuries, which, if committed, ought to have sent me, in my old age, to the penitentiary. Thus were the feelings of my wife and children outraged, and even where no credit was given to such atrocious accusations, many honest bee-keepers were so misled as to believe that they had a perfect right to the free use of my movable frames, or were induced to pay for infringing patents the money which would have provided amply for me and mine.

I do not think that the bee-keepers of this country will ever suffer a similar outrage to be perpetrated either against Mr. Heddon or any other honest inventor and benefactor. 928 Steele Ave., Dayton, Ohio.

BEES AND FLOWERS.

Benefits of Bees to Agriculture and Horticulture.

Read at the Fremont, Mich., Convention
BY GEO. E. HILTON.

From the very "pointed" argument used by the bee in self-defense, either real or imaginary, the masses believe that the sole occupation of the bee is to sting; and we often hear the remark that, "a bee will go ten rods out of its way, any time, to sting me."

Let us see if this be true. The bee, is never more happy than when hard at work, and at a time when honey is coming in rapidly. There is nothing

stingy about them. At that time of the season I have taken from the hives hundreds of pounds of honey without the least protection of either smoke, veil or gloves.

Why is nectar placed in the flower or blossom? Is it necessary for the setting and maturing of the fruit? The scientific horticulturist says, No! Was it placed there for the bee? Again the scientist says, No! Then let us examine the mysterious construction of the blossom, and see if we can solve the problem.

The blossoms are composed of one or more leaves called petals. The base of this is called the corolla, and there, as a rule, nectar is deposited. The stamens or pollen-bearing stems—in other words, the male organs of the plant—protrude beyond this nectar, and in order for the bee to secure this much coveted sweet she must brush by these stamens, and to a greater or less extent the pollen adheres to the legs and body of the bee. It no sooner drains the cup that Nature has filled for a two-fold purpose, than it hies away to another, and here is where the wise economy of Nature is being performed. The bee in coming in contact with this second blossom, mingles the pollen of the two, impregnation takes place, and all fruits and vines are made to bring forth fruit, "each after its own kind." If any doubt this assertion, next spring when your fruits, vines and clovers blossom, just before they open, with a bag having the meshes small enough to exclude insects, see how much fruit and seed you get from the blossoms thus treated.

In the West, in some sections where the bee and hornet do not exist, they fail to raise pumpkins, for the want of something to fertilize the blossoms. In some of the mid-ocean islands they could not raise red clover seed until they imported bumble bees to impregnate the blossoms. Now the Italian bee is aiding in this grand work.

The bee is the friend of horticulturists and agriculturists, and as there is no insect that increases in such vast numbers so early in the spring when their services are so much needed, they are of more value to the farmer, gardener and fruit-grower than all other insects.

A man near Boston makes a business of raising cucumbers for the winter markets. I am informed that he has several acres under glass, and until within the past few years he did all the fertilizing by hand. This was a most tedious and expensive piece of work, reducing the profits to a minimum. But now in each section of this vast winter garden, he has a colony of bees, and while the mercury is sporting with zero outside, these little helpers are gathering honey from cucumber blossoms, and at the same time doing the work of many hands; and one great advantage is, that they do their work so much better. The proprietor says that by the old method they never succeeded in fertilizing over 50 per cent. of the blossoms, but that the bees fertilize at least 80 per cent, thus advancing his industry from a basis hardly paying expenses, to one that is profitable.

I might dwell for hours upon things connected with this very interesting pursuit, but I will not tire you, for what may seem interesting to me may be idle talk to you; but let us learn a lesson from the bees to do all the good we can in this life. The bee that gathers the nectar from and fertilizes the blossoms, never lives to consume the honey stored for the winter months; but toils on uncomplainingly, and if the season be favorable it not only stores sufficient for the winter's supply, but a surplus sufficient to compensate the bee-keepers for the attention given during the summer months besides, and giving us the only pure sweet known to the civilized world.

Fremont, Mich.

EKE HIVES.

What they are, and What they are Used for.

Written for the American Bee Journal
BY CHAS. DADANT.

Although my description of eke hives on page 199, seemed to me very plain, the editor advised his readers to see comments on page 197, where he says:

"An 'eke' is a small additional story (generally a half story) placed under a hive to add to its capacity." And further: "These ekes and nadirs bear no relation to a brood-chamber that is divisible, and should not be confounded therewith."

To show that a hive raised with an eke is not an "eke hive," and that

eke hives were formed of divisible brood-chambers, as I described them, I send engravings of divisible brood-chambers; of which we have procured the electrotypes, with many others representing hives of the old country, which will appear in the new book, "Langstroth revised." One engraving shows a square hive formed of three ekes. The hive has 7 combs, and cannot hold more than a hive with seven Langstroth frames. Then the three ekes are about of sufficient capacity to satisfy partisans of small hives.

If this is not convincing, I will refer to the AMERICAN BEE JOURNAL for 1866, page 72, in an article written by our lamented Samuel Wagner: "All these sections or ekes are of equal size, without bottoms, and with an opening 6 inches square in the top. The bees, thus provided... will usually fill two or more such sections with combs, brood, and honey." On page 85: "The mode of dividing stocks [to make artificial swarms] by severing one or more ekes or sections from a hive, should be condemned and rejected, causing a lamentable destruction of bees and brood."

The other engraving shows a Soria "eke," with spaces. It is easy to

notice that the bars to support the combs, in this eke, are placed a little below the side of the eke, to afford a space between two ekes or sections, *a la* Heddon.

As soon as the book of Soria was published, about 43 years ago, a friend of mine, a notary in my village, was so enthusiastic about changing, inverting, etc., of these ekes, that for two years he hived his swarms in Soria hives. But these spaces, cutting the combs horizontally, interfered with the laying of the queens, and the crop was thereby decreased.

How many times in my career of bee-keeping, have I seen such inventions praised for several years, then disappear! The Soria hive was not alone to receive such acclamations of short duration; the Debeauvoys hive was awarded medals on medals, and its inventor published six editions of his book! Where are these hives now? I dare say that, in the whole of France, it would be impossible to find even one specimen of them. I was able to appreciate their qualities and defects. The "eke hive" was easy of manipulation for the bee-keeper, but hindered the laying of the queen. The Debeauvoys was good for bees, but difficult to manipulate. Other bee-keepers of France and Germany invented vertically-divisible brood-chambers, which, praised also for years, have disappeared before the movable-comb hive.

Most of the partisans of the new Heddon hive, using, as he does, Langstroth hives, reduced to 6 or 8 frames, are unable to see whether the laying of queens is hindered by the spaces between the ekes; for, in their small Langstroth hives, the laying is even more decreased; therefore, they may answer, with full confidence, as they did in the AMERICAN BEE JOURNAL, on page 54, that they do not consider the bee-space an impediment to the laying capacity of a queen.

Mr. R. L. Taylor, in answer to the question on page 39, on the influence of the spaces on the number of bees, in comparison with hives having full combs, writes that one of his colonies in the new Heddon hive produced, of comb honey, five times the average of his apiary, and about twice as much as the best of his colonies in Simplicity hives, and it was because of their numbers that they did it. Of course, as the veracity of Mr. Taylor cannot be questioned, such a result struck me dumb. All my experience—all my theories on bee-culture—had to be put aside, and I had to study the principles of the new school. A hard task for a man of my age!

But I never accept what is seen at the surface without looking at the bottom of things. What did I see in this case? The Heddon hive of Mr. Taylor, containing 16 half frames, offered to the queen a surface of $16 \times 17\frac{1}{4} \times 4\frac{1}{8}$, or 1,344 square inches, while his 8-frame Simplicity had but $8 \times 16\frac{1}{4} \times 8\frac{1}{2}$, or 1,136 square inches. This difference of 208 inches, offered to the queen of the Heddon hive, about 12,000 more cells, in which she laid 12,000 more eggs every three weeks. (See Feb. 8, page 85.)

Mr. Taylor was mistaken in putting to the credit of the spaces between the ekes, that which was the result of the enlarged size. No doubt the same mistake was made by Mr. Heddon, for his new hives contain 20 half frames, or 1,780 square inches, while his Langstroth hives contain but 8 frames, or 1,136 square inches. The difference is 644 inches, or 36,000 more cells.

These facts not only are in favor of enlarging the hives, but they answer also to the new, and, to my mind, strange idea of Mr. Hutchinson, that "It does not matter if our queens are hindered in their laying, for we do not make hives simply for the convenience of the queen." (See page 54.) According to my experience the convenience of the queen is the convenience of the bee-keeper, for the more our queens lay, the more bees are in the hive for the harvest.

The crop of Mr. Taylor would have been increased, had most of his colonies been as populous as the one which

gave him this large harvest. Then it is profitable to provide our queens with the means of laying abundantly, and to feel happy. But nothing is better than a large brood-chamber to attain such a result.

Hamilton, Ills.

[Knowing that our readers were not familiar with the "ekes" and "nadirs" used in Europe, and mentioned by Mr. Dadant on page 119, we copied from the *British Bee Journal* an explanation of these terms simply for general information. Perhaps that was unnecessary, as our friend Dadant intimates—thinking that he made the matter sufficiently plain. We certainly had no intention of interfering with, or taking any part in the discussion on hand.

Quoting from the AMERICAN BEE JOURNAL for 1866, pages 72 and 85. Mr. Dadant says that those articles were written by "our lamented Samuel Wagner." By referring to page 9 of that same volume, it will be seen that Mr. Wagner credited those very articles to "an experienced and intelligent German"—he would not thus refer to himself.

As to the engravings in Mr. Dadant's article—the first shows the French hive of Palteau, which had fixed bars or slats, the surplus honey to be cut out of any section desired by the bee-keeper.

The second engraving represents a Soria hive which shows a principle which was used in a hive with round sections without movable frames, figured and described in Hartlib's "Reformed Commonwealth of Bees," published in London in 1655, and mentioned by us at the Indianapolis Convention in 1886. (See the report on page 663.)

Certainly neither of these, nor the "ekes" and "nadirs" described by the item we copied from the *British Bee Journal*, are the same as a complete interchangeable brood-chamber, having the movable frames. Neither are those described by the "German" author on page 85 of the AMERICAN BEE JOURNAL for 1866—for such "ekes" required to be cut off "by means of a thin wire." Such "sections or ekes" were "without bottoms," and had "an opening six inches square in the top"—differing materially from

complete sectional brood-nests provided with frames, which are all movable and interchangeable at will!

But all this is a friendly chat on the definition of terms, having no reference to the discussion on the desirability of using large or small hives, or sectional brood-chambers. In that discussion we shall take no part. The average honey crop of our friends Dadant being over 20,000 pounds, they are abundantly qualified to argue upon the best size of hives for use, and are able to give an opinion of value to producers of honey.—Ed.]

HONEY-BOARDS.

How they Should be Made and Used.

Written for the American Bee Journal
BY J. M. SHUCK.

This honey-board consists of nine slats of clear, straight-grained white pine $\frac{1}{4}$ of an inch thick. The two outside slats are about $1\frac{1}{2}$ inches wide, and the seven inside ones are about $1\frac{1}{4}$ inches wide; they are as long as the hive that they are to cover, and the nine slats are intended to cover a brood-chamber 1 foot wide, and two side walls $\frac{7}{8}$ inches each in thickness.

These slats are held together by two pieces of heavy galvanized iron, one edge of which is folded at right angles $\frac{1}{4}$ of an inch, to cover the ends of the slats.

These honey-boards are nailed together in a cast-iron frame, bed-plate and elamp combined, so that the board may be true and properly spaced when done.

How to Nail Honey-Boards.

Lay the nine slats into the nailing frame; then lay on top of the slats the two end-pieces of galvanized iron, with the folded edge down and covering the ends of the slats; now put in the "spacers"—these are steel checks about an inch long, about $\frac{5}{8}$ of an inch wide, and 5-32 of an inch thick; they are held loosely upon a polished steel rod, so as to be handy, and not get lost; two of these rods are used, one near each end of the honey-board. After seeing that the spacers are in place, bring up the "following-bar" at the end of the board, and also the one at the side of it snug and close, and you are ready to nail.

Make holes in the galvanized iron with a prick-punch, and nail with $\frac{3}{4}$ -inch wrought tacks, or clout nails. Nail carefully, or the slats may split;

when the point of the nail has touched the cast-iron bed-plate, tap lightly three or four times, and the nail will turn back into the wood, when it may then be driven "home" without splitting. Drive two nails in each end of each slat, and a nice, light, stiff queen-excluding board, only $\frac{1}{4}$ of an inch thick, is the result. No perforated metal is needed, as the wooden one will be found to render better satisfaction in every way.

This honey-board is not on the "sink break-joint" principle. I get the bee-spaces all in the hives and supers themselves, so that when a hive or super is placed on any plain board, the bee-space prevents the wholesale slaughter of bees. This board, placed upon an 8-frame hive, with the frames accurately spaced $1\frac{1}{2}$ inches from center to center, would "break joint;" but when frames are not accurately spaced, the "break-joint" theory will in a majority of cases be at fault.

I take some pride in my honey-board, and can show some rich, dark specimens ten years old; yet, if any one wishes to improve upon it, either with or without my permission, he is welcome to do so.

Des Moines, Iowa.

SWARMING.

Do Bees Select a Home Before Swarming?—Rearing Queens.

Written for the American Bee Journal
BY J. E. POND.

I certainly do not wish to say anything that will tend to cause an unprofitable discussion, but the above question is one of some interest and importance to beginners at least, and any light given them may be of value. Whether bees ever select a home before swarming, is one that probably no one can answer, as their vagaries are such, that the facetious remark of the late Mrs. Tuttle, viz., "Bees do nothing invariably," may be taken as an axiom.

In my own experience I do not find that bees do select a new home before swarming. If they did, there would be no protection whatever, in my judgment, against leaving the new hive after being placed therein. My own belief, based on my own experience, is that as soon as the swarm settles, pioneers start out to find a new home; if they succeed in so doing they return and take the swarm with them. For this reason, I believe, that all swarms should be hived as soon as they have settled, and when this is done, I have no more trouble with their leaving the new hive.

It is true that no one can determine accurately, when a newly-hived swarm leaves the hive, whether they selected the new home before or after they swarmed; but I think that if the rule is followed, of hiving all swarms as soon as they fairly settle, but little trouble will follow.

My advice to beginners, who depend upon natural swarming is, to watch the apiary closely during the swarming season. Keep constantly prepared for issuing swarms, and hive them as soon as they have fairly settled. By so doing I believe they will find less trouble than in any other way.

Rearing Good Queens.

Much that is written in regard to good queens is misleading to the beginner. One bee-keeper writes that "good queens are only reared while the colony is under the swarming impulse;" another, "that it makes no difference whatever, whether they are reared under such an impulse or not." I am on record as urging the rearing of better queens, rather than poorer ones, and I fully believe that any method that will bring about this result is to the advantage of all.

There is no question that good queens can be reared in both ways. The evidence is full and complete that this is true. Every breeder of queens knows this, and has proved it time and time again; and for this reason I believe that we must depend upon the honesty and integrity of the breeder from whom we purchase our queens, rather than upon the matter whether he rears his queens under the swarming impulse or otherwise. All we need to do is to follow nature's law, in a natural way.

It is natural for a queenless colony to rear a new queen, and equally natural for it to do so, as to rear a queen when the swarming fever seizes the colony. This being the case, who is to say in the face of the existing state of things, that one queen will prove better than another, simply because natural laws are followed in one direction rather than in another?

My own view of the matter, based on my own experience, is this: If the queen is removed from a full colony, when honey is coming in freely, or if such is not the case, the colony is regularly fed in small quantities, equally as good queens are produced, as when the swarming impulse causes the queen production; and I have further found, that by the misnamed "artificial method" of rearing queens, there is far less risk of producing from 10 to 13 day queens, than under the swarming fever; and this for the reason that we can know positively and absolutely whether our queens are reared from

the egg, or from larvæ from 3 to 4 days old.

After all, however, the matter comes to this point: If the bee-keeper depends upon the queen-breeders for his supply of new queens, he must select those upon whose honesty and integrity he can depend.

North Attleboro, Mass.

STARK COUNTY, O.

The Bee-Keepers Meet in Regular Convention.

Written for the American Bee Journal
BY MARK THOMSON.

According to adjournment this Society met at Canton, O., on April 11, President Oswalt in the chair.

After approving the minutes of the last session, receiving J. R. Roebuck into membership, and deciding that the membership fee received at any other time than at the annual meeting in April, should apply only until the next April meeting, Messrs. J. A. Taber, A. Zimmerman, and W. S. Kline were appointed to draft resolutions relative to Mr. John M. Mowe, a member who had died since the last meeting.

Reports from the Apiaries.

W. S. Kline put 25 colonies into winter quarters, and lost 2, which were queenless in the fall. His bees in chaff hives on the summer stands came through in the best condition. One colony placed in the cellar early in the fall, seemed to winter the best of any.

J. A. Taber had 35 colonies and one nucleus in the fall. The nucleus had no chaff cushion on top, and it died, but the remainder are in excellent condition. His bees were wintered on the summer stands.

H. O. Best had 13, and lost none. They were wintered in the cellar.

M. Chamberlain had 19 colonies in the fall, and lost one. They are in good condition.

Mark Thomson put 13 colonies into the cellar in the fall, and all but one came through in good condition. That one was queenless.

A. Zimmerman said that from his four years of experience he favored cellar-wintering, and that he had never lost one thus wintered. He did not think that bees wintered outside were any more healthy than those wintered in the cellars.

W. M. Sweany had 40 colonies, and succeeded in carrying 35 through the winter. He put 5 into the cellar, 4 of which starved, and the other one came out very weak. Those on the summer stands were in chaff hives. He said

that it was possible to put too much packing on the top of bees, and in proof of this he had fixed one up specially well, as he thought, but it died with the diarrhea.

Mr. Trook had 8 colonies; he left them on the summer stands, and 2 weak ones died.

A. McKinney left 13 of his colonies on the summer stands, and put one into the cellar. The one in the cellar died.

Mrs. Pellon spoke of a colony in a box-hive, belonging to a neighbor, protected by a shed, which was quite lively, and in good condition. Her bees had wintered well, so far as she knew.

Mr. Chamberlain said that he believed in center ventilation, by means of a hole in the bottom of the bee-hive, covered with wire-cloth.

Mr. Roebuck lost several by neglecting to feed them enough in the fall; he did not feed them until October. He had 69 colonies (50 in the cellar, and 19 on the summer stands); 7 of those in the cellar were dead by March 15, when he took the balance out, and within a week 9 more died. Those in the cellar were nearly all weak.

Mr. Roebuck asked Mr. Zimmerman how his hives were arranged in the cellar. Mr. Zimmerman said they had a thickness of burlap over the frames, and a board on top of that, with the entrances wide open.

Mr. M. R. Welker packed 14 colonies on the summer stands, in single-walled hives, with chaff cushions on top, with a wind-break of straw. He lost only one nucleus. The others are in good condition, with some drones flying.

Mr. Kline said that the presence of drones indicated a drone-laying queen.

Mr. Oswalt's bees were wintered on the summer stands in Falcon chaff hives; the inner side of the outer-wall and the inner side of the bottom being lined with paper. He lost 3 colonies before winter began. He thought that was caused by the lack of late breeding. He had fed some rye flour, and put candy over the frames.

The afternoon session was opened at 1:20 p.m. The members paid their dues, and the following were elected officers for the ensuing year: Jacob Oswalt, President; Henry Beatty, Vice-President; and Mark Thomson, Secretary.

Various Bee-Questions and Answers.

Questions were answered as follows: "Would you use 10 frames or less for comb honey?" Mr. Beatty said that he used 12 frames. Mr. Kline thought that 8 frames were enough. Mr. Taber said that he used 11 frames, and had produced as high as 125 pounds to a single colony.

"Do young bees which had no flight in the fall, winter as well as older ones?" Mr. Beatty said that it made no difference.

"Do bees eat rye flour, or make pollen of it?" Mr. Sweany said that he fed common wheat flour, and that the bees used a great deal of it.

"Is it considered favorable for drones to be found in the hives as early as April 1?" Mr. Chamberlain said that it depended upon whether there was drone-comb in the brood-nest or not. Mr. Kline said that he thought it was of no advantage, unless you wished to rear queens early. Mr. Beatty said that he had had drones flying on March 20, from strong colonies. Mr. Waits said that if a colony is strong and in good condition, drones might be seen early.

"What time would you commence to rear queens?" Mr. Beatty said, as soon as the colonies are strong enough to divide.

"What would you put on after the chaff cushions are taken off?" Mr. Chamberlain uses oil-cloth. Mr. Beatty uses duck. Mr. Kline thought that a board was as good as anything. Mr. Taber preferred a honey-board the size of the top of the hive, with two auger-holes with glass over them.

"What is best to be done with a queenless colony having laying workers?" Mr. Waits advised giving them a queen. Mr. Beatty would give them brood and let them rear a queen. Mr. Sweany would unite them with another colony.

The convention then adjourned until Aug. 21, 1888.

MARK THOMSON, Sec.

FOUNDATION.

Experience in Making Foundation with Molds.

Written for the American Bee Journal
BY RANDOLPH GRADEN.

On page 23, Mr. G. M. Doolittle says: "Can it be that few, if any of our apiarists are using molds for making foundation? And if such is the case, why are they not using them?" Perhaps they were not more successful than I was in making molds.

When I first heard of molds I procured a perfect sheet of foundation, and soon had very good molds made. But in making foundation, I did not follow the directions which Mr. Doolittle has given, as that would seem almost impossible to me. The way that I made foundation on the molds, was almost the reverse of the way that Mr. D. describes.

I put the molds into warm water some time before using, and when they

became quite warm, I placed them over a tub of cold water to catch the wax that would run over the sides of the molds. Then I opened the molds and poured on the melted wax, and closed them. But in cold weather the molds would soon get quite cold, and the hot wax would harden as soon as it touched them; and as soon as the molds were closed, it could be again opened; but on account of the wax cooling too quickly in the molds, it would be all cracked, and the sheet would have to be again heated.

Perhaps my molds were too thick, as the sides are $\frac{3}{4}$ of an inch. Or perhaps the wax is not as it should be; but I used it as it comes from the wax-extractor into warm water to settle and cool.

I can make foundation on the molds quite as nice as that made on the mills, but it is slow work, and the molds must be neither too warm nor too cold. If I were to insert the molds into ice-water, the sheets of foundation would be so badly cracked that they could not be lifted from the molds without being torn into pieces.

Mr. Doolittle does not say that anything except water is used to prevent the wax from adhering to the molds. He must use wax at a boiling heat, or it would harden as soon as it comes in contact with the ice-cold molds, and the mold would be used more as a press than a mold. Cannot some who have been equally as successful as Mr. D., give us their way of making foundation on molds?

Taylor Centre, Mich.

LARGE HIVES.

The Large Hives vs. the Small Hives.

Written for the American Bee Journal

BY W. J. DAVIS.

I have just re-read my article on page 170, also Mr. Dadant's article on page 247, and I confess that I cannot see anything in the former that could in any way remind any one of the objections made 25 years ago, to the movable-comb hive. That such objections were made, I do not doubt, but the connection between those objections, and my own experience with different sized hives, I fail to see.

I have had an experience of 40 years, and with several apiaries a part of that time, running from 200 to 350 colonies, with almost 28 years with movable-comb hives, and using division-boards ever since adopting the movable-comb system. If experience is of any value, I at least ought to

know how it works in this immediate locality.

While I have no desire to promote any controversy on the question as to the proper size of a bee-hive, preferring that the bee-keeper should use just the kind and size of hive he chooses, I trust that Mr. Dadant will allow me a good laugh, for pronouncing me "guilty of a neglect" in not providing division-boards for winter, and then proceeding to prove how bees had wintered, 1 colony for 7 years, and another for 27 years, in a very large hive, when contraction was not thought of. Let us see. How large was that hive? As large as 10 Langstroth hives—or $2\frac{1}{2}$ sugar barrels, or, say 10 bushels. Now that was a whopper (the hive, I mean).

I wish to say further, that I have no ax to grind on the hive question; I make my own hives, and spoke of the smaller hive as I prefer them in my home apiary. In my house apiaries, away from home, I use 12 of the shorter frames per hive in one, and 8 standard Langstroth frames in another apiary.

The year 1886 was emphatically a swarming year in this part of the country, and I ran out of hives. In one of my out apiaries, I instructed the man in charge to procure boxes of any kind to secure the swarms, and I found, among the rest, two that were only $10\frac{1}{2}$ inches square, by $8\frac{1}{2}$ inches deep, or about 892 cubic inches. They appeared heavy for the size of the boxes. They were brought home in the fall, and at the usual time were placed in winter quarters with others, and wintered perfectly. The bees in them were transferred in the spring, and were prosperous colonies. Other swarms were hived in large boxes, had double the comb, and more bees, but not half as much honey. My observations reduced to words, would be about thus:

Two swarms of equal strength, hived on the same day, with a honey harvest of 30 pounds each to gather above their daily rations—one is hived in a box of 1,000 cubic inches, and the other in one of 2,000 cubic inches—each will fill its hive with comb, and at the close of the harvest the smaller will have 20 pounds of honey, and the larger but 10 pounds.

Backward Spring in Pennsylvania.

The spring here is cold and backward. The grass in spots begins to show the green. Not a drop of honey or pollen has been taken in yet (April 19). I use both the standard Langstroth and the shorter frame in my home apiary, but my strongest colonies are in short-frame hives.

Youngsville, Pa.

SWARMING OUT.

The Cause and Prevention of Bees Swarming Out.

Written for the American Bee Journal

BY JOHN S. REESE.

The time for swarming has arrived here (March 12), and the past few days has afforded ample opportunity for verifying my belief that I knew the true cause of the abominable freak of "swarming out," and, to give a lucid idea, I will state the facts just as they occurred.

About 2 p.m. on Feb. 21, the sun had so warmed up the hives that my 20 colonies of bees all seemed to be enjoying a general flight; when I observed 1 colony (a rather weak one) sending out more bees than any of the others, and some excitement at the entrance, and on stepping quickly to it I saw the queen running about on the alighting-board in an excited manner. In a few moments she re-entered the hive, and just then I took off the cover and packing, and found the four combs almost deserted of bees, but every thing was sweet, clean and warm, and there was plenty of honey. There was a small patch of brood from the egg state to that just being sealed over, and no evidence whatever that any bees had hatched so far this year. By this time the flying bees came tumbling back to their home and queen.

Now just at this time another weak colony, near by, started to go through the same performance, and I got to their entrance just in time to catch the queen in the act of taking wing, and an examination of this hive revealed exactly the same state of affairs as the first—a small quantity of young brood, but no young bees to remain with the queen, while the old bees were out for their first general flight.

The remaining 18 colonies are strong enough to have young bees hatching, and will not "swarm out." We of course know that bees will desert their hives for want of stores and other causes, but what is known as "swarming out" is most likely to occur with weak colonies only, and may be prevented by the use of queen-excluding entrance guards, but they should be arranged in such a manner so that the bees cannot clog the entrance in their efforts at "spring cleaning."

Winchester, Ky.

A Modern Bee-Farm, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*
 May 5.—Susquehanna County, at New Milford, Pa.
 H. M. Seeley, Sec., Harford, Pa.
 May 7.—Welland County, at Welland, Ont.
 J. F. Dunn, Sec., Ridgeway, Ont.
 May 8.—Keystone, at Scranton, Pa.
 Arthur A. Davis, Sec., Clark's Green, Pa.
 May 8.—Cortland Union, at Cortland, N. Y.
 W. H. Beach, Sec., Cortland, N. Y.
 May 19.—Nashua, at Nashua, Iowa.
 H. L. Rouse, Sec. Ionia, Iowa.
 May 22.—N. W. Ills. & S. W. Wis., at Rockton, Ills.
 D. A. Fuller, Sec., Cherry Valley, Ills.
 May 31.—Wis. Lake Shore Center, at Kiel, Wis.
 Ferd. Zastrow, Sec., Millhome, Wis.
 Aug. 3.—Ionia County, at Ionia, Mich.
 H. Smith, Sec. Ionia, Mich.
 Aug. 14.—Colorado State, at Denver, Colo.
 J. M. Clark, Sec., Denver, Colo.
 Aug. 27.—Stark County, at Canton, O.
 Mark Thomson, Sec., Canton, O.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Pollen from Skunk-Cabbage.—G. M. Doolittle, Borodino, N. Y., on April 19, 1888, writes :

The first pollen was gathered to-day from skunk cabbage, which is our earliest pollen-producer. The mercury is at 48°, so that very few bees are flying, and when the sun goes under the clouds, these pollen-laden bees fall to the ground and stay until the sun again comes out and warms them up. One day the last of March, the mercury went up to 58°, which gave the bees a fine flight; otherwise it has not been to 50° this year.

Bees Wintered Poorly.—C. W. Baker, Martinsville, Mo., on April 13, 1888, writes :

I began the winter with 12 colonies of bees, unprotected on the summer stands, except that I banked the snow around them when there was enough to do so. Three colonies are all that I lost, and two of them were late swarms. But almost all of the bees in this country are dead, or at least 75 per cent. of them.

Not Overstocked with Bees.—J. V. Caldwell, Cambridge, Ills., on April 17, 1888, says :

Bees have wintered in poor condition in this part of the country, and we will not be overstocked with bees this year. The prospect for a good honey season is not promising, to say the least. White clover was nearly all killed by the drouth last season, and unless we get much rain our crop will be a failure. Last season I obtained only 40 pounds from 200 good colonies.

Method of Rearing Queens.—D. P. Barrows, Nordhoff, Calif., on April 17, 1888, writes :

On page 252, Mr. G. Crouse asks how to rear queens. I would suggest this method, which I have used, and have seen used, with satisfaction :

Take two or three combs from an Italian colony, or as nearly pure as possible (providing the colony is strong, and the bees in

good, normal condition), well covered with bees, and containing honey, larvæ and eggs young enough to produce queens, or under four days old. Place these in a hive, partitioning it off with a division-board to a suitable size. Place this new colony on the old stand, first removing the original colony to a new location. The bees in the new hive, finding that they have no queen, will form embryos, and rear new queens.

Then two or three days before the young queens emerge, place the embryos in the queenless hives, and those needing new queens. Care must be taken to have the hive warm and tight, and the bees well provided with honey.

When all the colonies are supplied with queens, leave an embryo in the "queen-nursery," and you will thus have the queenless colonies remedied, and a new colony besides.

Many Colonies have Starved.—Thos. C. Stanley, Boyleston, Ills., on April 21, 1888, writes :

Last year 15 cases (about 300 pounds) was our crop of honey from 250 colonies, spring count. Perhaps there was a barrel or two of extracted honey, had we taken it out, but we never count it. Many bees are starved out through the country—I should say 50 per cent. I always keep a supply of honey on hand for such seasons, and consequently suffer no loss from that cause. But there is a cause from which we have lost heavily for three years.

Storing Pollen—Alsike Clover.—J. H. Stanford, Cherokee, Iowa, on April 12, 1888, writes :

I am happy to report that my bees have survived the terrible blizzards of the past winter, and are now gathering pollen from maples and willows. My new bee-cellar, built according to Dr. Miller's instructions, has proved to be a success so far. The temperature of the cellar has not varied more than 4° this winter, and at no time above 38°. I planted six acres of Alsike clover last spring, but very little of it has come up, as it was very dry here last summer. Can any one tell about Alsike clover seed growing the second year? I know that white clover seed will lie in the ground for two or three years, and then grow. I increased my bees from 12 to 29 colonies in 1887, extracted 775 pounds of honey, and took off 50 pounds of comb honey. I sold the extracted honey for 12½ cents per pound, and the comb honey for 20 cents a pound.

Keeping Bees in Houses.—J. H., of Ohio, on March 6, 1888, writes thus about houses for bees :

In an article by Mrs. L. Harrison, on page 57, she says that all attempts at keeping bees in houses have been failures, with one exception, which is pronounced a success, and that is 'patented.' I do not know what kind of a house she can mean.

When I was young and at home, my father used to keep from 4 to 6 colonies in a shed (open in front only), in the old-fashioned box-hives, 14x14 inches, and 2 feet high. He kept them thus for many years, until high water once destroyed them all. After that he built a room in the garret about 6 feet square, putting the hives on a frame 18 inches from the floor, and taking a brick out of the wall for an entrance to the hive.

The hive was a three-section hive, each section 14 inches square by 10 inches deep. He would take off one or two top sections each year, and fill one or two milk pans with nice, white honey. They never

swarmed, and it was a very large colony in time. They were there for five or six years. He would go up and sweep the room out once a week. They built the comb all over the hive, and the frames to the floor, and loaded them so heavily that one day it fell to the floor in a heap, losing the bees and all. My brother built a room of the same kind two years afterward, and had the same misfortune, and lost his bees in the same way.

Where I now live the water in 1884 was 10 feet deep in my yard and garden, so it is not a very good place to keep bees in my cellar. I have had one colony in the garret for two summers, in a sectional frame hive; but it is too much labor to go up two long stairs to see them, so I shall move them down to my bee-house that I have been building for them. The room is 7½ feet wide, 20 feet long, and 7½ feet high. I do not see why they should not do well in it, as I can pack them well for winter.

Ionia Co., Mich., Convention.—Harmon Smith, of Ionia, Mich., the Secretary of the Association, sends the following report :

The adjourned meeting of the Ionia County Bee-Keepers' Association was held in the office of Oscar Talcott, at Ionia, Mich., on April 18, 1888. It was called to order by Chairman J. H. Robertson, with Harmon Smith acting Secretary. Seventeen members reported 929 colonies put into winter quarters last fall, and a loss of only 42 of that number in wintering.

After deliberation and interchange of views on various matters, Mr. Robertson introduced a printed constitution, practically agreed upon at the March meeting, which was adopted. Copies of it may be had of the Secretary, upon paying a membership fee of 25 cents.

The following officers were elected: President, J. H. Robertson; Vice-Presidents, A. H. Gurnsey and Wm. H. Penny; Secretary, Harmon Smith; and Treasurer, Oscar Talcott.

After a profitable and pleasant exchange of views among the members, the convention adjourned to meet at Ionia, on Aug. 3, 1888, with a request to all the bee-keepers of the county and vicinity to meet with them, and bring in full reports of the summer's products, and become members of the Association.

That Ontario Convention.—Dr. A. B. Mason, Auburndale, O., writes thus :

"O wad some power the giftis gie us
 To see ourselves as ithers see us,
 It wad frae mony a blunder free us,
 And foolish notion."

When I saw the above quotation in one of Mr. W. F. Clarke's articles in the AMERICAN BEE JOURNAL last summer, while criticising Dr. Miller's position in regard to the desirability and practicability of bee-keepers getting the control of a limited area as pasturage for bees, I thought, "O how I do wish some power would take some of the egotism out of some writers, and lead them to make Burns's words their most earnest prayer, and that it might be heard and answered." Evidently it is "possible for a man to misunderstand himself," or the above lines would not have been penned by Burns. From his writings, I have no doubt that Mr. Clarke speaks the truth when he says, "I can afford to be pooh-poohed, and I rather enjoy the fun of tormenting prejudiced unbelievers." In reading the report of the Ontario Convention (see page 72), I thought it was unusually good, and since reading Mr. Clarke's criticism, on page 104, I have re-read it, and now it seems better than it did at the first reading. If the report is a "lop-sided affair," I hope some one will give us an equally good

report of next year's meeting, and put in as many more "of the most interesting discussions" as possible. As an interested, but unbiased "spectator," I cannot see the truthfulness of the assertion made in the fifth, sixth and seventh lines of the article on page 104. The reporter did say something about making a cellar somewhat like that of J. Alpaugh's, and I believe I am glad he did. Mr. Reporter, please give us some more "lop-sided" reports. What is there bad about that "father-in-law"? He is respected and honored by the Ontario bee keepers, and was elected President of their association, and was so unfortunate as to be chosen as one of their commissioners to the Colonial, and also chairman of the commission; but he has been annoyed and badgered until life is almost a burden. What did he do at the Ontario Convention that should merit such an insinuation? He presided over the convention and delivered the "annual address," which is published in the report, and Messrs. Macdonald and Hall also have essays in the report.

I gather from the few words reported, that Mr. Clarke was opposed to the use of the honey extractor at all, and if that is a correct inference, it is nothing new, for he has done the same thing before, but it did not get into the "report" to suit him.

Mr. Clarke says, "My own preference for comb honey is shared by me with some of our best and largest producers of honey, and this question is one that must come to the front." My truthfulness and "modesty" prevent my saying that I am one of the "best and largest producers of honey," and that probably accounts for my not "sharing" in that "preference."

Cold and Backward Spring.—

W. A. Hodge, Victory, Wis., on April 23, 1888, says:

I wintered 24 colonies of bees, mostly Italians, in the cellar, with a loss of only 2 colonies. They came out heavy, and seem to be all right. In 1887 I had 1,142 pounds of honey in 1½-pound sections, from 15 colonies. The spring is very cold and backward here, and the Mississippi river is very high—the highest, I believe, ever known in April.

CONVENTION NOTICES.

☞ The next meeting of the N. W. Ills. and S. W. Wis. Bee-Keepers' Association will be held in Rockton, Ills., May 22, 1888. D. A. FULLER, Sec.

☞ The spring meeting of the Wisconsin Lake Shore Center Bee-Keepers' Association will be held on May 31, 1888, in Mueller's Hall, at Kiel, Wis. FERD. ZASTROW, Sec.

☞ The Cortland Union Bee-Keepers' Association will hold its spring meeting on May 8, 1888, at Cortland, N. Y., at 10 a. m. All bee-keepers are invited. W. H. BEACH, Sec.

☞ The Keystone Bee-Keepers' Association will hold its sixth annual meeting in the Court House at Scranton, Pa., on Tuesday, May 8, 1888, at 10 a. m. All bee-keepers are invited. A. A. DAVIS, Sec.

☞ The Hardin County Bee-Keepers' Association will meet at the Court House in Eldora, Iowa, on the second Saturday in each month, at noon (12 o'clock), until further notice. J. W. BUCHANAN, Sec.

☞ The next meeting of the Susquehanna County Bee-Keepers' Association will be held at New Milford, Pa., on May 5, 1888. The following subjects are to be considered: Bee-keeping for pleasure and profit—Spring work with bees—Is it advisable to use foundation? If so, to what extent?—How can we make our Association of the most practical value to its members. All are cordially invited to come. H. M. SEELEY, Sec.

A Pocket Dictionary will be presented for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Honey and Beeswax Market.

DETROIT.

HONEY.—Best white in one-pound sections, 15c. Extracted, 9@10c. Large supply and few sales.
BEESWAX.—23@24.
Apr. 24. M. H. HUNT, Bell Branch, Mich.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 13@15c.; the same in 2-lbs., 10@11c.; buckwheat 1-lbs., 10c.; 2-lbs., 9c. Market dull.
BEESWAX.—24c.
Apr. 7. MCCAUL & HILDRETH BROS.,
28 & 30 W. Broadway, near Duane St.

CHICAGO.

HONEY.—Prices range from 16@18c. for best one-lb. sections, to 14@15c. for off color and condition; 2-lbs., 14@15c. Dark is slow of sale at almost any price. Extracted, 7@9c., with good supply. Light demand.
BEESWAX.—22@23c.
Mar. 22. R. A. BURNETT,
161 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 14@15c.; fancy 2-lbs., 12c. Lower grades 1@2c. per lb. less. Buckwheat 1-lbs., 10@10½c.; 2-lbs., 9@9½c. Extracted, white, 7@7½c.; dark, 5½@6c.
Mar. 19. F. G. STROHMEYER & CO., 122 Water St.

CHICAGO.

HONEY.—We quote: Fancy white clover 1-lbs., 16@17c.; 2-lbs., 15@16c. Dark is slow sale at almost any price. Extracted is scarce, and sells at 7@10c.
BEESWAX.—23c.
Mar. 13. S. T. FISH & CO., 189 S. Water St.

CINCINNATI

HONEY.—We quote extracted at 4@9c. per lb., for which demand is good. Comb honey, 14@17c.—Demand slow.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Apr. 23. C. F. MUTH & SON, Freeman & Central Av.

MILWAUKEE.

HONEY.—Choice white one-lb. sections, 16@17c.; 2-lbs., 15@16c.; 3-lbs., 14c. Extracted, white in kegs and ½-barrels, 8 to 8½c.; in tin and pails, 9½@10c.; dark in barrels and kegs, 5@7c. Market fair.
BEESWAX.—22@25c.
Apr. 23. A. V. BISHOP, 142 W. Water St.

DENVER.

HONEY.—Best white 1-lb. sections, 17@19c.; 2-lb. sections, 15@17c. Extracted, 7@10c.
BEESWAX.—20@23c.
Mar. 1. J. M. CLARK & CO., 1409 Fifteenth St.

KANSAS CITY.

HONEY.—We quote: Choice white 2-lb. sections, 17@18c.; dark 2-lbs., 14@15c.; choice white 1-lbs., 18 to 20 cts.; dark 1-lbs., 15@16c. White extracted, 7@8c.; dark, 5@6c. Demand is slow. White extracted in firm when 10 to 16-lb. tin cans.
BEESWAX.—21 to 22c.
Mar. 29. HAMBLIN & BEARSS, 514 Walnut St.

BOSTON.

HONEY.—We quote: 1-lb. sections, 16@17c.; 2-lb. sections, 14@16c. Extracted, 8@9c. The market is not very brisk and sales are slow.
BEESWAX.—25 cts. per lb.
Mar. 24. BLAKE & RIPLEY, 57 Chatham Street.

SAN FRANCISCO.

HONEY.—We quote: White to extra, 10@17c.; amber, 9@14c. Extracted, white liquid, 7@7½c.; amber and candied, 6@7c. Market quiet.
BEESWAX.—18@21c.
Mar. 20. SCHACHT & LEMCKE, 122-124 Davis St.

KANSAS CITY.

HONEY.—We quote: White 1-lbs., glassed, 16@17c.; unglazed, 17@18c.; and dark 1-lbs., glassed, 15c.; unglazed, 16c.; white 2-lbs., glassed, 16c.; unglazed 2-lbs., 17c. California white 2-lbs., 17c. California extracted in 60-lb. cans, 8c. Market quiet and receipts are larger.
BEESWAX.—No. 1, 20c.; No. 2, 18c.
Mar. 19. CLEMONS, CLOON & CO., cor 4th & Walnut.

Clover Seeds.—We are selling Alsike Clover Seed at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. White Clover Seed: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. Sweet, or Melilot, Clover Seed: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

and retail.** See advertisement in another column.

The Bee-Keepers' Review

IF ever a bee-paper was started with a place
ready and waiting for it, the REVIEW has
had that luck. The first number was welcomed
before it was read, and when it was read, it
took its place easily and at once among the
things that justify their own existence, and
need no probation before being fully and
finally accepted. It is an imitation of none of
its contemporaries, and it is on a level with the
best of them, both in the merit of its general
scheme, and in typographical neatness. This,
we believe, will be the verdict of the intelli-
gent bee-keeping public, and, as proof of the
correctness of this belief, we append the
following, which we select from a large
number of similar congratulations:

I am greatly pleased with the REVIEW, and think
it very creditable. It must take the lead with
intelligent bee-keepers.—R. L. TAYLOR, Lapeer, Mich.
You have made an excellent start; and I am very
favorably impressed with your plan of making each
issue a "special number."—E. M. HAYBURST,
Kansas City, Mo.

From a practical standpoint you are well qualified
to make the venture a success. I hope you may do
well financially, and establish an enviable reputa-
tion for editorial ability, as you have already as a
writer on apicultural topics.—EUGENE SECOR,
Forest City, Iowa.

REVIEW No. 1 lies before me, and I must say it
is like a chestnut-brimful of meat, properly cooked,
and served in first-class palatable order. Before
reading it I thought, "What can friend Hutchinson
say that has not already been said by others?" But
you have given us a feast of fat things. If the
REVIEW keeps up to the standard of No. 1, it has a
bright future before it.—W. E. CLARK, Oriskany, N. Y.

I like the REVIEW in every respect. There is more
in it than in any other bee-paper I have ever seen;
that is, more real meat, or what is called meat, as I
see it. The whole matter, including advertisements,
is tastefully arranged. I cannot conceive who would
not instantly subscribe, at the price, after seeing a
copy.—JAMES HEDDON, Dowagiac, Mich.

I congratulate you upon the excellence of the
REVIEW. It will be an honor to the craft, and to
our State, if you maintain it at the starting pitch—
and I do not doubt but you will. At first I was sorry,
What we want is fewer, better papers. But I forgot
for the moment who was at the helm. I believe you
will succeed, and if you do not go to the top, you will
stride well up.—A. J. COOK, Agricultural College,
Mich.

A sample copy of the REVIEW is at hand, and I
was agreeably surprised, to say the least. As a rule,
periodicals in starting furnish at first a sickly,
discouraging appearance that stamps failure all over
them. What a contrast in beholding the REVIEW!
Why, friend Hutchinson, the first glance at it shows
its success. And then its contents—the very cream
of advanced bee-literature. I read it through before
laying it out of my hand.—E. KRECHMER, Coburg,
Iowa.

Four numbers of the REVIEW have been
issued. The January number discusses "Dis-
turbance in Winter;" the February issue
is devoted to "Temperature," as applied to
bee-repositories; the March number takes up
the subject of "Planting for Honey;" while
"Spring Management" is the special topic of
the April issue. The special subject of the
May REVIEW will be "Hiving Bees."

Besides these special discussions, which are
carried on by the best bee-keepers of the
country, there are several pages in each issue
devoted to short, sharp, concise editorials
upon current apicultural topics. An exhaust-
ive review of Mr. Cheshire's book, "Bees and
Bee-Keeping, Vol. II," is begun in the March
REVIEW, and will be finished in the May num-
ber. If you wish for the cream of this great
work, read these three numbers.

Price of the REVIEW is 50 cents a year.
Samples cheerfully sent upon application.

The Production of Comb Honey,
A neat little Book of 45 pages, price 25 cents.
THE REVIEW and this book for 65 cents.
Stamps taken, either U. S. or Canadian.

Address, W. Z. HUTCHINSON,
18A1t 613 Wood St., FLINT, MICHIGAN.

EDITOR.

Vol. XXIV. May 9, 1888. No. 19.

EDITORIAL BUZZINGS.

Give us of your sunshine,
O! ye bonny spring,
Of your golden treasure,
Days of sunlight bring.

Come and deck with beauty
Hill and valley fair,
Every swaying tree-top,
Every meadow bare,
Robe all with beauty rare.

Acrostic. —LIZZIE GODFREY.

Christ Before Pilate, a painting by Munkacsy, the famous Hungarian artist, is on exhibition at Central Music Hall, Chicago, where it may be seen during the day and evening for several weeks. It measures 18x25 feet including the frame, and contains nearly forty life-sized figures. When gazing at the picture as it stands draped on the stage, in the large hushed hall, one almost waits to hear words issue from the canvas, so very realistic does the scene appear.

Honey on the Bill of Fare.—F. A. Huntley, in the *Minnesota Farmer*, says about the future of honey consumption:

Bee-keeping was one of the first rural occupations. At the time when man first commenced to stir the soil for his daily bread, bees were managed for domestic use, to furnish the only product then known and used exclusively as a sweet. The discovery of sugar making supplied a cheaper staple, which placed honey among the luxuries. For hundreds of years such has been the state of the honey trade. Now we see advanced bee-keeping increasing the production to an extent that will soon place honey on the regular bill of fare of the most unpretentious hotels. Indeed, we should see it there to-day.

The way to do it, is for bee-keepers and others to call for it when at hotels. "Mine host" will provide whatever is demanded. If honey is not required, it will not be provided.

Let Statistics Alone.—H. M. Moyer, of Berks County, Pa., writes as follows, for publication, on the subject indicated in the heading:

To get governmental statistics through the assessors may be good for some, but I am sure for the majority of bee-keepers it is not a good thing. If the assessors do such work they will surely tax the bees. We have to pay enough tax without the bees in such a poor locality as this. There are enough, without the bees, in the United States to pay taxes for. It is not pleasant, when we have not money enough to pay for other things. Why should bee-keepers pay a tax when the poultry-keepers do not? In some places they pay taxes, but in general they do not. What is the taxable value of a colony of bees? Somewhere I have read that it is \$2.00. They generally sell them for \$10.00; to value them to the assessors at \$2.00 does not look honest! In Pennsylvania we must make an affidavit as to the value of all our taxed articles, and to tax colonies of bees at \$8, \$10, or \$12 would make too much tax. If you will work for the benefit of bee-keepers in general, let the governmental statistics and assessors alone.

Evidently Mr. Moyer does not understand the object of obtaining statistical information. He thinks, perhaps, that what is desired, is prompted by idle curiosity; or, peradventure, for rivalry as between States or localities—to show which are the greatest honey-producing localities, or to indicate which are the most important in the industry of bee-keeping. But such is very far from the facts in the case.

It has been fully demonstrated that information concerning the supply of any commodity is of special value to its producers in fixing the prices at which such products may be put upon the markets of the world.

Not only is it desirable to know the number of persons engaged in the production of honey, and the number of colonies of bees they keep, but also the amount of the annual product of marketable honey (both comb and extracted), and also of beeswax.

Such information, furnished at the right time, would be of great value to those who are engaged in the industry of honey-production. The fear that assessors would tax the colonies of bees is not worthy of consideration. The blanks issued by many of the States for obtaining statistics are totally independent of the taxing blanks; and whether bees are to be taxed or not is determined by the laws of the State, and not the whim of the assessor.

It is all very well to say, "Let statistics alone!" but when the bee-keepers in convention assembled appointed committees to attend to the matter, map out plans and put them into operation—they, in their united wisdom, evidently thought that the statistical information was worth obtaining, and, if obtained, it would be of much value to the industry at large.

From the efforts put forth this spring it has been ascertained that the loss during the past winter was only 15 per cent., and that the prospect for a good honey crop is very fair! Is this not worth knowing? Many think so, even if Mr. Moyer does not!

Diabetes and Sugar-Eating.—Mrs. H. Hills, of Sheboygan Falls, Wis., on April 26, 1888, writes us as follows on the above-named subject:

In the *Union Signal* published at Chicago, dated April 19, 1888, James Clement Ambrose remarks as follows:

In every ten cases of diabetes nine are the result of sugar-eating, and honey is a more unwholesome sweet, for with the sweet the bees gather more or less of the volatile oils at the base of the flowers, many of which oils are poisonous.

Is this not some "wily" fellow's talk?

Yes; of course it is. We have consulted with many physicians, and with one accord they deny the wily assertions of Mr. Ambrose. Diabetes is not caused by sugar-eating or honey-sucking. It is a disorder of the general system from the non-assimilation of food, leaving an excess of animal sugar in the blood and secretions. Although its cause and cure are not fully known, yet it can be controlled to some extent by a careful diet, clothing and warm baths.

The ingeniously-worded statement of Mr. Ambrose, about honey being poisonous is too absurd for anything. For fifty centuries it was about the only sweet used by man, and is still a prominent ingredient in all the best and most potent medicines! Such a statement as that made by the *Union Signal* is of the most stupid and preposterous character!

The Best Advertising Medium.

—The *Bee-Keepers' Review* for April states that while its advertisement has appeared in all the principal bee-papers, that of all those who have answered it, three-fourths say that they saw it in the *AMERICAN BEE JOURNAL*! Straws show which way the wind blows. As a means of placing anything of value before bee-keepers, the *AMERICAN BEE JOURNAL* stands at the head. The *BEST* is the *cheapest*.

The above paragraph, which we published last week, Mr. Hutchinson desires to have amended thus: "Of all those who mention where they saw his advertisement, three-fourths state that they saw it in the *AMERICAN BEE JOURNAL*."

Since we have been asking our readers, when answering advertisements, to say where they saw them, our advertisers are very well pleased, and the "old reliable" gets full credit for its excellence as an advertising medium.

Every Fruit Grower should have a few colonies of bees, in order to insure the more perfect growth of the crops. The bees, while gathering honey, carry the pollen from flower to flower, and thus fertilize the bloom, spread the growth, and multiply the fruit.

The Wrought-Tacks or clout nails used by Mr. Shuck for nailing honey-boards are $\frac{3}{8}$ inch, not $\frac{1}{4}$ as stated on page 295, at the bottom of the first column. It was a typographical error.

Your Full Address, plainly written, is very essential in order to avoid mistakes.

GLEAMS OF NEWS.

Chapman Honey-Plant.—M. W. Shepherd, Rochester, O., on April 26, 1888, writes as follows concerning this honey-plant:

I wrote to Commissioner Coleman for seeds of the Chapman honey-plant, and received them. Please detail the best method of sowing the seed, and caring for the plants while growing.

The season thus far has been very unfavorable for bees. Owing to the continued cold weather the supply of pollen has been cut short, and the result is, the bees have not generally built up as they otherwise would have done. The outlook for white clover is bad, but linden may produce well. There has never been any honey gathered from fall bloom here—not more than for the keeping up of brood-rearing.

The following are the instructions given in the report of the committee appointed by the Detroit Convention to examine and report on this plant:

Its seed may be scattered in waste places, or it may be sown in drills or hills like onion seed. It seems to be characteristic of the plant to root out all other vegetation, and take possession of the soil. It may be sown broadcast, and harrowed in like rye. By the latter method it makes a vigorous growth, and seems to take entire possession of the soil.

The height of the mature plant is from 3 to 4½ feet; each root bears from 5 to 15 round balls or heads, from 1 inch to 1½ inches in diameter. These heads stand upright, and the entire surface is covered with small, white flowers bearing bluish stamens. The stalks and leaves so nearly resemble those of the common thistle, that, were it not for the head, the difference would not be easily noticed.

The flowerets on the top of the head open first, then they open later along the sides of the ball, continuing in the order of nature around the entire surface of the sphere. Near the stem the last flowerets open, after the blossoms on the top of the heads have disappeared, and the seed-capsules of the first blossoms have hardened.

From the time of the appearance of the bloom upon the tops of individual heads, until the fading of the last blossoms upon the lower part of the head near to the stalk, is about eight days, the continuance of the blooming depending upon the nature of the soil and the season; but the heads or buds sent out from each individual shoot and forming each individual cluster, vary in degree and size, so that the natural term of blooming and honey-bearing may be safely reckoned at from 20 to 30 days.

The term of blooming may also be prolonged to a considerable extent by cutting back a portion of the plants, and the facility with which the honey harvest may be thus prolonged constitutes an important feature when estimating the value of this plant. The plant is hardy, easily propagated, perennial, and appears to flourish in all kinds of soil, and there is no danger of its becoming a pest or noxious weed. It does not bloom until the second season, and as it does not spread in seeding, its extirpation would be easily accomplished.

New Catalogues for 1888 are on our desk, from the following persons:

J. C. Sayles, Hartford, Wis.—10 pages—Aparian Supplies.

J. N. Colwick, Norse, Texas—1 page—Italian Bees.

Bogus Comb Honey Again.—One of our subscribers being in Chicago recently, called at this office and left the card of a certain commission firm in this city, who bluffed him and almost made him believe that they could supply any amount of *manufactured* comb honey; that they knew where it was *made*, and that they could furnish it on short notice. He requested us to investigate it thoroughly.

Having the above information (?) we proceeded to look into the matter. We called upon the before-mentioned firm, and was shown some comb honey in cases holding 21 pounds each. The cases and also the sections were covered with propolis, and the combs were somewhat irregular—all indicating that it was genuine honey, and not the reported manufactured article.

In order to ascertain the truth regarding their claim to be able to furnish the manufactured comb honey, we asked if that really was the *bogus* article; and almost before we had finished our question, we were met with a strong assurance that the firm never had anything to do with manufactured honey. "Why," said they, "we would give \$500 for a sample of manufactured comb honey. The Michigan Bee-Keepers' Association has offered \$1,000 for a pound of it. You cannot find it in Chicago. It does not exist!" Thus was another false report exploded.

Ever and anon the famous—and infamous—Wiley lie appears in its various forms, but never without all its blighting effects; and just as frequently as it reappears, it is met and "downed"—but, alas, it will not stay down, so long as exist those who are so willing to do anything to cause a sensation. Enough has been written already to have a thousand times relegated that "scientific pleasantry" to the borne where many other fine-spun theories and hallucinations of attenuated imaginations have been forced.

But why will bee-keepers assist in keeping the "Wiley lie" upon its feet? Why do they not attempt to stop its ravages, instead of repeating what they know to be untrue? Hereafter let all compel every one who asserts that comb honey is manufactured, to produce the *proof*, and thus help to enlighten the public, and to close up the mouths of irresponsible reporters, whose perverted imaginations and greed for notoriety, is unequalled except by the falsity of the fabrications which they produce. By so doing the malicious slanderers would soon cease their abuse of this immaculate and inimitable sweetness—honey in the comb.

CONVENTION NOTICES.

☞ The next meeting of the N. W. Ills. and S. W. Wis. Bee-Keepers' Association will be held in Rockton, Ills., May 22, 1888. D. A. FULLER, Sec.

☞ The spring meeting of the Wisconsin Lake Shore Center Bee-Keepers' Association will be held on May 31, 1888, in Mueller's Hall, at Kiel, Wis. FERD. ZASTROW, Sec.

☞ The Hardin County Bee-Keepers' Association will meet at the Court House in Eldora, Iowa, on the second Saturday in each month, at noon (12 o'clock), until further notice. J. W. BUCHANAN, Sec.

INTERROGATORIES.

Cleaning Musty Combs.—A Subscriber at Creamery, Pa., asks the following questions:

Will the bees clean out old, musty brood-combs containing larvæ and dead bees? Or would it be better to melt them into wax?

Yes; the bees will clean them up better, quicker and cheaper than you can do it; and if the combs are straight and in good condition otherwise, it will be better to let the bees clean them, than to melt them up.

Bees Robbing.—P. M. Little, New Waterford, O., sends us the following to answer:

I have 10 colonies of Italian bees. A neighbor of mine, about one mile distant, has 13 colonies, and some of them are weak. Some three weeks ago, or less, he fed his bees outside; about a week ago he took the old hives from the stands and transferred the frames and bees into clean hives, (being careless about his work.) On Friday and Saturday of last week 3 of my strongest colonies attacked his weak ones, and destroyed 4 or 5 of them. He wanted me to shut my bees up, or he would kill them. In justice to both parties, what would be the proper method of procedure to allay the trouble; that is, to stop the robbing?

The careless work of your neighbor makes him responsible for the robbing; his bungling work *caused* it. As robbing is demoralizing, not only to his apiary, but also to yours, it was to your interest to do all you could to stop it, and should have contracted the entrances to your hives so that only one or two bees could pass at a time. The weak colonies of your neighbor should have been covered up with a large sheet; this would allow the robbers to leave, and keep others from getting in, and still not smother the bees; or they may be removed to a cellar for a few days, and when returned to their stands, the entrances should be contracted, so as to allow but a single bee to pass—thus enabling the bees to defend their hive.

"The Rulers, Flags, and Coats-of-Arms of all Nations," the title of the beautifully lithographed album published by W. Duke, Sons & Co., the cigarette manufacturers of Durham, N. C., is on our desk.

The album contains pictures of rulers and statesmen, which approximate the color and naturalness of fine and artistic oil paintings. The beauty and accuracy of all the portraits are interesting as an exhibit of the perfection attained in the art of lithography in colors. Aside from its completeness, the album has value as a book of reference. Its beauty and utility make it worthy of a place in any parlor. The firm sends it for 75 of their cigarette folders returned to them.

New Subscribers can obtain the full numbers for 1887 and 1888, for \$1.75, while there are any sets of 1887 left.

QUERIES REPLIES.

Records of Queens, and Superseding Them.

Written for the American Bee Journal

Query 540.—Is it best to keep a record of the queens, so as to supersede them when they are two or three years old, or let the bees manage it in their own way?—Indiana

It is best to keep a record.—J. P. H. BROWN.

Let the bees do it.—DADANT & SON.

I let the bees take care of that matter.—G. M. DOOLITTLE.

Perhaps so, but I never have superseded my old queens.—EUGENE SECOR.

Keep a record of everything, and supersede the queen when she ceases to be prolific.—A. B. MASON.

I have never kept a *perfect* record, but I am inclined to think that it is the best way.—MRS. L. HARRISON.

Keep a record anyway; but I do not know what is best as to the superseding.—C. C. MILLER.

It is much better to keep a record. Supersede the queens when they begin to fail—it makes no difference if they are 1 or 3 years old.—P. L. VIALON.

I let the bees manage it in their own way, with all valuable queens.—G. L. TINKER.

Deeds, not days, determine a queen's usefulness. With experience you can tell when a queen becomes unprofitable by looking into her hive, and I should assist the bees as much as possible to supersede worthless queens.—R. L. TAYLOR.

I prefer to keep a record of all queens, including pedigree, so far as ascertainable. But I let the bees supersede a good queen. They know when to do it.—M. MAHIN.

I keep a record only of my fine breeding queens, and the older they are, the better for breeding purposes. I let my bees supersede their own queens.—G. W. DEMAREE.

No; let the bees manage it. I keep records of sale queens only. The bees do it better than we can, cost considered.—JAMES HEDDON.

Keep a record always. Thus you will know the pedigree, etc., and be able at any and all times to know the age of every queen in the apiary.—J. E. POND.

Yes, keep a record of queens, but supersede them only when they decline in vigor. Superseding by rule would often depose queens of great value. The bee-keeper must have brains as well as a record.—J. M. SHUCK.

I think that the bees can manage the matter for themselves. If queens are found that are doing very poorly, it pays to supersede them; but age is not the test. Our vision will serve better.—A. J. COOK.

As a rule, the bees will attend to these matters more satisfactorily than you could possibly do, and before you are aware that such was their intention. It is well enough to know which gives your best queens occupy, and if you have many colonies it will necessitate a record.—J. M. HAMBAUGH.

I find that the bees manage that thing very successfully, if you let them alone. You will find many cases where it is best to supersede, and you will not be obliged to keep a record to find it out. For a beginner in the business, a record of all work is an excellent help.—H. D. CUTTING.

I think that it would be a good idea to keep a record of the age of queens. I do not think, however, that it would be advisable to supersede queens less than four years old, unless they prove inferior; in that case do so at once. I supersede only such as fall below my standard.—C. H. DIBBERN.

It is certainly best to keep a record of queens, but as to superseding the queens, the bees will manage that more satisfactorily themselves.—THE EDITOR.

Metal Rabbets in Hives—Prolific Queens.

Written for the American Bee Journal

Query 541.—1. Do you use metal supports (called metal rabbets) in your hives? 2. If not, why not? 3. With everything favorable, can a prolific queen keep more than 12 Gallup frames (or their equivalents in comb surface) filled with brood?—Q.

1. Yes. 2. Yes.—P. L. VIALON.

1. Yes. 3. No.—A. J. COOK.

1. I do not. 2. I do not need them.

3. I think that is sufficient space for brood.—MRS. L. HARRISON.

1. No, except on reversible frames. 2. They hurt my fingers in handling, and also get bent. 3. Yes.—A. B. MASON.

1. No. 2. They are of no use. 3. No.—M. MAHIN.

1. Yes. 3. For a short time in May and June, yes.—G. L. TINKER.

1. No. 2. Principally because tin rabbets make the frames too loose for hauling.—C. C. MILLER.

1. I have used metal supports for many years, and I like them on account of the bees not sticking them up with propolis. 3. I consider the number of frames mentioned as abundant for the purpose.—C. H. DIBBERN.

1. I do. 3. Twelve frames are about as many as an average queen can keep filled.—J. P. H. BROWN.

1. Yes. 3. I have seen queens that would do it; but when you say 12 frames filled with brood, you say a great deal.—H. D. CUTTING.

1. Yes, in some of my old ones, but not in any made within five years. 2. Because their disadvantages just about equal their advantages, and their cost is an entire loss. 3. No, but a very prolific one might for a time.—R. L. TAYLOR.

1. I use about one-half metal supports. Some object to them, but I look upon them as of value. 3. I have had queens keep 20, and in one case 30, Langstroth frames filled with brood during a whole season.—J. E. POND.

1. I do not. 2. My greatest objection is, that they allow the combs to slide around when moving the hive. 3. Yes. I have seen as high as 16 Quinby frames, well stocked with brood from one queen.—J. M. HAMBAUGH.

1. Not as a general thing. 2. Because they have as many disadvantages as they have advantages, and do not pay for their cost in my apiary. 3. Yes, and in some cases more. But it is not advisable to let them ever do things in that way. Eight Langstroth frames full of brood is enough for the best results. I want the other two of the ten frames full of sealed honey.—G. W. DEMAREE.

1. No. 2. Because I do not consider them enough better to pay for extra expense. 3. Mine do not average over 9 such frames full of brood when working for comb honey. However, in working for extracted honey, I have had them keep 20 or more frames filled for a month at a time.—G. M. DOOLITTLE.

1. Never, in the brood-chamber. Hanging frames bother enough in the movable-hive system of honey-producing without metal rabbets. I have tried them again and again. In extracting supers of the Langstroth system, I prefer them, but I am abandoning the Langstroth frame for extracting.—JAMES HEDDON.

1. No. My hives are not made that way. 3. Twelve Gallup frames full of brood from May 15 to Aug. 15 would be a good record for a queen in this locality. Some might do better, but with hives arranged for the average queen-bee, such would be uselessly prolific.—J. M. SHUCK.

1. I have quite a number of hives with metal rabbets. I like them better alone than in conjunction with metal-cornered frames; with both they are too movable for anything except ex-

tracting and queen-rearing. For comb honey it is not necessary to manipulate the frames every week. 3. Let us figure a little: One, authority gives about 125 square inches on each side of a Gallup frame. At 25 cells to the square inch, would give 3,125 worker cells; $24 \times 3125 = 75,000$ cells in the hive. A queen would have to lay more than 3,500 a day to fill the hive in 21 days. Allowing one-third of the above frame-pace for honey and pollen she would still have to average more than 2,500 eggs a day to keep it full.—EUGENE SECOR.

1. Yes; we used them almost exclusively for several years. Their chief advantage is in not allowing the bees to stick them down with propolis. 3. No; not in ordinary cases.—THE EDITOR.

CORRESPONDENCE.

EATING HONEY.

Educating the People to the Use of Extracted Honey.

Written for the American Bee Journal
BY W. J. CULLINAN.

Four years ago last June I began the keeping of bees, and since that time myself and family have not known what it is to be without honey in the house, and on the table—eating it almost three times daily during that period. We always ate and preferred it separated from the comb, and whatever I produced in the comb was sold to those who preferred it in that shape. I always considered them, however, more nice and particular in selection than sound and experienced in judgment, as to that which was best; for if comb honey is good, extracted honey is certainly better, and it requires but a brief trial in the case of the unprejudiced, to demonstrate the fact.

Let those who have been "wedded to their idols" so strongly as to eat nothing but comb honey, and who have been swallowing large quantities of the unpalatable and indigestible stuff called "wax"—which, by the way, is only a receptacle for the pure nectar which is secreted in the flowers—discard it for a time and resort to the use of the pure, clear and clean article, known to the bee-fraternity as *extracted honey*; and after using it three months, if they do not admit that their digestive organs have improved, and they feel better, and it was the *honey* they were after, after all, I shall have missed my guess, and still be inclined to doubt their judgment as to

that which is good. Let them try it and report.

It has been said before, and said so often that it scarcely needs repeating, that the leading objection to extracted honey, by those uneducated in the mysteries of the art of bee-keeping, is the fear and suspicion of adulteration.

"'Tis pity; pity 'tis;
And pity 'tis, 'tis true."

Now if the consumers of the country (ignorant through no fault of theirs) were educated to the fact that there is no such thing as adulteration at the present time; that glucose, sugar and other saccharine substances formerly used to adulterate honey, cost almost as much as the pure nectar itself, and that those unscrupulous enough to do the mixing, could not make it a success from a dollar-and-cent stand-point (which is about the only thing that would induce them to engage in it), they would soon begin to think differently, and this blight—or curse—which has hung like a black-winged messenger of despair over an innocent fraternity for so long a period, would be at once dispelled, and in its stead a new era be inaugurated in which that much-maligned, but ever-to-be-praised article, *extracted honey*, would occupy its proper niche among the products of the hive.

The difference in the price of comb and extracted honey at the present time is too great, and it is due to no other cause than the suspicion of adulteration. Here in Kansas City comb honey is retailing for 25 cents per pound, while they retail just as good an article of extracted for 12½ cents. To come down to the real merit of the two—and it is by merit that we arrive at value—the extracted honey is worth the most, pound for pound; and when you buy a pound of extracted honey you get 16 ounces; but it is different when you buy a *section* of comb honey (it is sold by sections here). The retail dealer would always rather have a 24-pound crate that weighed only 22 pounds, than one of full weight, because in that case he makes 2 pounds of honey to the crate clear, besides his profit; so that when you buy a pound of comb honey you get about 1 ounce of wood, 1 ounce of comb, and full 1 ounce short weight, leaving you only 13 ounces of honey.

Now why should 13 ounces of honey, because it is encased in comb and wood, bring as much in the market as 32 ounces of the pure nectar, thrown from the comb? Surely there is something wrong. And I cannot help thinking that most, if not all of the trouble is due to the name—"extracted honey." The name is so closely allied with extracts, essences and various artificial compounds, that it is scarcely

to be wondered at—though much to be deplored—that nearly nine-tenths of the people outside of the bee-keeping fraternity themselves, look with a suspicious eye upon the transparent nectar displayed, for sale in large quantities, and labeled "extracted honey."

After an experience of about five years in producing and selling honey, I cannot help entertaining the belief that the word "extracted," as used in connection with honey, has worked an injury to the honey-trade that it will take long years to repair, and created a doubt in the minds of the majority of consumers, that will require much time and patience on the part of the honey-vender to explain away.

I can well remember when a boy, that jars of clear "strained" honey were looked upon with an eye of pride, and their contents prized as a toothsome article in many a farm-house. More value was attached to it than to that much comb honey.

I have not written this article for the purpose of calling out any discussion upon the subject, but simply from a humanitarian stand-point. Should it set some genius to thinking, who might be able to hit upon a plan by which my favorite article of diet could be lifted from the mystery and doubt which at present surrounds it, I shall feel highly recompensed.

SPRING TALK.

Some Seasonable Hints to the Beginners.

Written for the Prairie Farmer
BY MRS. L. HARRISON.

In some localities it may pay to feed meal or unbolted wheat flour or ground oats; but here, along the Illinois river, there is generally natural pollen to be gathered as soon as it is warm enough for bees to fly. The overflow from the river draws out the frost and causes earlier bloom.

Ash-leaved maple (*Neyundo aceroides*), which is commonly known as box-elder, is a great favorite with bees, yielding both honey and pollen. One year a neighbor came in, saying, "Your bees are swarming in my trees." On going to them I saw at once why they were there; the trees were alive with bees, and the happy hum of industry prevailed, and not that peculiar note which is heard when bees swarm.

Ash-leaved maples are planted largely as a shade tree throughout the city, and some years are a source of much honey and pollen, which imparts new life to the bees, and stimulates brood-rearing. We drove through the streets yesterday to look at these trees,

and admired the pretty little tassels on every bough, as they blossom just as the leaves start. Like the country maid and her milk pail, we calculated how much profit we should reap by our bees gathering honey and pollen from them. But alas! like the milk-maid of old, our pail is upset, for last night (April 18) a heavy frost and freeze occurred, which blasted our hopes for honey from this source at least.

There will be no peach bloom, and very little cherry, for the trees have all been killed by drouth and cold, and we comfort our hearts that we may at least have bloom on crab-apples; and dandelions are hardy, if they are not all dug up for greens. The catkins on the silver-leaves and cotton-woods are growing, and yield pollen.

In the meantime, let bee-keepers, one and all, not sit idly on their hives whistling to keep their courage up, but go to work with a will, and clean up the apiary, and let it at least look prosperous, for honey comes like a thief in the night, at a time when we are not looking for it—so have all things ready. Do not disturb the bees and kick over hives. See to it that every hive stands true and firm, for if the hives lean to one side, crooked honey will be built, just as surely as water runs down hill. Look out for leaky roofs, closing cracks with paint.

I have never seen bad results follow painting hives with bees in them. You may find some dead colonies; if so, lift out the frames, and clean out the hive. A wide chisel is a good tool to use in scraping out a hive. If the hive is foul, scrub it out with hot suds and rinse with boiling water. Efface every trace of diarrhea, for who knows but it may breed disease. Scrape off the frames, brush off the bees with a whisk-broom, and cut off all queen-cells, for they are never used again, and are unsightly.

Do not spend time picking dead bees out of the comb with a pin or pinchers, for the bees have better tools to do it with than you, and can work more cheaply. The frames can be put back into the hive, which will be better for a fresh coat of paint, for a hive should last as long as a house, if kept well painted. A new swarm will be very glad of this hive well furnished, all ready for housekeeping, and not empty.

The old Scotchman said to his son: "Joek, plant a tree, it will be growing nights while you sleep." If you do not plant a tree in the apiary, plant a grapevine, and in three years you can eat the fruit of it. Then when you are tired in the fall, taking off honey, you can sit in the shade of the vine, and obtain from the refreshing fruit renewed courage for the fray.

Peoria, Ills.

EXPERIMENTS

In Making Hives Suited to the Art and Times.

Written for the American Bee Journal

BY G. M. ALVES.

I have experimented with many different kinds of hives, without finding one which exactly suited me. Probably some churlish bee-keeper will add, "and you never will." Be that as it may, I have recently constructed a few hives, for next season's experiment, which, in my humble opinion, contain less objections and more advantages, than any other that I have used or read about.

A description of my hive is submitted, for the consideration of those unfortunates, who, like myself, are always craving something better.

The hive consists simply of as many frames as one chooses to use, placed side by side with boards placed on each side of the frames. The upright pieces of the frames are $\frac{7}{8}$ of an inch thick and $1\frac{1}{2}$ inches wide, with holes as shown in the illustration. The top and bottom bars of the frames are $\frac{1}{4}$ by

$\frac{7}{8}$ inch. All of the corners of the frames are alike, and as shown in the figure. The side-boards are the same length and height as the frames, and have corresponding holes in the ends. The size of the holes of the side-boards and frames are $\frac{1}{2}$ -inch, excepting the centre frames, which have $\frac{1}{4}$ -inch holes.

I use $\frac{3}{8}$ -inch bolts without nuts, but with washers; hence the bolts screw firmly into the centre frame, and at the same time have ample play in the other frames and side-boards to provide for slight inequalities. Of course the bolts are to be manipulated with a wrench, and when so done you have the whole held together with a vice-like grip; in fact, you practically have a solid box which you could throw over the fence without injury.

Let us now consider the advantages of this hive:

1. By means of different length of bolts, you can expand or contract the hive to any desired extent. A 3-frame hive will take four 3-inch bolts; a 5-

frame hive will take 4 $4\frac{1}{2}$ -inch bolts; a 7-frame hive will take four 6-inch bolts; and a 9-frame hive will take four $7\frac{1}{2}$ -inch bolts, and so on. If you desire to divide a hive into 2 nuclei, you have but to introduce a thin division-board in the centre.

2. There can be no sagging, warping or dislocation of the frames, as is frequently the case with hanging frames.

3. A very precise accuracy in construction is not necessary.

4. The hive is easy of construction, and not expensive; $\frac{3}{4}$ by 6 inch bolts may be had at about 3 cents each.

5. It has all of the advantages of a box-hive (and it has advantages) and a movable-frame hive.

6. Last but not least, it is a reversible hive. This feature is tabooed by some, but when practiced at the proper time, it will nevertheless give excellent results. It affords all of the advantages of spreading the brood, without its serious risks.

Should the bee-keeper at the time when he finds the first clover blossom in some warm and protected fence-corner, reverse the hives or frames of thrifty colonies, take my word for it, he will have more gatherers for the harvest.

KENTUCKY.

Successful Wintering—Bee-Culture in Kentucky.

Written for the American Bee Journal

BY JAMES M. TYLER.

Having given, on page 821 of the AMERICAN BEE JOURNAL for 1887, the manner of wintering bees in Kentucky in the Langstroth hives, I will report the results.

The 24 of the 25 colonies packed, wintered in fine condition, and on March 26 each one had more or less brood, and were bringing in pollen from the elm and maple bloom with a vim. The one that perished was 1 of the 7 colonies made by division, about July 1, 1887. But for an oversight in allowing them all the frames, and failing to put them between division-boards, as I did with the other small colonies, I am sure that there would have been no loss.

These nuclei colonies did not build up much, owing to the severe drouth. They covered only from 2 to 3 frames. I would have doubled them up, but I desired to save my queens that I reared from my best stock. I gave them only about 10 or 12 pounds of honey to the colony, mostly uncapped and mixed largely with pollen, stored too late in

the fall to allow the bees time to cap it. Such stores doubtless would have proven disastrous to long confinement of the bees in cellars, or even on the summer stands. They had frequent flights at intervals of 8 or 10 days, and at such times they would spatter the tops of the hives with a yellow, watery excrement.

Bee-Hives and Frames in Kentucky.

In regard to my venerable and respected friend, Mr. G. W. Demaree, I would say that when I saw the heading of his article on page 184, I read it with great avidity, as just the information I wanted. He and my former countyman, Dr. Allen, now of Kansas, have been in the past the Gamaliels and Mentors of the smaller bee-keepers of Kentucky. From them and other specialists we have learned what little we know about bee-culture. But I was soon greatly surprised to find that with his pen (which he knows so well how to wield) he was after me, because I expressed my fears that I might be a little behind the times in adhering to the 10-frame, 2-story, cottage-roof, telescope-body, portico-front Langstroth bee-hive, which Mr. Muth calls his "favorite;" because I condemned the zinc, slotted, queen-excluding honey-board; because I thought the Heddon break-joint slotted honey-board was a good thing; because I did not give the orthodox method of wintering bees in Kentucky; and, it seems, because I recommended anything necessary other than an abundance of stores for wintering bees successfully here.

The fact is, Mr. Demaree's article reminded me very much of a colony of cross hybrids that had not been tamed. They will follow every person, animal or fowl about the premises, trying to sting, saying by their actions, "You have no business fooling around here, anyhow."

By way of apology, let me tell what inspired me to write. A few years ago I lived in Chicago for about a year, and while there, those go-ahead, pushing Northerners, with whom I became acquainted, talked to me after this fashion: "We like the Kentuckians pretty well, but do you know that you are about a hundred years behind, down there in Kentucky?" Ever since I returned I have believed this to be a fact, and I have an idea that we are far behind in bee-culture.

It occurred to me that the editor of the AMERICAN BEE JOURNAL was one of those who could enlighten me on the subject. I meant to inquire after the best form of the Langstroth hive for use in this locality. His answer was satisfactory, and I have laid in another supply of the Langstroth hives of the same pattern.

Mr. Demaree misconstrued my article, making me convey the idea that the Langstroth hive was but little used in Kentucky. The very universality of the use of the 10-frame Langstroth hive that I described, in small patches, compared to the bee-keepers, rarely exceeding a dozen at a place, and more often not more than two or three; constant reports in the spring, such as, "Half my bees are dead," "The Langstroth hive will not do to winter my bees in;" talk, by intelligent men, of going back to the box-hive, etc., impressed me with the belief that we were, as my Eastern friend said, "A little old-fogy and behind," in bee-culture as well as other matters. We Kentuckians are dreadfully "sot in our ways," and inclined to follow in the footsteps of our fathers. They are likely to continue in the same old rut, if they follow Mr. D.'s advice, that "An abundance of stores is all that is necessary in Kentucky," and read his severe criticisms against any who take the trouble to inform bee-keepers of methods of successful wintering, as followed by Mr. Demaree, Dr. Allen, and other successful bee-keepers.

The readers of my article referred to by Mr. Demaree, and his own article, will be curious to find any difference between that given by me, and by his method; except that he condemns the packing in of the brood-chamber by use of the division-boards and chaff, and does not mention that he uses "Hill's device" on the brood-frames to give a passage-way.

When I shall appear at our next annual bee-keepers' convention, which I expect to attend, I will have a bundle of bee-literature under my arm, and by his own record, condemn Mr. Demaree of contumacy, before a jury of his peers. I will show that while he condemns "all side-packing in the brood-chamber, as a positive injury to the bees," on page 167, in answer to Query 524, he said: "My practice is to place the combs on the south side of the brood-chamber, and close with a division-board on the north side;" and the evidence of the other answers to this Query, and by the editor on the very same page, who says, "To put the combs in the centre, and a division-board on each side is preferable, because of controlling the temperature by the use of absorbents on the sides when bees are wintered on the summer stands."

In the *American Apiculturist* for 1886, page 231, Mr. D. said: "For this climate the best preparation for bees in winter is protection on the north side and west ends of the hive." On page 740, of the AMERICAN BEE JOURNAL for 1887, in answer to Query

496, asking if winter passages were necessary, he said: "I prefer some strips of wood or pieces of corn-stalk between the quilts and tops of the frames, so that the bees can pass over the tops of the frames;" and the editor said that the combined evidence to the Query was, to use "Hills device or its equivalent."

His brother bee-keepers will surely laugh at him for condemning the method which I pursued in wintering bees here, which method is copied from the plan he and other experienced bee-keepers are following.

My condemnation of the queen-excluding zinc honey-board was doubtless hasty, and owing to the faulty use of it, as Mr. D. says; but I am not sure that it does not injure the bees as they rush through the sharp-edged slots, by tearing their wings and cutting the hairs from their bodies and legs more or less.

They will certainly laugh at my old friend for condemning the break-joint, slotted honey-board, now so universally recommended.

In the future I mean to talk in our county conventions more about the necessity of reading up our bee-literature, and urge the bee-keepers to take the bee-periodicals as the best way to improve bee-culture in this State.

Bowling Green, Ky.

WINTERING BEES.

Six Months' Sleep in the Cellar—Honey-Plants.

Written for the American Bee Journal
BY EUGENE SECOR.

Three weeks before the meeting of the North American Bee-keepers' Society last fall—on Oct. 26—I put into winter quarters about half of my bees. The remainder were put in on Nov. 8. By winter quarters I mean the cellar under the house. On April 21, 1888, I began removing them to the summer stands, and finished on April 23.

The longest time of confinement was 180 days. During that time they never saw daylight nor lamplight. I visited the bee-room less than usual. I had a thermometer in a convenient position, which I examined every few days. It registered as low as 32°, and as high as 50°, but most of the time between 40° and 45°. There is no ventilation in the room, other than what is possible through a plastered or stone wall.

The bees wintered quite well, on the average. Some showed signs of diarrhea, and others not at all. I lost 6 colonies out of 40, and all but one of these by starvation. I have packed

some colonies in dry forest leaves. The others are in single-walled hives.

Silver maple bloom was about over when the bees were brought out. The spring has been very backward, and there have been only a few days when bees ought to leave the home nest. Bees have generally wintered well, so far as I have learned.

Alsike and the Chapman Honey-Plant.

I sowed two bushels of Alsike clover seed this spring. Quite a good deal was sown last spring. Our farmers are beginning to believe that Alsike clover will do well on wet land. If it proves to be a fact, more of it will be sown in the future. The Chapman honey-plant seed which I sowed a year ago, is looking well. All who see the patch think that it is thistle.

Forest City, Iowa, April 27, 1888.

TRANSFERRING.

How and When to Transfer Colonies of Bees.

Written for the American Bee Journal

BY H. E. HILL.

The method given by Mr. Geo. F. Robbins, on page 222, is quite ingenious—perhaps even the “neatest, safest, cheapest, easiest,” etc., but I do not think that it is the “quickest;” and why it is cheaper or easier, I fail to see. The *simplest* effectual method is what the beginner wants, and improved ideas will follow experience.

If the beginner has more than one colony to transfer (if not, try Mr. Robbins' plan on that *one*), have some one to assist; have the empty hive, about fifty very thin strips of pine, $\frac{1}{2}$ inch in width, and of sufficient length to be tacked across the frame in any direction desired; two boards a little larger than the frame to be used, a light hammer, hatchet, smoker, a pail of water, sponge, a couple of sharp knives, tacks, and a table or bench; and last but not least, a half-dozen good wing-feathers, to be used as bee-brushes.

If but 1 or 2 colonies are to be transferred, I would select the morning or evening, when other bees were quiet. Smoke rather freely in the hive-entrance at first, then tap lightly on the box with the fingers, smoking gently for a few seconds at the entrance (not inside) to prevent the bees from rushing out.

Now lift the box from the stand and place it bottom upwards on the ground beside the new hive, which is placed upon the old stand, with 2 or 3 frames of foundation or empty frames. The bottom is now pried off, while keeping the bees under control by an occa-

sional gentle puff of smoke, as their actions demand. Then a side is removed, giving free scope for business.

It is but the work of a few minutes, to cut out each comb and brush the bees off into the new hive; while the assistant, with the combs and frame upon one of the boards previously prepared, “cuts and fits” the good worker-comb into the new frame, tacking the strips across the frame, so as to support the various shaped pieces. When the first side is finished, place the other board upon it; then lift both boards and frame, and lay them down with the other side upward. Remove the top board, and tack the strips across the other side.

To remove the frame with combs, do not attempt to lift it off the board, but raise one side of the board until the frame stands as it does in the hive, then lift up, drawing it off without displacing the comb. Leave these in the hive, and fill out with empty frames, or frames with full sheets of foundation or starters, as may be desired.

Cover down the hive, sponge off the table, boards, feathers and other tools, remove all particles of honey that might attract robbers, and if the colony is not very strong, contract the hive-entrance and slightly elevate the front, to prevent any dripping honey from running out, until they get “cleaned up.” The whole operation takes about the same length of time that is required to drum the first lot of bees into a “drum-box.”

One advantage that Mr. Robbins' method possesses over the plan described above (and the only one that I can see) is, the saving of brood, which is quite a consideration, especially when the operator is a novice; but this one weak point in my plan, may to a great extent be obviated, if the operator will remember that each cell of brood represents a worker, and exercise greater care in fitting the brood into the new frames.

During the past two years I have transferred more than 200 colonies of bees in the above way, from odd-sized frames, boxes, barrels, hollow logs, etc., with *invariable success*; and unless the combs are in a worse condition than any that I have met, from one to eight fairly good brood-combs can be saved in this way. If they are of the “cobble-stone pavement” kind, it is the fault of the workman, as any protuberant part may be easily pressed into position two or three days after transferring, and at the same time the sticks may be removed as carefully as possible.

If no eggs are to be found on the fourth or fifth day after transferring, and the bee-keeper has no laying

queen to give them, destroy all queen-cells but one, reserving the better looking one; though my loss of queens in transferring would not exceed 2 per cent.

I have transferred with equal success during every month in the year, but I prefer, and would recommend, doing it at the time of fruit-bloom in this locality.

Mr. Robbins says, with reference to drumming the bees into a box, “In 15 minutes most of the bees, including the queen, will have passed into the drum-box.” Admitting that in the majority of cases the queen would be “included,” it is by no means invariable, especially if it is a young queen, or one of those nervous (?) dispositioned ones that is “all over, and nowhere,” at such a time.

I think that Mr. Robbins should have gone a little further with his explanation, as the results of a beginner, being guided by the positive assertion might prove disastrous. He might follow the rules to the letter, and conclude that the new colony was all right—queen included—but if, upon investigation a couple of weeks later, he found “large white worms in the combs, the bees presenting a black, polished appearance, trembling, very irritable and venomous, and do not act at all like the other bees,” the bee-papers would be called upon to publish a report of “a terrible, nameless bee-disease.”

Titusville, Pa.

HIBERNATION.

Reply to Mr. Clarke's Critique, on Hibernation of Bees.

Written for the American Bee Journal

BY J. F. LATHAM.

Mr. Clarke supposes, on page 221, that I shall feel slighted if he does not “pay his respects” to my article on page 167. No, not in the least. When I wrote the article in question, the idea of reaching into the burrow of wood-chuck, that I might get bitten, in order to discover the whereabouts of the inmate, was totally absent from my thoughts; as well as the expectation of being made sensible of the existence of my mercurial hypercritic. But, as the resulting consequence of my inadvertency, in not defining my position, with strict regard to personality, I must admit that I do experience a satisfactory surprise at the explosion resulting from unconsciously pricking a bubble.

“It well-nigh bamboozles me,” wrote Mr. Clarke. Well, as my assumed monitor did not get *really* bamboozled, I presume the shock will not be fatal;

at least I hope it may not, for I have no desire to perpetrate a capital offense.

As to "soaring out of the jurisdiction of the court," with due deference, I think that, with proper discrimination, Mr. Clarke will discover an unfortified point in his position, when he attempts to exercise judgment in a sphere where title might be made a matter of dispute. "Rhadamanthus was not always *just*."

Androgynal—'tis a pretty big word, come to look at it, and requires ten letters to spell it! but, on review, if there is any indiscretion in its use, as applied in my article, I have, as yet, been unable to discover it; and as it is a factor in the English language, I presume its use is free to all; furthermore, if its scope of meaning was fully illustrated, and the deductions that might be drawn therefrom rightly applied, they might supply nourishing food for thought in regard to the phenomena of hibernation, besides, jostling some of the favorite theories of its advocates.

"We all know that hibernate, in its common unscientific use, means merely to pass the winter." Mr. Clarke says, "We human beings and insects hibernate. So do plants and stones." But our scientists tell us that there is another definition applied to hibernation, which describes the specific physiological condition of the hibernating subjects; and that all in nature, animate or inanimate, are not subject to that condition in cold climates; although the *act* may be termed spontaneous. If Mr. Clarke includes stones in the list of *his* hibernating subjects, I presume he has an undoubted right so to do; but I am not prepared to accept their condition other than that of a suspension of the elements of their composition, which has existed since the subsidence of the Plutonic epoch in the evolution of this planet.

Mr. Clarke avers that we can arrive at a positive knowledge of the actual hibernation condition, and says, "We can see that." See what? "Bees form a tight cluster and remain in an almost, if not quite, motionless state." So they do at any time when in repose, whether as a swarm hanging from a limb, secreting wax in the hive, loafing from lack of forage or other causes, or among the combs of the brood-chamber in mid-winter. The effect is prominent; but it is the cause that demands solution.

During the past winter one of my colonies remained, what might be termed, perfectly quiet for 158 days, and when it flew on April 6, it was, so far as I could ascertain, in a most satisfactory condition. Thirty other colonies were in very nearly the same

condition. But I do not consider the acts of the above 31 colonies more favorable to a confirmation of the hibernation theory, as set forth by Mr. Clarke, than those of the other 28 that had a flight on Feb. 22.

Mr. Clarke quotes me as saying that "the hive-bee is only physically constituted to experience to a certain degree the condition of *hibernation*." (Italics are mine.) The evasion exhibited by Mr. C. in the above quotation, seems to be a favorite method with him of substituting his own, for the language of those from whom he differs, in discussion. If I am correct in my recollections, the same spirit crops out in his pen-attacks on other correspondents of the AMERICAN BEE JOURNAL.

Had Mr. Clarke quoted correctly, he could have omitted the word hibernation in his comments. I used the word coma as a synonym of dormancy, to illustrate the quiescent condition experienced during cold weather, by such animals as scientists term the true hibernating species, viz: the bear, raccoon, etc. If the "hive-bee is only physically constituted to experience to a certain degree the coma (dormancy) to which the brute animals are subjected during the hibernal period," *it is correct* to say that the hive-bee does not hibernate in the accredited scientific definition of the term.

I am ignorant concerning the habits of Provincial red-squirrels; but the red-squirrels in this vicinity are out at all times, and in all weathers. They hibernate! certainly. The fiddle possesses a dual capacity, and when the theme is not reconcilable to the compass of one string, a "shift" can be made to the other. At the opening of his fifth paragraph, Mr. Clarke quotes me as saying that "no animated organized being 'can become frozen solid, or even become sufficiently benumbed by cold as to wholly destroy its vital functions and live;'" and says: "This is not so. The black ant can." Here again Mr. C. molds the phraseology to suit his purpose. I made use of the adjunctive phrase, "after having passed the limits of a definite grade of development, etc.," in accordance with its explanatory import.

Observation, and the teachings of those who have made the anatomy of insects a special life-study, prompt me to the belief, that the constituent fluids, the secretory glands, and, in short, the physical organisms of the hive-bee occupy a position in the line of progressive development far in advance of that of the black ant; requiring artificial means to protect existence, where, we are told, the black ant can freeze up in winter, and thaw out in the spring following.

I have never seen a carp; but if the carp possesses a pneumatic and circulating apparatus on a *par* with those of the hive-bee, it would require conversion to convince me that a carp can be frozen-to-death, and be susceptible of re-animation.

Again, Mr. C. writes: "Mr. L. says that, 'life without the influence of motion on matter is inadmissible.'" Admission requires proof. If the bear does not *breathe*, nor *change its position* while hibernating, I should say that the "flames of life" were extinct. The black ant is motionless when frozen solid, as I have observed while splitting partially decayed wood in the coldest weather in mid-winter. We often find the ants in a mass of ice in hollow trees, but I am not *sure* that they ever "come to life" again.

"Crysalids that freeze solid, thaw out and come to life again," says Mr. Clarke. So will the molecules of many of the vegetable species. The stone of the peach germinates more readily by being planted in the fall. The seeds of countless flowering plants freeze, and yet the *germ* of life is not destroyed. I am not informed that the black-ant can be frozen *solid*, *i. e.*, that its fluids are susceptible of congelation!

I think that Mr. Clarke will be compelled to go further than to where "our brethren of the Sunny South who keep bees" reside, to verify his remarks in his closing paragraph. "Bees must have a rest, surely, in the South, as well as in the North." But, when "in the South" means the Torrid Zone, with its "ever blooming flora," can that "rest" be termed *hibernation*?

In conclusion it is noticeable that, in his review of my article, Mr. Clarke skirmishes around allusions that savor of evolution. It seems to me that if the word evolve was substituted for create, in the English language, a huge stumbling block to right thinking would be removed. To talk of creating, is a continual butting against fact, when it is very apparent that everything possessing an organism, so to speak, is but the result of evolution—a manifestation of the attributes of one God, one Law, one Element.

Severe Winter and Backward Spring.

I can report 59 colonies of flying bees at present, all apparently in good condition; notwithstanding a severe winter, and a very cold, backward spring. My bee-yard is nearly covered with snow—in some places I foot deep. No pollen has been gathered yet; with unfavorable prospects of any for a week to come.

Cumberland, Me., April 16, 1888.

[One article on each side of this discussion is sufficient; it is now closed with the above article.—ED.]

SHIPPING BEES.

A Beginners' Experience in Receiving and Caring for Them.

A Letter written to the Shipper,
BY JOHN HILL.

The bees were very nearly starved when they came to Norton; there the express agent, by mistake, sent them to a man having a very similar name, and when he brought them back, there happened to be an apiarist in the office who asked whose bees they were. After examining them he said they were almost starved, and he would feed them. He bought some sugar, made syrup, took the bees into a room, let them out of the box, fed them, and then put them back again. If it had not been for this man, all the bees would have died, before they reached me; and then they got no more to eat until they came here.

I made some syrup for them at once, and they seemed to be almost starved. It was interesting to see how quickly they licked up large drops of it.

When I had their hive made, the comb foundation had not come yet, so I put them into the hive with empty frames. When I took them out of the box, I found one comb entirely broken loose from the frame, and as dry as if there never had been any honey on it. The next frame to that one was broken and bent to one side, and a part of it was loose at the top, with a very little honey in it. The other frame was all right, and had the queen on it.

I put the comb with the queen in the middle of the hive, the comb that was partly broken next to it, and filled the rest of the hive with empty frames. This was early in the morning. There was very nearly two handfuls of dead bees in the bottom of the box, which appeared to be mostly young bees. There was a little bunch of bees that did not hold to the combs when I took them out, so I brushed them out of the box on the alighting-board of the hive, and they all went in.

The whole operation was performed without receiving one sting. I was very much gratified, for I expected to be stung before I was through. They crawled all over my hands, and never appeared to sting me. I then sat down on the grass, with my nose almost to the hive-entrance, to see what they would do. I soon noticed that some of them came out of the hive and flew away, and before 10 a.m. they were returning loaded with pollen. They worked hard, but paid no attention to me, though I was almost in their way.

Everything appeared to be going on like clock-work; but between 1 and 2 p.m. they surprised me, by commenc-

ing to come out of the hive until about one-third of them were out, and kept flying around my head as though they wanted to alight on it. They finally alighted on a bunch of grass about 12 feet from the hive. I do not know what was the matter. The other bees did not seem to pay any attention to them. They came out of the hive and flew right through the others, and came back loaded. After all had settled on the bunch of grass, I carried them back to the hive, but some would return to the grass. I carried the most of them to the hive with my hands, and at sundown I had all but about a table-spoonful of the bees to stay in hive, but those would go back to the grass every time. So I thought if they were determined to cluster there, they might. Early the next morning there was not a bee on the grass. I think that when night came they went to the hive.

The second day everything was all right; but the third day there seemed to be more trouble. There was from three to six bees at the entrance that seemed to be angry, strutting around with their backs up, taking notice of every bee that went in and out, and "cuffing" them. Some of the bees were so weak that they could hardly rise from the alighting-board, and those they would kill. I saw them kill five or six, and a good many more were dead on the grass. This continued for about three days, when it ceased; while it continued there would be a buzzing in the hive at times, but all the time they were busy at work. Not knowing anything about bees, I knew not what the trouble was. I became greatly interested in the whole business; but I concluded that these bees were so nearly starved that they were weak and unable to work, and the strong bees killed them. All the dead ones seemed to be young bees. After this trouble was ended, all went well with them, and the buzzing in the hive ceased.

After they were in the hive about ten days, the feeder, smoker and comb foundation arrived; then I made more frames and filled them with foundation. I opened the hive and found that the broken comb had fallen down. I took it out, and there was about half a tea-cupful of honey in it. They had commenced to build comb in one of the empty brood-frames. This frame I did not take out, but I removed all the empty ones, and filled the hive with frames of foundation.

Up to this time I think there was not more than one-third of the bees a live, caused by starvation and rough usage. I had received but one sting from them, and that was when I gave them comb foundation. They were crawling

all over my hands, and one of them got under my wrist-band and stung me on the wrist. From the time the killing of bees was over, they worked with the greatest industry, but there was no more than about two handfuls of them left.

When they had been in the hive for about 20 days, I saw the first full-blooded Italian bees appear; they multiplied very rapidly, and about Oct. 1 the hive seemed to be full of young bees, not one of the old ones remaining. I believe that they will do very well in this country, and I do not think that bees could do much better in any country than these have done, considering what they had to endure.

Furnas Co., Nebr.

CALIFORNIA.

Keeping Bees in a Salubrious Climate.

Written for the American Bee Journal
BY A. D. STOCKING.

I left Cedar Beach, Ind., on Dec. 22, 1887, the weather being very cold there, and the bees all shut up in their winter quarters. I arrived in National City, San Diego Co., Calif., in the evening of Dec. 29, and what a contrast there was!

The following morning I found 2 colonies of bees, and they were flying all day, and seemed to be bringing in some honey. I do not think that there have been ten days since I came here, that bees have not been out, and now they are very busy getting both pollen and honey. Cultivated flowers have been in bloom out-of-doors all winter, such as geraniums, pansies, roses, candy-tuft, mignonette, etc., and now the country looks beautiful in its carpet of green—beautiful with its myriads of variegated wild flowers, with peaches and apricots in full bloom, and many other fruits are now (March 22) coming into bloom.

The weather, since I have been here, has been like beautiful spring and fall weather of the East. In January we had a few frosts; on three nights ice formed on water out-of-doors, and the ground froze lightly, yet vegetation was but slightly injured. The orange and lemon blossoms were not injured, nor the flowers blooming out-of-doors. The influence of the ocean breezes prevents injury from frosts.

National City is situated on the east side of San Diego Bay, and we can look across the bay to the west and see vessels passing, and the surf breaking on the low beach that separates the Bay from the ocean. We are surrounded by mountains on three sides,

distant from 6 to 12 miles, and we can see many snow-capped mountains, yet I have not seen a flake of snow, neither have we had either thunder or lightning, though there have been several heavy rains.

This is literally a land flowing with bees and honey. The bees occupy crevices in the rocks of the mountains, the church spires, and chimneys of houses in the town. I am told that hundreds of swarms were caught as they were going over the town last season. What bees I have seen were Italians, also a cross between Italians and a brown bee, and are very mildly disposed. All that is required in bee-keeping here is, to provide hives or boxes for the bees to occupy, and room for the storage of honey. No care or preparation is required for the wintering of bees. From what I can learn, bee-keeping is done in a very slipshod manner, and generally a large and cumbersome hive is used—a movable-frame hive, but only a few steps removed from the box-hive.

The most of the honey taken here is extracted. What comb honey is taken, is in the Harbison section, secured together with strips, and used as the Hill sectional box is used. They are put on the market, or in bulk, and the combs cut out of the frames. The improved one and two pound sections are not used here, but they are being introduced into the northern part of this county, and in the counties north of this.

Improved methods and improved hives are being introduced. What is called the "Harbison hive" has been extensively used. It is a large, cumbersome hive, and very unhandy to manage. But a form of the Langstroth hive is now being used, which takes 9 Langstroth frames in the brood-chamber, and 8 frames in the supers. For extracting they are tiered up as high as required.

I am told that the greatest difficulty in bee-keeping is to prevent swarming. Mr. Harbison, the great California bee-keeper, lives in San Diego, four miles from here. Honey is retailing here at the following prices: Comb honey 18 to 20 cents per pound; extracted, 5 to 12 cents per pound, and the quality is fine.

The best honey season ever experienced here is anticipated the coming season. Bee-keeping is not profitable on the low or mesa lands of the coast, but on or near the hills and mountains it is made very profitable, and honey can be produced at one-fourth the expense that it costs in the East.

National City, Calif.

Scatter the Leaflets.—Look at the list (with prices) on the second page.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*
 May 19.—Nashua, at Nashua, Iowa.
 H. L. Rouse, Sec. Ionia, Iowa.
 May 22.—N. W. Ills. & S. W. Wis., at Rockton, Ills.
 D. A. Fuller, Sec., Cherry Valley, Ills.
 May 31.—Wis. Lake Shore Center, at Kiel, Wis.
 Ferd. Zastrow, Sec., Millhome, Wis.
 Aug. 3.—Ionia County, at Ionia, Mich.
 H. Smith, Sec., Ionia, Mich.
 Aug. 14.—Colorado State, at Denver, Colo.
 J. M. Clark, Sec., Denver, Colo.
 Aug. 27.—Stark County, at Canton, O.
 Mark Thomson, Sec., Canton, O.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

SELECTIONS FROM OUR LETTER BOX

An Early Swarm.—Henry Patter-son, Humboldt, Nebr., on April 30, 1888, writes:

The weather is nice, with frequent showers. Apple bloom is opening, and is giving the bees the first nectar of the season. What bees survived the winter are building up very fast. We have better prospects for a successful harvest than we have had for two years. I hived a natural Italian swarm on April 26. Who had an earlier swarm in this latitude?

Honey from Hard Maple.—Geo. H. Kirkpatrick, New Paris, Ohio, on April 30, 1888, writes:

My bees are doing finely. I never have seen bees breed as rapidly as mine are doing this spring. I think that the majority of bee-keepers will have no trouble to get their colonies in proper condition for the white clover honey-flow. The hard maple trees are now in bloom, and the bees are gathering honey from them. Some of my most populous colonies are gathering surplus. I find it necessary to remove some of the filled combs and replace them with empty ones, to give room for the queen to lay. The peaches, pears, plums and cherries are in bloom; soon the apple trees will be in blossom, and as the white clover is looking fine, surely the prospects are good for a bountiful crop of honey.

Heavy Losses in Wintering.—Wm. Anderson, Sherman, Mo., on April 30, 1888, writes:

The outlook for honey this year is the poorest that I have ever known. White clover was killed by the drouth and the winter, and red clover is all dead. It looks as though there will be nothing for the bees to gather honey from. We have had no rain for four weeks, and everything is drying up, but it looks as if it would rain today. About 70 per cent. of the bees in this part of the country have died from starvation, and that dreadful scourge—toul brood. My loss was very heavy, after trying many of the so-called foul brood cures. I had a fine swarm on April 26, which is something very uncommon here. Everybody was surprised, and I thought something was wrong, but upon examining the colony I found them all right, with a fine young queen; the old colony seems to be in splendid condition, and will be ready to cast another swarm in due time.

Cool and Late Spring, etc.—G. M. Whitford, Arlington, Nebr., on April 23, 1888, writes:

The spring is cool and late. Bees are gathering some pollen, but it is nearly a month later than they commenced storing pollen last spring. As a general thing, bees did not winter as well the past winter as the winter before. I lost 3 colonies out of 13. I enclose my dollar for the "Union." It is the duty of each and every person interested in bee-culture, to aid the Union in its noble undertaking. I have received a package of the Chapman honey-plant seed from the Department of Agriculture.

**Cotton-Seed for Winter Pack-
ing.**—G. W. Crowder, Kosciusko, Miss., on April 24, 1888, writes:

I have 25 colonies of bees in the Simplicity hives, which I work with single story and super with 28 boxes on top. Bees are doing finely here this season. The readers of the BEE JOURNAL should try cotton-seed for winter packing. I think it is excellent for that purpose. Italian bees are far superior to the blacks here.

A Good Harvest Expected.—Mr. F. B. Reynolds, Rosburg, N. Y., on April 30, 1888, writes:

Bees are doing well. We are having some very hot weather here now—86° in the shade. The trees are all ready to burst their buds, and we will soon have a harvest for the bees. By the way they are carrying in the pollen, it seems as if they would fill the hives in a short time. I received two packages of the Chapman honey-plant seed in good time, from the Commissioner of Agriculture.

**Wintered Well and Working
Hard.**—S. Burton, Eureka, Ills., on April 28, 1888, says:

My bees have wintered well on the summer stands. They were packed the same as last winter, which is described on page 684 of the AMERICAN BEE JOURNAL for 1887. I lost one colony by its being queenless. I have 14 colonies, and they are building up fast. They have been gathering natural pollen for a week, and are working hard now.

Loss in Wintering.—Jas. W. Mills, Melleray, Iowa, on April 22, 1888, writes:

I lost 23 colonies out of 29 in the cellar, where the two previous winters I had no loss. Some of them starved, and the rest had the diarrhea, or some other disease. I had 25 colonies in the spring of 1887, some of which were very good, and some very poor. I doubled up the old ones that were weak, and gained only one colony, with about 2 gallons of extracted honey that I ought to have left. I bought 3 colonies about April 1, and I would rather have those than all the rest. I am not the only one to lose bees in this place.

High Water—Bringing Pollen.—C. Theilmann, Theilmanton, Minn., on April 26, 1888, writes:

I put out my 217 colonies of bees on April 21, all having wintered in fine condition, except one that starved. I had put them into two caves on Nov. 17, 1887. Three weeks ago we had about 3 feet of snow. Yesterday and the day before the bees brought in much pollen. Soft maples are

in full bloom. It is warm to-day, and bees are booming for this time of the year. The melting of that heavy snow-fall has made the creeks and rivers very high. The Zumbro river has not been so high since 1859. It has swept away nearly all the bridges and fencing, and the fields are flooded. The railroad was badly damaged. I had no mail for nearly two weeks; but it is all right now.

Gathering Pollen.—H. M. Seeley, Harford, Pa., on April 27, 1888, writes thus:

I know of three who have received seed of the Chapman honey-plant from the Commissioner of Agriculture; I being one. We received it very promptly. My bees gathered the first natural pollen yesterday, and all are doing finely.

Immense Forest Bloom.—N. D. Coffin, Westland, Ind., on May 1, 1888, writes:

I sent to Norman J. Coleman for the Chapman honey-plant seed, and received a package promptly. The bees are doing well. The forest bloom is immense; but the prospect for white clover is not flattering, by any means.

No Loss in Wintering.—Horace S. Ball, Granby, Quebec, on April 23, 1888, says:

It is quite warm here to-day—80° in the shade. I put my 40 colonies of bees out on April 25 and 26. They were in good condition after being 160 days in the cellar. Those in Langstroth hives came out in the best condition, as they always do with me. The first pollen was brought in on April 27.

Hiving-Box—Money-Plant Seed.—Randolph Graden, Taylor Centre, Mich., writes:

I used just such a hiving-box as is described on page 275. I find it the most convenient of any method that I know anything about.

I sent to the Commissioner of Agriculture immediately after I saw the item in the AMERICAN BEE JOURNAL, that the Chapman honey-plant seed could be had by applying to that Department for it. I received it with several other varieties of seed about three weeks ago.

Clovers Winter-Killed, etc.—Alex. Rose, Sullivan, Ills., on April 30, 1888, writes as follows:

I wrote to Norman J. Coleman, Commissioner of Agriculture, for the Chapman honey-plant seed, and in due time it arrived. I am an agricultural correspondent for this (Moultrie) county; I will also report bee-statistics for the county. I have three persons who will assist me in getting statistics. I find the employes of the Department at Washington very prompt in granting all reasonable requests that come under their care. Almost every county in the United States has regular correspondents who no doubt will look after the reports of bees and honey.

Bees have wintered poorly as a rule in this county. Some bee-keepers have lost $\frac{1}{2}$, some $\frac{1}{3}$, and some almost all; a few have lost none. Bees seem to be healthy, though weak. The white clover seems to be about all dead, and red clover is all dead. The apple, peach, cherry and plum trees are all in full bloom, but seem to yield but little honey. The hard maple or sugar trees

are in full bloom, also red-bud, which seems to have some honey.

I am selling my old honey at 25 cents per pound. I averaged about 25 pounds per colony last season, all of it being of a reddish cast. There was scarcely any white clover honey last year, and but little linden honey. Our crop was mostly from wild bloom, and red clover cut short by drouth, which made the blooms short, so that the bees could reach the honey.

I have no use for separators in sections; I look upon them as a nuisance. I find but little trouble in making foundation stick in the sections. I use full sheets in one-pound sections.

Results of the Season of 1887.—C. H. Jones, Pierceton, Quebec, on April 25, 1888, writes:

In the spring of 1887 I commenced with 13 colonies, 7 of them in box-hives, and increased them to 34 colonies. I bought 19 colonies in the fall, making 53 in all. I secured 500 pounds of linden and clover honey, and transferred those in box-hives, getting 41 pounds of wax. I use the Simplicity hive, and winter my bees in the cellar. The temperature has been from 38° to 42° all winter. I have lost 6 colonies.

Bees Wintered Well.—Mr. John R. Sample, Elizaville, Ind., on April 25, 1888, says:

My bees have wintered well. I commenced in the spring of 1887 with 3 colonies, increased them to 8, and took 100 one-pound sections of honey. I packed 8 colonies last fall for winter, of which 7 are strong, and 1 is weak.

Lucerne and Sweet Clover Honey.—George Hone, Jr., Benjamin, Utah, on April 27, 1888, writes:

I have wintered 150 colonies on the summer stands without loss. I took 2,500 pounds of comb honey, and 14,000 pounds of extracted honey last season, which was gathered from lucerne and sweet clover. This honey was gathered by 138 colonies, spring count, with an increase of only 12 colonies. I find that giving bees plenty of room is the best method to prevent increase. Last season was a very good one for honey in this locality.

Fairly Strong Colonies, etc.—Ira Adamson, Winchester, Ind., on April 26, 1888, says:

I began the past winter with 21 colonies of bees, and I have now 13. Two colonies died with the diarrhea, 1 was killed by robber bees, and 5 became queenless. The rest are tolerably strong. I have been feeding some. If a bee-keeper has but 1 or 2 colonies of bees, it will pay him to take the AMERICAN BEE JOURNAL. I am sorry to hear of Mr. Z. A. Clark's persecutions. Suppose his bees were just outside of the corporation; if there was anything inside of that corporation to work on, how long would it take the bees to get to it? The bee is a privileged character, and if there are any sweets to be gathered, it will have them, or will work very hard to secure them. I have received a package of the Chapman honey-plant.

A Pocket Dictionary will be presented for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now so CHEAP that no one can afford to do without it.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

Honey and Beeswax Market.

DETROIT.

HONEY.—Best white in one-pound sections, 15c. Extracted, 9¢@10c. Large supply and few sales.
 BEESWAX.—23¢@24c.
 Apr. 24. M. H. HUNT, Bell Branch, Mich.

NEW YORK.

HONEY.—We quote: Fancy white in 1-lb. sections, 13¢@15c.; the same in 2-lbs., 10¢@11c.; buck-wheat 1-lb., 10c.; 2-lbs., 9c. Market dull.
 BEESWAX.—24c.
 Apr. 7. MCCAUL & HILDRETH BROS.,
 28 & 30 W. Broadway, near Duane St.

CHICAGO.

HONEY.—Prices range from 15¢@16c. for best one-lb. sections; other grades are low, at lower prices. Extracted, 7¢@8c. Light demand, and supply larger than usual at this season of the year.
 BEESWAX.—23c. R. A. BURNETT,
 May 1. 161 South Water St.

NEW YORK.

HONEY.—We quote: Fancy white 1-lb. sections, 14¢@15c.; fancy 2-lbs., 12c. Lower grades 1¢@2c. per lb. less. Buckwheat 1-lb., 10¢@10½c.; 2-lbs., 9¢@9½c. Extracted, white, 7¢@7½c.; dark, 5¢@6c.
 Mar. 19. F. G. STROHMEYER & CO., 122 Water St.

CHICAGO.

HONEY.—We quote: Fancy white clover 1-lb., 16¢@17c.; 2-lbs., 15¢@16c. Dark is slow sale at almost any price. Extracted is scarce, and sells at 7¢@10c.
 BEESWAX.—23c.
 Mar. 13. S. T. FISH & CO., 189 S. Water St.

CINCINNATI.

HONEY.—We quote extracted at 4¢@9c. per lb., for which demand is good. Comb honey, 14¢@17c.—Demand slow.
 BEESWAX.—Demand is good—20¢@22c. per lb. for good to choice yellow, on arrival.
 Apr. 23. C. F. MUTH & SON, Freeman & Central Av.

MILWAUKEE.

HONEY.—Choice white one-lb. sections, 16¢@17c.; 2-lbs., 15¢@16c.; 3-lbs., 14c. Extracted, white in kegs and ¼-barrels, 8 to 9¢; in tin and pails, 9¢@10c.; dark in barrels and kegs, 5¢@7c. Market fair.
 BEESWAX.—22¢@25c.
 Apr. 23. A. V. BISHOP, 142 W. Water St.

DENVER.

HONEY.—Best white 1-lb. sections, 17¢@19c.; 2-lb. sections, 15¢@17c. Extracted, 7¢@10c.
 BEESWAX.—20¢@23c.
 Mar. 1. J. M. CLARK & CO., 1409 Fifteenth St.

KANSAS CITY.

HONEY.—We quote: Choice white 2-lb. sections, 17¢@18c.; dark 2-lbs., 14¢@15c.; choice white 1-lb., 18 to 20 cts.; dark 1-lb., 15¢@16c. White extracted, 7¢@8c.; dark, 5¢@6c. Demand is slow. White extracted is firm when in 60-lb. tin cans.
 BEESWAX.—2 to 2½c.
 Mar. 29. HAMBLIN & BEARSS, 514 Walnut St.

BOSTON.

HONEY.—We quote: 1-lb. sections, 16¢@17c.; 2-lb. sections, 14¢@16c. Extracted, 8¢@9c. The market is not very brisk and sales are slow.
 BEESWAX.—25 cts. per lb.
 Mar. 24. BLAKE & KILEY, 57 Chatham Street.

SAN FRANCISCO.

HONEY.—We quote: White to extra, 10¢@17c.; amber, 9¢@14c. Extracted, white liquid, 7¢@7½c.; amber and candied, 8¢@7c. Market quiet.
 BEESWAX.—18¢@21c.
 Mar. 20. SCHACHT & LEMCKE, 122-124 Davis St.

KANSAS CITY.

HONEY.—We quote: White 1-lb., glassed, 16¢@17c.; unglazed, 17¢@18c.; and dark 1-lb., glassed, 15c.; unglazed, 16c.; white 2-lb., glassed, 18c.; unglazed 2-lb., 17c. California white 2-lb., 17c. California extracted in 60-lb. cans, 8c. Market quiet and receipts are larger.
 BEESWAX.—No. 1, 20c.; No. 2, 18c.
 Mar. 19. CLEMONS, CLOON & CO., cor 4th & Walnut.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Sweet, or Melilot, Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices: —Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 18 cents per pound for bag and postage.

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, \$1.00 per 100, or \$8.50 per 1,000.

The Bee-Keepers' Review

If ever a bee-paper was started with a place ready and waiting for it, the REVIEW has had that luck. The first number was welcomed before it was read, and when it was read, it took its place easily and at once among the things that justify their own existence, and need no probation before being fully and finally accepted. It is an imitation of none of its cotemporaries, and it is on a level with the best of them, both in the merit of its general scheme, and in typographical neatness. This, we believe, will be the verdict of the intelligent bee-keeping public, and, as proof of the correctness of this belief, we append the following, which we select from a large number of similar congratulations:

I am greatly pleased with the REVIEW, and think it very creditable. It must take the lead with intelligent bee-keepers.—E. L. TAYLOR, Lapew, Mich.

You have made an excellent start; and I am very favorably impressed with your plan of making each issue a special number.—E. M. HAYBURST, Kansas City, Mo.

From a practical standpoint you are well qualified to make the venture a success. I hope you may do well financially, and establish an enviable reputation for editorial ability, as you have already as a writer on apicultural topics.—EUGENE SECOR, Forest City, Iowa.

REVIEW No. 1 lies before me, and I must say it is like a chestnut—brimful of meat, properly cooked, and served in first-class palatable order. Before reading it I thought, "What can friend Hutchinson say that has not already been said by others?" But you have given us a feast of fat things. If the REVIEW keeps up to the standard of No. 1, it has a bright future before it.—W. E. CLARK, Oriskany, N. Y.

I like the REVIEW in every respect. There is more in it than in any other bee-paper I have ever seen; that is, more real meat, or what is called meat, as I see it. The whole matter, including advertisements, is tastefully arranged. I cannot conceive who would not instantly subscribe at the price, after seeing a copy.—JAMES HEDDON, Dowagiac, Mich.

I congratulate you upon the excellence of the REVIEW. It will be an honor to the craft, and to our State, if you maintain it at the starting pitch—and I do not doubt but you will. At first I was sorry. What we want is fewer, better papers. But I forgot for the moment who was at the helm. I believe you will succeed, and if you do not go to the top, you will abide well up.—A. J. COOK, Agricultural College, Mich.

A sample copy of the REVIEW is at hand, and I was agreeably surprised, to say the least. As a rule, periodicals in starting furnish at first a sickly, discouraging appearance that stamps failure all over them. What a contrast in beholding the REVIEW! Why, friend Hutchinson, the first glance at it shows its success. And then its contents—the very cream of advanced bee-literature. I read it through before laying it out of my hand.—E. KRETCHMER, Coburg, Iowa.

Four numbers of the REVIEW have been issued. The January number discusses "Disturbing Bees in Winter;" the February issue is devoted to "Temperature," as applied to bee-repositories; the March number takes up the subject of "Planting for Honey;" while "Spring Management" is the special topic of the April issue. The special subject of the May REVIEW will be "Hiving Bees."

Besides these special discussions, which are carried on by the best bee-keepers of the country, there are several pages in each issue devoted to short, sharp, concise editorials upon current apicultural topics. An exhaustive review of Mr. Cheshire's book, "Bees and Bee-Keeping, Vol. II," is begun in the March REVIEW, and will be finished in the May number. If you wish for the cream of this great work, read these three numbers.

Price of the REVIEW is 50 cents a year. Samples cheerfully sent upon application.

The Production of Comb Honey,
 A neat little Book of 45 pages, price 25 cents. THE REVIEW and this book for 65 cents. Stamps taken, either U. S. or Canadian.

Address, **W. Z. HUTCHINSON,**
 18A4t 613 Wood St., FLINT, MICHIGAN.
 Mention the American Bee Journal.

WANTED,

Beeswax.—We will pay 20 cents per pound, delivered here, for Yellow Beeswax. To avoid mistakes, the name of the shipper should always be on each package.

THOS. G. NEWMAN & SON,
 923 & 925 West Madison St., - CHICAGO, ILLS.

THOMAS G. NEWMAN,
EDITOR.

Vol. XXIV. May 16, 1888. No. 20.

EDITORIAL BUZZINGS.

The Night is mother of the day,
The Winter of the Spring,
And ever upon old Decay
The greenest mosses cling.
Behind the cloud the starlight lurks,
Through showers the sunbeams fall;
For God, who loveth all his works,
Has left his Hope with all.—Whittier.

Hives, Sections, comb foundation, and everything needed should be obtained at once, ready for use at a moment's notice.

Some very Sensible Advice is contained in the following paragraph which is taken from one of our agricultural exchanges:

Keep all colonies strong. Provide abundant bee-pasturage. Handle bees carefully and intelligently. Study up bee-keeping thoroughly. Every one should realize how little is really known. Bee-keeping and honey production does not impoverish farms or soil. Bee-keeping can be successfully carried on by women. The best hive is the one you know how to handle best. The best bees are the ones that have best care and feed. Begin small and enlarge cautiously. One or two failures give more real knowledge than three or four successes.

E. T. Flanagan, Bellville, Ills., sent us his catalogue for 1888—12 pages—Bees, Supplies, Carp, Seeds, and Small Fruit.

Attention is called to the first two excellent paragraphs of Dr. Tiuker's article on page 330. That is the only way discussions should be made. And yet, strange to say, since this JOURNAL was ready for the press, we have an abusive letter from a correspondent, for omitting his offensive personalities.

Nature's Way.—We have just received a small pamphlet published by E. H. Cook, Andover, Conn., entitled, "G. M. Doolittle's Method of Rearing Queens," which is called "The nearest approach to Nature's way yet devised." It contains 30 small pages, is neatly printed, but poorly bound, and is sold at 15 cents. On the importance of good queens, Mr. Doolittle says:

In no one thing in bee-keeping does good quality count for as much, as it does with the queen or mother-bee. Upon her centers the whole of bee-keeping. It would be impossible to secure a pound of honey without the queen. While a poor queen is better than none, yet it must be patent to all that the better the queen is, the more workers we get; and the more workers we have at the right time the more money we obtain.

When we come to fully realize the great value of a *really good queen*, one that you can get to lay from 3,000 to 4,000 eggs a day, six or more weeks before the honey-harvest, so as to have our force of laborers when the field is ripe for the harvest, we shall hear of less queens which "cost the apiarist nothing."

Good queens cost something, and are valuable in proportion to the pains taken in rearing them. Hoping that the time is not far distant when all will take more pains in this part of our fascinating pursuit. I thought it might not be a bad idea at this time to give a plain statement of some of the plans I use to procure queens for my own use; always aiming each year to excel anything done in the past. In doing this it shall be my aim to make all as plain as possible, so that even the novice can understand the how and why of it.

Concerning the advantages of the method described, Mr. Doolittle remarks thus:

This mode of preparing the colony so that they will be ready with plenty of prepared queen-food, is ahead of everything I have ever tried. It will be seen that an hour before they were feeding thousands of larvæ, and several queen-cells, when, all at once, they are obliged to hold the accumulating chyme, and take on an anxiety for anything to feed as a queen, that is almost as strong as their existence. They are now supplied with from 15 to 20 little larvæ, all cradled in queen-cells, upon which they bestow all the provision and caresses they were before doing for a whole hive; and let me assure you if good queens can be reared outside of natural swarming, such queens as will hatch out of these cells are the *good ones*.

It may be obtained at this office at the publisher's price.

Apicultural Experiments.—Prof. A. J. Cook, of the Michigan Agricultural College, remarks thus in the *American Apiculturist* concerning his intended experiments:

Under the new Hatch Bill I am going to undertake two new lines of investigation looking to the advancement of bee-keeping. First, I shall select and breed with great care to secure a better bee. I have been at this for some years, using Syrian and Carniolan stock. The other is to experiment to see whether it will pay to plant for bees. If so, what?

With Rain plentifully distributed over the country, warm sunshine interspersed between the showers, and profuse fruit bloom with other early blossoms, a good honey harvest may very naturally be expected.

Many Compliments have been received concerning the excellent typographical appearance of the AMERICAN BEE JOURNAL since the new volume commenced last January. Much of the credit is due to the exquisite face, finish and general excellence of the body type, which was made expressly for the BEE JOURNAL by Barubart Brothers & Spindler, manufacturers of the celebrated "Superior copper-mixed type," at their type foundry at 115 and 117 Fifth Avenue, Chicago. We have dealt with this firm for 20 years, and cheerfully commend them to our "brother typos," for their business methods are the very essence of integrity and honor, and their make of type excellent and durable. Our "old dress" was made by them, and after using it regularly for seven years, one bee-publisher remarked incidentally that it still appeared so well that he did not see the necessity for our buying new type. This was a very flattering remark to our type founders and printers.

The Nebraska State Fair will be held at Lincoln from Sept. 7 to 14, 1888. There are \$30,000 offered in premiums. Class L. is devoted to bees, honey, and apiary goods, and E. Whitcomb, of Friend, Nebr., is superintendent. Here is the list of premiums in this department:

	1st	2d
	Pr.	Pr.
Best comb honey, not less than 20 pounds, crated and in single comb sections, weighing not more than 2 lbs. each.	\$10	\$5
Best gallon of extracted honey.	5	3
The above to be limited to competitors producing their own honey in Nebraska during the year 1888.		
Best colony of bees.	\$10	\$5
" 20 lbs. of granulated honey.	5	3
" and largest display by any one, including bees, extracted honey, apiary supplies.	20	10
The test for colonies shall be the net gain in stores, and will be determined by the weight of honey that can be extracted from the combs of the hive. Each colony shall be weighed, inspected, and sealed at the commencement of the trial, and extracted as above stated at its close. The test of colonies shall end on Wednesday morning of the Fair, and begin on Wednesday morning two weeks previous. No caging of queens will be allowed, or any other practice by which a colony is put out of a normal condition. The bees of each colony shall be the sole progeny of the queen therein, and no colony shall be entitled to compete for a premium not showing, when handled, the ordinary amiability of pure Italians.		
No colony shall be admitted coming from any locality in which there is reason to suspect the presence of foul brood.		
The test for colonies shall end on Tuesday of the State Fair.		
Best exhibit of brood and surplus comb foundation full, to partly drawn.	\$5	\$2
Best exhibit of apiarian implements and supplies.	10	5
Best display of honey in marketable shape.	5	2
Best candied honey.	5	3

These premiums amount to \$113 in all. Full particulars, blanks, etc., can be obtained of the superintendent.

Frank Leslie's Sunday Magazine for June is a number timely to the season, and two of its articles relate to Lake Champlain. Both are finely and fully illustrated, and they make one long to go thither. Lake George has so long monopolized attention that it is an agreeable change to find Lake Champlain receiving the recognition its beauties merit. Dr. Talmage contributes a capital article on "Woman her own Defense." The shorter articles are numerous as usual, and very interesting. The whole number is valuable.

GLEAMS OF NEWS.

Extracted Honey in California seems to be a non-paying production. The excessive freights when exporting it to Australia and Europe take away all the profits, and the production of the past two years has been at a loss. The San Bernardino *Times* of a late date contains the following characteristic article on the subject, to which we invite attention:

The fact cannot be denied that the bee-keepers of California have for several years past been having a pretty hard time of it. We have seen prices go down gradually, year after year, until now they are so low that there is absolutely no profit in the business, at least so far as the production of the extracted article is concerned. And the decline in price has seemed to have very little reference to the amount produced. Naturally, one would suppose that in seasons of short crops prices would become correspondingly stimulated. But such has not been the case. The price has gradually fallen until 2 or 3 cents a pound is about the limit of the price received by the producer, and one does not need to know that at such absurdly low prices there is no profit for the bee-keeper.

There seems to be some insuperable objection among the majority of people against the use of extracted honey. When that article was first put upon the market it was thought possible, and even probable, that its use might become general, and that so pure and healthful an article would quickly take the place of the impure and adulterated molasses, syrups and "drips" which are so largely consumed. Especially was it thought that this would be done when the price for the pure honey was put at a lower figure than those articles could be sold for. But for some reason it has proven all but hopeless to attempt to persuade people generally to become consumers of honey. As a consequence the price has, as already been stated, reached a very low point, both here and in the East, though it was much longer in getting down there than on the Pacific Coast.

Now, bee-keepers all over the country are seeking some method by which to make their business profitable. Many of the most experienced bee-keepers of the East have decided that there is nothing to be done except to put a stop to the production of extracted honey, and devote their entire time to the comb.

It is now claimed to have been a great mistake to have put the extracted honey at so low a price compared with the comb; but the damage has been done, and it was based upon the idea that the bees could make about 3 pounds of extracted honey to 1 pound of comb honey, and that therefore the relative prices should be about in the same proportion. But this does not work very well in practice, for while extracted honey at 3 cents a pound, no matter in how great quantity it is produced, does not yield a profit, comb honey at 8 to 10 cents pays very well indeed.

As a consequence the advice to stop the production of the extracted article seems to be well founded. It is certainly far better to produce two tons of comb honey that will give a profit of 2 cents a pound, than to produce six tons of the extracted that has to be sold at a loss.

The fact is that the honey-producers of California pushed the sale of their liquid product so extensively that the great markets of the Eastern States were crowded with it, and that brought down the price, not only of California honey but also of that

produced in the Middle and Eastern States. It also glutted the markets to such an extent that the demand for liquid honey was more than met, and sales were exceedingly slow. There was evidently an over-production on the Pacific Coast, with only an ordinary supply and demand in the older States.

Wisdom would seem to dictate that, instead of discouraging the production of extracted honey, bee-keepers should try to find avenues for its consumption. These have been greatly enlarged during the past decade, and may be doubled within the coming few years. Tons upon tons are used every year in the following manner:

It is used in the manufacture of confectionery, cakes and pastry, soda-water, mead and metheglin, jellies and jams, honey-wines and liquors, liquorice, honey egg-foam, and honey-vinegar, medicinal preparations, syrups, ointments and salves, popcorn balls and harvest drinks.

It is also used in canning and preserving fruit in its natural state, curing hams and meat of various kinds.

In making printers' rollers it forms a principal ingredient, also in the manufacture of beer, ale and tobacco, it holds a prominent place.

In making comb foundation it is used considerably.

In compounding medicines of all kinds, it has for ages held an important place; while as an article of food it has been esteemed as one of the principal delicacies for many centuries.

It will be well for all honey-producers to see if they cannot find out *new* avenues for the use of honey. In this way we can prevent a decline in prices when the future honey crops will be large.

The extracting of honey was not a mistake—but it might have been a mistake to put the price at less than that in the comb.

To-day honey out of the comb is retailing in this city at 15 cents per pound, and the demand is very fair. The great error was made years ago by bee-keepers themselves, by lively competition, to break down the prices, and it is very difficult now to boom it, even when the crop is short.

The Inter-State law is just what has killed the honey-production on the Pacific Coast, by increasing the freight tariff so much that it takes all the honey is worth to bring it to the Eastern markets.

But what is disaster to them is a blessing to apiarists in the Middle and Eastern States. By keeping Californian honey out of the latter markets enhances both the price and demand of the Eastern product. This is another illustration of the old adage, that "It is an ill wind that blows no one any good."

Carniolan Queens.—S. W. Morrison, M. D., of Oxford, Pa., has sent us a description of them, their progeny, and good qualities, with full directions for introducing them to alien colonies. It will be sent free by him to all inquirers.

Experiments.—Mr. C. H. Dibbern, of Milan, Ills., gives these graphic descriptions in the *Plowman* of some of his experiments in "the days of yore:"

While I am writing of experiments, I will say that my ideas have not always proved so successful. Many years ago, when I used surplus boxes holding 20 lbs., without bottoms, I was greatly puzzled as to how I should take them off without getting stung. I did not then understand the best use to make of smoke, and a good smoker was unknown. Often I would pry off the box and then try to blow smoke on the bees from a roll of rags, but often just at the critical time the fire would go out, and the bees would make it so hot for me that I was glad to let them alone, honey and all.

Finally an idea struck me, that if I would take two sheets of tin I could slip it under the box double, and then divide between the sheets, and remove the box of honey by holding on the tin bottom to keep the bees in and leave the other sheet on the hive to keep those in the hive down. This worked very well, till I tried to lift the box off, when the tin warped, letting out a board of infuriated bees, which immediately commenced a tour of conquest up my shirt sleeves, causing me to beat an inglorious retreat to the house. The bees in the main hive were soon "on their ear," as well as those in the box, and it was not till dark that any of us dared to venture out of the house. Even the chickens and dogs had to "climb" when they came too near the hive.

After dark I managed somehow to carry the hive to the cellar, allowing the bees to fly out through an open window afterwards. It was quite awhile, however, before I could go anywhere near that colony without them "going for me," and they "bummed" around the house for a week.

Another experiment I tried about the same time was a "new method" of hiving swarms that lit high up on a tall tree. I had such a tree that was the pest of my life. Every time a swarm would issue they would go right for the top branches of that tree, and perhaps before I could secure them 3 or 4 swarms would cluster in the same branch. It took some time to climb the tree, saw off limbs and let down the bees, and it was usually hot and tiresome work. Finally the idea struck me that by getting a light pole some 20 feet long, and nailing on a hook and a muslin bag, I could secure the most of these swarms by giving the branch on which they might hang, a sharp rap with the end of the pole, and catching the bees in my sack, then gently let them down, and shake them into my hive.

How strange I had not thought of that before! Now I fondly imagined that all my trouble, on this point at least, was at an end. A trial of my great invention, however, soon shattered my hopes, when I found that the first rap on the limb with my swarm-catcher landed a half dozen bees inside of my shirt collar, and oh! how hot they felt.

The climax was reached, however, when the weight of the bees brought down the whole affair with a crash, and killing many bees. This made them furious, and the way they "went for me," compelled me to seek shelter in a neighboring shed. Even there they tried to get through knot holes to get at me. It was a long time before I got that colony settled in a hive.

It is needless to say that I have ever since regarded any pole arrangement with suspicion. At any rate a great coolness soon settled over that invention, and I have never since been seen going around the apiary with a long pole with a bag at the end.

Give a Copy of "Honey as Food and Medicine" to every one who buys a package of honey. It will sell lots of it.

That Arkadelphia Case, etc.—Messrs. Harmon & Skinner, Zenos, Arizona, on April 25, 1888, write :

It was with feelings of joy that we read of that Mayor and aldermen being kicked out of office in Arkadelphia. It should not stop at that, but they should pay Mr. Z. A. Clark the damage and expense to which they have put him. We are ready to help the Bee-Keepers' Union if they need any means. There have been some threats made here lately, of passing a city ordinance to oust the bees from the city limits. We hope there will be no one so unwise and foolish, as to start any such thing here ; but it seems as if there is a craze on the subject of bees. We hope that Mr. Clark will receive full satisfaction.

Our bees are doing well this season. We extracted honey two weeks ago, and took a little over 26 pounds per colony, from 70 colonies. We use the Heddon 8-frame Langstroth hive, and like that size of hive. We have 2 colonies of hybrid bees, from each of which we took 20 gallons of extracted honey in one season. The honey was extracted seven times in the season.

The Bee-Keepers' Union will have use for all the means within reach next July, for it has decided to leave no stone unturned to win the suit against Mr. Clark in Arkadelphia. The very best legal talent has been employed, and every inch of ground will be hotly contested. The ousting of the Mayor and councilmen, and the election of men of reason only guarantees for the future. The suit, having been appealed to the upper court, will have to be fought just the same.

A Sugar-Producing Tree.—O. O. Poppleton, of Apartado 278, Havana, Cuba, writes as follows :

On page 164 is a clipping from the *Grocers' Criterion*, about a "Sugar-producing tree in India." Judging from the part of the description about the yield of sugar in the West Indies, the entire thing can be safely judged as being on a par with Wiley's "scientific pleasantries"—in plain English, as a regular, old-fashioned lie.

I have taken some trouble to ascertain what the average yield of sugar is here in Cuba, and I am told by those in a position to be well posted, that new land will yield from 6,000 to 6,300 pounds per acre ; and old land from 3,600 to 4,000 pounds, instead of only 400 pounds per $1\frac{1}{4}$ acres, as the *Criterion* has it.

Importers in Havana pay planters from 2 to 3 cents per pound for sugar delivered in the city ; so the reported yield of but little over 300 pounds per acre, would not begin to pay for seed and rent of land, saying nothing about the immense expense for labor and machinery. I wish there was some way that Cuban sugar could be placed on the American retail market, without its passing through any process in getting there. It would largely replace other grades of sugar, on account of its great richness and absolute purity.

The selection was sent to us by Mr. Lewis Proxmire, of Mount Union, Pa., and he cut it out of the *Grocers' Criterion*. In reply to his question, we replied that we knew nothing more of the tree described than was contained in the article, and our thanks are tendered to Mr. O. O. Poppleton, who is now in Cuba, for stating his opinion of the article. It seems it is another of those disgusting lies which are perpetrated as "scientific pleasantries !"

Chapman Honey-Plant Seed, etc.—Leroy Highbarger, Leaf River, Ills., on April 27, 1888, writes :

In reply to Mr. A. Fiddes' request on page 275, I would say that I have received a package of the Chapman honey-plant seed, through our Congressman. When I wrote him to get it for me, he replied by return mail, that he would attend to it, and so it came right along. Whenever I want seeds from the Agricultural Department at Washington, by writing to him I get them. I shall not plant the seed, as it is not a hardy plant, and will not stand the winters in northern Illinois. I raised about 400 plants last year, and to-day I have between 40 and 50 left. What I did save were under a snow-drift until April 1. Every plant that was not protected is dead. If any others raised plants from it last season, I should like to hear from them, and how they have wintered.

Wintering bees last winter in this (Ogle) county was a failure. I have taken considerable pains in investigating, and I find a loss of at least 50 per cent., from that great scourge—diarrhea. The colonies to which I had fed sugar syrup fared fully as badly as those that had natural stores.

John B. Lindle, of Muscatine, Iowa, on April 28, 1888, answers the same question thus :

I have received some of the Chapman honey-plant seed, and it was planted a month ago ; it is up, and has been cultivated once. There would be less complaints if orders were sent early, and not expecting it sent by return mail. I do not know what force of clerks are kept in the Commissioner's office, but it would require thousands to fill all orders on such short notice.

Among others who also report the receipt of this seed are C. W. M. Burroughs, Hillsborough, N. J., who got twice as much as he needed, and liberally divided with a neighboring apiarist. F. Wilcox, Maunston, Wis. ; L. B. Gilmore, Blooming Valley, Pa. ; G. H. Knickerbocker, Pine Plains, N. Y., etc.

Mr. Fiddes complained of not receiving his seed, and intimated that none may have been sent out. It is pleasing to know that "our public servants" at Washington have done their duty in this matter, and as Mr. Fiddes did not receive his, it is pretty evident that his letter was lost, or the seed miscarried. We are very glad that the question was asked, and answered so satisfactorily and numerously.

Removing Bees from the Cellar.

—B. T. Davenport, Aurorville, Wis., on April 28, 1888, writes :

I took the first of my bees from the cellar on April 24, about two weeks later than they have remained in the cellar for 13 years. It was too cold prior to that time to take them out. The weather turned very warm on April 25, and I noticed the first pollen. The following day was fairly hot, the mercury reaching 82° in the shade, which brought willows out very rapidly ; and on the two following days, bees gathered honey as fast from that source as I ever saw them gather it from clover. But to-day their work is stopped by a cold, northeastern rain-storm.

My 112 colonies were put into the cellar the last of November, 1887, making their confinement five months. They have wintered quite poorly, and I think I shall lose one-third or more, depending upon the weather from now on.

I have learned one of the best and most practical lessons since I have been engaged

in bee-keeping. It reminds me of a passage of scripture, "Ever learning, and never able to come to a knowledge of the truth." I carried out a great many colonies during the middle of the day, on two days, while the mercury was 82° in the shade, and they mixed up very badly, all pouring upon two other hives until they were covered, and strong colonies were almost entirely depopulated ; while those that I carried out after dark, and on the first two days while it was cool, came out slowly, marked their location, and returned to their respective hives. This was my first experience in putting out bees during such hot weather ; and of late years I have neglected to number the hives, so that they are not placed on the old stand, and I never had any trouble of this kind before.

Numbering the hives is a very important item when cellar-wintering is practiced, so that they may be placed on the same stands occupied during the previous season. The old bees cannot be spared thus early without materially interfering with the season's operations ; and there is danger of their being lost by entering the wrong hives.

INTERROGATORIES.

Wax Secretion—Moldy Combs.—J. B., of Ohio, asks the following questions :

1. Is the secretion of wax voluntary, or an involuntary act with bees ?
2. I have a great many frames of empty combs, and some of it is pretty moldy. What would be the best way to use them ? Would it be best to hive swarms on them, make nuclei and use them, or render them into beeswax, and have foundation made from it ?

1. We do not know whether it is always voluntary or not ; but we think that it is, as a rule.

2. If the combs are otherwise good, put them into or over strong colonies, which will soon clean them. Do not hive swarms on them, nor give them to nuclei.

Sprinkling Swarms in Trees.—Mrs. Jas. S. Stapler, of Tahlequah, Indian Territory, asks :

Is there any arrangement by which a lady could sprinkle bees that have settled in the top of a tree, in case where one has to wait for a man to hive them ? Or, are there any other means of retaining the bees ?

Yes, the Whitman fountain pump is the best thing that we have used. With it you can hold a swarm in cluster for an indefinite length of time, by sprinkling them often—every 10 or 15 minutes if the air is hot and dry. Be careful not to administer so much water at any one time as to break down the cluster. Experience will teach you.

New Catalogues for 1888 are on our desk, from the following persons :

Geo. H. Knickerbocker, Pine Plains, N. Y.,—20 pages—Queens and Bees.

M. E. Mason, Andover, O.,—8 pages—Bee-Keepers' Supplies.

QUERIES REPLIES.

Good Location for Successful Bee-Keeping.

Written for the American Bee Journal

Query 542.—Given, the latitude of Cincinnati creek and river bottoms, with clay hills as high as 200 feet, country well-farmed, white clover the principal source of honey, many lawns and much fruit-bloom, some melilot in the bottoms, and golden-rod and aster on the hills (no buckwheat and no basswood), and a good market. Would one who is qualified and loves the work, be apt to succeed as a specialist in the production of honey?—Southern Ohio.

Yes.—M. MAHIN.

Yes.—C. C. MILLER.

I think that he would.—MRS. L. HARRISON.

Yes, if he is qualified.—R. L. TAYLOR.

He would be apt to succeed.—J. P. H. BROWN.

Yes. We are in just such a country.—DADANT & SON.

I have no doubt that the locality would be a good one.—P. L. VIALON.

Most assuredly, if all you state be true.—J. M. HAMBAUGH.

I can see no reason why he could not.—G. M. DOOLITTLE.

Others have done so, and there is no reason why you should not.—J. E. POND.

I think that such a locality will average with the honey-producing States.—EUGENE SECOR.

I think so. If basswood could be added, it would be very desirable.—A. J. COOK.

Yes, if there is plenty of clover, and it yields plenty of honey. As it was here (northwestern Ohio) last season, the bees would starve.—A. B. MASON.

There are points along the rich river bottoms near Cincinnati where a specialist should succeed well.—G. L. TINKER.

I should be a little afraid of your location, but if you have plenty of nectar for the bees, you will succeed if you have the necessary qualification, and love the work.—H. D. CUTTING.

This depends upon many things, and is a difficult question to answer. If the person has a love for the business, is industrious and economical, and has ordinary business ability, he would probably succeed.—C. H. DIBBERN.

I rather think so. But I would sow sweet clover and pleurisy-root as I had opportunity, and coax the farmers to sow Alsike clover. I sowed three years ago, 40 acres of mammoth or peavine clover, and the bees frequent it as much as any plant I ever saw.—J. M. SHUCK.

I should call the location a fairly good one. It is a rare thing that any location combines all the desirable qualities in one. I would not fear to undertake it, if I was looking for a location, and other things suited me.—G. W. DEMAREE.

Yes; such a location and such a person as is described should make a success of bee-keeping.—THE EDITOR.

Marking the Hive of a Mating Queen.

Written for the American Bee Journal

Query 543.—The hives front east, are 4½ feet apart from centre to centre in the rows, and the rows are 8½ feet apart. If you find a queenless colony, and have no fertile queen to give it, but must give a caged cell or virgin queen, would you give the colony a new location, so as to give it more room in order that the queen returning from her mating-trip may be sure to enter her own hive?—Apiarist.

No.—M. MAHIN.

No.—A. J. COOK.

No.—A. B. MASON.

No, I should take the risk.—R. L. TAYLOR.

No; the distance is as far as needed.—P. L. VIALON.

No. I would lay down a wide board in front of the hive, or in some other way make it look a little different from the others, when you should have no trouble.—G. M. DOOLITTLE.

I would not. There is very little risk of the queen mistaking her own hive.—MRS. L. HARRISON.

If you want to incur no risks, it would be better to remove the hives for the time being, to a new location not crowded.—J. P. H. BROWN.

No, but I would move the hives together in pairs, and thus double the chance of the young queen finding the right hive.—C. C. MILLER.

I should not change the location at all. The chance of losing the queen is so small that the trouble of so doing will not pay.—J. E. POND.

No. Lean a board or some other prominent object against the hive, about the time the queen will hatch, to make it easily distinguishable from the others.—EUGENE SECOR.

Place a twig of green leaves either side of the entrance, and the young queen will not miss her hive.—G. L. TINKER.

I would let the hive stand right where it is. Entering the wrong hive is not what causes losses in the mating of young queens. I have spent hours, days and weeks in observing these matters, and no young queen ever makes the mistake of entering the wrong hive unless two young queens chance to fly at the same time from

the adjoining hives. Young queens return home guided by the signal "hung out" by her own bees. The loss is caused by the unaccountable disposition of the bees to "ball" their young queens.—G. W. DEMAREE.

By no means; but place some marks about the hive entirely different from any in the yard, that she may not fail to know on her return from her mating trip.—J. M. HAMBAUGH.

No. It is well to place a wide board on each side of the hive, projecting a foot in front, to enable such a queen in finding the right hive, they otherwise being similar.—C. H. DIBBERN.

No, she will be very apt to get home all right. The best plan to aid her is to place something over or against her hive, that plainly designates it from all others. Do not move it.—JAMES HEDDON.

No; but I would put an old carpet or an old coat over the hive for several days, and the queen will find the right hive, as far as location is concerned.—H. D. CUTTING.

It is not necessary to change the hive. Mark it in some way so that the returning queen will distinguish it from the others. Lean a board against the front of the hive, or lay a brick or an old shoe on the alighting-board; dozens of ways may be thought of, and all would be good.—J. M. SHUCK.

No. It is unnecessary to move the hive; but it might be well to place a bush or board slanting over the entrance, or something that would be a distinguishing object on the top of the hive.—THE EDITOR.

CONVENTION NOTICES.

The next meeting of the N. W. Ills. and S. W. Wis. Bee-Keepers' Association will be held in Rockton, Ills., May 22, 1888. D. A. FULLER, Sec.

The spring meeting of the Wisconsin Lake Shore Center Bee-Keepers' Association will be held on May 31, 1888, in Mueller's Hall, at Kiel, Wis. FERD. ZASTROW, Sec.

The Hardin County Bee-Keepers' Association will meet at the Court House in Eldora, Iowa, on the second Saturday in each month, at noon (12 o'clock), until further notice. J. W. BUCHANAN, Sec.

The Linwood Bee-Keepers' Association will meet at Eau Claire, Dunn Co., Wis., at 10 a. m., on Friday, May 18, 1888. A fine programme has been arranged, and an excellent time is promised. All are cordially invited. B. J. THOMPSON, Sec.

Always Mention your Post-Office, County and State when writing to this office. No matter where you may happen to be for the hour when actually writing—never mention anything but your permanent address. To do otherwise leads to confusion, unless you desire your address changed. In that case state the old as well as the new address.

CORRESPONDENCE.

CHARMING MAY.

Written for the American Bee Journal
BY J. F. LATHAM.

All nature hails bright, bonny May!
A new-born verdure crowns the spray,
Bursting buds, and springing flowers;
Balmy zephyrs, gentle showers,
Following in the merry train
Of the feathered songsters' strain.

The busy bee, with joyous hum,
Revels amid the willows' bloom,
Culling with care the choicest food,
Home bears it to her growing brood;
While perched aloft, with sportive lay,
Rod red-breast chants the charms of May.

The blue-bird, too, on listless wing,
Lends, by its note, a charm to spring;
From thicket dense, th' alluring spell
Responds t' the music in the dell
With countless throats, in sweet refrain,
A prelude of the summer's reign.

With heedless dash, the foaming rills,
In restless leaps, rush down the hills.
Or, babbling through the meadow wide,
To broader channels yield their tide,
And seem to lend, as zephyrs play
In glist'ning sheen, a charm to May.

At morn and eve the blushing clouds,
No longer frown on winter's shrouds;
The vernal sun, with smiling grace,
Betokens smiles from Nature's face
In countless hues, on wood and plain,
Proclaiming—Spring has come again.
West Cumberland, Me.

BROOD-CHAMBERS.

How I Arrived at the Size of the Brood-Chamber I Use.

Written for the American Bee Journal
BY G. M. DOOLITTLE.

Seeing that some still prefer a large brood-chamber, and seem to think that those who prefer a smaller one are just a little "off the track," a few words about how I was led to adopt the smaller brood-chamber might not be amiss, especially to those just starting in the business of bee-keeping.

When I first began to keep bees, all the old bee-keepers about me kept them in hives of 2,000 to 2,200 cubic inches; and knowing that both Langstroth and Quinby also recommended that size to secure the best results, and as I knew naught of the business, I supposed, of course, that they were correct; so I started out with the standard Langstroth hive with a capacity of 2,200 cubic inches in the brood-chamber, and surplus room on top for about 35 pounds of honey.

After using this hive for two seasons, I became convinced that the square form of frame was better adapted to this latitude than the shal-

low Langstroth frame, and so I adopted the Gallup form of the Langstroth frame, which is $10\frac{1}{4} \times 10\frac{1}{4}$ inches square, inside measure. As Gallup used 12 frames, giving about the same sized brood-chamber as Langstroth, I thought that I must, so I started out with 12 frames in each hive. I soon found, however, that as a rule three of the 12 frames would be filled with nice white honey early in the season, and generally remained in the hive the next spring.

After a little thought on the subject, I concluded to place three blanks or division-boards in the place of three frames, two on one end of the hive, and one on the other. To this end I nailed top-bars of frames on boards which were short, the depth of the hive, one-half of an inch at the bottom, and hung them on the rabbets in the place of the three frames.

I had previously found that my best queens would only occupy about 800 square inches of comb with brood, which left about 600 square inches of comb to be filled with honey and pollen, and my hive of 2,200 cubic inches gave me about 1,400 square inches of comb, surface measure. Thus each year I was losing the use of 25 pounds of the choicest honey, for the sake of insuring that the bees had abundance of honey for winter. This honey, placed in boxes, was worth \$5 at least, at the time, while if necessary to feed on account of a smaller brood-chamber, \$2 worth of sugar made into a syrup would provide them as much feed as the \$5 worth of honey would supply.

I tried about 10 colonies with the three boards in the place of three frames of comb, thinking it best not to go contrary to the old veterans on a large scale at first, fearing that they might be right after all. However, I was more than gratified to find that I not only obtained the 25 pounds in boxes, but that these 10 colonies averaged about 50 pounds more honey than those that had their 12 frames of comb. The reason soon became obvious why this was so. As the queen kept the nine frames nearly filled with brood, when the honey harvest came the bees had nowhere to put the honey which they gathered, except in the boxes, so they immediately commenced work in them. With the 12 frames of comb they had room to store quite a quantity of honey in comb already built, and so they were loth to go into the boxes, as they had made their first start below.

Another thing pleased me much, which was this: I found as cold weather approached in the fall, that the bees placed their fall or dark honey in the brood-chamber, as the

queen decreased laying preparatory for winter, and that as a rule the 10 colonies had enough honey for winter, namely, 25 pounds, and as this was not so salable as the white honey, I had made a great gain here also. The next year I placed boards in many more of my hives with like success, and the year after found me with all of my hives having only nine frames in them.

Having established the size of the brood-chamber (as nine Gallup frames) to my satisfaction, I found that unless I used the boards in the new hives that I made, I should not have room enough for boxes (60 pounds capacity being about right) on top of the hive. This set me to thinking of side boxes in connection with the top boxes, and I soon had the hive I have so many times described in the AMERICAN BEE JOURNAL.

These hives give me better results than any before obtained, and I was so well pleased with them that I adopted them altogether when working for comb honey. In 1877 the colonies in them gave me the average yield of over two hundred pounds of comb honey each.

For a few years I was satisfied, and each year gave me good results, but I soon saw that if I was to secure the greatest possible results obtainable, I must stop the rearing of too large a force of bees in the honey harvest, which not only took much of the honey while they were in the larval form, but became useless consumers when hatched, after the honey harvest was over.

To this end I commenced to contract those 9-frame hives to but 5 or 6 frames when hiving swarms, and also the parent colony as soon as the young queen began laying, where they were held until the honey harvest began drawing to a close, so that the queen which now began to cease her extra prolificness did not wish to occupy more room with brood; when the full complement of combs was again given in time to have their winter stores placed in them from the fall blooming flowers.

In the above way I have secured very gratifying results, and I would no more think of returning to a hive of from 2,000 to 2,200 cubic inches, than I would to the box-hives of our forefathers.

While I prefer the Gallup brood-frame to any other, I should not advise any one that had from 30 colonies upward, to change frames, for any of the frames now in use can be so worked as to secure good results, on the plan of small brood-chambers as above given.

Borodino, N. Y.

BEES IN WINTER.

Bees Flying in the Sunshine— Syrian Bees.

Written for the American Bee Journal

BY REV. M. MAHIN, D. D.

In the AMERICAN BEE JOURNAL of April 18, 1888, there are several things upon which I wish to offer a few thoughts and suggestions. The first is,

Bees Flying in the Sunshine.

I have been keeping bees for 19 years, and have always wintered them on the summer stands, because I have had no suitable cellar or repository in which to winter them. I have had them facing all points of the compass, sheltered and unsheltered, shaded and unshaded; and while I have kept no accurate statistics, the general results are pretty well fixed in my mind.

In some winters there has been but little difference in the condition of the bees in hives differently situated, and in others the difference has been marked. In winters in which the losses were great, those colonies have uniformly wintered best which were most fully exposed to the sunshine, and that fronted south. Sometimes a few bees will venture out when the temperature is too low for them to return; but generally they are diseased, and would die in the hives if they did not come out; and it is better for the colony that they perish on the snow than in the hive.

Careful observation has satisfied me that, as a rule, healthy bees will not leave the hives when the temperature is so low that they cannot return in safety; and I am satisfied that I have had colonies benefitted by flying when the temperature was considerably below 50°.

I wish also to speak concerning

Syrian Bees, their Temper, etc.

For six years or more I have kept Syrians and Italians in the same yard, in the same kind of hives, and with the same treatment; and part of the time in nearly equal numbers. I have had some Syrian colonies that were not good honey-gatherers, just as it has been with Italians; but every season I have found the rule to be, that the Syrians had the most honey. They have proved themselves superior both for comb and extracted honey.

Something needs to be said in regard to their temper. This is a question to which I have given careful attention, and my conclusions are that, as a rule—there are exceptions of course—they are more gentle, and easily handled, when honey is coming in plentifully, than are Italians, but more difficult to manage during a

honey-dearth. They will not bear much smoke. A little is an advantage, but if they are heavily dosed with it, they become so angry as to be unmanageable, and to subdue an angry colony with smoke is impossible. They require gentle treatment when the hive is first opened, and then they may be handled as easily as any bees. I have taken all the combs out of a full colony, and put them back again, without using a particle of smoke, and without a bee getting angry.

I have never had the least trouble with them when they swarmed. No bees are more gentle in swarming time. On the whole, I like and prefer the Syrians.

Prospects for the Season.

As far as I know, bees that had honey enough have wintered very well, and are in good condition. They will be, unless we have a very heavy frost, an unusually abundant fruit-bloom, which will give the bees a good start. But in this vicinity the white clover will be a failure. I do not remember ever to have seen it so badly frozen out. At New Castle, where all of my bees are except 2 colonies, the white clover does not seem to be damaged much; and there, and perhaps in the central and southern part of the State generally, the prospect is good for a large honey crop.

Bluffton, Ind., April 19, 1888.

PACKING BEES.

The Winter Preparation of Bees.

Written for the American Bee Journal

BY JNO. A. BUCHANAN.

When I wrote on page 788 of the AMERICAN BEE JOURNAL for 1887, stating that bee-masters of this State do not, for the most part, think that it pays in this latitude to pack bees for winter, or make and use chaff hives, I knew that the statement would draw some comments. The first was from Mr. Rau, on page 11.

He thinks that we have made an "astonishing revelation," and suggests that a house well lathed and plastered would be warmer than it would be without such lining. We will agree on that point, but let us go further and suppose that we had a colony of bees with their combs built to the ceiling in one corner of the plastered room, and another colony so situated in a room with only the siding of the building between the bees and the elements, which would winter best? I firmly believe that the bees with their combs built against the siding, where the sun would so often warm, cheer, and in-

vigorate them, would winter best. How often have we seen reports of colonies of bees being located in a building between the plastering and the siding, where for years they have lived and flourished!

Some years ago my bees had swarmed so much that I ran short of hives to put them in. One day three large swarms clustered together. After looking at their mighty proportions awhile, I concluded to experiment on them, so I got a board 2 feet square, nailed cleats 3 inches wide around it, put a stout staple in each corner, tied ropes to the affair, and hung it to a cross-beam in an old wagon-house, with one edge resting against the weather boarding in which were openings of half an inch, by shrinkage. Before putting this board up, strips of comb the full width of it were waxed to underside, as guides, running towards the openings in the siding. The big swarm was brought on, and made to cluster on the starters.

The bees went to work with a hearty good-will, and although late in the season, the center combs were built down as much as 3 feet, and contained a great abundance of honey for winter. Here we had a veritable curiosity, a powerful colony of bees without a hive, save the old wagon-house, which was about as cold in winter as out-doors.

"What will you do with them in the winter?" was asked by many. "Leave them there," was the reply.

"Will they live there?" I replied. "That is just what I wish to find out."

To my surprise this was as strong a colony at the time of apple bloom in May, as there was in any of my chaff hives.

Many times when there was zero weather during that winter, I would at night take a light out, and by holding it so that the rays would pass up between the combs, the bees could be seen clustered just as any one has seen them through the glass in a hive.

These bees, with the combs, were transferred during fruit-bloom the next spring. There was comb enough to fill 21 Langstroth frames.

Now I just relate this experiment to show that bees are not such tender, frail little creatures as some would have us believe they are. We all have seen bees wintering in boxes or hives so cracked and open as to expose the bees to view all the winter, and yet they would come out in the spring in the very best condition. But though all these things have been seen by hundreds of close observing beekeepers, in almost every State in the Union, they may be, to Mr. Rau, "astonishing revelations."

When I say that I have kept nearly 100 colonies of bees for 30 years, and for the last 15 years one-half of that number; and that they have been wintered in good chaff hives without showing any better record as to swarms and honey than those kept in single-walled hives, it may seem to be a still greater "revelation" to Mr. Rau. Were I constructing a thousand hives for my own use, they would be made of $\frac{3}{4}$ -inch lumber, square joints, with sectional or half-depth upper-stories adapted to the tiering system, either for comb or extracted honey.

Mr. R. says that he wants the "brood-chamber contracted for winter, and 3 or 4 inches of packing on the outside of the hive." I have no patience at all with this idea of packing to be put outside the hive. If we find a colony in the fall that is not strong in bees, it is well to contract with division-boards, filling between these and the hive-walls with chaff or other good material; and over all place a quilt and cushion. This protection is easily put in place, easily removed when not needed, and the hives so arranged are not cumbersome and unsightly. When spring comes, the packing on the south side of the hives should be removed, the combs moved to that side, and the packing all put on the north side. This places the cluster where it receives the benefit of the warmth from the sun, with all its life-giving and exhilarating influence.

As brood-rearing closes in the fall, we find that the bees generate but little heat, which grows less perceptible during the fall and early winter, until the approach of the breeding season, when there is a gradual increase of warmth, which reaches its greatest intensity at the height of brood-rearing. Now, it is during the cool months of spring that contracted brood-chambers and packing may serve a good purpose, where there are not bees enough to form a heat-retaining crust around a good-sized brood-nest.

As cold weather comes on, bees are wont to form themselves into a cluster and enter a semi-quiescent state where, if undisturbed and in a normal condition, they rest and grow no older. In this condition respiration and the vital forces are measurably suspended. This is the bidding of nature's laws. But here comes our tender-hearted bee-keeper, and wraps his pets so warmly that they scarcely cluster at all, but rattle about and wear themselves out prematurely, instead of sleeping the sleep of peaceful rest. Bees in this State are wintered without any loss worth mentioning in single-walled hives, and why should we trouble our-

selves with cumbersome double-walled hives.

I believe there is a possibility of a system being discovered in the near future, by which bees may be safely wintered with but little or no consumption of food, as in the manner of hibernating ants. Many things are possible in this age. In the meantime, hold to your packing, Mr. Rau.

Holliday's Cove, W. Va.

EASTERN BEES.

Characteristics of Cyprian and Carniolan Bees.

Written for the *British Bee Journal*
BY FRANK BENTON.

From Great Britain and from America letters similar to the following have so often been received by me that I deem the answers of sufficient general interest to warrant their publication on both sides of the Atlantic. They are given in accordance with my experience and honest convictions:

DEAR SIR:—1. Are the Carniolan bees as good honey gatherers as the Cyprians?

2. Will they at all times defend their hives?

3. Are the queens as prolific as the Cyprian and Syrian queens?

4. Do you consider them as well a defined strain or race as the Cyprians? The Cyprians, according to my experience, are a far better defined race than the Italians. When crossed, their markings are transmitted much further. I am inclined to give the Germans the next place. I have experimented with the German, Italian and Cyprian races.

5. How do the Carniolans winter in confinement?

JOHN W. GROUP.

ANSWERS.—1. No; but they are good both as honey gatherers and comb builders, and they seal their honey in such a manner that the combs look whiter than those sealed by Cyprians, Syrians, Palestines or Italians.

2. No. If made queenless, they are thrown into greater excitement than are other bees under the same circumstances, and if deprived of their brood at the same time, are frequently so disconcerted as to neglect, for the time being, the defence of their hives. At other times, that is, under ordinary circumstances, they are most excellent defenders of their hives.

Carniolan queens are not, as a rule, as prolific as Cyprian and Syrian queens, but are far more prolific than black or Italian queens. The best Carniolan queens do not fall far short of Eastern queens as regards prolificness.

I do not. Mr. Group is quite right in saying that "the Cyprians are a far better defined race than the Italians, and when crossed their markings are transmitted much further?" And the

same thing is true of Cyprians, as compared with Carniolans or any other known race. Cyprians are the "thorough-breds" among bees—the only ones whose pedigrees are pure, and their long line of ancestors bred in pent-up Cyprus, under conditions that must necessarily have produced a wonderful race of bees, reproduces its individuals to our admiring and covetous gaze—admiring because these bees transmit their markings and great beauty; and covetous, because they transmit also, even should their pure blood be adulterated by several generations of cross-breeding, their wonderful energy in collecting honey.

Among European races of bees, Carniolans, according to my experience, are, in all points of importance, decidedly superior, no matter whether we consider their qualities as honey collectors, or their ability, if their working force be so directed, to increase rapidly; their readiness to enter surplus receptacles and ability to build and seal over snow-white combs; their gentleness of disposition—their quietness under manipulation, and inclination to adhere to the combs, yet the comparative ease with which they can be brushed or shaken off; their ready defense of their hives under all ordinary circumstances, both against moths and robber bees; their quiet submission when confined for shipment; their readiness in constructing numerous queen-cells; the great prolificness of their queens; the indisposition the workers show towards gathering propolis to daub up sections and glue frames solid; the greater size and individual strength of the workers; their ready submission upon the application of smoke, if perchance they may have been aroused by rough manipulation; their disinclination to attack any one who merely enters the apiary; their hardihood, enabling them to withstand the severest climates, and their quietness and compactness in their winter clusters making them remarkably good winterers; if we test them in regard to any of these points, side by side with any other commonly cultivated European race of bees, all must yield the palm to the "silver race" of Carniola.

Mr. Samuel Simmins, in his excellent work, "A Modern Bee-Farm," tells the whole story in one sentence, when he says of Carniolans, "Scarcely a fault can be found with them."

5. Excellently. They have been developed in a cold, mountainous region, where snows are deep in winter, and rains often prolonged and even cold during the summer season. The past winter bees have been confined here without a good flight for four months continuously. Snow has been over two feet deep in the open coun-

try, while mountain ravines are drifted full. The thermometer several times indicated 13° Fahr., below zero. Very possibly this question is meant to refer to wintering in cellars or special repositories. In Carniola, bees are not wintered in cellars, so far as I know. The native bee-keepers pack their shallow box-hives (which are 6 to 8 inches deep, 12 to 18 inches wide, and about 3 feet long) side by side, and one above another, in old-fashioned beehouses or sheds, and surround them with moss or fine hay, letting a mat or trap-door close the front during the intense cold, or when the ground is covered with light snow and the sun is bright. In this sort of repository, with abundant stores, colonies winter well. Upper Carniola, Austria.

DISCUSSION.

Hard Arguments, but Pleasant Words the Most Effectual.

Written for the American Bee Journal
DR. G. L. TINKER.

The readers of the BEE JOURNAL will have seen that I have had little to say in reply to attacks upon me concerning my essay at the Ohio convention on hives. Now I desire to say that no angry communications to our bee-periodicals can be of any possible benefit to bee-keepers, and furthermore they should not be tolerated. For a long time there has been general good-will manifest among bee-keepers everywhere, and all differences of opinion have been tolerated in a fraternal spirit, and I desire to see this state of things continue. Until bee-keeping is reduced to a perfect art and science, differences will exist, and they should be tolerated in a proper spirit.

All will heartily concur with the editor in his remarks on page 260, that all "quarrelsome and jealous persons are not up to the spirit of the times." How very true this remark is, every well informed person of the present day must know. Angry contention never has, nor never will help any cause, but honorable and courteous discussions may do so. Selfishness and its offspring, jealousy, should give way to charity and fraternal good-will among all men, not alone bee-keepers, inasmuch as the latter qualities are indispensable virtues, and the foundation of moral and intellectual progress. In the new dispensation, the first commandment is to "love thy neighbor as thyself."

I am ready to fraternally discuss matters of importance with any one, but just at present I have no time to reply to such attacks as have been

made on me in the *Review* and in the *Bee-Hive*.

Probably no man in this country has had a larger or more varied experience in the contraction of brood-chambers in the past five years than the writer, and I am a firm advocate of it in the production of comb honey, and especially for young swarms, but I think that it has been carried to extremes.

A fair swarm of bees should not be hived in a brood space less than the equivalent of six Langstroth frames, for the best results. Even with six Langstroth frames, the bees are prone to swarm out, and need to be guarded. But once established in such reduced quarters the colony will continue strong, and rarely deposit bee-bread in the sections. But six Langstroth brood-frames contain about 800 square inches of comb, and any brood-chamber having only a capacity for 700 square inches of comb, more or less, is certain to result in more or less bee-bread in the sections. In some seasons little pollen will be carried above one division of shallow hives, in others a good part of the crop is liable to be ruined by bee-bread. Five Gallup frames, although having less capacity, give less trouble than 8 shallow 5-inch frames. My greatest objection to the latter is in the size of the brood-cases; the next is the horizontal bee-space in the centre of the brood-nest in the spring, which beyond any question is an impediment to the proper extension of the brood.

As to the use of queen-excluding zinc in honey-boards, I desire to say that I was the first to so use it, and first to make it public. In its construction I have had large experience both in the manufacture of the zinc and in the various plans for its use; and have finally settled the matter to my full satisfaction that single-rowed strips of zinc used in alternation with the brood-frames is a hindrance to the working of bees in supers; and whether it is because of insufficient passage way or insufficient ventilation, I am unable to say, but both causes may be operative. At least my trials of two-rowed zinc have removed all objections to its use in honey-boards.

The two-rowed strips I use are $\frac{3}{4}$ inch wide, and there is a margin of 5-32 of an inch for entering the saw-knives in the edges of the slats. The slats used may be $\frac{7}{8}$ to 15-16 of an inch wide for a hive with frames spaced $1\frac{3}{8}$ from center to center, leaving a space between the slats of 7-16 to $\frac{1}{2}$ inch, so that we have no serious trouble from brace-combs, except where the space between the slats and top-bars of the brood-frames is over 5-16 of an inch.

New Philadelphia, O.

QUEEN-REARING.

Various Methods of Rearing Queens.

Written for the American Bee Journal
BY THEODORE JOHNSON.

On page 252, Mr. G. Crouse asks for descriptions of queen-rearing other than by natural swarming; and on page 300, Mr. D. P. Barrows gives his method, which I have practiced very successfully, but I have now abandoned it except in extreme necessity. I have several large hives for queen-rearing, made to receive the common Langstroth frame, each hive being 15 inches wide inside, with the partitions $\frac{1}{2}$ -inch thick, which are let into grooves so as to be easily removed if desired. This gives four apartments, each holding two full frames, and an entrance on each side of the hive.

I select the queens from which I wish to breed (I keep nothing but pure Italians), and crowd two or three with brood from colonies I do not wish to breed from, so as to induce drone-rearing. At the proper time I divide one colony, leaving the most of the brood in the hive on the old stand, but remove the hive with the queen only a few feet. When the bees have completed a number of queen-cells, I remove the whole of the balance of the frames, putting one in each of the apartments in the queen hive. I destroy all of the small queen-cells, and leave one on each of the combs; the balance of the queen-cells I cut into other combs, from other hives, and put them into other queen hives. This being done, from other hives I remove combs partly filled with brood and honey, and well covered with young bees, and put one in each of the several apartments in the queen hives; and in this way I have the warmth of a full hive, and at the same time rear four queens from selected mothers.

As soon as the old colony is thus broken up, I place the nucleus containing the old queen back on the old stand, to receive the old bees on their return. By this means I generally have from 8 to 12 young queens on hand all of the time. This year I wintered four queens in one of those hives, and have had use for two of them to supply other colonies this spring.

My bees are in excellent condition. I put 77 colonies into a bee-cellar last December, just before Christmas; and the last week in March I took 77 colonies out. Four colonies were weak, and before I attended to my duty they were robbed. I am now extracting from 5 to 10 pounds of surplus honey from each hive, leaving a large supply for June use, which is our hardest

month here. All have considerable brood, and there is drone-brood capped in several hives whose queens are only one year old. I have stimulated by feeding each day a little uncapped honey in sections. I shall keep my bees back as long as possible, as I do not care to have them increase much.

Bower, Nebr., May 3, 1888.

SEASONABLE

Hints About Populous Colonies and Overstocking.

Written for the Western Plowman
BY C. H. DIBBERN.

The balmy days have come at last, and the bees and the bee-keepers are once more busy at their accustomed work, the former gathering honey and pollen from the bloom of the apple and peach, the plum and the myriads of wild blossoms that are found in the woods, over hills and valleys during this the loveliest month of the year. Everything is now springing into life—in spring such hope as one cannot always feel in the latter months of the year. The bee-keeper can now take heart and go to work with a will, at least that is what we must do if we hope to succeed.

The apiarist of the present day must be a general. The bees are his army. He must divide them into companies, regiments, divisions. If he has two or more apiaries he may regard them as separate armies. Like the true general he should know the exact condition of his army before starting out on the season's campaign. See that every company (colony) is full, if not, be sure that the recruiting officer (queen) is doing her duty, if not, supersede her at once. Remember that on the strength and discipline of each company (colony) depends our success in the apiary as well as in war. Never mind about lines of retreat, better burn the bridges behind you and keep ever marching to the front. If you find any lions in the way, there is always a way to make a "blank movement" on them. While the bees must be allowed to roam at their own sweet will among the flowers that suit them best, gathering their delicious treasures, the bee-keeper must ever know the condition of their hives, and keep their general welfare well in hand.

Another idea has suggested itself to me, and it is that many localities had become overstocked. During prosperous years we keep on increasing the number of our colonies, while perhaps our neighbors on all sides of us are doing the same thing, as if there was no limit to the honey resources. A

bad season or two, like the last, shows us the folly of such a practice. It is far better to keep only a limited number of colonies, and they as strong as possible. Nature produces honey, like pure gold, only in limited quantities, and we must so manage with our bees that the profit does not all go for expenses.

Perhaps some of us have missed it just as badly by caring for hundreds of colonies, involving much work and expense, when we could have produced just as much honey with fifty. We must remember that only a limited amount of honey is produced in any locality, and if we increase the number of our colonies out of proportion to what could gather this at a profit, we are working at a loss. As the colonies are thus increased, the quantity stored per colony is in inverse proportion to numbers of colonies kept. It will thus be seen that the bee-keeper having more bees than can find profitable work, is like the farmer trying to farm all creation. Now I would not be understood that I do not want plenty of bees, I want them by the millions, but I want them in a limited number of hives.

Milan, Ills.

SEPARATORS.

The Use of Wood vs. Tin Separators.

Read at the Ohio Convention
BY DR. H. BESSE.

I suppose that all are aware that separators are used between the sections in order to obtain straight combs. I have not yet progressed far enough to find any benefit in the use of separators made either from wood or tin, although I have experimented quite extensively with both kinds; and if I should continue the use of either, I should prefer the wood, on account of cheapness. I think that separators should be discarded entirely, except, perhaps, in side-storing hives, and this I do not recommend.

I have made many experiments to get straight and true combs in sections, and have succeeded just as well without separators as with them, and thus I do away with considerable time and expense, as well as objectionable fixtures to the bees. I am of the opinion that bees will gather from 10 to 20 per cent. more honey without separators, than by their use. I am aware that in about every 30 or 40 sections, I find where separators are not used, a bulged or "fat" section that cannot be readily crated for shipment; but these I lay aside, and can find use for

all such in the family, as well as retail them to friends and neighbors.

I should have said, that one of my objections to separators is, that the bees will persist in building brace-combs from the face of the beautiful comb to the separator; this has tried my patience a great many times. This trouble exists equally with wood and tin. Since foundation has become so cheap, and in such general use, I think it entirely unnecessary to use separators of any kind when the sections are placed over the brood-chamber; but, as I have stated above, they are indispensable in a side-storing hive, and this kind of hive, in my opinion, should soon pass out of existence.

I doubt if any one could tell the difference in my comb honey that has been built between separators, or without separators, after being crated and ready for market. It is not the separators that make the nice honey.

Delaware, Ohio.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*
 May 18.—Linwood, at Eau Galle, Wis.
 B. J. Thompson, Sec., Waverly, Wis.
 May 19.—Nashua, at Nashua, Iowa.
 H. L. House, Sec. Ionia, Iowa.
 May 22.—N. W. Ills. & S. W. Wis., at Rockton, Ills.
 D. A. Fuller, Sec., Cherry Valley, Ills.
 May 31.—Wis. Lake Shore Center, at Kiel, Wis.
 Ferd. Zastrow, Sec., Millhome, Wis.
 Aug. 3.—Ionia County, at Ionia, Mich.
 H. Smith, Sec., Ionia, Mich.
 Aug. 14.—Colorado State, at Denver, Colo.
 J. M. Clark, Sec., Denver, Colo.
 Aug. 27.—Stark County, at Canton, O.
 Mark Thomson, Sec., Canton, O.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

SELECTIONS FROM OUR LETTER BOX

New Honey—Early Swarm.—L. A. Miller, Covington, Tenn., on April 30, 1888, writes:

My bees have wintered well, out of 117 colonies only one having starved. I do not think that I ever have seen them in as good condition as they are now. Some of my colonies have stored 20 pounds each, of new honey in sections, which was put on the market on April 20. I had a swarm on April 4. White clover is beginning to bloom.

Condition of Bees in Missouri.—John Nebel & Son, High Hill, Mo., on May 4, 1888, write:

Bees are doing fairly well, now that we have had a week of warm weather. They came through the winter weaker, on an average, than we have known them to do in our ten years of bee-keeping. Stimulative feeding last fall would not induce queens to lay, consequently all colonies went into winter quarters with few bees, and the

most of those were old, leaving but few young bees to start and protect brood-rearing this spring, which commenced the latter part of March. We put into winter quarters on Dec. 1, 1887, 200 colonies in two cellars, where the temperature was kept at from 40° to 45°; on taking them out on March 26, we found our loss to be only 8 colonies. Bee-keepers in this vicinity, who work on the let-alone plan, have lost nearly all. There was great loss of bees in this State the past winter, and it will take several years to replace them. If we are favored with occasional rains, we may expect a surplus from clover, though the drouth of last year killed most of it, and the dry spell we had during last month, has done it a great injury. We find some clover looking exceedingly well.

Not a Colony Lost.—Lewis Carbino, Potsdam, N. Y., on April 26, 1888, says:

I put out my bees to-day, and found them all right. I had 42 colonies in a bee-house, and all wintered in good condition.

Bees are Swarming.—Mr. Jos. E. Shaver, Friedens, Va., on April 30, 1888, writes:

Bees are doing well now on fruit blossoms. I have not had any swarms yet, but one of my neighbors had a swarm yesterday, and another neighbor had a fine swarm to-day, which he saved; but the one who had the swarm yesterday, was not ready, and had to go 2½ miles to get fixtures before he could live the bees; when he returned the bees had become tired waiting, and left for the woods. The weather is very fine now.

I have received two packages of the Chapman honey-plant seed from the Commissioner of Agriculture, and the seed of the first package is up and growing finely. A friend of mine sent for some later, and he received seed of sweet clover, or melilot.

Drones Flying, etc.—Geo. W. Morris, Cornishville, Ky., on May 2, 1888, says:

I have had drones flying for three weeks, but this morning I found quite a number of them dead at the front of the hives. I suppose that the cool weather which we are having at present, is the cause. My colonies are more populous than I have ever had them this early, but the prospect for white clover is very limited at present. I have received a package of the Chapman honey-plant seed from the Commissioner of Agriculture, and will plant it in a few days. Will some one in northern Alabama inform me how it would do as a location for an apiary.

Beginning in Bee-Keeping.—L. W. Lighty, Mulberry, Pa., writes as follows:

"Buy black bees in box-hives, transfer them to frame hives, and Italianize them." The foregoing advice I see so frequently; I saw it in about the first bee-paper that I ever read, and to my sorrow. My experience and observation both show me that the advice is wrong. I have seen dozens of failures by following it.

I once bought 3 colonies of bees in box-hives, and as they were strong colonies, I concluded that I needed some one to help me to bring them home. I employed an old bee-keeper, with smoker, etc.; but we did not secure the bees. A few days later I had a greater bee-man to help me, with his implement, and he vowed that they must be queer bees if we could not bring them home; again we did not do it, but were stung half to death. We left those bees until winter,

in zero weather, and then had to go twice before we could conquer them. If I would have bought a colony of fine Italian bees, in a frame hive, in the beginning, I would have been better off in dollars, and would also have escaped many stings. I could then have studied the habits of the bees with more satisfaction, and less pain. I could relate the experience of others, but it would not be very instructive, as they generally gave up bee-keeping in disgust, and never tried it again. My advice is this: Buy a colony of gentle Italians in a movable-frame hive, and become acquainted with bees before you try to perform such operations as transferring or Italianizing.

Hiving Swarms Early, etc.—Mrs. S. E. Sherman, Salado, Tex., on April 27, 1888, says:

The prospects are very flattering here for a good honey crop. I have had 15 swarms, and would have had many more, had I not cut out queen-cells, and given the bees more room, shade and ventilation. I secured 14 of the queens in the queen-cage and drone-trap combined. There has been no climbing of trees, not a twig has been cut, and they have all been hived without any trouble. My hives are running over with bees.

Severe Winter and Cold Spring.—Wm. B. Ray, Alaska, Wis., on May 7, 1888, says:

Bees have wintered well here. The winter was a very severe one, with a very cold April following. There has been only two days when bees could fly.

Late Spring—Colonies Starved.—Charlie W. Bradish, Houseville, N. Y., on May 7, 1888, writes:

Bees have wintered in poor condition in this part of the country. It has been a very late spring, and many colonies have starved. I have just finished putting bees out; when I unite what weak colonies I have, my loss will be about one-third. The first pollen was gathered on May 5, from willows.

The Shaking or Palsy Bee-Disease.—N. M. Middlebrook, Patterson, Tex., on April 22, 1888, says:

My bees have been dying badly since last fall, with the shaking or palsy disease. I never saw the like before. Out of 56 colonies, 46 or 48 have the disease badly. I have lost 8 colonies, and of some of them, the ground in front of the hive has been covered every day since early last fall. Several colonies now show only a little of the symptoms of the disease. I have had several swarms.

How the Bees have Wintered.—O. R. Goodno, Carson City, Mich., on May 5, 1888, writes:

It is hard to guess the result of the wintering of the bees the past winter. I put 105 colonies in the cellar, and on March 19 I took out 100 colonies, and returned them the next day. On April 25 I took them out again, with six more dead ones, and many more have since died. The nights have been cold, and ice formed as thick as window-glass. More bees will die. I had out-doors 23 colonies in Root chaff hives, and on March 19 three colonies were dead, and since then several more have died. The weather is too cold to try to examine them. Soft maple, elm, and a portion of the wil-

lows have past their bloom, without giving the bees a chance to visit their flowers. The few box-elders within reach of my bees are visited when it is warm enough for bees to fly. It is anything but encouraging, so far, but it reminds me of the Dutchman who bought an organ to place in his saloon to draw custom. It was effectual; he held his crowd until a late hour, when Catherina, his wife, came down stairs, and ordered the music stopped. To this Hans said: "What for you s'posed I buy that organ? Wind her up, John!" So with the bee-business—wind her up again; make it boom if possible.

Good Honey Season Expected.—A. R. Simpson, State Line, Ind., on May 8, 1888, says:

The prospect is favorable for a good honey season in this locality. We are having good rains each week, that will bring out white clover, which is our principal honey source.

Cold and Backward Spring.—Alex. Sherington, Dutton, Mich., on May 4, 1888, writes:

It has been a very cold and backward spring. When soft maple and elm was in bloom, it was so cold that the bees could not fly, but the last week of April they did very well on willows. The hard maples are blooming, and the weather is damp. The spring of 1886 I bought one colony of bees for \$8.00, increased them to 4 colonies, and took 100 pounds of comb honey in one-pound sections. The winter of 1886-87 I wintered my bees on the summer stands, packed in straw, and had no loss. Last season was a poor one, but I increased the 4 colonies to 12, by natural swarming, and obtained 150 pounds of honey from Alsike clover and linden. I had one colony that was hived on June 12, and on July 4 it had three brood-chambers full, and 38 one-pound sections of linden honey. The past winter I lost 5 colonies, and all the rest were in good condition except one, and that was very weak. On April 25 I unpacked my bees, and by changing them around, I have the weak one as strong as any. On April 27 I caught a small swarm on the fence; I took it home, hived it on 5 frames full of comb, and a frame of brood, and now I have a very fine colony.

Results of the Season.—Mr. Wm. Crowley, Redwood Falls, Minn., reports thus:

After putting 20 colonies in the cellar in November, 1886, I began to figure on adopting a hive and improving my strain of bees for the next season. Upon these two features, with a little care and attention, depends the crop of surplus honey. I sent to apiarists in different parts of the United States for samples of the hives they used, and also bought an extractor, and a circular-saw for making hives. After the samples arrived, I examined each one carefully, and found some good points in each of them, and also some features that I did not like. It costs money to change the fixtures of a large apiary to keep up with the times. I finally constructed a hive incorporating the desirable functions of each of them, leaving out the objectionable ones, according to my opinion. I have named it the Minnesota hive. It takes a frame the same as the Langstroth hive, except the frame is 1-inch shorter; a super holding four tiers of one-pound boxes just fits on top of the hives. When spring arrived I put my bees out on April 9, a little too early. One-fourth of them were rather weak, and one queenless with a drone layer.

I Italianized my apiary, and gave my new hives a fair trial, hoping to get a crop of surplus honey. I found it a difficult job to transfer my bees and combs from old hives into new ones. I purchased two more imported queens in 1887, as I found that foreign blood introduced into my apiary had started a broom. Too much increase will lessen the crop of surplus honey, so I made only 23 swarms, worth \$5 each, \$115; 1,000 pounds of extracted honey, at 15 cents, \$150; and 500 pounds of comb honey in one-pound sections, at 20 cents, \$100. My total income was \$365. I obtained an average of 75 pounds of surplus honey per colony, spring count, and a profit of \$18.25 per colony. One colony from my choice strain of bees stored 140 pounds of comb honey in one-pound sections last summer, besides enough to winter on. The season of 1887 was poor for honey, there being only one-half of a crop in the United States, although Minnesota was better than the average. I have put in a hard winter's work making hives and fixtures, and getting ready for the season of 1888, hoping for better results than last year.

Fine Weather for Bees.—Leslie Stewart, Jefferson, N. Y., on May 7, 1888, writes:

My bees are in fine condition, though not removed from the cellar until April 26. They had large quantities of brood in all stages, and some young bees, when removed to the summer stands. They have wintered without loss. The weather is fine, and the bees are working for all they are worth on willow and soft maple. We have had a very late spring. White clover is in good condition, and I shall look for a grand honey crop during the season of 1888. The loss in wintering in this part of the country is about 10 per cent.

Bee-Keeping in Nebraska.—Geo. Gale, of Adams, Nebr., on April 27, 1888, writes:

The season of 1887 was dry, and consequently a very poor one for bees. I commenced in the spring of 1887 with 12 colonies, and 2 were robbed by the others in May. I had only one swarm, and the bees made very little above a living until September, when they stored a little surplus. I had 400 pounds of comb honey, and 100 pounds of extracted honey. One colony produced over 100 pounds of comb honey. My bees are blacks. I lost 3 colonies the past winter, but all had honey enough; one was destroyed by mice, and the others were probably queenless. Very few bee-keepers here had any increase last season, and I do not know of any that obtained more surplus honey than I did. Some of the largest and oldest bee-keepers lost more than half of their colonies last summer before the fall honey-flow commenced. I think that the bees which survived the drouth last summer, have wintered very well. The weather is as fine as could be wished for, and prospects for the season are now good. Wild plums are now in full bloom, and the bees are working on them. Our bees stored no white honey last season until late, and that was from a species of thorough-wort that grows in the timber land.

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

ALFRED H. NEWMAN,
BUSINESS MANAGER.

Business Notices.

If You Live near one post-office and get your mail at another, be sure to give the address that we have on our list.

Hilton's new pamphlet on Comb Honey Production has been reduced in price to 5 cents. For sale at this office.

If you Lose Money by carelessly enclosing it in a letter, it is without excuse, when a Money Order, which is perfectly safe, costs but 5 cents.

Please to get your Neighbor, who keeps bees, to also take the AMERICAN BEE JOURNAL. It is now SO CHEAP that no one can afford to do without it.

Preserve Your Papers for future reference. If you have no BINDER we will mail you one for 60 cents; or you can have one FREE, if you will send us 3 new yearly subscriptions for the BEE JOURNAL.

Yucca Brushes, for removing bees from the combs, are a soft, vegetable fiber, and do not irritate the bees. We supply them at 5 cents each, or 50 cents a dozen; if sent by mail, add 1 cent each for postage.

Please write American Bee Journal on the envelope when writing to this office. Several of our letters have already gone to another firm (a commission house), causing vexatious delay and trouble.

Home Markets for honey can be made by judiciously distributing the pamphlets, "Honey as Food and Medicine." Such will create a demand in any locality at remunerative prices. See list on the second page of this paper.

Photographs of Bee-Keepers.—The "medley" gotten up by E. O. Tuttle, containing the faces of 131 representative apiarists, and a printed sketch of each one, will be sent with the BEE JOURNAL for one year for \$1.75; or we will present it free, by mail, to any one, for a club of three subscribers and \$3.00.

Apiary Register.—All who intend to be systematic in their work in the apiary, should get a copy of the Apiary Register and begin to use it. The prices are as follows:

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 25
" 200 colonies (420 pages).....	1 50

Honey and Beeswax Market.

DETROIT.
HONEY.—Best white in one-pound sections, 15c. Extracted, 9@10c. Large supply and few asks.
BEESWAX.—23@24c.
Apr. 24. M. H. HUNT, Bell Branch, Mich.

CHICAGO.
HONEY.—Prices range from 15@16c. for best one-lb. sections; other grades are slow, at lower price. Extracted, 7@8c. Light demand, and supply larger than usual at this season of the year.
BEESWAX.—23c. R. A. BURNETT,
May 1. 161 South Water St.

NEW YORK.
HONEY.—We quote: Fancy white 1-lb. sections, 14@15c.; fancy 2-lbs., 12c. Lower grades 1@2c. per lb. less. Buckwheat 1-lb., 10@10½c.; 2-lbs., 9@9½c. Extracted, white, 7@7½c.; dark, 5½@6c.
Mar. 19. F. G. STROHMEYER & CO., 122 Water St.

CHICAGO.
HONEY.—We quote: Fancy white clover 1-lbs., 16@17c.; 2-lbs., 15@16c. Dark is slow sale at almost any price. Extracted is scarce, and sells at 7@10c.
BEESWAX.—23c.
Mar. 13. S. T. FISH & CO., 189 S. Water St.

CINCINNATI.
HONEY.—We quote extracted at 4@9c. per lb., for which demand is good. Comb honey, 14@17c.—Demand slow.
BEESWAX.—Demand is good—20@22c. per lb. for good to choice yellow, on arrival.
Apr. 23. C. F. MUTH & SON, Freeman & Central Av.

MILWAUKEE.
HONEY.—Choice white one-lb. sections, 16@17c.; 2-lbs., 15@16c.; 3-lbs., 14c. Extracted, white in kegs and ½-barrels, 8 to 8½c.; in tin and pails, 9½@10c.; dark in barrels and kegs, 5@7c. Market fair.
BEESWAX.—22@25c.
Apr. 23. A. V. BISHOP, 142 W. Water St.

DENVER.
HONEY.—Best white 1-lb. sections, 17@19c.; 2-lb. sections, 15@17c. Extracted, 7@10c.
BEESWAX.—20@23c.
Mar. 1. J. M. CLARK & CO., 1409 Fifteenth St.

KANSAS CITY.
HONEY.—We quote: Choice white 2-lb. sections, 17@18c.; dark 2-lbs., 14@15c.; choice white 1-lbs., 18 to 20 cts., dark 1-lbs., 15@16c. White extracted, 7@8c.; dark, 5@6c. Demand is slow. White extracted is firm when in 60-lb. tin cans.
BEESWAX.—21 to 22c.
Mar. 29. HAMBLIN & BEARSS, 514 Walnut St.

BOSTON.
HONEY.—We quote: 1-lb. sections, 16@17c.; 2-lb. sections, 14@16c. Extracted, 8@9c. The market is not very brisk and sales are slow.
BEESWAX.—25 cts. per lb.
Mar. 24. BLAKE & RIPLEY, 57 Chatham Street.

SAN FRANCISCO.
HONEY.—We quote: White to extra, 10@17c.; amber, 9@14c. Extracted, white liquid, 7@7½c.; amber and candied, 6@7c. Market quiet.
BEESWAX.—18@21c.
Mar. 20. SCHACHT & LEMCKE, 122-124 Davis St.

KANSAS CITY.
HONEY.—We quote: White 1-lbs., glassed, 16@17c.; unglazed, 17@18c.; and dark 1-lbs., glassed, 15c.; unglazed, 16c.; white 2-lbs., glassed, 16c.; unglazed 2-lbs., 17c. California white 2-lbs., 17c. California extracted in 60-lb. cans, 8c. Market quiet and receipts are larger.
BEESWAX.—No. 1, 20c.; No. 2, 18c.
Mar. 19. CLEMONS, CLOON & CO., cor 4th & Walnut.

Your Full Address, plainly written is very essential in order to avoid mistakes.

New Subscribers can obtain the full numbers for 1887 and 1888, for \$1.75, while there are any sets of 1887 left.

Clover Seeds.—We are selling *Alsike Clover Seed* at the following prices: \$8.00 per bushel; \$2.25 per peck; 25 cents per lb. *White Clover Seed*: \$10.00 per bushel; \$2.75 per peck; 30 cents per lb. *Sweet, or Melilot, Clover Seed*: \$6.00 per bushel; \$1.75 per peck; 20 cents per lb.—by express or freight.

A Pocket Dictionary will be presented for two subscribers with \$2.00. It is always useful to have a dictionary at hand to decide as to the spelling of words, and to determine their meaning.

Red Labels for Pails.—We have three sizes of these Labels ranging in size for pails to hold from one to ten pounds of honey. Price, \$1 for a hundred, with the name and address of the bee-keeper printed on them. Smaller quantities at one cent each; but we cannot print the name and address on less than 100. Larger quantities according to size, as follows:

	Size A.	Size B.	Size C.
250 Labels.....	\$1.50	\$2.00	\$2.25
500 Labels.....	2.00	3.00	3.50
1,000 Labels.....	3.00	4.00	5.00

☞ Samples mailed free, upon application.

Alfalfa Clover.—For habits and cultivation of this honey-plant, see page 245. We supply the seed at the following prices:—Per lb., 22c.; per peck, \$3.00; per half-bushel, \$5.50; per bushel of 60 lb., \$10.00. If wanted by mail, add 18 cents per pound for bag and postage.

A Modern BEE-FARM, and its Economic Management; showing how bees may be cultivated as a means of livelihood; as a health-giving pursuit; and as a source of recreation to the busy man. By S. Simmins. For sale at this office. Price, \$1.

We Supply Chapman Honey-Plant SEED at the following prices: One ounce, 40 cents; 4 ounces, \$1; ½ pound, \$1.75; 1 pound, \$3. One pound of seed is sufficient for half an acre, if properly thinned out and re-set.

Paper Boxes—to hold a section of honey for retail dealers. We have two sizes on hand to carry sections 4¼x4¼ and 5¼x5¼. Price, \$1.00 per 100, or \$8.50 per 1,000.

Advertisements.

OUR No. 2 One-Piece Sections are the cheapest in use—\$2.60 per M. No. 1 are the best in use—\$3.60. These are 4¼x4¼, of various widths. Address as in cut. 20A4t
Mention the American Bee Journal.

FOR SALE.

35 COLONIES of Italian Bees in Langstroth hives made frost-proof. Apply to, 20A2t PETER DIXON, Saginaw, Mich.
Mention the American Bee Journal.

ITALIANS on Langstroth frames—Two-frame Nucleus (no Queen) \$1.75; 3-frame, \$1.75. Each Nucleus in contain frames filled with brood and a plenty of bees. Orders filled promptly. **TESTED QUEENS**, \$2.00; Untested, after May 20, \$1. BEES per Pound, after May 20, 65 cents. Safe arrival and satisfaction guaranteed. No foul brood. 19A4t H. L. Pangborn, Maquoketa, Iowa.
Mention the American Bee Journal.

Dadants' Foundation Factory, wholesale and retail. See advertisement in another column.

The Bee-Keepers' Review

FOR MAY is now out. Having regained the time lost during his illness, the editor will hereafter take pride in getting out the REVIEW promptly on the 10th of each month. The special topic of the present Number is "Hiving Bees." The review of Mr. Cheshire's work, which was begun in the March No., is finished in the present issue. We have a surplus of the Numbers containing this review, and, so long as they last, these three Numbers will be sent free to all who apply.

☞ Price of the REVIEW, 50 cts. a year.

The Production of Comb Honey,

A neat little Book of 45 pages, price 25 cents. The REVIEW and this book for 65 cents. Stamps taken, either U. S. or Canadian. Address, **W. Z. HUTCHINSON,** 20A1f 613 Wood St., FLINT, MICHIGAN.
Mention the American Bee Journal.

(Patent applied for).

BEST FOUNDATION FASTENER for Brood-Frames and Sections. Description and Illustration sent free on application. **J. W. BITTENBENDER,** 20E1f KNOXVILLE, Marion Co., IOWA.

7 per cent. OFF

ON SECTIONS, from prices given in price-list. We make four grades of **COMB FOUNDATION**—Heavy Brood, Light Brood, Thin & Extra Thin for Sections. ☞ Send for free Price-List and Samples.—Dealers, write for special prices.

Address, **M. H. HUNT,** Bell Branch, Wayne Co., Mich. (near Detroit). 2E1f
Mention the American Bee Journal.

SAMPLE COPIES of the **AMERICAN APICULTURIST** and our Price-List of Winter Strain of Pure Italian Bees sent free. Address, 18E1f **APICULTURIST,** Wenham, Mass.

OUR ILLUSTRATED CATALOGUE FOR 1888

WILL be mailed free to any one who is not already supplied with it. Send us your address, *plainly written,* on a Postal Card. **THOS. G. NEWMAN & SON,** 923 & 925 W. Madison-St., - CHICAGO, ILLS.

HOW TO RAISE COMB HONEY, PAMPHLET full of new and improved methods; Price, 5 one-cent stamps. You need also my list of Italian Queens, Bees by the lb., and Supplies. **OLIVER FOSTER,** 13A1f Mt. Vernon, Lion Co., Iowa.

WANTED,

Beeswax.—We will pay 20 cents per pound, delivered here, for Yellow Beeswax. To avoid mistakes, the name of the shipper should always be on each package.

THOS. G. NEWMAN & SON, 923 & 925 West Madison St., - CHICAGO, ILLS.

SMITH & SMITH

We have one of the largest **Bee-Hive Factories in the World.** ☞ If you are interested in BEES, send for our Price-List—Free. Good Goods, and fair Prices. Address, **SMITH & SMITH,** 10E1f KENTON, Hardin Co., O.

BEE-SUPPLIES, RETAIL AND Wholesale.

The Largest Steam-Power Shops in the West; exclusively used to make **Everything** needed in the Apicary, of practical construction and at **Lowest Prices.** Italian Bees, Queens, 12 styles of Bee-Hives, Sections, Honey-Extractors, Bee-Smokers, Bee-Feeders, Comb Foundation, and everything used by Bee-Keepers always on hand. My Illustrated Catalogue FREE. **E. Kretschmer,** 16E1f **Coburg, Iowa.**
Mention the American Bee Journal.

THE NEW HEDDON HIVE

NAILED AND PAINTED. We have a FEW of the above hives, all complete, for sale, at \$4.00 each. As we do not handle these hives this year, we cannot fill orders for them in the flat. Those nailed and painted are left from last year's stock.

THOS. G. NEWMAN & SON, 923 & 925 West Madison-Street, - CHICAGO, ILLS.

100 COLONIES of Italian and Hybrid Bees for Sale at bottom prices. Also, **JAPANESE BUCKWHEAT** for Seed. It has a profuse bloom and is wonderfully productive.—Write for prices. **A. J. & E. HATFIELD,** 14E1f **SOUTH BEND, IND.**
Mention the American Bee Journal.

Eaton's Improved **SECTION-CASE.** BEES & QUEENS. Send for free catalogue. Address **FRANK A. EATON,** 7E1f **BLUFFTON, OHIO.**
Mention the American Bee Journal.

ITALIAN BEES and QUEENS.

ONE Untested Queen, \$1.00; 3 for \$2.00. BEES by the Pound and Nucleus. Send for Price-List. Address, **H. G. FRAME,** 9E13t **North Manchester, Ind.**
Mention the American Bee Journal.

IMPORTED QUEENS.

FRIENDS, I have **QUEENS** in my Apicary as fine and as good as you can import to the free land of America. My Bees equal any that ever spread wing 'neath the sunny skies of Italy. You have but to try them and be convinced. Untested \$1; Tested \$2. Select Tested, \$2.50; Standard Breeders, \$3.00. BEES by the lb., \$1; Frame of Brood, 75 cts. **R. H. CAMPBELL,** (Lock Box 215), 12E12t **MADISON, Morgan Co., GEORGIA.**
Mention the American Bee Journal.

2-Story Langstroth Hive, 80c.

We still have a few of those Two-Story **Langstroth HIVES** with 10 Brood-Frames, at 80 cents. Who wants them? Speak QUICK, or it will be too late. Address, **SMITH & SMITH,** 10E1f **KENTON, Hardin Co., OHIO.**
Mention the American Bee Journal.

LOOK HERE! If You Think of giving the Betsinger Case or the Paper Box a trial the coming season, send for Circular and Prices of these, and other **BEE-SUPPLIES.** If you wish to have your honey crop in the best shape for market, do not fail to send me your address (written plainly) on a postal card. **A. M. GANDER,** 14E4t (Box 591), **ADRIAN, MICH.**
Mention the American Bee Journal.

Vol. XXIV. May 23, 1888. No. 21.

EDITORIAL BUZZINGS.

Many Bees Need Feeding during this cold and unseasonable weather. Do not let them starve just before the harvest is ready.

Every Apiarist should be well informed, not only on the habits, but also on the natural history of the honey-bee.

Another lot of statistical information is presented in *Gleanings* for May 15, from which we learn that the majority report the prospects favorable for a good honey crop.

In Reference to Mr. Moyer's letter, and our comments on page 307, he says that he is in favor of getting statistics, but not by the Government and assessors. So many are now engaged in gathering statistics that it may not be necessary for the assessors to "take a hand" in it.

Bees are not Malable to Canada. We received an intimation of this from Dr. S. W. Morrisou, of Oxford, Pa., and immediately wrote to Mr. Bell, Superintendent of Foreign Mails at Washington, for the facts in the case, and here is his reply:

WASHINGTON, D. C., May 16, 1888.
SIR:—In reply to your letter of the 14th inst., I have to inform you that under the Postal Convention now in force between the United States and Canada, queen-bees are absolutely *excluded* from the mails exchanged between the two countries, and consequently are not allowed to be forwarded by mail from the U.S. to Canada.

A proposal has been made to the Canada office to so modify the Convention as to admit, for the future, queen-bees to the mails: should it be accepted by the Canada office, public notice thereof will be promptly given.

N. M. BELL,
Supt. of Foreign Mails.

Alfalfa.—Mr. C. Thielmann, of Thielmanton, Minn., writes us as follows concerning the difference between alfalfa and lucerne clover:

There is a great difference in the illustrations on pages 68 and 245. The first shows exactly the clover which my father cultivated in Germany (Baden), and which has been planted in that country for centuries back. It did not hold out very long in white clay soil; but was a good stand for hay and green fodder for 20 years on rocky, lime-stony soil. We had no sandy land there, and so I do not know how it will do on it. The illustration on page 245, resembles the clover which I have seen on the Pacific Coast, and was called alfalfa. I am sorry to say that at that time I did not feel so much interested in the plant as I do now, and I did not examine it very closely, but I noticed enough in going by to see that it was not exactly like our German alfalfa, or, as we called it, everlasting clover. In Switzerland it was called lucerne. There is also a county in Switzerland called Lucern. The most noted difference seems to be that, the stalks of the German alfalfa are larger, the leaves larger and longer, and the seeds or flowers further apart, though the difference may result from the land or climate.

The difference is probably similar to sweet clover—the common variety is called mellot, while the imported is Bokhara clover. Lucerne is the common variety, while the alfalfa (or sand lucerne) is the imported article, and costs more than the common article, as does Bokhara clover cost more than mellot.

To Strengthen Weak Colonies is good advice for Spring management. Mr. E. K. Hubbard, in the *Indiana Farmer*, gives this advice on the subject:

It is an excellent plan to equalize the strength of your colonies in the spring, and instead of having a few very weak and the rest very strong, bring up the weak ones by taking from the others and giving to them. The reason why this can be profitably done is that giving brood to a weak colony will do more good than to leave it in the strong colony. A good colony can spare a frame of brood, and still keep full of bees, but if enough brood is taken away to show, in a few days, that they have been materially weakened, the matter has been over-done, and it would have been better to leave them alone. A full colony will gather many times more honey than several weak ones, but by intelligent and careful management all colonies may be brought up to near the same standard, and the good ones not materially injured.

Rendering Beeswax.—The *London Gardener's Chronicle* recommends as a simple method of obtaining clean beeswax direct from the comb, that the latter be melted in hot water, and a hoop that will fit into the container, covered with cheese-cloth, fastened down into it below the surface of the water. The melted wax rises to the surface through the cloth, and when the water is cool, is found on top in a perfectly clean cake.

Foul Brood seems to be very prevalent in many portions of Australia, as we notice from the April number of the *Australasian Bee Journal*, which has just come to hand.

Putting Supers On.—A few timely suggestions are given to beginners, and those who are not thoroughly posted in apiculture, by Mr. W. S. Cullinan, of Kansas City, Mo., in the *Farmers' Review* for this week. After mentioning the importance which attaches to the time and manner of putting on and taking off the supers, he remarks thus:

Doubtless white clover is now in bloom, and it will be time to have the supers in place, especially upon strong colonies. If you have studied the condition of your bees, you will know the colonies that are needing more room, and by all means you should be ready to supply it. If working for comb honey, you should have your supers filled with sections, which have been previously supplied with comb foundation, and give to each colony one case of sections—no more. Many specialists who work their bees for comb honey contract the brood-chamber to 5 or 6 frames before giving the first case of sections; this gives the bees less room below, and less brood to take care of, and so drives a greater number of them into the supers, by which, of course, more surplus is secured. Should any one wish to practice this method, all they will need to do is to remove one or two frames from each side of the brood-chambers, and substitute a division-board or dummy in their stead. The division-board should be of the same dimensions as the frame, and have projecting tops, so as to hang in the hive just as the frames do, and one of them should take the place of each frame removed, for if the space occupied by a frame in the brood-chamber be left vacant, the bees will certainly fill it with honey when they become crowded for room.

The British Honey Company seems to have been unsuccessful in business, and it is proposed to wind up its affairs. The following from the *British Bee Journal* for May 3, 1888, will explain the matter better than we can otherwise do:

We very much regret to announce that we have received a circular intimating that a meeting of the above company will be held at Charing Cross Hotel on May 10, when the following resolution will be proposed, "That it has been proved to the satisfaction of the meeting that the company cannot, by reason of its liabilities, continue its business, and that it is advisable to wind up the same voluntarily."

The Best of its Class.—This is what the Bath, Maine, *Sentinel* says about our BEE JOURNAL and bee-book:

The BEE JOURNAL is the best of its class, and "Bees and Honey" not only the latest, but the best among the works on the apiary and the honey-bee. It is profusely illustrated, and the text careful, concise and to the point. Its arrangement is good.

New Catalogues for 1888 are on our desk, from the following persons:

George Neighbour & Sons, 149 Regent St., W. London, England—64 pages—Bee-Hives and Appliances.

Dr. G. L. Tinker, New Philadelphia, O.—16 pages—Bees, Queens and Bee-Keepers' Supplies.

B. P. Barber & Son, Colebrook, O.—16 pages—Bee-Keepers' Supplies, Fowls, Turkeys, etc.

J. B. Haines, Bedford, O.—8 pages—Bees, Queens and Apiarian Supplies.

GLEAMS OF NEWS.

THREE-SIDED HIVES.

Mention has several times been made in these columns of a three-sided hive made by D. Chalmers, of Poole, Ont. As we intend to keep our readers posted on the "developments of the times," we present the features of this hive with engravings from the *Canadian Honey Producer*. Mr. Chalmers does not claim to have invented any new kind of a hive, and the name "three-sided hive" is a misnomer. This is Mr. Chalmers' own description of what his invention consists:

New and useful improvements in bee-hives, consisting of movable sides, and a cut in the ends of the frames, by which the frames are suspended on iron slides, and one side of which engages a groove in the inner center of the ends of the hive, while the other side projects far enough to support the frames in C, a transverse groove in the center of the ends of the frames of about 11-32 of an inch in width; the slides pass

through the ends of the side pieces of the hive as well, and can be slipped in or out from either side; they are well adapted for supporting the frames, and at the same time are so secured that they cannot spring or bend under the weight.

When the hive is inverted, the comb frames drop 5-16 of an inch, and thus resume the same relative position as before. It is immaterial which side of the hive is up, and should the manipulator see fit to invert it, he may rest assured that on his return he will find the frames retaining their position, without danger of dropping out of place.

B indicates the comb-frames which are 5-16 of an inch less in verticle dimensions than the hive, so that when the latter is in position, the upper level of the top hive giving full bee-space between the top of the frames and the honey-board; they also hang slightly below the bottom of the hive.

By this arrangement it will be seen that when the latter is placed across the bottom-board, or of level pieces, that the frames will be raised to a degree sufficient to relieve the slides, which can then be easily withdrawn, allowing any of the frames to be taken out, or the hive lifted off, all frames at once, or without either changing the position of the hive or removing the slides, but simply by detaching the side, the manipulation is readily accomplished.

The reader will understand at a glance how nicely the movable-side works with my plan of suspending frames with closed ends,

the method of securing abjustable side is yet incomplete, it should have spring enough to come and go with closed-end frames (or sections side by side) as affected by weather.

The bottom-board is also invertible. It is made of a board of equal width with the interior of the hive, with pieces nailed to the sides, and one end corresponding in thickness with the sides of the hive, and wide enough to project $\frac{3}{8}$ of an inch on one side, and $\frac{1}{4}$ of an inch or more on the other side of the board; the former is for summer, and the latter for winter use, and requires to be turned up in early fall.

The winter extension I do not claim, but I am told that it is the invention of Mr. J.

B. Young, of Stratford (I also saw in a late issue of the *AMERICAN BEE JOURNAL* a similar board described, so far as I have gone). Across the center on the summer side of this board I drive a row of strong wire nails until the top of their heads come level with the top of the ledges, one nail under each frame. This is to prevent the frames from sagging; the interior of the frames are supported by a strong wire which reaches from the lower to the upper bar, and the frames in the cases above (should there be any) by a piece of tin 5-16 of an inch in width, which stands on the edge on the frames below. It is T-shaped on either end, and its position is maintained by those ends being placed between the lower and upper side frames.

The honey-board is made of woven strips of wood (same as window blinds); they are strong enough to carry their own weight across the hive, and only being propolized around the under edge of the hive, are easily ripped off.

The top, as shown in the engraving, consists of four narrow pieces being nailed together, rabbeted on one edge to rest on the hive. This is used for spring and fall packing, and in hot weather it keeps the cover at a distance from the combs and bees. The roof is flat, and is held in place by cleats being nailed to the lower side of it, which slips inside of the box.

The North American Convention was to have been held at Toledo next fall. It is proposed to change it to Columbus, O., and the following circular has been sent to each member to ascertain the views and votes in the matter:

Owing to the holding of the Ohio Centennial Exposition, at Columbus, O., from Sept. 4 to Oct. 19, next, and the consequent reduction of railroad fares, a goodly number of the members of the North American Beekeepers' Society, among whom are Miss Bennett, Messrs. Thos. G. Newman, A. J. Root, Eugene Secor, R. F. Hoitman, James Heddon, Geo. E. Hilton, Dr. C. C. Miller, H. R. Boardman and Prof. Cook, have expressed the wish to have the place of the next meeting changed from Toledo to Columbus, and the executive committee has

been urged to make the change, but the members of the committee are unanimous in the opinion that they have no more power to make the change than have any other members of the society; but at the request of some of the above named, and others, and in accordance with the best judgment of the committee, this circular has been prepared, and will be sent to every member of the society who has not already expressed their preference to the committee, and the request is that each one receiving this will say on the enclosed postal whether he or she is in favor of the change or not, and, if not, whether he or she is willing to abide by the wish of the majority. In corresponding, about 200, all who have expressed their preference, are in favor of Columbus. Please do not lay this aside, and make it necessary to write to you again, but put your answer on the enclosed postal card and return it at once.

A. B. MASON, Pres.

W. Z. HUTCHINSON, Sec.

MRS. L. HARRISON, Treas.

Executive Committee.

Swarming.—Mr. A. H. Duff, Creighton, O., gives his views upon the above subject in the *City and Country* in these words:

Excessive swarming is very detrimental to the crops of surplus honey, and to produce the best results in surplus, swarming must be controlled to quite an extent. To place a colony in the best possible condition for storing honey, is placing it in a condition to swarm also. The perquisites some colonies have for swarming is often very perplexing, and every manner of persuasion will finally wear out with them. We have found that if colonies are in first-class condition, or very strong in numbers at the opening of the honey flow, they are nearing the swarming point, and we can gain pounds by allowing a division, or a first swarm to issue. Too many bees can be kept in one hive to make it profitable, but, of course, we have reference only to powerful colonies, and would not wish to convey the idea that any profit can be obtained from weak colonies. Strong colonies is the road, and the only road, leading to large honey crops.

One of the most important points in securing large crops of honey is to give abundance of room for the bees to store it. This is also one of the best preventives of swarming. In the Italians and the other new races, however, this is not a decided prevention, but has some effect. But if this fails, and preparation is commenced (which will be the construction of queen-cells), we can postpone it by removing the queen-cells. This may be followed up just as long as it will produce the desired effect. This will oftentimes wear out, and the swarm, being tired of this kind of treatment, will come forth, leaving behind no trace of queen-cells whatever. There is but one remedy left, provided we wish them to occupy the hive as formerly. This is to take their queen away from them, and put them back again as before. This compels them to remain until young queens are reared, which will require 8 or 10 days.

Queenless colonies may for a time do well, but certain destruction is sure to follow if they are not provided with the same in due time. If a colony in the act of storing surplus should swarm, and the swarm hived to itself, the surplus receptacles should follow the swarm, as they can be brought to the condition for storing much sooner than the parent colony from which they issued.

All second or after-swarms are a failure if surplus honey is the object. After-swarms may be prevented by removing all queen-cells but one, or what is better, remove all and introduce a fertile queen, of which a supply should always be on hand for such emergencies.

CONVENTION DIRECTORY.

1888. *Time and Place of Meeting.*May 31.—Wis. Lake Shore Center, at Kiel, Wis.
Ferd. Zastrow, Sec., Millhome, Wis.Aug. 3.—Ionia County, at Ionia, Mich.
H. Smith, Sec., Ionia, Mich.Aug. 14.—Colorado State, at Denver, Colo.
J. M. Clark, Sec., Denver, Colo.Aug. 27.—Stark County, at Canton, O.
Mark Thomson, Sec., Canton, O.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

 SELECTIONS FROM
OUR LETTER BOX
Wintering on Summer Stands.

—Locke Ferree, Milroy, Ind., on May 12, 1888, says :

I winter my bees in the Langstroth hive, on the summer stands, with a 1/2-inch pine board laid across the frames, with a bee-passage over the frames and under the board. I use no cloth, but a piece of muslin laid over the boards.

I notice that some bee-keepers are not receiving the Chapman honey-plant seed readily from Washington. I received mine in a very few days after I sent for it, but it seems a little tardy about coming up.

Bees Wintered Finely, etc.—Mr.

John H. Martin, Hartford, N. Y., on May 8, 1888, says :

My bees have wintered finely, and I am hoping for a good honey season.

We are going to have a grand food products' exhibition at Albany, on Sept. 10 to 15. This was first started as a State exhibition, but it is now an assured fact that all portions of the country will be represented. If bee-men desire to make an instructive exhibit, this is a good opportunity. A space 12x12 1/2 feet will be given to exhibitors for an entry fee of \$10. I propose to make an exhibit. Are there other bee-men who will also exhibit? I will send a "bulletin" to any one who may desire to exhibit.

Good Outlook for Honey.—Mr.

Francis M. Merritt, Andrew, Iowa, on May 12, 1888, writes :

Owing to the backward spring, bees are not gaining very fast. They gathered natural pollen on April 1, but extreme cold weather beginning about that time, the pollen-bearing plants failed to bloom, until about a week ago. I wintered 3 colonies of bees last winter, and have bought 5 more this spring; some of them were in quite a weak condition. The outlook for honey this year is very good. White clover is just blooming, owing to a week's steady rain. To-day is cold, the mercury indicating 6° above the freezing point.

Losses in Wintering, etc.—M. O.

Tuttle, Osage, Iowa, on May 9, 1888, writes :

Sometime in March I reported my own anticipations and predictions for the wintering of the bees of this county. From what I have learned, I think that more than 50 per cent. of the number of colonies on Sept. 1, 1887, are now dead. As I stated before, I put 170 colonies in the cellar on Nov. 16 to 19, 1887. On April 7, 1888, I took 50 colonies out. On April 23 I took the rest out,

and 168 colonies were lively and apparently in fine condition. I soon found that 2 colonies were queenless, but had plenty of bees and stores. I have united some, as I prefer to lessen my number of colonies for the season, and I shall continue to unite when the weather is favorable. The past two weeks has been rainy, and the thirsty earth is getting a good drink. Our prospects for some clover is good.

Susquehanna County Con-

vention.—H. M. Seeley, of Harford, Pa., the Secretary of the Association, send the following condensed report :

The Susquehanna County Bee-Keepers' Association met at New Milford, Pa., on May 5, 1888. The meeting was called to order by President E. B. Smith, and then followed essays and discussions on the various questions pertaining to bee-culture. Taken altogether, it was a very enjoyable meeting, and doubtless of much benefit to those in attendance. Bees in this vicinity have wintered finely, but few being lost, but those that came through are in good condition. We have at present but 21 members, 16 of whom were present at the meeting. It is the wish of the association to have the name of all persons in the county who keep bees, on the roll as members; and it is intended to hold the meetings in the different towns in the county, to make it as convenient as possible for all to attend. The next meeting will be held in Montrose, Pa., on Sept. 8, 1888.

Very Rainy Weather.—C. Thiel-

mann, Thielmantou, Minn., on May 9, 1888, writes :

My bees have been confined for about 10 days, on account of wet weather. It rained nearly day and night. The ground is flooded, and creeks and rivers are overflowing. There is only a little seeding done here, as we cannot get into the fields for a number of days yet, even if the weather should be good. It is raining now, and there is no signs of any good weather. I have lived for 31 years, but I never saw such weather at this time of the year. We could always seed in April, with a few exceptions, which was then done in May.

I have just seen the Zumbro river. It is very high, and has hardly been within its banks for the past five weeks. In my estimation, more water has passed here in this river in the five weeks, than in four or five years altogether heretofore. Yesterday was the first day that the railroad trains have run regularly since April 9, and we expect another tear up to-morrow. It has rained very heavily the past 24 hours.

Prospects for the Season.—John

Blodget, Flag Springs, Mo., on May 14, 1888, writes :

Last October I packed 10 colonies of bees in chaff hives, and have lost only one colony. They are building up freely. Apple bloom has come and almost gone, and dandelion is in bloom. The weather has been so changeable that the bees could not work half of the time. We have had heavy rains, and the ground is more watered than it has been for four years. I think what white clover there is, will be good. I see ever so many young plants coming up after the rains, and it will be in good condition for another year. Most of the bees are dead in this locality, and what bees that are left will have plenty to work on. The black bees are all dead within three miles, so I can rear some fine bees from my young queens. I have started queen-cells. All my bees are pure Italians, except 1 or 2 colonies of good hybrids. All of my queens

are reared from an imported mother. I think that every bee-keeper ought to have a pure queen to breed from, for the bees will deteriorate fast enough then, if he has neighbors that keep black bees.

Long Confinement of Bees, etc.

—Wm. Malone, Newbern, Iowa, on May 11, 1888, writes :

I notice on page 312, that Mr. Eugene Secor kept his bees in the cellar 180 days. Some of mine were in 190 days. They were put in on Oct. 1, and taken out on April 1; this was for a test. Some were put in on Nov. 20, and 5 colonies were left out until the last of December; and those 5 were taken out the last of January, tucked up warm, and left out; I think that they are the strongest colonies in the yard to-day. Those that were left in 190 days are doing well. I wintered 47 colonies in a cave made for the bees, and 5 colonies on the summer stands. The temperature at which the bees are the most quiet is 40°, and the cave temperature has never been below that point.

One thing that bee-keepers should recollect when writing on the subject of hibernation is, that if hibernating animals, such as ants and snakes, be exposed to cold, freezing air for 30 minutes, there is no reviving them. They may be surrounded with frost for months and live; but 30 minutes of exposure as before stated, will kill them. Try it and see.

In 1887 I made a mistake in working 10 colonies for comb honey; and those 10 did little else but swarm. The 20 that I worked for extracted honey, stored 1,500 pounds, besides enough to winter them and the others—52 colonies in all. I had 5 colonies in the spring of 1887 that came nearly dying, and I had to feed them for winter. I lost 6 colonies last winter, 3 on the summer stands and 3 in the cave.

This has been a peculiar spring, being cold and dry up to May 5, and since then cold and wet. Buckeye is in full bloom, and the bees work hard when the sun shines. While I am writing I can hear the bees. A novice might think that the bees were swarming. Yesterday I prepared some colonies with two sets of combs, and if the weather is favorable, I will be extracting honey in a few days. I do not think that my bees were ever stronger on May 11, than they are this year.

A Peculiar Queen, etc.—Richard

Rawlins, Okalona, Ark., on May 3, 1888, says :

Rattan is in bloom, but not in full bloom; the honey crop from this source promises to be better than usual. The strong colonies are storing honey in the third story now.

I noticed a queen, reared this year, which lays about half drone eggs intermingled with worker eggs in worker comb. She is not very prolific, but her bees are fine looking. Is she likely to overcome the weakness, or will she get worse?

[Most probably the queen will deteriorate, and it would be advisable to supersede her.—Ed.]

The Convention.—The pamphlet containing the report of the proceedings of the Union Convention in Chicago, is now published, and can be obtained at this office for 25 cents. Or bound up with the history of the International Society, and a full report of the Detroit and Indianapolis conventions, for 50 cents, postpaid.

QUERIES REPLIES.

The Proper Time to Extract Honey.

Written for the American Bee Journal

Query 544.—I intend to work the greater portion of my apiary for extracted honey, and have been thinking of adopting the following plan to keep down the swarming fever: Allow the prime swarm to go out, then after the queen has been caged, remove the old hive a short distance, and place a new one on the old stand having a queen-excluder over the brood-frames. After the bees have been hived, I will shake all of the bees out of the old hive, and run them into the new one, then examine the old frames thoroughly and remove all queen-cells, after which I will put them in a super over the newly-hived bees. 1. How long should I wait before extracting from the super? 2. How am I to dispose of the drone-brood in the super? 3. Would it be advisable to adopt the above method?—Ontario.

1. Extract when about one-third of the honey is capped. 2. Shave their heads off as they are capped over.—P. L. VIALON.

1. I would extract from the super as soon as the honey is sufficiently ripened. 2. Let it hatch. 3. No.—M. MAHIN.

Instead of taking so much trouble, use 2 hives full of comb on top of each other, and you will have very few swarms, if you give them room in time.—DADANT & SON.

1. I should wait until at least a third of the comb was capped. 2. Cut it out. 3. I can see nothing gained.—J. P. H. BROWN.

Look here, my friend, letting the bees swarm is not a "plan to keep down the swarming fever." I doubt if you will like the plan so well as to simply keep the honey extracted close. C. C. MILLER.

1. So much depends upon so many circumstances. 2. Cut it out before it hatches. 3. No; you won't like this plan. I have tested so many similar principles, that I should say, no.—JAMES HEDDON.

1. It will all depend upon circumstances. 2. Cut it out and melt it up. 3. Your method will work all right, and if you prefer that way, follow it until you find a better one.—H. D. CUTTING.

1. Wait until all is sealed, or nearly so. 2. I do not have any to dispose of. Use only worker-comb. If there are patches of drone-comb, cut them out and put pieces of foundation in their place. 3. It is a good plan, but the queen-excluder is not needed.—A. B. MASON.

I do not like the method in theory; I have never tried it. I have had but little trouble to control swarming, when working for extracted honey.—EUGENE SECOR.

1. Until your frames are filled and capped. 5. With a honey-knife, slice off the heads of the drone-brood before you put the frames in the supers. 3. It would be tolerably fair practice.—MRS. L. HARRISON.

1. It will probably not do first until all the brood is capped over. 2. Cut it out and insert worker-comb; but how about the drones above the zinc queen-excluders? 3. I think that there are several better plans.—C. H. DIBBERN.

1. You could extract at once. 2. I do not know, unless you cut it out, and replace the vacancies with worker-combs. 3. I hardly think your plan advisable. Why not use *large* hives? You will then be trouble but little with swarms?—J. M. HAMBAUGH.

The plan would doubtless work fairly well, but it seems to me that you should have no trouble with swarming when running an apiary for extracted honey. In my experience along this line, not one colony in ten have attempted to swarm.—G. M. DOOLITTLE.

1. Wait until all the brood is sealed over. 2. A small auger-hole in any suitable part of the hive above the queen-excluder will let out all of the drones. 3. In producing extracted honey, the method may be advised where no increase is desired.—G. L. TINKER.

1. Until the combs contain a considerable amount of well-ripened honey. 2. That depends. You might cut out the drone-brood and destroy it; or let it hatch and fly away, as from time to time you open the hive. 3. No; as but few colonies in an apiary properly managed for extracted honey will cast swarms; unless their queens are past their prime, I should remove the queen, return the swarm and permit them to rear a young queen.—R. L. TAYLOR.

This question, or the questions, involve a big theory. The best I can advise is to test it thoroughly and report. The plan suggested would not work at all in my own apiary, as it will cause more labor and trouble than I can afford to give my bees.—J. E. POND.

1. Until room was needed, or sooner if desired. 2. Why not prune, so as not to have drone-comb. 3. I think that the plan is not a good one, though I have not tried it. If the queen is to be caged, why not put bees back in the old hive, and put on the super full of empty combs; or, if you have not combs, use foundation.—A. J. COOK.

In your statement you fail to tell what is to be done with the old queen, and this is a very important matter in the final results. If the queen is to go

with the swarm below the queen-excluder, you will delay swarming; but if the season is a lengthy one, you will most likely have it over again. 1. Till the honey is sealed over. 2. Raise the hive cover in the afternoon, and let the drones escape, and close it when they are out. Keep this up until all are out. 3. Not as you state it.—G. W. DEMAREE.

I have not found this plan to lessen the swarming-impulse. By this method you allow the preparations for swarming to be matured, and the swarming to actually occur, and then place the colony in almost the condition in which it was before it swarmed. I would prefer putting the new hive under the old one prior to the building of queen-cells. In a majority of cases this will prevent swarming entirely.—J. M. SHUCK.

1. When the brood is sealed over. 2. Decapitate the drone-brood. 3. The plan is too laborious and uncertain.—THE EDITOR.

Arc Drones Allowed to Enter Different Hives?

Written for the American Bee Journal

Query 545.—Will drones from one colony be permitted to go into hives of other bees without being troubled by them?—Dixie.

Yes, usually.—JAMES HEDDON.

Yes, they quite often do.—H. D. CUTTING.

Yes, sometimes.—P. L. VIALON.

Yes, at times.—J. M. HAMBAUGH.

I am not sure.—EUGENE SECOR.

They will ordinarily.—MRS. L. HARRISON.

Yes, as a rule, but not always.—G. M. DOOLITTLE.

Yes, if strong colonies.—J. P. H. BROWN.

Yes, at times; no, at other times.—DADANT & SON.

Sometimes they will, and sometimes they will not.—A. B. MASON.

In the swarming season, or at any time when honey is being gathered plentifully, they will.—M. MAHIN.

Yes, at times when the "other bees" will tolerate their own drones.—R. L. TAYLOR.

Yes, often; perhaps always when drones are tolerated.—C. C. MILLER.

I think so, but I am not sure that they will in all cases.—A. J. COOK.

During swarming time they will, but not at other times, as a general rule.—G. L. TINKER.

When honey is plentiful they probably often do so, but not when it is scarce.—C. H. DIBBERN.

In my own yard they are allowed to mix indiscriminately, and to go from one hive to another without being troubled at all.—J. E. POND.

Drones are free commoners until the time of their destruction arrives. I have set apart a nucleus for queen-rearing without a drone or any drone-brood, and in a few days I have found hundreds of drones in it.—J. M. SHUCK.

No, not as a general rule. They are admitted by queenless colonies as a general thing, but not always. Drones mark their location just as do worker bees; and if you introduce them to queenless colonies after they have marked their location, they will return to the old stand as do worker-bees. I have often proven this by direct experiment. If they are removed from their home before they have been out, they will stay where you put them just as do young worker-bees.—G. W. DEMAREE.

They will, as I have positive proof of the fact. I have one colony that hatched out select drones (Italians of course) on Jan. 10; it is the only colony out of 60 that has drones now (Jan. 25). I have another colony that hatched out a young queen last week, and after she was hatched I looked into the hive and found 4 or 5 drones on the middle combs, and I know this particular colony had not had any drones since last July—of course they came from the colony that had the young drones, which is nearly in front of the one with the young queen.—R. H. CAMPBELL.

Bees will usually admit drones from other colonies when honey-gathering is going on and the colony is strong in numbers, if drones are welcomed in other hives.—THE EDITOR.

CONVENTION NOTICES.

☞ The next meeting of the N. W. Ills. and S. W. Wis. Bee-Keepers' Association will be held in Rockton, Ills., May 22, 1888. D. A. FULLER, Sec.

CORRESPONDENCE.

WHITE CLOVER.

MRS. L. B. FLEMING.

My little maiden came to me,
Her small hands brimming over,
Not with the garden's choicest flowers,
But only sweet, white clover.

I took her gift, the while my thought
The long years traveled over—
When I, like her, with busy hands
Made wreaths of sweet, white clover.

I dream my childish dreams again,
In fairy land a rover,
A magic garland, this, I ween,
Though only sweet, white clover.

Yet much of life's best sweetness we
In homely things discover,
As honey-bees pass gaudy flowers,
To seek the low, white clover.

COMB HONEY.

The Best Methods for Obtaining a Good Article.

Written for the *Eastern Farmer*

BY E. P. CHURCHILL.

As the time is at hand for obtaining comb honey, a word about the methods to be employed may not be amiss.

No doubt shallow frames without comb tend to drive the bees into the sections; but at the same time the queen must be suppressed in her duty, namely, to keep the colony supplied with brood; for where there is ample vacant cells, the queen is sure to increase even beyond one's expectations. I believe that I first gave the origin of my own plan in the *Lewiston Journal*, a number of years ago, which is in full harmony with the instincts of the bees.

As the queen will only use comb $\frac{7}{8}$ of an inch thick, it must be shaved down to that depth. Now where there is much honey in the comb, it is to be extracted. But the combs must not be left, as it generally is, say $\frac{5}{8}$ of an inch or so apart. They are to be closed up to at least $\frac{3}{8}$ of an inch, and by using strips of wood $\frac{3}{8} \times \frac{1}{2}$, with a large-headed tack driven in the edge $\frac{1}{4}$ of an inch from the top (the strip is half the length of the end-bar to the frame); these are now hung on the tin rest, and the frames crowded against them, one at each end of the frame next to the side of the hive, and so on. At last they are hung between the division-board and the last frame, and all crowded up close. Thus the frames are all spaced alike, and we can move the hives, and yet all is secure. Thus close, the bees cannot bulge much of the comb, and the queen is sure to use the natural thickness, which she has

plenty of, and the bees are glad to enter the sections.

I am sure, too, that we need less comb in this way, and yet we are sure of more brood. I get nine frames into a hive only $11\frac{3}{4}$ inches wide; with even this number, the bees will work in the sections far better than in the old way, when crowded down on five or six combs, spaced away apart by bulged and thick comb. Such was sure to cause swarming, as instinct plainly teaches the bees that they must soon be unknown if no brood-room is provided; and how often we have found but little brood where there should have been an abundance, and yet the cause never occurred to us. This shaving and narrow spacing also prevents storing of pollen in the sections to a great extent, simply for the reason that there is plenty of room right among the brood, where it should be. Where one has a large number of colonies, there is a great saving in the comb, which is quite an item.

Of course for winter the combs are spread, and a "stay" like the above only $\frac{1}{4}$ of an inch would please any one when he comes to move the hives into and out of the cellar, as they are simple and cheap, and remain nicely in place. Try it.

After trying about every method, I have proved the above plan to be the one. Also that it pays to use full sheets of foundation in sections, and to cover the boxes up warmly, and then rest assured if there is honey in the field, it will be carried into the sections.

Hallowell, Me.

INCREASE.

Methods of Obtaining Comb and Extracted Honey, etc.

Read at the Nebraska State Convention

BY J. M. YOUNG.

Knowing the interest taken in the advancement of bee-culture, I improve this opportunity of making a short report of my labors in that direction. The honey crop of last season was considerably below the average in this part of the State, and in certain parts an almost total failure. The fall crop was very light, owing to the continued drouth during the summer months.

Fruit-bloom and the early blossoms of white clover put the bees in good condition, and kept them so until swarming; but they secured only enough nectar from these sources to build up rapidly, and not enough to store any surplus. White clover proved nearly, if not quite, a failure in this part of the country, so far as I know.

About June 20, there was a fine flow of honey from the basswood blossoms, which grow abundantly on the banks of the Missouri river, and all along our water-courses. This flow lasted two or three weeks, when it ceased, leaving the bees with well-filled hives and a fair surplus stored in the sections. The balance of the season furnished the bees only enough to keep them in good condition, and keep brood-rearing under good headway.

The present condition of bees in general is very good, with the exception of late swarms, which will starve long before spring. My bees, which are being wintered on the summer stands, began the winter with all the conditions favorable, the colonies being strong in numbers, and having an abundance of well-ripened honey.

During 13 years' experience in apiculture, I have always practiced outdoor wintering. By actual test and experience in this matter, I long ago arrived at the conclusion that bees wintered on the summer stands successfully, must have protection against the extremes of temperatures of the cold winters of Nebraska. The bees wintered with proper packing, invariably come through the winter stronger in numbers, build up more quickly in the spring with less dwindling, and are in better condition to receive the harvest than those in single-walled hives standing side by side.

The inventory of my apiary at this date (Dec. 31) shows that 73 colonies out of 96 are packed in chaff on the summer stands, and if my experience is anything like it has been heretofore, I do not expect to meet with any unusual losses in wintering.

Making Increase by Division.

While dividing colonies for increase is preferred throughout the country by a large majority of bee-keepers, I practice and prefer in my own apiary, "natural swarming," from the fact that apiculture is my sole occupation for a livelihood, and I work the business for all that is in it.

If the bee-keeper has plenty of time and extra combs, with which to supply his divided colonies, he will without a doubt succeed with this method. I will say this in behalf of dividing colonies, from the fact that I do not wish to be understood to say that bee-keeping cannot be made success financially without it, viz :

If increase is the bee-keeper's object, and he has plenty of comb foundation already drawn out, and plenty of money in his pocket, by all means use the dividing-method of increase. On the other hand, my experience has enabled me to arrive at the conclusion that *natural swarming* pays best, if

dollars and cents is the object to be sought.

The question might be asked, how do you control swarming? I do not always do it, but then to a certain extent I do. Just as soon as the bees begin to show symptoms of swarming, I put on the sections, and keep the bees supplied with plenty of room, never allowing them to be idle if there is honey in the fields. In a few days after the first swarm issues, I open the hive from whence the swarm came, and remove all queen-cells but one, if there seems to be no newly-hatched queen present.

Some apiarists may claim that bees will swarm too much, but my experiments in that direction have proven to the contrary. From 76 colonies, spring count, I obtained only about 30 swarms altogether, for the season of 1887; and in summing up all my reports from year to year, I cannot find one instance whatever, of doubling my number of colonies by natural swarming.

Dividing colonies is a safe way to increase, and can be carried to almost any extent; and while I have said so much against it, I could not well dispense with this new improvement in bee-culture; for it is by this means that all my nuclei colonies are formed, and queens reared.

Comb and Extracted Honey.

Now a few words as to my method of obtaining comb and extracted honey: The apiary is worked for both comb and extracted honey, from the fact that there is to be found in any apiary a number of colonies that do not feel disposed to work in surplus sections; whenever colonies of this kind are found, they are supplied with an extra set of combs, and by this means they can be induced to store a fair surplus of honey to be extracted. In this way a portion of my apiary is "rigged up" with two sets of combs, for extracting purposes. When honey begins to come in fast, these combs are placed in the extractor about once a week (or just as often as necessary), and the honey taken out. I seldom disturb the lower story in extracting.

The rest of the apiary, being composed of all strong colonies, is supplied with sections whenever necessary. When one case is partly full, it is raised and an empty one placed under it. My favorite section for obtaining comb honey is the $4\frac{1}{2} \times 4\frac{1}{2}$ inches. I use two widths, namely, the $1\frac{1}{4}$ -inch and the 2-inch. Which width is the best, I am not prepared to say.

My market demands a section that holds a pounds of honey; sometimes I get this pound in the $1\frac{1}{4}$ -inch section, and oftimes in the 2-inch section. My judgment, based upon experience is,

that a section which will hold as nearly as practicable one pound of honey, is what the trade and market demand.

In conclusion I will state that the season's work for 1887, summed up in a nut-shell, is not an encouraging report by any means. After uniting a few late swarms in October, I began the winter with 96 colonies, having had 76 colonies with which to commence the season's work. My sales of comb and extracted honey amounted to upwards of 1,700 pounds, about 1,500 pounds of which was produced during the last summer. The comb honey was disposed of at a good price. Extracted honey has had only a fair sale, but I am glad to say that the demand is increasing.

Rock Bluffs, Nebr.

QUEEN-REARING.

Methods for Rearing Good Queens.

Written for the American Bee Journal

BY S. A. SHUCK.

On page 297, concerning this subject Mr. J. E. Pond says: "Much that is written in regard to good queens is misleading to the beginner." Has not Mr. P. committed a greater error than those he endeavors to correct.

He also says: "I have further found that by the misnamed 'artificial method' of rearing queens, there is far less risk of producing from 10 to 13 day queens, than under the swarming fever." Here Mr. Pond conveys the idea that the production of 10-day queens under the swarming impulse is a common occurrence; also that 13-day queens are inferior.

If Mr. Pond has been troubled with 10-day queens under the swarming impulse, it is an exception that I have not met with in 12 years' experience with bees.

I am confident that the beginner, who secures his queens from his best colonies, under the swarming impulse, will not be wanting for good queens; and the results will be much more satisfactory than if he were to depend upon his own effort to secure them by the so-called "artificial method."

As I have no queens that are more than 13 days from the hatching of the egg, will Mr. Pond please tell why 13-day queens are not as good as any, provided that all other conditions are favorable?

How to Rear Good Queens.

To the beginner who would like to rear a few good queens for his own use, I offer the following method of securing them:

Select the best colony, and if there is little or no honey coming in from the flowers, feed this colony every evening, a little more than the bees will consume during the following 24 hours. Continue the feeding for a week, or until the colony is in a thrifty condition; then, on any afternoon remove the queen.

On the fourth day after removing the queen, open the hive and examine the combs carefully; if there are cells sealed, open them and examine the larva. Do not molest those not sealed. Replace the combs, and on the twelfth day from that on which the queen was removed, open the hive and cut out all the queen-cells but one, and put them where they are needed. Be sure to continue the feeding until the cells have been taken out. If you stop feeding, and there is no honey coming from the flowers, the bees are liable to destroy all the cells except two or three.

In the above way the queens will all be reared from eggs or larvæ less than 24 hours old, and the food from the cell from which the larvæ were removed can be given to the larvæ not yet sealed. This plan will produce good queens, and is much safer, and more economical for the beginner, than to purchase queens and take the risk of introducing them.

Liverpool, Ills.

FOUL BROOD.

Bee-Keeping and Curing Foul Brood in Germany.

Written for the American Bee Journal

BY WILLIAM KLINTWORTH.

My parents used to live about 18 miles from Bremen, Germany. They came to this country in 1836, and at that time there were many who kept bees there. They made their hives of straw in winter, as they were all made that way. Bees were generally fed in the spring, to get them strong, and to secure early swarms. The German bee-keepers would commence to feed by giving the bees a little once a week; as the season advanced, they would feed them once a day; and when spring opened, the bees could get pollen and nectar.

Great bee-keepers would move their bees three or four times during the season, where they could get the most honey. In the fall they would examine the hives, and those that weighed over 30 pounds were kept for the next season; for it took about that much honey to winter a colony. Those colonies that did not weigh so much, were killed, and the honey and wax were

taken from them. The honey was pressed from the comb, part of which was saved for the next spring. If the bees needed more room, they would raise the hive up, and put an addition under it, so that the bees could build downward.

The greatest bee-man that lived there at that time, was Geo. Danker, who made bee-keeping his business. One year Mr. Danker had foul brood in his bee-yard. It was a serious matter with him, as he depended mainly upon his bees for a living. He obtained some sulphuric acid, mixed it with honey, and fed it to the diseased bees. He said, after he had fed it, that it was terrible to see the stuff lying under the hives; but his bees got well, and he obtained only 1,000 pounds of honey, where he should have had 2,500 or 3,000 pounds. Mr. Danker removed to this country about the time my parents came. He became a minister, and was well known in Ohio.

Mr. Wendelkin, a neighbor of mine, who lived in Germany, and at the same place, told me that in 1835 he fed his bees and was looking for swarms, for they had built queen-cells. But time passed, and they did not swarm. He did not know what to think of it, as he was a beginner in the business. He went to an old bee-man who lived there (a brother-in-law of Mr. Danker), and asked him to come and look at his bees—they had built queen-cells, but did not swarm. The man went with him, turned up a hive, and blew smoke down into it. "They are foul," he said. After an examination of the others, he pronounced them all diseased.

Mr. Wendelkin asked, "How can you tell?"

"O," said he, "I will show you."

He took a knife, and soon said, "You see those little holes there. Those are full of a matterly substance." Mr. Wendelkin asked, "Can I do anything to cure them?" "I have something that I will give you," was the reply. He then gave him sulphuric acid, which Mr. W. mixed with honey, fed it to the bees, and they got well, and swarmed late in the season.

Mr. Wendelkin came to this country about ten years after my parents arrived, and is now keeping bees in this neighborhood. Last spring he fed sulphuric acid to some of his bees. When he first commenced to feed it, he gave it so strong that they would not eat it; then he weakened it with sugar syrup. If it is mixed with honey it can be fed to bees stronger than when mixed in sugar syrup. Sulphuric acid is also used for curing chicken cholera.

Marietta, Ohio.

HIVING SWARMS.

Clipping of Queen's Wings, and Other Methods.

Written for the Bee-Keepers' Review

BY R. L. TAYLOR.

In preparation for the hiving of swarms when the time for their issuing comes, while making an examination of the several colonies in my apiary in the spring, I seek out each queen and clip one of her wings if one be not already clipped. I find it quite an advantage to do this before young bees begin to hatch largely, because then the bees are comparatively few, and the queen is generally easily discovered.

Then in anticipation of the advent of the swarming season, other preparations must be diligently attended to. Hives must be all ready for immediate use, and in a cool, shady place, as convenient as possible to the apiary. If the apiary be large, three or four baskets will be necessary, and a good supply of cages for the queens as they issue with swarms is indispensable. The cages I use differ from anything I have seen described, and may be made thus: Take a piece of soft wood $\frac{1}{2}$ x 1 inch, $4\frac{1}{2}$ inches long, and with a $\frac{3}{4}$ or $\frac{7}{8}$ bit bore a hole through it from side to side so near one end as to leave at that end $\frac{1}{2}$ inch of solid wood, and cut the stick carefully and squarely in two through the centre of the hole. Then enlarge the half circle in the larger piece by boring through it (the stick) one or two holes with a smaller bit, and smooth out with a knife. Also form a piece of wire cloth, 4 inches long, and about $3\frac{1}{2}$ inches wide, around a piece of wood $\frac{3}{8}$ x 1 inch, beat with a mallet, and weave smoothly together where the edges meet, then withdraw the wood, and having pushed into one end of the wire-cloth tube the shorter piece prepared as above, tack it firmly in place. Now push the longer piece into the other end of the tube for a stopper, and you have a cage always ready, convenient, safe and durable.

With these preparations all made I will suppose I am set to hive the swarms in a large apiary on a warm day in the height of the swarming season. Everything likely to be needed, including heavy wire hooks for suspending the baskets, a pair of large, white cotton sheets and a lighted smoker are at hand in the shade of a centrally located tree. It is 9 o'clock, and a hive near by spurting forth excited bees indicates that work has begun.

With a cage in my hand I step to the side of the hive and watch for the appearance of the queen in front. In one or two minutes she is seen climb-

the blades of grass, and trying to take wing. The open end of the cage, the stopper being withdrawn, is held immediately over her, when she at once enters and the cage is closed, placed in a basket, and the basket hung by its hook in a tree out of the sun, at a place where the swarm may find the queen. Take a new hive to the one sending out the swarm, removing the latter from its place and turning it around, put the new hive where the other stood, and change the section-cases from the old hive to the new. In the meantime the swarm has found the queen, and is soon clustered in the basket, when I pour the bees out upon the ground in front of the hive prepared for them, and when they fairly take up their march for their new home, I release the queen and see that she runs into the hive, because many of the bees will refuse to go in until she does. This is hardly done before another swarm issues. I cage the queen and arrange the hives as before, but the swarm, instead of finding the queen in the basket, begins to cluster at another place, so I at once remove the basket and hang it near that point, and the swarm at once takes possession of it. Before this one is fully hived, another swarm is in the air, and by the time I have caged its queen, it discovers her absence, and is already returning as I place their new hive in position. I hasten the return by placing the queen at the entrance, and as soon as the bees are rapidly alighting I release and run her in.

It is now 10 o'clock, and swarming has fairly begun. Two swarms now come out almost at the same moment, and unite in the air. I cage their queens, but notice that the swarms are attracted by the commotion at the hive into which the last swarm was put, and are already beginning to alight there. I push the queens into my pocket, snatch a sheet and the smoker, and spreading the former over the hive threatened with invasion, with a few puffs of smoke from the latter, I drive away the flying swarms, when they begin to cluster on a neighboring branch of an apple tree. I at once put each queen in a basket by herself, and hang the baskets together where the cluster is forming. Soon one basket has its share of the bees, and I steal it away and hang it out of sight in thick foliage, or set it in the bee-cellar.

Now other swarms come out—five in pretty quick succession—so I take the other basket with the swarm and hang it in plain sight on a branch favorable for holding a large cluster of bees, and convenient for shaking them off. Here, attracted by the swarm in the basket, all swarms will

for the present congregate. I now proceed first to cage all the queens out, and all others as they come out and put them in baskets hung near the cluster, or out of the way in the shade until wanted. Then as I have time I arrange the hives, and hive swarms taken from the general cluster, giving each a queen until all the bees are distributed.

It would make a long story to recount all the expedients at times resorted to, to induce the bees to assist in making their hiving easy, but the foregoing indicates the general method pursued. Sometimes a swarm will cluster out of reach from the ground. In such cases, if practicable, a basket with the queen is hung under the cluster near the ground, and with a little shaking the cluster drops down, the queen is soon discovered, and the swarm gathers in the basket, or, if more convenient, a pole is used with a hook for the basket, say 20 inches from the upper end. The basket is raised with the pole and held under the cluster, while the latter is jarred off with the upper end of the pole.

With unclipped queens on a good day for swarms, I should be almost in despair. I have had but one queen superseded that I thought was superseded on account of clipping, and she had all four wings cut off short. My queens are not superseded soon enough to please me. I find too many that are approaching three years in age.

Lapeer, Mich.

HIVES AND NECTAR.

Winter Losses and Large Hives—Selling Nectar.

Written for the American Bee Journal
BY WILLIAM CAMM.

Out of 90 colonies my loss will be fully one-third. Looking for a better location last fall, I expected to move, or sell my bees, and would not break the brace-combs to look into them, preferring to let the winter weed them out, as we need a race of bees here that can stand drouth.

Most of the white clover was killed by the excessive dry weather of last year; our spring rains passed without getting much into the ground, as the frost was not out when they fell. The weather has continued dry, and though apple-trees are blooming profusely, the weather is too cool for bees to get much from them.

Many express impatience at the cool weather; but it is our only hope for rain. We have no moisture to send up to form the clouds that give us local rains, and summer showers; and should it turn warm, a calamity would

result: for the heat radiated by the exposure of so much bare soil to an ardent sun, would force up to the condensing point and exhaust, and clouds that could otherwise reach us from a large body of water.

Hives to Suit Localities and Seasons.

Small hives may do for southwestern Michigan, where prevailing winds give rains from the lakes, but they will not do here, unless we are able and willing to feed back more than the profits of our apiaries. My frame is 10x12 inches, outside measure. I have 60 hives with 10 frames and telescope caps, 5 Armstrong hives of the "Crown" pattern, and 25 hives with 13 and 14 frames, of my own make, but single-walled. All were treated alike, except the 25 of the colonies in 10-frame telescope hives had been used last season, with an upper story for extracting, and such colonies usually do not store as much in the brood-chamber as colonies used for producing comb honey.

All of my bees were exposed to the winter on the summer stands; but half of the colonies in the 10-frame hives are dead from starvation; 15 of those used for extracting having gone, although they had the advantage of double walls; only one in the 13 and 14 frame hives has died, though the walls were single, and no frames were taken out, or division-boards removed; while none in the Armstrong hives died.

I much prefer the 10-frame hive for convenience in handling, and with good seasons it will allow of as great a yield as a large hive; but since we cannot make the season to suit the hive, we must make the hive to suit the season.

Selling Nectar on Land.

On page 282, W. J. Willer suggests the selling of nectar land. Nectar is a natural product that cannot be gathered without the bee, and those who take the trouble to keep bees, should have the nectar for their pains. We must not forget, in this connection, that the bee was not made primarily, to gather honey, but to fertilize flowers; the gathering of honey is only incidental, and inducive to the fertilization of flowers. If, then, the bee-keeper should have to pay the land-owner for the nectar the bees gather, the land-owner should, in strict equity, pay the bee-keeper still more for the service performed by his bees.

But there is another phase to this question that must not be overlooked. We decided a hundred years ago that men were endowed by their Creator with an inalienable right to life, etc., but we have made a farce and mockery of this self-evident truth by prac-

tically denying men a natural right to the means of life, or to natural opportunities. We assert, in a national declaration, that the right to life is a natural right; but we legislate to make the means of life purchasable only. So far the right to gather nectar has been in accordance with our fundamental assertion of human right, but Mr. W. suggests a change, and that we carry the evil that is undermining our civilization, into practice, with regard to nectar as well as other bounties of nature.

A neighbor once asked me how much I was going to allow him for the honey that my bees had gathered off his pasture. My reply was that, if he would leave me enough for my family, he might take all the rest there was in my honey house—about 2 tons.

“What, for nothing?” he asked in surprise. “For nothing for the honey,” I replied, “but I shall take 15 cents a pound for the trouble of gathering it. You would not ask me to ‘work for nothing and board myself’ would you?” That was the last I ever heard of honey being wanted by the land-owner; but that land-owner became a good customer.

When it is reasonable to ask a man to control the flight of his bees it will be time enough to talk about limiting his pasture for them, provided they are taking what would otherwise not be wasted.

VENTILATION.

The Proper Way to Ventilate Hives.

Written for the American Bee Journal

BY L. W. LIGHTY.

Patent ventilations, or their vendors, have deceived so many bee-keepers that ventilation is a subject not much spoken of. Bees are not such large consumers of oxygen, comparatively, as some other living beings. When in a state of quietude, they want very little air; but when they are at work, and the temperature is high, they will need much. The air for the bees should generally be supplied at the entrance, or from the bottom of the hive.

In this latitude it is most convenient and most profitable, to winter bees on the summer stands, packed with chaff or something similar. After placing the chaff cushion (which should not be less than 6 inches thick) on top of the frames or Hill's device, there should be an air-chamber between the cushion and the hive-cover of at least from 2 to 4 inches, and that air-chamber should be ventilated by two opposite

holes from $\frac{1}{2}$ inch to 1 inch in size. In that way the cushions will always be dry, and naturally warm and clean. If the hive does not have this top air-chamber and ventilation, the cushions will soon become damp, moldy and frosty, and then it would have been better to have had no cushions on at all.

Most chaff hives are provided with this air-chamber and the holes for ventilation. When using single hives, I generally use a second story or half-story for packing, but I do not like to bore holes in those, so I generally make a rim to fit the hive, about 3 inches high, and bore the holes in that. As soon as bees begin to rear brood on a large scale in the spring, they need much moisture and heat in the hive; therefore it is then best to cover them tight, and keep all the heat and moisture in. The entrance may also be contracted to suit the size of the colony.

In the summer, when the weather is very hot, top ventilation is good; but in our climate of sudden changes in temperature, the temperature in the hive frequently falls so low that the bees cannot work the wax in the sections, and that is a serious objection which should be avoided, and can be done only by closing the top ventilators; but as that is generally neglected, it is better to use only bottom ventilation and shade over the hive. If the bees are given a chance, they will ventilate the hive themselves in summer, but the entrance must be of the proper size for them to do it.

WINTERING BEES.

In-Door vs. Out-Door Wintering of Bees.

Read at the Ohio State Convention

BY H. R. BOARDMAN.

There has always been a feeling of insecurity in bee-keeping as an occupation, on account of the uncertainty of wintering. This question settled, and some sure and reliable way of wintering, provided the business will be placed on a firm basis by the side of other industries.

The ground has all been gone over so many times, that it would seem useless to attempt to present anything new or interesting; and yet the wintering problem has not reached its solution. In-door and out-door wintering have their advocates, and both alike have their record of successes and failures. Out-door wintering is among my earliest, and, I may also say, my saddest experiences in bee-keeping. The most important factor

in the wintering problem is climatic influence. There are others important that come within our control; but the influences of the weather we can at best only modify.

Cold does not kill the bees; but it comes in contact with the warmth produced by the living colony inside the hive, and condensation of moisture ensues. Moisture, combined with the cold, furnishes one of the most demoralizing and destructive conditions with which we have to contend in outdoor wintering, both upon the bees and the stores. When a colony is so prepared that an excess of moisture accumulates within the hive, the stores (both honey and pollen) especially if unsealed, are contaminated by these conditions, and rendered unfit for the bees; and no amount of packing or protection against the cold will improve these conditions.

A large per cent. of the loss of colonies that have been specially prepared for out-door wintering is undoubtedly the result of improper preparation. Colonies exposed to the severest cold, in climates much colder than ours, often winter in good condition without any protection whatever; even when subjected to the most reckless exposure in old, dilapidated hives, crumbling to pieces with age, and split and seamed from bottom to top, colonies have wintered year after year, for many years, while others, protected in the most careful manner, according to the most approved methods of modern bee-culture, have died.

We are perplexed and astonished at such results. The existing conditions were not those anticipated. The only conclusions are, that the favorable conditions in such exposed colonies that wintered well, over-balanced the unfavorable conditions; and, also, in such protected colonies that perished, there was a preponderance of unfavorable conditions, or, in other words, that such exposed colonies were in more favorable condition for wintering than the carefully protected colonies. This sounds strange, but is it not true?

I have often observed, that if the stores are of good quality, and remain in good condition, that the bees will also keep in good condition, and winter well, while if the stores are in bad condition, no amount of protection from the cold will avail in preserving the health and vitality of the colony. Even stores of inferior quality, if in good condition, are not necessarily fatal to the bees, if other conditions are favorable.

Mr. Hutchinson, in the AMERICAN BEE JOURNAL for 1887, page 650 says: “I have yet to lose a colony having cane-sugar stores, and wintered in a warm cellar, and by the method I now

employ." Does Mr. H. know that the same colonies would not have wintered well by any other reasonable method?

Mr. R. L. Taylor, at the Chicago convention, reported in the AMERICAN BEE JOURNAL for 1887, page 777, says: "I am confident that I can winter any fair colony well on stores, which are certainly good, by any of the approved methods." Who doubts his ability to do the same? Mr. Taylor also says: "I am satisfied that I cannot winter a colony well on stores that are decidedly poor in quality, by any method with which I am acquainted." Who can tell me how to do it? Stores may be so decidedly poor in quality that bees would not winter upon them by any method; but I have an abundance of evidence that stores decidedly poor in quality, if preserved in good condition, will not necessarily produce serious results, if aided by other favorable conditions.

I am aware that the results of indoor wintering are far from being uniform, and are very far from being satisfactory. Disastrous losses are not infrequent, even with apiarists of experience. Success depends as much upon the careful attention to details of preparation as does out-door wintering.

In-door wintering is my preferred method. It enables me, by my present methods, to secure all of the conditions favorable to wintering, both to the bees and the stores, with more certainty, and, at the same time, with less labor and expense, than the methods employed in out-door wintering.

In the construction of my first beehouse, I gave much attention to the ventilation. I had ventilating-tubes put in for the purpose. This was based upon theory. I have been compelled to change my views very much upon this subject.

My ventilators are now all taken out, being worse than useless, and I now employ no special means of ventilation whatever for my bee-rooms. But the most ample ventilation is given to each colony by leaving the bottom of the hives entirely open, and placing them upon stringers, one upon another, with an open space between, in such a manner that each hive is directly over the open space below. This gives what I term downward ventilation. It also affords an opportunity for all dead bees and rubbish to drop out of hive.

Of course, it would not be a matter of prudence to leave the bee-rooms closed throughout the season, disregarding all circumstances. I visit them on tours of inspection as often as I think occasion requires, and at the approach of warm weather I frequently leave the doors and windows open at evening and morning, in order to keep the temperature from getting too high.

There have been, during the past few years, some extravagant notions in regard to proper temperature of bee-houses and wintering repositories, and some immoderate reports and statements have been made that are well calculated to mislead even those of some experience. Some of the advocates of high temperature for wintering have gone to unwarranted extremes. I am myself convinced, by a liberal experience, that a high temperature is important to the welfare of the country, late in the season after brood-rearing has begun. But 50° to 55° I shall explain as the maximum, and 60° as the extreme of high temperature. It is well to avoid extremes of temperature, but I am not quite sure that uniformity is essential or even beneficial. I should prefer that the temperature go not below the freezing point, nor remain very long near it. But I have never been able to discover any very serious results from a low temperature, if not too long continued.

The use of artificial heat in beehouses in winter has attracted some attention. I have had considerable experience in its use, and at one time I became quite enthusiastic over it. But I do not attach as much importance to it as formerly. There are times during a long cold spell when it may be employed with benefit. I dispense with it in several of my apiaries entirely, and the comparative results in wintering show but little difference. I prefer to have the rooms perfectly dry, and sometimes I use lime on the floors to secure this condition.

SUNDRY ITEMS

About Bees and Bee-Keeping in New York.

Written for the American Bee Journal
BY JAMES EVANS.

The winter of 1886-87, with me, was disastrous. I had packed my bees carefully in chaff, although rather late, but the same as I had done previously, and I lost all but 2 colonies, and those were in poor condition. I then bought black bees in box-hives, and transferred them to frames of the Gallup size, and waited for results.

The spring opened fairly well, but bees barely held their own until nearly June 1, by which date strong colonies gave every indication of swarming; but at this time Alsike clover began to bloom, and I had about 2 acres near by. From that time for nearly four weeks swarming was entirely given up, and all the bees were entirely devoted to the Alsike. The 2 acres

yielded about 100 pounds of surplus honey, besides what was used in the brood-chamber.

About July 1 Alsike and timothy was cut for hay, and better hay I never had. It was to most farmers a new thing here, but all were pleased, of the many who inspected it, and some has been sown, as a direct result. I vote for Alsike every time.

I produce only comb honey, and I have ready sale for all that I can spare, at 16 to 20 cents per pound. My yield per colony, spring count, was nearly 62 pounds per colony, mostly to be credited to the Alsike, without which I should have had much greater increase, as there was just yield enough to stimulate brood-rearing freely, but less surplus, for after July and sweet clover bloom we had very unfavorable weather—damp days and cool nights and mornings. Bees could not work freely, and they barely held their own for the remainder of the season, making it difficult to breed up nuclei and small colonies, so that many colonies went into winter weak in bees and with poor stores.

My strongest colonies I packed outdoors in chaff, the hives raised about 8 inches from the ground, over a box of leaves. The weaker colonies were put into a cellar where they could be looked after and fed when necessary, which I do by using partly-filled sections on top of the frames, covered by two thicknesses of carpet.

Fastening Foundation and Ripening Honey.

As to foundation, I use as little as possible in the sections—a V-shaped strip about 2 inches long by 1 inch wide at the base. I fasten it in the sections by using a stiff putty-knife, or a thin chisel, working where the sun can warm up both sections and foundation, with a little honey at hand to moisten the knife or chisel.

To start the bees in the section-case (I tier up), a few partly or wholly filled sections with comb, in the center of the case, is better than anything else that I know of.

To ripen honey, I leave it in the hives quite late, and by putting on 3 or more cases, bees soil the upper and finished ones but little, if any. To take off honey easily and rapidly, on a cool evening I take the cover off of the hive, and in the morning the filled cases will be mostly free from bees, and can, without smoke or disturbance, be removed bodily, and the hives covered again before the bees are flying, and thus avoid robbing. After taking it from the hives, I pile the filled cases 10 or 15 high, in a warm room, and cover them with cloths, when the few uncapped cells soon thicken so much that they will not break or leak.

Separators and Races of Bees.

In the beginning and at the close of the season, when honey comes in slowly, I think that separators are a necessity, to have the combs straight; but in a good honey-flow, I have no need of them; yet I cannot dispense with the small foundation starter or guide, to keep the combs straight in the sections. As to races of bees, the blacks are good, but disagreeable to work with; my best yield the past season was from a black colony—103 pounds of comb honey in sections. Carniolans have many good points, and I shall keep at least a few of them, if only to supply surplus combs in frames, partly built out and filled with brood for use at swarming time, and for making nuclei. Carniolans are good comb-builders, and wonderfully prolific breeders; and if the swarming impulse can be controlled, they are good honey-gatherers. In any case, for timid people they will prove valuable, being very gentle and easy to manage!

As for pure Italians, of a good strain, all things being considered, they are, in my estimation, *the bees*, and have come to *stay*. Too much cannot be said in their favor.

Hives for Producing Comb Honey.

As to hives, I will say that I have no Langstroth frames myself, but I am familiar with them and their workings, having occasion to handle them in neighboring apiaries. For comb honey in sections I do not like them—they have too much top area for the beginning and end of the season. It takes bees too long to get at work in the sections, and as soon as cool nights come, the bees too readily go down into the brood-nest for warmth. I like a hive with small top area, and a rather cramped brood-chamber. With me, the bees go up into the sections much more readily, and after once getting them at work, it is easy to keep them at it by tiering up. Besides, with a small section-case, honey is less liable to be mixed in the sections or case, as a good working colony frequently fills a small case in from 1 to 5 days in a good honey flow.
